[THE GARDEN

A SPANISH CHESTNUT IN GREENWICH PARK.

AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

W. Robinson, Author of the "English Flower Garden."

" You see, sweet maid, we marry
A gentler scion to the wildest stock;
And make conceive a bark of baser kind
By bud of nobler race: This is an art
Which does mend Nature,—change it rather: but
The art itself is nature."

Shakespeare.

M. HENRY DE VILMORIN.

M. HENRY DE VILMORIN was one of a family for several generations devoted to horticulture, and to whom we are much indebted for their publications as well as excellent cultures in their always interesting gardens at Verrieres and elsewhere. His father having died young, he took his place at the head of the firm at a very early age, and well he acquitted himself of that task; and not only of the affairs of his own house, but became a trusted authority on rural economy throughout Europe and America as well as in France. Charles Henry Philippe Lévêque de Vilmorin, the eldest of the four children of M. Louis Lévêque de Vilmorin, was born at Paris on February 26, 1843. The great-grandfather of Henry de Vilmorin, Philippe Victor de Vilmorin, who died in 1804, was a distinguished agriculturist, a correspondent of the Institut, and in 1791 was one of the first members of the association known at the present day as the Société Nationale d'Agriculture de France. He was succeeded by his son Pierre Philippe André, to whose reputation as an authority on fodder and garden plants was added that of a distinguished forester. He established at Barres (Loiret) an arboretum, since become a State property, where he pursued with ardour the study of forest trees. He succeeded his father as correspondent of the Institut, was elected a member of the society above named in 1804, and died in 1862 at the age of eighty-six. Candolle, the botanist, named a plant from St. Domingo, Vilmorinia, after him. The father of Henry M. Louis de Vilmorin, who died in 1860 at the age of forty-four, was also an observer of the first order. In 1842 he commenced to make researches in connection with Wheat, and from 1845 to 1857 he made some remarkable discoveries in connection with the Potato disease. He also effected improvements in Carrots and Beetroots, and was an acknowledged authority on most problems concerning cultivation on a large scale. Like his father and grandfather, he was a member of the Société Nationale d'Agriculture. He was assisted in his labours by his wife, Mme. Elisa de Vilmorin, a woman of rare intelligence, and who was employed by M. Decaisne to write a monograph on Strawberries for his great work, "Le Jardin Fruitier du Muséum."

In 1878, a commission, presided over by M. Bouley, of the Institut, was directed by the Prefecture of the Seine to study methods of cultivation with sewage, and Henry de Vilmorin was appointed reporter. His communications to the Société Botanique de France in 1879 and 1880 on the cross-breeding of Wheats of different species, and his studies on the sowing, selection and cultivation of Wheats led to the publication of a fine volume entitled "Les Meilleurs Blés." The bulletins of the Société Nationale d'Agriculture between 1885 and 1896 are filled with his communications on these subjects. His latest observations were, in fact, an argument in favour of unity of species in the various cultivated grains. In 1866 he published a second edition of the "Catalogue Methodique et Synomique des Principales Variétés de Pommes de Terre" commenced by his father, to which he added on his own account more than 200 varieties, classifying them into twelve divisions and thirty sections, which included all known forms. The collection has been maintained at Verrieres since 1815. His researches in Beetroot continued uninterruptedly from 1875 to 1889, and it is well known that his labours contributed largely towards developing the saccharine properties of this precious plant.

In 1893 M. Henry de Vilmorin visited the United States as delegate of the Société des Agriculteurs de France in order to study the methods of cultivation there which he had heard much extolled, and which he made the subject of a lecture under the title of "L'Agriculture et l'Horticulture aux Etats-Unis." In concert with his brother Maurice de Vilmorin, he thoroughly revised the illustrated work known as "Les Fleurs de Pleine Terre." His tastes as a hybridiser led him to institute experiments at Verrieres on the Salpiglossis, Poppies, Carnations, etc., his aim being perfection of form and colour. His investigations were not, however, confined to the region around Paris. The south of France had always its attractions for him. He spent with his family several winters at Antibes, where he was on friendly terms with M. Charles Naudin, director of the Villa Thuret. The delightful climate of Golfe-Juan decided him to form the Jardin de Satil, which contains amongst other rare things a Eucalyptus brought from Australia by M. Ed. André, and called after him E. Vilmoriniana.

The Société Nationale et Centrale d'Horticulture was not long before it attracted him to itself, and he became successively its secretary, vice-president and first vice-president. In the various posts which he filled in the committee and on the council he won the affection and esteem of his colleagues. His perfect urbanity might seem obscured by a certain coldness at first, but to those to whom he took a liking to he was full of cordiality, upright, obliging and generous, and he made a noble use of a fortune honourably acquired by the labours of his ancestors and himself.

He made numerous voyages to the different countries of Europe, to North America, to Algeria, Tunis and Egypt, and in the last-named country he commenced some experiments in cultivation. At Mont Dore, in the Pyrenees, which he sometimes visited for his health, he delighted to botanise, and his knowledge of the alpine flora of Auvergne was profound. In Pherault he made a particular study of Pinus Salzmanni, upon which he was able to speak as an authority. Eminent though he was and one to whom distinctions came quite naturally, he was simple in his private life, and whilst indulgent for others, exacting as regards himself.

The GARDEN.

ROSE GARDEN.

SOME INTERESTING ROSES AT KEW.

A VISIT to Kew is at all times pleasing, but to the Rose lover no period of the year can be compared to June. It is not that he will find the latest exhibition novelties, although the leading kinds are well represented, but the charming garden Roses that are here found make a visit very interesting. It will be worth a long journey to see the splendid mass of Crimson Rambler in the dell by the pagoda when the plants are in full bloom, which will probably be early in July. Anyone who has failed with this Rose (and they are not a few) will see here the ideal method of growing it. Judging from the enormous growths made last year, and which are now bearing such a profusion of buds, the soil must be of the best possible description. It would appear that many loads of good loam were carted into the dell to form what I should call a rotery. Standing upon the grass walk, one can see up above upon this bank innumerable arch-like shoots of Crimson Rambler waving and borne down with the weight of the large corymbs of buds. On some of the growths I counted as many as forty sprays of buds, each spray having on an average twenty-seven buds, thus making a total of over a thousand upon one growth. This is nothing very remarkable in itself, but the accumulation of growths so elegantly dispersed and elevated as they are upon this bank in the manner described, with Foxgloves darting out here and there, was to me a veritable treat, and no one able to do so should miss an opportunity of seeing this mass in bloom. In close conjunction is to be seen another bank covered after the same manner with the sempervirens Rose Flora and Blairi No. 2. The same treatment is afforded the plants as in the case of Crimson Rambler. It will be observed that the marvellous growths that are flowering are mostly one year old. Other strong young shoots were breaking up from the

base of the plants (accelerated by the natural style which the one-year-old growths were allowed to assume) that will doubtless ripen sufficiently so that they can be used next year to replace the majority of those now flowering. Of all the free-growing reliable climbers, Flora is one of the best. Having the appearance in colour of a miniature Captain Christy, its growths flower so profusely as to produce veritable wreaths of Roses. I saw it here used to fine effect upon tall pillars and chains. These pillars consisted of stout iron rods about 5 inches in circumference, each rod having three smaller ones to support it. The rods were about 8 feet high and placed about 18 feet apart, chains being festooned between. The variety Flora upon two of these pillars was a marvel of floral beauty. Having reached to the top of the pillar, the growths had been trained upon the chains and were flowering in the greatest profusion. I measured 12 feet of growth on one of these chains. The only fault I could find in the arrangement was that several pillars were badly furnished. To do this work well, only such kinds should be used as will grow well and flower simultaneously. Flora and Ruga go well together, and Félicité-Perpétue and Crimson Rambler would be good companions, and doubtless the newer Polyantha climbers, Aglaia, Euphrosyne, and Thalia, will be useful. Along this same walk alternate pillars of Ivies and Roses were a good feature. One pillar of the golden English Ivy would be difficult to surpass for colour and effectiveness. Here again one could see instances of the unsuitability of certain Roses for pillars, Gustave Regis being one. There were some very happy blendings of Roses and Tufted Pansies noticed by the Palm house, such as Mme. E. Resal and Viola Bullion, Viscountess Folkestone and V. Montgomeryana, Clement Nabonnand, a Rose not often seen, but a good grower, and V. Councillor Waters, Augustine Guinoisseau and V. J. Shires, and a grand bed of Hon. Edith Gifford carpeted with V. Montgomeryana.

A few notes appeared in these columns on June 25 of last year relative to some good early-flowering Roses, and it will not be necessary to reiterate or name the varieties mentioned therein. But I saw a few specially interesting kinds that must become of great value to our gardens when they are disseminated. The most remarkable of these was a cross between R. Wichuraiana and R. rugosa from the Arnold arboretum. The plant had the recumbent habit of Wichuraiana, and the foliage was shiny, but it was also thick and leathery with spiny growths like R. rugosa. The colour of the flowers was a soft satin rose, most pleasing in its freshness, and they were about as large as a Penzance Brier. This hybrid must become of great value by reason of its undoubted hardiness and creeping habit. To show the wondrous divergence of hybrids, a cross between R. Wichuraiana and General Jacqueminot produced flowers of an exquisite carmine colour, but the growths resembled neither parent, being more like those of a Noisette. One of the brightest-coloured rugosa Roses I have seen is the single variety from the same source—a cross between R. rugosa and General Jacqueminot. It is quite a rich crimson, just the colour required, and must be a valuable Rose for planting in large masses as cover or for hedges, and will probably supersede the type if it fruits well, because this latter kind is not a very taking shade of colour. A lovely Rose is Hargita, a hybrid, I should imagine, between Blairi No. 2 and R. rugosa. The semi-double flower had just the same style as Blairi No. 2, only the colour was a much deeper pink, merging almost to carmine. The growths were also inclined to red, although very spiny, as in R. rugosa. A grand Boursault variety named Calypso will be in great demand when it is put into commerce. As seen here, the flowers are immense; one bloom measured 5 inches in diameter. The colour is a soft pink and the blooms semi-double. As a rule the Boursault Roses are not very attractive, but this one entirely supersedes all previous kinds of this

tribe. On the rockery was seen a very pretty Rose named *Malyi*. The colour of the flowers was a rich deep rose, merging almost to crimson. An immense bush quite 12 feet through of *Rosa sericea* attracted attention, it being at the time of my visit a perfect mass of white, faintly lemon-tinted blossom. This variety resembles *R. spinosissima altaica* in bloom, although it is not so large. Some very dwarf forms of *Rosa gallica*, such as *nana* and *pumila*, would be useful on rockwork, the latter only growing about 1 foot high. A pretty little gem I came across was named *R. spinosissima var. picta*. The flowers were each not more than half an inch across, of a rosy crimson colour edged with white and the centre lemon-white. *Rosa rugosa* crossed with *macrantha* had growths resembling the former and flowers like the latter in shape, but not quite so large. The colour was a beautiful clear pink. *Rosa ferox* from Canon Ellacombe, though not in flower, was interesting. It has tiny foliage, smaller than in *Wichuraiana*, but in appearance much resembles the hedge Briers. Not the least interesting were some hybrids of *R. ferruginea* or *rubrifolia*. The foliage was not quite so red as in the type, but very glaucous and the flowers were of a good size.

Here at Kew one can see the true value of *Rosa multiflora*. Huge bushes smothered with blossom were a perfect picture. The blooms were very small, but the quantity contained in each corymb makes the show. A splendid form of this Rose is *R. m. Thunbergi*, a variety that has already received a notice in these columns. The double form of *R. multiflora* was also very pretty, and was growing most freely in the dell. It is to be hoped the various hybrids noticed will be distributed, also some forms of *rugosa* noted last season. The tribe is so very valuable by reason of its hardiness, that we may well desire to see the numbers increased if the colours can be improved. This would not refer to varieties like *Blanc double de Courbet* and *Mme. G. Bruant*. We are quite content with the snowy purity of these two, and would not desire any alteration in them, but I allude more especially to the washy rose colours that never appeal to one's idea of beauty. PHILOMEL.

Rose Mme. Willermoz (Tea-scented).—This is one of the hardiest of the Tea-scented Roses, of somewhat cupped form when expanded. The delicate fawn and creamy shading upon a white ground gives a fine appearance to the flower. It has been sent out now over fifty years, and was introduced by the late M. Lacharme, a raiser who has given us so many grand Roses. It produced a pink sport named *Letty Coles*, which created a slight stir when sent out, but it has long since gone out of cultivation.—P.

Rose Daniel Lacombe (hybrid multiflora).—This is a delightful rambling Rose. One thing is certain, that this will blossom on young plants; whereas some of the newer introductions appear to be very shy in blooming. The chamois-yellow buds, if very tiny, are nevertheless extremely pretty, and the open flowers, which are about the size of those of *Crimson Rambler*, are at first flushed with clear rose, then change to white. I can conceive of nothing more lovely than a fine plant of this Rose covered with the pretty trusses of blossom. It has a musk-like odour, which points to the probability that it is a hybrid between *R. multiflora* and *R. moschata*.—P.

Rose Kronprinzessin Victoria (Bourbon).—This sport from *Souvenir de la Malmaison* is very beautiful. Its flowers are milk-white, suffused with a faint lemon tint, and are most attractive upon the plant and when cut. Like its parent, it is lovely in the autumn as well as during the summer. It does not appear to be quite so free in growth as *Souvenir*, but it is not a bad

grower. I should not recommend it as a standard, but as a bush it is first-rate. I can see little or no difference between this kind and one introduced eight years later named *Marie Thérèse de la Davansaye*. Certainly they are not both wanted.—E.

Rose Dr. Rouges (Tea-scented).—A further acquaintance with this Rose has confirmed my first impression, that it would prove a most useful variety. The colour seems to come midway between that of *Marie d'Orleans* and *General Schablikine*, but the outer petals are of a far richer rose colour than in either of these kinds and there is also an orange shading. Apart from the delightful tint of colour the flowers are also very prettily formed, the petals not only being pointed similar to a *Cactus Dahlia*, but they are also curled at the edges. The plant, although of climbing habit, flowers very freely grown in bush form if the growths are left about 2 feet long when pruned.—P. L.

Moss Rose Reine Blanche.—Apart from the beauty of its flowers, this Rose has the most tender green foliage of any variety in cultivation. The leaves are of such a pale green shade as to amount to almost golden green. It is a very old kind, but I believe it is not much known. It has been considered by some to be too much like *Comtesse de Murinais*. A great difference, however, is manifest when they are placed together. In the case of the variety under notice the blossoms are very pure white, not quite so paper-white as in *White Bath* or *Blanche Moreau*, but certainly purer white than in *Comtesse de Murinais*. As a garden Rose it is excellent, for it grows and blossoms freely and it can be propagated easily by layers. These beautiful white Moss Roses are always interesting: the pretty buds, peeping out amid a mossy and in some cases Fern-like encasement, appeal to all lovers of old-fashioned flowers.

Rose Pink Rover (Hybrid Tea).—Fragrant Roses find a warm welcome even if there are slight blemishes in the variety. But in this case we have a Rose that not only grows well and flowers well, but its blossoms are in the half open state of a fine globular shape. There is not the finish in the outer petals one would like to see, but this is a small matter, and when we sum up its good points this defect is not noticed. The exquisite pink tint of the inner petals, resembling that of *Souvenir d'un Ami*, verges to silvery white near the outside. I prefer this Rose to *Climbing Captain Christy*, for in *Pink Rover* we have perfume, vigour and good colour, whereas in the latter, although the two last-mentioned qualities are there, the fragrance is wanting. *Pink Rover* is not exactly a rambling kind like *Gloire de Dijon* or *Rêve d'Or*; it, however, grows extremely well and quickly covers a wall. I like to see it in pillar form or growing as a standard. I would advise anyone wanting a good light pink or free-growing kind to plant this Rose, and I feel sure he will be satisfied. Many of these vigorous-growing kinds would be in greater demand if planters only knew their value as bushes, especially to grow in the vicinity of large towns. I have this Rose, *Gloire de Dijon*, *Mme. Berard*, *Reine Marie Henriette*, *Bouquet d'Or*, &c., flowering most profusely upon two-year-old plants. The growths of these plants when pruned were left about a yard long and the laterals shortened to 6 inches or 9 inches. They have now from two to three dozen buds and blossoms upon each bush of really good quality, free from that stunted, crippled condition too often found upon wall plants.—P.

NOTES AND QUESTIONS.—ROSES.

Rose Felicite Parmentier.—The old Roses of which the above is one of the loveliest can never be entirely expunged from our gardens. It is not from sentiment that this one should be retained, but simply for its own intrinsic value. Though not a large Rose by any means, it flowers in good clusters, so that the plant is very showy when in full bloom. The exquisite warm flesh-pink colour of the outer petals

and edges nearly white make it a great favourite. It must not be confounded with *Felicite-Perpétue*, a totally different Rose.—P.

Rose Crested Provence.—The fragrant old Cabbage Rose will always remain a favourite, and the above lovely variety, which is possibly a sport from it, in like manner is much esteemed. This, too, is very sweet. The peculiar crested Fern-like formation of the calyx gives the flower a most unique appearance. I think nothing is more beautiful than a spray of this Rose with the centre flower full blown and surrounded by several of the quaintly crested buds. It is a good grower, suitable alike for standard or bush.—P.

ORCHARD AND FRUIT GARDEN.

MANURE FOR VINES.

THE old idea that to grow good Grapes it is necessary to feed them upon all the garbage and filth of shambles and stock yard dies hard. Recently a visitor here on seeing large, well-finished bunches of Grapes in the early vineyard asked me what I had fed them on. On mentioning a well known manure he made a note of it and departed, evidently under the impression that the whole thing depended upon getting this and no other. But it is hardly necessary to point out that no amount of actual manuring can of itself be depended upon to grow fruit of good quality. That manure is necessary goes without saying, but it is a mistake frequently made to think that feeding liberally will make up for errors of culture. This it can never do, and applying a lot of strong manures, whether natural or artificial, to Vines, the roots of which are out of order or running in an unsuitable medium, is so much waste of time. It would be useless to feed a starving child on heavy, substantial food that only a strong man could digest, and it is the same in plant life. Before the Vine can assimilate and use a large amount of manurial constituents, there must be vigour and health in the plant itself, built up gradually and even slowly in some cases it may be, but none the less they must be there.

This is very often the rock that many founder on when making up borders or composts for Vines. Instead of giving a make up that roots can enter freely and ramify in, over-rich manures are used that only the strongest roots can enter, and these, as is well known, are not the best fruit producers. It is not enough that plant food shall be present; it should be in a form immediately available by the roots and to ensure a constant supply of plant food borders should be constructed of such material that air filters readily through it. To this end the addition of such materials as lime rubble, burnt garden refuse and well made charcoal undoubtedly tends. Cold, sloppy manure could never have the same effect, while that of artificials in many cases is but fleeting. Bones are one of the most useful aids to Vine culture, acting in the dual capacity of a mechanical agent to keep the soil porous and containing some of the most essential of plant foods which are given off slowly but surely over a very long period. These, of course, may be overdone, the exact quantity required largely depending upon the class of loam used, whether this is rich or the reverse. The large amount of lime in bones makes them a useful addition to soils deficient of this, but of course this constituent may be applied much more cheaply than by the aid of bones. Quick or newly-slaked lime should not be too freely used, as it has the effect of fining down the soil considerably, and this is why I always prefer the old mortar rubble to the more genuine article. There is not so much active lime in it, but it has a

better and more lasting effect upon the compost. In borders made up of this class of material the roots are soon running all through them, and being trodden and rammed very firmly when putting together, they will be of the best class for fruit production and the formation of sturdy, short-jointed wood. Then when a sudden call is made upon the resources of the Vine there will be hundreds of fibrous roots, their points hungrily seeking the necessary food constituents which may be provided by quickly acting chemical manures, aided by frequent doses of tepid liquid manure. The results of these will soon be manifest.

H. R.

Strawberry Lady Suffield.—This is a very distinct Strawberry, and, as I think, one of the highest flavoured in existence, combining as it does distinctly the Hautbois flavour with that of British Queen. Those who saw the exhibit of this Strawberry at the recent Temple show will hardly doubt its high flavour even if they had not the privilege of tasting it, for the aroma was most powerful, and one could not come within a dozen yards of the few plants shown without catching the delicious perfume the fruit exhaled. As shown, it appears to be a free cropper and a healthy grower; the fruits were not over-large, but quite large enough for all but those who care most for monstrosities. The high quality possessed by these pot-grown fruits shows this kind to be of the highest class, and one that is bound to become a standard variety with all who appreciate quality of the best. One can only hope that it will prove to be a variety suitable for all gardens.—J. C. TALLACK.

Strawberry President.—This Strawberry has been so long in cultivation and it is so well known that it is quite needless to describe it. I consider it an excellent kind in every way and used to grow it regularly. The plants always did well and ripened up a good crop of fruit, yet at the present day it is very seldom seen in good condition under glass. Ask nine out of ten experienced gardeners their opinion of it for forcing, and it will not be a good one. In conversation with a very capable gardener to-day he tells me that President has been the only failure this year among the forced plants. Why is it so is a question I have frequently asked, and never yet found a satisfactory reply. President is a good distinct Strawberry even now, despite the sheals of new kinds we get annually, too good to lose from our collections. It frequently fruits well and constantly in light sandy soil, where many of the newer kinds would fail, while if not in exactly the first flight for flavour, there are many no better that receive a great deal more attention, and certainly it is far before the large showy kinds that are now so popular. I cannot help thinking that there must be something wrong in the treatment that fails so utterly with President.—H. R.

Young wood on old fruit trees.—Though agreeing with the main points of "J. G.'s" note on p. 413, I must take exception to what he says about Vines. It is not the close pruning which accounts for the laterals not showing bunches, but the general weakness or ill-health of the canes; and it is to be hoped that the art of growing old Vines which will continue to produce good bunches from closely pruned spurs will not eventually be lost. I do not for a moment doubt that there are many old and sparsely spurred Vines which would be all the better if they were cut out in favour of vigorous young canes from the base, but to attribute the cause to the short-spur system of pruning is obviously a mistake. That the short-spur system is good when other conditions are favourable is illustrated in instances frequently to be met with of old Vines which in spite of age continue to produce as good Grapes as ever, and in face of the fact that at no pruning have there been more than one or two eyes left. The tendency at the present day seems to be that of trusting too much to young Vines

and fresh canes, whereas a thoroughly established and well treated Vine will go on bearing for an almost indefinite period. It is not the close pruning, but wrong treatment and neglect that are the prime causes of failure in old Vines, this necessitating their being cut out and young canes brought up to take their places.—H. H.

MULCHING STRAWBERRIES AND BUSH FRUIT.

MULCHING fruit trees is often carried out in a half-hearted manner, unsuitable material being used, and the time and way in which it is applied not calculated either to keep the fruit perfectly clean or to retain the moisture in the ground. The time at which Strawberry plants are mulched should be regulated entirely by the nature of the soil in which the plants are growing. In strong, retentive soils the work may safely be deferred until the bloom-trusses are well advanced or about to open, but in sandy mediums such delay would in the majority of seasons prove injurious to both plants and crop, as what moisture is in the ground soon disperses at this season unless retained by liberal mulching. From neglect of this I have seen what otherwise was a promising quarter of plants give way just when the fruit was commencing to soften. For a number of years I had to deal with a light, porous soil. Strawberries did very well, but only when the ground was mulched at the latest in January. I always got it on if possible in December, using short straw material well saturated with urine from the piggery. Two birds were thus killed by one stone, the roots being nourished and the litter washed clean by winter rains, keeping the ground moist and the fruit clean. In my opinion this is how Strawberries should always be dealt with on light soils. On strong soils where mulching is performed in May or June nothing equals Bracken. If this can be cut, dried, and stacked in autumn it can be cut out in trusses, and nothing is so sweet and clean. A little lime should be sprinkled round the base of the plants previous to ward off slugs. The next best material is short strawy litter. Grass mowings should never be tolerated. Where practicable, I would also mulch Gooseberry and Currant bushes with Bracken. It keeps the fruit on the lower parts of the trees clean, which would otherwise be splashed with dirt by heavy rains and thunderstorms. In this case also the mulch should be applied in good time. All this may seem a laborious task, but if done systematically it is not really so. J. CRAWFORD.

THE EARLY STRAWBERRIES.

SEASONS and soils vary so much that dates differ greatly as regards the ripening of fruit. This season my earliest Strawberry is Royal Sovereign, which was gathered on June 12 from a south border. I am aware the date given is not particularly early, as a few years ago I gathered Noble and No. 1 on May 29. It is only fair to add the fruits could not compare with those just ripe, which are very large and of good colour all through. Even for West Middlesex June 12 is early, as the season has been one of the most unfavourable for Strawberries I ever knew, as from 4° to 7° of frost the third and fourth weeks in May, then a wave of heat, and since then cold east winds have told sadly upon tender fruits. The frost killed a lot of the Strawberry blooms. Fortunately, the fruit set and of a fair size escaped injury. I still use long litter as a protector, and this may be made good use of in a cold season. It is not made firm round or under the plants, but is left loose, and in case of frost placed thus it answers well, as it covers the spikes of bloom. Though it does not look very tidy, it is an easy matter to place it in position under the plants when the flowers have set. I am aware there is an objection to litter, but it is not much soiled, and if placed on the quarters early in May it is thoroughly bleached by the weather and

sweetened by exposure. I prefer it to long, clean straw, which in wet seasons lies too close and harbours slugs badly. Grass is bad in any form. To many the date of gathering and the earliness of the variety will be of most concern. So far I find Royal Sovereign the most reliable for early supplies. It is all the more valuable on account of its size, and size in early Strawberries finds favour with many, and, as growers well know, size influences prices greatly. For earliest supplies I rely entirely upon last year's runners, and there is no loss of space, as the plants need not be so far apart. This season my plants are smaller than usual, as owing to the heat and drought last summer they made poor progress after planting till the autumn rains favoured growth. I find I am earlier this year than last, but with a much lighter crop. Of course this only refers to the early varieties. Last year during the swelling period we experienced very dull cold weather. The earliest crops are always the best after a sharp winter, as, having a very light soil with plenty of sunshine in the spring, the soil soon gets warm and growth is rapid. Such soils, however, need much attention in the way of food and moisture to build up a heavy crop. Without moisture the fruit fails to swell away freely, red spider gains a footing and the crop suffers. By growing different varieties and with north and east borders I endeavour to eke out the season as long as possible. From four to six weeks is usually the time, the latter if the nights are cool and we get enough rainfall. This season I hope it may be longer, as I am giving the new St. Joseph and Louis Gauthier a trial and they promise well for late supplies. I am surprised to see what effect the cold weather had upon the flowers of what may be termed choice varieties, as fully half of the bloom is ruined. This applies to the Queen and Pine varieties mostly. In some cases the loss of a few flowers is not a serious matter, as the plants often bloom so freely, that they are unable to perfect the fruits. La Grosse Sucrée, a favourite early kind here and one that follows the Royal Sovereign closely, is much cut by the late frost. This is unfortunate, as it is a splendid variety. The useful Vicomtesse H. de Thury is much better. It appears to do well in any soil or position. I grow it largely for preserving on account of its flavour and firmness, as the fruits may be cooked whole. There are many other early kinds, but of late years I have reduced the varieties, as those noted are the best croppers and the flavour is good also. King of the Earlies was too small and John Ruskin does not thrive.

G. WYTHES.

Strawberry Empress of India.—I wish I could grow this excellent variety more strongly, for I have no better flavoured or finer coloured variety. But on this stubborn, heavy soil the plant does not seem to get the mastery, and should the winter prove very wet, a number of the plants turn yellow and collapse. When they do get through a season they are very free, and I have a couple of rows in passable order this year. The berries are not large, but a beautiful deep scarlet in colour, quite distinct from any other. Where it succeeds it is one of the very finest Strawberries in cultivation.—H. R.

Pruning Black Currants.—If, instead of leaving the old wood year after year, the wood with the fruit on was cut right out and taken away to a shed to be gathered, the produce of these useful bushes would be much finer and more plentiful. A little judgment would be necessary in some cases, of course, as there are bearing parts that cannot be cut out without damaging the bush, but in most cases the greater part may be removed, and the sucker-like growths springing from the base reserved for fruiting. In the case of old bushes, some of these also may be removed, and a thin, open bush results. The air and light reaching every part of it will be a great help to the crop.

Late-kept Apples.—A "Looker-On" does not seem very enthusiastic over Apples, however

fine, exhibited at the end of May. He is, I take it for granted, not a nurseryman, and has no trees to sell. Were he such he would know the value of an advertisement. But the presentation of a fine lot of Apples at the end of May re-ounds, I think, more to the credit of the keeper than to the fruits themselves, because it is so obvious that, let the fruits be ever so handsome in appearance, they have comparatively little intrinsic merit for eating or cooking after having been gathered some eight months. After all, except to show as an advertisement, are these fruits then worth keeping? Is the game for a private gardener worth the candle? Unless the fruits are as good in May as they may be expected to be in midwinter they are not worth keeping. Do what we may in growing and storing we cannot have such quality in fruits at that late period as we find in proper seasons and under ordinary conditions.—A. D.

NOTES OF THE WEEK.

Hesperis matronalis lilacina plena.—This is a very distinct lilac-coloured form of the well-known double Rocket, and as such affords additional variety to these old-fashioned things. It is one of many useful things flowering with Mr. Perry at Winchmore Hill.

Paeonia Lemon Queen.—Though somewhat smaller than is usual, the one here named possesses the charm of a combined colouring of lemon-yellow and white. In the cupped appearance of the flowers, i.e., when about half expanded, these things are especially useful for cutting, and are then most effective.

Spiraea Aruncus.—I enclose a photograph of a clump of *Spiraea Aruncus* which has been taken by a friend of mine. It grew in the gardens here on the banks of the Wye. The clump is 18 feet in circumference and has produced sixty heads of bloom, many of which were 6 feet in height.—P. MACCABE, *The Gardens, Rotherwas, Hereford.*

Fabiana imbricata.—Although *Fabiana imbricata* is fairly hardy in the west of Scotland, I hardly expected to see it in bloom on a low wall at the Edinburgh Botanic Gardens this week. This Heath-like shrub is one which those who like to grow plants with which some have a difficulty ought to try. It is remarkably pretty and distinct.—A.

Lilium Thunbergianum Orange Queen.—This is an exceptionally good form, the chief differences being the decided tone of colour and the rather thicker and more decidedly obovate segments. In all these the variety is a distinct advance on any member of this dwarf section of the genus. Messrs. Wallace had nice blooms at the Drill Hall this week.

Saxifraga cochlearis.—Though the beauty of flowering in this plant is occasionally noted, it is rarely, if at all, that one hears anything concerning its fragrance, yet it is probably the most powerfully scented member of its race, and the strong Hawthorn perfume may frequently be detected at some distance. This is quite true of a large patch now in bloom.

Potentilla opaca.—We have a considerable number of dwarf *Potentillas* with yellow flowers, and several of these are grown in the Royal Botanic Gardens at Edinburgh. *P. opaca* this week looked rather well by reason of the manner in which the flower-stalks had arranged themselves. The centre of the plant showed a mound of green, while this was encircled by a line of the clear yellow flowers.—S. A.

Iris gigantea.—This showy *Iris* is doing well this year, and in spite of heat and drought a year ago when many things were parched up. At the time it was somewhat naturally thought this would affect the flowering of to-day, but it has not done so, for the plant is as fine and as free as ever. Another very bold and well-coloured *Iris* now in bloom is *I. Monnieri*, the rich golden flowers surpassing in size and effect the majority of its kind. In one or two instances in the Drill Hall groups this week it was very fine.

Deutzia Lemoinei.—Though living at no great distance from Mr. Arnott, and with similar conditions in climate and position, my experience as to this *Deutzia* is so far much more favourable than his. *D. Lemoinei* came well through the severe March frost, and is now flourishing and just going to bloom. I think Mr. Arnott's plant must have been rather precocious. *D. discolor purpurascens* seemed a little more tender, but both are very young plants, so it is

not safe to pronounce decidedly yet.—W. D. R. D., *Castle Douglas, N.B.*

Viburnum plicatum in New Jersey.—With this I mail photographs of *Viburnum plicatum*, young plant and branch. As you probably know, this is one of the best of shrubs, in good soil growing thriftily and rapidly and flowering freely. The dark green attractive leaves are seldom injured by insects. Some of the flowers had been stripped from this plant before I took a photo of it. We had a long, cold winter and spring, but just now it is hot and dry as the desert.—J. N. GERARD.

Eriogonum subumbellatum.—This rather useful and distinct plant does not appear to be a very free bloomer in many places. I am reminded of this by seeing a large mass of it at Edinburgh growing very freely and covering a considerable extent in the rock garden, but with very few flowers upon the mass. I believe it flowers better in a crevice of the rock garden where it is not too dry than in a place where its roots receive but little moisture. The few *Eriogonums* we have are pretty in their own way.—S. ARNOTT.

Buddleia Colvillei in Surrey.—In your issue of last Saturday the Rev. T. M. Bulkeley-Owen, of Tedsmore Hall, asks if *Buddleia Colvillei* has ever flowered in England. It has bloomed with me for the past three if not four years, and is now in full flower. I imagine this *Buddleia* is hardier than is generally supposed (it endured 21° of frost on three successive nights in February, 1895, with very slight damage), and the difficulty of cultivation arises more from atmospheric conditions, such as smoke, than from any great susceptibility to cold. It is a very handsome shrub.—B. E. C. CHAMBERS, *Haslemere, Surrey.*

Some Shropshire notes.—*Onuris coccinea*, about which there has been some correspondence in THE GARDEN, flowers here very well. There are now over 20 spikes of flowers on the plant. It grows in a shady position on a rockery amongst blocks of sandstone; the soil is very light and sandy. It flowered well last year. *Deutzia discolor purpurascens* is a beautiful shrub, and though as yet but small, it has flowered well both this year and last. *Polygonum baldschuanicum* is in the trade. I got it from M. Lemoine in 1897. It seems quite hardy, but it has not flowered here yet.—T. M. BULKELEY-OWEN, *Tedsmore Hall, Shropshire.*

Brodiaea coccinea.—It is quite true that a single bulb or even a dozen can give but little idea of the value of this fine plant when grown on a large scale. It is evidently grown in this way by Mr. M. Prichard, Christchurch, who brought whole sheaves of the crimson flowers to the Drill Hall this week. Not only were the spikes unusually strong and vigorous, but the flowers also were fine and much bolder in outline than is usual with the plant. We never remember before seeing the plant so good, so strong, or in such numbers. It is clearly quite at home on the south coast and near the sea, and as such worth growing for its fine colour.

Herbaceous Lupines at Edinburgh.—A small collection of *Lupines* in the Edinburgh Royal Botanic Gardens is at present worthy of some observation. It appears as if we must mainly look to hybridisers and seedling raisers for variety among these. The species at Edinburgh do not differ in flower from each other in any marked degree. *Lupinus macrophyllus* is rather good with its spikes of purplish blue. *L. luridus* has that shade of lurid colouring which makes the name fairly applicable. *L. micranthus* and *L. hirsutus* are not particularly distinct as regards the flowers. *L. nootkaensis* is taller than it grows with me, while *L. bicolor* looks, perhaps, the best of the lot.—S. ARNOTT.

Primula sikkimensis at Edinburgh.—There is at present a capital mass of the Sikkim *Primrose* at the side of the pond in the Edinburgh Botanic Gardens. A good many plants are flowering extremely well, showing how much they appreciate the moisture drawn up from the adjacent pond into the bank on which they grow. *P. sikkimensis* is not generally a long-liver, but not only is its life usually prolonged, but its

beauty is largely increased when it is given a moist position in rather light soil—at least this has been my experience. Plenty of water in spring and summer is its main requirement. It is worth a good deal of trouble to secure healthy plants with tall stalks laden with the fragrant yellow flowers.—S. ARNOTT.

Geranium Phœum (Dusky Crane's-bill).—May I draw the attention of those of your readers who are interested in bees to the value of this plant, whose insignificant flowers possess such a remarkable attraction for bees. I have watched it closely for some time, and find while the blossom lasts it is covered with bees hard at work all day, and these the ordinary hive bees. From time to time I have grown various plants recommended for bees, and have found them more frequented by wild or humble-bees than their garden relatives. When allowed to grow undisturbed for some years, the Dusky Crane's-bill attains a good size and deserves a place in front of a shrubbery or in the wild garden.—S. C. WHITE, *Charleville, Roserea.*

Dianthus Fettes Mount.—This is one of the best and most effective plants at present in flower in the rock garden of the Edinburgh Royal Botanic Gardens. A mass of its grey foliage freely covered with its double flowers of bright pink looks both showy and pleasing, while the fragrance of the blooms gives an added quality. This hybrid Pink, raised some years ago in the neighbourhood of Edinburgh, deserves to be brought to the notice of those who like Pinks with their delicious odours. Not the least of its good qualities is its perennial character. Unlike some of the mule Pinks, it gives little trouble in this respect and soon grows into large plants. On the top of a rockery and hanging over the stones the Fettes Mount Pink is one of the best of our June flowers.—S. ARNOTT.

Effects of the thunderstorm on Wednesday evening last.—This neighbourhood was visited by an exceptionally severe thunderstorm on Wednesday evening, accompanied by hailstones of large size. The effect of such a visitation has left its mark upon many plants in the garden. Splendid breadths of *Mignonette* have almost been spoiled, the foliage in many cases and lateral growths also having been completely broken off. *Michaelmas Daisies* in several cases have been more or less denuded of their foliage, and Tufted Pansies have suffered severely. The kitchen garden appears to have suffered quite as much as the flower garden, capital batches of Lettuces being completely riddled. This also applies to Cauliflowers, Cabbages, &c. Early breadths of Brussels Sprouts have their leaves completely broken—in fact, the effects are most disastrous. For some time the more sheltered positions were white with hailstones.—D. B. CRANE, *Highgate, N.*

Nymphaea odorata sulphurea.—Growers of *Nymphaeas* in tanks which admit of the water becoming warmed by the sun or otherwise should make a note of this lovely variety, especially the form called *grandiflora* by M. Marliac. The flower is of large size, nearly 6 inches in diameter, and of the peculiar stary shape of the *odorata* section, very full and of a rich clear yellow. With me it is the earliest of its section to flower and far the largest. The foliage is marbled with chocolate like that of most other *Nymphaeas* whose flowers are yellow. It also seems vigorous in habit and contrasts in shape of bloom very markedly with the well-known, but exquisitely lovely *N. Marliacea Chromatella*, another very vigorous form and now well known in many gardens. *N. Marliacea carnea* (bush) and *N. M. albida* or *candida* (pure white) are two other grand sorts. Even confined, as my plants are, in boxes, I have had several blooms over 6 inches in diameter, and many more fine buds are coming out. The first *Nymphaea* to flower with me is always *N. Laydokeri rosea*, and it keeps on blooming all the summer, as does the dainty little *N. pygmaea helvola*, and for weeks after the native *N. alba* has ceased till the weather of autumn becomes too dark and chill.—GREENWOOD PIM, *Monkstown, Dublin.*

TREES AND SHRUBS.

PRUNUS PSEUDO-CERASUS FL.-PL.

(JAPANESE CHERRY.)

ALL the forms of this species are valuable in the garden, and during the season when they are in bloom, which is the end of March and during April, there are no trees to equal them in beauty. The nearest rival among Cherries is the double-flowered Gean (*P. Avium* fl.-pl.), and this flowers a fortnight or so later.

In an interesting notice of this tree in his "Forest Flora of Japan," Professor Sargent says that in the forests of Yezo *Prunus pseudo-Cerasus* occasionally attains a stature of 80 feet. In this country it is rarely more than one-

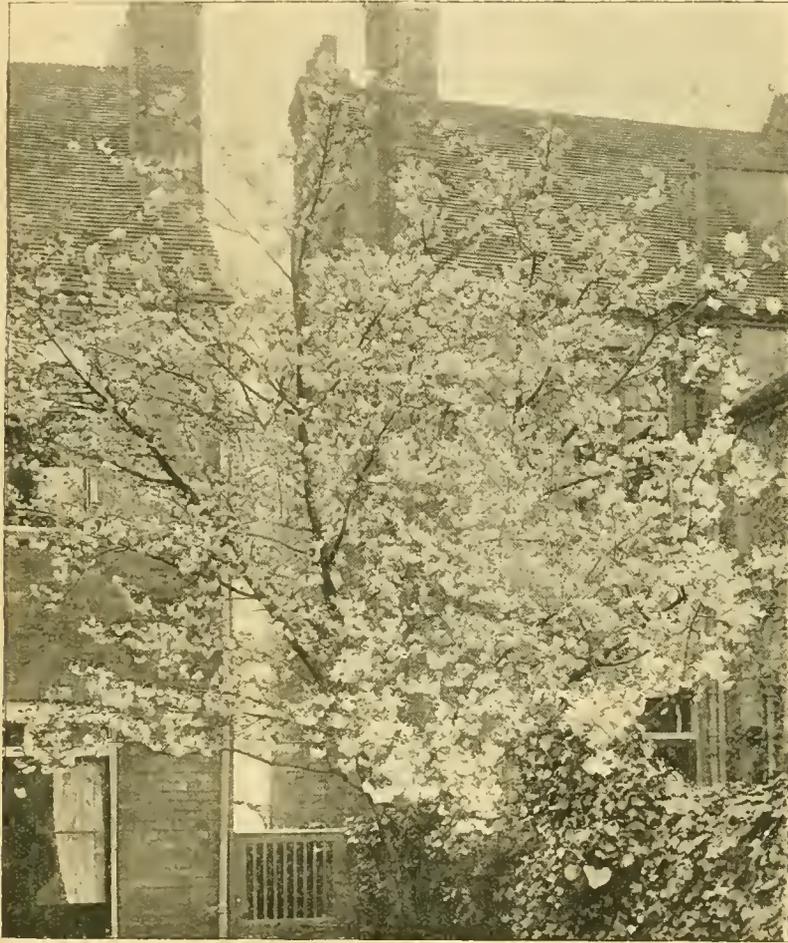

There is, in fact, no tree that is better worth planting in quantity. The illustration shows its beauty in what are apparently not particularly congenial surroundings. To see it at its best, a grove of about a dozen trees should be planted against a background of Holly or Evergreen Oak. In Waterer's variety the flowers are of a delicate rose, and they are of exceptional size—frequently over 2 inches across. In the catalogue of the Yokohama Nursery Co. it is stated that there are more than twenty of these double varieties. One of them called Ukon is rather curious and striking. The flowers are of the ordinary size and shape, but the petals are suffused with a yellowish green tinge that might have suited the wearers of the green Carnation who developed a small craze a

26 inches in circumference. It usually flowers in May, and is sheltered by the house from north and east winds. The soil is clay, topped with marl. As the ground slopes down towards the spot occupied by the tree, the roots are always kept moist, and they extend principally under the gravel paths. It is neither manured nor pruned.

Osmanthus ilicifolius purpurascens.—This is decidedly the best of the numerous forms of *Osmanthus* that we have in our gardens. The varietal name is derived from the purplish tinge of the young leaves, especially on the under-sides. As the foliage matures the purplish tinge partially disappears, but not enough to prevent its being readily distinguished from the ordinary form. It is in every way a most desirable evergreen shrub, and the hardiest of the different kinds of *Osmanthus*. This variety does not appear to be so well known as it should, but as its merits are more generally recognised we shall doubtless meet with it more frequently, for its propagation is not attended with any difficulty. Cuttings taken at this time of the year, put into pots of sandy soil in an ordinary garden frame, and kept close and shaded till rooted will strike before the autumn. Among other features possessed by the *Osmanthus* is the pleasing fragrance of the tiny blossoms.—T.

Hydrangea petiolaris.—A large plant of this *Hydrangea* on the north side of the herbaceous ground wall at Kew is flowering freely, and it is both an interesting and attractive shrub for such a position. In habit it is widely removed from the commonly known *Hydrangeas*, being quite a climber, attaching itself to the wall by means of its aerial roots exactly as the Ivy does. The large flattened corymbs of blossoms consist for the most part of the small fertile ones, the large sterile flowers which constitute the showiest portion of the inflorescence in the case of most of the *Hydrangeas* being limited to a scattered few around the outside of the cluster. Still, for all that they are sufficiently numerous to make a goodly show. In colour they are whitish. Besides its value as a wall shrub this *Hydrangea* is just the thing for rockwork, as it will clothe even large boulders with quite a network of its long, flexible stems, held in position by innumerable roots, which attach themselves to nearly everything within reach. At the same time it is not of a particularly aggressive nature, and may be readily kept within bounds, while it is perfectly hardy. This climbing *Hydrangea* boasts a plurality of names, as besides that at the head of this note it is also known as *H. volubilis* and *H. scandens*, as well as *Schizophragma hydrangeoides*. This last is a distinct plant, but the name is often applied to this *Hydrangea*, which it much resembles.—H. P.

Halesia diptera.—Among the May-blooming shrubs none surpass the *Halesias*, with us so profusely do they bloom, the branches being literally wreathed in snowy blossoms. *Halesia tetraptera* (the Snowdrop Tree) is pretty well known in English gardens, but the subject of this note I do not remember to have seen there, nor indeed is it offered in the lists of some of the best nurserymen on this side. At first I thought the distinction was a mere botanical one, the name denoting its two-winged fruits as compared with the conspicuously four-winged fruits of *H. tetraptera*, but after three years' observation of its behaviour here I note it has one distinct attribute that commends it to favourable notice. It is decidedly later in flowering, as proved by a number of trees we have in widely separated parts of the park, but more especially can this be seen in one particular group where are half a dozen specimens of each species. At the time of writing (May 29) every flower has fallen from the branches of *H. tetraptera*, whilst *H. diptera* is in full bloom. If there is any difference at all in the flowers individually, I should say that those of *H. diptera* are rather the larger, being longer, with more acute petals. This is but a minor feature, however, its great value being in its later season of flowering. Nicholson mentions

Prunus pseudo-Cerasus fl.-pl. in Mr. C. Beckingham's garden at Palmer's Green, London, N.
From a photograph by Mr. F. Connell, 3, Blenheim Place, St. John's Wood.

fourth that height. By the Japanese it is cultivated for flowers more than any other tree. How much they value it may be gathered from the following extract:—

For centuries they have planted these Cherry trees in all gardens and temple grounds and often by the borders of highways, as at Mukojima, near Tokio, where there is an avenue of them more than a mile in length, and at Koganei, where a century and a half ago 10,000 Cherries were planted in an avenue several miles long. The flowering of the Cherry tree is an excuse for a holiday, and thousands of men, women and children pass the day under these long avenues in more or less hilarious contemplation of the sheets of bloom.

In England it is a perfectly hardy tree, and the flowers are rarely injured by bad weather.

few years ago. This variety was introduced some six or eight years ago by Messrs. Veitch. Another very fine form was given a first-class certificate at a meeting in May of the floral committee. It was brought from Japan by Mr. J. H. Veitch and bears his name. The flowers are of a charming shade of pink. *Cerasus Sieboldi rubra* is another good form of this tree; still, as I have said before, all of them are worth growing.—W. J. B.

Mr. C. Beckingham, 9, The Villas, Palmer's Green, N., in whose garden the tree figured is growing, sends us the following particulars concerning it:—

The tree represented is estimated to be about eighteen years old, is 25 feet to 30 feet high, and is grafted. At the ground-level it measures

H. diptera in his "Dictionary of Gardening," but I do not find it mentioned at all in Gray's "Manual of Botany of the Northern United States," although *H. tetraptera* is given, with its distribution as "from Western Virginia to Illinois and southward." Both species seed freely here each year. — A. HERRINGTON, *Maulson, N.J.*

NOTES FROM OFFINGTON.

It is not often one meets with *Clianthus puniceus* in good condition. Being generally grown under glass and much subject to red-spider, it is often the reverse of satisfactory. Where, however, it is seen in good condition it is most attractive. I lately saw a fine plant in the gardens of Capt. Gaisford, Offington, near Worthing. The plant was growing against a wall and was covered with its bright red blossoms. It is, perhaps, only in favoured positions that it can be grown out of doors, but where sufficient shelter can be given it is certainly one of the most desirable plants for covering a wall. It was about the middle of May when I saw it, and it then appeared to have been flowering for some time and likely to continue.

In the same garden I saw several other semi-hardy plants flowering freely out of doors. In the north of London I found the first frost of any severity would kill *Clematis indivisa*, yet in the above garden I found it had stood out of doors for years, and at the time of my visit was in full flower, growing beside *Edwardsia grandiflora*, which was carrying large trusses of bright yellow flowers. *Ceanothus Veitchi* was a mass of deep blue. *Rhynchospermum jasminoides* and *R. pulchellum* also have withstood several winters. I was surprised to see *Habrothamnus elegans* outside. A large plant of this against a wall was just showing bloom. Some fine bushes of *Xanthoceras sorbifolia* were just opening their flowers. *Daphne Mazeli* (variegated foliage and flowers somewhat like those of *indica*) and *D. fioniana*, the latter a mass of deep mauve flowers giving off a rich perfume, were also in bloom. Several *Magnolias* were in flower. A large bush of *Cytisus scoparius* *Andreasii* showed how well suited this beautiful Broom is for the garden, being a mass of richly coloured blooms. *Cytisus purpureus* and *Cytisus elongatus* were flowering freely. Many other beautiful things might be enumerated all of which seem to be at home in this old English garden. A. HEMSLEY.

Azaleas.—The various sections of Azaleas, in considerable numbers and forming groups of varying sizes and shapes, have been splendid this year. For size of bloom, the palm must be given to the Boskoop seedlings of *mollis* and *sinensis*, and if anything is lacking in the masses they compose, it is the want of a few more deep yellows, something after the style of Anthony Koster, sprinkled amongst them. Taken altogether, the variety, depth of colour, and the immense size of the blooms are remarkable and quite a revelation. Owing to the intense heat and drought the blooming season proved shorter than when cooler weather prevails. I should be pleased to see more of these beautiful free-blooming hardy shrubs planted in thousands up and down the country. Their chaste and subdued colours and exquisite perfume would add beauty to many a hill and glen now occupied with far less worthy subjects, and, excepting on the limestone, they need no special preparation, merely fairly good light soil free of tree roots and coarse herbage and a modicum of light and air.—J. R.

NOTES & QUESTIONS.—TREES & SHRUBS.

Weigela Eva Rathke.—While *Weigela* or *Diervilla praeox* is on p. 422 referred to from the fact that it flowers in advance of any other variety, this is of equal value in that it serves to prolong the flowering season of this beautiful class of shrubs, being in full bloom when they are nearly, if not quite, over, while a succession is kept up till summer is well advanced; in fact, sometimes till autumn sets in. This *Weigela* is now pretty well known and generally

cultivated. The flowers are of a rich crimson tint, and larger than in some of the older varieties of the same colour. A bed of this kind is particularly attractive just now at Kew.—T.

GREENWAY, SOUTH DEVON.

On the lower Dart, opposite the picturesque village of Dittisham, embowered in Damson trees that in the spring-tide of the year shroud the low-eaved cottages in a wealth of snowy blossom, and hard by, where the storied "Anchor Stone," midway between the rock-margined, tree-clad shores, divides into two channels the lovely river, here at its narrowest, and sends the circling eddies to dimple the placid surface amid the sun-flecked shadows that lie beneath the overhanging boughs now verdant with unnumbered leaves, is situated Greenway, one of the South Devon seats of Mr. T. B. Bolitho, M.P. From the Reed-thatched boat-house on the river's verge the grounds slope steeply upward, thickly clothed with trees, until they reach a higher level, whence to the southward a charming view is gained of the river Dart, flowing seaward between densely wooded banks, its waters blue beneath the unclouded sky.

Many rare and beautiful plants and trees flourish on the walls and in sheltered nooks of the interesting gardens. Several large specimens of *Clianthus puniceus* were at the time of my visit covered with a profusion of their great crimson-scarlet blossoms, whose formation has led to the name Lobster-claw being applied to the plant. A fine bush of *Acacia armata* some 5 feet in diameter was yellow with flower, and the single white *Rosa flavigata*, that succeeds so admirably at Kingswear, at the mouth of the Dart, was also in bloom. Other plants at home on the sunny walls were the scarlet-flowered Mexican *Inga pulcherrima*, *Bignonia capreolata*, and *B. (Tecoma) radicans*, *Callicarpa rubella*, a native of China, the handsome white-flowered *Swainsonia albiflora*, and the pale blue *Plumbago capensis*, which was growing strongly on a sheltered exposure. In places where this plant will exist through the winter in the open, as it has proved its capability of doing in not a few favoured spots in South Devon, it creates a lovely effect when plentifully set with its silvery blue flower-clusters in the late summer or early autumn, its colour being quite unique in the garden. The sweetly-scented *Rhynchospermum jasminoides* was represented by a vigorous specimen some 10 feet in height, and the Chilean *Berberidopsis corallina*, *Chorozemas*, *Pomegranates*, *Hydrangea scandens* and the yellow-blossomed *Piptanthus nepalensis* also evidenced by their health an appreciation of their surroundings. Banksian and China Roses rambled up high old walls and were approaching the zenith of their beauty. Choice *Rhododendrons* were doing well on a slope the soil of which had been removed and replaced by peat, and many fine forms were in bloom, amongst which were noted *R. Aucklandi*, *R. Falconeri*, *R. Dalhousianum*, *R. fragrantissimum*, and *R. George Hardy*. Of shrubs and trees, many fine *Dracaenas* were already commencing to throw out their scented flower-spires a specimen of the Fire Bush (*Embothrium coccineum*) had expanded its vermilion flower-clusters, but is far inferior in size to one in Mr. Bolitho's garden at Trewidden, Penzance, which is held to be one of the finest, if not absolutely the largest, in Great Britain. *Eucryphia pinnatifolia* from Chili was present. *Metrosideros robusta*, 10 feet in height, was in vigorous health and flowers well in its sheltered site; *Correa bicolor* had made good growth; and *Camellias*, *Choisya ternata*, *Garrya elliptica*, and the commoner *Rhododendrons* had made enormous bushes, one of the latter having attained a height of close upon 30 feet. A fine specimen of the rare Chilean tree *Guevina Avellana* had formed a well-furnished specimen 20 feet in height; the Strawberry Tree (*Benthamia fragifera*) was showing its pale yellow flower-buds; *Photinia japonica* had attained a stature of 20 feet, a height that is

supposed to be rarely exceeded by this subject; while fine specimens of Japanese Maples, *Eleagni*, and other handsome shrubs were conspicuous amid the wealth of foliage, and the great New Zealand Flaxes (*Phormium*) flower well year after year. The hardy Palm (*Chamerops Fortunei*) was well represented, and Bamboos had formed graceful clumps on the sward. In an isolated position on the lawn is a splendid specimen of the Tulip Tree 50 feet or more in height and of great girth, while a towering *Wellingtonia* has attained a stature of 90 feet, and its trunk at 2 feet from the ground measures 21 feet in circumference. On the eastern side of the house a small rock garden was formed some years ago. It is constructed of limestone, and occupies a position on a steep slope facing south-west. The arrangement is at the same time natural and artistic, and in it many alpine are flourishing, such as *Androsaces*, *Saxifrages*, *Campanulas*, *Sedums*, *Gentians*, *Dianthus*, with *Mesembryanthemums*, *Aubrietias*, and *Alyssums*.

S. W. F.

Wall edgings.—When in one of the most remarkable of Surrey gardens recently I noted how singularly effective as covers or surface-edgings on low stone walls bordering the carriage-drive were such things as *Sedum acre aureum*, a mass of golden colour then some 15 inches broad and 10 feet to 12 feet long. Then would come an equal length of *Veronica prostrata*, a mass of blue, followed by a singularly effective length of *Thymus Serpyllum coccineus*, literally a mass of blood-red colour and beautiful beyond description. A little further would be seen a huge mass of the beautiful blue *Lithospermum prostratum*; next, perhaps, *Golden Stonecrop* again, then *Aubrietia Leichtlini*, and so on, ringing the changes on these and other creeping plants with marvellous effect. How very possible is it by the employment of simple hardy creeping plants in this way to produce effects of great beauty. What a charm attaches to gardening of this description when it presents some break away from the common rut.—A. D.

GARDEN FLORA.

PLATE 1229.

THE MANETTIAS.

(WITH A COLOURED PLATE OF *M. BICOLOR*.)

The species of *Manettia* figured is the best of the thirty known, so far as can be judged by the few that have been introduced into gardens and by herbarium specimens. It has been in cultivation about fifty years, but until recently it was practically lost and its place and name taken by a much inferior species, the correct name of which is *M. luteo-rubra*. I believe we are indebted to Mr. Godseff for the recovery of the true plant, he having found it in cultivation in the United States a few years ago. It is one of the most useful of stove twiners, rapidly covering a trellis or small pillar with its twining stems, and bearing a profusion of bright scarlet and yellow flowers almost the whole year round. It is easily propagated from cuttings. This and all the other species are natives of Tropical America. The best of the others are:—

M. CORDIFOLIA, which has shining green glabrous heart-shaped leaves, the largest 2 inches long, and slender-stalked, drooping, tubular, quadrangular flowers each over an inch long, with small recurved lobes and coloured bright rose-red. "This truly beautiful plant, raised from seed sent by Mr. Tweedie from Buenos Ayres . . . is just now opening its first blossoms, and being covered with a profusion of buds in every stage, it pro-

* Drawn for THE GARDEN by H. G. Moon in Messrs. Santer's nursery at St. Albans. Lithographed and printed by J. L. Goffart.

mises to be exceedingly ornamental during many weeks."—(*Botanical Magazine*.) It is grown in the Palm house at Kew.

M. MICANS was introduced from Peru by Pearce, collector for Messrs. Veitch, about thirty years ago. It differs from the other two in that it produces its bright orange-red flowers in leafy panicles, whilst its leaves are each 3 inches or 4 inches long and are ovate, not cordate at the base. It used to be grown at Kew, but is not there now. I shall be glad to learn if it is still in cultivation anywhere. There is a figure of it in the *Botanical Magazine*, t. 5495 (1865), where Sir Joseph Hooker said it was by far the most beautiful species known to him. The genus is closely related to *Bouvardia*. W. W.

THE WEEK'S WORK.

KITCHEN GARDEN.

LEEKs, MAIN-CROP.—It is now quite time the main batch of Leeks was transplanted. The best Leeks are grown in trenches, although on extra strong, retentive soil excellent results are obtained from planting on the level. If the manure has now to be dug in, see that it is in a well-decomposed state. Where ground is limited, three, or even four, rows of plants may be grown in one trench, extra care, however, being necessary in earthing up to prevent the soil entering the centres. The bed should be well soaked with water a day or two before planting and the seed-bed also, the young plants being carefully lifted with a small hand-fork. I cut a small portion of the top off with a sharp knife and drop each into holes made with a dibber, so that the foliage is just below the surface, watering afterwards with a fine rose. Of course, where ground is no object the one-row trench is the best, especially if exhibition produce is desired. Any small plants left in the seed-bed may be planted rather thickly on any convenient piece of ground, these coming in very useful for drawing for flavouring. The Lyon and Musselburgh are still very hard to beat, Dobbie's Champion being a grand variety for exhibition.

PEAS.—In many districts, especially on warm, shallow soils, second early Peas have had a somewhat hard time of it owing to the absence of rain. The value of early mulching will now be seen, as it not only enables the first formed pods to swell to a normal size, but also the secondary batch to come in. Where no other material is at hand, grass mowings may be used for mulching the rows. A good soaking of liquid manure or even clear water over this will often keep Peas growing until rain falls. On moist ground where any tall-growing varieties have overtopped the stakes, pinching out the terminal growths may be practised, this preventing the haulm falling about and hastening the filling of the pods. Where growth has fallen through between the stakes, stout string or tar-twine may be stretched along to keep it in its place, this being easily secured here and there to a stout stake. May-sown crops sufficiently advanced should be staked at once, as if allowed to fall about they never do so well after. Where another sowing is to be made for extra late gatherings, Chelsea Gem or William Hurst will be found as remunerative as any, allowing a space of 3 feet between the rows. Rows now in bearing should be closely picked, as this aids successional pods to fill properly, especially during hot, trying weather. All first and second early lots of haulm should be cleared off the ground as soon as possible, if only for neatness sake. These plots will often prove useful for late greens or for the earliest plantings of Rosette Coleworts.

EARLIEST TOMATOES.—Many batches will by now have reached the limit of trellis room, and fruit will have set up to that point. Where plants set fruit badly towards the lower parts, a few shoots may be laid in over the old stems, removing a portion of the foliage to avoid crowding. These may be pinched when they reach

that portion of the plant bearing green or half-ripened fruit. For many years I grew my earliest crop in a lean-to house, the pots standing on a shelf close to the front lights, growth being trained up a trellis on the single-rod system. Beneath the shelf in question, and at some 2 feet distant, there was a second, which accommodated an additional row of plants brought on at a later date. As the crop ripened and was cut from the lower parts of the first batch of plants the growths of the successional lot were trained up immediately by their sides, the leaves of the former being removed by degrees. By adopting this double batch system, even in a moderately sized house, it is surprising what a weight of fruit can be obtained.

MARROWS IN FRAMES.—Where these were planted out as soon as the earliest frame Potatoes were lifted, they will now be in a bearing state, and of such a size as to require much more root moisture and nourishment than before any fruit formed. If the plants have reached the sides of the frames, the best thing will be to remove the lights entirely and allow the Marrows to ramble over the sides and ends. Go over the plants and remove any weakly growths, these being of no use, but rather hindering the ingress of sun and air from the most fruitful growths. It is a good plan at this stage to mulch over the surface for some distance round the stems with decayed manure, as Marrows require much moisture. An occasional good soaking with farmyard liquid one half its strength will be of great benefit to Marrows. Remove all fruits as soon as full size is reached, as leaving them has an impoverishing effect, and Marrows will keep in a usable condition for some time if placed in a cool, even temperature. Any plants that have been grown in pots, for supplying a few early Marrows may now be thrown away, the frame ones keeping up the supply. J. C.

FRUITS UNDER GLASS.

VINERIES—When many varieties of Grapes are grown together in one house it is almost impossible to deal in the best way with all, and one of the most troublesome things with which the grower has to cope is the tendency shown by some, of which Madesfield Court may be taken as a type, to splitting just before the fruit ripens. Whatever may be the actual cause of this splitting, it may be accepted that any great fluctuations between drought and moisture either in the atmosphere of the house or in the soil of which the border is composed are certain to bring on an attack; consequently it is such fluctuations that we ought to avoid by keeping the atmosphere fairly charged with moisture, and by so regulating the watering that the border is never entirely dry on the one hand, or given a big soaking on the other. It is sometimes recommended that the Vines bearing these splitting Grapes be allowed more latitude in the matter of lateral growth than others, but I have not found that this makes any difference provided care is taken to keep the laterals in hand in such a manner that no great amount of growth is removed at any one time. In a word, I pin my faith more to regularity of treatment in all things than to any one supposed preventive in particular, and have no reason to regret doing so. Where some of the big bunched varieties, such as Barbarossa or Gros Guillaume, are grown in the late house, these should now require shouldering up, and this should be done with the greatest care to preserve or to produce a handsome form of bunch tied out to the fullest extent possible consistent with the desirable compactness which is one of the good points of well-finished bunches. As rubbing the berries spoils their appearance, deftness in handling the bunches is necessary to preserve them from being marked. Most late Grapes require some amount of fire-heat to keep them going and to bring out their best qualities; consequently this should not be overlooked, and whenever the nights are inclined to be at all cold, it is wise to give them the benefit of sufficient fire-heat to keep the water circulating in the pipes.

MUSCATs.—These will in most cases be now advanced beyond the stoning period, and from this time onward a night temperature approaching 70° may be given with advantage, this not only giving greater size of berry, but, what is still a greater advantage, it brings the Grapes forward enough to ripen up while the sun has still a great deal of power, and this gives them the clear amber colour so desirable in the Muscat—a colour it never attains when ripened late in the season, however much fire-heat may be used. Feed the Vines with alternate doses of ordinary manure water and some concentrated manure, as the roots like a change of provender, but in both cases the manure should be well diluted, and I prefer to err rather on the side of weakness than on that of strength. Should the border be at all sour or badly drained, care must be taken not to give water in too great quantities, as Muscat Vines especially resent this, and their foliage will turn yellow under its influence.

PEACHES.—Early Peach trees which have been cleared of their fruits should be at once gone over with the knife and all surplus wood removed, so that what remains for next year's fruiting may have the advantage of ample room. Time should also be spared to cleanse the trees of any insect pests which may have gained a footing earlier in the season, and if mealy bug is present the only way of dealing with it is to look well over the stems of the trees and apply to all nests found a solution of insecticide strong enough to kill the brood. By attention to this at a time of the year when these pests are active, much future trouble may be saved. It is early yet to talk about ripening of the wood, and I only allude to it now to say that early ripening, and the consequent shedding of the leaf, are a mistake, and whenever I see any sign of this I am careful to apply a light shade to the glass, so that the leaves may be preserved as long as possible. Trees that are leafless during late summer are prone to cast their buds the following season. See that the roots have plenty of water and syringe overhead daily. This, together with plenty of ventilation night and day, will enable the trees to finish properly. Mid-season houses with fruit swelling on the trees should be kept moderately cool, and fire-heat may be entirely dispensed with or reduced to a minimum, for the trees do not like it, and with proper management in the matter of ventilating carefully and shutting up early, swelling goes on, or should go on, at this time of the year as quickly without as with artificial heat, and the fruit will certainly be better flavoured and coloured. Tie in the growths as they extend, but not in such a way as to cover and shade the fruits. Bring up to the light and support in that position all fruits which have a tendency to grow in an obscured position, and fix them so that the apex of each points towards the glass. Use the syringe freely up to the time when they show signs of ripening, and be careful only to use soft and very clean water, as the Peach in its later stages is easily disfigured by hard or dirty water. Above all things see that the borders are not allowed to become dry, and that the roots are well fed during the time still left in which to perfect the fruits.

PINES.—Continue to pot up into fruiting pots the stock of Queens as soon as the plants seem in a fit condition for the move, so that they may get well established and able to bear the cooler treatment which may be given in winter, for well-rooted stock can safely be kept in a lower temperature than those which are not so forward, and this lessens the need for hard firing at a time of the year when excitement or forcing is bad for the plants. Where there are the necessary conveniences for growing the main batches on the planting-out system, no time should be lost in establishing the plants in their beds. For such plants a good command of bottom-heat, that may be regulated as occasion requires, is a necessity, and unless this can be afforded it is best to stick to the pot system, a most convenient one where dependence has to be placed on fermenting material for the requisite heat. CORNUBIAN.

KITCHEN GARDEN.

NOTES ON EARLY POTATOES.

THE value of observation as to the quality and earliness of various kinds of vegetables, Potatoes included, is often negated by the absence of any particulars as to soil and locality, and as doubtless many correspondents will be relating their experience of varied kinds it would be a great help in forming correct conclusions as to suitability or otherwise for various soils if these particulars were given. In the garden from which I write the soil is heavy and unless plenty of opening material is used, practically unworkable unless caught just at the right time, while the situation is the highest part of Suffolk and very exposed. A good part is sheltered from north and east winds by a belt of trees and high Box hedges, and the border on which the Potatoes named are grown has been well worked and manured. As showing how some excellent kinds vary from year to year, I may mention that popular variety Ringleader. With respect to quality it is by far the best variety here this season. I have before recommended it as an excellent forcing kind owing partly to its short top and also the fact that the tubers are usually fairly regular, that is, there is not a number of small worthless ones when the earlier ones are fit for taking up. Last season the crop was good, but the quality was not first-rate by any means. Still, I think, taken all round, it will be hard to beat.

Ninety-fold I am growing for the first time this season, and I must say that I am very agreeably surprised with it. It is a strong, but not too vigorous grower, and is fit to take up very early. Planted on March 3 it was fit to dig on June 10, and the fine crop of beautifully-formed tubers was quite a revelation to me. And what is more important than appearance, the cooking quality of Ninety-fold is excellent. It is true that the newer kinds do not in after years always keep up their reputation, but, judging by its present form, this Potato should become a very popular kind in the not far distant future. Among the Ashleaf section I can find nothing to beat Hammer-smith Kidney. The good quality of all these varieties is well known, but the fact of their being somewhat later than many of the newer kinds has led in many cases to the substitution of the latter for the first crops. But no collection of Potatoes will be complete without at least one or two of the Ashleaf kinds, and as far as my observations go on various soils I should select at least three in the order named, Hammersmith, Veitch's Ashleaf, and Myatt's. Sharpe's Victor I am still growing, and I see no reason for altering my previous opinion of it, though I still think there are spurious stocks of it in the market. But if, as noted above, Ninetyfold proves as good in the future as it has done with me this year there will be no need of growing Victor. Neither in my opinion comes up to the Ashleaf kidneys for flavour, though Ninety-fold runs it very hard, but both of them are distinctly earlier. There are several of the second early kinds that in cases where a large demand exists may with advantage be grown for filling the breach that sometimes exists after the stored tubers have passed their best and before the usual second early lots are ready for digging. Those I have found useful are Early Rose, Reliance, and Satisfaction. The first of these is too well known to need description. Reliance is a good kind, but does not keep to the true kidney shape on this soil. This is, I believe, contrary to the experience of others, but I speak of it as I have found it. Satisfaction has, I think,

been more grown by farmers than gardeners, and a friend of mine who grows somewhat largely advised me last year to plant it among the early varieties. I did so, and got passable tubers to look at, but worthless to eat. As a

provement in recent years as in Carrots. Culture has so much to do with the good quality or otherwise of these useful and delicately flavoured roots that selections of the old forms have been well grown and sent out as new over and over again

under different names. I have for the last ten days been drawing excellent roots of Short Horn, and these are not a whit behind several new kinds planted next to it. I sow the Carrots in drills 9 inches apart, and between these sow a drill of Radishes, the latter coming away before the Carrots require all the room. To do them well, Carrots like a deep, but not over-rich tilth, and more frequent sowings than most other vegetables. An old and fully grown Carrot has never the same flavour as small, quickly grown roots, few roots being so sweet and tender as the latter. Large Carrots are, of course, useful for flavouring.—H.

Leeks in June.—

The Leek is very useful from October to the early part of May. After the latter date the plants show their seed-spikes and the flavour is lost. I think the good-keeping properties of the Leek may in some cases cause those who purchase roots at the season named to dislike this vegetable, as, though the lower portion of the plant looks well, being thick and well blanched, the inside is mostly composed of a hard seed-stem and is useless. The plants other than for seed are useless, and should not be used as a vegetable, but when the public see such fine roots at shows they think them excellent. It is impossible to prevent large roots seeding. Frequently these plants have been raised in heat some fifteen to eighteen months previous. From a quality point of view they are useless, and should not be recognised at shows, however large they may be.—S. H. B.

A good keeping Beetroot.—For many years I have grown

second early or main-crop it is useful, as it is an immense cropper, seldom taking disease, the tubers large and of good quality later in the season. H. R.

Carrot Short Horn.—There are, I think, few vegetables in which there has been so little im-

Dell's Crimson, not on account of its splendid colour, but for its keeping properties, as given cool storage from December to June there is no difficulty in having good roots at mid-summer. I am aware many growers object to this variety on account of its small size, but this in my opinion is an advantage, as coarse Beets

Spray of Japanese Cherry (*Prunus pseudo-Cerasus fl. pl.*). From a photograph by G. Champion. (See p. 5.)

neither keep well nor cook well. I notice at wioter exhibitions a much larger root under the name of Dell's, the foliage being much lighter and coarser. Soils and plenty of food may be the cause of increased size and colour. Too early sowing may also cause roots to be large, but I fear in some cases the stock is not the true Dell's. This variety is very distinct, owing to its intense bronzy foliage, deep crimson colour and small smooth root. For keeping I have not found its equal, sown in May or June in an open quarter and lifted as late as possible in the autumn.—G. WYTHES.

Tomato: Vegetable or fruit?—As we are generally agreed as to the Tomato being a fruit, there is but little in "A. D.'s" criticism (p. 402) which calls for a reply from me, but I should like to point out that the exhibits at the Temple show are in no way a test in the matter, for no restrictions as to the number or kind of exhibits are placed on exhibitors there; neither are the exhibits competitive in the ordinary sense, nor shown for money prizes. Can "A. D." induce any competitor in the fruit classes at the Royal Horticultural Society's Crystal Palace show to put up a dish of Tomatoes in the collections of fruit for competition? If so, and a full number of points are allowed for them, I shall be satisfied, and many exhibitors who are sometimes at a loss for a dish to complete their exhibits will be gratified at the opening given them. I am aware that the Royal Horticultural Society have in a half-hearted way admitted that Tomatoes may be sometimes shown as fruits, but these must be either small or shown in clusters, and the admission has been of no practical benefit to the exhibitor up to the present time. Why should a dessert Tomato be small, and what is smallness? We do not ask for small Peaches or small Grapes. Some moderately large Tomatoes are preferred to the small ones for eating raw. I still hold that up to the present the Tomato is not given its proper status as a fruit from an exhibitor's point of view.—J. C. TALLACK.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JUNE 27.

It has become quite usual now for the Drill Hall to be filled with flowers at the fortnightly meetings, and on Tuesday last another large and beautiful display was to be seen. There were Orchids, indoor and hardy flowers, with a charming show of Roses, which were remarkably fresh and true in colour. It was in every way a delightful exhibition.

Orchid Committee.

First-class certificates were awarded to the following:—

ODONTOGLOSSUM HARRYANO CRISPUM.—This is the reverse cross of the variety exhibited at the Temple last year. It differs both in the colour and also in the shape of the segments, the lip especially being nearly twice the size. The sepals are creamy-white, slightly tinted rosy-violet, the whole surface mottled and marbled with light brown; the petals creamy white tipped with violet at the apex, mottled and blotched with light brown in the centre. The lip, upwards of an inch across, is pure white in front, spotted with deep purple around the sides. In front of the deep yellow disc there are numerous rich brown spots. The plant carried two racemes of three and four flowers respectively. From Sir F. Wigan, Clare Lawn, East Sheen.

LÆLIA DOMINIANA VAR. FIRE KING.—This is a beautiful form, the sepals and petals deep rose-purple, the lip rich crimson-purple veined with a darker shade and margined with rich rose-purple. The side lobes are rose-purple shading to yellow at the base, longitudinally lined with rich crimson through the throat. It is the result of crossing *L. purpurata* and *Cattleya Dowiana*. From Mrs. Briggs-Bury, Bank House, Accrington.

LÆLIO-CATTELEYA EUDORA VAR. EXIMIA (*Cattleya Mendeli* × *Lælia purpurata*).—In this the sepals and petals are pale rose, the lip intensely rich crimson-purple, with a broad margin of light rose, the side lobes rich crimson, shading to yellow, with numerous brown lines through the base of the throat. This is by far the finest form of this hybrid we have seen. From Messrs. J. Veitch and Sons.

ODONTOGLOSSUM CRISPUM SERAPHIM.—This is one of the finest white varieties we have seen. The sepals and petals are white, except a faint colour in some of the lower flowers on the spike on the bottom sepals. The lip is pure white, except the bright yellow disc. The plant carried a ten-flowered raceme. From Mr. de B. Crawshay, Rosefield, Sevenoaks.

Awards of merit were adjudged to the following:—

MASDEVALLIA RUSHTONI (*M. ignea* Eicharti × *M. racemosa*).—The habit of growth and shape of the flowers resemble those of the parent species. The flowers are orange-scarlet, veined with a darker shade of colour. It is a fine addition to the *Masdevallia* hybrids. From Captain Hincks, Terrace House, Richmond, Yorks.

LÆLIA TENEBROSA VAR. VICTOR WARBURTON.—This is a distinct form, differing in the colour of the sepals and petals and also in the lip from the Walton Grange variety. The sepals and petals in Mr. Warburton's plant are rich bronzy yellow, the lip white, slightly tinted with rose. The side lobes in front have a broad band of reddish purple. The plant carried a two-flowered raceme. From Mr. A. Warburton, Vine House, Haslington.

CATTELEYA MOSSIE VAR. LAWRENCEE.—The sepals and petals are pure white, the lip white in front, suffused with a faint shade of lilac in front of the bright orange-yellow disc. The side lobes are white, shading to yellow towards the base. From Sir T. Lawrence.

CATTELEYA GASKELLIANA FORMOSA.—The sepals and petals are pale lilac-tinted, the lip almost white, with some veinings of rose-purple in the centre; the side lobes white, shading to light yellow through the base of the throat. The plant carried a three-flowered raceme. From Messrs. J. Veitch and Sons.

ODONTOGLOSSUM CRISPUM PURPURASCENS.—This is a beautiful form of the *O. c.* Starlight section, the sepals white, heavily tinged with rose, the whole of the centre area covered with rich brown-purple spots. The petals are white, tinted with light rose and sparingly spotted with small brown spots; the lip white, shading to yellow on the disc and having some rich brown spots in the centre. The plant carried a ten-flowered raceme. From Sir T. Lawrence.

Messrs. J. Veitch and Sons sent a pretty group, consisting principally of fine varieties of *Cattleyas* and *Lælias*, both hybrids and species. In the back row were several good forms of *Lælia purpurata*, a finely-flowered plant and variety of *Cattleya Warneri*, several good forms of *C. Warscewiczii*, good varieties of *C. Mossie*, *C. M. Reineckiana*, and *C. M. Arnoldiana*. The most prominent among the hybrids were several forms of *Lælio-Cattleya Canhamiana*. *L.-C. albida* had almost white sepals and petals and a broad white fringed margin. *L.-C. Aphrodite Eidora* was well represented. The cinnabar-yellow-petalled *L.-C. Hippolyta* was most effective. Several finely-flowered plants of *Disa Veitchii* and *D. kewensis* were also included. *Cattleya Juliet* (*C. Mossie* × *C. labiata*), with deep rose sepals and petals, the broad open lip deep rose, veined and suffused with crimson-purple, was most attractive. A silver Banksian medal was awarded. Messrs. Hugh Low and Co. sent a large group, consisting principally of finely-flowered *Cattleyas* and *Lælias*. *Lælia Digbyana* and *L. purpurata* were most attractive. *Dendrobiums*, *Odontoglossums*, *Cypripediums*, *Oncidium*, and *Masdevallias* were very prominent and well represented. Under a glass shade was a good plant with one flower of the rare *Cypripedium callosum Sanderæ*. A silver Banksian medal was awarded. Messrs.

B. S. Williams and Son sent a nice group. In the back row were some finely-flowered *Oncidium serratum* and *O. macranthum*, a good plant of *Vanda tricolor*, and two finely-flowered plants of *Thunia alba*. *Lælia purpurata* and *L. tenebrosa* were also included. *Cattleya Mendeli* and *C. Mossie* were well represented. *Aerides Lobbi* and *A. affine* were also noticeable. A good plant of *Utricularia montana*, several finely-flowered *Cypripediums*, *Epidendrums*, and *Odontoglossums* were well represented (bronze Banksian medal). Messrs. Stanley, Mobbs and Ashton sent a large group, consisting of finely-flowered *Cattleyas*, *Lælias*, *Odontoglossums*, *Oncidium*, and *Cypripediums*. A bronze Banksian medal was awarded. Messrs. J. Charlesworth and Co. sent a *Cattleya Wagneri* with seventeen flowers, a pale form of *C. Mendeli*, and *Lælia cinnabrosa*.

Mr. J. Bradshaw, The Grange, Southgate, was awarded a silver Banksian medal for a nice group, consisting principally of good forms of *Odontoglossum crispum* and a pretty form of *O. excellens*. Among the many fine *Cattleyas* was a plant of the now scarce *Lælio-Cattleya exoniensis* with two spikes of flower. *L.-C. Thorntonii* has the intermediate character of the parents, the sepals and petals delicate lilac, the lip bright rose on the fringe, creamy white in the centre and yellow through the throat. *Anguloa Clowesi* and other interesting species were also included. Lt.-Col. Shipway, Caiswick, sent a small group. The most prominent among these were a dark form of *Lælia purpurata* and a good variety of *Cattleya Mendeli*. *C. Mossie*, *Odontoglossums* and *Cypripediums* were also represented. Lord Burton sent fine forms of *Cattleya Mendeli* and *C. Warneri*. Mr. W. P. Burkenshaw showed a spotted *Odontoglossum crispum* Mrs. Briggs-Bury sent *Lælia tenebrosa* (Walton Grange variety), and Mr. W. A. Bilney an exceptionally dark form of *Cattleya Gaskelliana* and *L.-C. Canhamiana alba*. Mrs. Temple, Leyswood, Groombridge, had a dark form of *Coelogyne Dayana*. Baron Schroeder sent a three-flowered raceme of the lovely *Cypripedium Stonei platytanum*, and Sir F. Wigan a dark form of *Cattleya Mossie* and a good variety of *Lælio-Cattleya eximia* with two flowers. Sir T. Lawrence had a dark form of *Lælia purpurata*, and Mr. de B. Crawshay a good shaped *O. crispum* with an eleven-flowered raceme. Mr. R. I. Measures sent *Masdevallia angulata*, a distinct variety of the *M. Mooreana* section, and Mr. W. C. Walker showed a finely-flowered plant of *Burlingtonia fragrans*.

Floral Committee.

First-class certificates were awarded to—

DAVALLIA ILLUSTRIS.—This plant seems to bear a relationship to *D. Mooreana*, though both in colour and height it is distinct from this. The plant is 2½ feet high, of spreading habit. From Messrs. Jas. Veitch and Sons, King's Road, Chelsea.

DRACÆNA INDIVISA SCHNEIDERI.—A well-marked form of this plant, being compact and free in its leafage. The leaves are each nearly 2 feet long, slightly channelled on the upper surface, and heavily saturated with reddish crimson at the base. From Messrs. Veitch and Sons, Chelsea.

Awards of merit were given to—

PELARGONIUM FIRE DRAGON.—A curious novelty in which the petals, which are brilliant scarlet, have a distinctly reflexed appearance and quite blunt at the tips. From Mr. E. S. Towell, Hampton Hill.

CARNATION LADY GERARD (Malmaison).—A distinct primrose and white, the flowers full and of the same form as is usual in this type. From Mr. H. Walters, Eastwell Gardens, Ashford, Kent.

DELPHINIUM SIR WALTER SCOTT.—A fine kind with massive spikes of intense violet-purple flowers. From Messrs. Kelway and Sons, Langport.

CARNATION TRUMAN.—A finely-formed pure white flower, very full and freely produced, though, unfortunately, without perfume. From Mr. James Douglas, Edenside, Great Bookham.

Messrs. Paul and Son, Waltham Cross, Herts, set up a fine bank of Roses, in which some three dozen Moss varieties figured, Zenobia, Blanche Moreau, Crested, Comtesse de Murinus (fine blush-white), and the old common Moss being the best. Cluster Roses of the Polyantha section were likewise numerous, and very showy were the rugosa forms, Mme. G. Bruant and Blanc double de Courbet being very good. The Hybrid Tea Belle Siebrecht was in fine form. Among pot kinds, Triomphe de Caen and Chas. Lefebvre, both excellent dark sorts, were noticeable, and equally so the now well-known Enchantres (silver Flora medal). Our reporter had not moved from this group when from unforeseen causes, though presumably inadequate staging, the stage carrying the above collapsed with all that was upon it. Messrs. J. Peel and Sons, Roupell Park Nursery, West Norwood, had set up a lovely bank of single and double Begonias, but, owing to the above accident, the entire staging collapsed just as our reporter was commencing his notes. It was, however, obvious that the plants and strain were of the best description, well grown and freely flowered, and but for the accident referred to would have made a notable feature in the day's exhibition. A very fine bank of Malmaison Carnations with a background of tall Bamboos came from Messrs. Wm. Cutbush and Sons, Highgate. The plants were models of good culture. Some of the best were Souvenir de Chas. Freemantle, red; Jane Seymour, pink; Albion, salmon-pink; Soult, red-scarlet; Princess of Wales, Calypso, deep blush and pink; Margot, red; and the clear scarlet Sandridge, the latter of the border class. A capital lot of the Goldea Calla (*Richardia Elliottiana*) occurred at intervals in the group, which was bordered with Ferns (silver Banksian medal). Mr. John Russell, Richmond Nurseries, Richmond, had a fine group of ornamental trees and shrubs in pots, in which *Acers*, *Cotoneasters*, *Ivies*, *Catalpa springifolia atrea*, *Catalpa purpurea*, a very distinct plant; Golden Oak, and such things largely predominated. A few good things were *Rhus glabra laciniata*, *Aralia Maximowiczii*, a handsome plant with digitate leaves, *Andromeda speciosa*, full of its snowy blossoms, *Andromeda pulverulenta*, and *Rhus japonica Osbeckii*. *Robinia hispida* was also freely employed. *Euonymus* and small things formed the margin (bronze Banksian medal). Messrs. B. S. Williams and Son, Holloway, set up a small group of border Carnations, in which were yellow, scarlet, rose and pink shades. The plants were all in small pots, thus demonstrating what can be done in an ordinary greenhouse. The Messrs. Veitch and Sons, Ltd., Chelsea, had a fine display of their pink Canterbury Bells (*Campanula Media calycanthema rosea plena*), the plants models of good culture, excellent in habit and freely flowered. Some of the flowers were of great size and very rich in colour. The same firm also had an enormous group of cat herbaceous Peony blooms in which it was difficult to find a weak flower. Of the semi-doubles, *Abotis*, white with numerous white ligaments; in centre, and *Lachesis*, pink guard petals, white twisted petals in centre, were very charming. Among the doubles, *Zephyrus*, blush-pink; *Leonie*, pale pink, very full; *Aurora*, pink and rose; *General McMahon*, rich purple; *Vesta*, full pink; *Duchesse de Nemours*, pure white, and *Rubens*, crimson-lake, were the best. At one end a pretty group was made of the early-flowering *Gladioli* and English *Iris*s (the former in some dozen or more kinds), *Delicatus*, *Rosy Gem*, and *General Scott* being very fine. The well-marked *G. insignis* was also shown. *Ixias* in variety bedded in Maiden-hair Fern completed this imposing array of flowers (silver Flora medal). Messrs. Watkins and Simpson, Exeter Street, Strand, staged a group of their strain of dwarf bedding *Lantanas*. Mr. F. G. Foster, Brockhampton Nurseries, Havant, set up a wonderful array of Sweet Peas. Of the whites, *Emily Henderson*, *Snowdrift* and *Blanche Burpee*; of blues and kindred shades, *Emily Eckford*, *Lady Hamilton*, *Countess of*

Radnor; of pink and red, *Gorgeous*, *Oriental*, *Lady Mary Currie*; of primrose, *Mrs. Eckford* and *Cream of Brockhampton*, were the most important. *Navy Blue* is very fine, while *Pink Friar* is white, splashed pink. There were some eighty varieties set up in this group (bronze Flora medal). Hardy flowers from Mr. Maurice Prichard, Christchurch, Hants, though not so numerous as on a former occasion, contained some choice things, such as *Orchis foliosa*, *Philadelphus Lemoini erectus*, *Kniphofia caulescens*, *Clematis integrifolia Durandi*, *Lilium umbellatum Cloth of Gold*, *Lilium Martagon album*, a dozen spikes, very fine; *Brodiaea coccinea*, a grand lot, and *Calochortus venustus citrinus*, the two latter showing how well such things do in the south. Mr. Prichard also had a series of M. Marliac's hybrid Water Lilies arranged in large bowls, the flowers very fine and fresh (silver Banksian medal). Messrs. Wallace and Co., Colchester, had a large and varied group of the best hardy flowers. These for the most part were set up in large blocks that at once created a good effect and likewise gave a good idea of their worth. In this way we saw a great variety of *Lilium Thunbergianum*, or elegans as the group is sometimes called, two of the finest being *Alice Wilson*, with delightful yellow flowers, and *Orange Queen*, a kind with clear rich orange flowers, remarkable not only for colour, but equally for its substantial petals and their well-rounded form. Other kinds of this set also were numerous. Then came *L. Browni*, *L. Washingtonianum*, *L. Szovitzianum*, *L. Henryi*, and *L. Hansoni*. The charming hybrids *L. Dalhousii* and *L. Marhan* were also noted. Not least of the many kinds here was *L. platyphyllum* with towering spikes of its massive flowers away in the background. Other notable things in this group included a choice array of *Ixias*. *Calochortus* were naturally plentiful, though largely of the *Eldorado* group and the ever-welcome *C. citrinus* among others. Some of the loveliest of summer *Iris*s, such as *I. juncea*, *I. Monnierii*, *I. gigantea*, and *I. spuria*, were also here, and many different forms of *Brodiaea*, among which *B. coccinea* is ever a conspicuous flower. Spikes of *Incarvillea Delavayi* nearly 2 feet long gave evidence of being quite happy. Tree Peonies were also largely represented. The Messrs. Barr and Sons, Covent Garden, also brought a fine group of things, though here the herbaceous Peony was largely in evidence. Of these, however, there was a large display, embracing the finest of the section, some of the lighter shades being very pleasing and fragrant also. A few flowers of *Iris Kämpferi*, probably the earliest of this set to bloom this year, were also noted, besides which such things as *Inulas*, *Crocopsis*, *Polemonium coerulum album*, *Potentillas* in variety, *Lupinus arboreus*, *Cypripedium spectabile*, and such things were also shown. Some three distinct *Heucheras* gave a very pretty result in near proximity, the richly-coloured *H. splendens* being a very striking lot (silver Banksian medal). Messrs. Dobbie and Co., Rotherham, N.B., had an imposing array of Sweet Peas set up in huge bunches and to the number of about 100. The cream of this beautiful family was included in this comprehensive group. The varieties, however, are well known, and we therefore refrain from giving them in detail (bronze Flora medal). Mr. Joseph Lamb, Burton Joyce, Notts, exhibited a basket of blooms of the Carnation-flowered *Pink Albino*, perhaps the nearest approach to a Carnation of all the Pink family. It is a pure white flower and deliciously fragrant. Mr. James Douglas, Edenside, Great Bookham, set up a few good Carnations, mostly of the border sorts. *Lady Grimston* of the Malmaison set is distinct, with rose-scarlet spots on a pink and white ground. Other good border kinds included *Cardinal Wolsey*, *Frances Wellesley*, *carmine-rose self*, quite a novel shade among red Carnations; *Mrs. Colby Sharpin*, *Trojan*, pure white; *Cecilia*, fine yellow; and *Mrs. Sydney H. Divers*, scarlet. A capital lot of mixed hardy flowers from Messrs. Geo. Jackman and Sons, Woking, contained some good things,

such as *Geum miniatum*, *Delphinium Balladonna*, *Inula glandulosa*, *Campanula grandis*, (*Eoothera speciosa*, together with a variety of Pinks, such as *Anne Boleyn*, *Emerald*, white, dark centre, *Mrs. Pettifer*, and others. *Lupinus arboreus* was also good, while the hybrid *coccinea Clematis* and hybrid Sweet Briers proved most interesting. Some good Roses were also shown, *Fisher Holmes* and the lovely *Tea Sunset*, *Kaiserin Augusta Victoria*, *Mrs. Sharman Crawford*, *Margaret Dickson*, and *Mrs. Grant* being notable flowers (bronze Flora medal). The Stocks and hybrid Columbines from Messrs. H. Cannell and Sons, Swanley, were very pretty in the mass. It was an unusual bank of blossom, both families being represented by much variety and good colour. The Stocks were of an excellent strain and the colours well defined (bronze Flora medal). A large bank of herbaceous Peonies with *Delphiniums* was set up by Messrs. Paul and Son, The Old Nurseries, Cheshunt (bronze Banksian medal). Peonies and *Delphiniums*, too, were quite a feature in the large display from Langport by the Messrs. Kelway and Son. Here, however, some novelty presented itself, more particularly among the Larkspurs, though even these appear to have reached the very acme of perfection so far as size and colours are concerned. The most noticeable of these, however, are *Miss Gladys Wilson*, a fine double blue; *Beauty of Langport*, white; *Primrose*, a rather good spike; *Lady Battersea* and *Norah Green*, fine blue with pure white eye. Some good Peonies are *Queen Victoria*, pink and white; *Olivia*, white; *Breeda*, white and blush. The new *Lupinus polyphyllus Somerset* with soft and pale yellow flowers showed this to be a distinct addition to the hardy plant class. *Gaillardias*, too, were very fine (silver Banksian medal). A collection of *Selaginellas*, containing some fifty species and varieties, from Mr. H. B. May, Elmington, was thoroughly representative of this pretty and useful group of plants, the fresh green tints from these forming a refreshing group (silver Banksian medal).

A grand lot of flowering and decorative plants was arranged on the floor by Mr. E. Backett, gardener to Lord Aldenham, Elstree, and was greatly admired. The group was apparently arranged from diverging centres of Palms, *Kontias* and *Areca lutescens* being employed for this purpose. These primary plants were splendid examples of their kind, well grown and finely furnished. Around these a considerable variety of *Liliums*, such as *longiflorum*, *tigrinum*, *Kretzeri* and others, was used, while *Dracaenas*, *Crotons* splendidly coloured pieces and finely grown, *Begonias* of the *Rex* or allied set, *Aralias*, *Tuberoses*, *Ericas*, *Crassula coccinea*, *Saxifraga pyramidalis*, a few *Orchids*, *Rose Crimsons* *Rambler* and such things filled up the intervening spaces. This group well deserved the silver-gilt Flora medal awarded it. A most charming group, probably one of the finest ever seen at the Drill Hall, was composed simply of *Crotons* and *Humeas*, which alone conveys but little to those removed by distance from the place of exhibition. The *Humeas* were giants of their kind, fine plants towering away to 12 feet and 15 feet high, perfect examples of cultural skill, to say nothing of the care and judgment in bringing such fine plants a long distance by road. The lovely and fragrant plumes constituted a screen of indescribable elegance, and contrasted finely with the rich colour of the well-grown *Crotons* below. The group was margined with *Caladium argyrites* and extended to some 30 feet in length. These lovely plants came from the gardens of Sir C. Pigott, Wrexham Park, Slough (Mr. J. Fleming, gardener), and worthily gained a silver-gilt Banksian medal.

Fruit Committee.

The premier exhibit came from Messrs. Rivers and Son, Sawbridgeworth. The Peach trees in pots were remarkable specimens of culture, carrying from fifteen to eighteen fruits of enormous size and splendid colour. The varieties were *Sea Eagle* and the less known *Thomas Rivers*, a

splendid fruit and much admired for shape, size, and colour. There were also gathered fruits of this variety. It is evidently a splendid variety for forcing. The trees of Sea Eagle had been forced yearly for eight years. Princess of Wales Peach, Grosse Mignonne, and Gladstone were also very fine. Victoria and Byron Nectarines were very fine fruits, as were the Cherries Frogmore Bigarreau, Elton, and Early Rivers, and The Czar Plum (silver-gilt Knightian medal). A very fine collection of Queen Pines was sent by Mr. Thos. Coomber, The Hedges Gardens, near Monmouth. The fruits were large and well grown, with small crowns and large, well-ripened pips, beautifully coloured, and well meriting the silver Knightian medal awarded. A small collection of fruit was sent by Mr. W. J. Prewett, The Gardens, Frensham Place, Farnham, Surrey, including very good Foster's Seedling and Black Hamburg Grapes, Peach Hale's Early, Early Rivers Nectarine, Royal Jubilee Melon, a nice fruit, and excellent Royal Sovereign Strawberries (silver Banksian medal). Messrs. Laxton Bros., Bedford, sent some fine fruits of Monarch and Mentmore Strawberries, the former remarkable for size and colour. Messrs. Veitch, Ltd., Royal Exotic Nursery, Chelsea, sent Veitch's Prolific Strawberry, a new variety, given a certificate last year. Fruiting plants laden with fruit were also sent. This evidently is a reliable setter, as Strawberries this year in the London districts are none too plentiful, owing to late spring frosts. Melons came from various sources, the best being Gunton Scarlet, from Mr. W. Allan, Gunton Park Gardens, Norwich. To this the committee unanimously gave an award of merit, but after the committee had left it was discovered the same Melon received a similar award last year. This was not stated. Of course the award was not in order, as a first-class certificate was the only award available. Doubtless this would have been given had it been discovered in time. Mr. W. R. Pettigrew, Hewell Grange Gardens, near Bromsgrove, sent two Melons of good quality. One, the result of crossing Read's Scarlet and Blenheim Orange, was a good fruit, but not ripe, and the committee asked to see it again in better condition. The other was the result of crossing Golden Perfection with High Cross Hybrid, but inferior in quality to the first-named. A new Cucumber was shown by Mr. T. Haynes, Carlton Gardens, R.S.O., Yorks, but too large and old for the committee to test quality. A new Tomato named Klondyke came from Mr. M. Taylor, The Gardens, Penbedw, Nannerch, N. Wales, the result of crossing Ham Green and Early Ruby. In appearance the fruits were not unlike Ham Green, evidently not superior. The committee decided to give it a trial at Chiswick to test its cropping qualities. Other vegetables were sent, but of no value whatever either as regards quality or appearance.

Rose Show.

In the open class for twenty-four single trusses, distinct, Mr. B. R. Cant, Colchester, came first with good blooms throughout, his Prince Arthur, Maman Cochet, Marchioness of Downshire, Helen Keller, Mrs. John Laing, Sultan of Zanzibar and Catherine Mermet being excellent. The second prize was awarded to Messrs. D. Prior and Sons, also of Colchester, some of the best blooms here being Mrs. Sharman Crawford, Mrs. Grant, The Bride, Caroline Testout and Prince Arthur, Messrs. F. Cant, Colchester, securing third prize in a good competition. For eighteen single trusses (amateurs), Mr. O. G. Orpen, West Bergholt, Colchester, was first, Maman Cochet, Rainbow, Souv. d'Elise Vardon, and Mrs. Grant being some of the best. Mr. T. B. Haywood, Reigate, who was second, had Mrs. Grant, Abel Carriere, Marchioness of Downshire, A. K. Williams and Grand Mogul, the two latter being in fine colour, Mr. E. M. Bethune, Donne Park, Horsham, taking third place. For eighteen single trusses, distinct (open), Mr. Chas. Turner, Slough, took the leading place, having some of the best blooms in the show. His Francois Michelin was grand. Good also were Her

Majesty, Caroline Testout, Mrs. J. Laing, Prince Arthur and Xavier Olibo. Messrs. J. Burrell and Co., Cambridge, were second, having very fine Marquise Litta, Duke of Teck, Bridesmaid, and Prince Camille de Rohan, Messrs. G. Cooling and Sons, Bath, taking third place. For twelve single trusses (amateurs), Mr. G. W. Cook, The Briars, North Finchley, was first, his best being Medea, Captain Hayward, Mrs. Grant, and Louis van Houtte. Mr. W. Kingston, Grey Street, Bedford, had Catherine Mermet and Princess of Wales very good, Mr. R. W. Bowyer, Haileybury College, Heits, being third. Six single trusses (amateurs) brought Mr. B. H. Langton, Raymead, Hendon, to the front, and here we noted Captain Hayward, Charlotte Guillemot, Mrs. Grant, and Gustave Piganeau, all good and superbly finished flowers—indeed, among the freshest and cleanest of the entire exhibition—Mr. J. Biteman, Archway Road, N., being second. For nine single trusses of any one variety of H.P., H.T., or H.B. (amateurs), the first prize was taken by Mr. Percy Burmand, Hill Range, Reigate, Mrs. Grant being the variety. The second place was occupied by Mr. T. B. Haywood, who had Mrs. J. Laing very good, Rev. R. F. Page Roberts, Rectory, Seole, coming third with Mma. Gabriel Laissez. For six trusses in the three sections named above, Mr. G. W. Cook, North Finchley, took the lead with Mrs. Grant, Mr. E. M. Bethune being second with Kaiserin Augusta Victoria. For eighteen trusses in not less than twelve kinds, Rev. R. F. Page Roberts came first, M. Cusin, Maréchal Niel, Maman Cochet, Niphotos, and Golden Gate were the best, Mr. O. G. Orpen, who had very fine Amazon, deep golden yellow, and Anna Olivier in his lot, being second. For eighteen single trusses (open), Messrs. D. Prior and Sons, Colchester, took first, Mme. de Watteville, Souvenir d'Elise, Rubens and Maman Cochet being good flowers. In this class there appeared to be only one prize awarded, yet there were some four competitors. For twelve single trusses, not less than nine varieties (amateurs), Mr. Conway Jones, Blenheim House, Hugglescote, was first, Mme. de Watteville, Niphotos, Ethel Brownlow, The Bride and Golden Gate being best. Rev. A. Foster-Melliar had good Catherine Mermet, Maman Cochet and Cleopatra. For six single trusses, not less than four varieties, Rev. F. R. Burnside, St. Margaret's Bay, Dover, took leading place, having Mme. Hoste, Medea and Mme. de Watteville, Mr. H. P. Langdon being second with good Maman Cochet and Souvenir d'un Ami. For nine single trusses of any one variety, Mr. O. G. Orpen secured first place with finely-coloured Maréchal Niel, the following class being for six single trusses, and here Mr. H. P. Langdon, Shenfield, was first with charming blooms of Anna Olivier, Miss B. H. Langton, Raymead, Hendon, coming second with good flowers of Hon. Edith Gifford. For thirty-six distinct varieties of garden Roses, Messrs. G. Cooling and Sons, Bath, easily took leading place with a splendid display of fresh-looking blooms. It is a pleasure at any time to see so fine a lot of these free-flowering kinds, of which a few are given: Alistair Stella Gray, very charming; Camoans, bright rose; Mme. Eugene Resal, rose, shaded orange; Rosa Mundi, Dr. Grill, Mme. Falcot, Souv. de Catherine Guillot, the pure white Thalia, Ma Capucine, Marquis of Salisbury, crimson and semi-double; Cooling's yellow Noisette, Homère, the single white Himalayan, Cooling's single Crimson Bedder, Dr. Rouges, deep red and orange, &c., &c. Messrs. Paul and Son, Old Nurseries, Cheshunt, were second, their best being Royal Scarlet, l'Idéal, Polyantha grandiflora, white; Carmine Pillar, W. A. Richardson, Una, a charming white; Blanche Moreau, and rugosa in variety. A similar class for eighteen varieties for amateurs followed, Mr. Alfred Tate, Downside, Leatherhead, being first with Hebe's Lip, Rosa Mundi, Marquis of Salisbury, Crimson Rambler, Safrano, Réve d'Or, &c.; Mr. F. W. Camp, Colley Manor, Reigate, and the Rev. J. H. Pemberton, Havering, Essex, taking second and third prizes respectively.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE Earl of Derby presided over the sixtieth anniversary festival dinner of the Gardeners' Royal Benevolent Institution, at the Hotel Metropole, on Wednesday evening. A large company assembled, and among those present were Sir J. Whittaker Ellis, Messrs. Harry J. Veitch, James H. Veitch, Arthur Turner, Harry Turner, J. Hudson, J. James, G. Wythes, Rudolph Barr, H. Cutbush, J. H. Laing, W. Baker, J. G. Veitch, B. Wynne, G. Munro, and W. Poupert and Lieut.-Col. Pilkington, M.P.

The chairman, in proposing the toast of "Continued Success to the Gardeners' Royal Benevolent Institution," disclaimed practical knowledge of gardening, but gave some amusing instances of attempts made by him when in the army to establish gardens at different stations. These attempts were not regarded favourably by the authorities, and led to the despatch of huge folio sheets of inquiry as to the authority by which such attempts had been made. It was rather late in life that he was brought into contact with practical gardening, and he could tell them that although Lancashire did not enjoy a climate favourable to vegetation, he knew no people who had more genuine love for flowers than the Lancashire people. But even those who had no practical acquaintance with the art shared the feeling of sympathy with those who, from misfortune, or illness, or other causes, had fallen back in the race of life, and to whom this institution stepped in as a ministering angel, making life easy, and in many cases prolonging it. At the present time there were 174 recipients of annuities. Of these, 4 were over ninety years of age, 36 over eighty, and 87 were over seventy, and these persons who had passed the allotted span of man were helped by the institution and relieved from that anxiety which wore more men to their tomb than did illness. The annual amount of the annuity was £20 for men and £16 for women, and the institution further inculcated the principle of self-help, giving what was practically a bonus or credit in votes to those who had for a certain period subscribed to its funds. Those who subscribed to the institution could be sure that the funds were devoted to deserving recipients of the bounty, while the office expenses were on almost an exiguous scale, the able secretary, Mr. G. Ingram, having a staff of only one. He appealed for subscriptions even from those who could give but small sums, and spoke also of the claims of the fund commemorating the Jubilee, which was used to aid candidates who had not yet succeeded in obtaining pensions. A sympathetic letter from the Dean of Rochester, who quoted an instance within his own knowledge of the great good done by the institution, was read by Mr. Ingram, and the chairman then formally proposed the toast, coupling with it the name of Mr. Harry J. Veitch, treasurer.

Mr. Veitch, in his reply, said that the work was progressing satisfactorily; more good work had been done in the past year than in any previous year, and the warmest thanks of the committee and of the friends of the institution were due to Mr. Ingram. He mentioned that of the 174 pensioners one was a woman whose husband was elected as far back as 1863 and died in 1881; his widow succeeded him, and thus the two had been on the pension list for thirty-six years. The husband had subscribed a guinea for eighteen years, and together up to the present the two pensioners had received £568. The amount required for paying pensions alone was £3200 per annum, and in addition they had to meet the expenses of management, which amounted to between £600 and £700. The income from investments was about £900, so that apart from the subscriptions about £2000 was required from donations. In addition, they wished assistance in the formation of a Samaritan fund, which was to be invested, and the interest devoted to helping candidates who were known to be deserving, but

had not from various causes been subscribers. The sum of £2000 would enable them to do what was required. Sir J. Whittaker Ellis proposed "Horticulture in all its Branches," and Mr. Wm. Atkinson, of Sheffield, responded. Mr. W. A. Bilney proposed "Our Country Friends," and Mr. R. Piper, whose name was associated with the toast, in replying insisted that the subscriptions of those who joined the institution simply with a view to future benefits were not wanted. Let those able to subscribe cast their bread upon the waters, and if in after years they were in need they would find it return to them. Mr. Ingram, in announcing the subscriptions promised, stated that the Victoria fund was now complete. Inclusive of 200 guineas from the chairman, the contributions as the result of the festival amounted to £2500. Mr. N. N. Sherwood proposed "The Chairman," and Lord Derby, in responding, accepted the position of vice-president of the institution.

An admirable programme of music was performed under the direction of Mr. Herbert Schartau. The tables were profusely decorated with choice flowers and the whole of the arrangements were admirably carried out by Mr. Ingram.

OBITUARY.

MR. T. W. GIRDLESTONE.

ON Sunday last, after a brief illness, there passed away in the prime of life one of the keenest amateur horticulturists this generation has known. I need scarcely say I refer to the late Mr. T. W. Girdlestone. Notwithstanding the many arduous and anxious duties involved in the management of a large school and a naturally frail constitution, his interest in floriculture never flagged; indeed, it was while superintending the planting of his unrivalled collection of single Dahlias only a few weeks ago that he was seized with an attack of illness which ultimately proved fatal.

At one period of his life the Rose almost exclusively engaged his attention, and at that time it may truly be said that no other amateur rosarian possessed such an extensive knowledge of Roses generally, especially of the decorative and single varieties, as was clearly evidenced by the admirable articles which in those days appeared week by week in the pages of THE GARDEN. For several years in succession he came in third in the amateur champion class at the National Rose Society's Crystal Palace exhibition, and had circumstances allowed, must sooner or later have risen to the premier position, although greatly handicapped by the light character of the soil in his garden, so skilfully were his Roses grown and staged. As is now well known, but for its re-introduction by Mr. Girdlestone, one of our finest exhibition Roses, Suzanne Marie Rodocanachi, would have been altogether overlooked and lost to cultivation. He next turned his thoughts to Dahlias, as coming into flower at a period when he had a little more spare time, and especially to the single Dahlia, of which at his death he certainly possessed the finest strain in the world. Not only were his flowers in this section unapproachable at an exhibition, but his method of staging them was also the envy of all competitors. For many years past Mr. Girdlestone has undoubtedly been the mainstay of the National Dahlia Society, first as secretary and treasurer, and more recently as its president. His far-seeing judgment proved on several occasions of inestimable service to the society as well as to the Dahlia itself. Never more was this the case than when, some years ago, he so firmly impressed upon the committee, when wavering between the Cactus and so-called decorative varieties, to decide once for all in favour of the former, and to issue each year lists of the best Cactus kinds until they had reached such a degree of perfection, that this section might be left to stand alone upon its own distinctive merits.

Anyone who has seen Mr. Girdlestone's lovely garden at Sunningdale and the admirable taste displayed in its arrangement will know that it was not only as a rosarian and Dahlia specialist that he might have shone in horticulture. To say nothing of landscape gardening, his knowledge of alpine and herbaceous plants was almost as extensive.

I feel that I have not written in any way extravagantly of one with whom it has been my privilege to be intimately acquainted for nearly twenty years both as a friend and brother horticulturist, for I cannot but think, considering all that Mr. Girdlestone managed to accomplish in such a comparatively short space of time, and when thronged with so many other pressing duties, how much greater things he would have been able to do had only his life been spared and more leisure fallen to his lot. His chief characteristics outside his many social and winning gifts were, I should say, his singular independence and originality of thought and action combined with an exquisitely refined sense both of form and colour. Few men, I should imagine, with such slender opportunities of meeting his fellow horticulturists have ever made themselves so generally respected and beloved as the subject of this brief and imperfect tribute to his memory.

Berkhamsted.

E. M.

James Anderson.—It is with regret that we have to record the death of Mr. James Anderson, who passed away at Glasgow on June 16, in his sixty-eighth year, after a protracted illness. The deceased was for many years gardener to Mr. T. Dawson, Meadowbank, Uddingstone, N.B. Mr. Anderson was for some time editor of the *Northern Gardener*.

PUBLIC GARDENS.

Proposed extension of Brockwell Park.—At the meeting of the Lambeth Vestry on Thursday evening, Mr. J. A. J. Woodward in the chair, it was unanimously resolved, on the motion of Alderman Hubbard, seconded by Mr. Harris, to urge the London County Council to acquire a piece of land adjoining Brockwell Park, Herne Hill, for the purpose of enlarging the park. Mr. Hubbard said he understood that the strip of land in question, which is beautifully wooded, was about to be developed for building purposes, and reminded the vestry that at the opening of the park Lord Rosebery said it would be a thousand pities if this land should ever be covered with houses.

The Paragon open space.—The open space known as the Paragon, in the New Kent Road, which has been acquired by the Vestry of the parish of St. George the Martyr, Southwark, from Lord Llangatock, as well as a smaller space on the opposite side of the way, leased from St. Bartholomew's Hospital, was formally opened yesterday by Lady Llangatock in the presence of a large gathering. The space has been acquired at a cost of £3400, towards which Lord Llangatock has given £1000, the L.C.C. £1700, the Vestry of St. George £600, and St. Mary's Vestry £100. Part of the expenses of preparing the ground and laying it out has been borne by the vestry and the remainder by the Metropolitan Public Gardens Association. The size of the larger space is 4000 square yards, and of the smaller 525 square yards, and the larger includes a bandstand and several flower beds.

Dollis Hill Estate.—Lord Hobhouse presided over a meeting held in the Guildhall, Westminster, on Friday evening last, to consider the purchase of the Dollis Hill Estate as a public recreation ground to be dedicated to the memory of Mr. Gladstone. Mr. Basil Holmes, secretary to the estate, stated that the London County Council had been approached by a deputation, and had promised to contribute £3000 towards the purchase of the estate on condition that the Willesden Urban District Council undertook to

keep it open to the public for ever as a recreation ground. The Gladstone National Memorial Committee regretted that it could not contribute to the purchase, as its funds were pledged for other objects. The total sum required by the trustees for the estate was £50,000. The Willesden Urban District Council contributed £30,000, the Middlesex County Council £12,500, Hampstead Vestry £1000, and Hendon District Council £500; and these contributions, with the London County Council contribution of £3000 and voluntary subscriptions of £494 18s., brought the total to £47,500, leaving £2500 still to be raised. It was resolved to approach owners of land abutting on the estate, asking them to contribute to the purchase in view of the fact that their property would be greatly increased in value. The Paddington Vestry is also to be asked to contribute. The Earl of Aberdeen wrote suggesting that if the owners of adjoining land saw fit to contribute, others would be more willing to co-operate in the scheme.

National Viola show.—The report of the Viola Society's show at Winchester House is unavoidably held over until our next issue.

The weather in West Herts.—A warm week. On one day, the 26th, the shade temperature rose to 82°, and during the preceding night the exposed thermometer did not fall lower than 55°, making this the warmest night as yet this year. At 1 foot deep the ground is but little warmer than is seasonable, but at 2 feet deep it is about 2° warmer than the average. A little rain fell on the 22nd and again on the 27th, but the amounts were altogether insignificant. In fact, no measurable quantity of rain-water has come through either of my percolation gauges for over three weeks.—E. M., Berkhamsted.

Water Lilies in America.—*Nymphaea odorata* Luciana and *N. Richardsoni* are now in bloom with us. *N. Richardsoni* is very fine for a white, and, although we have plenty of white kinds, *N. Gladstoniana* is indispensable. It is a larger flower than *N. Marliacea alba*, and without a shade of pink in the sepals, as in the latter variety. We wish very much you could see our Lilies in bloom. *Marliacea*'s varieties are fine with us, especially *N. Robinsoni*. We have most of his varieties except those of recent introduction. They are fine in colour, but they do not come up to our standard in size, but that will soon be met, as we have some very promising seedlings, amongst them being one that we have named after Mr. Wm. Falconer. This variety is much larger than *Marliacea*'s *N. ignea*, deeper and richer in colour, and as large as *N. alba*. Another variety is of a rich deep carmine, changing to wine-red, the arrangement of the stamens being also peculiar.—HENRY DREER, Philadelphia.

Names of plants.—*R. W. W.*—*Tellima parviflora.*—*Reginald Eager.*—*Epidendrum falcatum.*—*Walter Warton, jun.*—*Dendrobium moschatum* var. *Calceolaria*, differing from the type in its smaller and more highly coloured flowers.—*J. Meade.*—*Briza minor.*—*G. T. S.*—*Cyrtanthus McKeni.*—*W. Hatfield.*—Quite impossible to name from such a specimen.—*F. N. Garnett.*—*Polygonum amphibium.* We should think that constant cutting would get rid of it.—*F. F. F.*—1, *Geranium arvense*; 2, *Geranium striatum*; 3, *Escallonia macrantha*; 4, *Thalictrum anemoneoides*; 5, *Dianthus superbus*, form of; 6, *Lilium croceum.*—*Gardener.*—*Styrax japonica.*—*J. D.*—1, send fresh specimen; 2, *Sidaicea candida*; 3, *Centranthus ruber*; 4, *Crepis aurea*; 5, *Veronica rupestris*; 6, *Thalictrum* sp.—*H. G. O.*—*Sisyrinchium striatum* var.—*Mrs. Johns.*—Common *Sanicula* (*Sanicula europaea*); native plant.—*W. D. R. D.*—Neither of the plants you send to name is cultivated, and therefore should be sent for names to some herbarium, such as Kew. The *Hieracium* is nearest to *H. prenanthoides*, and the *Veronica* is nearest to *V. austriaca pinnatifolia*. The *Iris* is *I. ochroleuca*.

"The English Flower Garden."—Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s. Special edition (2 vols.) bound in sage-green morocco, suitable for library or presentation, one guinea. Of all booksellers.

FERNS.

FERNS ON TREE STUMPS.

THIS method has much to recommend it. It is, however, necessary to select only Ferns with spreading rhizomes, most of which never root deeply into the soil. Young free-growing plants should be selected for the purpose. Where large quantities are grown or where the space is not limited, each stem may be confined to one species or variety, but this is not always convenient, in which case several varieties may be grown on the same stem, care being taken to select those most suitable for growing together, and to so dispose them that the larger-growing sorts have the most roomy positions and also that they do not overrun the smaller kinds.

Taking the Davallias, at least six sorts could be grown on the same stem, the sorts most suitable being *D. dissecta*, *D. dissecta elegans*, *D. Tyermanni*, *D. Mariesi*, *D. Griffithiana*, and *D. decora*. Those of the fijiensis type may also be used, but the rhizomes do not spread so freely. Of the Platyceriums, which are the most suitable of all Ferns for the purpose, the three best are *alcicorne*, *æthiopicum* (*Stemaria*), and *Willincki*. As the fronds of the last hang down a considerable length, it should have the most elevated position. I might add *Hilli* to the list. This has almost circular basal fronds (or sheaths) and the fertile fronds grow erect, forming a nice contrast to the erect shell-like basal and long drooping fertile fronds of *Willincki*. All of these Platyceriums produce young plants on the roots, and after the plants are well established on the tree-stems young ones will soon appear, but where they are produced too thickly they should be thinned out. *P. Stemaria*, for instance, requires plenty of room for its large fronds, and being very prolific in young ones, they soon get overcrowded and choke each other. I may here add that although the Platyceriums may be grown without any soil, or even without the Sphagnum, they do better if some fibrous peat

is bound on with the Moss. It is not necessary to cover the whole surface, but if used where most convenient to bind it on, the roots will soon find it. With the *Adiantums* it is best to confine each sort to a separate stem and use comparatively small stems. *A. assimile* is one of the best for the purpose. *A. setulosum* may also be recommended, and most of the varieties of *Capillus-Veneris*, *imbricatum* being the most beautiful and particularly adapted for the purpose. It has sometimes been called the hardy *Farleyense*, and when seen at its best it certainly has some claim to the distinction, for, though of dwarf habit, the individual pinnules are almost as large and beautifully cut. The *Nephrolepis* most suitable are *pectinata* and *philippinensis*, the larger-growing sorts requiring more root-room than can well be given. The two referred to should have as much soil bound in with the Sphagnum as possible. If a plant is put at the top of each branch of the stem they will soon make long rhizomes and cover the lower portion with young plants. The rhizomes may require regulating a little or binding to the stem. As the rhizomes of *Blechnum occidentale* spread slowly, more plants may be used, and as seedlings are usually plentiful they may be had at a small cost. There being few with spreading rhizomes which have the brightly-tinted fronds, this should always be included. *Hypolepis distans* and *H. repens* both spread freely and soon cover a large space. All the smaller-growing Polypodiums that have spreading rhizomes do well under this treatment, and many others not referred to above. I should hardly recommend the beautiful *Pteris scaberula* for the purpose, for, though the rhizomes spread freely, it delights in a moist, cool atmosphere and requires a good loamy compost. The *Gleichenias* also love the atmosphere of a damp, cool pit, where they get the light without being exposed to the sun. *G. dichotoma* is an exception, and though this likes more warmth and spreads freely, it does best in a moist, shady nook. In selecting stems for the purpose almost any

trees of suitable shape may be used. The first I saw used were cut from Cherry trees. Oak stems are perhaps the best where they can be had. I believe those used at the Temple show were Plum, and used green as they were cut down. In preparing them for use I prefer to fix them on to a good block of wood. They may be fixed in pots, but in moving about they are liable to get broken. A block of wood is more in character, and a few erect-growing Ferns may be grown and form a nice base. In fixing the Ferns, wire should be used for those which do not take hold of the stems readily, and until well established they require careful attention in regard to watering. If new Sphagnum is used it will soon grow, and then will retain a great amount of moisture, moist Sphagnum always keeping fresh and sweet when it is growing.

A. HEMSLEY.

Hardy non-British Ferns in Yorkshire.—*Adiantum pedatum* grows luxuriantly here and resists spring frosts, which turn brown the fronds of *Pteris aquilina*, *Lastrea Filix-mas* and *Athyrium Filix-femina*. *Polystichum crinitum* is also luxuriant, but not so hardy as *Adiantum pedatum*. *Polystichum acrostichoides* is sometimes very slightly touched by frost. *Onoclea sensibilis* is never damaged. *Struthiopteris germanica* is luxuriant and very hardy. *Struthiopteris pennsylvanica* is weaker in growth and liable to be touched, but not seriously hurt, by spring frosts. *Struthiopteris orientalis* is hardy, producing, as do the others of this genus, its fertile fronds each year. *Osmondia cinnamomea* and *O. Claytoniana* are quite hardy. *Osmondia gracilis*, brought me from the Organ Mountains, Brazil, where it grows on dry grassy banks with *Zygopetalum Mackayi*, is earlier in growth, its pinkish fronds resisting the spring frosts better than *O. regalis*. To these we must add the neat and fragrant *Lastrea fragrans*.—R. MILNE-RED-HEAD, *Holdenclough, Clitheroe, Yorks.*

Gold and Silver Ferns.—These belong to the tropical fernery, and must have a temperature of 65° at night. They will do with 5° more, but it always seems to me to be a waste of heat to run up the thermometer higher than is necessary

for keeping the plants in health. Many of the *Gymnogrammas* make very handsome specimens, and as they are easily raised from spores it is a mistake to keep the plants when they begin to decline, or to attempt propagation by division. The plant is never so handsome as when it is grown vigorously, and seedlings are more vigorous than plants raised in any other way. These should be grown in a lighter, sandier soil than *Adiantums*. A third of very turfy loam, and the remainder fibrous peat, leaf-mould, crushed charcoal and sand, will suit them well. Drain the pots well, and place a handful of rough, fibrous bits of soil on the drainage. Pot firmly, and guard against over-watering till the roots are running freely in the new soil.—H.

Exotic Ferns for the open air.—The American Maiden-hair, sometimes called the Bird's-foot Maiden-hair, from the formation of its fronds bearing a fancied resemblance to the spread foot of a bird, is one of the most beautiful of the *Adiantums*. It succeeds admirably in the open garden in the south-west, where, if planted in a sheltered nook in deep, moist soil of a peaty nature, its elegantly-arched fronds will attain a height of 2 feet. It is a deciduous species, and on this account is often passed over for conservatory decoration in favour of less ornamental kinds that retain their foliage through the winter. Its deciduous habit, however, renders it practically hardy, as a little leaf-mould scattered over the dormant crowns makes it secure from effects of frost, even as far north as Yorkshire. Though many of our native Ferns leave little to be desired in the way of beauty, the charm of the open-air fernery is considerably enhanced by the introduction of such exotics as *A. pedatum* and other graceful strangers, whose presence lends an additional charm to the picture. Of these the Ostrich Fern (*Struthiopteris germanica*), that, in spite of its name, is as uncommon in Germany as it is common in North America, is a noble subject bearing tall, arching fronds, which, although they do not in this country attain the length of 10 feet, as they are said to do in Pennsylvania, are strikingly effective. The Sensitive Fern (*Onoclea sensibilis*), also a native of North America, is another charming plant for naturalisation in the outdoor fernery. This, although not such a vigorous grower as the preceding, is equally decorative, producing deeply-cut, polished fronds about 2 feet in height. The Japanese *Davallia Mariesi*, a dwarf evergreen Hare's-foot, will also live in the open in sheltered spots in warm localities, as will the fine *Woodwardia radicans*.—F.

ROSE GARDEN.

NEW OR LITTLE-KNOWN ROSES AT THE CRYSTAL PALACE.

It seems to me that raisers are introducing too many of the unattractive magenta-rose-coloured varieties that have such a lamentable tendency to fade when cut. Conway Jones, Daisy, and Robert Duncan belong to this type. They may have good form, but that is useless if the colour is not bright. Mrs. Cocker is evidently a Rose come to stay. It is of a beautiful clear pale pink, and the high globular centre of the flower seems to make this Rose a formidable rival to Baroness Rothschild, a variety but sparsely represented at the Crystal Palace. Mrs. Edward Mawley was well shown by Mr. Mawley and also the raisers. Other promising kinds not in commerce were Mildred Grant, something in the way of Catherine Mermet, but lighter. This may be a good variety, but I did not think there was sufficient difference between it and Muriel Grahame. Alice Grahame is more distinct; it has lovely pointed petals, and of a shade of colour in the way of Souv. du President Carnot. Killarney is of a pretty colour, but very thin. It reminded me of a refined Mme Marie Lavallée. Agnes Henderson resembled very closely a little-known variety named Rosomane Alix Hugier. Janet Scott appeared to be very distinct. In style of flower it resembled

Caroline Testout, but in colour it was of the Victor Verdier type. Ulster is rather disappointing this season, although when it obtained the gold medal I was very pleased with it. Bessie Brown was shown very good. It has a well-formed centre, deep and pointed, but in competition White Lady surpassed it. This latter Rose was shown in magnificent condition. Another kind having a close resemblance to the two last-named was Mme. Jules Finger. I have always liked this Rose, but I have never seen it shown so well as at the Crystal Palace this year. Beauté Lyonnaise is evidently a good exhibitor's Rose. The colour is lemon-white, clear and beautiful, and the massive globular-formed flowers are nearly 3 inches deep. Perhaps one of the loveliest new Roses shown was Ferdinand Batel. The flower, somewhat resembling Antoine Rivoire, was of a lovely apricot and orange tint, a colour at all times most attractive. Antoine Rivoire was also well exhibited. Its somewhat flat, but very regular flowers were rich in colour. Another of these Hybrid Teas to gain admiration was Mme. Cadeau Ramey. It is such a grand high-centred flower, that one will expect to see it in every stand in a year or two. Mme. Eugène Boulet was very good, reminding one of Clara Watson, but with more orange colour in it. Jubilee appeared to me to be too much like Prince Camille de Rohan. It is an attractive dark Rose, and if it turns out only a shade or two darker than the old kind mentioned it will be a great gain. It is here we want more advances made. Empress Alexandra of Russia was most attractive in the first-prize box of Teas. It is of a lovely colour and will doubtless be more frequently seen when it can be had from cut-back plants. Tom Wood was well shown. It is a good light red Rose and very reliable. Mrs. F. Cant and Edith Turner are both very pale pink Roses of good form. I cannot see that so many of these H.P. and H. Tea Roses are wanted. It is true both these kinds have a silvery whiteness about them rather different from other Roses of their colour. I was very pleased to see a very beautiful Rose steadily coming to the front. I allude to Golden Gate. It was one of the very few Roses other than sports that we have received from the United States. Mrs. Pierpont-Morgan was well shown, and by the side of the variety from which it sported, Mme. Cusin, it had quite a deeper shade of colour. Doubtless under glass this colour would be much increased; if so, it would be a very valuable forcing kind on account of its great freedom of flowering. Medea was noticed in excellent form. It seems to be a great favourite with exhibitors. Mr. Gray from his immense stock had selected it as one variety among eight trebles in his first-prize box. The lovely Tea Rose raised by Mr. Bennett and named Princess Beatrice was seen in good condition, and one flower received the medal as the best Tea bloom in the amateurs' class. Generally speaking, it is a bad outdoor Rose, but under glass or in a good sheltered spot its splendid flowers, something like Comtesse de Nadailiac, are very charming. Mr. Haywood had the white Maman Cochet, very pretty. At present the season has not suited Maman Cochet, but when this Rose is good the white variety must be superb. I cannot say I care much for the white Maréchal Niel. It has a soiled appearance, and it is neither white nor yellow. Marquise Litta was much in evidence, which proves it of great value both to the exhibitor and in the garden. The colour of Countess of Caledon seemed to be brighter on this occasion than I have ever seen it before. Its form is very good. The Rev. Alan Cheales is a good garden Rose, with something of the colour of John Hopper, but a much larger and less regular flower. It might possibly be a seedling from Paul Neyron.

Of the Roses put up for the gold medal, Sunrise was well to the front by reason of its very distinct colour. If it grows as well outdoors as it does under glass it will become very valuable for cutting. Duchess of Portland was promising, and Alexander Hill Gray, if not too hard to open, will perhaps even yet secure this coveted award.

It is a flower something in the way of Comtesse de Nadailiac; indeed, it might even be from the same seed-pod as Princess Beatrice already alluded to, for I believe it is one of the late Mr. Bennet's raising.

Of novelties in garden Roses, which were well to the front, *Aglaia* was most interesting. It is not so yellow as I expected, but certainly it will be a valuable companion to *Crimson Rambler*. I should take it to be of a very hardy nature, and in growth it is most rampant. Dawn is of a very beautiful tint of colour, and the semi-double flowers are attractive in the mass. *Psyche* is almost like a climbing *Cecile Brunner*. *Royal Scarlet* will possibly be the forerunner of some good bright show Roses. Mr. Turner's seedling *Damask* was pretty. The flowers are crimson, and fashioned after the manner of single *Cactus Dahlias*. The single Teas from Ireland are very beautiful in their way. *Irish Beauty*, a lovely white with flowers 4 in. across, will be a valuable addition to our single Roses. PHILOMEL.

Moss Roses, common and gracilis.—If I were restricted to the cultivation of only one Moss Rose, *gracilis* would be my selection. It is the most beautiful of all the Mosses, the deep pink buds being well surrounded by Moss. When seen together, a great difference is manifest between the common pink and *gracilis*, or, as it is sometimes named, *Prolific*. In the first place the colour is a deeper pink and the growth is much more dense. As regards the mossy characteristic, there is little difference in the two kinds. For cutting, *gracilis* is the better of the two. These Moss Roses are freely increased by layers; indeed, there can be no question that this method of propagation is best for all old-fashioned summer Roses where they are planted as permanent features in borders or shrubberies.

Two brilliant bedding Roses.—There is a difference of opinion as to which is the more brilliant Rose in the mass, *Marquise de Salisbury* or *Princesse de Sagan*? Personally, I prefer the latter, although it is not such a good grower as the former. *Marquise de Salisbury*, brilliant enough in the half-open state, has a tendency towards a purplish shading when fully developed. Not so with *Princesse de Sagan*; its scarlet-crimson opening flowers shade off to a lovely velvety maroon, which only serves to enhance its beauty. The habit of the plant is not so rigid as in *Marquise de Salisbury*. In a measure this is to be regretted, for in a garden Rose one requires every flower to be seen, but with this variety this defect somewhat disappears with age. But there is room for both varieties, and if a third be wanted, then I would select *Cramoisi Supérieur*, one of the most brilliant of the Monthly Roses.—P.

Roses at the Temple show.—The display of Roses at the Temple show was a wonderfully attractive one for the end of May, but *Crimson Rambler* was needlessly abundant and was easily surpassed for beauty by *Carmine Pillar*, good pot plants of which were shown well set with their bright crimson single blooms. *Sunrise*, with its deep bronze foliage and blossoms, in which tints of saffron, apricot, fawn, and chestnut blended in delightful harmony, was an exquisite Rose, and *Corinna*, creamy pink; *Cléo*, silvery rose; *Beauté Inconstante*, shaded scarlet and orange; *Empress Alexandra*, coppery pink; *Mme. Abel Chatenay*, with deep vermilion-crimson centre, paling in the outer petals to faint rose and shell-pink, and *Perle d'Or*, yellow and orange, were charming in their suave colouring. The pretty little *Rosa altaica*, with its single white blossoms, was also shown in more than one collection.—S. W. F.

Sweet Brier Anne of Geierstein.—This, to my mind, is the second best of the whole sixteen varieties raised by Lord Penzance. The first place must always be accorded to *Lady Penzance*, for it is perfectly unique in colour, but for brilliancy the above variety is decidedly the brighter. Its shade of colour is identical with that of *Gloire de Margottin* or *Gloire des Rosomanes*. I can conceive of nothing more beautiful or showy than a

large group of this excellent kind where the bushes are allowed to grow naturally. It is a wonderfully vigorous variety, so much so that upon four-year-old plants I have growths as thick as the stem of an ordinary standard Rose. I saw this variety and one or two others effectively employed as a low hedge at Kew. If taken in hand when young, the growths can be bent down quite low, and in time a hedge 2 feet to 3 feet thick may be secured, which will not only give a brilliant effect for two or three weeks in June, but will also remain a sweet-scented and substantial dividing line in the garden.—P.

A fine pillar Rose.—One could almost imagine that the splendid free growing *Rosa robusta* was a descendant from Louis van Houtte, so very rich are its crimson blossoms. It is reputed to be of Bourbon parentage. Why this is so I cannot say, for we usually look to the Bourbons for some autumnal bloom, but this kind does not flower late. However, even though it be summer-flowering only, it must become very popular, not merely for its glowing colour, but also for the sturdy 7-foot to 8-foot growths it will annually produce. The effect of its brilliancy is somewhat marred by the dying off purplish colour of the old flowers. Many brilliant Roses have the same propensity, and it is quickly remedied by hand-picking. A dozen or so of this Rose planted in a large bed and trained as pillars with bushes of the sweetly fragrant bluish-pink Stanwell Perpetual intermingled would produce an excellent combination, and the latter Rose would continue to blossom till frost came to prevent its buds expanding.—P. L.

Rose Mme. Wagram.—Very few people know this excellent Rose. It is true it has not been in commerce more than four years, but it certainly merits more extended cultivation. It will quickly grow into a large shrub, and yet its blossoms have all the refinement of a Tea Rose. We usually take Grace Darling as a typical variety for vigorous growth among the Teas and Hybrid Teas, but the Rose under notice surpasses this well-known kind, and yet it blooms freely, although some might be disposed to place it among the climbers. I have an idea that Mme. Wagram is a seedling from Grace Darling, for both in wood and bloom it resembles this kind very much. Its flowers are even larger than those of Grace Darling; indeed, they almost equal those of Her Majesty, but there is not quite the solidity about them as in the last-named variety. This Rose is destined to become very popular, for it is just the kind to plant in positions where Roses do not generally thrive well, and it has been noticed by many dwellers near large towns that the Teas and Hybrid Teas flourish best provided they are good growers. I know of no Rose that has the same glistening sheen upon its young foliage as this one.—P.

Rose Mrs. W. J. Grant.—In a somewhat cool season this glorious Rose is at its best. It stands unrivalled as a rich pink variety, and how freely it blooms. I like to look upon this variety in the early morning or during a showery day. Market growers should cultivate this variety by the thousand, for its buds are far prettier than those of La France, although the expanded blooms may not be useful and lasting, they being less substantial. There is always a large demand for coat flowers, and it would be difficult to name a more beautiful kind of its colour than Mrs. W. J. Grant. I have had enormous blooms of it this year upon pot-grown plants. It pays well for a little extra feeding. If I wanted a quantity of Roses just before the outside plants began to flower I should pot up a quantity of this kind and grow the plants in cold pits. Pruned early in February, such plants could be had in flower by the second week of May. In a late season the growth may be accelerated by putting on the lights about half-past three in the afternoon. This will make a considerable difference to the period of flowering. I generally find that about twelve weeks are required from the time of pruning to the blossoming for pot-grown plants, such plants having been potted the autumn previously.

Established plants would come along rather faster than this. If brick pits are not available, a good substitute would be found in turf for the sides and ends.—P.

Two miniature Moss Roses.—Many of the Moss Roses introduced in the past have certainly had traces of the Moss-like formation, but it has in many instances been of a very meagre description. This cannot be said of two charming Roses, Little Gem and Moss de Meaux. They are both delightful little Roses, the former perhaps the more interesting by reason of its rich rosy-crimson colour. It has been very happily named Little Gem. The small buds completely enveloped in Moss are no larger than robins' eggs, and even the expanded flowers so regularly formed are barely 2 inches across. Moss de Meaux has a resemblance in flower to that pretty old Rose de Meaux. Perhaps it is a little paler in colour, but it certainly is beautifully mossed similar to Little Gem. The expanded flowers in this case are even smaller than those of the latter variety. Grouped together they would make a delightful feature in the garden. Both kinds form themselves into compact round bushes. Little Gem, being the stronger grower of the two, should be placed in the centre. I like to see Little Gem upon dwarf standard Briers about 18 inches high. Most of the Moss tribe are very suitable for growing in this manner.

NOTES AND QUESTIONS.—ROSES.

Rose Mme. Abel Chatenay, raised by Pernet-Ducher, will be found of considerable value. It is not a very full Rose, but charming in colour and very free-flowering. The flowers are pale fawn-pink, shaded salmon, especially at the base of the petals.—D.

Rose Killarney seems as if it would be a valuable addition to our garden Roses, its substance is so good and the colour so bright—a soft clear pink—that it will probably be often found on our exhibition stands. The habit is good, branching, and it continues in flower throughout the season.

Rose Mrs. Frank Cant.—This is a very attractive Rose of a peculiarly clear shade of pink, the reverse of the petals silvery white, the shape good and the flowers sweet-scented. The plant is vigorous and the growths upright, each stem producing a flower. It will be found a valuable acquisition for exhibition. I am told that it is a valuable pot Rose.—D.

Tea Rose Beryl.—This is a very pleasing addition to what are now known as button-hole Roses; the bud is long and pointed and the colour a bright orange-yellow, approaching that of William Allan Richardson. It is a strong grower and flowers continuously throughout the season. I think it might be aptly described as a deep yellow Gustave Regis. How is it that this latter Rose is described as a Hybrid Tea, while Beryl is described by its raisers as a Tea?—D.

Rose Cheshunt Hybrid.—This I find satisfactory in all soils and situations where a Rose will grow. In this garden it does well in a cold Peach house, as also on a north wall outside. In this position I get some grand blooms, and from early in June they are most abundant. Last year I saw this grown in a garden near Sherborne as a standard on the turf, the shoots, a mass of bloom, sweeping the ground. Reine Marie Henriette is a glorious Rose when growing on a warm wall in the open.—J. CROOK.

Rose Bennett's Perpetual.—I cannot understand why this was named Perpetual, except that the large heads of bloom continued to open over a long period. This is a Rose that ought to be more known. This kind is a grand companion for Crimson Rambler. The habit is much the same and it blooms at the same time, and being pure white, blends well with Crimson Rambler. Growing against a high wall it makes a fine show when not cut in too close. I have several old trees growing about the abbey.—J. CROOK.

Rose Mme. Rene Gerard.—This will assuredly be as much sought after as its assumed sister, *Souvenir de Catherine Guillot*. Whilst embodying in its colouring much of the coppery tints that are so characteristic of *Ma Capucine*, we have in this Rose not only a large bloom, but also other tints such as saffron-yellow and delicate mauve upon the edges and outer petals that make it one of the most attractive varieties in point of colour that I know. It will never be a show Rose, the petals being too few in

number, but it must take rank as one of our best Teas for the garden. It is a good grower, much superior to *Ma Capucine*.—P.

Rose Myrianthes renoucle.—The varieties of *Rosa sempervirens* furnish us with some of the most rapid climbers. The peculiar beauty of the above kind is found in the deep rosy crimson buds and the pinkish white expanded flowers, the combination producing a very beautiful effect especially when a plant is covered with a mass of its graceful sprays of blossom. Another uncommon feature of this Rose is that the centre petals have a button-like appearance produced by several of them curling over as if to protect the stamens. I consider this variety, with *Félicité-Perpétue* and *Flora*, the three prettiest Roses of the group.—P.

FLOWER GARDEN.

PLANTING PYRETHRUMS.

IF I could do so, I would always transplant in August. As regards autumn and spring planting, the Pyrethrum grower is in a measure on the horns of a dilemma. If he moves them in autumn they have to face the winter without active fibres, for, so far as I have observed, they make no new roots at that time of year. If, on the other hand, they are disturbed in spring, they do not get sufficiently established to resist a dry, hot time when coming into bloom, and unless occasionally well watered the flowers are small and they quickly fade. The flowers of the double varieties require a lot of moisture and nourishment to sustain them, and are poor in colour if these essentials are wanting. If transplanted early in August they are bound to make new roots, and this in good ground will have the effect of stimulating the formation of new leaves from the crown, so that, no matter what the weather may be in winter, they are in a condition to resist it. The objection to August planting is that where Pyrethrums are used in private gardens in the usual way it would not do to be disturbing borders at that time of year. Where they are grown simply for cutting in beds by themselves it is quite practicable to move them when necessary in late summer. In a dry time they should be well watered in, and with a couple of waterings afterwards their safety would be assured. Autumn transplanting will never again be practised by me. Some years ago I bought in 100 good stools for propagating, and, not knowing so much about Pyrethrums as I do now, I planted them at once. Although the winter was mild I lost 20 per cent., and many of those that came through started badly. I lifted several and found that they had not made any new fibres. Had the winter been severe with hard frosts succeeding heavy rains or melting snow, I should have lost many more. If this happened in my light soil, how would it be in heavy land? Profiting by this experience, I plant and divide now in early spring, choosing a fine dry time as early in March as possible. The ground is laid up in rough lumps during the winter, some manure being worked in with the fork, and a thorough stirring given before planting. Early in May a top dressing of manure is given, and in this way watering is not much needed, although a good soaking in May, if that month is dry, is very serviceable. In this manner very few losses are experienced and the plants make a good growth.—J. CORNHILL.

— At page 434 of THE GARDEN "J. C." gives his experience in the cultivation of these useful and beautiful garden flowers, and asks for my opinion on the relative merits of spring and autumn planting. A very great deal depends on circumstances—as much, indeed, those surrounding the plants as any that pertain to soil and

locality. I have planted within five weeks of Christmas in just the soil "J. C." describes, viz., rather light and well drained, with the most perfect success, the plants yielding splendid flowers the following spring, though, of course, not the wholesale sheaves of blossoms that older plants produce. It is well to add, however, that a neighbour who had 100 of these self-same plants fully a month before mine were planted and had quite the pick of a batch of some 3000 plants came to me in the early spring ensuing to complain that all, or nearly all, his plants were dead. And he added, by way of emphasising the care he had taken of that hundred, "I put them into $\frac{1}{2}$ -inch pots and framed them all the winter," "which is exactly what I would not have done," I responded. Being a well-known grower and prize-winner of hard-wooded plants, the thought had not occurred to him that his kindness was a mistake, if not a fatal error. But as he was fully aware that I had not put out a plant when he made his purchase, I took him to a batch of beds twenty or thirty in number and 5 feet wide and 40 feet long wherein a dead or failing plant was scarcely to be found. On the contrary, each plant was represented by a tuft of young shoots that in themselves foretold what was to follow.

The complete success in my case was due to the fact that the plants were young, freshly established pot plants, and, put out into a light, warm soil in mid-autumn, began to root afresh at once. I would not put out any sort of plant at the same time as those now referred to, and particularly would I name those divided roughly with a spade, or such as have been starved a whole season, if not more, in small pots. These *Pyrethrums* are perfectly hardy. I have never known frost harm them in the slightest degree, but I have known the plants rot and perish through deep burying of the crowns; so much so, in fact, that instead of the foliage lying prostrate on the earth, it stood erect in the air. I pointed out that the plants were 4 inches too deep in the soil, and suggested immediate lifting as a remedy, seeing they were newly planted. Many are lost by this and similar means, and just as many are lost by spring planting from various causes; so much so, that unless a system is followed in every detail, great losses may occur from either. I give two instances to illustrate my meaning, both having come under my notice within the past nine months. In the first the plants were roughly divided by the spade and planted in open beds after flowering a year ago, the planting and dividing being done before fresh growth had started. The fault was in the work being done too soon after flowering, and lack of attention in watering, &c., afterwards. In the result some hundreds of plants were lost. In the second case so-called spring division was adopted too early, and the divisions, being put forth into a heated pit, were unable to endure the experiment. In short, in every 4-foot light of the frame there were probably not more than a dozen plants that would grow at all. If well grown and properly treated there are few plants more showy than these, but they are not destined to be handled by anyone.

Many fail to grow *Pyrethrums* because the potting-up after dividing is too much trouble, yet it is the only way that anything like a high percentage of the plants can be made secure. I have planted *Pyrethrums* at almost all seasons, even when 15 inches of growth have been made, without losing a plant, but then I never failed in the water supply, for, as "J. C." aptly remarks, they are very thirsty subjects. In those gardens where the soil is light and well drained, and provided the plants were only recently established in the pots, I would not hesitate to plant at any time. Taking the plants from the open and dividing roughly with a spade should only be done in early spring, say the first two weeks of April, or rather earlier if growth is early in the season. It is a fatal mistake to shorten the roots of such as these quite close with a knife. On cold soils, and indeed any heavy or wet or low-lying land, autumn planting is best avoided. In these the *Pyrethrum* generally requires more care

than on lighter soils. The best all-round success may be had from the following treatment: Select the plants when 4 inches or 6 inches of fresh growth have been made in early spring, lift them, wash away all soil in water, and with the point of a strong knife wrench rather than cut the plants asunder. This wrenching applies rather to plants that are yearlings and divided as such, and not to two-year-old plants or upwards, for these will provide as many good rooted plants as there have been flower-stems to the plant, and are much more readily divided with certainty than are the younger plants of a year old. These latter I have propagated by tens of thousands, not merely from divisions, but also from cuttings, i.e., shoots that could not be secured with roots attached. This, however, is frequent in year-old plants, and it is here that the washing of the roots is a great gain. This not only enables the operator to see how to work, but he is able to secure cuttings of the right stamp, namely, those with a heel attached. In short, no others of these *Pyrethrums* will root. Thus carefully divided and potted at once, shortening neither top nor bottom beyond what is absolutely needed, the plants must be put into a cold frame for a month or six weeks. Heated frames are a great mistake. Thoroughly water after placing in frame and ventilate each morning, watering being done when needed when the frame is first opened. Years ago, and indeed still, with new or choice kinds these plants are always divided up to a single crown or growth, and if small at the start these make far better plants than large tufts divided and replanted in any crude fashion. For many years it was my custom to divide up in early April and have the plants ready for planting by the third week in May, the plants frequently flowering well in the ensuing autumn. Another way of increasing is after the summer flowering is over and when young growth once more is in evidence. At this time even greater care is necessary because of the usually dry state of the earth, and potting is just as necessary then as in spring. I would, however, sanction dividing and planting in the ground at once, provided the plants had been thoroughly saturated a day or so previous, that not more than six or eight divisions were made of any two-year-old stools, that the roots were left intact to be planted in deep trenches, and that at least one thorough soaking be given after planting. If this cannot be done the plants will be best potted as before, and when established plunge in the open air in ashes or the like. *Pyrethrums* are such voracious subjects that they require dividing and replanting every two years.—E. JENKINS.

The Sweet Sultan.—Among the host of popular annuals there are few more useful for cutting than this, and it is a great pity it is not more grown. Here on this heavy soil strongly impregnated with lime it does well, growing very strongly and flowering with great freedom. Both the mauve and the white forms should be grown, as they are both pretty either arranged together or separately. The easiest plan is to sow very thinly in drills in March and thin out the plants when large enough, as they are impatient of root disturbance.—SUFFOLK.

Spanish Irises.—Presumably these are the very cheapest of the Irises, but they are none the less beautiful on this account, and should be seen in every garden. Some people object to them owing to the dry-looking foliage standing so long after the flowers are over, but they are no worse in this respect than many other bulbous plants, and in any part of the garden where tidiness is particularly essential the plants may be drawn up and thrown away or planted about the shrubberies, so cheap are they. But cheapness ought not to be made a reason for ill-treating a lovely plant, and that the Spanish Iris undoubtedly is.

Lilium rubellum.—I have just bloomed this very charming addition to our dwarf-growing Lilies. My bulb produced two blooms. The habit of the growth is slender and from 18 inches

to 2 feet in height. The colour is very soft and chaste; it varies, I believe, a good deal from light pink to rose. It somewhat resembles *Lilium Kramerii*, though evidently of a more robust habit than that species. There is no doubt that it will be found a charming addition for the front places in borders and also for pots. It flowers in June and seems to do best in light sandy loam, not in peat and leaf-mould, as many Lilies do. In addition to all this, the price of the bulbs is not high, so that Lily lovers may procure them in quantity if they like.—D.

Lily of the Valley in the Norfolk.—I think Lily of the Valley in a wild state is much more common in Norfolk than in most counties; at least, I know of three estates where it grows in great profusion, large quantities being picked. This season large consignments have found their way to Norwich Market, where they have found a ready sale. The improved strains so much grown for the London markets, the bells of which are very numerous and large, are all very well in their way, but to my mind not to be compared for fragrance to the wild flowers from the woods. I do not consider that retarding the crowns, so as to have them in bloom during the summer and early autumn months, answers any good purpose, as, flowering at that date, they seem equally as much out of place as Violets would be.—J. C.

Tree Lupines.—The awarding of a certificate of merit recently at the Drill Hall to a new white-flowered tree Lupine may well help to draw attention to the merits of these hardy plants, of which there are several other varieties. I saw recently growing against a south wall a wonderfully fine plant of *luteus* that spread from 10 feet to 12 feet wide and several feet in height, and was a mass of yellow flowers. The plant gets fairly hard cutting in each spring, and that form of treatment all the section seems to appreciate. Elsewhere, a fine plant of *L. polyphyllus* was very effective. Whilst making huge shrubs when in somewhat sheltered positions, plants have a tendency to become loose unless occasionally cut back. No one need be afraid to use the knife upon them if the pruning be done about March.—A. D.

Showy rockwork and edging plants.—Reference was recently made in THE GARDEN to the value of *Aubrietias* for the rock garden and for use as edging to other beds. The finest display of *Aubrietia violacea* I have ever seen was in a villa garden in this neighbourhood during last April and May. Not only was it used for draping rocky banks which formed the boundary to the garden, but whole beds on the well-kept lawn were filled with it. The garden being comparatively new, the soil in the beds and borders was in good heart, which the various spring-flowering subjects seemed to appreciate. The dense mass of violet-coloured flowers contrasted finely with the pure white trusses of *Arabis*. These two subjects of themselves make a fine display, and they last in full beauty a long time provided the weather is at all favourable.—NORWICH.

A proliferous Nymphaea flower.—In the current number of the *Paris Revue Horticole*, M. H. Dauthenay gives on the authority of the well-known French horticulturist, the Comte de Bouchaud, an account of a most curious instance of reproduction which occurred in his garden during the latter part of last and early part of this year. He noticed that a flower of the beautiful yellow-flowered Water Lily named by its raiser (M. Marliac) *sulphurea grandiflora* did not die away with the others produced during the season, but remained with its stem still plump and green all through the winter after all the others had quite disappeared. On examining this flower and stem in March of this year, he was astonished to find an entirely new young plant had developed out of the old flower with a set of new roots, measuring a foot in length, issuing from its base, which had not yet, however, reached the soil. It will be curious to see what flowers this new plant produces when it blooms.—W. E. GUMBLETON.

ACANTHOLIMON GLUMACEUM.

THERE are few plants which for general usefulness can rival this charming prickly Thrift, known also by the name of *Statice Ararati*. Its native home is in the mountains of Armenia and adjacent countries, where it may often be seen covering the hillsides in great profusion. For rock garden or border we have few plants to equal it. The extremely narrow grass-like leaves end in sharp, stiff points, and form an evergreen carpet somewhat glaucous in colour, from which spring in early summer a profusion of flower-spikes each about 4 inches high, and bearing from five to eight flowers of a pleasing rose-pink colour.

The plant here illustrated I photographed in Messrs. Veitch's nurseries at Exeter, where it does excellently on a small rockwork. Here it is planted among pieces of volcanic rock known as "trup," but I have often planted it in soil mixed with broken sandstone or limestone with equally good results. *Acantholimon glumaceum* is also an excellent plant for massing, and large colonies of it on sloping ground, either on rockwork or in an ordinary border, look exceedingly well and last for a great number of years if the position is sunny and well drained. I have seen in a previous number of THE GARDEN the statement that *Acantholimon glumaceum* cannot be propagated by division. This is certainly not my experience, as I have here in Exeter seen plants divided year after year with the best results. F. W. MEYER.

Elmside, Exeter.

Hemerocallis aurantiaca major.—This has been a most disappointing plant with me. I have had it three seasons, and although planted in a bed where the older kinds *H. fulva*, *H. flava* and *H. graminea* make immense clumps and flower freely, this has never done much. The growth on most of the plants is very poor, and one only is throwing up what looks to be a very puny flower-spike. It may improve in time, but so far I am afraid I shall not get such flowers as I have seen exhibited at the Drill Hall and other places. —SUFFOLK.

Gillenia trifoliata.—It is not everywhere that a suitable soil exists for growing this, one of the most charming of hardy plants; but where it does, or where the soil may be altered to suit it, it ought to be grown. The stems are peculiarly elegant and are terminated by loose panicles of variously coloured flowers, the red form being the prettiest. It does best in a moist, light soil, and the roots have a great affinity for peat and leaf-mould. The margins of ornamental streams or low-lying parts of the garden suit it, and it is easily propagated by division of the roots any time when at rest, preferably, perhaps, just before starting to grow.

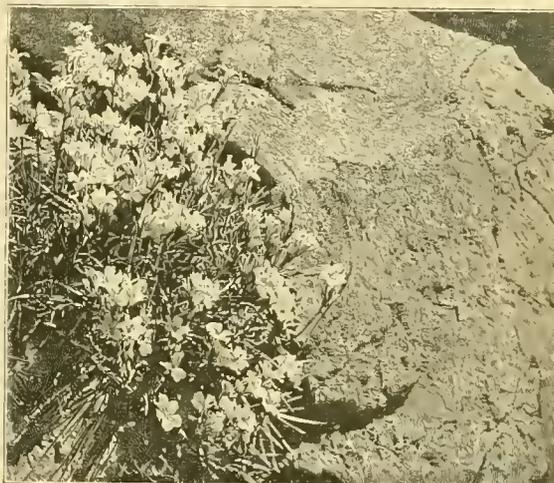

Pæonies and Roses.—It was an open question at the recent Drill Hall meeting whether the Pæony or the Rose predominated, for certainly both were represented in great force and splendid quality. Not that all were alike first-rate, for there were inferior kinds in both families, and perhaps the weak point is that the reds are too much alike in each group. The fact that some of the best Roses are devoid of fragrance is just as much marked in the Pæony family, the very showiness of the flowers compelling one to put the matter to the test, only to feel disappointment at its absence. In the garden, however, these things are the finest of midsummer flowers, and just now the Pæonies are superb.

Erigeron glaucus.—Some few plants, notwithstanding their decidedly showy character, appear slow to come to the front, and this, I think, is one of them. For a plant so comparatively dwarf, free-flowering, and so good a perennial for the most part it is by no means an everyday subject. The large flower-heads are fully 2 inches across, the ray florets of a blue-lilac

tone, which with the yellow disc render the plant attractive for some time. Some nice plants of it in a position sheltered from the sun from 1 p.m. daily, have been a long time in flower; indeed, with such burning heat and general dry weather as have been experienced recently the plants appear rather to relish this place. In the border, however, in deep soil the plant is not at all difficult to please or establish, and fully appreciates a good all-round treatment. For the rock garden it is perhaps less suited. It is from North America and of sub-shrubby character.—J.

PROPAGATING PINKS.

THE propagation of the Pink is effected by a variety of means, each and all having their advocates. Perhaps the most common way is by taking cuttings, or what are more generally known as pipings, striking these in pots of fine sandy soil. Others adopt the more rough-and-ready, though I do not think so satisfactory, plan of dividing old clumps into tiny tufts and planting these out in well-prepared beds where they are to flower. These separated portions root fairly quickly from the base and produce a good many blooms the following season. The best plants, however, I ever had were rooted by simply layering in the same way as Carnations. A little extra time and care are needed, as the old

Acantholimon glumaceum in Messrs. Veitch's nursery at Exeter. Engraved for THE GARDEN from a photograph by Mr. F. W. Meyer.

clumps are somewhat dense and need thinning out, so as to allow of the fine leafy, sandy soil being worked in and the knife used. Some who require only a few plants place soil round the old clumps and layer only from the edges. Stems having several healthy growths on are selected, and thus fine stocky plants are secured for early autumn transplanting. Layering is best done when the plants are two years old, before the growths become crowded, and the sooner after flowering the better. For cuttings, a frame or handlight behind a north wall is the best, and it is imperative that plenty of coarse sand or road grit be mixed with the compost. The pots should be frequently examined, as sometimes slugs and snails attack the cuttings. Pinks do very well and have a very pretty effect in the front rows of mixed hardy borders, but both plants and bloom are often seen in an indifferent state owing to an impoverished condition of the soil. When planting fresh stock in such positions, I like to take out a good spit of the old soil and replace with some new loamy compost. Old gardeners used to bestow much time and labour on Pinks. I knew one who grew all his plants on a west border in beds. He used a rather light compost, and always mixed abundance of good leaf-mould and grit with it, in which the plants

did splendidly. He attributed great importance to early propagation. I remember the grand beds he had of the old white Pink. The improved sorts Mrs. Sinkins and Her Majesty are fine solid flowers and soon fill the basket, but the old white is charming when well grown.

J. C.

NOTES ON HARDY PLANTS.

Erythraea diffusa.—Treating this just as you would the softer and precumbent kinds of Gentians will not prove far wrong, *i.e.*, giving a porous soil of peat and turfy loam and moist position, and besides, the seeds as they ripen falling on such a surface will readily grow and afford a patch as big as desired. This pretty species may be termed for all practical purposes a creeping Gentian with bright rosy flowers, and as they come in succession the plant is one of great value. Both flowers and the evergreen foliage have a glossy effect, so that it is a good wet weather plant.

Rubus deliciosus.—There have been discussions as to where the feature or property "delicious" came in with this shrub. Fruit or seed we have never seen, so that we sought for the sweetness in the odour of the flowers. Oddly enough, some of us could never find it—practically no smell at all. Still more strange this spring, my big bush, now like a hillock of snow, is most powerfully fragrant. There is another fact that I might as well give. The flowers are less imbricate, are not much more than half the size they have been for the past twelve or fifteen years, and there are signs that fruit may form.

Potentilla flagellaris (Willd.) and **P. villosa** (Pall.).—So far as the two plants grown here under these names are concerned, if not identical, they are the same for garden purposes, and in point of fact they are both Siberian plants. The more important matter is they are early for their family and strikingly beautiful. The flowers are large, deep yellow, with orange eye, and so borne up by the stolon-like stems as to be seen to the best advantage. The dense habit and silvery grey foliage, thickly villose, go far to render them characteristic plants. Naturally these plants do not like our wet winters, but a bit of glass kept over them makes them quite safe.

Scilla verna.—Though this is the heyday of Scillas, and even if one chances to live in a Bluebell district, there is something about this pigmy species, with its sheeny dark blue bells topping the stout 2-inch-high scapes, that one cannot fail to at once recognise. If grown in groups of a foot or more in diameter, such groups are distinctly telling among other dwarf things. The way in which the grass sets off at right angles with the flower-scapes helps to make the most of the flowers, bringing them into the boldest possible relief.

Morisia hypogæa.—This is at once one of the humblest yet gayest of all our spring bloomers. It has been in flower quite two months. A plant more indifferent to conditions of soil, wet and every kind of weather it would be hard to name. Only those who have seen it can form an idea either of its peculiar habit or beauty.

Woodville, Kirkstall.

J. WOOD.

Propagating Polygonum baldschuanicum.—In the article concerning this *Polygonum* on page 454 its propagation is spoken of as rather difficult, which is indeed the general experience. A correspondent of the French journal *Le Jardin* in the number for May 20 of the present year points out a method of increasing it which is at least well worth trying. After a few general remarks concerning the plant and the different means of increase that have been tried, the writer

goes on to say: "After trying various methods with but little success, we resolved some weeks ago to take the woody shoots of the preceding year and treat them in the same way as is done in the case of the Vine when propagated from eyes. The branches were cut up into lengths and laid flat in well-drained pans of soil with a layer of silver sand on the top, the whole being placed on a moderate hotbed. Slightly burying them in the sand by simply pressing them with the fingers and kept sufficiently moist, these cuttings gave very good results, especially those that had been made rather long—that is, from 8 to 10 centimètres in length."—H. P.

Top-dressing Pyrethrums.—Owing to the severe drought experienced last summer, and which was in this locality prolonged through the month of September, my Pyrethrums were much defoliated and had a very miserable appearance. Early in October I gave them a liberal top-dressing of manure, and with the advent of cool, moist weather new leaves pushed from the crowns, so that by the close of that month the plants looked as fresh and green as is usually the case in spring. The effect of the top-dressing, which was in a great measure worked into the ground by worms and rain during the winter, is very striking, and shows that to have Pyrethrums in their best form they must have an abundance of rich food, which in the case of established plants should be applied early enough to ensure the manurial properties being absorbed by the soil by the time the plants come into growth. A bed of two-year-old plants is very effective and will furnish a quantity of good blooms for cutting for several weeks to come. Pyrethrums are, I think, at their best in the second and third years after planting. In most soils they are better for being occasionally divided and replanted in fresh well-manured ground. In forming a collection of these showy flowers, it is well to secure as lengthened a blooming time as possible by means of the early and later-flowering kinds. Some varieties come into flower quite a week or ten days later than others.—J. C. B.

OUTDOOR FLOWERS FOR CUTTING.

THE spell of exceptionally hot weather experienced since the beginning of the month has brought the flowers out very fast, and at the present time (June 13) material for cutting, both in the way of rough and choice things, is abundant. Roses on walls, including Gloire de Dijon, Safrano, Homère, W. A. Richardson, and Waltham Seedling, are a mass of bloom. Considerable difficulty is, however, experienced in keeping them clean, aphid being very troublesome. How strange it is that those who ought to know better and who have repeatedly heard the true reason will persist in calling the deposit on the leaf that comes from the aphid "blight," and imagine that it is in some direct way attributable to an easterly wind. That this is in a measure answerable for the same when a sudden fall in the temperature occurs and growth is thereby arrested is doubtless the case, but the actual cause of the disfigurement is a different matter altogether. It seems a trivial matter to note, but it certainly is extraordinary that after all the information furnished in gardening papers one is continually asked for a remedy for blight on Roses. The maggot is very troublesome in places, and where not carefully picked will, I fear, be answerable for much disfigurement of buds. Next to Roses, perhaps the flower most in favour at the present time is the Spanish Iris. All are beautiful, but clearly defined pure shades in white, blue, and yellow seem most acceptable in a cut state. They flower freely on dry sunny borders, but the foliage goes quickly in such a position, even, in fact, before the flower is at its best. They are more satisfactory with me in partial shade, that is, on a west or north-west border. Naturally the expansion of the flower is delayed here, which considerably prolongs the season. Aquilegias are just now at their best. The pale yellow *A. chrysantha* is much in request, and a large flower with (to borrow a description

from the Daffodils) a white expanding trumpet, if the inner petals can be so termed, and a lavender perianth is a very refined and beautiful bloom. Good forms of *Pyrethrum* and East Lothian Stock, just now at their best, also furnish an abundance of flower and are very acceptable. If flowers of gorgeous hue are in request, two of the best things at present available are *Antirrhinum*s and *Gaillardia*s. Those who have only tried the dwarf bedding *Snapdragons* in shades of white, yellow, and crimson have a treat yet in store in the tall branching varieties of very vigorous habit with very large spikes and individual blooms. From seed sown last July I have plants now 3 feet high with the first spike just at its best, the shades in self varying from white and yellow to deep crimson and maroon, besides very striking mixtures, as dark scarlet with a golden lip, and crimson and carmine striped on a yellow ground. The selection is from a firm who are specialists in hardy flowers, and who catalogue twelve distinct named varieties in this strain. To obtain plants for next season it is advisable to start soon. Prepare boxes by filling with a rather light compost, and give a good soaking before sowing; cover the seed lightly, place in cold frame, and shade from hot sun. Transplant into nursery beds as soon as the seedlings are of sufficient size and plant out in autumn or early spring as may be most convenient. Planted in clumps in different shades with an undergrowth of Tufted Pansies, they make very fine summer beds. The first spike should be removed as soon as it shows signs of seeding to allow of the development of side growth. It is almost needless to add that the *Antirrhinum* is a capital dry weather plant and stands drought well. The same cultural remarks so far as time and manner of seed-sowing, pricking off and after-planting are also applicable to *Gaillardia*s, which are just now very showy. A special bed might well be devoted to these, for they are of very vigorous habit, and if planted on a border with other things are apt to monopolise much more space than has been assigned to them. Of things that last but a short time in water now either in bloom or coming out, as, for instance, *Pæonies* and *Poppies*, both single and double, I use very few, time not admitting of the constant attention in the way of replenishment that they require. They are, however, employed on special occasions, such as dinner-table work, where they are only wanted for a few hours. Among the choicest outdoor white flowers at present available besides *Roses* are *Spanish Iris* *British Queen*, *Princess Alice Stock*, *Albino Pink* (far and away the best white) and *Pyrethrum Aphrodite*. The tiny flowered annual *Gypsophila*, although insignificant in the individual blooms, is very useful when the panicle is fully expanded. E. BURRELL.

Claremont.

Water Lilies.—The prevailing tropical heat seems to suit the *Water Lilies*, for their growth is now very rapid and the blossoming is profuse. I fancy so much bright sunshine causes some of the deeper coloured varieties to be a little paler than is the case in duller weather. As yet all the varieties grown here are not in bloom. The following are some of the most prominent at present, and commenced blooming in the order placed: *Nymphaea caroliniana perfecta*, a comparatively old-established plant, opened its first blooms at the end of May, followed quickly by *N. Laydekeri rosea* and *lilacea*, *N. gloriosa*, *N. Marliacea albida*, *N. Chromatella*, *N. lucida*, *N. fulva*, *N. Ellisiana*, *N. odorata sulphurea grandiflora*, *N. odorata exquisita*, and I expect more to expand during the week. In planting one (the chief) pond I planted strong clumps of *Richardia aethiopsica* thinly, and now they form pleasing objects in full bloom, producing very fine spathes in quantity, and effectually breaking the flatness of the surface. I think the beauty of the pond is enhanced thereby. Another experiment was tried at the same time, viz., introducing fish (golden of sorts), with a view to their agitating the sur-

face water and thus preventing the growth of *confervæ*. Of course it is yet too soon to say positively that it is a success, and that the fish will permanently prevent the growth of *confervæ* in stagnant water; still, they have justified expectations in this respect so far, that more fish have been introduced to other smaller ponds with the same end in view. Certain it is that the water stood twelve months before the pond was emptied and refilled with no sign of *confervæ* disfiguring its surface. I should be glad to learn the experience of others on this point.—J. R.

FLOWERS IN THE ROCK GARDEN, KEW.

HAVING but an hour to spare in Kew Gardens after visiting the Temple show, I had but little time to even glance at its diverse attractions, but bent my way at once to the rock garden, which I found interesting as ever. *Achillea umbellata* was a mass of white flower-heads, and *Arenaria balearica* clothed the rocks with its tracery of creeping foliage thickly starred with diminutive white bloomlets, while *A. montana* was also flowering profusely. *Achillea rupestris* was also a breadth of white, and the pretty lemon-coloured *Alyssum saxatile citrinum* still showed its soft tint. *Anthemis carpatia* was bearing its white stars, and *Anthyllis vulneraria* var. *alpestris* its yellow flowers. Of *Anemones*, *A. baicalensis* and *A. multifida* were in bloom, as were *Aster alpinus* and *A. peregrinus*, the flowers of the latter being slightly larger and of a rather deeper shade of blue, while *Aubrietias* in variety were also blossoming. *Chrysogonum virginianum* disclosed its yellow flower-heads, and a colony of *Cypripedium montanum* in full bloom afforded a pleasing sight. *C. spectabile*, in a moist rock-surrounded nook looked the picture of health and was throwing up vigorous leafage. *Daphne alpina* was carrying its white flowers on its spreading branchlets, and *Delphinium trollifolium* was in bloom. A hybrid between *Dianthus casius* and *D. deltoides* was bearing blossoms of a very bright cerise-pink, and the handsome *D. superbus* displayed its deeply lacinated petals. *Dicentra eximia* was thickly set with its flower-scapes of reddish purple, and *Dryas octopetala* was studded with its white golden-centred blooms, while on the bank above some fine specimens of *Eremurus himalaicus*, with lofty bloom-spikes but partially expanded, towered to a height of 7 feet. The beautiful *Gazania nivea* var. *latifolia* was bearing its chaste white blossoms, and *Geranium cinereum album* showed its snowy flowers, and a number of corms of *Gladiolus anatolicus* were also blooming. *Hippocrepis comosa* was a cloud of yellow, and the *Violet Cress* (*Ionopsidium acaule*) bore its countless minute blooms of pale amethyst, while *Lathyrus hirsutus* was set with its mauve and white blossoms, and *Linum arboreum* made a spot of bright gold. *Lonicera pyrenaica* was in flower, and *Maianthemum bifolium*, perhaps better known under the title of *Convallaria bifolia*, was blooming well in a large mass, the small white flower-scapes exquisitely set off by the broad Lily of the Valley-like foliage. *Onosma tauricum* held its flower-heads of pendent yellow bells, and *Ornithogalum arcuatum* reared fine spikes of white bloom to a height of well-nigh 3 feet, while *Paradisea liliastrum*, more widely recognised under the title of *Athericum liliastrum*, was carrying spires of drooping white flowers. *Pentstemon confertus* bore its little flower-heads of light blue, *P. Scouleri* crowned a rocky ledge with its mauve blossoms, and *Potentilla splendens* had its spreading growth starred with white flowers. *Ramondia pyrenaica* was in the best of health on the perpendicular face of a moist and shaded mass of rock facing the bed of *Cypripedium spectabile*. Both the mauve-blue and white varieties were represented, there being about fifty plants in all, some of them being of large size and bearing as many as thirty blooms. The fine leaves of *Rodgersia podophylla* bordered the path at one spot, and two lovely single *Roses* were objects of great beauty on the slope above the rockwork. These were large bushes angled

with expanded blooms and buds, one being the Himalayan *Rosa sericea*, with white blossoms, and the other *R. cinnamomea*, bearing pale pink flowers. Of *Saxifragas*, a number were in bloom, amongst which may be mentioned *S. aizoon* and its yellow variety, *S. cartilaginea*, *S. cochlearis*, *S. cotyledon*, a hybrid between *S. cotyledon* and *S. pyramidalis*, *S. crustata*, *S. cuneifolia*, *S. Hosti*, *S. lantoscana*, *S. lingulata*, *S. luteo-purpurea*, *S. montavoniensis*, *S. pyramidalis*, *S. stonoglossa*, and *S. Vandelli*. *Vancouveria hexandra* was bearing its graceful white flower-scapes well above its light green foliage, *Veronicas* in variety were in bloom, *Viola pedata* and *V. pedata alba* were in flower, and *Wahlenbergia Kitaibeli* was covered with its mauve-blue blossoms. S. W. F.

Peach-leaved Campanulas.—These are now very showy in the border, and in their varying forms are valuable when in groups and the like. Of the white forms the best are *C. persicifolia alba coronata* and *C. p. alba grandiflora*. In some soils these plants are quite at home, and in others require some care to prevent the stock becoming greatly diminished. In some measure this may be due to the free-flowering character of the subjects, which naturally assists in lessening the vitality of the plant. The old double white is still a good plant, particularly where the soil is not too sandy or hot. Where a too light soil exists, and where the plants become a prey to thrips in summer, greater attention should be given them. Shade when not accompanied by hungry tree roots is excellent for these Peach-leaved kinds, and in such position the plants suffer less from insect pests. At a recent meeting of the Royal Horticultural Society a new variety of this group was shown in which the flowers are much larger than in any of the older forms, more widely expanded than the fuller double kind, and less confused generally by the petals being fewer in number. Hardy plant growers were surprised so good a plant received no recognition.

NOTES AND QUESTIONS.—FLOWER.

Gaillardia Langport.—This is the name of one of the largest *Gaillardias* yet seen, probably a selected form from the well-known *G. grandiflora maxima*, which it strongly resembles. Provided it is as free and as good as the old kind, it should prove a showy subject for the border.

Tufted Pansy Ophelia.—This has been in splendid form lately, and during the last few days its large rayless blossoms have developed almost phenomenal proportions. The flowers are circular and of good substance, and the colour may be described as a deep heliotrope-blue, the deeper colour being more pronounced on the upper petals. Although the growth is strong and vigorous, it is not in the least unruly.—C.

Lupinus polyphyllus Somerset.—Till the advent of this kind the herbaceous *Lupines* were in colour confined to blue, purple, and white, but this kind provides the totally distinct shade of soft and pale yellow. Judging from the soft, glistening and downy character of its leaves, one may surmise that the yellow Tree *Lupine* had played a part in its production. In any case so good and distinct a plant deserves attention from hardy plant growers generally.

Tufted Pansy Miss Gertie Waterer.—This is one of the latest acquisitions. It is a flower of medium size, absolutely rayless and pure white, with a neat yellow eye. During the prevalence of cold or very cool weather the blossoms become slightly bluish-tinted, but as seen during the present week it is one of the most delightful kinds imaginable. It is wonderfully free-flowering on stems of medium length, these standing up erect on a beautiful tufted habit of growth.—D. B. C.

Tufted Pansy A. J. Rowberry.—This variety for the two or three seasons following its introduction was often condemned because of its weak constitution and also because of the unsatisfactory character of its growth. I ventured to suggest at the time that this defect was probably owing to the stock plants being worked too hard, and this opinion seems

now to be verified, if one may judge by the plants at the present time. There are few kinds in my collection which look better, and the variety under notice is just now in the pink of condition. For some weeks these plants have blossomed most profusely, the rich deep yellow of the blossoms being very effective. Several raisers are using this variety for crossing purposes, and we may yet get the same colour with an ideal habit.—C.

STOVE AND GREENHOUSE.

HYDRANGEAS IN POTS.

In the south and south-western counties *Hydrangeas* are perfectly hardy, and when in bloom during the later summer months they are very beautiful, isolated specimens or groups having a fine effect. To ensure freedom of blooming, the growths must be thoroughly ripened, consequently there must be free exposure to the sun from all sides, the soil being a warm and well-drained one. On some soils the heads of bloom will come of a beautiful blue colour, reminding one of the colour of the blooms of *Vanda cœrulea*. Soil with a deal of iron in it is said to favour this, but I think a dry season also appears to favour this change from the normal pink colour. At Witley last season the heads of bloom were of this blue colour. This I have not noticed before. A head of

Hydrangea Hortensia in a pot. Engraved from THE GARDEN from a photograph sent by Mr. A. Young, Witley Court Gardens, Stourport.

bloom was also brought me from a cottage garden, so I take it that the extreme heat and drought have been the cause of certain chemical changes in the soil which have led to this development. One need not, however, fear the want of a particular soil in which to produce this change of colour, as it can be had quite artificially by watering with a solution of alum water. I have seen most beautiful plants produced by this means in the late Mr. Lea's garden, Parkfield, near Worcester. The plants, however, were growing in pots. As soon as fresh growth started in the spring the plants were watered with this alum solution. From the effect produced by this change of colour the experiment is well worth the little extra trouble involved.

What a fine effect large old plants have when grown in pots or tubs for standing in prominent positions about the garden. The plant, one of several, shown in the illustration was grown by Dr. Horace Swete, The Lodge, Lower Wyke, Worcester. It has been growing in the same pot for some time. In this case the plants have winter protection from severe frost, also to prevent injury to the pots from split-

ting. As soon as growth starts in the spring the plants are stood in the open air in a sunny position, where they grow away freely. The well-ripened, plump growths of the previous autumn will produce flower-heads, other shoots being formed simultaneously for next season's supply. Water must be freely applied, weak manure water being added occasionally to strengthen the flower-heads and to give tone to the whole plant.

Single heads of bloom of *Hydrangea Hortensia* in 5-inch or 6-inch pots are well-known objects during the early summer months, many thousands being produced annually by the growers who supply Covent Garden Market. I have grown them for this purpose with heads of bloom 15 inches in diameter. Strong cuttings were inserted singly in small pots in May, and as soon as rooted these are potted firmly into 5-inch pots. When established the plants are stood in the open air with full exposure to the sun. Being well supplied with water, the plants remain in the open air till the early part of November, when they are stored in light, cold frames. From Christmas onwards batches are introduced into an intermediate temperature when they come into bloom. As soon as the flower-heads show, manure water must be freely applied, so as to encourage large heads of flower.

The white-flowered *H. Thomas Hegg* is a very free-flowering variety, whereas *H. Hortensia* flowers from the plump buds at the apex only of the well-ripened shoots. The variety in question will form flower-heads from all prominent-looking buds along the whole length of the growths. I once produced a plant in three years from the cutting which had 100 heads of flower and grew to be 6 feet in diameter. Many more flower-heads would have formed, but quite one-half of the young shoots was pulled off as growth was starting so as to give the remainder strength.

Hydrangea paniculata is quite a distinct looking variety both in its growth and flower-heads, requiring different treatment. The best results are obtained in what is termed a moist holding loam. After flowering and when the leaves have fallen, at any time previous to growth starting again, these long growths must be pruned back to three or four eyes. Each long shoot is surmounted with a panicle of flower, the blooming season being the later summer months. This variety is readily increased from cuttings, these being formed from the portions of growth that are pruned off during the early winter. These should be cut into 6-inch lengths and inserted firmly in sandy soil in the open air. This, like the preceding, may be utilised for forcing. A. YOUNG.

Witley Court, Stourport.

Summer treatment of Arums.—I quite agree with all that "G. H. H." advances with regard to the summer treatment of Arums, viz., keeping them in pots in preference to planting out. After flowering, Arums require rest and an opportunity to ripen their tubers. This is given in the case of planting out by about a month's rest before being put in the open ground—in reality no rest at all. On the other hand, by being kept in pots and not over-watered, they are thoroughly ripened. By potting a few at a time through June, July, and even as late as August, a succession of flowers is obtained throughout the winter months. The tubers should be shaken out and potted up singly into as small pots as possible without crowding the roots, the lack of pot-room being compensated for by liberal doses of manure-water when growing freely. A batch of Arum Lilies in pots outdoors during the summer months is not a

very pleasing sight, as the leaves turn yellow and die off, but the tubers are ripening well.—C.

Carnations.—Malmaison Carnations are now in full beauty, and I saw a few days ago a splendid collection in the west country that was the picture of health and blooming freely. Many varieties of the Malmaison were represented, but the dark-coloured kinds lack much of the beauty of the old flesh-coloured and newer shell-pink varieties. Horace Hutchinson, which was lately shown at the Temple, gives promise of being an acquisition to the dark-coloured Malmaisons, being very broad of petal. The large yellow Cecilia, exhibited at the same show, was perhaps the most remarkable Carnation shown, being particularly fine and of good colour. Duchess Consuelo, a handsome bloom of the same tint, is also a splendid yellow, while Baldwin, soft rose, Daybreak, flesh-pink, Calypso, bluish, and Mme. Thérèse Franco are all attractive varieties.—S. W. F.

Torenia Fournieri.—Where a greenhouse has to be kept gay with flowering plants throughout the season this *Torenia* affords a pleasing variety. It is a low-growing, much-branched plant, whose curiously-shaped blossoms are of various shades of lilac and violet. There is a second species, *T. Bailloni* or *flava*, whose flowers are yellow, thus furnishing a good companion to the first-named. Both succeed best treated as annuals—that is, sown in a gentle heat in the spring and pricked off as soon as they are large enough to handle. They may be either potted singly or three in a pot 5 inches in diameter, under which conditions they attain an effective size in less time than when potted singly. For an edging or such purposes 4-inch pots are sometimes the most useful, and in this one plant will attain to flowering size. A fairly open compost such as is suitable for Fuchsias and similar subjects will suit these *Torenia*s well. By varying the time of seed-sowing they may be had in flower at different periods, but for late autumn blooming more heat than an ordinary greenhouse gives is necessary. Another species, *T. asiatica*, is a stronger grower than either of the preceding and more woody in texture. It is best struck from cuttings and is very effective when grown in a suspended basket.—T.

Ipomæa Leari.—Though the blooms of many *Ipomæas* are very fugacious, such a succession is maintained that a display of blossoms is kept up for a considerable time. Blue flowers being so generally admired, those which are of some of the various shades of that tint are perhaps the most attractive. To this class *I. Leari* belongs, the large *Convolvulus*-like flowers being of a pleasing shade of lightest blue. It succeeds best in the temperature of an intermediate house, and is just now flowering in the Begonia house at Kew. The foliage, like that of several of its allies, is thin in texture and somewhat liable to the attacks of red spider, to prevent which a liberal use of the syringe must be resorted to. It passes the winter in a comparatively dormant state, starts into growth in the spring, flowers throughout the summer months, and then goes to rest. A very beautiful species which forms a succession to *I. Leari* is *I. rubro-cerulea*, which is of annual duration. The seeds should be sown in the spring, and, grown on freely in a greenhouse or rather warmer structure, they will commence to flower early in the autumn and continue for a couple of months or so. The cool part of the stove is, however, necessary during the flowering period. The flowers of *I. rubro-cerulea* are of a beautiful clear light blue, becoming with age suffused with purplish red.—H. P.

Tydas.—The quaintly-marked blossoms of these generoseous plants are more generally met with during the autumn and early winter months than at the present time, yet they may with little trouble be had now, and I recently saw several flowering examples that were very attractive, particularly at this season of the year. They had been ripened off somewhat earlier than usual last autumn, and were shaken clear of the soil and repotted early in February. Grown on

in an intermediate temperature they are now flowering freely, and will continue for a long time to come. The whole of these *Tydas*, or *Isolomas* as they are often called, will succeed with very ordinary treatment, all they need being in the autumn or winter, when the flowering season is over, that the soil be kept pretty dry, but not parched up, and then when intended to start them into growth the curious caterpillar-like rhizomes may be shaken clear of the old soil and repotted into fresh compost. These rhizomes should be about half an inch below the surface of the soil, which may consist of loam, leaf-mould, and sand. Where the plants are intended for late blooming they need not be potted till March, and may be grown during the summer in a cold frame. Propagation is effected by seeds, which ripen freely, by division, or by taking off the tops when about 3 inches long and putting them in as cuttings. Some varieties produce new rhizomes more freely than others, but in a general way this is the readiest mode of increasing any particular form.—T.

Acalypha Sanderiana.—Having given this plant a good trial, I am convinced of its usefulness. Although, like many other introductions, it has not found universal favour, where grown well it will always find many admirers. One great recommendation is that it will keep up a display throughout the year, being equally bright at Christmas as at midsummer. Another recommendation is that it can be easily propagated and attains to a useful size in a very short time. I now have plants which are not three months old about a foot high, with long crimson racemes from the base of every leaf. The chief points in the culture of this useful plant are first to secure strong cuttings. If the stock plants are weak, they should be potted on and treated liberally till they have made strong growths. Weak cuttings run up tall, but strong ones will flower from the surface of the pots. I like to put the cuttings in singly into small pots, using a fairly rich open compost. They require to be kept close and shaded until they are rooted, which will not take many days. As soon as rooted round the pots they may be potted on into 5-inch pots and stood up as close to the glass as possible. This plant will make more rapid progress in a high temperature, but I find it can be grown well in an intermediate house and will make shorter jointed plants. A liberal supply of manure may be given as soon as the pots are filled with roots. Red spider is its greatest enemy. Plants get too tall in a comparatively short time, but as there is little risk in taking the tops off to propagate, young plants may always be had for succession.—A. HEMSLEY.

NOTES AND QUESTIONS.—STOVE.

Shading regal Pelargoniums.—As mentioned on p. 443, the blossoms of these remain fresh and in good condition much longer when shaded from bright sunshine than they do if fully exposed, yet the plants are greatly weakened if it is carried to excess. The dark-coloured flowers are much more affected by the sun than those of a lighter tint, the intense purple (almost black) of *Beauty of Oxtou* turning in a short time to quite a rusty hue. In the case of those with dark blotches on a white or light ground, it will be often found that the blotched portion is quite disfigured, while the light coloured part is uninjured. Not only does this apply to regal Pelargoniums, but to all the different sections, such as show, decorative, French, and fancy.—H. P.

The double Ragged Robin in pots.—At Hardwicke House, Bury St. Edmunds, I recently noticed a nice lot of plants of *Lychnis Flos-enculi*, the double pink variety, grown in pots for conservatory decoration. For this purpose it is admirably adapted. I have grown it since it was sent out as a border plant, but, though it is very pretty and useful for cutting, it seems to lack something of boldness and is not altogether satisfactory. The Hardwicke plants are in 6-inch pots, and the pretty feathery spikes rise to the height of about 18 inches. They are covered with flowers which last well, and the plant is

certainly worth making a note of for the purpose indicated.

Pelargonium Mr. W. Bealby.—Although now some years since this was sent out—if my memory is not at fault it was among Messrs. Pearson's 1887 set—it is still one of the finest habited and brightest of zonal Pelargoniums, and I was recently reminded of it on seeing a large batch of it being used for bedding in a neighbouring garden. It must not be thought on this account that the flowers are not of a good standard, for there are few of the very newest that can beat it for size or shape, while as noted its habit is all that could be desired.—A GROWER.

ORCHIDS.

CATTLEYA ACLANDIÆ.

It is surprising how seldom one comes across good healthy specimens of this pretty *Cattleya*, and this is the more unfortunate when one considers how very distinct it is from all other kinds. Nor is it particularly difficult to grow provided a little thought is brought to bear upon it. The habit of the plant itself is in a manner a guide as to the kind of receptacle it will thrive in, its short bulb and roots pointing to quite a different mode of treatment from that followed for the labiate forms. In many cases growers have tried baskets for it and failed, but this is not the fault of the baskets. They are not sufficiently drained as a rule, and in consequence a lot of peat and Moss comes into contact with the roots, and this they are not able to push through. Had the baskets been filled to within an inch of the top rods with crocks and the remainder filled with compost, all would have been well, provided other conditions were favourable. Perhaps the best way to treat this plant is to place it on flat rafts or trellised blocks of teak. Sometimes it is inclined to ramble, and the blocks allow for this. Again, new compost can be given about the leads without disturbing the back part of the plants, and this is a great advantage, as the roots of *C. Aclandii* greatly dislike being pulled about.

This system of adding to the compost piecemeal is a good one, and far preferable to overloading the roots, as described above, or of placing them upon bare blocks. I have seen healthy plants under the latter system where they had been very carefully looked after both as regards rest and atmospheric moisture, but in no case had they the same vigour and size of pseudo-bulbs or flowers as are produced when the roots are running in a little compost. Again, when the blocks decay, as they do rapidly in the moist heat of the Orchid house, it is very difficult to transplant the Orchid to a fresh piece without either leaving a lot of decayed wood in or damaging the roots badly. That the latter is injurious goes without saying, while decayed wood is the surest producer of fungoid growth known, and the latter is very destructive to Orchid roots. The most important point then in its culture is to secure a healthy lot of roots clinging to something of a suitable nature for their ramification and health. The question as to atmospheric treatment is more difficult to solve. While *C. Aclandii* undoubtedly delights in warm, moist conditions, especially when growth is most active, there must be a kind of hardening or ripening of the growth going on at the same time, or else if the growth is soft and sappy, without due attention to this the flowers will be few and poor in substance and the plants very liable to be checked by any slight mistake in culture, such as a cold draught of air in winter or a little too much sun in summer.

The plant is peculiar in its seasons of growth and rest, and not at all to be depended upon. I have often known it to flower, say, in June and then grow away again and produce another lot of bloom in autumn, but I have never seen this class of plant keep so healthy as others that flower regularly and annually. The more light and air they are exposed to in autumn and winter the better, and with regard to root-moisture, this will depend entirely upon the state of growth, giving a full supply to healthy, well-rooted plants when growing freely, but less to those that are weak and when resting. The flowers of *C. Aclandiae* are very distinct from those of any other *Cattleya*, the sepals and petals being greenish yellow, spotted with deep purple, the lip, which does not enfold the column as is usual in *Cattleyas*, being bright rosy purple with deeper lines.

Aerides Warneri.—This is really a good form of *A. crispum*, the plant and flowers being almost identical, but the colour is quite distinct. It is not by any means common in collections, nor has it ever been since it was first imported by the late Mr. Warner. The flowers appear on racemes, each 18 inches or more in length, and are among the largest in the genus. The sepals and petals are almost pure white, having lost the rosy suffusion common to the type, while the lip is of a pretty bright rose-purple margined with white. It does well with other species in the East India house.

Oncidium cucullatum.—One of the prettiest varieties of this species I have seen is now in bloom. The sepals and petals are of a pretty soft purple-rose with quite a distinct narrow white border or margin. The lip is entirely white with the exception of rosy-violet spots at the base. Thus it comes nearest the *O. c. nubigenum* forms, but is superior to any of these I have seen. *O. cucullatum* is well known to be one of the most variable kinds in existence, and, being a native of high mountains in equatorial regions, is not easy to keep in health over a number of years. Very cool and moist conditions suit it best.—H.

Masdevallia Barlaeana.—Though not very large, the flowers of this species are pretty and bright, and it is certainly worthy a place in every amateur's collection. It is cheap and easily cultivated; the scapes are single flowered, of a very pretty bright red, and they are abundantly produced. The plants should be grown in medium-sized pots only, and these must be well drained, the upper inch or so being all that is needed for compost. Add plenty of rough broken crocks and charcoal to the peat and Moss, and place it firmly in the pots. Grow in a light, cool house, with ample light in winter, shading somewhat freely in summer.

Saccolabium ampullaceum.—The erect spikes of rosy carmine blossoms borne by this species are now very bright and effective, and though fairly common in collections, one does not see so much of it as of many other less beautiful kinds. Like others of the dwarf *Saccolabiums*, it requires careful culture, but there is nothing particularly difficult about it, and in a nice light position in a warm house where the growth gets well consolidated in autumn, the leaves will usually stand the winter all right. Weak plants kept in a very moist and shady house without due regard being paid to hardening their tissues in late summer and autumn often lose many of the lower leaves after a cold, dull winter. It should be grown in baskets of Sphagnum Moss and crocks only.

Dendrobium superbum.—The flowers of this species are not so bright as are those of many others in the genus, while the peculiar fragrance, though liked by some people, is distasteful to others. But a well-flowered plant is decidedly handsome, the blossoms occurring very freely along the upper part of the long vigorous stems,

their colour a deep purplish magenta. Owing to the length of these stems and the fact that the plants bloom somewhat later than most *Dendrobies*, the most favourable position in the East India house should be given it, or the growths will not be finished in time. A frequent cause of its not flowering freely is found in this backward tendency, for there is not time to get the stems really well ripened after they are grown. Otherwise the plant is of the easiest culture and thrives with the usual treatment given to the deciduous group.

Brassia Keiliana.—This species is noted for its variations from the typical form, very few being exactly alike in every particular, and I recently saw a very nice lot of varieties flowering at Mr. Bull's. One especially had deep sepia-brown sepals, the ends of which were contracted into bright golden yellow tails, a fine contrast against the deep brown being formed. *B. Keiliana* is one of the best of the *Brassias* and easily cultivated in a house kept at a medium temperature and nicely moist. The plants should be grown in pots of medium size, and the compost may consist of equal parts of peat fibre and Sphagnum. A very free moisture supply is necessary while growth is active, and even while at rest the plants must not be too much dried at the root.

Galeandra nivalis.—This is not a very common species in cultivation, but an extremely pretty one in which the white funnel-shaped lip shows up strongly against the olive-brown sepals and petals, the flowers occurring in terminal racemes from the erect stems. The bane of *Galeandras*, as of many other South American Orchids, is insects, of which thrips and red spider are doubtless the most troublesome, but if by careful fumigation and syringing these insects can be kept in check, little other difficulty will be found in their culture. Like the *Thunias*, they enjoy a constantly hot and very moist temperature all the time they are growing and until the tops of the flower-spikes are seen, but in order to preserve the blossoms, a cooler and drier atmosphere is necessary then and afterwards to induce rest. The usual compost of peat fibre and Moss suits them, with a little good fibrous loam for the strongest plants, but the pot must not be unduly large.

Epidendrum arachnoglossum.—The Spider's-tongue Orchid, as this species is called, is not particularly showy, but it is very interesting, and also remarkable for the time it remains in flower. Where a fair number of plants is grown the display goes on for months owing to the spikes following each other, these elongating individually and producing flowers towards the ends long after those lower down are decayed. There are good and bad forms of it, some having flowers of a bright crimson with yellow lip markings, others having blooms of a cloudy white with many intermediate shades. The best position for the plant is a light and well-ventilated part of the *Cattleya* house, where in fairly large pots it grows freely and flowers annually when strong enough. In a hot and very moist house with insufficient ventilation, though it may grow freely for a time, it is never really happy and often fails to flower. It is a native of the southern part of New Grenada, where it was found growing on a volcanic mountain by M. Ed. André in 1876.

Leptotes bicolor.—Few Orchids have received more names from our botanists than this, but the name so long in use in our gardens and nurseries is the best known and as good as any. The plant is flowering freely now in many collections, and its distinctness as well as its quiet beauty ought to ensure it more attention from cultivators than it receives. The plant has cylindrical leaves and stems only a few inches high altogether, and from the base of the former springs the flower-spike, containing one to four flowers, according to the strength of the plant or the individual growth producing it. The sepals and petals are white, the lip purple, with a white

border. *L. bicolor* thrives best in an intermediate house, and though not by any means difficult of cultivation, it is important that the roots are not surfeited with compost. The safest way to grow it is in shallow baskets suspended from the roof, these being well drained and rather small in comparison with the size of the plant. Equal parts of peat and Moss suit it well, and abundance of water is necessary during the growing season. In winter it should be kept well up to the light, as the young leads are apt to damp off. It was introduced in 1831 from Brazil, and first flowered in the Duke of Bedford's collection.

Saccolabium Hendersonianum.—The pretty rose-coloured flowers of this species are freely produced upon the short, erect racemes, making a very bright and beautiful little plant, worthy of being included in every collection. Its culture is not always attended with success, but some failures may, I think, be traced to keeping the plant in too moist and shady an atmosphere. Moisture it delights in, but all available light should reach the plant if it is to be healthy and flower freely. The plants like the buoyant brisk heat set up by closing early in the afternoon and raising the blinds after thoroughly damping down. The rising moisture keeps a film on the glass and prevents scorching, while the full sunlight reaches the plant from all sides. Thus growth is not only rapid, but it is hard and free-flowering, while if the roots are confined to small receptacles, these cling firmly and send up ample supplies of moisture which must be freely applied. It will thrive in clean Sphagnum Moss and charcoal or crocks without any other addition, and though not needing a long season of dry rest, may well have a limited moisture supply after the plants have finished growth for the season. The atmospheric moisture must also be reduced in dull or cold weather, a good minimum temperature being 60° in winter.—H.

ORCHID ROOTS.

THE various kinds of Orchids grown under glass in this country are remarkable not only for the great variety of their flowers, but also for the difference in the life and likings of the roots. I was rather forcibly reminded of this recently when repotting a lot of *Odontoglossum citrosimum*. The roots of this species are much longer-lived than are those of many others in the same genus, though in outward appearance they differ but little. Plants that were imported about five years ago and placed in small pans had not only rooted well from the bulbs first formed in this country, but in almost every case these roots were alive and healthy. Doubtless had the plants been disturbed in the meantime they would have died, and this leads to the reflection that in many cases this species and others are disturbed a good deal oftener than there is any need of. Everyone with a little experience must have noticed that the roots of an epiphytal Orchid when once disturbed seldom obtain a fresh hold, though in a few cases they keep alive and produce new feeding points about their lower extremity. This Orchid in particular, if it has not grown out of its receptacle and has the drainage in good order, may with advantage be left for quite a number of years without disturbance. The plants will certainly flower more freely, and this, of course, is the end in view.

On the other hand, such free-rooting and healthy feeding Orchids as *Cypripediums* show by their improved appearance that fresh food in the form of new compost is quite to their taste, and though it is not always necessary to shake the old material entirely from the roots, the mere new compost can be got about them the better. Again, we have a class of Orchid roots that, though disliking disturbance as much as any, yet, owing to their sensitive

nature, they abhor anything in the least close or sour about them, and in consequence they have to be frequently repotted or else grown on bare blocks, which is too poor treatment for them. Instances that occur to mind are the *Promeneas* as a whole and many of the smaller growing *Zygopetalums* and kindred plants. They differ from such true epiphytes as *Phalenopsis* and the small *Angræcums*, for instance, whose roots, could they be assured of moisture in plenty, show their great affinity for bare wood by clinging to it firmly. The singular wiry roots of *Celogyne cristata* and some of the *Gongoras* again seem capable of taking care of themselves in a remarkable manner, and if they cannot find exactly what they want, make the best of what is nearest. They will run about on a moist pot surface quite exposed or burrow into several inches of compressible material, whether this is peat, loam, leaf-mould, Moss or what not. They may not be long-lived in some of these substances, but they are among the most able to take care of themselves in the whole Orchid family, and in the event of their disturbance the plant feels the check badly.

I recently gave my ideas upon the subject of the failing of Orchid roots, especially those of *Cattleyas* and *Lælias*, in answer to a correspondent, so it is not again necessary to allude to this. The study of Orchid roots as a whole and their variety and adaptability or otherwise to various circumstances are extremely interesting and instructive. Any Orchid-growing readers who have noted peculiarities in the plants under their charge may mention them with advantage.

H. R.

Lycaste Deppei.—This old species varies a good deal, and some of the forms are much prettier than others. At Hardwicke I noted some very well-flowered plants of a nice form, the sepals broader than usual, light emerald-green with the usual purplish spottings, the petals pure white, and the lip entirely golden yellow spotted with bright red. It is singular that this plant has been let go out of cultivation, or nearly so, for it is well worth growing for cutting. A cool house and a compost of light loam, peat fibre, and chopped *Sphagnum* suit it well.—H.

Odontoglossum polyxanthum.—This is one of the *Odontoglots* that are often very disappointing to buy except in flower, as the forms vary so, and anyone seeing a good form of it at a show or elsewhere may on ordering it get an entirely different flower. Many are in the habit of purchasing either newly-imported plants on the chance of getting good forms or else selecting from a collection in flower, and unless one has full confidence in his nurseryman, either of these methods is preferable to buying promiscuously. A good form of *O. polyxanthum* bears long arching and branched spikes, the individual flowers upwards of 3 inches in width, yellow, variously blotched with brownish red and other tints of the same colour. Others there are with narrow-petalled flowers less than 2 inches across, very dull in colour and unattractive. Its culture does not differ much from that of *O. Halli* and other species from Ecuador, the plants delighting in a cool, moist, and shady house in summer with abundant root moisture as long as growth is active.

Masdevallia nycterina.—In habit and some other characteristics this plant is a good deal like *M. Chimæra*, and, like it, thrives well in wood baskets with an open bottom and large pieces of charcoal placed on the rods, so that the spikes can find their way down easily. Although when growing in pots most of the spikes may push up and find the light, yet the plants have a much more natural and pretty appearance when these are hanging about the basket as indicated. Like all of this section, *M. nycterina* is easily in-

commoded by stale or decayed compost, and it shows a decided liking for clean *Sphagnum* Moss and charcoal, so when making up the compost let this be freely added, and never allow the roots to get into a bad state before renewing it. The plants can hardly be kept too cool during the summer months, and where the *Odontoglossum* house is always kept as high as 50° during the winter nights, this is the best place to grow it. But where the *Odontoglossums* are kept cooler than this—as they unfortunately are in many places—the *Masdevallia* should be removed to a slightly warmer house in November. The flowers are produced on single-flowered scapes and are of the usual singular shape, principally tawny-yellow in colour.

Aerides crassifolium.—Although one of the commonest, there is no doubt this is one of the finest *Aerides*, and the large semi-drooping spikes of rosy purple flowers are very beautiful. On the front lobe of the lip in good varieties the purple-crimson tint is as fine as in some *Cattleyas*, the graceful habit of well-grown and well-leaved specimens being also very much in its favour. Although of the easiest possible culture, the true beauty of these plants is soon ruined by carelessness to their wants atmospherically, and quite recently I saw what must have been fine specimens quite ruined by having been kept in a dry

Flowers of the Horse Chestnut. From a photograph sent by Mr. T. O. B. Norman, Holly Hill, Ditchingham.

and draughty house. The plants like plenty of head and elbow room and large pots or square baskets filled with *Sphagnum* Moss and crocks or charcoal. In these they may remain undisturbed for many years by simply top-dressing once a year. Fine specimens are assured if the offsets at the bottom of the plants are allowed to remain and extend at will, and these have a much nicer appearance than single-stemmed plants, besides flowering more freely. The plants should be always in the East India house, and during the time the roots are active abundance of water is required. While at rest give less, but avoid drying them off.

Celogyne pandurata.—The singular contrast of colour in this fine species makes it a very distinct and beautiful Orchid, and when it is well grown, with large spikes containing a dozen or more of its remarkable flowers, it is a very showy one as well. The latter issue horizontally, and the sepals and petals are a deep emerald-green, the fiddle-shaped lip, from which the species takes its name, being marked with several black raised ridges, which show up remarkably well against the green of the outer segments. *C. pandurata* likes a very brisk, moist temperature, and though doubtless it may be easily overdone with sunlight, too much shade is not conducive

to freedom of flowering. The pseudo-bulbs occur on rambling rhizomes, and this necessitates a rather large receptacle for its roots, such as large trellised blocks or baskets, over which the rhizomes can extend at will, and a rough and very open description of compost. It is rather a thirsty subject, and delights in ample supplies of moisture nearly all the year round. This may in part be gathered from the fact that the locality in which the plant grows naturally is under water during some parts of the year, the plants growing on the tree trunks in the most swampy part of Borneo.

NOTES AND QUESTIONS.—ORCHIDS.

Trichopilia tortilis.—There are several forms of this pretty old species all more or less distinct, including the rare white form *T. t. alba* and many fine colour varieties. *T. t. virginalis* is a very chaste and beautiful form I noticed recently flowering with Mr. W. Bull, of Chelsea. In this the usual twisted petals were prettily shown up by a quite pure white lip, a novel and pretty effect being produced.

Oncidium carthaginense.—In this we have one of the finest of the *Oncidiums*, bearing long spikes of small flowers. I have had spikes several yards in length. The little side branches may with a little skill be very effectively employed in almost any kind of decoration. In its strongest state *O. carthaginense* produces immense leaves, these being deep green, spotted with dark purple. It likes ample warmth and light, thriving well in the warmest part of the *Cattleya* house if given a rather thin layer of peat and *Sphagnum* Moss.—H.

GARDEN FLORA.

PLATE 1230.

INCARVILLEA GRANDIFLORA.

(WITH A COLOURED PLATE.*)

This plant flowered for the first time in a greenhouse at Kew in June last year, as was recorded in *THE GARDEN*, vol. liv., p. 431, where a plate of *I. Delavayi*, with an account of the genus, was published. A comparison of the two species shows a close relationship between them, the differences being in the shorter leaves, rounded leaflets and shorter flower-scape of *I. grandiflora*. There are also differences in the flower characters, but in a general way the two species are alike, and therefore of probable equal value as garden plants. Of the value of *I. Delavayi* it is now scarcely necessary to speak; it has proved a useful pot plant for the greenhouse, good plants of it being in flower in a greenhouse at Kew now. It is also an excellent border plant for a cool conservatory, as is proved by its behaviour in the Himalayan house at Kew, where a number of plants are in vigorous growth. As a plant for the herbaceous border in the open air in summer it has been again and again shown to be a worthy addition. So far as I can make out, *I. grandiflora* will be equally serviceable. The Kew plant of it has not been tried in the open air, but it has grown well and flowered freely both in a pot and in a border in a sunny, cool greenhouse. For the discovery and introduction of this new addition we are indebted to the expedition to Tibet and Western China by Prince Henry of Orleans in 1890, and to Messrs. Vilmorin and Co., Paris. It was pointed out last year that *I. grandiflora* may be only a form of *I. compacta*, discovered some years previously in Kansuh. Dried specimens of this species show it to be very free flowering, as many as a dozen flower-scapes springing from a single tuft of leaves. Should these two prove to be identical, then in *I. grandiflora* we

* Drawn for *THE GARDEN* by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by J. L. Goffart.

18

have a plant of quite exceptional beauty for the garden. The yellow-flowered species, similar in all characters except colour to that here figured, and which was found at the same time, has not yet found its way into English collections. It is, however, said to be in cultivation in France. W. W.

PARK AND WOODLAND.

THE HORSE CHESTNUT.

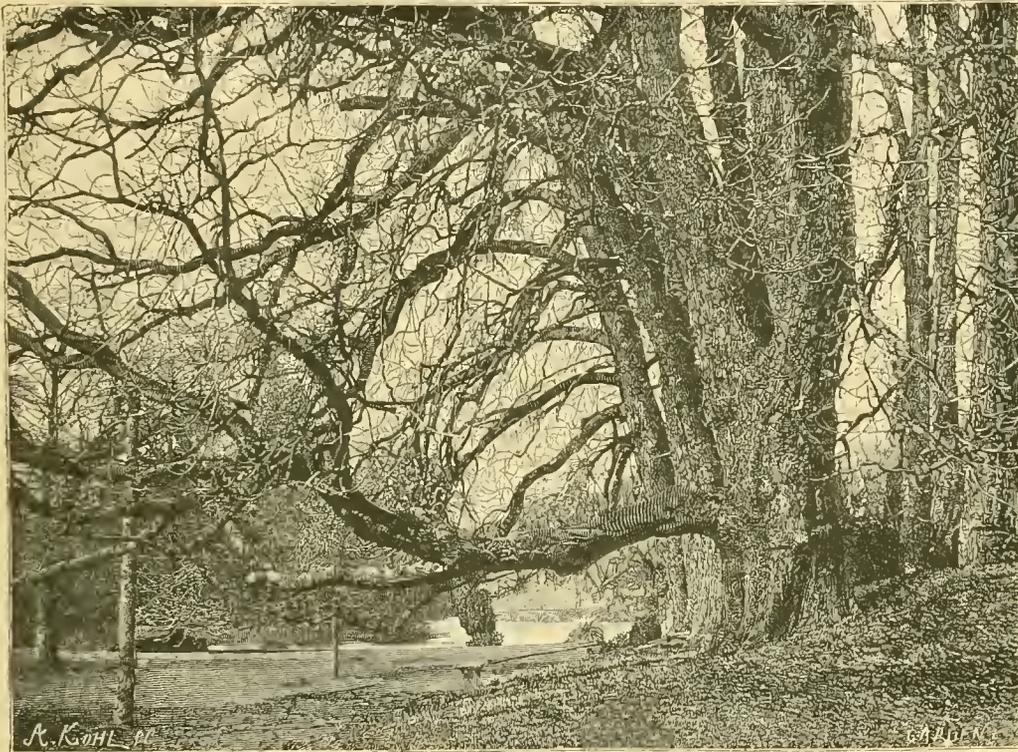

WITHOUT doubt one of our most beautiful flowering trees, the Horse Chestnut is, however, an almost perfectly worthless timber tree. The soft wood may be used for a few common carpentry purposes for which several other kinds of timber are better adapted, but it is certainly not worth growing for timber, and it is one of the worst trees that can be intro-

Horse Chestnut in the plantation and filling the spaces up with Beech as an under-plant. The Beech itself is a bad neighbour in a mixed wood for the same reasons as those given against the Horse Chestnut, but when planted in an established wood (after the other trees have attained height) on the "uneven aged" principle adopted on the Continent, it is not so much to be feared, and it will grow in the shade as a straight pole, as few other species will do. If anyone will examine a Horse Chestnut growing in a plantation at this leafy season of the year they will be struck by the density of its foliage and shade, and the persistent way it pushes out horizontally and crushes other trees near it.

I have often wondered how the prejudice in this country against the seeds of the Horse Chestnut has originated. The schoolboy who hunts sedulously for wild fruits of all kinds prizes the nuts of the Spanish Chestnut, but

CORSICAN AND AUSTRIAN FIRS. EVEN Dr. Schlich, in his carefully selected list of timber trees, omits the Corsican, giving the Austrian only a place as the *Pinus Laricio* of Poir. As forest trees no greater mistake could be made than that of confounding the two as the same or even similar. At one time the Austrian used to be commonly substituted for the Corsican for general planting, causing much disappointment in many cases, and such mistakes are committed yet. Botanically, I suppose the two varieties are identical, but as forest trees they are thoroughly distinct, and in all respectable nurseries the two have been carefully separated and may now be had quite true. The Corsican can be told from the Austrian at a glance, either as a single tree or in the nursery quarter. The Corsican is a truer and more fixed form than the Austrian, everywhere distinguished by its more rapid height, longer nodes, thin, cylindrical habit, sparse branches, comparatively glaucous twisted leaves and general uniformity of habit. Lastly, it has a fault that the Austrian has not got: it is a bad transplanter unless moved early in autumn or late in spring; whereas young and old Austrians up to 10 feet in height may be moved with impunity, and I have transplanted many such. The Corsican Fir may be regarded as an ideal timber tree, because it grows very fast in almost any soil and situation up to a high altitude; increases in bulk of timber much faster than the Scotch Fir, which it equals in quality of timber, and, owing to its thin habit, will bear crowding well, producing probably the cleanest trunk among all the Firs except the Larch. Last, but not least, rabbits will eat it, but they do not like it, and in a mixed plantation they will clear off any Scotch and Austrian Fir first before beginning on the Corsican. These qualities constitute a difference that botanists ought to take notice of.

As to the Austrian, trees of the true type grow nearly as broad as high, but they vary prodigiously, hardly any two trees being quite alike. Indeed, the Austrian is the most variable Fir I know of. Its most valuable quality is its dense bushy habit, which renders it valuable as a shelter tree; there are indeed none better, only it grows rather slowly. As a timber tree it is rough and knotty. Its stiff horizontal habit makes it also a bad neighbour in a mixed wood, so much so that I have long ceased planting it except at the margins. Wherever an Austrian is planted in a mixture of Scotch and Corsican Firs, there you will find a depression in the plantation owing to the slower growth of the tree, which also occupies more than its share of space. It is not apt to be smothered because it pushes its neighbours back laterally and occupies far more space itself than it is worth. Planted by itself as a timber tree it behaves better, but it is very long in shedding its lower branches, which are thick and stiff, and I know where many ugly examples of this kind could be found. Some years ago a gentleman engaged a nurseryman to plant a large tract of Corsicans for him, and some years after asked me to see them. As far as I could see, there was not one Corsican in the lot, the Austrian having been substituted, and the crush among the trees was such as I have never seen in any pure plantation. J. SIMPSON.

The Horse Chestnut.

duced into a mixed plantation. Owing to its power of enduring shade and the stiff horizontal spread of its branches, it destroys all other trees near it, and no vegetation of any kind can exist under its branches. This is my experience of the tree wherever I have seen it in woods. As for timber merchants, they will not look at it. For windfalls an odd tree or two may be smuggled in among other kinds, but no one thinks of mentioning it in lots for sale except among the "mixed." I had once to look over a young plantation about thirty years of age that was in an unsatisfactory state owing to the indiscriminate nature of the mixture of species of which it was composed—one of the faults of our home forestry—and found that the chief offender was the Horse Chestnut, which had been used in the same proportion as the others and had usurped far more space than it was entitled to. Even gamekeepers complained of the wood because of the nakedness of the ground under the Chestnuts. The remedy adopted was the removal of every

will not touch the Horse Chestnut, and cattle-feeders shun it as a food for stock. Yet cattle, deer, and sheep eat the nuts when they can get to them, and deer bark the tree and eat the leaves. On the Continent Horse Chestnuts are used extensively as food for cattle, sheep, pigs, and poultry. They are said to improve both the yield and flavour of milk in cows, and are given to sheep crushed in the same way as artificial foods are given to cattle in this country. Rooks are no mean judges of good food, and, according to Mr. R. Ellison in "The Berwickshire Naturalist," they carry off the Horse Chestnut seeds as soon as they are ripe.

For ornamental planting there is no finer variety than the common Horse Chestnut with its creamy white flowers and luxuriant habit of growth, and the red variety is also fine, but if anything it is a worse neighbour in a plantation than the other, being of a very stiff, aggressive habit. There is also a semi-double variety, but the single varieties are the freest flowerers. J. S.

Wortley.

THE FORESTRY QUESTION.

THE following extracts from a letter from M. David Cannon, of Les Vaux, Loir et Cher, France, will, we think, prove interesting to our readers at a time when forestry is engaging so much attention:—

The "natural regeneration" system, imported all of a piece from Germany some seventy years ago, applied by means of successive cuttings at an age fixed arbitrarily beforehand, is very much contested now-a-days. In mountain Fir forests the superiority of *jardinage* as modified by Gurnaud—frequent and prudent thinnings, always leaving trees of all ages on the soil—is, I think, fully proved. On the other hand, in Oak forests in the plains of Normandy, a State forester, M. Prouvé, observes that it is better and cheaper when trees are mature to cut down the whole crop and plant. The reason in both cases is that years of abundant seeding are irregular; that three to six years may elapse before a good one; that during that time, in fertile soils especially, the soil gets occupied by grass, Thorns, Heaths, &c., which choke the seed and it becometh unfruitful, or smother the plants as they come up. Then the trees left as *porte-graines*, suddenly isolated, get blown over. Of course, there are parts and times where natural seeding does very well, but the defect of government regulations is to impose uniform treatment everywhere, so I very much doubt whether so-called scientific forestry is of much use to us poor private woodmen.

Brown, with all his faults, has the great merit of inculcating careful thinning. Would you believe that the scientific continental authorities are much behindhand on that question; that they are only beginning now to acknowledge it in a very half-and-half sort of way? They used to talk a deal of rubbish about struggle for life between the young trees and natural selection, the result being that they all grew up lanky and weakly and lost a long time before they could get stout again. With early and rational thinning it is admitted now that a valuable crop of trees can be got in two-thirds of the time imposed by regulations till now. I have just been through Southern Germany, and the woods I saw from the railway—mostly Pine—struck me as much too thick and suffering from their close state. I have certainly much better growth here on my poor soil. They seemed to be private property, but I am told State forests are no better. In Austria, especially in the Tyrol, where the woods are mostly Larch and Spruce, they are, as far as I can see, kept thinner and better managed.

THE WEEK'S WORK.

HARDY FRUITS.

SUMMER PRUNING.—Shortening the growth of all trees which are trained in the various forms of wall trees, pyramids, espaliers, and the like is a necessary part of the season's work, and the time has now come for extensive operations in this way, for there will now be no fear of the shortened shoots breaking into growth from the back buds and throwing the trees out of gear. If my former advice has been carried out, all that will have been done in the way of restricting growth will have been the removal of some of the crowded shoots while in a very young state and the stopping of any very strong shoots that promised to destroy the balance of the tree, the only exceptions in which an earlier application of more wholesale stopping was advised having been in the case of cordon Apples and Pears on dwarf stocks. The danger of these breaking too freely into second growth is eliminated by the action of the stocks; therefore it is safe to deal with them earlier, and less wasted growth is made. No hard and fast lines can be laid down as to the proper number of leaves which shall be left on each shoot at the summer pruning, as this will vary with the individuality of the trees, but as a general rule for guidance it may be said that

not less than five leaves should be left on a shoot, and if the tree is naturally a strong grower, more still should be left, so that there shall be plenty of good leaves to carry out their own particular functions in bringing the fruit to perfection and plumping up the buds for next year's crop. Trees that have reached their limits of space may have the leading shoots of each branch shortened in the same way as the side shoots are treated, but where further extension is desired, I prefer for the present to let these shoots grow to their full extent and fasten them to the walls or to some support. The foregoing remarks apply equally to Apples, Pears, and Plums, except that perhaps it may be advisable to lay in to full length a few shoots of the latter where room can be found for them, it being found advisable to provide these trees with new wood from time to time.

CHERRIES.—As soon as the fruits are picked I like to do to the sweet Cherries whatever pruning may be necessary for the year and to let it be as little as possible in every case, for Cherries abhor the knife and are still more liable to be injured by its use in winter than in summer, gumming being much more prevalent after pruning in winter from the action of cold on the newly-cut surfaces. Excepting those trees grown in bush form, which should have the points of the shoots pinched out now, summer pruning is not applicable to the Morello Cherry, which bears its finest and best fruits on the young wood. It may be advisable to thin out the wood, removing a few of the surplus and weakest growths altogether, but more than this should not be done, and it may also be borne in mind that the Morello as a wall tree will bear to have its wood laid in more thickly than almost any other fruit tree without injuring it in the least, so it is wise not to overdo the thinning at present. The growths ought to be secured to the wall either by thin twigs stuck at each end behind the branches and holding back some few shoots, or by tying back with raffia. The former is an old-fashioned method, which has the advantage of being efficient and quickly done, and it is applicable also to other wall trees, such as Peaches and Nectarines, which are not shortened back during summer.

APRICOTS.—Old established trees should be looked over, and the growths being made from gross shoots stopped earlier in the season may now be pinched hard, as no harm will accrue by so doing; the fruits will get more light and a better balance be maintained. Lay in here and there a few shoots of full length to fill up any gaps as advised in the case of Plums. Where field mice are plentiful, these little pests will be sure to find out the Apricots; therefore, trapping, as I advised some weeks back, must be persisted in, not only in the neighbourhood of the trees, but in all likely haunts around the garden. Young Apricot trees should be allowed more freedom of growth than those older trees above mentioned, and well placed shoots should be encouraged. See that the trees get plenty of water almost up to the time of the fruit ripening, as it will be better to withhold anything like heavy soakings while ripe fruits are on the trees.

GENERAL WORK.—Undoubtedly one great point to be always striving for in dealing with hardy fruits is cleanliness of the trees, and to this end it is necessary to be ever on the alert with the syringe or garden engine and frequently with insecticides; at any rate, the latter must be at hand to deal with the sudden appearance of some members of the aphides. Trees may be apparently clean to-day, while to-morrow sees them with perhaps what one thinks lightly of as "a touch of fly." A day or two more of letting them alone and the trees are filthy, smothered with insects insignificant individually, but collectively an abomination. I have found the present season one of the worst I have known for aphides, black and green, but they must be fought vigorously and often if the trees are to do well. Perhaps one result of the constant deluging will be to keep red spider at bay, and that will be something to be thankful for.

CORNUBIAN.

KITCHEN GARDEN.

LATEST CELERY.—Where rain has fallen it will be well to plant out late-raised Celery. If the plants were pricked out in sheltered nooks or corners as advised and kept well moistened, growth will by this time be strong and robust and not liable to run to seed. Provided the autumn is fine, this extra late batch will often grow to a respectable size quite fit for table use and the salad bowl. At any rate, it will be useful for soups and flavouring, the main lot being reserved for ordinary table use. The trenches need not be quite so deep as usual and the plants may be placed a little closer together. Planting completed, lay a good mulch of spent Mushroom manure down each side of the rows and give a thorough soaking with water. If ordinary weather follows, it will then take care of itself until the sticks are freed from suckers and the first earthing-up is given. If, as advised, Leicester Red and Standard-bearer were sown, very few of the heads will be likely to rot if the winter is wet, as, brought on under such exposed conditions, their constitution is so hardy.

COLEWORTS.—The present is a good date to make the first sowing of the useful London Colewort. Get the seed from a good firm, as I have met with some very inferior strains of this vegetable which run into a coarse, flavourless growth. A south-east or east border answers, except in particularly dry, hot soils, when a north aspect is preferable. Here, if kept comfortably moist, the plants will come on gradually but surely. I simply mark out the beds, sow the seed broadcast, scuffle it in beneath the surface with a small-toothed rake, and finally tread and rake level. I find it safest to net my Coleworts over as soon as sown, as if this is postponed the seed sometimes comes through without being noticed, and the chaffinches take all the plants. I sow on July 7 and again on July 15 or 20, the latter sowing sometimes proving the more serviceable if the autumn is warm and moist and the first batch grows away too freely. Many gardeners do not grow Coleworts, but all should do so, as nothing equals them for hardiness or surpasses them for flavour.

CUCUMBER HOUSE.—Plants which have been yielding fruit since March will in many instances show signs of partial exhaustion, and should be treated accordingly. Provided others either in houses or pits are yielding freely, the first-named batch should have a partial rest, that is, if they are to be retained throughout the season. Thin out the growth freely, leaving only that which is more robust and free from spider. Give a good rich top dressing and assist root-action by occasional doses of liquid manure the colour of pale ale. Syringe regularly and copiously, close early, allowing no fruit to form for a fortnight or so. If a little freedom of growth is allowed instead of close tying in, it will assist the plants to grow out of their weak state, and tying in can again be resumed when fresh fruits are allowed to swell. Perpetual is a first-rate Cucumber either for house or frame work, having a grand constitution, the fruits, which are borne in great numbers, being of good quality. In surface-dressing use plenty of opening material, such as old mortar rubble, so as to allow of superfluous water passing quickly away. Cucumber plants are often exhausted by the fruits remaining on them too long, thus robbing them of their vitality. The fruit should be cut as soon as ready and placed in cool quarters, the stem end being laid in damp Moss. Old Cucumbers should not be used in the salad bowl, as they impart a bitter flavour and are unwholesome.

BLANKS IN WINTER STUFF.—In consequence of the drought experienced in some gardens, a good many blanks will have occurred in quarters of winter greens, especially Brussels Sprouts, these often suffering from the disease known as finger-and-toe. The foliage then quickly assumes a sickly bluish colour and the top becomes infested with insects. These gaps should now be made good from the seed-bed, and if the young plants are at all overgrown, take out a good-sized hole and make the soil about the roots firm, also well soak the plants the

day prior to lifting them. They will then stand a chance of making headway. It is next to useless pulling up those extra large plants from a dry bed and planting with a dibble, as thus treated all the principal fibrous roots are snapped off. Of course, where any extra late sowings of such things were made, the plants from these beds may be used, as with a fine autumn they will yet make good-sized stems and prove of extra value by reason of forming their sprouts later. If any healthy plants of Broccoli, such as Methven's June or Late Queen, are still in the seed-beds, they may be planted on a north border, if such is at liberty, from which some other non-impoverishing crop has been taken, no turning up of the ground being advisable. In such positions Broccoli sometimes stands the winter better than in more open ones, the hard root-run favouring a firm, frost-proof growth. J. C.

KITCHEN GARDEN.

CONSTRUCTING AND HEATING EARLY TOMATO HOUSES.

It is useless attempting to produce early Tomatoes in insufficiently heated, badly-ventilated, leaky houses. As well might one attempt to grow early Cucumbers in such. I maintain that no indoor crop pays better for any outlay in the erection of a suitable house than Tomatoes, this holding good either from a private or market grower's point of view. Houses in which it is possible to husband every possible ray of sunshine through January, February and March, furnished with abundance of hot-water pipes, with ventilation on the most approved principles are absolutely indispensable if even fair results are to be achieved. I consider front air advantageous, as when the plants are in flower, even in the early months of the year, a chink on the front ventilators aids in producing a buoyant atmosphere, so essential for setting the fruit. The roof should have a rather sharp pitch, and sliding ventilators should be fixed in the brickwork. The bed for the reception of the plants should be within a short distance of the roof-glass, as stocky a growth as possible being desirable from the very first. The need for the existence of plenty of hot-water pipes lies, not in the great amount of heat needed by the Tomato, but in the fact that the night temperature needed for setting the fruit, or say 60°, must be maintained without unduly heating the pipes. A genial, somewhat arid atmosphere is what is wanted. I do not approve of open water tanks in early Tomato houses, the object being to secure a moisture-free atmosphere. Watering the plants will supply quite sufficient atmospheric moisture to support growth and fruit. Of course, every possible convenience will not secure success unless cultural details are attended to. Very narrow, shallow ridges of soil, or, if grown in pots, those 9 inches in diameter, will hold sufficient compost for the support of extra early plants, provided judicious feeding be practised when the crop tells upon their energies. This should consist of loam pure and simple, kept open with old mortar rubble, firm ramming being practised. Then a good deal depends on varieties. A market grower recently informed me that the varieties which set their fruit freely in wet weather were few in number, and the same may be said of the early comparatively sunless part of the year, February and March. My choice would be Ladybird and Up-to-date for principal batches, with a less number of Early Ruby and Earliest of All. Were the fruit required for cooking only and I could guarantee

a true stock, I would grow largely the old dwarf Orangefield. NORWICH.

Early French Beans.—My first gathering in the open was made on June 24, quite a fortnight later than usual. This has necessitated growing a much later supply in frames or houses than usual. To have French Beans, say, from February to midsummer under glass entails a lot of labour, and the outside crop is a relief, so that I always endeavour to get an early supply from plants raised under glass and planted out. Plants raised with as little heat as possible do so much better than those raised otherwise. Few plants suffer more from cold and too much moisture at the start. My earliest dwarf French Bean is Early Favourite, a fine forcing variety with a good-sized pod.—G. W. S.

Lettuce Continuity.—I find this the most reliable of all in dry, hot seasons and in a light soil. I note at p. 402 "J. R." says Continuity is much over-praised. I have failed to find it as poor in quality as "J. R." describes, and I think in some cases the quality may be influenced by the soil, which if at all poor will affect the quality. I have tried most of the Lettuces catalogued. Having a very light soil on gravel, and needing very large quantities of Lettuce daily and for use in June and well into August, the above variety has proved the most valuable. Another variety named Marvel, a red-edged kind, is my next best. This hearts well, and is valuable on account of its standing so long before running to seed. I need Lettuces at the rate of several hundreds weekly, and these must have good hearts in the hottest weather. The Cos varieties find little favour in my case. The most reliable are the dark coloured Cabbage varieties. The colour may be objectionable to some, but as the hearts are well formed, the colour is very slight. I find no difficulty in providing a succession when such kinds as Marvel and Continuity are grown for summer use.—G. W. S.†

Self-protecting Broccoli.—For late use to succeed the Autumn Giant and Walcheren Cauliflowers, none that I am acquainted with can equal Veitch's Self-protecting. The sooner now the first batch of seedlings is put out the better, and if a second sowing has not been made, the smallest plants may well be pricked out in a nursery bed and finally transplanted three weeks hence for succession. Plenty of room must be given as the variety is a very strong grower, and the soil must be rich. There need be no fear of overdoing it in this respect, as those plants which have not furnished heads when frost comes, will have to be lifted and laid in shelter. Some gardeners grow this Broccoli in trenches and doubtless such treatment ensures large succulent heads, as when once the roots get thoroughly well moistened it is a comparatively easy matter to keep them so by occasional doses of liquid manure. See that the seed bed is well moistened the day previous to planting, or many of the best plants will snap off in drawing them. Examine the plants as sometimes there is a percentage of blind ones, and shade if but with evergreen boughs.—N. N.

Early Broad Beans.—The seed sown in the open in November or early December was badly cut by the severe frost and cold winds late in the spring, when most growers hoped their troubles as far as the frost was concerned were at an end. Even with these drawbacks I am a strong advocate for autumn sowing of the above, as, provided a strong plant is secured, it is surprising how soon the plants pull through as the stem-growth is uninjured. Plants raised under glass were this season quite ten days later than those sown in the autumn, as planting-out was later than usual. My autumn-sown plants gave dishes the first week in June, the variety being Early Longpod, whereas the same variety was not ready till the 17th sown under glass. I am aware such kinds as Dwarf Gem and Early Mazagan are recommended for first supplies, but I have found Longpod equally early. These give larger pods

and a heavier crop. By growing a fair-sized podded variety in preference to the Mazagan a few days in earliness are gained, as the larger-podded varieties may be gathered earlier. A white-seeded variety of the Longpod is excellent, as, while giving a good-sized pod, it is remarkably early and of excellent flavour. Given frame protection, I find there is a great gain in sowing in 4½-inch or 6-inch pots, three seeds in the former and five in the latter. I prefer sowing sufficiently early so that it is not necessary to use much heat; indeed, none at all is best, as, given cold-frame culture, the plants do better when planted out. The plants, after the flowers have set and been topped, may with advantage be given a little quick-acting fertiliser in showery weather. I find pots preferable to boxes, as with the latter the roots are broken in planting out.—G. WYTHES.

Potatoes.—The weather during the past spring has told very unfavourably on Potatoes, it would seem, in market as well as private gardens, both in the size of the tubers and extent of crop. The Cornish Potatoes were, so far as I could see, very much under their usual size, which is probably attributable to the frost, which, in some districts at any rate, was said to have blackened many acres. Not only have they been small, but late, and the quality very poor. Many even small tubers when cooked had a bad taste. It is only within the past few days, or since the middle of June, that Potatoes have been really good, and even now their size falls short of the average. There are, of course, two reasons which easily explain this, namely, the extremes of heat and cold, which will make the season a memorable one. Since the rain which occurred on the 18th and 19th ult. Potatoes have shown much improvement in growth, though many of the early section growing in light soil are fast ripening, and had almost passed the stage for obtaining benefit from the rain. Another remarkable feature connected with early Potatoes is the early date at which disease has appeared in the tubers. In the haulm no trace has been noticed, but many tubers when lifted have been found to be affected. This early disease must be attributed, I think, to the cold and variable weather. Many complaints have been made of the broken and uneven rows of Potatoes. Plenty of sets never developed a leaf, but tubered slightly under ground; others came very weak and late. In my principal breadth of Snowdrop and Beauty of Hebron there were so many failures that I had to fill the extensive gaps. What the ultimate results may be cannot yet be estimated, but certain it is that in my case I have never before had such uneven growth in midsummer as this year.—W. S., WILTS.

WINTER AND SPRING CARROTS.

I HAVE no admiration for the large, long, huge roots often displayed in shop windows and at times often too frequently at shows and given first prize. It is not possible to buy at all times sweet, freshly drawn small Carrots. It may be asked, why divide the two into winter and spring supplies, because to do this means two distinct sowings. In a private garden I fail to see what need there is for large, coarse roots. In these days, when good vegetables are appreciated, I do not think Carrots of the Altringham and Long Red Surrey types are so useful as the Intermediate and the Short Horn section. From June to September, or say October, there should be no lack of excellent young roots drawn from the soil. My method is to continue the supply. To do this scoring will not be needed. So far I have found the Carrot quite hardy. I am aware it is very much subject to attacks of wireworm, slugs and snails, but to grow winter and spring roots the land must, if at all infested with the above, of which wireworm is the worst, have a thorough dressing. I use gaslime freely and escape injury. There are other aids, such as soot, fresh lime and salt. The seed of roots that are grown for winter use in the ordinary way is usually sown in April or even earlier to get a long season's growth.

These are lifted in October, and this supply is supposed to last from six to seven months, but the roots are poor in quality when kept so long. Carrots are much better left in the soil, as after being lifted they grow out badly and lose flavour. A great deal depends upon the store and size of root as regards keeping and quality.

I advise sowing for the early winter supply early in June, say from the 10th to 20th, or even earlier in cold soils, sowing such kinds as the Intermediate or Model. The Nantes and Short Horn in poor or heavy land are good, and these will give good material from September to December. In a light soil I find it well to sow at the date named, and again a month or six weeks later for the spring supply. It is important that the ground be well prepared. I advise an open border in no way shaded by trees. By all means avoid thick sowing, especially for the latest lot. For the early winter supply a well-manured quarter is advised, as growth must be quick, and if the season is dry, the manure will retain the moisture. Should there be any difficulty with fly, I water in the evening and dust with fresh soot. Ample space should be allowed between the rows—15 inches at least. This allows of using the hoe freely, and thinning as soon as the plants can be handled is necessary. Carrots grown thus need less thinning than larger kinds, as it is an easy matter to thin out for use as needed. The early winter roots last well into the new year, and these may be drawn at all times. Of course, in hard weather, with the ground frozen, this would be out of the question, but it is an easy matter to lift a row or two, place close together, and cover with long litter. For the spring supply I do not manure other than with a fertiliser just to give a start, as size is not needed. In a very dry season sowing may be deferred a short time. I find wood ashes or burnt refuse a splendid fertiliser, as it keeps the land sweet. For this purpose an open quarter and sowing in July or early August are advised. These roots will not be large, and they will be good from the early part of the year till the end of May.

G. WYTHES.

Asparagus Purple Argenteuil.—I have a very high opinion of this variety, it being of special value where a prolonged supply of this delicious vegetable is needed. It fully merits the title late, not because it is later than such sorts as Battersea, Conover's Colossal and Reading Giant in starting into growth, but by reason of its continuing to throw up good usable grass over a longer period. Under good culture it produces large heads of a delicate purple colour. Those who purpose increasing their stock of Asparagus next season will do well to procure this variety, taking care to order it from a reliable firm.—B. S. N.

Early Beet.—It sometimes happens that the stock of Beet stored away in autumn runs out sooner than one has bargained for, and when this is the case it is advisable to get roots along from the spring sowing as early as possible. I think Early Red Globe about the best variety for the purpose. It is after the style of the Turnip-rooted Egyptian, but the foliage is stronger and the root is formed rather more quickly. From seed sown April 7 I was pulling this year by the middle of June roots a little over 3 inches in diameter and as much in depth. It is also very good in quality. The Turnip-rooted Egyptian comes close behind it and is also an excellent Beet for early work.—C. E. S.

Cabbages in November.—In some gardens Cabbages, either in ordinary hearting or sprouting form, are expected all the year round, and the present is a good time to sow seed of some small quick-maturing variety for use during November. These come in just before the Rosette Coleworts, which are not at their best until they have had a few frosts on them. A cool site and rich ground should be chosen for the seed-bed, as unless a quick growth is secured from the first good hearts cannot be expected. Thin out the seedlings as soon as practicable and prick out the permanent

plants on a convenient plot where their wants can be attended to. When a fair amount of leafage has been made, lift the plants carefully with a trowel, making sure that the roots are in quite a moist condition. Plant out on good land, and when established, give one or two waterings with liquid manure. Two useful sorts for the purpose are Wheeler's Imperial and Cocoa-nut.—C. N.

Spinach.—In the occasional correspondence that has appeared against size in vegetables I have not seen any disparaging note as to the improved form of Spinach, whose leaves in comparison to the old type are about in the proportion of a Rhubarb to a Cabbage leaf, so that this probably is a case in which size does not mean inferior quality. Of these newer forms, which are undoubtedly a marvellous improvement on the old kind, whether for size and substance of leaf or long-standing properties (I am writing of the round-seeded summer Spinach), there are, so far as I have seen, only two distinct types, although there are many different names. The one has a leaf nearly as broad as long, is dark green in colour, and very thick and fleshy. In the other the proportion of length to breadth would be as three to two, the colour is a pale instead of a deep green, and the leaf is lacking in substance when compared with the broader leaved form. I should prefer the last-named.—E. BURRELL.

Turnips.—I tried a large number of varieties of Turnips, both early and late, last season with the view to determine if possible the most reliable kinds, and to confine myself this year to as few sorts as possible. The best kinds respectively for first early, second early, main-crop, and late (for winter work) were Early Purple-top Munich, Snowball, and Red Globe. The first mentioned is valuable for its earliness, as, sown with several other sorts, it was ready nearly a week earlier. Snowball is an excellent Turnip, doing its work quickly and standing well; it is of first-rate quality. Red Globe is far and away the best winter Turnip, not that it stands the weather any better than sorts like Orange Jelly or Chirk Castle, but it is equally hardy, and, what is a chief consideration, of superior quality. Yellow-fleshed Turnips, in fact, are always objected to, and so Orange Jelly is shelved, whilst Chirk Castle goes very hard long before the season is over, and also retires in favour of Red Globe.—E. BURRELL.

Early Peas.—Pickings from William Hurst Pea sown on a south border the last week of November, 1898, were made this season just ten days before any could be gathered from the earliest taller sorts sown on the open quarter late in January. Daisy sown on the latter date is close on the heels of the tall Peas. For small gardens where there is a daily demand for Peas in their seasons and the space at disposal does not admit of growing many tall sorts, I should recommend a second sowing of William Hurst with Daisy in January. Equally good Peas of dwarf habit as early and second early are Dwarf Defiance, Favourite, and Dwarf Mammoth, all of dwarf, compact habit, splendid croppers, and of excellent quality. It is fortunate that the several firms who have turned their attention to the improvement in Peas have made a special point of working on fairly dwarf strains, as anything up to, say, 4 feet in height is much better for the average garden than varieties of the Ne Plus Ultra type. Not that I wish to disparage the last named, for, given plenty of room and tall stakes, it is still one of the best.—C. E.

Feeding Tomatoes.—In most cases a good lot of fruit will have set upon Tomatoes by this time, and if the most is to be made out of the space at command, feeding must now begin in earnest. As I have before now pointed out, I use a very much thinner bed of soil on the benches than is usually given, and in my case I begin to top-dress and feed as soon as the first bunch of flowers has set well. These are usually within a few inches of the soil, and before ripening have to be tied up, or the weight would bring them on

the top-dressing, when they would be spoilt. The top-dressing this year consisted of a little loam with one-third of burnt refuse, and another of manure prepared as for Mushroom growing. The bed was first well soaked and equal parts of superphosphate and kainit sprinkled on at the rate of about an ounce to the yard surface. This the roots have already pushed through, and a little more must be added shortly. The way the plants respond to this treatment is very satisfactory, the fruit swelling very rapidly and leaf growth being very strong. As a matter of fact, Tomatoes may be fed very strongly with almost any kind of manure not too rich in nitrogen directly they have fruit upon them, but not before.—H.

Transplanting Celery.—It matters little how stocky and healthy the young plants of Celery may be, satisfactory results cannot be expected unless due care is taken at the time of removal into the trenches. A very common mistake is lifting the plants while the roots are in a semi-dry state. Many of the roots then snap off and are left in the frame. Moreover, the plants soon flag if exposed only for a short time to sun and wind, also losing their lower leaves. Then, again, the trench is often insufficiently moist, and watering after planting performed in a half-hearted manner. Under these conditions one cannot wonder at Celery bolting. The chief things to be observed are thorough moistening of the bed in which the plants are growing, this being best done the day previous, the trenches also being served similarly. Planting completed, a thorough watering with rosed water pots should be given, and if in a very exposed situation, a few evergreen branches should be fixed in the soil on one side of the trench in a slanting position. These will afford a grateful shade till the plants become established. In watering avoid mere dribbles, these leaving the bottom roots untouched. Occasional thorough drenchings are what are needed, the plants then standing some time without being distressed. Celery if healthy and moist at the roots will stand any amount of sunshine, and growth in tropical seasons is more firm and less liable to decay should the winter turn out wet.—N. N.

Bad growth on Potatoes.—Whatever may be the aspect of Potato breadths a few weeks hence, certainly seldom have they borne a more ragged appearance than now or just recently. Seldom have Potato plants come up so badly as they have during the past spring. Not only has there been great irregularity, but there are also many blanks and generally weak growth. It seems so very certain that the primary cause of this unevenness as well as comparative weakness was due to the long spell of cold nights endured some time since. I have no recollection of Potatoes remaining so long in the ground before the tops came through as this season, due no doubt to the coldness of the soil and frosty nights. That even tops just beneath the soil did get nipped with frost there could be no doubt, whilst those above ground, even where they apparently were not hurt, yet were so far as to greatly check growth and cause the foliage to present a browned or unhealthy appearance. It is not possible that generally we can have a good Potato season, but if the breadths somewhat escape disease something will be gained. No doubt a contribution to this growth defect was the comparative mildness of the winter, which rendered it so difficult to keep the seed tubers restful. There were times in the winter when temperature ranged very high and growth or sprouting could not be checked except where the stores were exceptionally cool. It is, however, very difficult to keep any stores cool when the atmospheric temperature ranges from 50° to 60°. Naturally tubers prematurely sprouted and disbudded suffered, whilst those planted in cold soil with even stout sprouts attached also suffered from the check furnished.—A. D.

Broad Beans.—Possibly it is due to the excellence of garden Peas, of which we have now such a wonderful variety and of first earlies so superior

to the old hard rounds that formerly were chiefly grown, that Broad Beans seem every year to become less in request. A very hardy and early product, and when gathered fresh a very nice one, these Beans should be much more widely consumed than they are. But possibly they are now generally regarded as of low caste amongst vegetables. In any case they do not now enjoy the popularity that was once existent. It is possibly the case that the introduction of the long-podded Seville type has not increased our liking for Broad Beans. One of the nicest of all no doubt is the Early Longpod, as the Beans are small and of nice flavour. The green form is probably the best. I learned last winter that in some parts of Surrey the old and generally discarded Early Mazagan was greatly esteemed. The beans being produced in great abundance, are smaller than those of the Early Longpod, and in flavour bear closer resemblance to that of Peas. I had some seed given me, but, unfortunately, forgot to sow until too late. However, no one dreams of growing the Mazagan Bean in large gardens now, and the Seville type has become almost the only one grown. The Broad Windsor, whether of the old stock or the green, produces beans too large for ordinary use, although the flesh is nice when the shucks are removed after cooking and thus served to table. Those who still like these Broad Beans will find that the old Johnson's Wonderful, also sometimes known as Mackie's Monarch, is on the whole the most prolific and best. Exhibiting Longpod Beans has given the Seville a prominence it hardly deserves.—A. D.

FEEDING ONIONS.

"A. D." could not have read my notes carefully, or he would have seen that they had reference to autumn and not to spring-sown batches. The latter make their earliest growth at the most favourable, the former at the most unfavourable time of the year, which makes all the difference as to what kind of larder is most suitable. "A. D." compares the soil of an Onion bed to which liquid manure is applied to that of a sewage farm. The comparison, however, is very wide of the mark—the one, as used by practical kitchen gardeners, being clear, sweet, and highly nutritious, the other thick and sour. Besides, gardeners do not pour liquid manure—which is by far the best stimulant for Vines and Peach trees—on to their Vine and Peach borders until it becomes a sodden mass, and why do so with Onion beds? I grew autumn-sown Onions for many years, and have shown bulbs 5 inches or 6 inches in diameter by the middle of June. I used to incorporate a moderate quantity of manure only when digging the ground, and mulch with spent Mushroom manure and feed with farm liquid in spring. The mulch was necessary to keep the surface comfortably moist. I am not a believer in so much extra deep trenching as some, its merits being, I think, more imaginary than real; besides, when manure is buried 3 feet deep the Onion roots do not reach it before the bulbs are three parts grown, and by the roots rushing into a thick layer of rich manure so late in the season, the very thing complained of by "A. D.," viz., soft, bad-keeping Onions, is produced. It is just this excessive underground manuring that is the cause of so many Onions going bad or growing out at the crowns during winter. Years ago when a more rational method of cultivation was adopted we heard very little of Onions failing to keep. It is quite certain that large quantities even of the Tripoli class are kept sound through the winter, or how could so much seed be offered for sale. I think the Giant Rocca and the straw-coloured variety, Golden Rocca, the best for autumn sowing. I have seen large breadths of these grown on moderately rich land and one or two waterings with liquid manure given, the bulbs swelling to a large size and keeping splendidly. In regard to the practice of sowing Onions under glass it is advantageous in low-lying, cold, late

gardens or where the Onion maggot is troublesome, but I do not think it is ever likely to become general. N.

Cucumber Royal Osborne.—In reading the note on the above (p. 387) I was unable to see what Mr. Burrell intended. I am aware there are certain growers who see no good in anything new, but there is any number of good Cucumbers. I question if a good type of Telegraph can be beaten, and if the new variety is any improvement on that, it is certainly a decided acquisition. I note that this variety is certainly new to many, as it did not pass the ordeal of the Royal Horticultural Society's committee. By this I do not infer it is any the worse. There is always room for new things if good. I fail to see why one new Cucumber which few have grown should be so highly commended by Mr. Burrell when he says it is difficult to see the necessity for sending out new things at all. I have this season grown Royal Osborne, but prefer to give it another trial as a winter fruiter before praising or condemning it.—GROWER.

Lifting Shallots.—These are often lifted much too early, and the old adage, to plant on the shortest and lift on the longest day, though good advice in some seasons, will certainly not be so this year—in this locality at any rate. Pulled too early, the bulbs, though they may look ripe, are not really finished. They will lose more weight than they ought to in the ripening, and as a rule will start to grow earlier than others properly developed. Early thinning of the clumps and allowing the remainder to develop properly will ensure large and heavy roots for keeping, while the half-grown thinnings are very useful for salad or cooking. The distinct flavour of the Shallot is very much liked by many people who dislike or are indifferent to the Onion. As with many other vegetables, the largest or giant kinds are not the nicest; indeed, many of these resemble the underground Onion more than the Shallot. Shallots like a firm and not too rich root-run; they are better planted with a trowel or dibber than merely pushed into the soil with the fingers. Leave the upper half inch of the bulb out of the soil. When they are harvested they should lie in the sun until thoroughly dry, and the cottager's plan of hanging them on a sunny wall is a very good one.

Peas Earliest Marrow and Chelsea Gem.—These are the varieties which I usually choose for sowing in boxes to be planted out in March to supply the first dishes in early summer. This season Earliest Marrow was earlier in its podding than Chelsea Gem, the reverse of what has happened in other years. They, however, were separated only by a few days. Both are good early sorts, the latter a dwarf, or 15-inch Pea, the other 3 feet. Some rows sown in February on a narrow border in front of some forcing houses are as early as the box-sown plants, and being in soil quite fresh to Peas they have grown almost, or quite, 2 feet in height, producing an abundant crop. Peas are later than usual this season through the extreme cold that has prevailed, general pickings not commencing until June 13. Small dishes were obtained a little earlier. The extreme heat and drought tell unfavourably on Peas in soil not well manured and deeply dug, the haulm having quite a yellow cast about it, although freely mulched with half-decayed manure. Early Morn, sown with these and planted on a portion of the same border, is several days later.—W. S.

Runner Beans as garden breaks.—Lately I observed an orchard on grass shut off from the better-kept garden by a row of Scarlet Runner Beans 350 feet long. This was one of the longest staked rows of Beans I have seen. It backed a broad herbaceous border that contained a fine representation of hardy plants. Now useful as this line of Beans will be and doubtless enormously productive, yet will it lack some variety, as the blooms will all be scarlet in colour. Certainly had some white-coloured ones been mixed

with the reds there would have been pleasing variety added. So far we seem to have in runner bloom no other colours, but we have some varieties that produce pleasingly coloured pods—purple, carmine striped, and golden, and a few of these sown here and there would have lent some charm to the line. Then very pretty would have been a plant here and there of Canary Creeper or of Convolvulus major. We seem in our kitchen gardening so utilitarian, that we forget what pretty effects can be obtained from even a row of Runner Beans at trifling sacrifice. Sweet Peas, where a good trench has been prepared for them and the seed is thinly sown, also make beautiful breaks or hedges for kitchen gardens, and so grown they produce flowers of great beauty and exceeding usefulness. But whilst a well-staked row of Runner Beans is whilst in bloom a pretty object, it is so easy to add to its beauty very much when other varieties are employed. Even some of the ornamental Gourds trained over rough wood supports make a pretty background. We may well seek to carry into our vegetable gardens all the beauty we can.—A. D.

Cardoons.—Those who grow this vegetable will by this time have the main batch sufficiently hardened off for planting out in trenches. I like to give them a rather wider trench than that usually accorded Celery and a rich root-run. If the best results are expected, plenty of room must be allowed between each plant, 2½ feet being none too much. Dryness at the roots must at all times be guarded against, a fortnightly soaking of liquid manure when the plants get established being none too much if the season is dry. No less a distance than 5 feet should be given between the trenches; plenty of soil will then be available for earthing up, and in the interval such quick-maturing subjects as Lettuce may be grown on the ridges. Earthing up should not be proceeded with until the plants are fully grown, when hay-bands should be wound round to prevent the soil getting in amongst the leaves. Being tender, lifting must be practised as soon as sharp weather sets in. Cool pits or even sheds, where Bracken or short litter can be laid over them, answer well for storage during winter. Cardoons are useful in helping out other vegetables, and at some tables are much appreciated.—B. S. N.

Winter Onion plots.—This note may seem premature, but Onion growers know that the firmer the rooting medium, the better chance there is of a satisfactory crop; therefore, timely preparation is certainly advisable. Plots from which early hand-light Cauliflowers have been cleared are often utilised for Tripoli Onions, and as these have been subjected to a continuous treading since last autumn, at least between the lights, air has to some extent been excluded. Turning up and exposure are therefore necessary before another crop is planted. Cauliflower roots are often infested with tiny grubs, some of which are unavoidably left in the ground when the old stumps are pulled up. These in the necessary preparation for the Onion crop are effectually destroyed. First of all wheel on to the plot a moderate quantity of manure, a little soot, gas-lime, and if at hand some burnt refuse or wood ashes. Let this be worked well in to a depth of 18 inches, so that the young roots get the benefit of it from the start. Trenching completed, give a thorough treading, repeating it in a month and again when the seed is sown.—J. C.

Forced Potatoes.—The best dish of Potatoes in the wonderful collection of vegetables exhibited recently at the Drill Hall by Mr. Beckett was that labelled Mona's Pride. This variety, if true, is of the Walnut-leaf order, and not an Ash-leaf. The true Walnut-leaf variety throws green sprouts, and is a bad one to break fresh shoots should the first or primary ones get broken off. But whilst having this feature, yet the variety produces tubers of the greatest excellence. Indeed, it is doubtful whether there are in commerce any of superior quality. Mona's Pride used to be a popular variety in the Isle of Man, and was largely grown there for supplying the Lancashire

markets. The late Mr. W. Dean was largely the agent for introducing it into this country under this name, but there seems reason to believe that it was but a good stock of the old Walnut-leaf variety after all. Whatever its deficiencies in some directions, at least, it seems to have been productive in Mona's Isle. Of the Ashleaves there is more diversity in names than in distinctions. Any selected short-topped stock is good, and where the sets are well preserved during the winter and are planted in rich, deep, sandy soil they still produce wonderful crops. Laxton's Early, Sutton's Ringleader and Ninetyfold, Sharpe's Victor and some others of similar character are all good for forcing or very earliest border work. Somehow we do not seem in first early varieties to have by any means reached perfection. The ideal early one with short top, abundant cropping and of the best table quality still seems lacking.—A. D.

ORCHARD AND FRUIT GARDEN.

NEW NECTARINES.

It is yet full early to write on the merits of Nectarine Cardinal (here illustrated) as regards its general cropping, but there can be no question as to its value for forcing. The raisers, Messrs. Rivers, of Sawbridgeworth, who during the past few years have given us some splendid additions to our stone fruits, sent out Cardinal in the autumn of 1896. I believe it is a most profitable fruit for the market, as the high prices obtained for Cardinal some days before any other variety made its appearance well repaid the outlay, and as the trees attain size it will become more valuable. When I first saw this variety at the Temple show in May, three years ago, I was pleased with its quality. I am aware size is almost of equal importance in these days, as small fruits find less favour and are not so valuable. In Cardinal Nectarine we have size, flavour, and crop, and I must not omit appearance also, as the illustration will show. Few, if any, Nectarines have a nicer appearance. With this note I send a fruit from a maiden tree planted only last November to show that trees in a small state fruit freely. This variety I first planted two years ago, and I am so well pleased with it, I intend having more trees this autumn. In pots this, with Early Rivers, is a great favourite with Mr. Hudson at Gunnersbury House. Those who have seen Messrs. Rivers' trees will have noted their free-bearing under pot culture. In a great many gardens there is no convenience for pot trees, and not the labour to give them the necessary attention, as, unless the best culture is given, pot trees are not profitable. With pot trees, forcing may be begun earlier, and this is important where large quantities of fruit are needed. There is a great gain with Cardinal even over Early Rivers, as this ripens from a week to ten days earlier, and growers who supply the market well know what a few days' earliness makes in the prices of fruit in the London season. For home supplies Nectarines are a welcome addition to the dessert in May and early June. This variety may be had then without severe forcing. The Cardinal is not suited for open-wall culture, and the Messrs. Rivers did well in giving us these facts, as we have plenty of Nectarines that do well, and the new Early Rivers in my opinion is even superior to the well-known Lord Napier in this respect. Cardinal is a grand variety for the cool house. I have some small trees at the back of a low pit that promise well. Grown in pots it is very prolific, the growth is not so spreading as in some kinds, and the fruits colour well.

Early Rivers is a larger fruit than Cardinal and different in colour, being of a darker hue. It is certainly one of the best of the Messrs. Rivers' introductions. It does well in most soils, and being so good on open walls will make it more valuable. For many years my favourite Nectarine was Lord Napier, and I was slow to believe that it could be superseded. I have grown the two together, and Early Rivers when forced is quite a fortnight earlier. The same remarks apply to trees on open walls. Last season on a south-west aspect I gathered Early Rivers eighteen days before Lord Napier. Early Rivers is a much stronger grower than the newer Cardinal. On walls it makes a splendid growth in a light soil. This year, I regret to say, this variety suffered badly, as did all others, from the severe weather we had when the trees were in bloom. Early Rivers is equally valuable, as being a few days later it forms a good succession. I note in very light, porous soils Early Rivers has a tendency to stone-splitting. This can be remedied by the

Nectarine Cardinal. From a photograph of a fruit sent by Miss Solomon, Centre Avenue, Covent Garden.

addition of more suitable soil at planting, and I notice the fruits are freer from this as the trees increase in size. I am a strong advocate for free extension with young trees, and given this, Early Rivers on walls in the open will, I am sure, prove a most profitable variety.—G. WYTHES.

— Cardinal is the earliest Nectarine with me, being from ten to twelve days earlier than Early Rivers. It is of the highest flavour, highly coloured, sets well and swells away very quickly. This is where the gain in time comes in. It is clingstone to a certain extent, but scarcely enough to be noticed when well matured. It hangs well on the tree. The growth is not gross under pot culture. If planted out, I think a limited border would be the best.—J. HUDSON.

Melon William Tillery.—Only green-fleshed Melons are tolerated here for the table, and flavour is the crucial point, size and appearance being a secondary consideration. I have tried many varieties, new and old, and have grown the above annually

since its introduction, and I am conservative enough to believe even now, after so many years, that William Tillery is the best all-round Melon I have tried. Knowsley Favourite and Dicksons' Exquisite follow, both being delicious.—J. R.

Strawberry Royal Sovereign.—Experience with this variety in the present season confirms the opinion already formed of it, viz., that it certainly is not one of the best for outdoor work; not, at least, on this light dry soil. Even during a dry time like the present the fruit keeps badly, and that despite precautions in the way of wide planting and early mulching with nice dry litter. It is of large size and good quality, but as a cropper far below Noble, Vicomtesse H. de Thury, and Sir J. Paxton. I have tried it under annual treatment, but the amount of fruit obtained was very small. Vicomtesse and Paxton are still two of the most reliable. The former throws a fair proportion of large fruit at the first ripening, which serves very well for dessert until Paxton comes in, when the bulk of the small berries is reserved for preserving. With those who like a very deep rich-coloured fruit either for stewing or as a preserve Black Prince is still a favourite.—E. BURRELL.

Strawberry President.—I do not think "H. R.," who notes the value of this variety at page 3, will have cause to fear its disappearance, as in this locality there are many acres of it grown, while in Kent there are much larger breadths under cultivation. I quite agree with all "H. R." says regarding its value for the open air, but I do not think he is quite right in stating that it is in such little favour with growers under glass. In this locality it is still grown for market in quantity by growers who know its value, as it travels well, and, what is better, it sells well. I have for a quarter of a century grown this variety for forcing, and should certainly hesitate before removing it from my list. I admit some years ago I did grow too many kinds. The advent of some new varieties weaned me from the old kinds, but I never put President on one side. Instead of 1000 plants for forcing I now grow 2000. For latest supplies it is a grand Strawberry and not liable to mildew.—WEST MIDDLESEX.

The Gooseberry caterpillar.—This terrible pest is too familiar to most gardeners, being most troublesome in dry seasons. If allowed to go unchecked, the present year's crop is much affected, and the wood and buds for next season rendered puny. There are many so-called remedies, some of them being positively dangerous, as they are of a poisonous character. The old-fashioned plan is, I consider, hard to beat. I mean dusting the lowermost parts of the bushes with lime and soot the moment the pest appears. It invariably shows itself first towards the base of the tree, and if the mixture is dusted in an upward direction the caterpillars will fall wholesale, when another dusting on the ground will settle them. The soot and lime should be used in equal proportions. I have always found this an effectual remedy provided it is applied in time and in earnest. The few fruits which unavoidably get covered with the mixture can easily be washed before being used. I certainly do not

believe in the poisonous mixtures one often sees recommended.—J.

SOCIETIES AND EXHIBITIONS.

NATIONAL ROSE SHOW.

JULY 1.

THE show of 1898 was indeed a memorable one, and this in spite of the remarkably dry time that preceded it. This year also we have had heat, and some cold also. Cold nights, cold winds, and biting frosts as Roses were starting into growth may possibly have had something to do with the general slight falling off noted in some classes. The show just held was a good average one, for in not a few classes the blooms were superb, colour, form, and fulness being well-nigh perfection. Really new Roses were not numerous, the only one selected for gold medal honours being the lovely H.T. Sunrise, which is destined to be in every garden before long. In most classes the competition was keen; so much so, that the judges must have had some difficulty in making the awards. Happily, the sun was not so overpowering as on a similar occasion a year ago; consequently the blooms in a large number of instances remained in perfect condition till the closing of the show.

NURSERYMEN.

There were some seven competitors in the first class for the champion trophy, which is for seventy-two blooms, distinct, the first prize being secured by Mr. B. R. Cant, Colchester, who had many admirable specimens—indeed, a strong lot throughout. His flowers of The Bride and Comtesse de Nadaillac were superb, the colour of the latter particularly so, while Souv. d'Elise Vardon and Muriel Grahame were exquisite, a similar remark applying to Mrs. Grant, which, if rather small for this kind, was perfect in form and grandly coloured. Other good things were Souvenir d'un Ami, Mrs. J. Laing and Helen Keller. Mrs. Cocker, a fine pink, was also noted, while Abel Carrière and Xavier Olibo were especially good among the darker kinds. Messrs. D. Prior and Sons, also of Colchester, took the second prize, having excellent blooms of Dr. Sewell, Mrs. W. J. Grant, Victor Hugo, Reynolds-Hole, Comtesse de Nadaillac, Souvenir de S. A. Prince, while Maman Cochet and Mrs. J. Laing were really of high order. The third prize was secured by Messrs. Harkness and Son, Bedale, Yorks, Her Majesty, Jean Ducher, Mrs. Sharman Crawford, Souvenir d'Elise, Captain Hayward, all very fine, Mme. de Watteville in this group being of exceptional colour. For forty distinct varieties, three of each, Messrs. D. Prior and Sons took the leading place, having really magnificent trebles throughout. Their finest, however, were Mrs. W. J. Grant, Maman Cochet, both faultless in colour and form, Prince Camille de Rohan, Mme. de Watteville, Ulrich Brunner, Mrs. Sharman Crawford, Margaret Dickson, Her Majesty, Mme. Suzanne Rodocanachi, Prince Arthur, &c. Messrs. B. R. Cant and Co., Colchester, were second, having good Mme. G. Luizet, Kaiserin Augusta Victoria, François Michelin, Her Majesty, Mme. Cusin, Mrs. Paul, Mrs. W. J. Grant and Mrs. Sharman Crawford. Messrs. F. Cant and Co., Colchester, were third. For forty-eight distinct, Messrs. Townsend and Son, Worcester, were first, having Gustave Piganeau, Mrs. J. Laing, Mme. Suzanne Rodocanachi, Mrs. Sharman Crawford and Horace Vernet particularly good, the second prize going to Messrs. G. and W. Burch, Peterborough, whose best were Helen Keller, Laurence Allen (a delicate pink, resembling somewhat Mrs. W. J. Grant), Her Majesty and Mrs. Sharman Crawford. For twenty-four blooms, distinct, Mr. Geo. Prince, Oxford, secured the leading prize, having The Bride, Reynolds-Hole, Comtesse de Nadaillac, Beauté Lyonnaise, Catherine Mermet, Innocente Pirola among the best, Mr. Chas. Turner, Slough, being second with Prince Arthur, Maman Cochet, Her Majesty, Muriel Grahame, Mrs. Laing, and

Kaiserin Augusta Victoria as the best. Mr. John Mattock, Oxford, for third place showed Comtesse de Nadaillac, Her Majesty, Souv. d'Elise, and Mme. de Watteville. There were seven competitors in this group, the flowers being good throughout. For twenty-four distinct, three blooms of each, Mr. John Mattock took the premier place, being specially strong in Teas, Mme. Cusin, Souv. d'Elise, Mme. de Watteville, Catherine Mermet being excellent; Mrs. J. Laing, Mrs. Sharman Crawford, and Her Majesty being also good. Messrs. G. & W. Burch, Peterborough, were second with flowers of larger size and superb quality; indeed, in a class for H.P.'s alone these would have taken a good deal of beating. Her Majesty, Gustave Piganeau, Mrs. J. Laing, Margaret Dickson, Mrs. Sharman Crawford, and Captain Hayward were superb. Messrs. Townsend and Sons, Worcester, were third. For twelve blooms, distinct, sent out by Messrs. A. Dickson and Son, Messrs. F. Cant and Co., Colchester, came first, Ethel Brownlow, Mrs. W. J. Grant, Marchioness of Dufferin, and Mrs. Sharman Crawford being best; Messrs. Dickson, Newtownards, second with Mrs. Grant and Mrs. Ed. Mawley (very fine), and an exquisite bloom of Muriel Grahame. Mr. B. R. Cant was third, with the lovely shell-pink Killarney, Mrs. Grant, and Marchioness of Dufferin among his better flowers. For twelve distinct varieties, Teas and Noisettes included, space not to exceed 6 feet by 4 feet, Mr. Geo. Prince, Oxford, secured leading place, staging his blooms in vases on a velveteen cloth. These were very attractive. Capt. Hayward, Catherine Mermet, and Comtesse de Nadaillac were among the best of this pretty group. Mr. John Mattock came second, having Marie van Houtte, Comtesse de Nadaillac, Mme. Hoste, and exquisite flowers of Hon. E. Gifford and Anna Olivier. Messrs. Paul and Son, The Old Nurseries, Cheshunt, were third.

TEAS AND NOISETTES.

For twenty-four blooms, distinct, Messrs. Frank Cant and Co., Colchester, were first with good all-round blooms of Edith Gifford, Niphetos, a superb flower; Mme. de Watteville, Medea, Comtesse de Nadaillac, Ethel Brownlow, Maman Cochet, Rubens, &c. These were a really superb lot, faultless throughout. Mr. B. R. Cant, who set up excellent Amazone, a rich full yellow; Cleopatra, Bridesmaid, Hon. Edith Gifford, Catherine Mermet, Ernest Metz, and the rather white-looking flower called Golden Gate, was second. Mr. Geo. Prince, Oxford, was third. For twelve blooms, as above, Mr. J. Mattock was first, having some capital blooms of Amazone, Elise Vardon, Comtesse de Nadaillac, Maman Cochet, and Mme. de Watteville. Messrs. J. Burrell and Co., Cambridge, had a superbly coloured Luciole in their lot. For eighteen kinds, three of each, Mr. Geo. Prince obtained the leading position, his finest being Maréchal Niel, Souv. de S. A. Prince, Maman Cochet, Comtesse de Nadaillac, the lovely tinted Princess of Wales, and Innocente Pirola. Mr. B. R. Cant, Colchester, had Muriel Grahame, Cleopatra, Ernest Metz, The Bride, and Golden Gate in his second-prize lot, Messrs. Frank Cant and Co. being third. For thirty-six distinct varieties of garden or decorative Roses, premier honours were secured by Messrs. Paul and Son, Cheshunt, with a lot of handsomely arranged bunches, Gustave Regis, W. A. Richardson, L'Idéal, Mme. Pernst-Ducher being fine. Many of the single kinds were here also in equal profusion and delightfully fresh. Messrs. Geo. Cooling and Son, Bath, with one of their fine collections, among which Etoile de Mai is a fine white, were second. For eighteen similar kinds, Messrs. Frank Cant and Co., Colchester, were first, having some charming masses of Ma Capucine, Rambour, Gustave Regis, Mme. Falcot, W. A. Richardson, Mme. C. Guinoisseau, and Souv. de C. Guillot. Mr. Chas. Turner, Slough, was second, having Bardou Job, Hebe's Lip, Rosa Mundi, W. A. Richardson, Princess Marie, white, and Gustave Regis in capital form. For eighteen garden kinds, open to all nurserymen, Mr. Chas. Turner

was first, Messrs. F. Cant and Co. second, and Mr. Geo. Prince third, many similar varieties being employed as previously. For twelve Hybrid Teas, open to nurserymen and amateurs, Messrs. F. Cant and Co. were first with Clara Watson, Viscountess Folkestone, Souv. du Président Carnot as best, Mr. B. R. Cant being second, his best being Marquise Litta, Killarney and Antoine Rivoire. For twelve blooms of any yellow Rose, Mr. Geo. Prince was first with Comtesse de Nadaillac, followed by Mr. J. Mattock and Mr. B. R. Cant, who put up Marie van Houtte and Madame Hoste respectively. For twelve blooms of any white Rose, Mr. B. R. Cant had White Lady, Bessie Brown and The Bride, following in the next two places being Messrs. A. Dickson and Prior and Sons. For twelve blooms of any dark or light crimson, Messrs. Prior and Sons showed General Jacqueminot, Mr. C. Turner and Mr. J. Townsend having Ulrich Brunner and Gustave Piganeau. In class 18 Mr. Chas. Turner set up a superb lot of Mrs. J. Laing, Mr. B. R. Cant an exquisite set of Mrs. Grant, while Messrs. Prior and Sons staged Mrs. J. Laing, the prizes going in the order given, with splendid flowers and a strong body of competitors. In class 19 Mr. Geo. Prince had a splendid dozen of Comtesse de Nadaillac, Mr. J. Mattock, also of Oxford, having Catherine Mermet, and Messrs. F. Cant and Co. Mme. de Watteville. In the next class Messrs. Dickson, Ireland, had Bessie Brown, and Messrs. Prior Maman Cochet, very nice flowers. For twelve distinct Roses, offered since spring, 1896, Messrs. Dickson, Newtownards, were first, Mr. B. R. Cant and F. Cant and Co. taking the other places. For decorative Roses in a space of 4 feet by 3 feet, Messrs. Paul and Son, Cheshunt, were first with Royal Scarlet (very fine), Mr. C. Turner, also second, having Moschata alba in capital form, also Polyantha grandiflora, Mr. J. Mattock being third. For nine varieties of button-hole Roses, Mr. J. Mattock was first with a decidedly pretty lot, Mr. G. Prince and Messrs. Townsend taking second and third places. For three sprays of Roses suitable for ladies' wear, an exquisite triple arrangement from Mrs. O. G. Orpen, Colchester, who employed Polyantha Cecile Brunner, Ma Capucine, and Perle d'Or in long spray-like outline, was first, Miss B. H. Langton and Mrs. G. W. Cook being second and third.

AMATEURS.

For thirty-six distinct kinds, Mr. E. B. Lindsell, Hitchin, was first, Mrs. W. J. Grant, Mme. G. Luizet, Innocente Pirola, Mrs. J. Laing, François Michelin, and Kaiserin Augusta Victoria being among his best. Mr. T. B. Haywood, Reigate, had excellent Gustave Piganeau, Eugénie Verdier, Comtesse de Nadaillac, and Her Majesty, Rev. J. H. Pemberton being third with a splendid lot of slightly early flowers. For twenty-four, distinct, the Rev. A. Foster-Melliar, Ipswich, took leading place. Dr. Sewell, fine crimson; Caroline Testout, Ulrich Brunner, Mrs. W. J. Grant, and Her Majesty were all fine, Mr. Alfred Tate, Leatherhead, being second, having a magnificent bloom of Princess Beatrice, which was also selected for the silver medal bloom; Maman Cochet, and Xavier Olibo, the latter grandly coloured; Mr. F. W. Campion, Reigate, taking third. For twelve triplets, Mr. E. B. Lindsell was first, having excellent Marie Baumann, Her Majesty, Caroline Testout, and Mrs. Laing. Mr. T. B. Haywood, Reigate, was second, having finely coloured blooms of Mrs. Sharman Crawford and Mrs. J. Laing. Colonel J. H. Pitt, Maidstone, who was third, staged in good form Mme. G. Luizet and Marquise de Castellane. For twelve blooms of any Rose except Tea or Noisette, Mr. T. B. Haywood was first with Her Majesty, very even and full coloured; Mr. C. J. Grahame, second, with Mme. Gabriel Luizet, Mr. O. G. Orpen having Kaiserin Augusta Victoria in the third place. For twenty-four distinct, Mr. E. M. Bethune, Horsham, showed Caroline Testout, Marie van Houtte, Captain Hayward, Suzanne Marie Rodocanachi in good style; second, Mr. W. C. Romaine, Windsor, Prince Camille de

Rohan and Princess of Wales being his best. For eighteen distinct, Mr. Conway Jones, Gloucester, was first, having Maman Cochet and Mrs. J. Laing, Mr. Edward Mawley taking second, having Mrs. W. J. Grant, Caroline Testout, Dr. Andry, and Mrs. Sharman Crawford in good form. For eight distinct kinds, three of each, Mr. Ed. Mawley, Berkhamsted, took leading place, having beautiful sets of Marie Finger, Mrs. Sharman Crawford, Etienne Levet, Caroline Testout, and Mrs. E. Mawley, a good second being Mr. P. G. C. Burnard, Reigate, with François Michelin, Mrs. Sharman Crawford, &c. This gentleman took the lead for nine blooms of any Rose except Tea or Noisette with superb Mrs. S. Crawford, Rev. Hugh A. Berners second, and R. E. West third, showing Margaret Dickson and Mrs. Laing respectively. For twelve distinct, Miss B. H. Langton, Hendon, was first, Captain Hayward, Mrs. W. J. Grant, Her Majesty, Mrs. Sharman Crawford, Xavier Olibo, and Marquise Litta being excellent, the last being also selected as the best and awarded the silver medal. Rev. F. Page Roberts, Scole, had Maman Cochet very good. For six blooms, Mr. G. W. Cook, North Finchley, was first with Mrs. J. Laing; second, Mr. J. Bateman; third, Mr. R. Foley-Hobb, Worcester, all having the same variety. For nine distinct varieties, Mr. L. E. Times, Hitchin, was first, Gustave Piganeau and Mrs. Laing being good; second, Mr. E. R. Smith. For six blooms, distinct, Mr. J. Thompson, Rounds Green, was first, Captain Hayward and Prince Arthur being best, the two following places being taken by Mr. Freshfield and Mr. J. Hurst. Six blooms, excepting Tea or Noisette, brought good forms of Mrs. J. Laing from Mr. F. Wellesley, Woking, and Mr. R. W. Bowyer, Mr. J. A. Hammond, Burgess Hill, being third with Caroline Testout. For twelve blooms, distinct, Mr. G. Moules, Hitchin, had nice blooms of Souv. d'Elise Vardon and Niphotos; second, Mr. R. A. C. Johnson, Capel St. Mary, Suffolk, Cleopatra, Madame Verdier, and Madame G. Luizet being good. For four distinct varieties, three of each, Rev. F. Page Roberts was first, having Comtesse de Nadaillac, Mrs. J. Laing and Cleopatra, very fine; second, Mr. H. P. Lundgon, with good Ulrich Brunner and Mrs. W. J. Grant. Mr. G. W. Cook had good triplets of Mrs. J. Laing and Mrs. W. J. Grant. For twelve blooms, open to all amateurs, the prize was the Ramsay cup, and here the Rev. J. H. Pemberton, Havering, was first with Her Majesty, Mrs. Laing, Comtesse de Nadaillac, Victor Hugo and Marchioness of Dufferin; second, Mr. C. J. Grahame, who had Innocente Pirola and Madame Gabriel Luizet. Mr. Pemberton was also first for nine varieties, of five trusses each. These were disposed in vases, Clara Watson, Caroline Kuster, Mrs. Grant and Caroline Testout being good, Mr. O. G. Orpen being a good second. For six blooms from amateurs who have never won a prize at a National Rose show, Mr. J. T. Thompson, Rounds Green, was first, Maman Cochet, Mrs. Laing and Caroline Testout being his best; Mr. F. Wellesley, Woking, second, and Mr. G. H. Baxter, Brentwood, third. For amateurs who have never won a first prize as above, Mr. H. Adamson, Bedale, was first, with good Captain Hayward in his lot, Col. Pitt having La France and Caroline Testout. For six blooms, confined to amateurs who have joined the society since the last Crystal Palace show, Mr. E. Malthy, Feltham, was first with Maman Cochet and Niphotos. For the Langton Memorial cup for six blooms grown within eight miles of Charing Cross, Mr. G. W. Cook, North Finchley, was first, having a really splendid lot that included Caroline Testout, Mrs. W. J. Grant, Marquise Litta, Mrs. J. Laing and Capt. Hayward, all very finely shown, Mr. J. Bateman and Mr. E. Smith following second and third. For six blooms of new Roses, Rev. J. H. Pemberton was first, having Eugénie Bouillet.

TEAS AND NOISETTES.

In the Tea and Noisette trophy class for eighteen blooms, Mr. O. G. Orpen, Colchester, was first, having in capital form Cleopatra, Anna Olivier,

Bridesmaid, Corinna and Souvenir de S. A. Prince; second, Mr. Alex. Hill Gray, Bath, with Caroline Testout, Comtesse de Nadaillac, Catherine Mermet and Maman Cochet; and third, Rev. A. Foster-Melliard, who had nice flowers of Mme. Cusin and Maman Cochet. For twelve blooms shown by amateurs regardless of the number of plants grown, Mr. Alex. Hill Gray, Bath, was first, Ernest Metz, Cleopatra and Comtesse de Nadaillac being his best, Mr. A. Tate, Leatherhead, being second, and Rev. Hugh A. Berners, Harkstead Rectory, third. In class 50, Mr. A. Hill Gray again took the lead, The Bride, Catherine Mermet, Comtesse de Nadaillac, very fine, and Maman Cochet being all excellent. Mr. O. G. Orpen second, having Sylph, Ernest Metz and Anna Olivier; and third, Mr. E. M. Bethune, Horsham. For nine blooms of any one variety, Mr. Hill Gray took premier place, having The Bride, very fine, the same variety securing second for Mr. E. M. Bethune. For nine blooms, distinct varieties, Miss B. H. Langton, Hendon, came first, the Rev. R. Powley, Warminster, being second. For six blooms of any one variety Mr. Conway Jones, Gloucester, was first, having splendidly coloured blooms of Maréchal Niel; second, Rev. R. Powley, Warminster, who had Mme. Cusin. For nine blooms, open to growers of less than 200 plants, Mr. A. Munt, Slough, was first, having Comtesse de Nadaillac and Mme. de Watteville good in his lot, Mr. G. Moules coming second with Souv. d'Elise, Niphotos, &c. For six blooms as above, Rev. F. R. Burnside, St. Margaret's Bay, Dover, was first, having exceptional flowers of The Bride, Marie van Houtte, and Medea; second, Mr. R. W. Bowyer. For six blooms of any one kind, Rev. A. C. Johnson, Suffolk, was first with Hon. E. Gifford, Rev. F. R. Burnside being second. For four distinct Teas or Noisettes, three blooms of each, Mr. Conway Jones, Gloucester, came first with The Bride, Niphotos, Maman Cochet, and Mme. Cusin; Mr. H. P. Langdon second, having a very fine triplet of Hon. E. Gifford and Cleopatra. For six distinct varieties, seven trusses of each, Mr. O. G. Orpen, Colchester, took the leading place, his bunches of Caroline Kuster, Medea, Anna Olivier, Homère, and Souv. de S. A. Prince being all good, Miss B. H. Langton, Hendon, being second with mostly similar kinds. For six blooms of not less than three varieties, for amateurs who have never won a prize at the National Rose Society's show, Mr. E. Bewley, Rathmines, Dublin, was first, having as his best Muriel Grahame and Mme. Hoste, Mr. A. C. Turner being second, having good Mme. Watteville. For garden Roses, twelve distinct varieties, Mr. A. Tate, Leatherhead, was first, having a pretty lot that included good Bardou Job, Perle d'Or, Gustave Regis, the pretty Polyantha Anna Marie Montravel, Etoile d'Or, and Marquis of Salisbury; Mr. O. G. Orpen, Colchester, second, Macrantha, Ma Capucine and Gustave Regis being very good, and l'Idéal, a lovely bunch. For nine varieties of a similar character, Mr. A. F. Perkins, Holmwood, Surrey, was first with capital bunches of Camoens, Celestial, semi-double and deep pink; Beauté Inconstante, Mme. C. Guinoisseau, Carmine Pillar, and Marquis of Salisbury, Miss D. A. Nesfield, Spedhurst, near Tunbridge Wells, being second with several of the above sorts. For nine distinct varieties of garden Roses, Rev. J. H. Pemberton, Havering, was first, his set of W. A. Richardson being very fine in colour, and Alba rosea very attractive. For nine vases of Sweet Brier Roses in not less than six varieties, Mr. F. W. Campion, Reigate, was first, Meg Merrilies, red; Lucy Ashton, pink; Flora McIvor, deep rosy pink, being all charming and pretty kinds. For a vase of cut Roses arranged with any cut foliage, Ferns, or grasses (open to lady amateurs only), Miss E. Turner, Hendon, was first with La France blooms and foliage, Mrs. O. G. Orpen, Colchester, being second with Tea Roses and grasses, &c.

The gold medal for any new seedling Rose was this year awarded to Mr. G. W. Piper, Uckfield, Sussex, for his lovely new Tea Sunrise, which has already been described in these columns. Upon

this occasion Mr. Piper made a fine display both of pot plants, that demonstrated the free flowering of the variety from an early stage, and also of blooms set up in company with the coppery tinted foliage in large Princess flower-holders.

MISCELLANEOUS.

Hardy plants were in strong force on this occasion, Messrs. John Laing and Sons setting up an enormous exhibit. A splendid lot of Cannas in flower and an additional group of hardy trees, Acers, and the most attractive shrubs and such things were also included. Messrs. Wallace and Co., Colchester, had one of their interesting displays of Lilies. The very fine new kind L. Thunbergianum Orange Queen was conspicuous. The Calochorti were very fine both in quality and in numbers, and exhibit a vigour of growth and freedom of flowering that are most encouraging. Some pretty Pæonies included the lovely Lemon Queen, the incomparable Margaret Attwood with its double row of snowy white petals, and the richly coloured Mikado. Iris gigantea and I. spuria were among the species of this group. Mr. M. Prichard, Christchurch, also had many good hardy things, among which we noted Cephalaria tatarica, the white Everlasting Pea, Campanula Burghaltii, Orchis foliosa, Heliopsis patula, &c. Mr. F. G. Foster, Brockhampton Nurseries, Havant, had a fine array of Sweet Peas, something like one hundred named kinds. Another fine display was that of Messrs. Jackman and Sons, Woking, who had good hardy perennials set up in sensible bunches, with a display of Roses of nearly all sections, a very strong feature, however, being made of W. A. Richardson in large bunches in the centre of the group at front. Mr. Wm. Spooner, Woking, also had a large display of Rose blooms in boxes. Messrs. Cutbush and Sons, Highgate, had an irregular group of Malmaison and border Carnations. Messrs. Joseph Cheal and Sons, Crawley, staged hardy flowers, such as Delphiniums, Pentstemons, Pæonies, Alströmarias and the like, together with a collection of Tufted Pansies and cut examples of hardy decorative trees and shrubs. Messrs. Banyard and Co., Maidstone, had a large and varied display of Roses that included many first-class blooms, and Mr. Rumsey, Joyning's Nursery, Waltham Cross, had a large group of the new Pink Mrs. Rumsey. Messrs. Paul and Son, Old Nurseries, Cheshunt, were the exhibitors of the pretty new climbing cluster Rose Psyche, the fine rods shown being wreathed with clusters of blooms for many feet in length. The Messrs. Laxton Bros., Bedford, sent large flat baskets of several new Strawberries. Among the kinds shown were Mentmore, said to be an enormous cropper, and Thos. Laxton (new), which may be said to be an improved Royal Sovereign and an excellent market kind. L'Amiral is another new kind, and, with Monarch, said to have firm flesh and be good for packing. The French kind Louis Gauthier was also well shown, and for those who appreciate light-coloured fruit should prove acceptable. Mr. J. Williams, Oxford Rd., Ealing, had a table arranged for the most part with Roses of varying colours amid Asparagus and other foliage in profusion.

A full prize list will be found in our advertisement columns.

NATIONAL VIOLA SOCIETY.

JUNE 22.

The display made by the members of the above society did not come up to expectations, although it was thought that by bringing the exhibition into the precincts of the City of London, where the majority of amateur exhibitors are daily engaged, a larger number would exhibit, and, at the same time, City men be brought into contact with a hardy flower which it was thought so many were interested in. Although the show was brought to the people, advantage was not taken of its nearness, but this may have been owing to the fact that payment for admission could not be made at the doors, the only means of entrance being by tickets obtained beforehand.

The display was held in the Great Hall, Winchester House, Old Broad Street, E.C., and although but of limited extent, was interesting. The trade was ably represented by two splendid displays not for competition, but the open classes were very poorly filled. The chief interest was centred in the amateur exhibits, and these were of a varied character. There were very few fancy Pansies staged, the Tufted Pansies again predominating. Decorative exhibits, which were catered for on this occasion, found only one representative, so that, taken as a whole, the show must be considered altogether unsatisfactory.

OPEN CLASSES.

The leading classes for forty-eight sprays *Violas* and forty-eight sprays or bunches of *Pansies* respectively found no entrants. The class for twenty-four fancy *Pansies*, distinct, found Mr. J. Smellie, Busby, near Glasgow, leading with a tray of very nice blooms, some of which were of exceptional beauty. His best blooms were J. P. Tait, Colonel M. R. G. Buchanan, Amy Barr, Mrs. W. Steele, Geo. Stuart, R. C. Allen, Marmion, W. H. Clarke, Susan Stuart, Miss Niel, Mr. Mandrill, Maggie Watson, and others. The only other exhibitor, who was placed second, was Mr. A. Ollar, Kilkerran, Campbeltown, N.B., who had a nice lot of blooms, Colonel Buchanan, John McGee, W. H. Clarke, and Miss Niel being his best sorts. In the class for twelve fancy *Pansies*, distinct, Mr. Smellie was again first with a neat and even lot of flowers, Lord Dunraven, John McGee, Julia (fine), Colin Pye, Colonel M. R. G. Buchanan, Maggie Watson, and Susan Stuart being above the others in point of merit. Mr. Ollar was also second with a good lot of blooms, Col. Buchanan and J. P. Tait standing out above the rest. There was only one competitor in the class for twenty-four sprays *Violas*, distinct, six blooms in each, this being Mr. Smellie, who was awarded first prize. This was a very handsome lot, each individual spray being represented by large, clean, fresh and nicely coloured flowers. The most noteworthy among them were White Empress, A. J. Rowberry, Lemon Queen, Cissy Mellowes (syn., Mrs. C. F. Gordon), Stobhill Gem, Princess Ena, Nellie, Lizzie Paul, Dorothy, Lark, Goldfinch, Duchess of Fife, Liz. Barron and Duchess of York. First prize was awarded in this instance, as it was again to the same exhibitor in the next class for twelve sprays rayless *Violas*, distinct, this being the only stand. The flowers were very fine. A special class for six vases of *Violas*, distinct, found only one competitor, Mr. J. Smellie being awarded second prize for a nice lot of blooms arranged in suitable vases with Maiden-hair Fern.

AMATEUR CLASSES.

It was in this division where the best competition took place, but even here there were several instances in which there was only one exhibitor, although the stands of blooms were of a high order of merit. For twelve *Pansies* in not less than six varieties, Mr. A. Ollar was the only exhibitor, and was awarded first prize, B. Doulton, Marmion, W. H. Clarke, Col. Buchanan, Susan Stuart and Miss Niel being his best flowers. There was a better competition for six sprays *Violas*, distinct, six blooms in each spray. Dr. A. H. Beadles, Sydenham, S.E., was placed first with a neatly arranged and clean lot of blooms of good quality. The varieties staged were William Tell, Katie Bell, Primrose Dame, Devonshire Cream, Lark and Pembroke. Second prize fell to the lot of Mr. W. E. Reeve, Woking, Surrey, Goldfinch, Primrose Dame and Blanche being distinctly good. Mr. D. B. Crane, 4, Woodview Terrace, Archway Road, Highgate, N., was the only exhibitor in the respective classes for six sprays rayless *Violas* and six sprays rayed *Violas*, six blooms in each. The former were very pretty, and included a splendid rayless yellow flower in the way of Pembroke, but larger, Flrizel, Ophelia, and other seedling sorts. In both classes Mr. Crane was awarded first prize. For three sprays, distinct, three blooms in each spray, Mr. L. Brown, Seven Arches, Brentwood,

Essex, was first with a very fine lot of flowers, Mrs. C. F. Gordon being grand. Mr. D. B. Crane was second. For three sprays *Violas*, rayed, distinct, Mr. Crane was first, having Lord Salisbury and two seedlings. Mr. J. M. Read, Winchmore Hill, N., was second with smaller flowers, Goldfinch being his best. Dr. A. H. Beadles was first for three sprays rayless *Violas*, having Primrose Dame, Blanche and Devonshire Cream in good form. Mr. Crane followed closely. The last-named exhibitor led for three sprays miniature-flowered *Violas*, distinct, having these little flowers beautifully represented, King of the Blues, Walter B. Child and a yellow seedling being the sorts staged. Mr. B. G. Sinclair, Highgate Road, N.W., was second with a less even lot. For three sprays yellow, the contest was keen, Mr. Reeve winning first prize with a fine lot of flowers. Lizzie Paul, A. J. Rowberry and Pembroke were the varieties shown. Mr. Leonard Brown was a good second, the blooms being somewhat rough. The last-named exhibitor was first for three sprays white, distinct, these being some of the best flowers in the exhibition. Blanche, Nellie Cruse and a rayed variety were those shown. Mr. Reeve was placed second with a nice lot of flowers. For three sprays edged *Violas*, three sprays of Countess of Kintore type and three sprays of any other colour, Mr. D. B. Crane was placed first, having seedlings of promise in each class in addition to sorts in commerce. For a table decoration, the prizes for which were offered by Mr. W. Sydenham, Tamworth, Mr. Crane was the only exhibitor, arranging with taste yellow and white *Violas* with grasses, sprays of Hawthorn, Maiden-hair Fern and other greenery in small tubes and glasses, &c. This was awarded first prize.

TRADE DISPLAYS.

In this department Mr. William Sydenham, Tamworth, Staffordshire, excelled, and for an exhibit of forty-eight sprays *Violas*, together with a large number of neat little rustic silver-plated table decorations arranged with *Violas*, was awarded a silver-gilt medal. The most noteworthy sprays of *Violas* were Nellie Cruse, Niobe, a lovely white, rayless, awarded a first class certificate: Virginius, pale blush; Symphony, white; Cottage Maid, a good fancy; Primrose Dame; Melampus, a grand rayless yellow sort; Mandarin, Ophelia, Britannia, Bouncer, A. J. Rowberry, Mrs. C. F. Gordon and Kitty Bell, and a pretty little miniature, Minnie Warren, of a lavender shade, was also admired. Messrs. Cheal and Son, Lowfield Nurseries, Crawley, Sussex, had a superb display. These were set off with sprays of Maiden-hair Fern in a tasteful manner. New and old sorts were about equally balanced in this display, and it was quite an object-lesson to compare the old and new varieties. A silver medal was awarded.

Royal Gardeners' Orphan Fund.—We are requested to state that the annual dinner of this institution will be held in the Hotel Metropole on the evening of July 18. Alderman Sir Reginald Hanson, Bart., M.P., in the chair.

Royal Horticultural Society.—International Conference on Hybridisation, Chiswick Gardens, July 11.—The ordinary committees of the society will meet at Chiswick, on Tuesday, July 11, at 12 punctually, and plants, &c., for certificate will be placed before them as at the usual meetings in the Drill Hall, but with the exception of plants, &c., for certificate and hybrids and their parents, no other plants, &c., may be exhibited on this day.

The weather in West Herts.—During the past week the day temperatures have been as a rule below the average, while the nights, on the other hand, have been mostly warm. Both at 1 foot and 2 feet deep the ground is at the present time of about seasonable warmth. Rain fell on five days of the week, and to the total depth of 2 inches. More than half of this fall was deposited

on the 30th ult., when the measurement for the twenty-four hours ending 9 a.m. on the 1st inst. amounted to nearly 1½ inches, or more than in any day since July 18, 1895. The heaviest down-pour occurred at 2 a.m., when in a quarter of an hour four-tenths of an inch fell, or at the mean rate of over 1½ inches an hour. June proved remarkably changeable as regards temperature, but taken as a whole it was a warm month. Rain fell on but six days, all after the 17th, the aggregate fall amounting to nearly 2 inches, which is about a quarter of an inch short of the June mean. The sun shone brightly on an average for about 7½ hours a day—making this the brightest June for twelve years. It was also very calm; in fact, calmer than the same month in any of the previous thirteen years. The Rose Marie Bauman came first into blossom in my garden on the 27th ult., or one day later than its average date of first flowering in the previous eleven years, but a week earlier than last year.—E. M., *Berkhamsted*.

NOTES OF THE WEEK.

Everlasting Peas.—The perennial or Everlasting Peas in one or two varieties are now among the finest of old-fashioned garden flowers, the pure white kind being of especial value, not merely in the garden where it blooms long and continuously, but also for cutting.

Silene alpestris.—Spreading cushions of this plant have of late been quite a sight with the pure white flowers, which, if small, appear in great profusion. The plant, fortunately, is of the easiest culture, though at all times preferring a deep soil. Seeds usually germinate quite freely.

Heliopsis patula.—Among the early-flowering composites this is a good and attractive subject, the rich golden orange hue being very fine. It is, however, not a large-headed flower, though belonging to a group lending itself freely to improvement. The habit is by no means coarse, which is in its favour.

Hybrid Columbines.—One point that is at least forced upon the observer is quite noticeable in these plants. It is the apparent standstill that at present exists in so far as the raising of new shades is concerned. A dozen years ago many pretty shades were appearing, but now these to all appearance have reached their highest point.

Campanula Burghalti.—This showy Bell-flower is now in bloom, and of the section to which it belongs is certainly one of the finest. It is perhaps scarcely so pale in colour as *C. van Houttei*, to which it would appear nearly allied, and is also somewhat stronger. Where it succeeds the latter is the more frequently favoured for the border, and it is certainly a deserving plant.

Rose Gustave Regis.—Among so-called garden or decorative Roses this would appear to be an especial favourite, if one may take the frequency with which it is included in almost every exhibit of these kinds. That it is a popular as well as a free-growing kind there is no doubt, and for the garden just the kind that pleases both by its freedom and its colour. Its long buds tapering almost to a needle point render it of value also as a button-hole flower.

Tropæolum Leichtlini.—In your issue of June 24, p. 457, I see a note on *Tropæolum Leichtlini*. I quite agree with the praise bestowed by the writer on this fine plant, but I think he is mistaken in speaking of it as a distinct species. It is a hybrid between *T. polyphyllum* and *T. edule*, obtained five or six years ago by M. Leichtlin, of Baden-Baden. It was figured in the *Revue Horticole*, 1897, p. 400, from plants that flowered in my garden.—M. MICHELI, *Geneva*.

The Strawberry crop.—The South Hants Strawberry growers have a very light crop this season, and although prices keep high it will by no means repay them so well as a good crop at lower rates, for the average yield is not more than one-third. It is difficult to account for such a failure, but my impression is that last season's drought so weakened the plants that they had not time after the rains came to mature their crowns; consequently the bloom was weak and failed to set.—J. G., *Gosport*.

Fatsia japonica ripening seed.—In consequence of the very mild winter this shrub was in full flower in January, and numerous large flies buzzing

among them reminded one more of June than mid-winter. The plants ripened a full crop of seed, from which I have raised many young plants. I shall be glad to hear from any of your readers who have been successful in ripening seeds of this Japanese shrub in the open air. Single specimens or clumps of this should be planted in all favourable localities, as its large digitate leaves give a warm appearance to the landscape in mid-winter.—W. O., *Fota*.

Ourisia coccinea.—Since writing the recent note on this brilliant flower I have seen it doing well in the rock garden of Mr. P. Neill-Fraser, of Rockville, Murrayfield, Edinburgh. It is grown there in the pocket of a sheltered rockery but a few yards above the level of a pond. One meets now and again with exceptional gardens in which *O. coccinea* does well, but in the majority of instances it refuses to bloom.—S. ARNOTT.

Campanula pulla at Kaimes Lodge.—One sees so many places where, from various causes, this beautiful little Bellflower, or Harebell, grows so indifferently that it is always a pleasure when one sees it growing into a mass. It is then that its beauty can be properly appreciated. At Kaimes Lodge it is delightful to see how quickly it has become established in the rock garden in such a comparatively short time. Some sheets of its deep blue drooping flowers looked very fine recently.—A.

Coronilla iberica.—This is ever a favourite when seen in bloom with its clustered yellow flowers hanging over a ledge in the rock garden. Like many other plants, it resents being overshadowed by other flowers or shrubs, and may be lost if overgrown by its neighbours. One of the easiest ways of raising a stock is by means of seeds. Small seedlings planted out have often a much better chance of doing well than older plants unless the latter are in pots and can be turned out without disturbing the roots.—S. A.

Campanula persicifolia alba grandiflora.—This is decidedly the finest of the Peach-leaved Campanulas in so far as its flowering is concerned. In some soils, however, and those more particularly of a very light character, the plant does not increase with the freedom of its kind, and in one or two instances the stock has perished and had to be renewed. It would appear there is more than one form of this handsome plant, one greatly inferior to the other. The finest form is usually known as Backhouse's variety. This is a grand garden plant, the stems being literally hidden with snow-white flowers.

The Oriental Poppies.—I recently saw several of the newer Oriental Poppies sent from Newry. Of these I thought Cherry Ripe among the prettiest. It was brightly coloured. I also liked in its way one called Darkness, the deepest maroon of any I have seen. Carminum was also good. Pictum, with salmon-pink flowers, is also pleasing, and so is Lilacinum. The flowers were comparatively small, a point of value for some purposes. For purely decorative effect the large-flowered bright forms are of most value in the garden. *Papaver orientale bracteatum* remains almost unequalled for this purpose.—S. A.

Incarvillea Delavayi.—Those who a year or two back had fears concerning this plant may be glad to know that in Messrs. Wallace's nursery at Colchester the flowering stems are fully a yard high, and the richly coloured flowers most profuse. Cut spikes from Colchester have been set up at the Drill Hall on each occasion during the past few weeks with stems quite 18 inches long. Stronger plants that have been left alone are even more vigorous, and still flower continuously. The plant is so distinct, that the news of its great vigour is welcome. The plant seeds freely, too, so that it is likely soon to be quite plentiful in gardens generally.

Deutzia Lemoinei.—I am pleased to observe that "W. D. R. D." has been more successful with this *Deutzia* than some of us have been. I hope to see his plant before long, when I may be able to receive some guidance which may lead to my being more successful than hitherto. Al-

though "W. D. R. D.'s" garden is only a few miles from here, and also close to the sea, there is, I believe, some difference in the temperature. Here it is only in exceptionally mild winters that I have been able to grow *Cotyledon* (*Echeveria*) *glauca* in the open, but in his garden it forms a fine group quite hardy at the foot of a rock, at the base of which is a pool.—S. ARNOTT, *Carse-thorn, by Dumfries, N.B.*

Ixia viridiflora.—The shade of colour in this is quite remarkable in the tone of green, and as rare as it is remarkable. It is difficult to give expression to the colour, which is a pale or very delicate peacock-green, or perhaps sea-green is a nearer approach, and shaded with grey. Then, as rendering the flower all the more conspicuous, is the intense blackish violet-purple base internally. The soft silken touch of the slightly pendent blossoms is also a feature. When cut, the *Ixias* are even more valuable than in the garden perhaps, though the brighter shades of colour play a rather important part in such decoration. The frail stems render the plant especially useful in the cut state.

Finely-grown Humeas.—Possibly no finer or better cultivated plants have ever appeared in any exhibition than was the case at the Drill Hall last week. Plants of 12 feet or more high, with the fine bronze-tinted plumes so freely developed, are indeed of rare occurrence. The notion of exhibiting Humeas and Crotons mixed is certainly not a common one, and the effect was unique, for it was one of the most attractive groups that has ever graced the Drill Hall. Such plants tend to show what may be accomplished by timely potting and liberal culture from the first, as no Humea, once it gets into a hide-bound condition of the stem, can ever make such a perfect example as were the plants referred to.

Gnothera fruticosa Youngi.—Comparatively common as are the varieties of *G. fruticosa*, they are indispensable in the flower border at this season. Unlike the true Evening Primroses, they are at their finest when their bright yellow blooms are lightened up by the sun. They do not require full sun to give them brilliancy, but it seems to give them that glowing appearance which makes them so summer-like. (*G. Youngi* does not differ much from *Fraseri*, and is a capital border plant for a soil which is not too heavy, but where it is not allowed to flag and droop in dry weather. In a border here it grows about 3½ feet high, which is quite as tall as I care to have it.—S. ARNOTT, *Carse-thorn, by Dumfries, N.B.*

Notes from Yorkshire.—For the last twenty years the Red Chestnuts (*Pavia rubra*) have not flowered here so luxuriantly as this year. They remind me of the beautiful avenues at Baden-Baden. The Rhododendrons also have been very fine. Against the house walls I have now in bloom *Solanum crispum*, *S. jasminoides*, *Olearia Gunni*, *Loasa lateritia*, and *Calampelis scaber*. *Carpenteria californica* and *Tropeolum speciosum* are beautiful. *Eremurus* raised from seed sent to me by Mr. W. E. Gumbleton is just going over. *Linnaea borealis* is covered with its pretty bells, and *Trientalis* has had several of its white stars. The above plants cover a wide geographical range, yet all are thriving here.—R. MILNE-REDHEAD, *Holdenclough, Bolton-by-Bowland, near Clitheroe.*

Pyrus coronaria flore-pleno.—*Pyrus coronaria* is one of the Malus (or Apple) section of the genus, and is a native of the eastern side of North America. From the other species of the same section it is distinguished by the frequent lobing of the leaves, the charming fragrance of its flowers, and the late date at which they appear—i.e., the latter part of May. This double-flowered variety has all these attributes, but it is, besides, far superior to the type in the size of its blooms. Some I measured recently were well over 2 inches in diameter, and having two or three rows of petals, they formed very striking and beautiful clusters. This is, indeed, probably the finest *Pyrus* in existence as far as the individual flower is concerned. The colour is rose, tinted

white, and the trees are in full leaf at the time of flowering. It is decidedly a tree to be noted by planters.—W. J. B.

Saxifraga mutata.—One does not frequently meet with this Rockfoil, which I saw at Kaimes Lodge, Murrayfield, the other day. With me in the west of Scotland it seems to be more difficult to keep in winter than in the east, where the climate is drier. Mr. Lindsay had a nice tuft in his rock garden the other day, when its orange-yellow flowers, with crimson anthers and pistils, made a pleasing sight. There is a good, if rather highly coloured, plate of this Rockfoil in the second series of Wooster's "Alpine Plants" (plate xxxix.). As stated in that work, the flowers, which open saffron or orange colour, pass off to pale yellow. One cannot but regret that *S. mutata* is rather a difficult subject for wet districts. It belongs to the section *Euaizoonia*, and was introduced about 1779.—S. A.

Philadelphus microphyllus.—Like many other plants from which hybrids have been raised, this species is better known in gardens by its progeny than it is itself. It is from this species that the beautiful Lemoinei race of *Philadelphus* has been partly derived. The species itself is the most distinct in the genus. Many of the *Philadelphuses* in gardens run so much one into the other that it is difficult to say where one ends and another begins. But it is different with this; a great gap separates it from any other. It is the dwarfiest *Philadelphus* and has the smallest leaves. It forms a round bush, 2 feet to 3 feet high, of very dense leafy habit, the leaves being of a grey-green colour and about the size of Box leaves. The flowers are each a little over 1 inch across, pure white, and possess a fragrance that is sweeter than that of any other *Philadelphus*. It needs a sunny position and a soil that is not more than moderately rich.

Halimodendron argenteum.—Having been introduced to Britain from Siberia 120 years ago, this shrub may now be considered an old garden plant, yet it is by no means a common one. Of its value, greater proof is being afforded this year than ever I have seen before. It is flowering with the greatest freedom, and its charming pink blossoms hang in profusion on the graceful pendent branches. The leaves are of a grey colour and consist of four leaflets arranged pinnately, the leaf-stalk ending in a spine. Belonging to the Leguminosae (and nearly related to the Caraganas), this has pea-like flowers borne not more than three together on slender stalks. Their pink, or purplish-pink, colour accords well with the grey foliage. It is not often that a good word can be said for grafting as adapted to hardy trees and shrubs, but it is useful in the case of this *Halimodendron*. It is not an easy plant to raise from seed, being so apt to damp off during the first or second winter before it has had time to become woody. The best plan with it, therefore, is to work it on *Caragana* or *Laburnum* stocks. These should be 3 feet or 4 feet high, so as to show off its exceedingly graceful mode of growth.—B.

Making bouquets (N.).—We know of no book on the subject you mention. The articles you want can be supplied by any horticultural sundriesman.

Names of plants.—Suffolkian.—Should like to see better specimens; too shrivelled to identify.—*A. Bowles*.—*Clematis montana* probably.—*Alice Wilson*.—Sweet Chestnut.—*J. R. Jefferies*.—1, *Paneratium* sp.; 2, *Orechis maculata*.—*J. L.*—*Rosa alpina*.—*A. Kingsmill*.—*Olearia macrodonta*, New Zealand (also called *O. dentata*).—*M. M.*—1, *Cistus hirsutus* var. (white); 2, *Campanula Rapunculus*; 3, *Cistus villosus* (red); 4, *C. hirsutus*; 5, *Oxalis vespertilionis*; 6, *Saxifraga aizoon* (white); 7, *Dianthus crenatus*; 8, *Saxifraga aizoides* (yellow).

"The English Flower Garden."—Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.

Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.

ORCHARD AND FRUIT GARDEN.

AIR FOR VINE BORDERS.

In our anxiety to secure a fertile soil and enrich it with the constituents essential for the Vine, I fear we omit considering some of the conditions necessary to preserving the mass sweet and enabling it to yield all the plant food it is capable of under favourable circumstances. Thirty or forty years ago some provision was made whereby every Vine border could be well aired. This important item in Vine culture does not now seem to receive the attention it did then, for it is nothing new to find a solid brick and lime wall forming the boundary of the borders. The borders, too, instead of being raised, are frequently kept low and level. Borders of this kind can only be aired from above—by the water supplied to moisten them driving out the air between the particles and taking its place, fresh air getting in as the water percolates through to the drainage. With dry seasons and a porous soil well drained, the air in the borders will thus be frequently changed, but the question still remains, is this enough? Even were it so, what about wet localities and borders consisting chiefly of heavy loam or loam approaching clay? Borders of this impervious nature hold moisture longer than more porous ones, and consequently will seldom need watering, whether rains can reach them or not. In the absence of sufficient air among the particles of soil, &c., the border is cold, sluggish in giving up plant food, has a tendency to acid properties, and becomes unsuited to the healthy growth of the roots of the Vine. Change these unsatisfactory conditions by providing a means for the atmospheric air playing through the soil, and the gases of which the air consists will break up quantities of the insoluble compounds and enrich them with their own manurial constituents. Besides this, the solubility of valuable substances is secured, heat imparted to the earth by the chemical actions which take place, and anything approaching

sourness avoided. Knowing this, the airing of Vine borders should receive as much attention as the draining of them does. In low-lying situations, especially in wet localities, perhaps the best plan to adopt in the formation of Vine borders would be to keep them wholly above the level of the surrounding ground. Those outside the houses could be finished off with a grass slope kept well cut during the summer months, and which would look much nicer than brick and mortar walls. Drain pipes surrounded by a few stones could intersect the borders from back to front, and be placed at different levels to admit air. The wall at the back of the border and inside the house could be honeycombed and built a few inches from the wall against which the house was placed. By this means a current of air could be got to play right through the whole of the border. In drier situations and with sandy soils the borders might be kept lower, but a similar arrangement to the foregoing for securing air passages should always be obtained. In renewing any existing borders which are bricked round, it would be wise to form marginal walls to the border of turves a foot or so within the brick and lime one. Some borders I have seen were all above the ground-level outside, and were limited in extent by turves receding from the ground to the surface of the border. This was an excellent plan, only there was a conspicuous absence of tidiness about it. Every case requires to be dealt with on the spot, as new difficulties arise at different places, awakening fresh channels of thought in devising means to overcome them. The suggestions in the preceding remarks may, however, serve as a base to work upon, and when well-aired borders have been assured, all other things being satisfactory, it will be found that vigorous, healthy, fruitful growth will follow. J. RIDDELL.

Pear Fertility.—I note the remarks of "J. G." on this Pear at page 442. "J. G." says it does well as an espalier. It may in some soils and situations, but with me in a light, porous

soil with the roots well mulched it was a complete failure. I had no fault to find with the crop, as it never failed to yield abundantly, but just before the fruit was fit for gathering decay set in all of a sudden, and that not at the core only, but right through the fruit. Where the fruit remains firm till ripe, there can be no doubt of its usefulness, as it is such a persistent cropper, of useful size and fair flavour; just the Pear, in fact, for amateurs and those with only limited space.—J. C.

Gooseberry Leveller.—This is a remarkably fine yellow Gooseberry, and, unlike some of the large Lancashire varieties, is excellent in point of flavour as well as size and appearance. Leveller is a capital poor man's Gooseberry, and has succeeded admirably with me year after year on a light soil. I had the roots well mulched in spring and watered several times during summer, for there can be no doubt that were Gooseberry roots kept more moist there would be fewer complaints of insect attacks and blight. The fruit of Leveller is delicious for dessert about the end of July. It hangs on the tree better than the majority of sorts and is less liable to split in changeable weather. If the berries are thinned out when young and one or two good waterings with liquid manure given, it will prove one of the best exhibition sorts in cultivation.—N. N.

Strawberries and the drought.—From many quarters complaints come about Strawberry plants giving way and the fruit becoming hard and brown when little more than half grown. This is especially the case where the soil is light and shallow. In a few favoured localities copious rains fell recently, but in others the soil is scarcely more moist than it was last autumn owing to a comparatively rainless winter and spring. No wonder then that Strawberries under ordinary treatment show signs of distress. I do not say that where, say, acres of this fruit are grown this premature collapse can be avoided, but in private gardens and market gardens of limited extent the evil might be met by timely mulching. I say timely, as I find that the majority of growers postpone the operation till the plants are coming into bloom. In average seasons and in fairly strong, retentive soils no harm occurs from the delay, but in seasons like the present, light, porous soils lose what moisture

they had before the mulch is applied, inferior crops being the inevitable result. I contend that it is not wise to postpone mulching later than the beginning of February, as that month is frequently dry and windy, and speedy evaporation leaves the roots of Strawberry plants insufficiently moist for the formation of stout, vigorous bloom-trusses, but when timely mulching is practised, what moisture there is is preserved and the roots get the benefit of it. If an early and liberal mulch is given, it is rarely necessary to water the plants except in exceptionally dry seasons.—B. S. N.

CATERPILLARS ON GOOSEBERRY TREES.

CAN you tell me why caterpillars attack some Gooseberry trees and not others? I have recently taken charge of a garden, and some of the trees have hardly a leaf on them, all being eaten away by caterpillars. My employer tells me the trees were the same last year. I have picked the Gooseberries, so I have a chance to syringe them with anything you advise.—W. F.

* * The reason for some bushes being attacked by caterpillars and others escaping must be a purely local one, my experience being that none are safe. Possibly those most infested are the nearest to frequented walks, and friendly birds may be scared by passers-by from coming to the bushes and clearing the grubs away. Unless the number of bushes is too great, the very best remedy is to look them over daily and hand-pick the caterpillars from the time the first attack is noticed until no more are to be found; but these pests are so voracious, that the value of this method lies in the immediate application, and a watchful eye is needed. It really takes very little time for a boy to clear a plot, for though the pests are to some extent concealed by their colour and the positions they take up, the eye soon gets accustomed to detecting them readily. Dusting with soot and lime in a dry state while the bushes are wet with dew has some deterrent effect; dry road grit frequently applied acts in the same way. As "W. F." has cleared off the fruits, an application of hellebore powder will prove very destructive to the caterpillars and can do no harm, but this remedy, though a very effective one, I never like to recommend for fruit trees or bushes, as the powder is so poisonous. If the bushes are too thick to be really cleared by hand-picking, shake them vigorously now and then and kill the caterpillars which fall with the back of a spade. I have never found any solution of insecticides very effective when syringed on, though a fairly strong solution of soft soap, into which some flowers of sulphur has been stirred, applied early enough appears to check the deposit of eggs. It is too late for this now, however. I should advise that a clearance of the top 3 inches of soil be made in the winter, replacing this with some fresh soil; then in early spring cover the surface with 2 inches of fresh tan. Tan has been proved over and over again to be the most effective application, and its effect appears to last for several years. The same effect has been claimed on behalf of a heavy dressing of soot to the soil, but I have not found its effects so lasting.—C.

Apple Emperor Alexander.—No doubt many after seeing this handsome-looking Apple at exhibitions have been induced to plant it in their own gardens, only to be disappointed with its behaviour. It requires very careful cultivation and pruning with judgment, it being one of those Apples which fruit largely on the points of the shoots. The best way for standard trees is to carefully thin out the wood annually and shorten back any growths that may have taken the lead. Even standards are unsatisfactory from a cropping point of view in many gardens, cordons and espaliers even with judicious root-pruning sometimes remaining almost barren for years. When fine fruits are obtained, few varieties surpass it for showing in November, but when kept for a longer period they quickly lose

weight and quality too. As a market fruit it is too tender in the skin unless disposed of near home.—C. N.

Peach Thomas Rivers.—This new Peach was shown in quantity by the Messrs. Rivers at the meeting of the Royal Horticultural Society at the Drill Hall on June 27, and was much admired. There were several trees of this variety in pots, and the quantity of fruit each tree carried and the size of the fruits were sufficient evidence that this new Peach is a grand cropper when forced in pots. Some may say that we do not need such large Peaches which invariably lack flavour. I have always found large Peaches with the colour of Thomas Rivers much admired on the dessert table, and growers for market know which pays best. I had an opportunity of tasting this variety last June twelvemonth, when it was given a first-class certificate, and it was very good indeed. I think this is a good addition to our Peaches. If it proves suitable for the open wall it will be most valuable.—G. WYTHES.

Melon Royal Favourite.—One of the most reliable all-round Melons I have grown of late years is Royal Favourite. It has a good constitution, sets freely in pits or houses, swells its fruit up to a good size, is of handsome shape, and well netted. Surely these are the attributes of a good Melon. I may be told that these count for nothing if the flavour is not satisfactory. Flavour in Melons is beginning to be regarded as a most uncertain quality. Fruits have been grown in hundreds of cases and placed before judges, both at the Royal Horticultural Society's shows and committees and in the provinces, that when tasted were very poor as regards flavour. It is quite true that Melons need to be treated with some amount of judgment before deciding on cutting them. A day too soon or too late makes a deal of difference, and to this may be attributed many disappointments. Some kinds ripen up more quickly than others. Royal Favourite needs a good time to soften throughout from core to skin, and a cool fruit room develops flavour better than hurrying the fruit on the shelves of warm houses, as some do. Royal Favourite is a good keeper, though it is not one of the tough-skinned varieties. The flesh is white or a greenish white. It is too late for sowing Melons, except in a few cases, but those who are on the look-out for a good all-round Melon and have not given this one a trial, should note it for future growth. To my mind it possesses every good quality, including flavour, provided it is well grown and is given time to mature perfectly.—W. S.

Scarcity of Strawberries.—I have never seen such a poor crop of Strawberries. This is anything but local, as I note growers in various parts of Kent and Middlesex have lost a good portion of their crop. In later districts the crop is better, as it was the early bloom that suffered, and no one can wonder at this with the low temperature that prevailed for quite ten days during the setting period. A quarter of plants that should have produced 4 cwt. to 5 cwt. of fruit this year gave me 60 lbs. Unfortunately, the best fruit was destroyed. One grower told me that instead of clearing a ton of fruit, about 2 cwt. would be the crop, and this only seconds. There is no scarcity in some places, as I note the market is well supplied from the southern parts of the country, but in this—the West Middlesex district—the crop is much lighter. It would be interesting to know how general this failing is. In the north there was less frost, and of course with later bloom there are no losses. In light soils the plants made less growth than usual, owing to the protracted drought last season, and fewer crowns were formed, this affecting the crop. It is surprising how some varieties succumb to frost and drought. For instance, Royal Sovereign, having a long leaf-stalk and the flowers being much exposed, suffers badly from late frosts. Kinds with ample leafage, like Vicomtesse II. de Thury, are much less affected. This points out the value of growing more than one variety, also of having the plants in diverse positions, as often one may escape when others are injured. There

will be no lack of runners, as the loss of the crop will cause runner growth to form freely, and with a genial season next year there should be splendid crops, as the plants will make much growth. Such seasons show us the value of late kinds, which will eke out the scanty supply obtained from the early plants.—G. W. S.

CURRENT WORK AMONG PEACH TREES.

UNDER the influence of warmer weather outdoor Peach trees are now making much progress, and will require a great deal of attention for some time to come. Fortunately, aphid, which at one time threatened to prove troublesome, yielded to a thrice-repeated application of an insecticide. Red spider, which has been very much more troublesome, has also been subdued. Blister, which has, I believe, been very prevalent in some parts of the country, has affected but two trees here, and that only to a trifling extent. The most pressing work, therefore, at the present time is the tacking in or fastening back of the young shoots, together with the thinning of fruits on all heavily laden trees. Before proceeding with the first-mentioned operation give the trees a look over and remove all surplus shoots, as it often happens that a good few more are left than are actually required at the final disbudding, especially by those unaccustomed to the work. Overcrowding of the wood should always be avoided, and in no case should more be laid in than is needed for furnishing the tree with fruiting wood for next season. The observance of this rule is equally as essential to the well-being of the trees as is that of the avoidance of overcrowding. The reduction of the young shoots to due proportions having been accomplished, the next thing is to fasten them back to the wall. If the walls are wired, tying with raffia will suffice; if not, shreds and nails or young twigs of Privet are needed to hold them in place. Thinning of the fruits should be done simultaneously with the tacking in. In some places I fear there will not be much thinning to do, but in all cases where the trees are heavily laden, a reduction of their numbers to safe limits should most certainly be effected. That fine early sort, Alexandra, has again set a splendid crop of fruit. Alexandra Noblesse and several others are equally as good.

Thinning must not of course be too liberally done, as a margin must be left for any eventualities in the shape of dropping through failure to stone properly. On the other hand, if the trees are healthy and the roots in good condition, thinning may be done with a pretty free hand, but it is only those possessing an intimate knowledge of their trees and the condition of the borders in which they are growing who can thus boldly deal with them in this way. As with indoor trees, one fruit to each square foot of wall space covered by each tree is an ample number to leave at the final thinning, and this will serve as a guide to those who are in a dilemma as to what to do in the matter. If they act on this advice and leave that number, with a few to spare, they cannot go far wrong, and the surplus can be pulled off after the stoning period is safely passed. If not already done, the alley should be loosened and a dressing of some artificial manure applied. For this purpose a mixture of bone-meal, superphosphate of lime and muriate of potash is excellent if mixed at the rate of 3 lbs. of the former to 1 lb. each of the latter, and strewn on the surface at the rate of 2 ozs. per square yard. This may be washed in should the condition of the border warrant the application of water. In any case it should be incorporated with the surface soil either by raking or forking it in. Hot weather having set in dry, the alleys will be best covered with straw litter both to conserve moisture and to prevent too rapid evaporation. A weekly examination of the borders from now and on through the summer months should be made and water applied as often as necessity arises. This is a most important matter, for if all conditions are right Peach trees require a great deal of water, and without

adequate supplies of moisture the fruits will not attain to full size. The garden engine, it is almost needless to say, should be kept at work as often as time and labour will admit, and if this is on every fine day so much the better. If this can only be done frequently the use of insecticides will not be necessary, as the fact of washing the trees frequently or daily will suffice to keep them clear both of aphids and red spider, while the usual haunts of earwigs will be rendered untenable by the oft-repeated applications of water.

A. WARD.

Peach Dagmar.—I was pleased to see mention of this Peach as exhibited by Messrs. Rivers at the Temple show. How is it that this variety is grown in so few places? I never forced it in the first early house, but found it one of the most reliable free-setting and highly-coloured sorts in cultivation. If anything it colours better than Stirling Castle and I consider the quality is average. That Dagmar is adapted for early forcing in pots is evidenced by the exhibit of Messrs. Rivers, and I would advise those who grow pot Peaches to include it in their list. There are certain of the most useful all-round Peaches which, nevertheless, seem to be almost discarded, while other capricious kinds are universally grown. Dagmar is, I think, one of them.—J. C.

Gooseberry Rough Yellow.—This is always one of the first to ripen and the fruit is already taking on a bright yellow tint, so in about a fortnight, or say the middle of July, the fruit will be ripe. Although by no means one of the largest varieties, its bright colour and delicious flavour make it much more useful than some of the larger kinds. Here the Gooseberry bushes are covered with fine fruit this year, and on espaliers, where the best flavoured kinds are grown for dessert, they have had to be thinned somewhat heavily, the thinnings of course having been used for cooking in a green state. The trees here are mulched with short manure every spring, and, should the weather prove very dry, are given one or two thorough soakings of water through the season. It is surprising what an amount of fruit can be gathered from a few well-fed trees, but in too many cases this useful fruit is left to take care of itself on poor soil.

Plum Belle de Louvain.—This Plum, I think, is likely to become a great favourite with market growers on account of its free-bearing habit. When looking through the famous Plum orchards belonging to Mr. J. Riley, of Putley Court, Ledbury, in conjunction with the other members of the Herefordshire Association of Fruit Growers, on Monday last, trees of this variety were noticed as being heavily cropped. Mr. Riley holds the opinion that it is one of the best Plums for market, and has accordingly a great number of trees of it. Intending planters of Plums would do well to make a note of this, as, in addition to its succeeding well as a standard, it also makes a fine and healthy pyramid. My trees are, I am sorry to say, barren this season, which fact is owing to sparrows having not only picked out many of the buds, but also to their having pulled the blossoms to pieces after they had opened. The fruit is large, long, oval-shaped, and reddish purple in colour, the flesh yellow. It is an excellent Plum both for preserving and cooking.—A. W.

Grape Lady Hutt.—Last season I noticed that the foliage of this Vine was rather given to scalding, and the same thing has occurred again this season, only to a much greater extent. The evil, no doubt, has been aggravated this season by the brilliant weather of the past ten days having been preceded by a long spell of dull, cloudy weather, with the wind blowing from the east and north-east nearly the whole of the time. Although such was the case, other Vines in the same house, which consist of such varieties as Lady Downe's, Black Alicante, and one or two other sorts, were but little or totally unaffected by the sudden transition, so to speak, from a dull, cloudy atmosphere to one of almost unclouded sunshine. This has therefore led me to

think that the foliage of this variety is tender and susceptible to sun-scalding while in a yet undeveloped state, and I should be glad to hear if any other reader of THE GARDEN who grows this Vine has experienced the same difficulty. Since shading the roof no further scalding has taken place. It being a strong grower, I have given this Vine more room this season, and am glad I did so, as it is carrying a fair crop of good-sized bunches. As a late white Grape it has, I think, no equal, and I am hoping to hear that the complaint I have to make respecting it may be but a passing one and confined to my own case, and not found to be of common occurrence.—A. W.

Cherry Rivers' Early Black.—This Cherry was ripe and ready for gathering on an east wall outdoors by June 15, and when the backwardness of the season is taken into consideration this further emphasises all that has hitherto been said and written as to this variety being one of the best early Cherries we have for outdoor culture. In addition to ripening at any early date, the fact that it is a vigorous grower and a free cropper must not be lost sight of. The fruits, which are purplish black in colour when fully ripe, are also large, juicy and luscious. This season the fruits have been very large. This was produced by a form of potash used in conjunction with two other manures and applied as soon as the fruit had set. Many neglect to feed Cherry trees, thinking that it is unnecessary, but I find it pays to do so, and trees of both sweet and cooking varieties are as regularly fed here as are Peaches and other choice fruits, with the result that both trees and their crops are greatly benefited thereby.—A. W.

STONE-SPLITTING IN PEACHES.

CAN you explain why the Peach I send you does not ripen satisfactorily? Several have dropped this season, each being hollow in the middle.—M. J. B.

** Some kinds of Peaches are more addicted to stone-splitting than others, though it happens sometimes in a variety not commonly given to that failing. There is no particular reason for splitting of the stone, or it would be a more easy matter to advise so as to prevent a recurrence. To imperfect fertilisation of the flowers may be traced the origin of some such cases, and where this is so, there is no remedy that can be applied benefiting the present crop. The health or vigour of the tree itself affords no solution of the difficulty, because stone-splitting is not an outcome of indifferent health; indeed, the reverse is more likely to be the case. When Peaches are flowering, it is never safe or advisable to trust to chance in the setting, for without being fertilised with their own pollen or from other flowers by the aid of a camel's-hair pencil, rabbit's tail or something of a similar character, the fruit may swell away for a while, even to ripening, and then drop from premature softening accelerated by the unsound stone. In this condition the fruit sometimes falls and appears ripe, but an examination shows that it is soft only on one side, the other being congested and hard, quite unfit for dessert. It is among the early sorts that these troubles occur most frequently. Alexandra Noblesse, mentioned by "M. J. B.," does not usually have split stones, although, as previously intimated, any variety may develop this failing in a few fruits if the cultural conditions favour it.

In over-rich borders I have known some Peaches to drop when nearing the ripening period, and if they remain until they can be gathered, they invariably ripen some time before the remainder of the crop is ready, which the expert grower at once recognises as a symptom of stone-splitting. Freshly slaked lime applied in quantity sufficient to whiten the surface is a good remedy in such cases, giving it once or twice during the growing season. With trees that are over-luxuriant, root-pruning or lifting and placing the roots nearer the surface correct more than the one evil, bringing with it the lessened tendencies to split-

ting of the stone. Over-head shade from other trees hinders proper ripening of the wood, and without this neither perfect setting nor stoning can be assured. Extremes of root moisture or drought are both inimical to the progress of the tree's growth in summer, and should be as far as possible avoided, as also should strong doses of animal or artificial manure, because they stimulate an excess of vigour which is most undesirable. With a comparatively new border and healthy trees clear water is all-sufficient; it is for older trees with borders fully occupied with roots and carrying heavy loads that stimulating liquid food is necessary. Lime, however, may be given in small quantity with advantage to Peaches, as this assists the formation of the seed-shell or stone. Although I have gathered many hundreds of Peaches and Nectarines this season, I have not recognised one among them having a split stone, and this immunity I owe to the regular courses of watering with clear or diluted liquid manure as the case requires, thinly disposing the growths in training and tying, moderated temperatures, applications of lime occasionally, and daily fertilising of the flowers with a dry rabbit's tail. As "M. J. B." says Alexandra Noblesse has only a small crop and other trees are doing well, there must be some local condition to account for it, or perhaps some of the causes enumerated above may be in evidence. Unripened wood caused from over-head shade, imperfect fertilisation of the flowers, or an absence of lime in sufficient quantity may, however, give the clue for the failure complained of, and for two of them, at any rate, steps may be immediately taken to correct it for another year. Carefully lifting the trees and replanting will correct grossness, the autumn, when the leaves begin to fall, being the most suitable time. A mistake that is often made is neglecting the watering of the borders and syringing of the trees after the crop is cleared.—W. S.

DESTROYERS.

A PEAR TREE DESTROYER.

(*AGRILUS SINUATUS*.)

IN 1889 I noticed for the first time the attacks of this insect. The young shoots of a branch of an espalier Pear tree were withering. On examining the lower part of the branch I saw that the bark was slightly scaling off and was brown and dry for about a foot in length, and presented every appearance of the beginning of a canker. Thinking I had to deal with a fungus, and in order to try and heal the injured branch, I cut away the bark from the wood and plastered the wound with vegetable mould moistened with Bordeaux mixture. The branch soon healed and is still alive. Some months afterwards I found other branches presenting the same appearance. Being surprised to find so many branches attacked by canker, I examined them more closely, and on carefully raising the bark I noticed a winding gallery formed by a larva, and on continuing my examination I found a larva which had all the characters of a larva of one of the Buprestidae. After this first discovery I noticed that the larva before undergoing its metamorphosis made its way diagonally into the wood of the branch, where it excavated an oblong cell flush with the under-side of the bark. The latter was not pierced until the perfect insect made its way through it to gain access to the outer world. Until the end of May, 1896, I was only able to find the larvæ under the bark or undergoing their transformations in the cells. In May, 1896, seeing that the branches were very badly attacked, in trying to destroy the larvæ I found in one of the cells a perfect insect, which I recognised at once as an *Agrilus*. Afterwards I found some ten of the perfect

insects, but never, either before or afterwards, could I discover the insect on the leaves.

DESCRIPTION OF THE INSECT.

Agrilus sinuatus is a small beetle from four-tenths of an inch to six-tenths of an inch in length, and from one-tenth of an inch to one-eighth of an inch in width. The head, thorax, and wing cases are finely rugose. All the upper surface of the insect is of a brilliant coppery violet colour. The under-side is of a violet-green, tinted with coppery reflections. The segments of the body are finely punctured, whilst the under-sides of the head and thorax are closely wrinkled. The eyes are large and prominent. The head is nearly as wide as the thorax. The larvæ are legless, and measure from six-tenths of an inch to nearly nine-tenths of an inch in length when full grown, and are of a pearly white colour. The head is partly sunk into the first joint of the body, which is nearly round and much larger than the other joints. The latter, which are ten in number, are rather flattened and are slightly winged on their edges. The last joint is terminated by two horn-like appendages curved in the arc of a circle, forming a kind of fork. Persons who are interested in this subject will find a fuller and historical description of this insect in a communication made to the Société National d'Agriculture de France by Dr. Laboulbène on May 19, 1897.

THE LIFE HISTORY.

In the course of June or July when the bark is still smooth the female lays an egg on the branches of Pear trees, which soon hatches. The larva makes its way into the thickness of the bark, generally taking a downward direction, making the gallery more winding as it goes on. One then generally finds that the bark splits above the passage formed by the larva. After having thus followed the bark in its approach to the wood the larva reaches the growing layers; there the larva feeds on the young woody and other tissues, making its gallery deeper, which becomes more and more winding in zigzags. Often the gallery describes a complete turn round the branch. One often finds that the bark on either side of the gallery dries up and dies, with a characteristic appearance that at once reveals the presence of the larva. When towards the month of September in the second year the larva has attained its full growth, and after having made a gallery not less than from 31 inches to 35 inches in length, it penetrates obliquely into the wood, excavating a little oblong cell, opening under the bark. This cell being finished, the larva closes the mouth with a little sawdust, its extremity projecting under the bark for about one-twentieth of an inch; then it is transformed into a chrysalis, and into a perfect insect about the end of May. It then opens out the end of the cell with its mandibles, pierces the bark and flies away, and soon, at its convenience, lays its eggs on the bark. This *Agrilus*, like all the Buprestidæ, is very agile, and flies off as soon as it is the least alarmed. I had made the foregoing observations without being sure if this insect was known. The researches that I made to find out if this insect had been previously noticed were without effect. No treatise on arboriculture mentioned the insect. The principal works on agricultural entomology to which one could turn—Maurice Girard, Brehm, Boisduval—do not allude to the insect. Kaltenbach in his important work on the enemies of the Pear does not mention it. The determination of the species of *Agrilus* is very difficult, and as I could not find in any of the works just mentioned anything relating to an *Agrilus* at-

tacking Pear trees, I thought it would be best to consult Dr. Laboulbène, the president of the Entomological Society of France, who kindly interested himself in this subject. He sent the perfect insects that I had brought him to Dr. Fairmaire to determine the species. Dr. Fairmaire recognised this insect as *Agrilus sinuatus* (Olivier). Just at this time, and even before I knew Dr. Fairmaire's opinion, there appeared in the *Revue Horticole* of March 16, 1897, an article by Prof. Gitton, of Orleans, describing this insect and giving its life-history. An editorial note stated that the insect in question had been noticed and studied by Dr. Puton. I then made Dr. Laboulbène aware of this fresh information. Dr. Laboulbène put himself into communication with Dr. Puton, and on my part I wrote to M. Gitton. The observations of M. Gitton agreed on nearly all points with mine. He had always noticed that galleries were from 63 inches to 71 inches or more in length and very winding, particularly at the end, and he had only observed the insect on the Pear. The observations of Dr. Puton differ considerably from mine. Firstly, Dr. Puton has only found galleries from 10 inches to 12 inches in length and nearly straight. The galleries that I noticed were always much longer and they were always very winding. Secondly, according to Dr. Puton, the insect only attacks trees in the open. I have met with them equally on trees in the open and on trees against walls, and it is on the latter that I have most frequently detected the attack. This may be that these trees are more easily watched, but, unfortunately, these espaliers suffer only too often. Thirdly, Dr. Puton points out that this insect attacks Pears and Apples indifferently. I have never seen an Apple attacked, though this tree with me is often side by side with a Pear, and sometimes the branches even cross one another. M. Gitton has told me that he has never seen this insect on Apple trees. Fourthly, Dr. Puton shows that the Mountain Ash also serves as a habitation for the larvæ of this insect. The investigations that I have been able to make are too limited for me to form an opinion on this subject. It is not, however, surprising that this insect should attack both the Pear and the Mountain Ash, a tree very nearly allied to the former. Mountain Ashes are common in the neighbouring woods, so that if the insect is common on these trees it could easily reach Pear orchards and propagate itself, finding in this tree a desirable home and a better host. There is still the question of the direction and length of the galleries. I have always noticed the arrangement referred to above. The number of observations that I have made on this subject, and which amount to several hundreds, enables me to assert that at least in the places where I have observed the insect it always behaves in the same manner, and forms a winding gallery 20 inches to 35 inches in length.

VARIETY OF TREES ATTACKED.

On my part, as I have already said, I have only noticed this insect on Pear trees, but, contrary to the statement of Dr. Puton, on trees on walls as well as on those in the open, all the varieties that I have grown have been attacked, and I cannot point out one that is more subject to the attacks of this insect than another. I have found this insect in the winter on Doyenné du Comice, and in the summer on Duchesse, William's, Cure, Passe Crassane, Olivier de Serres, Bonne d'Ezée, Beurré Diel, Beurré Hardy, &c. I have observed this insect also at the School of Horticulture of Versailles, at the school at Grignon and at Louveciennes, but without being able to make any very careful

observations. The injuries caused by this insect are often very considerable. On my trees I have counted the branches that have been attacked by hundreds. The branch often dies as the result of the attack by this larva (even though the gallery it forms is so small), or at least it droops for several years. Sometimes the insect even attacks the stem; the whole tree then dies or continues in a weak, unhealthy condition for several years after the insect has left it.

Are there, then, any means of protection against the ravages caused by *Agrilus sinuatus*? Indeed, I have not seen any that are really efficacious. The stems of standard trees one can protect with a coating of tar, or perhaps with a thick layer of lime, or one may wind bands of straw round the stem, as Dr. Puton has suggested. Tar is mischievous; it will prevent the insect from laying its eggs, but it injures the bark, making it unyielding, and so prevents the proper growth of the tree. The straw would be preferable, but it is troublesome, as it will not last for more than two years. Lime would be only a poor remedy, I should think; it would come off very quickly, in certain parts at any rate, which the insect would search for to lay its eggs on. However, liming has other advantages (above all, in being able to add to the lime a certain quantity of sulphate of copper) and it can be used all the year. As to the branches, it is impossible to try and protect them. It is necessary, then, to try and destroy the insect. The perfect insect is very difficult to capture; it is, therefore, against the larva that one must contend. When it is noticed that a branch is attacked, either by the buds not opening or by the death of part of the bark, the injured part of the bark should be removed with a grafting or pruning knife, and the gallery should be followed until the larva is found. If this operation is carried out in time the branch will recover and the bark will grow again; if, on the contrary, the larva continues its course, the branch often droops more or less. The wound caused by searching for the larva is, however, much more extensive than that made by the larva, but in spite of that it heals more rapidly. It seems without doubt that the larva produces a substance that is poisonous to the tree, a kind of toxine, which impedes the healing. One sees, indeed, the bark wither quickly on both sides of the gallery for a considerable width, and even beyond; the wood also dies rapidly to a considerable depth. Even if the branch is very vigorous, and the decay only exists a little on either side of the gallery, the cicatrisal swellings of the growing tissues do not seem able to grow over the gallery, which may still be found after many years. A wound of the same size made by a cutting instrument on a healthy branch would be covered in the first year. The branch seems to suffer most as soon as the larva penetrates into the wood. If the branch is not of great importance, or if it has been already badly attacked, it is often best to cut it away altogether below the part attacked, near a bud which will eventually form a new and healthy branch. The parts of the branch that have been attacked should be burnt, so as to kill any larvæ that they may contain. As I was communicating this paper to the society I received a letter from M. Gitton saying that he had sent me some specimens of an *Agrilus*, and he told me that he had found this insect in the branches of the Azarole Thorn. The *Agrilus* sent by M. Gitton were identical with those that I had found on my trees. The question then arises, are they the same species?

M. PIERRE PASSY.

TREES AND SHRUBS.

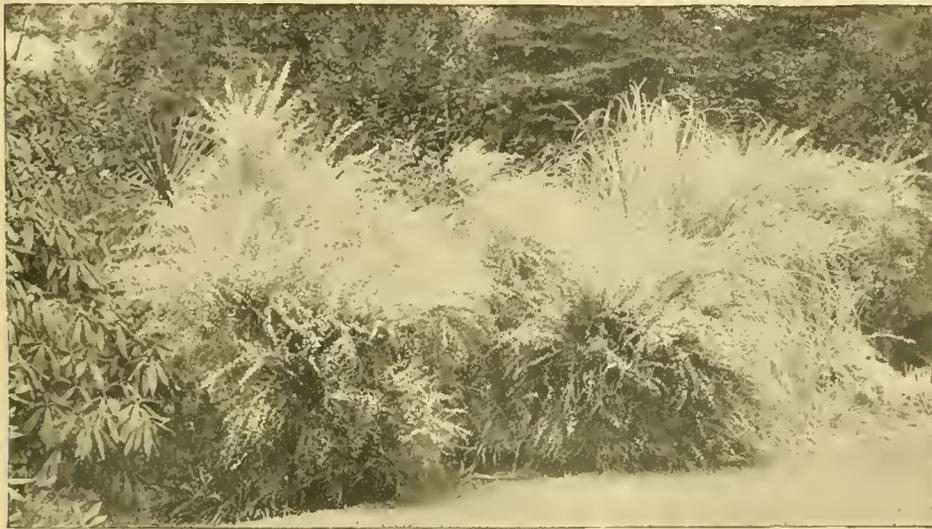

CYTISUS PRÆCOX.

It is now more than thirty years since this beautiful shrub was first noticed by the late Mr. G. Wheeler, of the Warminster Nurseries. He found it growing in a bed of seedlings of *Cytisus purgans*, and it was, as was afterwards proved, a hybrid between that species and the white Portugal Broom (*C. albus*). From Mr. Wheeler's plant the thousands now scattered over the gardens of this and other countries have, I suppose, all descended. The cross had no doubt been effected by a bee or other insect; indeed, there does not appear to have ever been a hybrid raised artificially between any two members of the hardy shrubby Leguminosæ. I cannot, at any rate, call one to mind. *Cytisus kewensis*, in its way as distinct and beautiful a shrub as the one now figured, appeared also as a chance seedling among a sowing of *C. Ardoini*, one of its parents.]

Cytisus præcox is, as a rule, in flower by the middle of April and continues from that time

neglecting the plants when young; at any rate, it may be deferred by proper attention at that time. The plants simply require to be topped with a knife occasionally from the time they are a few inches high till they are 18 inches or so high. By this means a thick crop of branches near the ground is obtained, as seen in the illustration. I have not seen this shrub more than about 8 feet high, but no doubt it will grow taller. It seems in stature to follow the pollen parent (*C. albus*) closer than *C. purgans*, which makes a sturdy, compact shrub with little or no pruning.

The best way to propagate *Cytisus præcox* is by means of cuttings. These may be taken in August and dibbled firmly into sandy soil in some shady, sheltered corner under a bell-glass or handlight. It ripens seed in any quantity, but only a small proportion comes true. Some of the seedlings revert to the yellow-flowered *C. purgans*; others produce various forms intermediate between that species and the pure white *C. albus*. It is, I believe, sometimes the practice to propagate it by grafting on roots of common Laburnum, but longer-lived, better

Cytisus præcox. From a photograph sent by Mrs. Tatton, Wythenshawe, Northenden.

well into May. There are many beautiful shrubs in bloom then, but it would be difficult to find among them one to surpass this Broom in the beauty and wealth of its blossom. It is essentially a shrub for every garden. In habit it is free and graceful, making each year when in vigorous health shoots 1 foot or 1½ feet long. These are clothed almost from end to end with a profusion of soft sulphur-yellow blooms—so abundant, indeed, are they, that there is little else but flowers to be seen when they are in full bloom. But even out of flower this shrub has its uses and attractions. It produces a thick mass of shoots, which, although almost destitute of foliage even in summer, are themselves of a lively green and give the shrub quite the character and value of an evergreen. The odour of the flowers, whilst not exactly offensive, is too heavy and powerful to be pleasing, especially when the plants are grown in a large group. For this reason it should not be planted close to dwelling-room windows and such like places. Like several others of the taller Brooms, this is liable in time to become bare and leggy at the base. This condition, however, is often in a great measure due to

plants are got with less trouble by means of cuttings.

A word may be here appropriately introduced in favour of *C. purgans*. Considering the beauty of its golden-yellow flowers, which appear as early as those of *C. præcox*, it is curious that it is now so neglected. It has not the vigour of its hybrid progeny, and, according to my experience, is healthier and better when raised from seed than when propagated by any other means, even by cuttings. It is grown in some nurseries under the erroneous name of *Genista anxantica*. W. J. BEAN.

Philadelphus grandiflorus.—Under this name I have a small tree of the so-called Mock Orange that eclipses every sort I have seen in the size of the individual flowers. In a small state it is very striking. This would seem to be a mid-season variety, as many are over, but there remain a few still to come into bloom. For cutting the Mock Oranges are by most people avoided because of their sickly and powerful scent. A spray or two arranged in small vases would be admissible in cases where highly-scented flowers are not objected to, the pure white of the blooms and enormous size making up a most dis-

tinct and desirable flower. Nature seems to have endowed *P. grandiflorus* with a habit to suit the flower, for I notice the blooms are thinly disposed instead of clustered on the branching growths.—W. S.

TREES AND SHRUBS IN BLOOM IN DEVON.

ABUTILON VENILLARIUM is again in full flower, its long curving shoots studded with crimson, gold-centred pendent blossoms. This is one of the most persistent bloomers that we have, carrying its flowers into November and December in mild winters, and often commencing to bloom again after an interval of about four months. Both the white and mauve varieties of *Abutilon vitifolium* have been flowering well in sheltered situations, but in exposed positions they suffered considerably from the late March frosts and have blossomed but sparingly. Large pyramid specimens of this *Abutilon* 8 feet or 9 feet high covered with blossom are particularly ornamental when seen standing in an open space amid surrounding foliage. This is also the case with the Strawberry Tree (*Benthamia fragifera*), whose pale yellow blossoms are thrown up to the best advantage by a background of verdant leafage. *Carpenteria californica* has been blooming in not a few gardens, and at the close of the month I saw a fine specimen some 6 feet in height and 8 feet through liberally set with its white scented flowers. Many of the *Ceanothus* family have also been in flower, their blue tints being especially effective when contrasted with the white blossoms of the Mexican Orange Flower (*Choisya ternata*). In the early days of the month the Ghent Azaleas formed a brilliant display with their suavely harmonising hues of fiery scarlet, orange, saffron, sulphur, and cream, while towards its close the *Cistuses* bore their fragile blossoms, the yellow, maroon-blotched *C. formosus*, the white *C. florentinus*, and the large white *C. ladaniferus maculatus*, with clarot-coloured spots at the base of each petal, being especially noticeable. The pure white *C. ladaniferus* is apparently uncommon in the south-west. In Spain it grows in quantity upon the steep hillsides, the large white flowers being about 5 inches in diameter. Many varieties of *Crategus* have been in flower throughout the month, some being in full blossom up to the concluding days. *Cytisus Andreanus* swathed its shoots in gold and chestnut; and the yellow Broom brightened the shrubberies with its gleaming yellow. The former appears to come true from seed, as I saw a bush which had been raised from seed and which bore flowers the exact counterpart of those of its parent. *Deutzias*, double and single, have been white with flower, and many specimens of *Dracaena australis* have perfected their odorous flower-spikes, one plant about 8 feet in height bearing two large spires of bloom, each nearly 3 feet in length. The Fire Bush (*Embotrium coccineum*) bore its vermilion flower-clusters well into the month of June, and *Escallonia macrantha* and *E. Phillipiana* have been in bloom. The *Habrothamnus* and *Hedysarum coronarium* are also flowering, as is the yellow *Jasminum revolutum*, which in some gardens is grown in bush form. The Mountain Laurel (*Kalmia latifolia*) carries its clusters of cupped blossoms, white, with the faintest tinge of pink, and the old Portugal Laurels have been smothered in the profusion of their ivory-white bloom-spikes, whose heavy odour is somewhat oppressive on breathless days. The Tulip Trees (*Liriodendron tulipifera*) have borne their daintily-tinted blossoms of fawn, yellow and green, but no white chalice has as yet expanded on the great standard *Magnolia grandiflora*. Last year the first blossom opened on May 10, and the two preceding years on June 21 and June 15 respectively, though in 1895, after the severe frost, the early buds were all killed back, and it was September 21 before the first flower opened its petals. *Ozothamnus rosmarinifolius* has bloomed most lavishly, every branchlet being hidden beneath a layer of minute tightly-packed flowers that are exceedingly fragrant. The blossoms last a long while on the

shrub, and sprays if cut and dried retain the flowers throughout the winter. Of the Daisy bushes, *Olearia stellulata* and *O. Gunni* are thickly set with their white star flowers, while the *Syringas* have commenced their odorous blossoming, and on moonlit nights stand wraith-like in their shimmering apparel by the side of winding garden ways. *Philadelphus speciosus*, which bears a flower of snowy whiteness over 2 inches in diameter, is the most effective of all the *Syringas*, but the charming *P. mexicanus* with its small, cupped blossoms is a particularly choice shrub. *P. grandiflorus*, *P. hirsutus*, *P. Gordonianus*, and *P. microphyllus* have been in bloom amongst other varieties. The New Zealand *Flaxes* (*Phormium*), both the type and the variegated form, have sent up their towering dark red flower-stems, and great bushes of the Jerusalem Sage (*Phlomis frutescens*) are bearing their yellow flowers on the cliff-edges. Many specimens of the hardy Palms, *Chamærops Fortunei* and *C. humilis*, are producing their large bloom-clusters, now bright yellow in colour. In the opening week of June *Panlownia imperialis* still retained its lilac-blue flower-spikes, and the Fuchsia-flowered Currant (*Ribes speciosum*) and the Golden Currant (*R. aureum*) were bright with their blooms of vivid crimson and yellow, while many *Rhododendrons* made gorgeous pictures. The False *Acacias* (*Robinia*) bore their drooping bloom-tassels of white or pink, and appeared to the best advantage when backed by Copper Beeches. *Rubus palmatus*, the so-called Strawberry-Raspberry, can scarcely be termed a shrub since it is practically herbaceous, but, though dwarf, it is distinctly decorative, its deeply pinnate leafage and large white, Blackberry-like flowers rendering it decidedly ornamental. Great bushes of *Solanum crispum* bore clusters of mauve, yellow-centred blooms. *Styrax japonica* has flowered, and many of the shrubby *Spiræas* perfected their inflorescence, amongst the most noteworthy being *S. flagelliformis*, *S. bella*, and *S. Bumalda*. Guelder Roses were white with nodding flower-heads, the Japanese Guelder Rose (*Viburnum plicatum*) being of remarkable beauty and purity, and the hush Honeysuckles (*Weigela*) in their many varieties have also added much to the interest of the garden, the pure white form and the dark maroon *Eva Rathke* being particularly noteworthy.

S. W. F.

Torquay.

THE TWO ELMS.

THERE are more than two species of Elm, but the two species generally recognised as timber trees in this country are *Ulmus campestris*, or common English Elm, and *Ulmus montana*, Wych or Scotch Elm, and some confusion appears to exist about these. Professor Marshall Ward says that *U. montana* "is difficult to distinguish" from *U. campestris*: whereas it is certain that the two varieties generally grown as timber trees and distributed by nurserymen are so thoroughly distinct in habit, foliage and general appearance, that they can be distinguished at a glance near or at a distance. *Ulmus montana* is described by the writer on trees in the "Encyclopædia Britannica"—where one expects correctness of description—as a tree usually attaining a height of 50 feet, but reaching 120 feet when drawn up among tall trees, a fact that speaks volumes for density, but both statements are off the mark, as the tree when full grown considerably exceeds 50 feet anywhere, and does not often attain 120 feet under the most favourable circumstances. The description of the general habit of *U. campestris* in the Encyclopædia applies to *U. montana* more than to *U. campestris*. Brown asserts that *U. montana* is not much cultivated in England, *U. campestris* being preferred; whereas it is grown far more extensively in woods and parks in England than the other, its timber being preferred, being tougher and more useful for many purposes than that of the English Elm. In these respects the qualities of the two trees are very marked. The timber of the English Elm is hard and close grained, and is useful where these qualities are

needed, but at all ages it is brittle compared to the Scotch Elm. If even the one or two-year-old twigs of the two are bent by the fingers, this difference of texture will be seen. From growth to old age the English Elm has a stiff and rather stumpy appearance, and it sheds its leaves a fortnight later than the other. In some old avenues that I am acquainted with the two varieties are mixed, and the difference between the two is seen. The Scotch Elm grows as tall as the English Elm, but has longer, wide-spreading limbs, cleaner furrowed bark, and a partly weeping habit at the extremities of its branches, qualities which render it one of the finest of park trees. Some of the tallest and finest examples to be seen grow in the New Forest in the parks near Beaulieu. The Dutch or Sand Elm is a large growing tree, said to be like the Scotch Elm, but the Elm one sees growing commonly in Dutch pastures is the English Elm, *U. campestris*. In Yorkshire the English Elm is called the Dutch Elm by timber merchants, and the Scotch Elm is regarded as the English Elm. Buyers are very particular in distinguishing between the two, as the one cannot be substituted for the other for many purposes, and the Scotch Elm is generally preferred. In plantation culture this variety produces a tall, clean stem, which in fifty or sixty years reaches a useful size, fetching about 1s. per cubic foot; very large butts fetch more.

The Elm grows in a great variety of soils, poor and rich, its rapid growth depending more upon shelter than upon the quality of the soil; hence the tallest and cleanest trees are usually found in the densest part of the wood. Near here the Elm and a variety of forest trees are thriving on the "pit hills," which were planted about forty years ago, these hills, as they are called, being the huge mounds of blue shale from the coal pits, and got out in working the coal. Cattle are very fond of the young shoots and leaves of the Elm, and park trees are regularly cropped by cattle and horses as high up as they can reach. I noticed in some parts of the forest regions of Germany, where the cows are fed in the house more than in the field, that the women field hands who passed my window in the evenings often carried back-loads of leaves and twigs of the Elm and other trees for their cows to eat, and which, I was told, formed a considerable part of their food. In German forestry works, trees the foliage of which provide good fodder for cattle are noted; hence probably the reason why the value of trees in that respect is better understood on the Continent than in this country. The Elm not being one of the most extensively grown timber trees, diseases that attack it do not attract notice so much, yet it is one of the trees that suffers severely from the attacks of two beetles—*Scolytus destructor* and *Hylesinus vittatus*—one of which attacks the top branches of the tree and works downwards. In setting out a fall of timber in a mixed wood last year, hardly an Elm was free from signs of this pest, while numbers were dead, or so far gone that they had to come down. The district was, however, smoky and unsuitable for trees, which perhaps promoted the ravages of the pest.—J. S., in *Field*.

Robinia neo-mexicana.—The Robinias (or *Acacias*, as they are commonly called) are flowering better this year than they have done for some time, this being due no doubt to the prolonged hot, dry weather of the autumn of last year. This New Mexican species, which is a plant of comparatively recent introduction, is certainly flowering better than it has done hitherto in this country. A small tree about 15 feet high in the collection of Leguminosæ at Kew is bearing a large number of racemes, and is distinct enough to be recognised among all the other Robinias at a considerable distance. The flowers are of a pretty rose colour, deeper in shade than those of any form of the common species (*R. Pseudacacia*); indeed, of almost as fine a rose colour as that of the flowers of *R. hispida* (the Rose *Acacia*). They appear in pendent racemes about 6 inches long. The single flower is larger than in *R. Pseudacacia*,

the standard petal being nearly 1 inch across. The whole raceme is very like a small one of *R. hispida*, but this is a shrub only, whilst *R. neo-mexicana* is a tree. The species is a decided acquisition, and although it comes from such States as Colorado and Arizona, besides New Mexico (from which it takes its name), it is perfectly hardy. It is the only species of *Robinia* found on the western side of North America. First discovered by Dr. Thurber in 1851, it did not reach cultivation on the eastern side of the United States till 1882, and five years later was sent to Kew.—W. J. B.

NOTES & QUESTIONS.—TREES & SHRUBS.

Syringa Emodi.—It is a pity this Lilac is not more frequently seen. It has many good points to recommend it, not the least being its large heads of white flowers standing erect and its late flowering. It is blooming grandly, and making a fine show now (at the end of June) with me. When this and the late-blooming *Laburnum* are placed somewhat close together they harmonise and give a piece of fine colour.—J. CROOK.

Genista cinerea.—This is a decidedly attractive member of the Broom family that produces its rich yellow blossoms about the end of June. It is of upright growth, reaches a height of 4 feet to 5 feet, and does not flower till many of the Brooms are over. This *Genista* is a native of South-western Europe, but is not much known in this country. Like most of its immediate allies, it is less affected by drought than many other shrubs.—T.

Spiræa bracteata.—This Japanese species of *Spiræa* merits a place among the more desirable of the shrubby kinds, as it is free in growth, flowers profusely, and as a rule seems to be proof against spring frosts, which, at least in the case of some, play havoc with the future display of bloom. It forms a bold-growing bush 5 feet to 6 feet high, that during the flowering period is thickly studded with rounded clusters of white blossoms. Like the other members of the genus, a fairly moist soil is essential to its well-doing.—T.

Deutzia discolor purpurascens.—I was greatly interested in the note by W. J. Bean (p. 422, June 17) on the above *Deutzia*, and was delighted to find he could bestow such praise upon it as growing at Kew. I had formed a very favourable opinion of it from small plants growing here, for they bloom freely, the colour is charming, and it is apparently a good grower. The specimens are too small to enable me to form a definite opinion upon its merits as an all-round hardy shrub, but I am pleased Mr. Bean is in a position to do so.—J. ROBERTS, *The Gardens, Tun-y-bwlch, N. Wales*.

Escallonia langleyensis.—This pretty and interesting *Escallonia* was recently shown in good condition at the Drill Hall. It is of hybrid origin, the parents being *E. macrantha* with pink blossoms, and *E. Philippiana*, whose tiny white flowers are borne in the greatest profusion. In this hybrid the flowers more nearly resemble those of *E. Philippiana*, but they are of a pleasing shade of pink. It is a decided acquisition to this pretty class of flowering shrubs, and one that will doubtless in time become popular. This is the second *Escallonia* of hybrid origin that we have had within recent years, *E. exoniensis* being the other.—H. P.

Bulbous plants at the Temple show.—In addition to the Lilies, Irises and Tulips, various other bulbous plants were represented. Many of the Mariposa Lilies (*Calochorti*) were shown in bloom, amongst which were *C. Purdyi*, *C. roseus*, *C. Benthami*, *C. pulchellus*, *C. amicus*, *C. citrinus*, and *C. venustus oculatus*, this last being the only one of the larger-flowered section in bloom the date being a full three weeks too early for the handsomest of the *Calochorti* to be at their best. A good collection of spikes of *Ixias* was shown, the most charming of which was the sea-green and purple *I. viridiflora*. Of *Sparaxis*, Five King was particularly brilliantly coloured. *Brodieas* and *Tritonias* were also exhibited, and of the early *Gladioli*, the exquisitely tinted *Blushing Bride* and *delicatissima* were very charming, as was *Salmon Queen*, while the brightly coloured *insignis* was particularly

attractive. It is a pity that these beautiful flowers are not more generally grown in gardens where *Gladiolus* The Bride flourishes and increases year by year, and there are not a few such gardens in the south-west, since there seems to be no reason why, under similar conditions, these other early forms should not succeed equally well. The Quamash was represented by *Camassia esculenta*, *C. cusicki* and *C. leichtlini alba*. These handsome bulbous plants are too rarely seen in gardens. *Ornithogalum arabicum* was shown in fine bloom, and *Fritillaria pyrenaica* and *Trillium stylosum* were also to be seen in flower.—S. W. F.

FLOWER GARDEN.

ASTER STRACHEYI.

THIS, it may be said, is one of the dwarfest of this great genus. It is, however, a good distinct early-flowering species from the Western Himalayas, and by reason of its earliness alone may be of some service to the hybridist if associated with the other early-flowering alpine kinds. The plant usually flowers in May or early June, and is therefore in touch with *A. alpinus* and its varieties, as also the North American *A. pelegrinus* that blooms at much the same period. *A. Stracheyi* is a comparatively recent introduction, having been known in cultivation a dozen years or so. The plant, little more than 6 inches or 8 inches high, bears flower-heads of a pale lilac-blue shade, each about 1½ inches across. In habit of growth the species is less vigorous than *A. alpinus* vars., with obovate leaves from the radical portion, those on the creeping stems or stolons, so clearly shown in the accompanying illustration, being much smaller. This pretty species is worthy of good cultivation in the rock garden; indeed, if at all neglected would soon present a poor appearance by reason of its small size. In rich and gritty loam this little species spreads out more quickly than when grown in pots where but a limited supply of soil exists, and smallness of stature should not be taken to mean a small amount of soil to grow in particularly with these high mountain plants. The flower-heads in the illustration are apparently of larger size than I have seen in this species, but which I accept as the outcome of good culture and suitable environment. Indeed, good culture often brings out characters in size and colour in such things that by ordinary methods are too frequently kept in abeyance.

E. J.

Clematises.—Many a garden archway and pergola are now beautified by the large pale stars of the earlier-flowering Clematises. Of these, *Lawsoniana*, pale mauve; *Gloire de St. Julien*, white, shaded mauve; *Anderson-Henryi*, white, with dark stamens, and *Excelsior*, deep mauve, are amongst the handsomest, some of them under liberal cultivation producing flowers almost a foot in diameter. The hybrids of *Clematis coccinea*, ranging in colour from pale flesh to deep rose, are also pretty with their bell-shaped contour, *Duchess of York*, *Grace Darling* and *Countess of Onslow* being especially attractive. The alpine *Clematis* (*Atragene alpina*), with its gracefully fashioned blue and white half-opened stars, has a charming effect when seen festooning an old trunk or clambering over rockwork. There is also a totally white form of this latter plant.—S. W. F.

Lilies and Irises at the Temple.—A fair number of Lilies was exhibited in bloom at the Temple show, amongst these being the beautiful *L. Szovitzianum*. *L. Hansoni* and its two hybrids, *L. Dalhansoni* and *L. Marhan*, were present, as were the bull *L. excelsum* or *testaceum*, the yellow evil-smelling *L. pyrenaicum*, numerous varieties of *L. umbellatum* and *L. Thunbergianum*

of various shades of orange-red, *L. Martagon album* and *L. longiflorum giganteum*, but of *L. rubellum* only one or two puny plants were shown, specimens in no way comparable to those exhibited in 1898. It is to be hoped that this does not mean that this beautiful Lily does not possess the hardy constitution attributed to it when it was first distributed, but I have known cases where it has failed to appear above the ground this year. Another plant that in 1898 was exhibited at the same stand where the fine specimens of *Lilium rubellum* referred to were shown was conspicuous by its absence; this was *Watsonia iridiflora*, whose tall white flower-spikes were so effective last year. Of Irises there were good collections of the German Flags and the Spanish sections, while *I. Korolkowi*, *I. K. violacea*, *I. K. Leichtlini*, *I. susiana*, *I. lupina*, *I. Leichtlini*, *I. missouriensis*, *I. Tolmieana*, *I. virginica* and forms of *I. sibirica* were shown.—S. W. F.

ROCK AND DWARF PLANTS AT THE TEMPLE.

AMONGST the collections of plants for the rock garden the following were noticeable: *Achillea argentea*, *A. mongolica* with its tall scapes of white flowers, *Adonis vernalis* with its yellow blooms and fennel-like foliage, and *Antennaria dioica rosea* with its bright pink corymbs of flower. *Anthericum liliastrum maximum* bore its white blooms, *Antirrhinum asarinum* and *Anthyllis atrorubens* were flowering, and *Arenaria*

Aster Stracheyi.

montana and *A. grandiflora*, as well as *A. verna*, were to be seen bearing their white flowers, and the rare little *Asperula hirta* was present, as was *Aster alpinus*. *Delphinium nudicaule* was conspicuous with its scarlet blooms, and *Dianthus alpinus* and *Dielytra formosa* were among the collections. The American Cowslips were represented by *Dodecatheon elegans*, *D. Jeffreyanum*, *D. Meadia*, and *D. M. album*, *Edraianthus serpyllifolius* and the white-flowered *Epimedium niveum*, the orange-bloomed *Erigeron aurantiacus*, the purple *E. Roylei* and *E. salsuginosus* were on view, while of the *Gentians*, *G. verna* and *G. acaulis* displayed their deep blue, and *Geum Heldreichi* and *G. montanum* were effectively shown. The Himalayan *Gypsophila cerastoides* was bearing its white flower-heads, and *Haberlea rhodopensis* its pale lilac blooms. The white-flowered *Helianthemum umbellatum* was in evidence, and *Heuchera sanguinea* bore its coral-red bloom-spires, while *Hippocrepis comosa* revealed its yellow Vetch-like flowers, and the little *Hutchinsia alpina* was also in bloom. Candytufts were represented by *Iberis gibraltarica*, *I. linifolia*, *I. Little Gem*, *I. sempervirens*, and *I. superba*. *Ionopsidium acaule* showed its countless minute flowers of palest mauve, *Linaria hepaticifolia* and *L. origanifolia* were in blossom, and of the *Flaxes*, *Linum alpinum* was bearing its blue flowers and *L. arboresum* its bright yellow blooms. *Leiophyllum buxifolium prostratum* was shown, as were *Lychnis alpina* and *L. dioica*

rubra plena, *Menziesia polifolia alba*, and the yellow-flowered *Morisia hypogea*. *Onosma tauricum* was bearing the drooping bells that earned its name of Golden Drop, and *Ononis rotundifolia* its rose-coloured blooms, while the somewhat intractable *Ourisia coccinea* displayed its vermilion flower-spikes. The delicate little *Papaver alpinum* was exhibited. *Potentilla rupestris* and the yellow *P. verna* were also present, as well as many of the dwarf *Phloxes*, of which *Vivid* was the most striking, while *Primula luteola* was also shown. *Ramondia pyrenaica* carried its mauve-blue flowers, *Ranunculus monspeliensis* showed its blooms of polished gold, and *R. platanifolius* was also represented. A large pan of *Saponaria ocymoides alba* covered with white blossoms was a pleasing object. Many *Saxifrages* were shown, *Smilacina* (*Maianthemum*) *bifolia* was bearing its delicate little white flower-spikes, and *Trientalis europea* its white *Omphalodes*-like blossoms, while *Veronica gentianoides taurica* and *Viola pedata* were to be seen in flower.

S. W. F.

NOTES ON HARDY PLANTS.

Veronica Fairfieldi.—This is one of the very dwarf evergreen species from New Zealand, most, if not exclusively, fitted for the rock garden or the company of alpine; hence its classification with plants as above. There are two specially commendable features about this plant, and they have induced me to make this note. They are (1) early flowers, and (2) plenty of them. Of course, these features are spoken of only in relation to other of the new kinds of the dwarf Veronicas, many of which give a paucity of flowers and some practically none at all, and generally those that do flower are rather late. The present kind has been in bloom with me in Yorkshire since the middle of May, and the flowers are in spikelets from all the axils of the upper leaves, which are small, thick, and glossy. The effect of the little bushes, only 6 inches or 8 inches high, is both pretty and uncommon, and they at once suggest themselves as suitable material for rocky fissures in sunny aspects.

Silene pusilla is the name of a plant I wish everybody could see at its best about June, though it begins in April and lasts with a fair show until September. I believe it is a variety or near relative of *quadrifida*, from which, by those who know that excellent creeper, its habit and masses of starry pure white flowers will in some measure be realised. It is a gem amongst alpine, its herbage scarcely more than Moss-like, and the dainty flowers only 2 inches to 4 inches high. Moreover, it is a reliable plant. You hardly ever see a gap when it has once been planted carefully. It not only runs slightly, but in spring it breaks back to the centre of the plant again. It also comes from self-sown seed, and it is, I think, by such development more than anything else that you may be sure you have it under the right cultural conditions, and that you will not be likely to lose it. I mention this because I know some expert growers of alpine plants have lost it more than once. Give it a moist, flat position on the rockery, a bit of chalk in the soil, and so much fibrous loam or sand that the surface of the soil can never cake with hot sunshine, and with here and there a boulder on the top to check evaporation, and I cannot think this all-summer bloomer will fail you; indeed, conditions like these would suit almost all the other alpine *Caryophyllaceae*, always supposing that capillary attraction had not been cut off by faulty building.

Gaultheria trichophylla.—I think it is some nine years ago that I introduced this to commerce, and still, though so very beautiful, one rarely meets with it except in the collections of the most advanced class. Just now the plant, which is but 2 inches or 3 inches high, is covered with its bell-shaped flowers, big for the size of the plants, and which will so soon be succeeded by the big sky-blue berries, which look like small blue eggs resting on the ground among the minute twigs. In the same conditions as *G. pro-*

cumbens it does fairly well, or with a little more peat it does splendidly. It, however, needs a fairly pure atmosphere, being very hairy in the foliage. I learn this from seeing the plant do so much better in other gardens than my own where they are not reached by smoke, or at least not Leeds smoke. Besides, we may usefully keep in mind that this Himalayan species has an alpine habitat of 1400 feet.

Campanula tridentata is lovely when seen in flower, as it is on this first morning of June. The flowers remind one of those of the Platycodons, and the whole plant of a dwarfed and perennial *Campanula Wanneri*. Most of the leaves are radical and have long stems.

Viola pedata.—No one can see this and its varieties without feeling that its beauty is of the most pronounced kind, but it does not flourish in every garden. I heard it asked the other day by a gentleman who has grown most things in his time in the way of hardy flowers, "Has anyone ever succeeded in making *V. pedata* flourish and increase in this country?" Whilst the question fairly indicates the difficulty about the culture, I certainly could answer from experience that the plant could be grown well. It is a bog plant practically; treat it as such, and get good fresh specimens for a start, not such as have the knobby crowns pulled asunder and then remain some time unplanted, but entire plants with long roots untern. The same roots just before planting may be cut off to 2 inches long. The best plants are those established in pots, which may be set out in early summer, when they start freely into growth. Be sure they are clear of green-fly.

Gentiana bavarica.—Certainly this is not one of the most difficult of all alpinos to grow, nor even the more so of the plants of its own genus. It is all-important, however, to transfer the plants at the right time, which, according to my experience, is late September or early October. You need to get the benefit of the autumnal issue of roots. Of course, it is totally different and much easier if you secure established pot plants; then a soil made up of humus and sand in a moist and sunny place is all that is needed. The plant is smaller than *vena* in all its parts except the flowers, which are larger (much longer in the tube) and darker blue, and without the distinct white eye of the flowers of *G. verna*. It is true that *imbricata* is commonly met with in collected plants; it is but a variety of *bavarica* of L., and often passes under the typical name in commerce. Still, it is a well-marked form in the way that its name indicates. J. WOOD.

Woodville, Kirkstall.

Early Gladiolus Ackermanni.—This early-flowering *Gladiolus* merits more than ordinary praise. The colour may be described as a warm orange-salmon. The main attraction is centred in the blotches upon the three lower petals. Each blotch is composed of pure orange on the outside and the inside commencing with rich lilac shading off to pale pink, a lovely combination of tints. These *Gladioli* succeed well in warm borders under greenhouses in a mixture of peat and loam, afterwards mulching them with peat moss litter. By affording frequent waterings in very hot weather a lovely display is assured. The bulbs are best lifted in autumn and replanted in spring, but they will stand an ordinary winter if the beds are well covered with leaf soil.

Carnations failing.—Many of my Carnations this spring have been very unhealthy: the points of the leaves first become yellow, then the whole shoot withers and soon the plant perishes. This has been going on since February. They are grown in a border at the bottom of a hill, which is rather damp in winter, although well drained, as there is a sunk road immediately below the border. I enclose a whole plant and also shoots of others for your inspection, and should be glad if you would inform me of the cause of the unhealthiness, also what I could do to remedy it. We had a cold and wet spring followed in June

by a long drought. Up till now Carnations have done very well in this garden, and the border is changed about every two years.—ANNIE F. DAVIE.

* * * Your Carnations shoot duly to hand. In one of the shoots that you send we found symptoms of wireworm, and we have no doubt this is the cause of your plants failing. The only way to get rid of the enemy is to grow your Carnations in another part of the garden. Into the piece of ground now affected with wireworm it will be well to fork, after the Carnations have been removed, a good dressing of gaslime, letting the ground lie fallow for a year, frequently stirring it with a fork or hoeing deeply. You can in the meantime put thick slices of Carrot on the ends of pointed sticks, burying these 2 inches or 3 inches in the ground and examining them daily. The wireworm will be found feeding on the Carrot slices and can be destroyed. It is not advisable to grow Carnations in the same soil for two years in succession.—ED.

NOTES FROM NEWRY.

SEVERAL uncommon shrubs and plants have flowered here this season, amongst them *Sorbus* (*Pyrus*) *thiansbanicus*, a most distinct dwarf growing tree. Although my largest specimen is only about 8 feet high, it has ten main stems besides many secondary ones, all of which are ascending. The flowers are borne in terminal, corymbose panicles, and, unlike any other Mountain Ash, are bell-like and pendulous, so that they a good deal resemble those of *Andromeda formosa*; it sets its fruits very sparingly. *Onosma tauricum album* has been very beautiful; the habit, foliage, and flowers are exactly those of *O. tauricum*, but the flowers are waxy white. *Eriogonum compressum* is very distinct. The habit of the plant is very compact, leaves in rosette-like tufts, the creamy white flowers being borne in close capitate heads each 2 inches to 2½ inches across on stems a foot high. *Fendlera rupicola* is a near relative of the *Philadelphus*, with slender, erect shoots, small dark green leaves and handsome white star-like flowers very freely produced. Seedling plants of *Iris tenax* are growing very well in rather elevated ground and in a relatively dry situation. The peculiarity of this is that imported plants refuse to thrive in such a situation, and usually dwindle away unless they are planted in a swamp. These are flowering freely at two years old, and there is a good deal of variation amongst them, the reddish tinge being in some cases much deeper than in others. *Rosa rugosa* × *R. polyantha*, a chance seedling obtained here, is of vigorous habit, my big bush being 10 feet or so across and about 8 feet high; the pure white flowers are borne in the freest possible way, and the petals, unlike those of any other Rose known to me, have serrated margins. *Rosa rugosa* × *rubiginosa*, also a Newry seedling, is of vigorous habit with arching branches, the flowers each about 3 inches across, deep rose in colour and produced in the freest possible way, so as to form close racemes half a yard long. It is also one of the handsomest of fruiting Roses, the fruits being slightly pendulous and of a bright red sealing-wax colour. In *Iris ocaurea*, a seedling from *I. aurea*, the falls are broad and much shorter than in either of its assumed parents, buter yellow in colour, with a very narrow margin of creamy-white, the standards short and broad and similar in colour to the falls. The scape is 5 feet high. It is a very handsome plant. *Enkianthus cernuus ruber* is unlike any other member of the genus known to me; the branches are more or less horizontal, the flowers dull red in colour, pendulous and looking much like bunches of Red Currants. *Enkianthus japonicus* has also flowered freely this season; the blooms are of the purest white, solitary and distributed all over the bush apparently without any order whatever. *Delphinium trolliifolium* deserves a word of praise apart from its being the first of the species to flower. The habit is distinctly pyramidal and the colour a very good shade of blue.

Amongst many combinations worked out this season, a corner of *Lastrea dilatata* filled in with *Hedysarum multijugum* is now very pretty; indeed, the pinnate leaves of the latter harmonise perfectly with the Ferns, while the whole topped with the brightly coloured flowers is most satisfying. T. SMITH.

BORDER FLOWERS AT THE TEMPLE.

WINDFLOWERS were represented by *Anemone alpina* and its variety *sulphurea*, *A. palmata alba*, *A. sylvestris*, and *A. s. flore-pleno*, while the Pasque Flower (*A. Pulsatilla*) was displayed, bearing its pretty downy seed-heads. Of *Aquilegias* there was a charming bank of hybrids, with their long-spurred flowers, the very embodiment of grace, as well as the scarlet *A. canadensis*, *A. cœrulea*, and *A. Stuarti*, perhaps the handsomest of all the Columbines; but in many gardens, unfortunately, these three latter refuse to become established. The old double white Rocket (*Hesperis matronalis alba plena*) was represented by a sheaf of odorous bloom-spikes. This plant is one of the most valuable for the herbaceous border, as its blooming period is a prolonged one and it yields the palm to no flower in the sweetness of its perfume. Annual division and transplantation into fresh soil are, however, a desideratum if its vigour is to be maintained. The pink-flowered *Lathyrus Sibthorpi*, one of the earliest flowering Peas, was shown, as were spikes of *Libertia grandiflora*. This is a fine subject in porous soil and a warm locality, where it will grow to a height of 4 feet and increase rapidly, being a most decorative subject when white with blossom. Double varieties of the Iceland Poppy (*Papaver nudicaule*) were shown, but these are less graceful than their single sisters. Tufted Pansies were largely shown, some of the shades being especially charming. No lovelier surfacing for beds of Tea Roses can be imagined than these Pansies, their soft colouring setting off the fair blossoms of the Roses to the best advantage. Of the Globe Flowers (*Trollius*), Orange Globe is a splendid variety, being far larger than the type and of particularly deep colour. *Verbascum phœniceum album* is also a pleasing border plant. Some towering bloom-spires of *Eremurus robustus Elwesianus* and *E. himalaicus* were staged, as were a few flower-heads of the New Zealand Forget-me-not (*Myosotidium nobile*). This plant succeeds best if grown almost entirely in sea sand. *Incarvillea Delavayi* was shown in a few instances. This beautiful plant has bloomed well in certain gardens in South Devon this season, notwithstanding the cold of the late spring. Fortin's giant Lily of the Valley was on view, as was a fine form named *Victoria*. Terrestrial Orchids formed an interesting collection and were represented by *Cypripedium spectabile*, *C. parviflorum*, *C. pubescens*, *C. Calceolus*, *C. macranthum*, *C. acaule*, and *C. occidentale*.

A good collection of Bamboos and Japanese Maples was arranged in the open, near which examples of topiary work in the live Yew formed a useful object-lesson of the futility of such in-artistic methods. S. W. F.

Propagating Myosotis.—It is surprising the difference there is in the quality of the growth of Forget-me-nots year by year. In some seasons one has no trouble to get as many as one wants of the right sort for propagating, *i.e.*, nice, fresh, young and vigorous shoots that come away freely when planted out. In this case older material has to be used, in consequence of which the growth is late even when they are propagated early, and mildew sets in quite early in the season. In some cases growers have given up the dividing up of plants and rely on seedlings, as these are less likely to be attacked, but I have never found much trouble when the young plants have rooted and taken a good hold early. When they are taken from the beds to make room for summer bedding and allowed to lie about until this is finished, they are bound to be weakened and sure to take mildew badly. Here I choose as open a position as

possible for the Myo-tis, but where a little shade at some time during the day is secured. The plants are put into a piece of ground that has not been newly dug and well watered home at once. There are plenty of plants this season, but I do not like the look of them so well as last year, when they made a very vigorous summer and autumn growth, and were, if anything, too large at planting time.—H.

Mimulus Burnettii.—Mr. Robert Lindsay has in his new garden at Kaimes Lodge, Edinburgh, gathered together a most interesting collection of plants, among which are many rarities. A *Mimulus* which pleased me much has been named *Burnettii*, in honour of the raiser, I believe. It is a hybrid between *M. cupreus* and *M. luteus*, and has a good deal of the colouring and habit of the former with the hardiness of the latter. A truly hardy *Mimulus* of this nature is a valuable acquisition. At Kaimes Lodge a large pocket in the rockwork was filled with a mass of the deep orange flowers only a few inches above the soil. The garden is at present a good deal exposed, and will be until the sheltering belt of trees and shrubs planted by Mr. Lindsay grows up, but this *Mimulus* promises to be quite hardy there. The use of *M. luteus* as one of the parents may be noted as being valuable to some who may think of working upon these plants.—S. ARNOTT.

SOME OF THE NEWER TUFTED PANSIES.

By those who have closely followed the development of this plant during recent years a great change has been noted. If we are to interpret the ideas expressed by many, we ought to be absolutely satisfied with, say, about half a dozen sorts in about as many colours, these generally being represented by white, yellow, blue, purple, and perhaps two others with fancy markings. It is very easy to appreciate a few good self-coloured sorts, but to confine the selection to a limited number would be to lose the charm of a goodly number of those of an intermediate shade of colour. The beauty of a large number of the newer introductions is their soft and pleasing shades. Unfortunately, in the minds of prejudiced individuals these newer and refined shades of colour cannot be appreciated. The colours often are designated as washy and unworthy of a place in the hardy flower garden. Take the different shades of blue; it would be most unwise to confine the selection to one or two sorts represented by such as True Blue and the richer indigo-blue Archie Grant. The pretty blue-tinted mauve of Blue Gown, a perfect bedding plant; Magnificent, also a paler shade of blue, and Ophelia, a splendid heliotropa-blue, used in conjunction with these older kinds would each set off the beauty of the other. Again, take those of a lavender shade, and among these are some extremely beautiful sorts. The habit in almost every instance is what a Tufted Pansy should be—dwarf and spreading. Florizel may be described as a pretty lilac-lavender, very free on erect stems, and also a continuous flowering sort; and Kitty Bell, a new sort, makes a capital plant for massing with blossoms of pale lavender. The rose-coloured blossoms are worthy of notice, and as these are a limited quantity, additions of this colour should be highly prized. William Niel has been in cultivation for some time, but to this may now be added an excellent sort by name Magie, of a pretty shade of rose. The flowers are large and freely produced, and the constitution is robust. John Quarton, a deep mauve self, is a very effective bedding sort. Of yellows, many exceedingly fine sorts have been added to the list within the last two or three years. Prior to this there was quite a dearth of really first-class yellow varieties, but now, thanks to persistent work on the part of the hybridiser, the most fastidious taste can easily be satisfied. The finest introduction of the present year among the rich yellow sorts is undoubtedly a variety named Melampus. The flowers are of good size on stout foot-stalks, and produced on a plant with a perfect habit. It is a most persistent bloomer, and plants subjected

to constant division soon attain a good size and are literally covered with lovely rayless blossoms. There should be a good future for this variety. Early in the season—say until the middle of July—Pembroke is invaluable, and this is the parent of a promising progeny. Stephen is another rich yellow flower, useful for an early display. In this instance the flowers are neatly rayed. Of the paler shades we have a beautiful primrose in Primrose Dame, and with its neat orange eye this flower is very effective. The blossoms are large, almost circular, and produced on a rather strong-growing plant. Bouncer is a cross between the well known Ardwell Gem and Mary Scott, the flower retaining the sulphur colour of the former. Princess Louise, the bright yellow rayless flower, still retains its value as a good tufted sort, and may be noted as specially useful for late displays. Cream-coloured flowers may be had in Devonshire Cream, a remarkably free-flowering plant, having neat, rayless blossoms of a telling kind, and William Tell, a very large creamy white self with a rich yellow centre. Of white flowers, the prettiest and neatest of this season's introductions is White Beauty. I know of no other plant that has such a pretty creeping-like style of growth. The flowers are produced on fairly long foot-stalks well above the foliage, and the blossoms are of medium size and pure white. The constitution is splendid. Blanche and White Empress, which appear to be synonymous, are the best of the large cream-white flowers, and are very fine at all times. Masterpiece has medium-sized pure white blossoms and rayless. Anne is another rayless pure white. Councillor W. Waters is still a striking crimson-purple, free, robust, and with an excellent habit.

D. B. CRANE.

HERBACEOUS PÆONIES.

GREAT strides are being made in this section of Chinese Pæonies, not only in France, where they have longer been popular than with us, but also in England, where they grow and thrive perhaps equally well on deep, rich, and moderately warm soils. Their flowers are so varied in form and colour and so bold and beautiful as seen growing or as cut in the early opening stage for the house, that the wonder is they are not more grown for cut bloom and for market than is already the case. It would be a good thing if our flower show committees would make a special class for these noble and effective summer flowers. Cut with fairly long stalks and arranged either singly or three blooms in a vase, very effective groups would result.

The following are notes on a few very fine blooms of good, and in some cases new, varieties recently sent to me by Messrs. Clibran and Son, of the Oldfield Nurseries, Altrincham, Cheshire, who evidently grow these flowers to perfection and think a good deal of them at this season of the year. Amongst those I specially noted as above the average in beauty, so far as one can judge from cut flowers, were the following: Duke of York, Albert Crousse, Agnes Mary Kelway, Festiva maxima, Queen's Perfection, and Leonie. The present season has been a most favourable one for these flowers, and I never saw them bloom so well or last fresh and fair so long as they have and are now doing. As a rule their buds are apt to suffer from late spring frosts, and the blooms do not open so well during cold, wet seasons, but they are so noble that no efforts should be spared in growing them to perfection.

CRIMSON BLOOMS.

DUKE OF YORK.—Dark crimson, semi-double, central mass of petaloid stamens of a pale orange-yellow colour behind and incurved; very fine distinct flower.

M. GALLAUD.—Crimson-purple, double, very rich and full.

CRIMSON KING.—Rich dark crimson, full-petalled with median ring of golden stamens.

AUGUSTIN D'HOUE.—Very full double, crimson-purple.

ROSY BLOOMS.

EMILIE LEMOINE.—Full half-double, bright deep rose.

DR. BRETONNEAU.—Duplex or Anemone-like flower, guard petals rich bright rose-cerise, stamens petaloid, soft pale rose; very distinct.

DUGUESCLIN.—Anemone-like flower, guard petals soft rose, stamens petaloid, pale rose, fading to white, with central tuft of pale rose petals; distinct.

BEAUTÉ DE VILLICANTE.—Semi-double, soft salmon-pink or rose, with yellow stamens; delicate and distinct flower.

ALBERT CROUSSE.—Full double, cupped flower, petals soft rose or peach and serrated at the tips; exquisite bloom.

AGNES MARY KELWAY.—Anemone, with central tuft of rosy petals, guard petals lilac-rose with inner whorl of white, petaloid stamens like the florets of a Japanese Chrysanthemum; very distinct and effective flower.

FAUST.—Similar to the last in form, but paler; guard petals very pale flesh, petaloid stamens white, tuft of petals in centre rose; very delicate and effective bloom.

LEONIE.—This is one of the most superb blooms I have seen; full double, the broad and rose-like petals gently undulated and rarely slightly fringed. The colour is exquisitely pure, flesh, shading to soft salmon-rose in the centre of the flower, the guard petals shading off nearly to pure white. This variety has also a very delicious Rose perfume.

WHITE BLOOMS.

FESTIVA MAXIMA.—Very fine full double, pink in bud, fading to white; one of the best of its class and very free bloomer, bearing several flowers at top of each stalk.

SNOWDRIFT.—A beautiful Anemone-like flower, guard petals white, petaloid stamens white, ovaries dark crimson or chocolate; very neat and effective flower.

QUEEN'S PERFECTION.—A splendid semi-double bloom, guard petals white, flushed rose, cupped and fringed, petaloid stamens pale primrose or sulphur, with central tuft of white crumpled petals; fine distinct bloom.

F. W. BURRIDGE.

Canterbury Bells.—These are among the most charming hardy plants just now, and from a good strain of seed some exceedingly beautiful forms may be raised. I have a large number in the centre walk in the kitchen garden, a very fine effect being produced by the immense spikes of variously-coloured blossoms. One is a very beautiful shade of pink with fine graceful bells, while some of the whites are exquisite. I destroy all that show any tendency to doubling or the cup-and-saucer style, for in my opinion these are monstrosities not worth perpetuating.—H.

Seedling Delphiniums.—It is surprising what an amount of pleasure may be got out of the raising of seedling Delphiniums. I bought a dozen named varieties some four years ago and planted these among seedlings of my own raising, and the result has been very pleasing, many beautiful shades of colour appearing among seedlings since raised. I have noticed among the named kinds that the very deep blue kinds are often of weak growth, the paler ones being stronger, but I have one very richly coloured form that is only flowering for the first time, yet produces immense spikes for its size and the habit is very vigorous.—H. R.

Planting Pæonies.—Though doubtless the herbaceous Pæonies dislike being disturbed as much as most things, they would not have the bad name they have if the work of transplanting were carried out carefully and at the proper time. To leave Pæonies until February or March, then lift them and expect them to take a fresh hold and flower freely in May and June, is asking rather too

much; but taken up soon after the flowers are past and before the foliage has entirely died down, they will obtain a good hold and flower well. Nothing is much finer on the herbaceous border than large clumps of these very showy perennials, but it must not be lost sight of that they are strong-feeding plants, and if allowed to remain many years in the same position without thorough manurings in the form of top-dressings annually, they soon impoverish the soil in their locality. Then, of course, division becomes necessary, as such large clumps are seldom transplanted whole. This is simple enough, but more care than is usual should be taken not to break or damage the crowns and roots. Plants carefully divided and replanted here early last autumn have flowered well in the new positions.—H.

Eremurus himalaicus.—During the last twenty years or more several species of this tall and stately family have been introduced, and the two which have been most prominently brought forward have been *E. robustus* and *E. himalaicus*. The former reaches a height of from 8 feet to 10 feet, and the flowers, of a peach colour, are borne in a close spike about 2½ feet or 3 feet long. In a large garden it forms a conspicuous object, but the foliage is liable to be broken by high winds. *E. himalaicus* commends itself, I think, to most growers of hardy herbaceous things. I have had a good spike of it this year, and the flowers are very closely placed together, forming a dense spike; the colour is pure white and the spike about 1½ feet in length. Where a number of plants could be grown together they would form a very conspicuous object in the herbaceous garden in the month of June. It seeds freely, and many have been successful in raising plants from seed.—D.

Polygonum baldschuanicum.—Judging from the illustration which appeared in THE GARDEN of June 24 of the above new introduction and the interesting note accompanying it by "E. J.," it must be a splendid acquisition to our hardy herbaceous climbers and worthy of being extensively planted. I am pleased to inform "E. J." that it is in commerce, for I had a plant of it from M. Lemoine, and look forward to its proving distinct and effective as it gains in age and strength. It is very commendable of the numerous correspondents of THE GARDEN who have opportunities of seeing new and valuable introductions at Kew and elsewhere to bring them conspicuously to the front for the benefit of those who are less fortunate in that respect, but who, nevertheless, are as keen to possess and grow the good things as they are. I beg to tender my hearty thanks to all for their kindness and great assistance rendered in this way.—J. R.

East Lothian Stocks.—These beautiful Stocks are often seen in a very indifferent condition. Amateurs frequently fail in securing a healthy growth and fine bloom-spikes by giving too poor a root-run. Of course, too much manure is not advisable, this encouraging a rank growth. What the plants like is an open, loamy compost and about a fifth part well-decomposed manure dug in several months previous to planting. I have grown them in the same position year after year, but in that case the old soil should be removed and replaced with new to the depth of a foot or 15 inches. Mulching and watering are often neglected, and the plants when showing flower freely are much benefited by frequent applications of diluted liquid manure. Exhausted blooms should be removed, as if allowed to remain they quickly impoverish the plants and the flowering season is thereby shortened.—N.

Iris tingitana.—Observing a note on this Iris by "J. H. P." on page 458, I send a few lines which tend to confirm that note. I have had the plants in my garden for about twenty years, my first bulbs having been collected in Morocco by Mr. C. Maw. It is a most tantalising plant, flourishing and multiplying quickly, with bulbs as large as those of *Iris xiphoides*, but I have never had a flower on it either in a frame or under a south wall. I have seen it blooming in April in

Mr. Ewbank's garden at Ryde, and Professor Michael Foster has told me that it will flower at Shelford potted in a frame. A few years ago I sent a parcel of fine bulbs of it to be grown in the garden of my cousin near Bayonne, which is on a hillside facing due south and is a regular Dutch oven. There it thrives under a sunny wall even more than in my garden, but not more than one bulb in twenty flowers, so I must confess myself quite at a loss to know what its requirements are. It may perhaps like confinement at the root. I know that to be the case with *Iris filifolia*, another of the *Xiphium* section, which grows in the sunny crevices of the rock at Gibraltar, and which I have persuaded to flower with me once or twice by giving it as far as I can its natural conditions. I think perhaps the crevices of a sunny rockery or potting in a small pot and burying the pot under a south wall might

Pea Michaelmas. From a photograph sent by Mr. Wythes, Syon House, Brentford.

be successful in warm situations, but this is only conjecture, as I have never proved it.—C. WOLLEY-DOD, *Edge Hall, Malpas.*

Sempervivums at Rockville, Edinburgh.—Those who have a few *Sempervivum*s and have taken an interest in the plants cannot fail to have observed how uncertain is the nomenclature of the genus. Even if it could be reduced by an expert, or a body of such authorities, into something like order, it would only remain settled for a short time even if generally accepted, which is hardly likely. We must thus, I imagine, just rub along with the names as they are. Yet it is useful to see a large, carefully named collection. Such shows us little differences, perhaps unobservable unless the plants are near each other,

yet noticeable when grown together. At Rockville, Murrayfield, Edinburgh, Mr. Neill-Fraser has a large and most interesting collection of these *Houseleeks*. Apart from the flowers, which give a considerable range of colour or shade, the rosettes of foliage are exceedingly attractive in their own way. There are various shades of green, from pale yellowish green to a deep glaucous green, with brown and purple-coloured leaves. Then there are distinctions arising from the absence or presence of tomentum, such as is so plainly seen in the *Cohweb Houseleeks*. Some are hairy, while others, much alike to look at, are on examination found to be quite pubescent. There are, in fact, many little distinctions which add to the interest of a large collection. Apart altogether from small differences in appearance, dear to collectors, these *Houseleeks* are beautiful, and are not enough made use of to decorate our walls, roofs, rock gardens, and borders.—S. ARNOTT.

GARDEN FLORA.

PLATE 1231.

CYMBIDIUM TRACEYANUM.

(WITH A COLOURED PLATE.*)

THIS remarkable *Cymbidium* first flowered in the nursery of Mr. H. A. Tracey, of Twickenham, quite unexpectedly in December, 1890, and when exhibited at a meeting of the Royal Horticultural Society received a first-class certificate. A few days later the plant was put up for sale, when it was purchased on behalf of Baron Schroeder for 75 guineas. The plant remained the only known specimen until the end of 1894, when a second plant was offered for sale, this plant having flowered in Mr. Prewett's nursery at Hammersmith. Since that time it has appeared in several collections throughout the country. The flowers of none of the later introductions, however, can be compared in point of size with those of the original plant in The Dell collection.

The habitat of the plant has always remained mysterious, and no definite particulars, except that the later-flowered plants came from Upper Burmah, have as yet been recorded. The original plant was purchased at a sale of *C. Lowianum* by Mr. Tracey. All the other plants purchased at the same time proved to be *C. Lowianum*. The plants, which afterwards flowered in Mr. Prewett's nursery, were purchased from an importation, and were supposed to be *C. giganteum*; several turned out to be *C. Lowianum*, and there were also several *C. Traceyanum*. This would lead one to suppose that there is a possibility of these varieties growing close to each other. The plants that have recently flowered in continental collections were imported for and grown as *C. grandiflorum* (*Hookerianum*), but on flowering proved their identity with *C. Traceyanum*. The characteristics of the last-named are so intermediate between *C. grandiflorum* and *C. giganteum*, that there would be good grounds for thinking it possible to be a natural hybrid between these species were it known they grew together. The number of plants that now exist indicates pretty clearly that it must be fairly plentiful in its native habitat.

One of the most distinguishing features of *C. Traceyanum* is its peculiar root action; the whole surface of the pot quickly becomes covered with erect rootlets, which project above the soil some 3 inches. Although it is sometimes seen in *C. giganteum*, I have never met with it to anything like the same extent as in

* Drawn for THE GARDEN by H. G. Moon in Messrs. Sander's nursery at St. Albans. Lithographed and printed by J. L. Goffart.

C. Traceyanum. The habit of growth can scarcely be distinguished from that of *C. giganteum*. The flowers are produced on racemes 3 feet to 5 feet in length, each flower from 4 inches to 6 inches across. There is no need to describe the flowers, the colours of the typical form being well shown in the plate today. It is a most distinct and desirable variety and worthy of a place in every collection.

Its cultural requirements are easily supplied, as it possesses a robust and vigorous constitution. I find it does well in a light position in the cool intermediate house, where the temperature at night during the winter months is maintained at 55°. *Miltonia vexillaria* is grown in the same house. It requires a liberal amount of water at the roots during the growing season and until the flower-spikes have been removed, when drier conditions are maintained, only sufficient moisture being given to prevent shrivelling of the bulbs and foliage during the resting period. The potting is done when root-action is commencing, the material used consisting of good fibrous peat, a little loam, and Sphagnum Moss, to which is added a liberal sprinkling of finely broken crocks or rough sand. The pots should be filled to one-half their depth with clean broken crocks, and every precaution should be taken to ensure free drainage. It may be increased by division of the bulbs. The back bulbs, especially of fresh imported plants, break freely, and they make good progress with careful treatment. The pots used for the potting up of back bulbs should not be too large, and they should also be carefully drained.

I noted the variety *C. T. grandiflorum* when exhibited at one of the Drill Hall meetings of the Royal Horticultural Society. I could not then discern sufficient distinction to merit such a descriptive name, for there are varieties much superior in colour and larger in flower than the one then exhibited or that represented in the coloured plate under the above name.

H. J. C.

KITCHEN GARDEN.

LATE PEAS.

In such seasons as we have just passed through late Peas will be specially welcome. At one time the tall varieties of the British Queen and Ne Plus Ultra type were principally grown for August and September supplies. We now have a much better selection of varieties, and the dwarfier kinds I find more reliable. Most growers will admit it is a difficult matter to beat the well-known Ne Plus Ultra. Some attention has been paid to this variety by raisers in the way of getting a 3-foot variety with equal quality and no loss of pods. Few vegetables have been given so much attention of late years as Peas, with the result that we now have an unlimited selection and some excellent kinds. The varieties illustrated—the Michaelmas and Syon House—are very late kinds. Syon House was raised by crossing Ne Plus Ultra with the well-known Stratagem. We have by so doing a 3½-foot high variety with the free podding and good qualities of both parents. In the Michaelmas Pea we have somewhat similar colour, quality, and crop, but this is even dwarfier than Syon House, being a 2½-foot variety and having a much thicker growth than the older Ne Plus Ultra. This is well named, as in a good holding soil there is no difficulty whatever in having it in quantity at the end of September; indeed, much later if the weather is open. I place much importance on a free grower with ample strength in

the haulm, as such kinds, I find, are better able to resist drought and are less subject to the attacks of mildew than the weaker growers. The nearest approach as regards quality to Ne Plus Ultra is Late Queen. I do not know the parentage of this variety, but it is of vigorous growth and noted for its specially good flavour. This very much resembles Syon House in height, growth and crop and is equally late. Last year I saw this Pea in the north good well into October. Late Queen is more valuable on account of its freedom from mildew, which is so fatal to many of the late Peas. In a measure much depends upon the soil and climatic influences. When I lived in a midland county

Pea Syon House. From a photograph sent by Mr. G. Wythes.

my best all-round summer and early autumn Pea was Veitch's Perfection. Here in a hot, shallow soil resting on gravel it is not at all good. I find those kinds with a sturdy habit and strong haulm are the best. A month ago I covered the soil between the rows of succession Peas with several inches of rotten cow manure, this being done to retain moisture.

For September or August supplies so far I have never failed with Autocrat. I am aware there are later kinds, but few superior as regards quality and cropping. This, like those noted above, stands drought well, and, what is so important to the grower, it gives a successional crop, as whilst one lot of pods is perfecting its growth, others are forming. For some years I grew Sturdy as my latest variety. It has the true Ne Plus Ultra flavour, but

lacks the robust growth of the kinds noted above. In a heavy or cool soil it is very good, but in a lighter one it is less reliable. For very late crops many growers depend upon the first earlies sown in June or the early part of July, but I find it best to grow the kinds that are less subject to mildew. Even then success is not always assured, as germination is faulty unless special culture is given. In some localities a great deal depends upon the time of sowing, a few days too late making a great difference in the growth. Much more room can be given these late crops, not so much between the rows as in the row, as if thick sowings are necessary it will be well to thin afterwards to get a strong plant. The soil must be taken into account, as if at all heavy it is well to give more space to allow the sun to reach the plant at the time the pods are filling. Those who have poor, thin soils have a great difficulty in growing late Peas, and to do so entails much labour and the returns are not always reliable, no matter what variety is grown, as should a wet autumn follow a dry, hot summer, mildew is rampant, more so with some of the tall well-known kinds so often advised for late supplies; indeed, mildew is such a plague to growers, I would strongly advise using a mildew specific or a sulphur solution as soon as the pest is noticed, as this will arrest its course and save the crop.

I find the dwarf growers more reliable and worth special culture, as often if the plants are tided over August there is no further trouble and growth continues till late in the autumn. There are failures. Even this July I have experienced much difficulty in getting the seed to germinate freely. New seed germinates much better than old, and there must be no lack of moisture during growth to get the best results. —G. WYTHES.

By late crops I do not mean those of the Ne Plus Ultra and British Queen type, which are sown say from the second to the last week in June, according to locality, for a supply through September, but those of the dwarf type which are sown in July for a chance crop during October and until frost cuts them down. This batch requires good management, or fair results cannot be expected. A south or south-west border suits best and the soil should be in good heart, though it is a mistake to dig in very rich manure immediately previous to sowing. If the border was well enriched early in the year and has since been cropped with Lettuce or other non-improving subjects, all that will be needed is to turn it up a spit deep, give a sprinkling of some approved fertiliser, tread firmly, and draw out the drills, or where ground is limited, take out the soil the width of the spade and 4 inches or 5 inches deep, sowing the seed thinly and evenly. This will allow of abundance of haulm without overcrowding. As to varieties, I think Chelsea Gem and William Hurst two good ones, 3 feet between the rows being a suitable space. If the ground is in the least dry, the best way is to water well with rosed pots a couple of days before sowing; no more attention will then be needed till growth is sufficiently advanced for staking. At this time a good mulch on each side of the rows must be given, anything in the shape of short manure or old Mushroom manure sufficing to conserve root moisture. If the autumn is dry, fortnightly soakings with liquid manure will be needed, especially on light, well-drained borders. Sparrows also must be watched for, as autumn Peas sometimes fall victims to their ravages. It is always wise to sow two, or even three, varieties where space permits, as if one fails, another may succeed. —NORFOLK.

Potato Famous.—Last year this Potato out-distanced all others grown here in point of earliness, and the same thing has happened again

this season. As it proved to be such an extra early kind, I had a good quantity of tubers saved for planting, and accordingly had a long length of border planted with it the first week in February. Where it will succeed there is no question as to its being a valuable kind for supplying very early tubers, and I am glad I bought it in when I did, as I have not seen it offered for sale since. So long as it continues to give such satisfactory results this Potato will be planted for affording the earliest supply here.—A. W., *Stoke Edith*.

Pea Prodigy.—Having grown this Pea for the first time this season, I am now in a position to speak of its merits as I find it here. The seed was sown on March 20 and the pods are now ready for gathering (July 4). It is a vigorous and rather tall-growing Pea, the haulm being from 5 feet to 6 feet in height, pale or light green in colour and plentifully clothed with long straight pods, which are well filled with from nine to ten Peas in each. In general appearance Prodigy much resembles that fine Pea Boston Unrivalled, only the pods are of a slightly darker colour and perhaps more blunt at the points. A sowing of the latter was made on the same date as Prodigy, but the latter was ready quite five days earlier. It is a remarkably fine green wrinkled Marrow and worthy of extended cultivation where sticks can be had.—A. W.

Pea Dickson's Fertility.—This I have tried this year, with the result that it will be grown again another season. It has not turned out quite so early as I expected, for although sown on March 8, the same time that the first sowing of Boston Unrivalled was made, the latter was ready for gathering quite ten days in advance. In spite of this apparent drawback it is a splendid Pea of the green Marrow type, and is very prolific. The pods, which are deep green in colour, are long and well filled, the Peas of excellent flavour when cooked. The haulm is dwarf and distinct in appearance. The pods, which are produced in pairs and very plentifully, too, contain from nine to ten Peas each. Altogether it is a decided acquisition and well merits the award given by the committee of the Royal Horticultural Society at the Chiswick trials.—A. W.

Early Peas.—In consequence of the wave of very hot weather that set in about the middle of last month, early Peas came in with a rush, and afforded but little or no opportunity for forming an opinion regarding the dates as to when each kind arrived at maturity. Among the five following kinds, Selected Early, First and Best, Harbinger, Earliest Marrow, and May Queen, the last had the advantage by about two days, but whether the result would have been the same had normal weather prevailed it is hard to say. Under the circumstances the present season's results cannot be taken as a fair criterion for the reasons already stated, and I hope next season to again put the matter to the test, and make the trial a more extended one by growing several other reputedly early sorts in addition to those already named. I find May Queen a medium grower, a good cropper, and altogether an excellent kind for first sowing.—S. E. P.

Thrips on Peas.—For some years past the Peas sown in my gardens have been greatly troubled by a small black parasite, the proper name of which I believe is thrips. I have two gardens a quarter of a mile apart, and this pest appears in both. From other gardens close by it is absent. Can you help me in the matter by telling me—1, the best remedy for it when it appears; 2, how to prevent it?—T. NEIGHBOUR.

* * * In some gardens the Pea crop seems peculiarly liable to the attacks of thrips as described by Mr. Neighbour, and the attack is generally worse when there are a few weeks of dry weather about the time when the flowers are opening. Some years ago I was for two or three seasons greatly troubled in the same way, and though I cannot claim to have found any sovereign remedy, the experience of those seasons enabled me to baffle the insects to a certain extent and to obtain

good crops. Mr. Neighbour asks for a remedy and a preventive. The first I found in very frequent dustings of soot and wood ashes all over the foliage and flowers. These dustings were applied from the time the first blooms showed until flowering was quite over. The soot was the active portion of the mixture, the wood ashes being added to cool its burning nature, and would not be necessary if soot over two years old could be obtained. The above is both a remedy and a preventive if applied early enough, as the insects which haunt most of all the flowers and the young pods just as they are forming appear to dislike the soot immensely and would not attack any plants so dressed. Other means which appeared to have a strong bearing on the freedom from insects were, first, heavily mulching the rows with rotten manure, so that the haulm was kept growing quickly and did not suffer from drought, and secondly, choosing for the main-crop those varieties which run tall, for the worst attack of thrips was always found on dwarf or semi-dwarf varieties that were short-jointed and large-leaved naturally.—T.

PLANTING BROCCOLI.

Those who have a light, thin soil will find it difficult to get out the Broccoli plants where double cropping is practised, and I fear there are but few who have ample ground at command to get out their crops at the right moment. Last season many growers were in a difficult position owing to the heat, drought and condition of the soil at planting time, and I fear many suffered by the poorness of the crop in the spring in consequence. When in the midlands I always planted my midseason and late Broccoli in an open field, the soil being very heavy and of good depth. I have never had such fine crops since. There can be no question whatever but that Broccoli does far best in heavy land. I am aware the growth, say from August to October, is not so strong, but that is of little consequence, as a sturdy plant will tide over our variable winters much better than a gross one, and the latter in many cases I have found does not always produce heads in proportion to the plants. By having a short-leaved sturdy plant there is a much better head, and I advise those who can give this plant the position named to do so. Good Broccoli no doubt can be grown on light land, but much better results follow planting on a holding soil. I admit growth in a light soil is more rapid, but this in the case of vegetables for many months on the land is not advantageous, as a soft, rank growth does not mean quality. I have referred to field culture, and am aware that many growers cannot adopt this plan, but it is patent to everyone that if the fine breadths of Broccoli that supply the large markets during April and May depended upon garden culture alone, the supply would be small indeed. I find the quality of these hardy grown Broccoli is often superior to that of those in rich or light garden soils, the curd being closer, whiter, and much firmer. There is no need to dig previous to planting. I get the worst results from land that has been recently turned up, as the plants fail to make that sturdy growth that enables them to stand the winter. It is an excellent plan where land is available to reserve several quarters for this crop, as it will be found that those on the most exposed portion will often give a crop whilst others fail. My only Broccoli saved out of a great number during the severe frost a few winters ago was some plants on a north border. Plants in a more favourable position were killed. I advise plenty of manure for the previous crop, and if the latter is not long on the land it will be in condition for the Broccoli. In my case the late Broccoli follows the early Strawberries. Drills are drawn and the Broccoli plants got in as early in July as possible. The ground being very hard, drills are useful to hold moisture. The seedlings suffer badly in a crowded seed-bed, and it is far better even at this late period to prick out into rows till the quarters are at liberty. This will prevent the seedlings drawing and give a much

better plant, as if lifted with a fork there is plenty of roots. A dwarf, sturdy plant is a great gain, especially in a light soil. Plants treated thus will not need the heeling over in winter to protect the stems, as they will be much dwarfer, stronger, and less susceptible to injury, and well moulding up the stems will be sufficient.

G. WYTHES.

Lettuce Continuity.—In spite of the bad character given to this Lettuce by "J. R." it is still a favourite with me, and I have not yet found any one of the Cabbage section more useful. The season of 1898 was in the south a disastrous one for Lettuce, and yet I was never without a good supply; and when I say that I relied almost entirely on Continuity, I think it will be agreed that this is sufficient reason for saying a good word for it. By commencing early and planting in succession I was never short of Lettuce in spite of the drought; not a single plant ran to seed and only a few rotted, and this I attribute to being left too long before cutting. Instead of being soft and spongy, I found them hard and crisp, with excellent hearts; whereas most of the Cos section were a failure and other Cabbage varieties bolted wholesale.—H. H.

Peas on early borders.—The note by "H." (p. 387) on the above subject is to the point. I know the difficulty of having to grow the earliest batches of Peas on the same borders year after year, and that, too, in a warm, shallow soil. Often the haulm will look well enough until the bloom appears and a spell of hot weather sets in. This soon tells a tale unless good mulchings and waterings are resorted to. I have found, however, that occasionally—say every three years—the border is better for replenishing by the addition of fresh compost. Any spare loamy soil of a mixed character, also burnt garden refuse, answers the purpose. The best way to mix it evenly is to take out an opening at one end of the border and throw the soil forward, working in the new material as the work proceeds. Mulchings and manurial waterings may then be given as well. I have sometimes taken out trenches a spit deep on early Pea borders, filling them in with fresh material. In this the dwarf Peas did well.—B. S. N.

The Cauliflower grub.—How often is this vegetable infested by a small white grub which clusters round the base of the stems and roots. I have had batches, especially at midsummer, which until three parts grown and about to form hearts looked all that could be desired, then suddenly a collapse came, and they had to be thrown to the rubbish heap. I have thought that in addition to incorporating the usual complement of such ingredients as soot, gas-lime and burnt refuse when the ground is turned up, a mixture of the first and last placed round the ball of roots at planting time would be beneficial, as grubs and insect pests generally are opposed to them. Some people, especially amateurs, are apt to plant such infested plots with some other crop immediately the Cauliflowers are cleared off. Better by far well dress it and let it remain vacant for say six weeks, although this is a difficult matter where space is limited.—C.

Early Cauliflowers.—Mr. Wythes (p. 402) beat me by a few days with the early Cauliflower, as my first heads were not cut until June, but there was practically no break this season between these and the Broccoli, late varieties of the latter being very plentiful and holding out well. The variety of Cauliflower is Early Snowball, and was sown in boxes the first week in February, sufficient for a good batch being potted as soon as the seedlings could be handled. I experienced considerable difficulty for several seasons in getting good early Cauliflowers, as before potting them up the plants invariably clubbed, and that despite trying them in different parts of the garden and measures such as puddling the holes with a thick mixture of soot, lime, and soil, partially filling in with coal ashes and other things. Planted out from pots, however, they come away

without a check and never club. Early Snowball is a splendid little Cauliflower, the small, dense heads being of a snowy whiteness.—E. BURRELL.

Tomatoes not setting.—I have often thought the corrugated varieties of Tomatoes set their fruit more freely than the smooth ones. This may be more imaginary than real, but I am not alone in the opinion. More reliable wet or dull weather varieties appear to be needed. A Scotch grower recently told me that that was the greatest need, as variety was now endless, and the flavour and appearance of many as good as could be expected. I have previously expressed the opinion that were it not for its rugged shape, there would not be a more profitable Tomato than the old Dwarf Orangefield. I well remember the enormous crops produced year after year on a south Peach wall in an Essex garden, when our summers were longer and more even. Its flavour also is grand, though the fruit contained many seeds. I do not think with some that the fewer seeds the better the quality of the fruit. I presume, however, that it would now be difficult to obtain Orangefield true to name.—C.

THE WEEK'S WORK.

KITCHEN GARDEN.

GHERKINS.—These are still grown in some gardens, and prove very useful in autumn. Some appreciate them for mixing with other vegetables for pickling. Provided the plants have been favoured with a sheltered position, growth will now be vigorous. Do not on any account allow many fruits to remain on the plants for the present, as there is yet a good long season for fruiting in front of them before the foliage is cut down by frost. Before any more growth is made mulch the plants liberally for some distance round the main stems with short manure and give a good soaking of farmyard liquid once in three weeks. See that all weak and deformed laterals in the inside of the plants are removed as soon as visible. I have known red spider trouble some when the situation is very hot and dry, and this pest if not destroyed at once soon cripples the plants. In order to check it, apply the hose or garden engine, plying it forcibly on the under side of the leaves.

SPRING PARSLEY.—There is frequently a scarcity of this during the early spring months and until the spring-sown plants are fit for picking. There is usually such a demand for it for garnishing during the winter months, that all full-grown plants, even if favoured with frame or pit protection, get sorely crippled, new growth coming away but slowly in spring. In order, therefore, to meet this emergency, I have always sowed seed on well-worked pieces of ground in good heart about July 20 or 25. The beginning of August would be soon enough for the warmest of counties. If this is well treated as regards moisture and duly thinned out, it will make capital strong stuff for standing the winter if a frame, or frames, are placed over it. If the autumn is fine, the forwardest fronds will sometimes grow sufficiently to allow of their being picked for use during winter, but all except the very strongest of them should be left. In February the plants will rush into new growth and furnish a plentiful supply of fine Parsley when it is often at a premium. I like to prepare the plot for this sowing tolerably early in the season, and if there is any wireworm in the soil, a fair quantity of gas-lime and burnt earth should be worked in, further precaution being taken at sowing time by strewing some wood ashes in the drills. Thin out the young plants freely as soon as fit for handling, that is to say, if they are healthy and strong, this being very important at this season.

LATE VEGETABLE MARROWS.—Seed of this much-esteemed vegetable sown now will produce plants which, grown on with care, will yield fruit at a time when the bulk of the Pea and Bean crops is exhausted. Place the seed pots in a close, warm frame or greenhouse, and after germination bring

the plants on as hardy as possible. This will induce a hardy constitution and one that will stand a few moderate frosts, should they occur extra early in autumn. As soon as the roots are well round the sides of 4½-inch pots, remove them to their final quarters, letting these be as sheltered as possible, and where rough protection can be given as soon as the cooler nights of October set in. A good reliable variety for this sowing is Pen-y-hyd, this being a short-jointed moderate grower, and more easily covered with stakes and mats or strong canvas than the more rampant growers. Leave a small basin round each plant, so that the balls may be kept well moistened, until the plants become thoroughly established and are better able to take care of themselves. Mulching will be advisable even with these late planted lots, as, provided there is ample drainage, Marrows can hardly be kept too moist.

ENDIVE, MAIN-CROP.—I have usually sown my main crop of Endive from July 15 to 20, choosing a rather cool, moist border formerly occupied by Peas or Potatoes. Sow broadcast in preference to drills, using only a moderate quantity of seed, and netting the beds over at once, as chaffinches are very partial to Endive. Fraser's Improved Broad-leaved I find as good as any for winter and spring supplies, not being so liable to bolt as some sorts. Sow also the Moss Curled for earliest use, this being very liable to decay when the fogs of November and December set in. I like to make a second sowing of the Broad-leaved at the end of the month. One of the principal points to be observed with this salad is early and liberal thinning out of the seedlings, finally transplanting into good rich soil, and keeping the roots in a moist condition should the weather prove dry. I have generally left a portion of the young plants at equal distances on the seed-bed. These receiving no check will grow away rapidly and be fit for use early in November, being blanched by placing either pots or slates over them. Endive always pays for extra good culture, as if grown on poor, hungry soil it is tough and bitter, spoiling the salad bowl.

OLD SEAKALE BEDS.—Where these have been forced from year to year with pots and leaves the plants will, on account of early growth, now be covered with flower-stems. These should all be cut off, and if more side growths have sprung from the old stools since the thinning out advised some time ago, all these must also be cut away. Now is the time to apply stimulants either in the form of liquid manure of fair strength or artificial manure sown broadcast and watered in.

J. C.

FRUITS UNDER GLASS.

MELONS.—Seeds for the latest batch of Melons should now be sown, for the fruits of any raised later than this cannot be expected to attain good flavour. Where space is limited and close planting and training on the cordon system are adopted, it is far better to depend on old and tried favourites than to waste much space on new varieties, no matter how well recommended. A case in point has occurred with me this year, as among others I tried in one house four plants each of two new Melons that gained certificates last year, and which have been sent out with the usual character of being free setters and good doers. In one case I have a grand set on the laterals, each fruit at present being about the size of a cricket ball; in the other case no fruits have shown on the laterals, and not sufficient for a crop on the first set of sub-laterals, so that if ever I do manage to get a crop on the plants it will not be until that part of the house is a perfect thicket of leaves, entirely out of keeping with the system under which they were intended to be grown. It is impossible that this failure to show fruits can have arisen from any defect in management, as the two varieties in question are, and have been from the time of sowing, growing side by side, and two other varieties growing in the same house are all one could wish. There is plenty of good free-setting Melons that one could name, so that it is needless

to swell the quick-growing list of certificated varieties by adding to it those which need to be grown on the extension system and which must require at least a month longer to bring the fruits up. In the house which is to be devoted to the late Melons there should be an easily regulated supply of bottom-heat, preferably from hot-water pipes running underneath the beds. Keep a sharp look-out among the earlier batches for spider and for canker, as neither of these must be allowed to spread. Where the fruits are too far advanced to admit of syringing freely and spider appears to be gaining ground, the leaves should be sponged; this requires great care to prevent damage to the leaf, and should only be necessary in extreme cases of neglect, for the syringe well used will generally do all that is needful up to the time of netting, and if the fruits enter on this stage fairly clean, the spider which develops later will not matter much. With canker there should be no delay in applying the usual remedies of air-slaked lime and flowers of sulphur; watering near the stems should be avoided and all possible means taken to keep the affected parts dry. If the lime or anything else which is applied becomes damp, it should be scraped away and replaced by some fresh. When Melons require water, take care to give the soil (except for that portion next the stems) a good soaking and wait until fairly dry again before giving more; this suits them better than adopting the little-and-often method. Of course it will not do to give a heavy soaking just as the fruits are ripening; indeed, they are best then without any, but if the plants are looked after with judgment the soil will at that time be in just that moist condition that will carry the plants through safely. Continue to pinch off the sub-laterals from plants that have set a sufficient crop, as these are neither necessary nor convenient to have on the plants; the fruits come up better without them, as they then get more light and the main leaves if well preserved are all that is necessary.

ORCHARD HOUSE.—In the orchard house the pots will now be full of roots, and these require ample supplies of liquid manure water to enable them to bear the great strain put upon them. As the fruits on the various occupants get towards ripening, overhead syringing, which up to this time has been such an important factor in supporting the trees, must be withheld to prevent the fruits, such as those of the Green Gage and other Plums, from splitting, and Apricots from being blemished. Pears and Apples, if these are grown inside, may be syringed freely for some time to come. These and other trees should have their growth stopped close, except in the case of leading shoots, the latter being simply shortened back to six or eight leaves. It depends on the style of structure whether any shading should be used, but in case of doubt it is always safe to apply a very light shade, movable preferably, but a thin brush over of summer cloud or whitening, the latter mixed thinly with milk, does no harm and prevents the trees from becoming too much distressed on hot, windy days which now and then occur. Damping down, too, in the heat of the day is refreshing. Ventilation must be ample both night and day, and this necessitates netting over the ventilators of houses containing fruit sufficiently forward to attract birds and vermin. Rats frequently do damage to stone and other fruits and should be rigorously kept down in the neighbourhood of houses.

FIGS.—The second crop on early trees should be swelling freely and needs all the aid it can get from sunshine and from feeding at the roots. Heavy waterings may be given now with impunity, and the house should be shut up early enough in the afternoon to run the temperature up well above 90°; this with a moisture-laden atmosphere will be perfectly safe and the trees will gain by the forcing treatment. Syringe heavily twice a day while the fruits are green, but withhold directly they begin to soften, as drops of water hanging on to the points of such fruits are apt to cause blemishes. Take advantage of every close picking to ply the

syringe freely again, if only once now and then while the crop is ripening off, as the damaging of a few fruits is nothing to be compared to the loss which will occur through spider if syringing is neglected. If room can be found, tie in all shoots to full length. It is only when trees are grown in small houses that stopping is excusable, and in such houses planted-out Figs cannot be made an entire success, though stopped trees sometimes do passably well, but never give a heavy crop.

CORNUBIAN.

ORCHIDS.

LÆLIA PURPURATA VAR. MRS. R. I. MEASURES.

THIS, here figured, is one of the most charming varieties of *Lælia purpurata* in cultivation. It was obtained by Mr. R. I. Measures, Cambridge Lodge, Flodden Road, Camberwell, as a special variety from Mr. E. Kromer, who imported it direct from Brazil. The plant was first exhibited at the Drill Hall on October 26, 1897, when the Orchid committee gave it an award of merit. The flowers, though good in colour, were small, no doubt partly owing to its having been just imported, and partly to the dull surroundings of the London atmosphere at the time they were expanding. The sepals are deep rose-lilac, the petals fine in substance and form, deep rose-lilac, suffused with a darker shade on the apex, where it is also veined and feathered with a dark crimson-purple as seen in the lip. These veinings are clearly distinguishable in the illustration. The whole of the centre area of the lip is rich crimson-purple, margined with rose-purple, the surface being thickly covered with deeper coloured veinings. The side lobes are crimson, shading to yellow, which is thickly covered through the throat with longitudinal crimson-purple lines. The plant at the time the photograph was taken carried three racemes, two with five and one with three flowers.

When this plant was first shown, a cut-flowered raceme was exhibited by Mr. G. W. Law-Schofield, which was considered similar in many respects to Mr. Measures's plant, under the name of *L. p. Annie Louise*, but it had passed its best and no notice was taken of it by the committee. At the recent Temple show a finely grown plant with a two-flowered raceme was again exhibited by Mr. Law-Schofield and a first-class certificate was awarded. Alongside of this Mr. Statter exhibited a plant which was only just expanding its flowers under the name of *L. p. Statteriana*. This variety was considered altogether inferior to Mr. Schofield's and no award was made. Cut flowers of *L. p. Mrs. R. I. Measures*, though past their best, were also brought for comparison. Notwithstanding the great similarity of the three plants before them, Mr. Measures's plant having been previously dealt with and the name registered in the society's list of awards, the committee decided to adopt the name of *L. p. Annie Louise* and give it the higher award. It afterwards transpired that the plant Mr. Statter exhibited was part of the plant for which Mr. Schofield got his certificate. True, Mr. Schofield's flowers were larger than those from Mr. Measures, but the raceme brought for comparison carried five flowers, whereas *L. p. Annie Louise* only had two. Surely such a plurality of names is unnecessary, especially now the Orchid committee have the coloured drawings to fall back on. There are surely blunders enough in the nomenclature of hybrids in the past, where distinctive names have been recognised over and over again of plants from the same parentage.

Continuation of this system can only cause still greater confusion. S.

Epidendrum radiatum.—The flowers of this species are very pretty and very sweetly scented, the sepals and petals of a delicate creamy-white tint, the shell-like lip having radiating lines of bluish purple. The pseudo-bulbs are short, but the tall leaves give the plant the appearance of being stronger than it really is. Its culture is not difficult, the plant thriving well in the Cattleya house if potted in equal parts of peat and Sphagnum. It is very free-flowering, and should be rested in a cooler temperature after the flowers are past. It is a native of Mexico, and was introduced by Messrs. Loddiges in 1841.

Oncidium incurvum.—This is one of the prettiest and most easily grown and one of the most distinct of small-flowering Oncidiums, its blossoms opening now and lasting a very long time in perfect condition. Large plants of it thrive well here in a cool fernery, and the flower-

renew the compost is when the leads are starting in early spring. Besides the type there is a very pretty variety called *O. S. flavidum*, which has paler yellow flowers than the type, greenish suffusions taking the place of the brown blotches. Both this and the type like rather more heat than the species with which I have compared it, and thrive in company with *O. grande*. It is a native of Costa Rica, and first appeared among an importation of Orchids from that region in 1856, but has been collected many times since.

Odontoglossum crispum var. Lily.—This is one of the most distinct and beautiful forms yet seen. It belongs to the *O. c. Starlight* section, but the spottings in the sepals are different. The sepals are white, suffused with rose, the centre having some large brown spots and some smaller spottings at the base. The ground colour of the petals is white, tinted with rose towards the centre, the whole of the centre area and towards the base thickly covered with a suffusion of small rose-purple spots and a few small brown spots towards the base. The lip is white, shading to yellow at the disc. There are several irregular prominent brown spots in the centre and on the margin of the yellow disc. It has recently flowered in the collection of Mr. W. Thompson, Stone, Staffs.

Oncidium Lanceanum.—This is rather widely distributed naturally, and possibly to this fact may be referred its great variety and also the fact that some plants of it live and do well for quite a number of years, while others, do what one will with them, are not a success even the first season, and rapidly dwindle away. It is very queer in its likes and dislikes this way, and though liking a very hot and moist atmosphere while growing this must not be carried too far, and I believe, if it could be anyhow managed, the leaves would be finer and the plant healthier in every way if the house wherein it was growing could be well dried for an hour or two daily, ample moisture being again supplied in the evening. But to carry

Lælia purpurata Mrs. R. I. Measures. From a photograph by Geo. Champion.

ing season is the same as that of the bulbs finishing, so that the plants may be placed in drier quarters for a time to conserve the flowers and ripen the growth. The compost and treatment are the same as for the cool house Oncidiums generally, and ample moisture supplies are necessary.

Odontoglossum Schlieperianum.—There are few more useful *Odontoglossums* than this, for it flowers at a time when many of the choicer kinds are getting over and is a showy and beautiful Orchid. The spikes are erect, the flowers pale yellow and covered with blotches and spots of deeper yellow or brown. The plant is not difficult to grow in any cool, moist house, such as a greenhouse, fernery, or cool Orchid house, but it requires different treatment from the usual run such as *O. crispum* and similar kinds. The roots are much stronger than those of these well-known kinds, and like a much rougher, more open make-up of material, with plenty of crocks for drainage and larger, more roomy pots. The best time to

out this plan would in all probability lead to an attack of insects, and would therefore be productive of more harm than good. The next best plan is to give as much light as possible, so that the leaf growth is hard and well ripened by autumn. It does best in the East India house, and for compost should be given more Moss than peat, with plenty of large, rough lumps of charcoal and crocks mixed with it. The flowers occur at the base of the last-formed leaf on tall, erect spikes, the sepals and petals yellow, with spots and bars of chocolate, the lip varying in colour, but usually some tint of rose.

Lælio-Cattleya Aphrodite.—A very lovely form of this grand hybrid comes from Mr. G. W. Law-Schofield's collection. It is almost identical with *L. C. Aphrodite var. Ruth* that was certificated at the recent Temple show. The sepals and petals are pure white, of fine form and substance. The whole of the open portion of the labellum is of a deep crimson-purple, with the

exception of a small portion of light rose at the apex. The side lobes are white, shading to yellow at the base. It is lined and suffused at the base of the throat with bright rose-purple. The brilliant front lobe of the lip is in striking contrast to the white segments of the remaining portions of the flower. It is one of the finest varieties of this hybrid we have seen. It is sent as L.-C. Eudora var. The original name given to the hybrid that first flowered from intercrossing *C. Mendeli* and *Lælia purpurata* was L.-C. Aphrodite. The name Eudora must therefore be suppressed. It is a great pity that the plurality of names in hybrids should be of such frequent occurrence. There is no reason whatever why the published lists of hybrids should not be consulted before naming in the haphazard manner resorted to.—C.

CATTLEYA GIGAS.

This is one of the most distinct of the labiata group, as it is undoubtedly one of the finest. Strong-growing with much larger spikes of flower than any other, it is a very welcome addition to the occupants of the flowering house, which are now daily lessening in numbers. There is, perhaps, less variety in the forms of this plant than in the other members of the section, but there are a few well-marked ones, and a poor *C. gigas* is very seldom seen. Plants usually arrive in good condition, the additional strength probably enabling them to pass the journey with less exhaustion than those that are weaker with smaller bulbs. In selecting plants the preference must be given to those having healthy-looking foliage, firm at the axils, and with the eyes at the base of the pseudo-bulbs dormant, not started into growth and turning white through want of light. These blanched growths may sometimes recover their colour and grow away all right, but in most cases they soon daup off or shrivel up when the light reaches them. Should no others be obtainable, the most likely way to bring them round is not to expose them more than is avoidable to draught, cold air, or bright light, but to place them at once in a shady, moist, and fairly warm house, where, if all goes well, they will regain their colour by degrees and go on growing, eventually forming pseudo-bulbs in the usual way.

Some of the growths, it may be, will have lengthened out considerably and will have long white points. These are far better removed at once, as in all probability they will die, and even if they do not the leaves and bulbs must of necessity be malformed when they do appear. With such plants back breaks have, of course, to be depended upon, and these are as a rule fairly strong on *C. gigas*. The plants often flower at once upon the newly-made growths, and as we like to see what the variety is, it is usual to let the flowers open. But the sooner they are removed the better, as the plant is not sufficiently established to carry them over a long season and they weaken it unnecessarily. Although such a strong grower, I have never found *C. gigas* to have a liking for particularly large pots, and it always flowers more freely when the roots are feeling the sides of the pot or pan. This makes it all the easier to arrange for the plants to be suspended near the roof-glass, in which position the growth is finer and always well ripened, almost ensuring freedom of blooming. In this connection it may be noted that occasionally there are plants of this species that seem to defy all efforts to make them bloom, while others have a habit of flowering regularly twice a year. The best plants and most long-living under cultivation are those that keep dormant through the winter after flowering in July. But I have never found

any advantage in trying to force or to check their growing propensities, and leave them all the year round in a warm, sunny position in the Cattleya house temperature. The treatment as to compost, potting and watering when in growth or at rest does not differ from that of other labiata Cattleyas. In a good form of *C. gigas* the flowers will measure nearly 8 inches across, so that when five or six are produced on a spike a very fine effect is produced. The sepals and petals are rosy purple or mauve. The lip is much deeper in colour, except for a pale eye-like blotch on either side of the column, which is more or less marked in different plants. This species was first discovered by M. Warszewicz in New Grenada about the year 1848, but many of the plants he collected were lost and the species remained very rare until sent home in quantity about thirty years ago. It was named *C. Warszewiczii* by Professor Reichenbach, but is much better known as *C. gigas*.

Odontoglossum Harryano-crispum.—This lovely hybrid was recently noted in flower in the collection of Sir Frederick Wigan, Clare Lawn, East Sheen. The hybrid is of continental origin, having been purchased last year as the reverse cross of the plant which gained a first-class certificate at the Temple show of 1898. It is the result of intercrossing *O. Harryanum* with the pollen of *O. crispum*. The ground colour of the sepals is white, suffused with rose-purple on the apical halves, with numerous dark brown blotches and spots through the centre area, and several smaller spots on the outer margins. The ground colour of the petals at the base is white, with numerous bright purple spottings almost forming a solid blotch. The ground colour on the apical half is tinted with yellow on the outer edges and suffused with rose at the apex. There is almost a solid blotch of reddish brown covering the centre area. The lip is white when first expanded, with a bright yellow disc. The ground colour as the flower gets older changes to lemon-yellow. In the centre are numerous bright purple spots, outside these there is a thickly spotted band of violet-purple. The habit of growth has the intermediate characteristics of the two species used in its production. It differs from *O. crispum* principally in the broader and finer marked lip, and is much more like *O. Rolfei* (*O. Pescatorei* × *Harryanum*) in this particular respect than the hybrid shown at the Temple on the above date. It is a most desirable and useful addition.—H. J. C.

Lælio-Cattleya Dominiana var. Frances Mary.—A cut flower of this has been sent from Mr. G. W. Law-Schofield, Newhall Hey, Rawtenstall. In comparison with hybrids of L.-C. Dominiana raised by Messrs. Veitch, it differs principally in its slightly darker segments, and the lines in the throat as seen in the typical forms are entirely suppressed in Mr. Schofield's flower by a heavy suffusion of brownish purple. It was purchased as of unknown parentage, and is of continental origin. The sepals are of an intense rosy lilac colour. The petals, similar in colour to the sepals, have a slightly darker suffusion through the centre. The front lobe of the lip is rich crimson, becoming suffused with velvety crimson in the centre. There are numerous darker coloured veins running through the front lobe. The side lobes are crimson-purple in front, rose at the back. Over the whole of the base and the throat is a suffusion of deep brownish purple, giving it a most distinct appearance. This hybrid was exhibited at the last meeting of the Royal Horticultural Society in June as L.-C. Fire King, parentage unrecorded, but the Orchid committee, after a reference to their coloured drawings of plants previously certificated, determined it to be clearly a form of L.-C. Dominiana, and certificated it as L.-C. D. var. Fire King. On the following Thursday this plant was again shown at the Manchester and North of England Orchid Society's

meeting and certificated as L.-C. Fire King. Mr. Schofield's plant, which is from the same pad of seed, was also exhibited at the same time and received a first-class certificate as L.-C. Fire King var. Frances Mary.—S.

BOOKS.

ALBUM DES ORCHIDÉES.*

This is a very clearly written and well illustrated monograph of the hardy Orchids found wild in the centre and south of Europe, and including most if not all the species found in Great Britain and Ireland. It is composed of six chapters dealing with—1, generic characters; 2, fertilisation by insects, &c.; 3, classification; 4, our Orchids, their mode of growth, their geographical distribution, and their variation; 5, study, culture, and acclimatisation of Orchids; 6, description, &c., of the sixty species illustrated by coloured plates. The work itself is a large octavo, about the size of the *Botanical Magazine*. It is well printed, and the plates are carefully drawn and neatly printed in colour, each having underneath the figure the name of the species in French, English and German, as also the conditions of the locality or habitat, &c., where it naturally grows wild. For the hardy Orchid amateur, or for those cultivators who may wish to grow these exquisite, even if capricious, little flowers there is no better handbook, and it will, moreover, interest all who are fond of wild flowers and like to know their history. Although all European Orchids are supposed to be terrestrial species, we may, nevertheless, discover the beginning of epiphytal conditions in the genera *Malaxis* and *Liparis*. The former is found growing upon living Sphagnum and the latter upon tufts of Rushes, and both have above-ground stems or pseudo-bulbs, and not underground tubers so common to the majority of terrestrial kinds. The rare Irish Ladies' Tresses (*Spiranthes Romanzoviana*) is figured in black and white and alluded to as being limited to one locality at Bearhaven, near to Castletown, in Bantry Bay, but it is now known to exist in other Irish localities, so that there is really no fear of its total extinction for many years to come. It is perhaps of all our native species the most interesting, even if also not the rarest, found in Kerry, Armagh and Londonderry, in Ireland. It is not known in England nor elsewhere in Europe, but is said to be found in the United States at intervals all the way from New York to San Francisco. In England perhaps the head centre of our native Orchids is on the chalk downs of Kent, where the weird Lizard Orchis has again been found after a lapse of nearly forty years. No less than thirty-three out of a total of forty-four British Orchids are found in Kent, and as they are rarely seen except when in full bloom, it is to be hoped that they will never be exterminated, as so many of our rarer wild flowers have been during recent years.

We can boast of two epiphytal Orchids only in Britain, but we have also one or two leafless saphrophytes with short, swollen, coral-like roots, in each of the cortical cells of which is a mass of fungous spawn threads, or mycorrhiza. This association of fungous spawn threads and a root is common in many plants such as White Poplar, Alder, conifers, many Ericaceæ and Cupulifera, and is not strictly parasitism, but really a subtle kind of symbiosis by which both guest and host plants are mutually benefited. Orchids such as *Limodorum abortivum*, *Epipogon aphyllum*, and *Neottia nidus-avis*, which are leafless, and even some of the leafy kinds, enjoy the benefits of this symbiosis or co-operation. MM. Bonnier and Ed. Griffon found that in their power of assimilating carbonic dioxide terrestrial Orchids showed a sliding scale of capabilities. The green-leaved species, such as *Epipactis* and others, having no

* "Album des Orchidées de l'Europe Centrale et Septentrionale." Par H. Correvon. Soixante planches colorées; pp. 92. Geneva and Paris. 1899.

† *Comptes rendu*, December 5, 1893.

root-fungus could abstract all the requisite carbon from the air during sunlight by their green leaves. On the other hand, all the Orchids such as *Neottia*, *Coralorrhiza*, *Epipogon*, &c., are wholly saphrophytic, and can only obtain the carbon, &c., necessary for their due nutrition from humus by the aid of fungous mycelia. Some species of green-leaved Orchises even avail themselves of the aid of mycelia, and so become partially saphrophytic. In a manner these form an intermediate group between the true terrestrial Orchids and the true saphrophytes. This need of fungous co-operation in some of the species may to some extent explain the difficulty practical growers so often experience in cultivating terrestrial Orchids in our gardens.

After all it is in the woods and fields and on the chalk downs that our native Orchids are at their best, and one advantage possessed by M. Correvon's hand-book is that the plants are so carefully figured that there is no difficulty in at once recognising any of the species we may happen to meet with in our rambles either at home or on the Continent.

F. W. BURBIDGE.

MURRAY'S HAND-BOOK OF SOMERSETSHIRE.

VERY opportunely at this time of the year one of Mr. Murray's guides comes to remind us that Somersetshire, one of the most lovely, if not quite the loveliest, of counties, ought not to be neglected by persons bent on making holiday. In former editions bound up with Wilts and Dorset, the county has now a volume all to itself. Probably no county is more rich in archaeological and antiquarian interest. The number and richness of its ecclesiastical foundations, as evidenced by what remains of them, must have been surprisingly great even in those days. Its hillsides and valleys are dotted over with venerable shrines. Its gardens and country seats can compare with those of any other county; witness Longleat, Montacute, and many others. Its river, winding among sometimes wild, always beautiful scenery, is one of the most charming. The editor has omitted none of these things from his survey. The book is clearly printed, light and handy to carry. There are several maps, including a detached general map of the county. The price is 6s.

STOVE AND GREENHOUSE.

ACALYPHA GODSEFFIANA.

THIS is one of the numerous species and varieties of *Acalypha* which have handsomely variegated leaves and grow rapidly into large shrubs. They are consequently largely grown in tropical and sub-tropical gardens in much the same way as we grow common *Aucuba*. They are also valuable as stove plants in this country, such sorts as *Wilkesiana*, *obovata*, *marginata*, *Macfeeana*, *Chantrieri* and *musaica* being not uncommon among the tropical plants cultivated in English gardens. Some of these at least are merely varieties of *Wilkesiana*, and probably *A. Godseffiana* is another. It has, however, been accepted by Dr. Masters as a good garden species. It was one of the new plants shown by Messrs. F. Sander and Co. at the Ghent Quinquennial last year, and it has won general admiration both last year and this when shown at exhibitions in this country. Messrs. Sander and Co. state that it was discovered in New Guinea by M. Micholitz. They recommend it as a bedding plant for warm situations, as it did well in the open air in the summer of 1898 at St. Albans, forming compact, dwarf, leafy plants, evenly and exquisitely variegated with white, green and yellow, the white encircling the whole leaf. They also recommend it for

winter use, for which purpose it should be ripened outside in autumn. When well matured the plants should be removed into a warm, moist house, where they will burst into new growth and remain as bright as tricolor *Pelargoniums* all through the winter months.

At Kew it has proved of the easiest possible culture and a most useful plant for brightening up collections of indoor fine-foliaged plants.

W. W.

Coleus Beckwith Gem.—*Coleuses* no doubt have lost favour considerably, and rightly so, I think, for they take up a lot of valuable room which might be more profitably utilised for the growth of better things, and which, moreover, remain in their full beauty a much longer time.

produced on slender, arching stalks, which after a time droop in a graceful manner and produce on their ends several tiny plants. When a basket is furnished with a pendulous fringe of these young plants it forms a decidedly attractive feature. In a moist atmosphere they commence to root while still hanging, and finally drop, when, if the conditions are at all favourable, they soon become established. In this way the plant can be rapidly increased. It is a native of New Calabar, and was, I believe, first introduced to Kew, but it is now in the hands of several of our nurserymen.—H. P.

Adenocalymna nitidum.—This Brazilian climbing plant forms a very noticeable feature just now in the Victoria Lily house at Kew, where it clothes a portion of the roof. The upper part of the plant is laden with blossoms, borne on the

Acalypha Godseffiana. From a photograph by Col. Taylor, Norbiton.

In spite of this, I find the above-named variety very useful and ornamental grown into tolerably large plants for standing in large vases in windows and corridors. It is the best kind I am acquainted with for the purpose, for it is a free grower, producing bold leaves of rich telling colours. There is an advantage in growing these kinds of plants for such unfavourable positions, for as they become shabby they can be thrown away and are easily replaced by others of the same class.—J. R.

Cyperus fertilis.—This is a very distinct species of *Cyperus* that is seen to the best advantage when grown in a suspended pot or basket. The bright green leaves, each about 6 inches long and nearly an inch wide, are arranged in a regular rosette. From this tuft the flower-spikes are

slender secondary shoots, which are more or less pendulous. At the first glance the flowers suggest those of an *Allamanda*, but closer inspection reveals the fact that they are in shape just like a *Bignonia*, to which genus this *Adenocalymna* is nearly related. The colour of the flowers is a deep golden-yellow, and they are about 3 inches in diameter. It is indeed a noble climber for such a position—that is, on a hot, sunny roof in a lofty structure kept at a stove temperature, for it would be useless to expect flower if cut and cribbed or if heavily shaded. A good companion to it, also blooming freely in the same structure and under similar conditions, is *Thunbergia grandiflora*, whose large pale blue blossoms, each from 3 inches to 4 inches in diameter, are borne in great profusion and for a lengthened period.

Such vigorous climbers as these that are needed to cover a considerable space should be planted out, as it is difficult to keep them in good condition in pots. At the same time a border should be prepared for them, as, given unlimited room, more growth than flowers may result.—H. P.

CALIFORNIAN NOTES.

The spring in California has done much towards atoning for the dry winter. There have been several timely rains, and long-continued cool weather has, by reducing evaporation, conserved the moisture in the soil. It is now (June 3) close to harvest time, and for Northern and Central California as a whole the prospects for all crops are very gratifying. The crop of grain varies from an immense yield in the central coast belt to a half crop or less in portions of the San Joaquin valley. In the great wheat-producing sections the crop will be splendid. In fruit the yield will be very large, although the crop is spotted. In some places Apricots are very short, and the general opinion is that Prunes will fall far short, while Peaches will be exceptionally heavy. Beet sugar has become a large factor in several localities, and the Beet crop is promising. Large refineries are built in favourable sections and contract for the Beets with the farmers. The sugar industry is one of the most promising.

At my mountain garden on May 29 I picked fresh flowers of *Narcissus poeticus* fl.-pl. and breeder Tulips, also of *Lilium columbianum* and *L. washingtonianum*. On the way I noticed *Nemophila insignis* in full flower, while lower, *Pentstemon heterophyllus* and *Clarkias* were flowering—rather a jumbling of seasons within a mile I thought. There is scarcely any difference between the flora of our mountain-tops hereabout and of the valleys below. They are later, and that is about all. *Brodiaea californica*, now flowering in good form with me, is when well grown a large plant. It grows from 24 inches to 30 inches high, with flowers 1½ inches to 2 inches across and as long. A pure white sport is very effective, and could it be propagated would be very desirable for cutting.

In my notes of March 19, 1898, I described *Synthyris reniformis* as being white, and at a later date Mr. Arnott referred to the matter, stating that as usually grown it is purplish. To be sure that I was not in error, I waited until this season and carefully noted the colour. As it grows here the flowers are white, faintly tinged with pinkish purple. I have known and flowered for many years what was called by all of our botanists *Fritillaria biflora* without in the least doubting that I had the correct thing. This spring a lot of *Fritillaria* bulbs from Southern California flowered here and proved to be what I had never seen before, the true original *F. biflora*. These *Fritillaries* grow to a height of 4 inches to 8 inches with a stout stem, and bear leaves in the manner of *F. liliacea* and *F. pluriflora*. The flowers are very large for the size of the plants, broadly bell-shaped, the tips of the segments recurved and of a very deep rich brownish purple colour, the capsules very large. It is in every way a very attractive plant. The plant I have long known as *F. biflora* has the same leaves, but the flower is more narrowly campanulate, the tips slightly incurving; colour greenish, lined with brown-purple. *F. liliacea*, *F. biflora*, and the other just described, *F. pluriflora*, and *F. glauca* of South-western Oregon form a group very much alike in bulb, leaf, and general shape of flower. To these five will probably be added a sixth, which came to me from Hum-

boldt Co., California, this spring, in which the flower appears to be white, marked with purple. I defer naming it until bulbs flower next spring. All of these are interesting, easily-grown plants, and *F. biflora* and *F. pluriflora* are among the finest *Fritillaries* that I know.

Ukiah, California.

CARL PURDY.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JULY 11.

If only for the change in the exhibits as a whole, and equally in the manner of arranging, the displays of flowering and other plants at the hybrid conference on Tuesday at the society's gardens at Chiswick were decidedly welcome and full of interest. It was not a day for the exhibitors of all the plants, large or small, that may be in flower, but rather a sort of ingathering from as large an area as was possible under the circumstances of a great variety of hybrid or cross-bred plants that individually are possessed of an interesting history. In this particular way the exhibition, if we may so term it, was quite unique in so far as it related to plants all meritorious in themselves, and, indeed, in many instances already the possessors of the hall-mark of horticulture. This being so, it is scarcely necessary to add that *Orchids* and *Rhododendrons* figured largely in the display, while *M. Marliac's Water Lilies* as representing hardy things—such, too, as may be enjoyed to the full in the hot summer days in the open air—were welcome and beautiful. It was, however, a disappointment to many who brought small exhibits of this or that hybrid or cross-bred plant that little or no notice was taken of such, and that no questions or other information were requested from the raisers. The plants were there; the cut specimens were there, some from long distances, but, so far as we are aware, no one to refer to their merits or otherwise—a subject which we think might have been undertaken by the several committees, assisted by the raisers of the plants themselves. As it was, the cards placed with the exhibits had to suffice, and though these contained very ample details, these might surely have been amplified in a very interesting way.

Orchid Committee.

First-class certificates were adjudged to the following:—

CATTELEYA HARRISONÆ ALBA.—This is a lovely pure white form of this well-known species, the base of the lip showing the faintest tinge of greenish yellow. The plant carried a two-flowered raceme. From the Rev. F. Paynter, Stoke Hill, Guildford.

LELIO-CATTELEYA DUVALIANA (*L. purpurata* × *C. Luddemanniana*).—The sepals are considerably curled, pale rose, the petals very much deflexed, similar in colour to the sepals. The lip is of a most extraordinary colour, rich distinct shade of maroon-crimson. The side lobes, of the same colour, shading to yellow, are lined and suffused through the base of the throat with rich purple. From M. Maron, Brunoy, France.

Awards of merit were adjudged to the following:—

LELIO-CATTELEYA MARTINETI (*C. Mossiæ* × *L. tenebrosa*).—The sepals and petals are pale lilac, the front lobe of the lip and outer margins similar in colour, heavily veined and suffused with rich crimson over the central and basal areas; the side lobes suffused with the same colour and having some yellow at the base. The plant carried a two-flowered raceme. From M. Maron.

LELIO-CATTELEYA ADOLPHUS (*L. cinnabarina* × *C. Aclandiae*).—The sepals and petals are deep yellow, slightly spotted with purple, the lip yellow, suffused and heavily veined with rich crimson. The plant carried two flowers. From the Rev. F. Paynter.

CYPRIPEDIUM SCHILLIANUM (*C. Goweri* × *C. Rothschildianum*).—This is a lovely form, to which the Veitch Memorial medal was awarded, but it was afterwards pointed out that the plant had been shown at Manchester last week, and the medal was accordingly withheld. The dorsal sepal is white, shading to green at the base, and heavily lined and spotted with dark brown. The petals are pale green, heavily spotted with dark brown, the outer margins being thickly covered with rich purple hairs. The lip is deep purple, shading to green at the base. The plant carried a two-flowered raceme. From Mr. G. W. Low-Schofield.

CYPRIPEDIUM STONEI CANDIDUM differs from the typical form in having pure white upper and lower sepals and lighter petals. The plant carried a three-flowered raceme. From Sir F. Wigan, Bt.

EPI-LELIA CHARLESWORTHII (*L. cinnabarina* × *Epidendrum radicans*).—The sepals and petals are deep orange, suffused with a bright shade of scarlet, the lip orange in front, shading to yellow, with a few spots of purple around the column. The flowers are produced in clusters, as in *Epidendrum radicans*. From Messrs. J. Veitch and Sons.

LELIA TENEBROSA GIGANTEA.—This is an exceptionally large and highly-coloured form, the sepals and petals being deep purple, the lip deep rose, shading to crimson-purple in the centre and through the basal portions of the throat. The flowers are of fine form and substance. From Sir F. Wigan, Bart.

Messrs. J. Veitch and Sons sent a choice group of hybrids, and in most instances the parents used in their production. The most prominent of the hybrids was a fine plant of *Phalænopsis Luddeviolacea* (*P. violacea* × *P. Luddemanniana*), the flowers larger than in either of the parents, the sepals and petals rosy violet, marbled with white, the lip crimson-purple, with some yellow at the base. In *Disa Veitchi* (*D. grandiflora* × *D. racemosa*) the flowers are of two shades of bright rose. *Sobralia Veitchi* (*S. macrantha* × *S. xantholeuca*) has the sepals and petals delicate lilac, the lip of a darker shade of rose, and yellow through the throat. In *Dendrobium rhodostoma* the flowers are white, tipped with deep purple. *Epidendrum elegantulum*, *E. O'Brienianum*, *E. radicante-vitellinum*, derived from the species indicated in the name; *Spathoglottis aureo-Viellardi*, with its yellow and purple flowers; and *Epiphronitis Veitchi*, with five spikes of its yellow and scarlet flowers, were also shown. *Odontoglossum excelens* was represented by a pale form. Among the *Cattleya* hybrids were *Lelio-Cattleya Canhamiana* (*L. purpurata* × *C. Mossiæ*), *L.-C. Aphrodite* (*L. purpurata* × *C. Mendeli*), *L.-C. eximia* (*L. purpurata* × *C. Warneri*), *L.-C. Stella*, and *L.-C. Zephyra*. Among the *Cyripediums* were included such well-known forms as *C. Harrisonianum* superbum, *C. Orphanum*, *C. superciliale*, *C. Drurio-Lawrenceanum*, *C. Cupid* (*C. cardinale* × *C. Lindleyanum*), *C. leucorrhoda*, *C. marmorophyllum*, *C. Alice*, *C. Ashburtonæ*, *C. selligerum*, *C. Morganeæ*, *C. Euryale*, *C. vernixium*, and *C. grande*. *Thunia Veitchi* was also included. Messrs. Hugh Low and Co. sent a choice group of hybrids and a few select varieties of *Cattleya*; among the latter was *C. Mendeli enfieldensis*, white, except the faintest tint of colour in the centre of the front lobe of the lip. A light form of *C. Gaskelliana* with very similar characteristics and a white form of *C. Eldorado* were also included. The hybrid *Cyripediums* included *C. PAnsoni giganteum* (*C. Rothschildianum* × *C. Morganeæ*), the dorsal sepal creamy yellow, suffused with purple towards the base, lined at intervals with brown-purple veinings, the petals greenish white, suffused with brown at the margins and thickly covered with deep brown spots; the lip purple, mottled with creamy yellow. The flower had a double column, yellow, thickly covered with bright purple hairs. The two parents were also included. *C. Lawrenceano-Mastersianum*, derived from the parents indicated in the name, had the intermediate characteristics of the two species used in its production.

C. selligerum (*C. barbatum* × *C. Stonei*), *C. Alice* (*C. Spicerianum* × *C. Stonei*), a beautiful form of *C. T. W. Bond* (*C. hirsutissimum* × *C. Curtisi*) *C. Milmani* (*C. philippinense* × *C. Lawrenceanum*), *C. Alfred Hollington* (*C. philippinense* × *C. ciliolare*), an exceedingly dark form, having the intermediate characteristics of the parents, *C. De Witt Smith* (*C. Lowi* × *C. Spicerianum*), *C. superciliale*, and a plant of *Lælio-Cattleya Arnoldiana* with two flowers were also included. Messrs. F. Sander and Co. sent *Cypridium Adrien de Germiny* (*C. Swanium* × *C. Rothschildianum*), *C. Premier* (*C. buchanense* × *C. Rothschildianum*), *C. Duchess of Sutherland* (*C. Youngianum* × *C. Rothschildianum*), *C. Garbari* (*C. Lawrenceanum* × *C. Rothschildianum*), *C. A. de Laresse* (*C. Curtisi* × *C. Rothschildianum*), and *C. Lady Maple*. Sir F. Wigan sent *L.-C. Arnoldiana*, *L.-C. eximia*, *L.-C. Canhamiana*, *Lælia Euterpe*, *Cypridium macropterum*, and *C. Gertrude Hollington*.

Sir T. Lawrence sent the lovely *Vanda Agnes Joaquim* (*V. teres* × *V. Hookeri*) with three racemes of flowers, several *Cypridiums*, *Disa kewensis*, *Odontoglossum excellens*, *Masdevallia Ajax*, *M. Hincksiana*, *Cattleya Breautiana* (*C. Leddigesi* × *C. superba*), and *Epiphronitis Veitchi* with four spikes. Mr. Maron sent a choice lot of hybrid *Cattleyas*, which included *L.-C. callistoglossa*, a dark form of *L.-C. Henry Greenwood*, *L.-C. Canhamiana*, *L.-C. Eudora*, *L.-C. Berthe Fournier* (*L. elegans* × *C. aurea*), *L.-C. intermedia flava*, *L.-C. radiata* (*L. purpurata* × *C. dolosa*), *Cattleya punctulata* and *Lælia nigrescens* (*L. pumila* × *L. tenebrosa*). Mr. C. Ingram sent *Cattleya Firebrand* (*L.-C. elegans Schilleriana* × *C. Lawrenceana*), which had the intermediate characters of the parents. Mr. W. Cobb showed the beautiful *Cypridium l'Ansoni*, which was certificated last year, and was a great improvement on what it was when exhibited then. It is undoubtedly one of the best of this section. Mr. de B. Crawshay showed *Odontoglossum crispum* Mrs. de B. Crawshay with white flowers of good form, *O. c. Crawshayanum* with heavily spotted flowers, and a home-raised hybrid in *O. Cooksoni*, *Crawshay's variety* (*O. Halli* × *O. crispum*). This might have passed for a form of *O. Wilckeanum*.

Floral Committee.

The following received the award of merit:—

CALADIUM A. SIEBERT.—This is one of the new type of *Caladiums*, having the leaf lobes suppressed, the group generally being of a hardier nature than the larger growing forms. In this instance the red ground colour is surrounded by a green margin to the distinctly undulated leaf. From Messrs. F. Sander and Co., St. Albans.

DELPHINIUM MICHAEL LANDO.—This kind has a dense spike of the deepest indigo-blue, the flowers of large size and very showy. From Messrs. Jas. Veitch and Sons, Chelsea.

CARNATION HEATHER BELL.—A good yellow ground with scarlet lines, the flowers large and possessed of a perfect calyx. The flowers were cut from the open. From Mr. J. Douglas, Great Bookham.

CARNATION THE BARON.—A dark coloured fancy of medium size and excellent form: a very desirable kind in this section. From Mr. Douglas.

CARNATION ROSALIND is a rich dark purple-crimson self of capital size and form. From Mr. Douglas.

DIANTHUS BARBATUS ELIZABETH.—A clear and distinct salmon-pink coloured *Sweet William*, which appears identical with Messrs. Sutton's *Salmon Queen*. It is fully 18 inches high, free in habit, and a great bloomer. The plants, which were in pots, came from Viscountess Enfield, Barnet.

CALADIUM MITJANA.—A very striking form, with richly coloured, almost ruby-red foliage. From Mr. McLeod, Dover House Gardens, Rehampton.

PELARGONIUM (ZONAL) COUNTESS OF DERBY.—A very fine salmon-pink, with a suffusion of lighter

pink near the edge of the flower. From Messrs. Cannell and Sons, Swanley.

PELARGONIUM CASSIOPE.—This is a clear soft pink, with a distinct, though small, white eye. The form is also good. From Messrs. Pearson, Chilwell, Notts.

VIOLA PENCAITLAND.—A good tufted bedding kind, the flowers white with lemon centre, very compact habit. From Messrs. Dobbie, Rothesay.

VIOLA J. B. RIDING.—A well-known kind; flowers rose-purple, a striking kind. From Messrs. Dobbie and Co. and Mr. J. Forbes, Hawick.

VIOLA ARCHIBALD GRANT.—Perhaps the most vigorous of the tufted strain, the rich deep violet-purple flowers being borne on stems fully 8 inches high. It is somewhat later to flower than many kinds, but is not surpassed, or even equalled, for its holdness, fine colour and constitution. From Messrs. Dobbie and Co. and Mr. J. Forbes, Hawick.

VIOLA JACKANAPES.—This partakes of the typical *Viola* in form, with the lower petal smaller than the rest. The lower petals are gold, with a brown-velvet shade in the upper petals. From Mr. J. Forbes, Hawick.

ROSE WHITE MAMAN COCHET.—This is a pure white form of the ever-popular *Maman Cochet*, which it resembles. It is a lovely *Tea Rose* of great beauty. From Messrs. W. Paul and Son.

ROSE MME. CADEAU RAMEY.—A Hybrid *Tea* of good form, the flowers soft or delicate flesh colour and white. It is very free flowering. From W. Paul and Son.

Messrs. James Veitch and Sons, Ltd., Chelsea, contributed largely to the actual display, most noticeably by their group of *Rhododendrons*, the hybrids resulting chiefly from the crossing of *Javanicum* and *Jasminiflorum*, the forms originally raised from these being again employed as one or both of the parents. These *Rhododendrons* are a very striking lot, but the majority having been frequently noticed we refrain from a list of names. One of the finest, however, is *Souvenir de J. H. Mangles*, raised from *Javanicum* and *Crown Princess of Germany*, the latter a yellow kind. *Ne Plus Ultra*, a kind having flowers of an almost vermilion orange hue, is considered the finest of all this race, at least from a colour point of view. This last was raised from *Javanicum* and *Duchess of Edinburgh*, the former the seed parent and the latter the pollen parent. The Messrs. Veitch also staged a fine collection of hybrid *Nepenthes*, exhibiting either pitchers or plants of the parents with each. Another remarkable group from the same source may be termed graft hybrids, mostly of trees and shrubs and the like. A few of the examples were *Photinia* grafted on *Quince*, *Phillyrea* on *Ligustrum*, and the same plant on *Olea*, *Choisya* on the *Skimmia* being also shown among a large variety of plants, some of which, however, did not appear of a robust or flourishing character. Hybrid *Water Lilies* were also shown by Messrs. Veitch, and *Kalo-Rochea langleyensis*, with a small head of bloom, having resulted from crossing *Kalesanthes coccinea* and *Rochea falcata*. The hybrid, however, is a long way behind either of the parents in its decorative effect. *Delphiniums*, *Begonias*, *Streptocarpus*, and a group of some forty-two supposed hybrid *Ferns* were also in evidence, *Adiantum*, *Gymnogrammas*, *Polypodiums*, &c., figuring strongly in the latter group. A group of *Ferns*, dried specimens and living examples, with full and liberal details, was contributed by Mr. C. T. Drury. Messrs. Jackman and Sons, Woking, had a good display of their cross-bred *Clematises*, which are well known and as greatly valued. A very distinct hybrid *Day Lily*, *Homocallis Pioneer*, was stated to be raised from *H. aurantiaca* (?) as pollen parent and *H. Thunbergi* as seed parent. The pollen plant, however, was the single form of *H. disticha*, and quite distinct from *H. aurantiaca* both in foliage and in flower. The hybrid carries largely the form of the seed parent, while the foliage is intermediate between that of the parents. It came from Mr. G. Yeld, Clifton Cottage, York. A beautiful lot of *Sweet Peas* came from Mr. Eck-

ford, Wem, Salop, and contained some pretty shades of colour. From Cambridge Mr. Lynch brought the last fragments of the *Cinerarias* that have proved so valuable in the raising of the new race of these flowers. Some *Caladiums* of the new type came from Messrs. F. Sander and Co., St. Albans, one of which, *C. A. Siebert*, is very rich in colour. The hybrid *Campanula Balchiniana* was, with the parents, *C. isophylla* and *C. fragilis*, exhibited by Mr. Richard Dean, Ealing, Mr. E. H. Jenkins, Hampton Hill, also contributing two cross-bred *Campanulas*, the result of crossing *C. isophylla* alba with pollen of *C. pyramidalis* alba. Only one plant was in flower, and this was almost a reversion to the typical *Campanula isophylla*, absolutely uninfluenced by the pollen parent and equally so the seed parent in so far as colour was concerned. Some good *Carnations* were shown by Mr. Douglas, and *Sweet Peas* by Messrs. Dobbie and Co., Rothesay. *Lilium Marhan* and *Hymenocallis macrostephana* came from C. G. van Tubergen, Haarlem, Holland.

The lovely batch of hybrid *Water Lilies* from Mr. Leopold de Rothschild, Gunnersbury House (Mr. Jas. Hudson, gardener), was perhaps the most fascinating group in the entire exhibition. There were some twenty-six varieties of these lovely things, arranged in a perfectly natural way in large, spacious pans on the floor, the receptacles completely hidden by the foliage of the *Lilies* and a margin of fresh green Moss. These were deliciously cool and refreshing in the sultry tropical heat of the great conservatory. Foremost was the lovely blue-flowered *stellata*, so valuable with its long stems, and around such things as *Marliacea rosea*, *M. albida*, both in grand form; *M. carminata*, *M. Chromatella*, *M. rubro punctata*, &c., while among the odorata group were *o. rosacea*, *o. Exquisita*, and besides these the rich-flowered *igneus*, *Robinsoni* with gold stamens, *lucida*, *gloriosa*, and others. The great vigour and freshness formed quite a feature in the group, which was backed by *Nicotiana sylvestris*, a fine *Tobacco*, with long tubular white flowers that while drooping in the sunlight do not entirely close. It is a striking plant, fully 4 feet high. A very remarkable exhibit was that of *Clematises* and *Roses* from MM. Morel et fils, 33, Rue de Souvenir, Lyons, the former group being well represented by some half-dozen boxes of blooms all carefully grouped and arranged with the parents of each. The *Roses* shown were chiefly of a decorative character, and, considering the distance traversed, were quite fresh at the opening of the conference. *Roses*, too, were abundant from Messrs. Paul and Son, Cheshunt, and Wm. Paul and Son, Waltham Cross, Teas and Hybrid Teas and decorative kinds being chiefly shown in each instance. Perhaps one of the most valuable things, both from its showy character and, indeed, from a commercial standpoint also, was the new *Kalanchoe flammea* from Somaliland sent from the Royal Gardens, Kew. A group of this at the entrance to the conservatory attracted the attention of all-comers. It is a most remarkable plant, almost as vivid in its colouring as is the well-known *Crassula coccinea*, though not of this shade of colour. The flowers, which are freely disposed in flattish forked corymbs, are of a decided red-orange tone. It appears the plant has already been in flower some weeks at Kew, and succeeds admirably in an airy house. It is certainly an acquisition. Of special interest, as indicating what may be accomplished by an individual in one particular branch of horticulture, was the group of *Ferns* raised entirely by Mr. H. B. May, Edmonton. Here were *Aspleniums*, *Adiantums*, *Gymnogrammas*, *Pterises*, *Davallias*, and others, the following being a few of the most conspicuous: *Adiantum fasciculatum*, raised from *A. fragrantissimum*, *Asplenium Mayi* from *A. Baptisti*, *Davallia insignis* from *D. elegans*, *Gymnogramma flavescens* from *G. peruviana*, *Pteris tremula grandiceps* from *P. tremula*, *P. Reginae* from *P. Victoriae*, *Lomaria ciliata fimbriata* from *L. ciliata major*, *Polypodium Mayi*

from *P. glaucum*, and *P. glaucum cristatum* from the same source. In all some eighty-five varieties were shown—a highly creditable display for at least one group and one department. Messrs. Wallace, Colchester, had *Lilium Burbanki*, which, said to be derived from *L. Washingtonianum* as seed parent and *L. pardalium* pollen parent, showed the greatest evidence in favour of the latter, the hybrid *L. Dalhansoni* from *L. dalmaticum* seed parent and *L. Hansonii* pollen parent being also shown. MM. Duval et fils, 8, Rue de l'Ermitage, Versailles, staged a very remarkable set of *Vriesias*, with *Tillandsia Duvali*, *T. Lindeni* major, and *T. L. superba*, the former group being of a varied and striking character; while Messrs. Barr and Sons showed a group of Japan Irises of considerable variety and colour, with other hardy flowering things that had but little in common with the object of this particular gathering.

Fruit Committee.

The committee met on June 29 at Chiswick to examine the Peas and Lettuces sent in for trial. Over sixty varieties of Peas were on trial, but the season has not been altogether favourable. Some kinds showed but little advance on older kinds, whilst a few failed to reach the ordinary standard of merit. All the varieties were sown the first week in March. Among the Lettuces there was nothing new. The older kinds, such as Brown Cos and Paris White, were good in this section. Among Cabbage varieties, Crystal Palace, Continuity, White Dutch, and All the Year Round were good. A very late Broccoli, seed of which came from Mr. Beale, Loughborough, if it can be kept true, will be suitable for private garden supplies.

A very large number of members attended the meeting at Chiswick on July 11, but comparatively few exhibits attracted notice so far as fruit and vegetables were concerned.

A first-class certificate was given to

RASPBERRY GOLDEN QUEEN, a perfect fruit as regards size and shape. It is the result of crossing the well-known Superlative with *Rubus laciniatus*. It is of good flavour, a free bearer, and in this respect resembles Superlative. An award of merit was given it in July, 1898. From Messrs. Veitch and Sons.

Awards of merit were given to the following:—**STRAWBERRY LORD KITCHENER**.—This is a fine large dark-coloured berry, the deep crimson colour running through the fruit. It is the result of crossing British Queen with Waterloo, and mostly resembles the latter in size and colour. From Messrs. Veitch, Ltd., Chelsea.

PEA GLORY OF DEVON.—Pods of a deep green colour, having eight to ten peas in each, of excellent flavour. It grows 3½ feet high. From Messrs. R. Veitch and Son, Exeter.

PEA DUKE OF CORNWALL.—The height of this is 5½ feet, the peas of true Marrow flavour. The haulm was entirely covered with pods at 18 inches from the soil. From Messrs. Toogood and Son, Southampton.

PEA NOBLEMAN.—A dwarf early variety, 2 feet to 3 feet, and of first-rate quality. The pods, produced freely in pairs, are above medium size. From Mr. Deal, seed grower, Kelvedon.

PEA WINIFRED.—Also a dwarf variety, 2 feet to 3 feet. The pods are large and the quality excellent. This also came from Mr. Deal.

PEA DALBY PROLIFIC.—A 3 feet to 4-feet high variety and of first-rate quality; pods deep green, well filled. It is a fine dry weather variety, as it was remarkably free and healthy. Messrs. Veitch, Ltd., Chelsea.

PEA ALDERMAN.—A very fine type of the *Ne Plus Ultra*, nearly 6 feet in height; pods of great length and the peas of fine colour and splendid quality. It is a good cropper.

Mr. Hudson, Gunnersbury House Gardens, sent a collection of Cherries, some ten varieties in all; splendid fruits they were, especially those of the Bigarreau type. Frogmore Bigarreau was a fine dish, the large pale yellow fruits, marbled with red, being much admired. Governor Wood, one

of the most reliable of all the white Cherries, was also excellent. Early Rivers and Black Circassian were splendid black varieties, the former being remarkable for its small stone and rich flesh (silver-gilt Knightian medal). Mr. Allan, Gunton Park Gardens, Norwich, sent his new Strawberry Lady Sutfield, both pot plants and lifted plants in baskets. This is an excellent variety, free cropper, of medium growth and good flavour. The same exhibitor sent a new Melon, Gunton Scarlet. This has received an award of merit; it is a small, but splendidly flavoured fruit. The Messrs. Laxton Bros., Bedford, sent a new Strawberry, Climax, a large, firm fruit of good appearance and flavour. It resulted from crossing Waterloo with Latest of All. The Messrs. Veitch, Chelsea, sent some excellent fruits of Strawberry Veitch's Perfection. A new Apple called Early Victoria, the result of crossing Lord Grosvenor and Kentish Codlin, the committee desired sent later. Messrs. W. Paul and Son, Waltham Cross, sent two varieties of little-known Apricots, splendid looking fruits, above the average size, the varieties being the Early Boulton and Domazan. A new Currant, a sport from Raby Castle, was sent by Mr. Smythe, Basing Park Gardens. Messrs. Laxton sent twelve varieties of Peas. Of the Peas the most noticeable were the new Duke of Rutland, a free grower with good colour; Gradus and Thomas Laxton. Peas Duke of York and Prince Edward were sent by Mr. T. Basham, Fair Vale, Newport, Mon., but the committee could not deal with these unless growths are sent or the varieties tried at Chiswick. A Pea named Nero with purple pods was sent from Burford Lodge Gardens by the President of the society. A novelty in the way of the Raspberry Blackberry, a cross between *Rubus fruticosus* and Raspberry Belle de Fontenay, was sent by Messrs. Veitch, Chelsea.

The conference was continued on Wednesday at Westminster Town Hall. In the absence of Sir Michael Foster, through illness, the chair was taken by Professor G. Henslow, and there was a good attendance. Mr. Herbert J. Webber, from the United States Department of Agriculture, gave an interesting lecture, with lantern demonstration, on the work of his department in plant hybridisation. The following papers were also read: "The Structure of certain New Hybrids (*Passiflora*, *Albica*, *Ribes*, *Begonia*, &c.)," with lantern demonstration, by Dr. J. H. Wilson, St. Andrews, N.B.; "Hybridisation viewed from the standpoint of Systematic Botany," by Mr. R. Allen Rolfe, Kew; "Hybrid Poppies," by M. Henry de Vilmorin, Verrieres; "Self-Fertilisation of Plants," by M. Lemoine, Nancy; "Hybrid and Cross-bred Fruits," by Mr. Luther Burbank, Santa Rosa, California, U.S.A.; and Mr. T. Francis Rivers, Sawbridgeworth.

The festival dinner of the conference was held at the Whitehall Rooms on the same evening, Sir Trevor Lawrence presiding. Among others present were the Netherlands and Belgian Ministers, Lord Annesley, Sir Edward Fry, Lady Lawrence, the Master of the Rolls, Mr. W. Bateson, F.R.S., Mr. H. Webber, and the Rev. W. Wilks (secretary). The toast of "The Queen, Patron of the Society," having been honoured, the Rev. Professor Henslow proposed "Horticulture," and Mr. H. J. Webber, in responding, said he brought with him the friendly greeting of the United States Secretary of Agriculture. He added that he hoped to see the time when the originator of a new fruit or flower, in addition to the satisfaction he might feel in conferring a benefit on humanity, would receive the just and practical recompense to which he was entitled. Professor Hugo de Vries (Amsterdam University) and M. Henry de Vilmorin also responded. Mr. Bateson proposed the toast of "Hybridists," Mr. W. T. Swingle (Washington) responding. The Master of the Rolls gave "The Royal Horticultural Society," and referred to the early work of the society in sending out collectors into various parts of the world. The chairman, in reply, said it was owing to the work of Robert Fortune, who was

sent by the society into China, that the cultivation of the tea plant was introduced into India and Ceylon and an immense trade was thus almost wholly transferred from China. The society, which was founded in 1804, would soon have to consider how it was to celebrate its century. Of late years the society had been progressing by leaps and bounds, but it needed a hall in London and a new garden in place of the old garden at Chiswick. The Belgian Minister, responding for the visitors, said it was the common experience of the diplomatic body that British hospitality was unsurpassed throughout the world.

NOTES OF THE WEEK.

Rubus deliciosus in fruit.—Two large plants of *Rubus deliciosus* which I have had some twenty years, and which have never fruited before, have a quantity formed, and those facing south are quite ripe.—J. R. D., Reigate.

Lathræa squamaria.—In his garden at Rockville, Murrayfield, Midlothian, Mr. P. Neill-Fraser has this interesting parasite established and flowering freely on the roots of some trees. I saw it at the end of June, and one noted its erect spikes of streaked flowers with pleasure.—S. ARNOTT.

Rose White Maman Cochet.—The lovely Rose Maman Cochet is one of the best known and most admired of all Tea Roses, and this new-come, a pure white form with the same characteristic beauty, should not be less popular than its parent. It is a really delightful flower.

Saxifraga Hirculus major.—This yellow form is by no means seen every day, though quite a pleasing plant, the large golden yellow flowers having at first sight more the appearance of one of the Rock Roses or Helianthemums, a notion, however, quickly set aside by the foliage and habit generally. This pretty yellow Saxifrage delights in plenty of summer moisture.

Philadelphus microphyllus.—Referring to the paragraph *re* the above in last week's issue of THE GARDEN, it may interest some of your readers to know that I have this shrub growing in poor clay, measuring 4 feet 2 inches in height, 18 feet in circumference, and a mass of bloom.—E. HUTCHINSON, *The Elms, Darlington*.

Ferula tingitana.—This can scarcely be seen to advantage when small, but when with years it is fully developed, it is indeed a fine plant. Examples of it were noted recently in Messrs. Jackman's group at the Drill Hall, when information was forthcoming that a specimen some 10 feet high was a mass of golden-yellow in the nursery of the firm at Woking.

Nymphæa stellata.—Most Water Lilies flower in such a way that the flower-head alone just floats on the surface of the water, but in this lovely star-flowered kind the blossoms are borne aloft out of the water on stout stems to nearly 2 feet high. It is this strikingly distinct characteristic that renders it so valuable when cut. Mr. Hudson had a fine display of it at Chiswick on Tuesday last from the Gunnersbury House gardens.

Nicotiana sylvestris.—This is a handsome white Tobacco brought to the hybrid conference by Mr. James Hudson, gardener to Mr. Leopold de Rothschild, on Tuesday last. The plant has handsome leaves and an inflorescence—even when grown in pots, as in this instance—fully 4 feet high, which is terminated by a head of long tubular flowers that, while assuming a drooping attitude during the heat of the day, do not close as do those of many kinds, hence its greater value generally. From many points of view this is a valuable plant.

Campanula carpatia (Riverslea var.).—I herewith enclose my new *Campanula carpatia* Riverslea. The growth is stronger than in this type, but it is quite as free-flowering. The flat, Clematis-like flowers give the plant a very distinct effect indeed, being so very much larger than those of the other sorts in commerce.—M. PRICHARD, *Christchurch*.

* * A very handsome form, the flowers of a richer blue than we have ever seen. Some of the individual blooms measured fully 2 inches across.—Ed.

Hailstorm at Canterbury.—A fierce hailstorm swept over Canterbury on Saturday afternoon, and with it a thunder-storm of great violence. In many cases the lumps of ice, says a correspondent measured over an inch and a half in diameter. Fruit

and hop plantations, corn crops, and market garden produce have suffered greatly from the deluge of ice. Many of the fruit orchards have been nearly stripped of their crops, and the loss will be very severe. Owners of glass houses have also suffered severely, one nurseryman having over 1000 panes of glass broken, and the damage in this case alone is estimated at over £100.

Veronica paniculata.—Under its synonym of *V. amethystina* this Speedwell is grown at Shambellie, Dumfries, N.B., where it is very fine this season. It is an old species, introduced from South Europe more than 100 years ago. In the border it was very handsome with its rather loose racemes of bright blue flowers. If one could only get this colour into the spike of the plant referred to in another note as *V. sibirica*, a handsome and valuable plant would be secured.—S. A.

Rose Fellenberg.—This Rose is apt to be overlooked among the multitude of new introductions, but I may be pardoned for bringing its free growing properties and freedom of flowering before those interested in garden Roses. It is made good use of in beds in the garden of Colonel Blackett, of Arbigland, Dumfries, and a grand plant covering the potting shed was a fine sight in the beginning of July. As Mr. W. Houlston, the head gardener, says, the knife is never put to it, and the display it made was of the most brilliant description.—S. ARNOTT.

Incarvillea Delavayi in shade.—It may be of value to some of your readers to know that this handsome plant appears to flower quite freely in the shade. Last autumn I put out a few seedling plants in a small border with a north-east exposure which gets neither western nor south-eastern sunshine. The plants did not make growth early, and I was afraid that the cold snap we had in March had destroyed them. The first flower opened about the first of this month and the plants look quite healthy in their present position. They are not overhung by trees or other plants.—S. ARNOTT, *Carsethorn, Dumfries, N.B.*

Veronica sibirica.—Under this name there is grown in the garden of Captain Stewart, Shambellie, Dumfries, N.B., what appears to be a variety of *V. virginica*. I am aware that *V. sibirica* is considered synonymous with *V. virginica*, and that there is so much variation among the Veronicas that names count often for little. The plant to which I refer has unusually long spikes of flowers of a pale blue. The colour is not pronounced enough to be good, but the spike is finer than that of any *V. virginica* I have ever seen. The whorled leaves clearly mark it out as belonging to that species. It looks like a plant which would be worth seeding from to get a better colour.—S. ARNOTT.

Salvia carduacea.—This was one of the most remarkable plants in the group shown by Messrs. Jackman and Soas, Woking, at the last Drill Hall meeting. It was remarkable by reason of its peculiar growth, the rather square stems being terminated by several cushion-shaped whorls, soft, downy and flexible to the touch, and emitting, under cover of long, sharp spines, the soft, delicate lavender blossoms. In the construction of the flowers the margin of the lip is divided into numerous thread-like filaments of a silvery grey tone, which under a powerful lens are very beautiful, the rich orange anthers contrasting with the deep blue of the stigma. A peculiar, though not particularly pleasing, odour pervades this very curious plant, which is a perennial at Woking. It is not a flower or even a plant to attract from a distance, but at close quarters and under examination it is a most interesting subject.

Verbascum Hookeri and V. Lychnitis.—From Carton I have specimens of two Mulleins received under these names. Unfortunately, the box had been crushed in the post office, and the spikes are somewhat damaged. That named *Hookeri* is probably *Hookerianum*, a North African plant with bright yellow, purple-centred flowers. Compared with *V. nigrum* they are brighter both

on the exterior and interior of the petals. The stem-leaves are also more toothed and the stem branches freely. When closed, *V. Lychnitis*—a Caucasian species—looks as if the flowers would open out white, but they are of a kind of buff colour with an orange centre. At least this is what one can make out from the specimen sent in its present condition. The calyx is quite white, and it looks as if it would be rather a nice plant with its branching stems. Mr. Black speaks well of it, and one may accept his opinion of its merits.—S. ARNOTT.

Notes from a Cornish garden.—One or two effects in colour have been striking here lately, notably two small hedges of *Crimson Rambler* laden with bloom and completely surrounded by *Sidalcea candida*, also a clump of that useful old free-flowering Rose, *Anna Alexieff*, with *Anemone rivularis* round it. Again, *Prunella grandiflora* on the rockery contrasts well with *Liairia tristis*. The *Physalis* have had their numbers enriched by *peruviana*, which is growing fast against the wall, and also near, *Franchetti* as a standard. *Orchis foliosa* seems to go back here. Next to it come *Primula imperialis* and *P. sikkimensis*, both well out. *Romneya Coulteri* opened its first flowers a fortnight ago. *Ipomoea rubro-cerulea* has the warmest spot in the garden, and has already gone 4 feet up a brick wall and is showing many flower-buds. The *Convolvulus* hed has certainly profited by the dry weather. *C. Cneorum* is flowering well and *C. althaeoides* is hard to keep within bounds, whilst *Convolvulus minor* gives us a sheet of blue and *C. lineatus* grows fast.—C. R.

PUBLIC GARDENS.

Public garden for Dalston.—The Albion Square (Dalston) public garden was opened yesterday afternoon by the Earl of Meath, the chairman of the Metropolitan Public Gardens Association. Mr. Reuben Clarke, chairman of the Open Spaces Committee of the Hackney Vestry, presided. Lord Meath said that Albion Square had existed as an eyesore to the neighbourhood for many years. The association and the local authority had made efforts since 1893 to secure the ground as an open space for the benefit of the public, but it was not until last year that the trustees of Lady de Saumarez, the owner, had consented to its being handed over for this purpose. The sum of £400, given by the City Parochial Trustees, had been spent on the land.

Open spaces.—At the monthly meeting of the Metropolitan Public Gardens Association, the Earl of Meath presiding, it was announced that the Paragon and Portland Place Gardens, New Kent Road, which have been laid out by the association, had been opened to the public on June 28 by Lady Llangattock, and that Albion Square Garden, Dalston, would be opened by Lord Meath on Wednesday next. It was resolved to communicate with the Westminster Vestry and the Wandsworth Board of Works respecting certain vacant land suitable for recreation-ground purposes near the Vauxhall Bridge Road and at Earl's-field. It was also agreed to take all possible steps to save Albert Square, Commercial Road, from the hands of the builder, and to lay out Marian Square, Hackney Road, and Granville Square, Clerkenwell, if their transfer to the local authorities for maintenance as public gardens could be secured. It was reported that the Court of Common Council had resolved to consider the desirability of taking over for maintenance the various public gardens which the association had laid out in the City, and that £2500 was still needed to complete the purchase money required for Dollis Hill. Lord Teynham, Lady Hobhouse, and Mr. Basil Holmes, the secretary, were appointed as representatives of the association to serve on the Thames Preservation League.

The weather in West Herts.—During the past week the weather has remained very warm

both during the daytime and at night. On the 11th the shade temperature rose to 82°, and during the previous night the exposed thermometer never fell lower than 59°, making this not only the warmest night as yet experienced this year, but also the warmest night recorded here at any time during the past fourteen years. The ground has also become very warm, the temperature at the present time exceeding the July average by 4° at 2 feet deep, and by as much as 6° at 1 foot deep. About a tenth of an inch of rain, or only sufficient to moisten the surface of the soil, fell during the night of the 10th.—E. M., *Berkhamsted*.

Red spider on Vines (R. H. J.).—Water freely and keep the atmosphere moist, syringing freely with clear rain water, also applying sulphur to the hot-water pipes. We found no other insect on the Vine leaves you sent.

Hardy non-British Ferns.—In your list of non-British Ferns hardy in Yorks, published last week, *Polystichum munifolium* should have been printed, and not *P. cernitum*, doubtless owing to my bad writing. I should have added *Gymnogramma triangularis*, a so-called Silver Fern.—R. MILNE-REDHEAD, *Holden Clough, Clitheroe*.

Apple tree unhealthy.—Would you let me know what this disease is? It is on a Peach Apple tree in my garden here.—W. W.

** The leaves of your Apple are attacked by a fungus, but they were so shrivelled that I cannot name it. The best thing that you can do now is to pick off what you can of the diseased leaves and collect any that have fallen and burn them. As soon as any sign of the fungus appears next year, spray with Bordeaux mixture.—G. S. S.

Insects on Water Lilies.—I have in my garden a tank with cemented sides and bottom, about 30 feet by 15 feet or 18 feet, and say 3 feet 6 inches deep. The water is supplied from the town mains through a fountain, which as a rule plays by day and is turned off at night. A month or two ago some Water Lilies were planted in the tank, and for a time seemed to be doing well, when, however, something attacked the leaves and ate them almost as soon as they came up. At first it was attributed to some gold fish which swim about in the tank, but presently it was discovered to be the work of an insect, a lively, active sort of fellow, reddish brown in colour, about three-sixteenths of an inch or so in length and fairly slender. As I have not been able to learn anything of this pest from any of my friends, nor from the nursery where I procured the Lilies, I am venturing to send you a few specimens by parcel post, which I hope will arrive in good condition, and I shall be much indebted if you can tell me the name and origin of the creature and how to get rid of it.—W. H. N.

** I have carefully examined the Water Lily leaves and the water in the bottle, and the only insects that I could find were the larvae of one of the gnats. I have no doubt that they are the insects you allude to, but I very much doubt if they have caused the injury to the leaves. I cannot say that they have not. As to destroying them, the only way that I can suggest is to pour a little paraffin oil on the surface of the water. This forms a very thin film, which prevents the larvae from being able to obtain air, as they have to do occasionally. It has been proposed to destroy mosquitoes in this manner by pouring oil on the tanks and pools in which their larvae live, and in some places it appears to have been successful.—G. S. S.

Names of plants.—*M. Moody*.—1, *Iris ochroleuca*; 2, *Rudbeckia speciosa*; 3, *Coronilla varia*.—*Clifton*.—A good form of *Cattleya Mendeli*.—*H. Hallet*.—1, *Tippisporium Buchananii*; 2, we cannot recognise; please send when in flower; 3, *Leptospermum scoparium*.—*J. M.*.—1, *Cytisus capitatus*; 2, *Sempervivum arachnoideum* Laggeri; 3, *Sempervivum flagelliforme*; 4, *Syringa japonica*.—*J. L.*.—1, *Iris foetidissima* variegata; 2, *Lycium europaeum*; 3, *Cytisus capitatus*.—*H. Archer-Hind*.—*Antirrhinum asarina*.—*Joseph Milburn*.—*Rosa rubrifolia*.—*H. G. R.*—*Cobæa scandens*.

"The English Flower Garden."—*Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.*

Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.

ORCHIDS.

RARE & BEAUTIFUL ORCHIDS.

THERE is no doubt that in the past many Orchids have been admired and highly prized much more for their rarity than their beauty, and money value has had, I am afraid, in a few cases a far greater weight than beauty. Because a plant is a rare hybrid and possesses some distinct characteristic it has been much lauded whether it was superior to anything previously known in the same section or not. I for one—and I think most true Orchid lovers will join with me—am very pleased to see that of late a taste is springing up for kinds that are really beautiful as well as rare, and that our principal society is less lavish in its awards than formerly. At one of the Royal Horticultural Society's shows a well-known trade grower complained rather bitterly that a hybrid shown by his firm had not received a certificate, and when I ventured to disagree with him he came down with the very crushing intelligence that it was a hybrid, the result of a cross that had never been made before. The plant was absolutely inferior to either of its parents, and the committee very wisely, I think, passed it by. Too much has been made of raising hybrid Orchids, and the fictitious value placed upon some of them has brought Orchid lovers a name for delighting in unlovely plants with long names instead of beautiful and rare flowers. For this reason some people that should know better decry Orchids and let off a cheap kind of wit against men who have enriched our collections with some of the most lovely plants in Nature.

Take, for instance, the splendid series of hybrids raised by crossing the almost useless Brassavola Digbyana with the best of the labiata Cattleyas. A more beautiful flower than the first of these is inconceivable, and the later additions are almost equally meritorious. Look, again, at the innumerable Cypripediums that are improvements beyond question upon anything that has been imported. The men who have raised such plants are entitled to all the praise they are likely to get, and have conferred real benefits upon horticulture. They

are not to be named in the same breath with those who raise or purchase seedlings of reputed parentage and bring them to exhibitions with the idea of getting a certificate which will enhance their monetary value. To keep their good name, Orchid hybridists must make up their mind to disappointments the same as raisers of other flowers, and not think that every cross they make is worthy of perpetuation. It is hard lines to have to throw away a plant after years of patient waiting and care, but it is better to do so than to bring the cult into disfavour or even ridicule. If the plant is so far worthy, by all means keep it and grow it for cutting if suitable or for home decoration, but do not endeavour to force it upon a public taste quite satiated with such, not to use a stronger term.

To a more limited extent the same principle obtains regarding varieties of well-known species. There are the albino forms of the labiata and other Cattleyas, each and all of which are most chaste and lovely Orchids, and no one could fall out with the high regard in which they are held. Then among the Dendrobiums there are many most exquisite varieties that no one, unless absolutely devoid of the sense of beauty in form and colouring, could fail to admire, and the same is true of fine colour varieties in the Cattleyas referred to above. What should be avoided is raising on too high a pedestal such things as Dendrobium nobile Cooksonianum and Laelia purpurata Ashworthiana, in which the colouring, though unique, does not add to the beauty and, therefore, the intrinsic worth of the plant.

A GROWER.

Anguloa Ruckeri sanguinea.—The flowers of this variety are among the brightest and best of the Anguloas, and it is a beautiful plant that anyone may add to his collection with advantage. As distinct from the type, the whole of the interior of the flower is a deep red, and when a number of flowers are open the effect is very good. I have noticed more of the decaying of the flowers of Anguloas this season than I have ever seen before, and I cannot help thinking that some of this is due to allowing the plants too much heat. A little more than the coolest house affords may do no harm if the flowers are wanted by any

special date, but beyond a few degrees it is not wise to go.

Dendrobium Wardianum.—It is strange how suddenly plants of this species collapse, sometimes without apparent cause. It is over seven years since I have purchased any newly-imported plants, and this is longer than they usually thrive under cultivation. This spring when flowering I noticed one of the plants threw a lot of badly-formed blossoms, and since then it has made nothing but small, worthless growths, which will never be strong enough to flower, and the plant is, of course, useless. Yet last season the plant apparently grew well and was well ripened, but all was not right as evinced by the poor flowers.

Masdevallia oethodes.—I noted a fine plant of this singular little species recently with a number of its tiny flowers so prettily set upon the scapes, the sepals not very showy in colour, but forming a peculiar boat-shaped cavity peculiar to this section. This and a few allied species are, perhaps, more constantly in flower than any other Orchid, and it is nothing unusual for the spikes that rise in early autumn to go on producing the little flowers all through the winter and spring months. The plant is of the easiest culture, thriving in a cool house with the other members of the genus, but is not showy enough to be generally cultivated.—B. S.

Miltonia Regnelli.—Flowers of this pretty species come from a correspondent. They are large and handsome, showing well the pretty bright rose suffusion that is a marked characteristic of the best forms of this species. In growing these Brazilian Miltonias many people are apt to give them too much heat at certain times in the year, particularly in summer and early autumn, when for very good cultural reasons the Cattleya house in which they are grown is allowed to run up a little higher than usual. Where a proper intermediate house exists there are many plants that may be accommodated in it all the year round, and this fine Miltonia is one of them. Regular temperatures and regular supplies of moisture both at the root and in the atmosphere will ensure healthy plants, other conditions being favourable. A thin compost of peat fibre and Moss suits it well.

Cattleya Eldorado.—This species is not so strong in growth as the majority of the labiata Cattleyas, nor has it such large flowers, but it blooms at a very useful time, and is therefore

well worth growing. It is easily distinguished by its tubular lip and flowers of less substance, and though keeping fairly well to its seasons of growth and rest, it does not always do so. One plant here almost always flowers in late autumn and is a very good form. There are many varieties of it, including several that have received names and a large number of others. It thrives well with the usual *Cattleya* treatment, and, like *C. gigas* and one or two others, likes best a position not far from the roof glass in baskets or pans. The compost must be free and open, consisting of rough peat, Moss, and charcoal over good drainage. It is a native of the Rio Negro district, and for a time after its introduction in 1866 was rare. Frequent importations have arrived since.

Lælia purpurata Williamsi.—This superb variety is now in flower, and it is among the finest of Orchids now blooming, the rich crimson-purple on the lip being a magnificent bit of floral colouring. The plant is of exceptionally strong growth and very free-flowering. Like all free-rooting subjects, this plant when healthy must be given ample room in the pots, and it is not well to leave it to get very badly pot-bound before giving fresh compost. I have a large plant of a good variety that, like the above, usually flowers after the typical *L. purpurata* is over, and being a little chary of disturbing it, I let it go too long without repotting a few years since, in consequence of which it is now only just recovering the check given when disturbed. Had the plant not been allowed to go back, but been given new material when still healthy, all would have been well. As it is it has taken several seasons to recover. In the large pots necessary for such specimens it is imperative that plenty of good charcoal or other hard porous material be placed with the peat and Moss, or a closeness will ensue that is fatal to active rooting.

Zygopetalum maxillare.—Many hundreds of plants of this have been imported, only to flower respectably for a year or two and then to dwindle away, and the likeliest plants to do are those that are sent home on the native Tree Fern stems, a practice not so common, perhaps, as formerly. I remember receiving some plants of it about eleven years ago that were nearly all attached to this material, and, dried as they were, most of them plumped up and came away all right, but all those that had been torn off died. The plant does not seem able to store sufficient nutriment in its small pseudo-bulbs to enable it to withstand the rough treatment it is exposed to as well as its stronger growing brethren. When under cultivation, if the stems referred to cannot be obtained, then a thin make up of well-drained compost is the next best substitute. The rhizomes extend a good deal laterally, and room must be found for them, or weakness will ensue. Roots outside a pot or basket are always in danger from insects, besides which they are more liable to be dried and to suffer from external injury. The material ought to be of the most lasting description, not very much peat, but plenty of Moss being used, as this, by its decay, does not get into such a solid, close mass as the peat, and forms, perhaps, some little food for Orchid roots. *Z. maxillare* is a very old garden Orchid, having been introduced by Mr. Warne through the then well-known firm of Loddiges very early in the present century.

NOTES AND QUESTIONS.—ORCHIDS.

Lælio-Cattleya Arnoldiana (Pickering Lodge var.).—This is an exceedingly dark form of this hybrid. It is derived from the intercrossing of *Lælia purpurata* and *Cattleya Warscewiczii* (*zigas*). The sepals and petals are of a deep rose-lilac tint. The whole of the front lobe of the lip is rich crimson-purple, heavily veined with a darker shade of crimson, the side lobes rose-purple, shading to yellow at the base, where there are a few lines and a slight suffusion of purple through the throat.—C.

Paphinias.—In my note on "Orchid roots" at p. 22 I have mentioned *Promenæas* as Orchids

with very sensitive roots, but it was *Paphinias* I should have written. These singularly pretty Orchids, though related to the other genus, are more impatient than they of checks, whether these are caused by closeness at the roots or in any other particular, but I know of very few kinds that are so easily injured by the former mischance. To do them well, insects must be kept in check by constant atmospheric moisture, and everything about them must be very clean and sweet.—H. R.

FERNS.

CHOICE PTERISES.

PTERIS SCABERULA.—This beautiful and distinct *Pteris* is difficult to deal with. Where it once gets established and finds genial conditions it grows freely, and the spreading rhizomes soon cover a large space. The greatest difficulty is when it is necessary to disturb the roots, especially when dividing plants to increase the stock. As it rarely produces spores, it is necessary to propagate by dividing, though when it does prove fertile the spores germinate freely. I have raised seedlings on several occasions. The first time I found fertile fronds was nearly thirty years ago, and I still have some dried specimens collected then. Some few years ago I saw a very large specimen which had a number of fertile fronds. The plant having become too large it was divided, but this proved fatal. I believe the whole of the divisions died. To divide successfully, young plants must be taken before the pots have become too full of roots, or, if grown in a shallow pan, it gives the rhizomes room to spread, and they may be taken off with roots and soil. Treated thus and grown in a cool, rather shady position where the atmosphere is fairly moist, it is one of the most beautiful Ferns grown. It should be potted in good fibrous loam, and good drainage should be given.

P. VICTORIAE.—This is another very desirable Fern which requires careful treatment, and when raised from spores it is much inclined to vary in habit. While some of the seedlings will, under good treatment, grow freely enough, there are sure to be some which have a tendency to be dwarf, congested, refusing to grow freely and make good plants. It is therefore necessary to select a good free-growing form for saving the spores from, and then see that the seedlings are grown on freely from the start without receiving any check. I have found the spores germinate freely, and soon throw up their first fronds. They should be pricked off as early as possible, and when ready to pot, a good open compost with plenty of drainage is advantageous. Many of these more slender-growing Ferns are often ruined through using a fine compost from which the best elements have been removed with the sieve. Fine soil and overwatering are common errors in Fern culture, and those of less natural vigour almost invariably suffer. The above *Pteris* succeeds best in a stove temperature, though it will do fairly well under cooler treatment. When well grown the very distinct white variegation gives a good contrast among other Ferns, and also renders it a desirable variety for decoration. Since its introduction several distinct varieties have occurred, *Regina* being one of the best. This is a more vigorous grower. There is also a crested form of this which is equally free, but these do not come so freely from spores as the parent. In Mr. Goodliff's nursery, Worthing, there are plants of these two varieties with fronds upwards of 2 feet 6 inches in height from top of pots, the plain form giving one the idea of a variegated *P. serrulata*. *P. tremula variegata* also came from *P. Victoriae*, and though very pretty in a young state, it does not keep the variegation so well and gets straggling with age; further, it is difficult to propagate either from spores or divisions.

P. TRICOLOR is another beautiful Fern rarely seen in really good condition, being of slow growth and much liable to damage if wet settles

on the fronds. It should be grown in an elevated position and well exposed to the light, but some shade is necessary in very hot sunshine. In potting, the crown of the plant should be kept well down. The stem lengthens with each frond, and roots are produced from the upper portion as it advances, and these perish if not close enough to take hold of the soil, which is often the cause of this beautiful Fern being seen in a sickly condition.

P. MEMORABILIS VARIEGATA.—Although not so delicate as the last named, some care is necessary to have it in good condition. When grown freely in a suitable position the young fronds have a beautiful rosy tint which distinguishes them from those of *argyrea*, which under any conditions does not give any colour except green and white.

P. ASPERICAULIS, or *rubricaulis*, as it is sometimes called, has dark bronzy brown tinted fronds, which give a distinct shade in a collection of Ferns. A. HEMSLEY.

ROSE GARDEN.

ROSE MME. LAURETTE MESSIMY.

OF all Roses I should recommend for groups it cannot be gainsaid that the variety *Mme. Laurette Messimy* gives the greatest satisfaction, being of vigorous growth, with an abundant and uninterrupted bloom from May till the frosts come. The colour of the flower is a tawny china rose, increasing in depth of tone in deep and fertile soils in northern climates; its leaf a blue-purple, elegant in form, in which it resembles a Tea Rose. In its general aspect it is vigorous, elegant, bushy, and quite hardy. In many countries, like Switzerland, Germany, and especially England, this variety is the object of peculiar care. It is fashionable; in all Rose gardens it has its allotted place; it is much cultivated in groups and masses; isolated, it often reaches gigantic proportions in rich deep soils and situations favourable to it. In a certain Normandy estate a Rose bush of this splendid variety planted in conditions very favourable to it reached in the space of two years a height of 6 feet 6½ inches and a circumference of more than 13 feet 1½ inches about 4 feet from the ground; it formed a round bushy shrub from the base upward. Its vigour is such that on May 20 last its owner counted more than 450 buds on the point of opening and a multitude of others to follow. Comment is superfluous. Many another analogous fact could be cited in proof of the merits of this Rose. The credit of obtaining this remarkable Rose is due to M. Guillot, of Lyons, who brought it out in 1887. It is the result of crossing the Bengal Rival de Pestum and the Tea Rose *Mme. Falcot*. A most happy gain it is, which has endowed Rose culture with an extraordinary variety by creating a veritable type which has given us other varieties having the same qualities of vigour and freedom of blooming in different colours.—P. GUILLOT, in *Les Roses*.

Sweet Brier Anne of Geierstein.—Although one does not profess to be a Rose expert, when one sees a good many gardens it is possible to select some of the most valuable without special knowledge of the host of Roses in cultivation. I am thus pleased to see that your correspondent "P." gives this variety so high a place among the sixteen raised by Lord Penzance. It is at present remarkably beautiful in my garden, and a gardener of extensive experience was greatly struck with its colouring the other day. Its vigorous growth is also remarked upon by your contributor. It is growing on a pillar here, and in this light, dry soil it is doing very well. In some respects it is finer than *Lady Penzance*, but

then the colour of the latter is, as "P." says, perfectly unique. In some soils this colour is, however, not well brought out, and a fine bush I saw the other day was hardly recognisable as Lady Penzance, although careful observation showed that it was correctly named.—S. ARNOTT.

Rose Duke of York (China).—The intense heat of the last few days has produced a wonderful effect upon this most uncommon Rose. It is at all times very variable, some of the flowers being almost white with a pretty carmine edging like a high tinted *Homère*, others nearly a pure light pink self until the flower expands, then the centre is flamed with rich rosy-red. This latter colour is now most intense; in some flowers it nearly approaches to blood-red. When this is so the under part of the petals, which is usually very pale, produces a surprisingly beautiful combination. Under glass and also outdoors many of the expanded flowers have the two outer rows of petals nearly white, the centre ones, which are irregularly placed, glowing with rosy-crimson. Duke of York is a good kind for the garden, succeeding well either as a bush or standard. It has a good vigorous constitution, with an elegant yet erect habit of growth.

Rose Coquette Bordelaise.—Rarely has a Rose appeared with a more distinct character than the above beautiful kind. To judge from the blossoms exhibited recently at the Chiswick conference by Messrs. W. Paul and Son, of Waltham Cross, this variety belongs to the Hybrid Perpetual class—in fact it is said to be a sport or seedling of Paul Neyron. The growth is certainly in the style of the latter Rose, but the form of flower is totally distinct, being when expanded almost flat, which enables the markings upon each petal to be distinctly visible, and appears like a huge *Carnation*. The ground colour is a pure pink, each petal being heavily flaked and blotched with white and sometimes slightly scalloped. This Rose will certainly become a more general favourite than *Pride of Reigate*, for somehow the latter never inspired one with any great liking for it. It is novel, but the markings are very irregular and the combination of colours not at all happy, whereas in *Coquette Bordelaise* the white blotches and lively pink ground colour are most attractive. As a garden Rose I should say it will gain much favour by the Rose-growing public, who are always ready to welcome really distinct novelties.—P.

Roses on pillars and arches.—It would be very interesting and useful if anyone who has good varieties of *Polyantha* or other Roses that will cover long lengths of trellises of any kind would give their names and short description, for out of the large number recommended for the purpose it is surprising how few quite fill the blank. I have *Crimson Rambler* 18 feet long, but, like many others, the bottom parts get very thick before the upper portion is furnished. It is the same with the *Dijon Teas*, as *Mme. Berard*, *Bouquet d'Or*, and others, also most of the single *Briers*. What is wanted is something that makes good shoots from the upper parts like the *Monthly Roses*, *Carmine Pillar*, and one or two more. There are several climbing forms of well-known Roses, such as *Captain Christy*, *Niphotos*, *Souvenir de la Malmaison*, and others, that make fine growths, but being almost strictly deciduous are hardly suitable, as the trellises and arches show too plainly in winter. I had that to keep Roses in health and vigour in such positions a great deal of feeding is necessary, much more than for trees growing in beds or borders. A rather pretty combination is *Crimson Rambler Rose* and *Clematis montana* on adjacent pillars and allowed to grow together, the former making a fine succession to the *Clematis*.—H. R.

Ayrshire and Evergreen Roses for massing.—Odd pieces of ground might be very usefully filled with some of the above Roses so that they can run about in wild confusion. They are a most useful race, growing and flowering where other kinds refuse to exist. If plants are produced upon their own roots and set out about 4 feet apart, in three years a delightful effect

would be produced. The long, trailing growths are then smothered with blossom, and yet there is an entire absence of formality owing to the new shoots breaking up from the centre of the plants. Particularly beautiful grown in this way is *Myri-anthes renoncule*, its pretty blush-pink flowers and elegant buds showing to great advantage. Another fine kind is *Leopoldine d'Orleans*, white, with red buds. Indeed, the whole of the collection would be sure to thrive. Even such a rampant grower as *The Garland*, a charming hybrid Musk, is now blooming freely grown in the manner described, and *Crimson Rambler* would be glorious. A certain amount of pruning is necessary. The growths should be shortened each year to about 3 feet or 4 feet from the base. Even this would not be required if the plants were set out further apart, because the growths are bound to blossom from almost every eye when they are allowed to grow in this creeping manner for a year or two. Overcrowding must, of course, be avoided, or the flowers will not be seen. This can be easily accomplished by entirely removing now and then some of the older growths.—P.

ROSES AT WOKING.

THE hot, dry, sandy nature of the soil in this neighbourhood is not conducive to the lasting powers of Rose blooms, and it is difficult to grow the flowers up to a good exhibition standard in a dry season. Nevertheless, this is a perfect home for Roses in the garden. In few localities can one see such a display of Roses or so early. During June one noted many splendid examples of W. A. Richardson, and the deep apricot tint in the flowers was especially noticeable. *Crimson Rambler* was seen in fine bloom, many trees being of large dimensions. Another Rose that does well is *Viscountess Folkestone*. Although this is not generally a good show Rose, the huge blossoms of flesh colour have a noble appearance on the plant. *Gustave Regis*, light yellow, so perfect in bud, has a splendid effect when fully open, even if not so double as many kinds. *Mrs. John Laing* is everywhere good, thus proving it a most desirable Rose for light soils. The most satisfactory light Rose, perhaps, has been *Mme. G. Luizet*. It was noted in perfect form about the middle of June. Roses generally appeared backward, but the hot sun brought them on with a rush, and the first bloom was quickly over. Here, however, new growth is readily formed, and we get an almost continued display of flowers. *Ulrich Brunner* is a sort that does well, except that it is only on strong plants that one sees a perfectly double flower. *La France* is always good, but this year is not so fine as last. *Suzanne Marie Rodocanachi* gives fine blooms, although somewhat thin. The greatest difficulty is with the dark-coloured kinds. *Prince Camille de Rohan*, *Xavier Olibo*, *Louis van Houtte*, and *Victor Hugo* are all unsatisfactory, and the lighter crimsons, A. K. Williams, *Alfred Colomb*, *Marie Baumann*, are but little better. The few dark Roses that do fairly well are *Duke of Edinburgh*, *Crown Prince*, *Prince Arthur*, and *Fisher Holmes*. *General Jacqueminot* grows as freely as any, but the buds open fast and are quickly over. *Captain Hayward* and *Thomas Mills* are other bright-coloured sorts whose beauty is fleeting. *Gustave Piganeau* and *Earl of Dufferin* do not grow well, and *Charles Lefebvre* is only a fair success. *Her Majesty* is a Rose suited to our soils, and *Mrs. Sharman Crawford* does well also, but the blooms this year are not so good as last. *Baroness Rothschild* and *Merveille de Lyon*, two kinds of similar growth, make fine trees and blossom well. *Margaret Dickson* and *Marchioness of Londonderry* have grown well, but do not flower freely. *Comte de Raimbaud*, a Rose not unlike *Chas. Lefebvre*, is a dark one that will be tried by planting more of it. It is an old, but somewhat neglected variety.

Except in the nurseries on newly-budded plants, Hybrid Perpetuals generally do not produce ideal show blooms in this locality. The Hybrid Teas and Tea-scented Roses, however,

grow much better. *Caroline Testout*, salmon-pink, surpasses *La France* in beauty and abundance of bloom. *Kaiserin Augusta Victoria* is a favourite both under glass and in the open. *Mme. Abel Chatenay*, rather a new Rose of a salmon-pink shade, was seen in more than one garden, but is not very well known. It is likely to be valuable as a garden Rose. *Marquise Litta* is one of the successes of the year. It bears large carmine-coloured blooms and has exceptional petals. This is handsome on the tree. *Mrs. W. J. Grant* does well. Another Rose, new to me, noted in Woking is *Souvenir de President Carnot*. It bears full blooms of a pretty pointed shape, the colour being white, with a pink tinge. *Anna Olivier* is among the best of the Tea Roses. It grows freely and the flowers are very distinct. *Maman Cochet* does exceedingly well. Its salmon-rose blooms are of perfect form. Grown on strong soil they are apt to split, and therefore less valued generally. I saw the white *Maman Cochet* in bloom recently. It is hardly pure, as its outer petals have a pink tinge, but it is a decided acquisition for all that, and is as distinct from the parent as is *The Bride* from *Catherine Mermet*. What a splendid family we are getting from the last-named!—*Bridesmaid*, *Muriel Grahame* and *The Bride*, all of faultless and similar form, but different in shades of colour. These do capitally here. *Marie van Houtte* comes with blooms more pink in tint than one meets with elsewhere. *Hon. Edith Gifford* grows well and blossoms freely. The somewhat tender sorts, *Cleopatra*, *Comtesse de Nadaillac*, *Mme. Cusin*, and *Mme. de Watteville*, do not make nice plants. I think they should be tried on low standards. *Medea* does fairly well; so, too, does *Souvenir d'Elise Vardon*. *Rubens* is a good old Rose, but does not come over double. *Souvenir d'un Ami* and the sport, *Souvenir de S. A. Prince*, grow well and flower, but the blooms are comparatively small.

Is *Gloire de Dijon* Rose wearing out? Whether it is that W. A. Richardson does so well in the neighbourhood and the former suffers in consequence or not, it is not happy in many cases, and one rarely sees it in that rampant style of years ago. *Laurette Messimy* is a charming Rose of the China class. It blooms the whole season and is quite charming in colour, satiny rose. *L'Idéal* is represented by some fine specimens. These will by-and-by run W. A. Richardson close in attractiveness, the shades of colour in the blossoms being unique. H. S.

KITCHEN GARDEN.

VEGETABLES AND DROUGHT.

In many gardens the soil is light, resting on gravel, and in a dry season the culture of vegetables from June to September is difficult. I may be told watering will remedy the evil, but it is a poor remedy if used alone. It is almost labour in vain in the case of certain crops sown very thickly, as unless done daily, it is useless. For several seasons past we have had long periods of drought, and it is a difficult matter in light soils to maintain a healthy growth. It is surprising what may be done by mulching sufficiently early between the rows of growing crops, also by sowing thinly. A strong plant is an important item in such seasons. I have referred to mulching and advised early attention to crops perfecting their growth, such as Peas, French Beans, Cauliflowers, salads, and similar crops. During the latter part of June I have after mulching watered daily for quite a fortnight, and have already reaped great benefit by the same, as the plants, given a thorough watering once a week, will pull through and growth will be clean and strong. Few vegetables collapse sooner than Peas in dry, hot soils. I find that, to get them after June is over, mulching is a necessity.

Few materials are available for mulching, and one is obliged to use those at hand. There can be no doubt as to the value of cow manure for light soils. This is much better than horse manure, but, as previously stated, it is not always obtainable. I use spent Mushroom manure largely. This is obtained at small cost and is most valuable as a mulch, as it retains moisture so well if used freely. As regards feeding on a light porous soil, it is not the best, but one must think of the present crop and act accordingly. It would be far better in the winter months to cart some heavier material on to the land in the way of soil of a clayey nature, but this is not practicable in many cases. In mulching with the material advised, it is well to use sufficient down the side of the rows, so that when moisture is given it is retained. Of late years I have found the strong growing Peas of the Stratagem type the best dry weather varieties. These only growing 3 feet, often less in dry seasons, may be sown much closer than tall varieties. I find it well to mulch the whole space between the rows, and if this is done it is surprising how the plants thrive. The mulching is necessary just as the podding commences, and in watering a thorough soaking is given. In the case of salads, I fill up the space between the plants. The same treatment is carried out with Cauliflowers, French and runner Beans, or other shallow rooting crops. Long litter will prevent loss by drought. I admit straw litter does not add to appearance, and if it can be obtained with the long straw removed so much the better. On heavy land using the hoe freely in dry weather is of great advantage. On such land light materials are beneficial. Here such aids as leaf-soil and burnt refuse will be found serviceable.

G. WYTHES.

CUTTING ASPARAGUS.

SEVERAL notes on this subject have lately appeared in THE GARDEN. As to which is right, cutting large and small grass alike, or leaving the weakly growths to develop, there appears to be a divided opinion. It has always been my practice to leave the weak grass, and I think it is beneficial, especially where the soil is not the best for Asparagus culture, as it certainly increases root action and strengthens the plants generally. I have lived with three or four very good Asparagus growers, and each of them, if I remember rightly, allowed all the thin, weak grass to remain. A few days ago I was speaking to a very successful grower who is strongly in favour of leaving all small growths. These, he maintained, formed stout eyes at the base, these producing strong growths the following season. Their remaining also increases root-action, and the whole stool is strengthened. The grower in question takes more trouble with his seedlings than most gardeners. The permanent beds are not planted at random, the young plants being first proved in nursery beds. The seed is sown not too thickly in a not too hot position, the young plants being kept well moistened while growing. Mulching is serviceable in dry seasons, spent Mushroom manure answering very well. The second spring the young plants are transferred to a nursery bed and allowed fair room to develop. When in berry the plants are marked, those only with large berries being selected. Planting into the permanent beds is performed the following season. This grower thinks that if male plants only were planted finer grass would be produced. Of course, one would require to sow a large quantity of seed to be able to select all male plants. Male plants, he contended, having no seed to support grew much higher and stronger and formed stouter eyes for producing the following year.

The same grower described the behaviour of different varieties of Asparagus in the garden under his charge. There were three sorts, one of

which he found on the premises when he took charge many years ago; the two others were Conover's Colossal and Argenteuil. The first named, though treated exactly similarly to the rest, produced inferior grass, though in greater quantity. Conover's Colossal is finer, and Argenteuil finest of all. The last is my friend's favourite strain. I may add he is an advocate for blanched produce, and states that if when away from home he eats ordinary green stems they are never enjoyed like the blanched heads of his own garden. I have grown the Argenteuil variety myself, and consider it fine in every way. Anyone planting it on fairly good ground and dealing patiently with it for the first three seasons will, all other conditions being equal, be pleased with it.

NORWICH.

LETTUCE IN DRY, HOT SUMMERS.

OF Lettuce in certain seasons it is difficult to keep up regular supplies. From years of close observation I have found that the Lettuces with deep coloured leaves are most reliable. A great deal depends upon the soil and culture, but in hot, dry seasons a great deal also depends upon variety. Doubtless many growers have found that the autumn varieties, if they can be called such, are more reliable for summer cropping in dry seasons than the quicker growers. I allude to such kinds as the Black-seeded Cos, Champion Brown and Bath Cos, Hammersmith Hardy Green, Lee's Immense and others. These sown in May or June are all good for the season noted, and given a cool root-run are most useful for July and August supplies. To sow at short intervals on a dry, hot soil through July and August will end in failure. The seeds with sufficient moisture germinate freely, but in a thick seed-bed so quickly run to leaf that planting out is impossible, as if the plants are pricked out very small the sun takes all life out of them, and if allowed to get any size they are weakly, being drawn and run to seed instead of hearting. There is no better plan than sowing very thinly in rows and on a north or cool border for the June or early July sowings if this plan can be adopted. The chief work is thinning out sufficiently early to prevent crowding. Many may think this mode of culture waste of seed, but it is not, as in sowing one may drop a little seed at say intervals of 9 inches to 12 inches apart, and thinning is soon done. I find it best to draw drills with a flat bottom not less than 6 inches wide. These drawn 15 inches apart give nice space and the drills allow of watering. Another plan, and one that rarely fails, is to draw a single drill at the foot of a north wall and sow very thinly. Here I have even got good results by transplanting, as the soil is cool, but this is not always reliable in hot summers. It is best to rely on sowing and thinning out. A poor thin soil is so soon dried up that those who can use cow manure for salads in such soil and in liberal quantities will find it invaluable. Much may be done by mulching between the rows with spent Mushroom manure, or even short litter; in fact anything that retains moisture will be of great value. The best summer Lettuce in a light soil is Continuity, a variety raised in the eastern counties and specially good for summer crops. This is a dark or red coloured form of Cabbage Lettuce, and it remains fit for use a longer time than any other variety I have grown, as even when full grown and in dry hot weather the plant remains solid for some time. I have heard objections made to the colour of these plants and others of similar type, but the quality is good and that is important, and the colour when the outside leaves are removed is rather pleasing than otherwise, as the heart is a beautiful pale pink and very firm. Another variety and but little behind Continuity is Marvel, also a Cabbage variety. This kind has red edges, the heart being of a pale golden colour. It is a splendid variety for dry, hot soils. Sown with Continuity it is earlier, but keeps longer. A variety named Standwell is excellent. This will suit those who object to the deeper coloured forms, and the Victoria, an

old but good kind, a black-seeded variety, is excellent for the summer and equally good in winter. For years I grew Kingsholm Cos, a splendid form, but of late years have grown Intermediate, a most distinct form, smaller than the ordinary Cos, but not unlike the Bath Cos, and invaluable for light soils, as it remains good so long and takes up little room. This variety can be grown closer together than the others named. There are several kinds of black-seeded or Bath Cos, some much better than others, but few are superior to the Northern King Cos, a variety well worth growing for late summer supplies.

G. WYTHES.

Cabbage Lettuce.—Having tried most of the varieties of Cabbage Lettuce catalogued, owing to the fact that this type is much more in demand with me than the Cos, I should like to add a note to the correspondence on page 402. My selection would be Golden Queen, Perfect Gem and Continuity. The first named is the quickest variety either for in or outdoor work. The first outdoor crop should, however, be planted on a narrow south border so that a little protection can be given in case of frost or very cold winds. Sown at the same time as Perfect Gem and grown under exactly similar conditions, it is ready for cutting a few or ten days before the other variety. It is not a good mid or late summer Lettuce, running very quickly if the weather prove hot and dry. I have, however, grown it all through the summer under opposite conditions, and endeavour to do so if possible, as it is a great favourite. Perfect Gem stands well and is a very useful variety. On page 402 "J. R." suggests that "A. W." has a spurious or inferior variety of Golden Queen. Is "J. R." equally unfortunate in the matter of Continuity? This with me is the most reliable for the summer months, as it stands drought well, does not run away quickly, and the heads attain a large size. Being a strong grower, it wants deep tilth and plenty of manure. I get occasionally in each batch plants of a sort that correspond with the description given by "J. R.," growth being coarse and ragged, with an Endive-like outer edge of leaf. This is a long time turning in and the heart is small when compared with the huge outer leaves.—E. BURRELL.

NOTES AND QUESTIONS.—KITCHEN.

The Cauliflower grub.—This is the larva of a small fly very like the common house fly. It especially attacks Cauliflowers planted in recently manured ground. Any preparation of carbolic acid dusted round the Cauliflowers when planted will prevent an attack.—G. M.

Lettuces in trenches.—Where many hundreds of Lettuces are needed transplanting is almost compulsory, and then should the weather be hot and dry difficulty is often experienced in inducing the plants to start away freely, or growth is such that wholesale premature running to seed occurs. When the demand is limited means are more easily practised for the prevention of collapse or unsatisfactory growth. Shallow trenches capable of holding a few score of plants are easily thrown out, and in these the plants can be easily watered and temporary shade afforded by placing a few evergreen branches on either side of the trench. The labour of this may at first sight seem great, but in shallow, porous soils it is a gain in the end.—C.

The Parsnip fly.—I take it that this pest is synonymous with the Celery fly, though, fortunately, the damage caused by the grub among Parsnips is by no means so great as in the case of Celery. This season, however, I have noticed several instances where Parsnips have suffered severely through it, but they were all in one locality where the soil is very dry and close to the chalk. Whenever Parsnips are badly attacked it has a serious effect on the crop, for the mutilation of the leaves causes a stunted growth and the roots suffer in consequence. Strong, healthy plants are rarely affected, and if sown at the end of February or early in March they become so vigorous that by the time the fly is on the wing it shuns them for leaves less leathery and consequently more toothsome.—H. H.

THE GLEN, INNERLEITHEN.

THIS charming seat of Sir Charles Tennant, Bart., is situated on Quair Water. It was built in 1852, enlarged in 1873, and is said to have cost, with the surrounding grounds, some £50,000. The style of architecture is the old Scotch baronial, and Mr. Bryce, the architect, has been known to quote The Glen as his best illustration of this style. Notwithstanding its name, there is but little level ground to be found in the gardens at The Glen; in fact, one of the chief charms of the place is the rolling character of the site. This prevails throughout

of the Irish Yew some 30 feet through; some venerable Scotch Firs and other fine trees, including a Beech 14 feet in circumference at 4 feet from the ground. The tree has its branches chained together.

It is emphatically a picturesque rather than a fertile garden, and it adds greatly to the credit of the cultural triumphs achieved that they have mostly been won in the teeth of very great difficulties. The soil is hungry as well as thin and poor, only an inch or two thick in many places over the barren whinstone which forms the base of the stratum. In some parts the rock,

collections of herbaceous plants in various directions were prepared to make good the supply of flowers through the season. The entire domain is emphatically a garden beautiful, and each step reveals new pleasures.

The fruit and kitchen gardens, old and new, that cover some 5 acres, are on different levels. Notwithstanding the height and free exposure, however, the fruit trees and bushes and all the crops in the open were among the very best I had seen. The crops were abnormally late this year, but they bore no traces of frost-bite or trail of disease. Even the ubiquitous Black Currant mite has not yet been seen at The Glen, and seldom have these and other bush fruits, Apples, Pears, Plums, Cherries, &c., looked more promising. Fruit indoors is also all that could be desired. The seedling Strawberry Glen Diamond is the favourite Strawberry here indoors and out. It is said to be a seedling from Keens'.

In the plant houses there were some fine specimens of Ericas, Palms, &c., while in one house was a fine lot of Malmaison Carnations.

D. T. F.

A view at The Glen, Innerleithen. From a photograph sent by Mr. D. T. Fish, 12, Fettes Row, Edinburgh.

the kitchen garden as well as the lawns and pleasure grounds. The elevation and unevenness culminate in the kitchen garden. It is almost a unique experience to find one's self climbing upstairs to the fruit and kitchen gardens. The crops suffer far less from the severities of spring frost on rolling grounds than on the flat or in the troughs of valleys.

Almost the first thing specially noted at The Glen was the very fine examples of Hodgin's Holly some 20 feet through, clothing the bareness of the square of gravel and grass at the front door. Further up were a unique example

fortunately rather rotten on the surface, had to be dug out and good soil put in for the roots. In others the surface was deepened by additions of good soil. Over all a surface tilth had to be provided that would carry good grass and all other crops through all weathers. Oaks, Ashes, Beeches, Birches, Elms, and the fine golden Corstorphine Planes form important features in the furnishing of The Glen. The chief flowering shrubs hardly yet in flower in the last week in May were hardy Azaleas and Rhododendrons, though Thorns, Lilacs, Roses, Sweet Briars and other shrubs, and some fine

The wood of the False Acacia possesses for industrial purposes a higher value than that of native woods such as the Oak, Elm, Ash. It is excellent for fuel, producing a lively, lasting warmth, and is especially well suited for open hearths owing to the very great proportion of radiating heat it gives out. Nevertheless, it is held in little estimation by consumers on account of the fault attributed to it of emitting too many sparks. From what has been said above, the result is clear that the production of this tree as timber would not be profitable, but that it may be very useful as undergrowth. The tree is very suitable for planting in sandy soils and for holding embank-

Value of the Locust Tree (Robinia Pseudacacia). — In the last century the advantages of cultivating this tree were somewhat unduly insisted upon, and as the results did not realise the hopes which were formed, the inevitable reaction followed, and it has since been too much neglected. To day, however, we are enabled to form a juster estimate of its value. The Robinia is a very long-lived tree and may grow to a height of 70 feet to 80 feet and over with a circumference of 6 feet to nearly 10 feet, but to grow to these dimensions it should be isolated. In plantations and clumps of trees it thins itself at a very early stage and never comes to a great size. The root is at first a deep tap-root, but produces very long thin lateral spreading roots, which give out a wealth of suckers for some distance. The young stocks produce vigorous shoots. All soils suit it, and though it prefers those which are light and slightly cool, it thrives on dry, sandy ones. The wood of the Robinia, which shows very distinct annual increments, is heavy, hard, elastic, as durable as that of the Oak, with a vertical resistance superior by a third to that of the Oak, which places it in the first rank as a wheelwright's wood for making spokes. It is preferable to all other woods for laths, props, hoops, pegs employed in maritime construction, it takes a polish well, and is suitable for turner's work. It is not adapted for building, because the stem is seldom regular enough to yield timber of great size.

ments together, and the leaves, green or dried, are good as fodder.—*Flore Forestière.*

FLOWER GARDEN.

A NOTE FROM KIRKCONNEL, N.B.

FROM early spring until late autumn one can hardly visit the garden of Mrs. Maxwell-Witham at Kirkconnel, Newabbey, N.B., without seeing something interesting in the way of hardy flowers. A visit paid the other day gives one pleasant recollections of the flowers then seen. The old garden Roses were at their best, and beautiful indeed was a number of the great bushes, some of which must be of great age. Some years ago Mrs. Maxwell-Witham gave an interesting account of these Roses in THE GARDEN, and I have more than once referred to them in your pages. One of the best is one named Swiss Boy, which is free-flowering and very beautiful. There were also big bushes, or rather trees, of others such as the Danask, the old Velvet, Maiden's Blush, Celestial, one with a curious spicy odour called here Plum Cake, besides a good many more or less well known. Some great bushes of *Kalmia latifolia*, which must, judging from their appearance, be very old, were also fine. The collection of herbaceous plants is very large, and now includes the greater number of our best border flowers. There was nothing finer, however, in its own way than the Kilmarnock form of *Orchis maculata*, with which Mr. Harper, the head gardener, seems very successful. There is a good stock of this magnificent *Orchis*, and the long, handsome, deep-coloured spikes made a fine effect in groups. There was a capital specimen of the creamy white *Amianthium muscetoxicum*, a plant which appears to be coming into favour in the south-west of Scotland, and which does well in the district. *Alstromeria revoluta* has now become well established, and is apparently thriving and giving plenty of its deep orange-red flowers. *A. aurantiaca* and *A. lutea* were also good. *Erigeron salsuginosus*, said to be the true plant according to the late Asa Gray, and which I have seen at Kirkconnel before, is also good—better, indeed, than another plant offered under the name of *E. salsuginosus*. There is a small stock of the true old double white Scotch Rocket, now getting scarce in Scotland. I suppose we have now so many plants that people do not care to be at the trouble of propagating this, which is so much superior to the French White. At Kirkconnel there is a nice plant of the *Lychnis* sent out several years ago by an American firm as *L. Flos-cuculi plenissima semper-florens*. At first I did not care for this, but it improves upon acquaintance, and its long-flowering habit is certainly an advantage. *Inula glandulosa grandiflora* is very fine, but it may be noted that of the plants received at Kirkconnel from various sources under this name only one seems to be correct. This gives handsome flowers. *I. Hookeri* has also been good. *Chrysanthemum Clusii*, although not an effective garden plant, is useful for cutting. *Sidalcea oregana* was very pleasing, and I observed a nice plant of a *Morina* which seems like *Coulteriana*, but was not in flower. A capital double yellow *Potentilla californica*, which seems even better than *Vase d'Or*. The old double Martagon Lily is plentiful at Kirkconnel, while other Lilies which succeed are also represented. The large collection of *Pentstemons* looked hardly so vigorous as usual, but the choice and extensive variety of *Phloxes* will be fine in a short time.

S. ARNOTT.

Salvia Tenoreana.—This is a plant of really exceptional merit and one that ought to prove valuable to those who prefer to rely mainly on hardy things for the summer decoration of their gardens. It is dwarf, but robust, very free-flowering, and in colour is sufficiently bright to be really effective. It cannot, of course, compare with its relative *S. patens*, but might well be used in combination with this useful old species. The

individual spikes last a long time and are produced in succession, so that the blooming period is a long one.—J. C. B.

Larkspurs for cutting.—I find these of great service through the summer months for supplying a quantity of cut bloom. The tall branching strain is the best, and by sowing about three times between the middle of March and the end of April one may have a good supply of bloom during July and August. With me these Larkspurs have become in a measure naturalised, springing up among Daffodils and other things, so that by leaving a plant here and there I get flowers for cutting with little or no trouble.—J. C. B.

Sweet Peas in hot weather.—I saw the other day in an amateur's garden a very showy row of mixed Sweet Peas, and could not but notice how happy they seemed in their semi-shaded position. I think gardeners would do well to avoid very hot positions for Sweet Peas which are to supply bloom say in July and August, especially when the soil is shallow and of a sandy nature. These beautiful flowers are often treated in a rough-and-ready manner, hence the limited period of blooming and sudden collapse of the haulm. Sweet Peas are often sown too thickly, the haulm consequently being too dense for the admission of sun and air and the rooting medium soon becoming exhausted. At this season, too, a mulching ought to be applied when growth is 6 inches high and manurial waterings given from that time till the last flower-trusses are opening. Frequent picking of exhausted blooms is also necessary, nothing being so impoverishing as a large number of seed-pods.—J. C.

Sweet Pea Butterfly.—I must confess that in most instances I prefer the bold, self-coloured tints in Sweet Peas, and such delightful kinds as Cardinal, with its rich red blossoms, appeal to me more than the paler-shaded and suffused colours. But the one named above is really a charming kind, almost snow-white, with a bluish mauve edging as distinct as that of a *Picotée*. The blossoms are large and of great substance, yet they lose nothing of the elegance and grace that we have learnt to associate with Sweet Peas. It is, in fact, one of the flowers that has been greatly improved in size and lasting qualities without being spoiled in any other way. Careful attention now to removing the old seed-pods is well repaid by the increased amount of flower produced, but unfortunately at this busy time of year the labour even of a boy can hardly be spared, and the Peas have to make the best of it. No plant pays for good culture better than these lovely annuals, and, looking through a so-called botanic garden in the neighbourhood recently, I could not help noticing the short-sighted policy that there obtains, viz., spending money upon seeds of named varieties, yet begrudging a little good soil and manure to enable these to show their true character.—H.

Coreopsis grandiflora.—Seedlings of this fine plant raised now and pricked off into nursery lines or beds will make nice stocky little plants for putting out in any vacant places that may occur in herbaceous or shrubby borders at any time in autumn or spring. This method of having a few herbaceous seedlings coming on is a very good one, for a bare place may be made gay, and if the right class of material is on hand, flowers for cutting will be produced in plenty. Whether for this purpose or for garden decoration, this *Coreopsis* is a plant for everybody and all seasons. No matter how wet and rough the weather is, the pretty yellow blossoms recover more quickly than almost any other, while should drought set in, it is as constant in bloom as in more seasonable weather. All through the drought of last summer, when everything in the flower garden seemed to be all but killed, its bright golden-yellow blossoms could be gathered daily, while the plants held their own bravely. It is best raised from seed occasionally, as, although it will last for years and continue flowering freely, the blossoms are always finest and best coloured

in the second and third years. It seems equally at home in all descriptions of soil, but of course does best when it is free-working and in good heart.

Water Lilies.—So far the beautiful new varieties of *Nymphaeas*, of which we have so many now, seem to be found only in private gardens, and thus the public have few opportunities to see them. There may be some few cases where cultivated in public gardens, as they are found at Gunnersbury House, for instance, but I do not know of them. I have often thought when visiting the popular gardens of Hampton Court of late what a fine opportunity is presented for the culture of these Lilies in the broad fountain basin. At present the water is bald and much lacking colour. Scarcely anywhere at a place of popular resort is a more suitable place for the purpose presented, for the basin is accessible all round; the Lilies would get ample sunshine, which they so much like, and the water is constantly being changed. There are at the palace end of the long water and the adjoining moat some luxuriant yellow *Nymphars* and common white *Nymphaeas*, showing how admirably the water suits them. Very much labour is expended both in spring and autumn in filling, at considerable expense, the many large flower beds in the grounds, and whilst every effort is made to vary the arrangements from year to year, yet little that is done can be described as novel. But Water Lilies once well established at Hampton Court would not only constitute to myriads a standing novelty, but would seem to be in singular harmony with the grand old palace and its surroundings.—A. D.

CALOCHORTI AT WISLEY.

THESE beautiful bulbous flowers are blooming with unusual vigour in Mr. Wilson's garden at Wisley this season. The flowers are large, fine in colour, and borne on stout footstalks from 2 feet to 3 feet high. Seeing them in this robust, happy condition, one might imagine that they are of comparatively easy culture, but, as many hardy flower growers have found to their cost, the requirements of these *Mariposa* Lilies are not easily realised. This at any rate is the impression that one gets from their appearance at blooming time in so many gardens wherein their culture has been attempted. The elements of success at Wisley appear to consist in a very free soil, perfect drainage, full exposure to the sun, with shelter from cold winds. They grow in a bed somewhat raised above the ordinary ground-level, and where it is impossible for the bulbs to suffer from stagnant moisture in a time of continued heavy rains. This probably is a most important factor in the successful culture of *Calochorti*, and unless it can be assured, expense and labour bestowed on them would be wasted. The character of the soil is an important item, that in which they grow at Wisley apparently being sufficiently light and free to preclude the possibility of it becoming clogged and sour when frequently saturated by heavy rains. Backed up by trees and facing the sun at noonday, the place is a sun-trap, which catches up and stores the solar warmth so that in late summer, when the bulbs are maturing, the soil around them must become very hot. No bulb can bloom well unless it is exposed to a certain amount of heat after flowering. The amount required varies wonderfully, as may be seen in the case of the Daffodil and the *Freesia*, the latter requiring exposure to the greatest amount of solar heat that can be accumulated in a glass structure after the foliage has died away; whereas *Narcissi* are content with that which they get in the early portion of an English summer. The *Calochorti* naturally demand as much sunshine as we can give them. It is possibly from want of realising this simple matter that many have failed to grow with success a race of hardy flowers which in quaint beauty and distinctness stand quite apart from hardy flowers generally.

I have endeavoured to describe the conditions under which these charming bulbous flowers grow

at Wisley, and those who have failed with them may perhaps gather enough from what is here written to enable them to rectify any errors hitherto committed and may give them courage to make a fresh start. One of the finest blooming at Oakwood is a form of *venustus* named *Vesta*, which has large, bold creamy white flowers with a dark ring round the throat. *Beothami* is very similar, but the ring is broken up, which, I think, renders it less attractive. *Citrinus* is very bright yellow with dark spots; this is a charming and distinct kind which should be in every collection. *Luteus* is also bright and showy, and *venustus purpurascens*, suffused with purple and having the reverse of the petals deeply stained, is very handsome and distinct. J. CORNHILL.

Pentstemons.—There need be no fear of Pentstemons attaining to a good size and producing abundance of bloom the first year from cuttings provided good soil and good treatment are given. I recently saw a grand row in an amateur's garden. The cuttings were struck last autumn and planted out in February. One great point to be observed in order to obtain the best results is to give the cuttings a fairly rich, sustaining soil to root in. This makes all the dif-

ference. I do not advise putting them in too thickly, as they crowd each other and draw up spindly. The young plants also should be stopped when a few inches high, this securing side growths and good stocky plants. Nothing answers better than a frame in which the plants can be fully exposed in mild weather, even at midwinter. The plants also pay for a good larder in their flowering quarters. Pentstemons are excellent for cutting.—N. N.

the flower. There seems to be some mystery or uncertainty as to whether there really is a yellow-flowered form of this plant, as a well-known introducer of new plants in Germany wrote to me recently that he had received a short time previously from St. Petersburg a quantity of seed of what purported to be *Incarvillea lutea*, but when it germinated the seedlings turned out to be *I. variabilis*. The fact of the flowers of the so-called *I. grandiflora* all rising on separate footstalks from the crown of the plant, as shown in your coloured plate, instead of being borne in bunches of from four to eight on the top of tall stems about a yard high, as in *I. Delavayi*, seems to me to constitute the only real difference between *I. grandiflora* and *I. Delavayi*, as the individual flowers do not seem to be of any greater size.—W. E. GUMBLETON.

NARCISSUS BISHOP MANN.

The illustration shows a group of the giant Irish cernuus or Bishop Mann (Swan's-neck variety). The photo was taken in a children's garden (the Misses Cornwall) at Moulefield, Cork. The variety is quite distinct from the type, by its length of trumpet and its twisted

A group of *Narcissus Bishop Mann*. From a photograph sent by Mr. W. B. Hartland, Cork.

Incarvillea grandiflora.—The writer of the note accompanying your fine plate of the above-named most beautiful hardy plant seems to be of opinion that it is identical with *I. compacta* of Maximowicz. If, however, he had referred to the portrait of this plant in the volume of Regel's "Gartenflora" for 1882, plate 1068, I think he would have found good reason for altering his opinion, as the two plants are to my eye totally different—at all events from a horticultural point of view. The flowers of *I. compacta* are of a deep pink shade, much smaller in size than those of *I. grandiflora*, and do not rise out of the foliage on footstalks, as do those of the latter variety. They have also no different colour round the entrance to the throat, but merely a slight deepening or intensification of the colours of the rest of

petals, and was named at the Daffodil conference in 1886. It is very early, often flowering in the south of Ireland in February. In 1889, when the Countess and Lord Aberdeen occupied the Vice-regal Lodge in Ireland, the Countess expressed a wish that she should have a bouquet of open-air flowers for one of the drawing-rooms at Buckingham Palace. This beautiful Daffodil was made into a spray and was much admired. H.

Lilium testaceum.—This is in every way a charming Lily, the prettily reflexed blossoms being arranged in a very graceful manner, while their colour (a kind of nankeen or buff) is particularly pleasing and totally distinct from anything else. The contrast, too, between the bright red anthers and the rest of the flower is also very noticeable. The blossoms remain fresh for a longer period than those of most other Lilies. When well established it is a particularly tall stately Lily, hence the name of *excelsum* which is sometimes applied to it is an appropriate one. Besides this it is sometimes known as *L. Isabellinum*. It is not at all a difficult Lily to cultivate, as it will succeed in any ordinary garden soil that is not

dried up at any time. Unlike several other species, it may be depended upon to flower well the first season after planting, while if required it may be successfully grown in pots. This Lily is a hybrid between *L. candidum* and *L. chalcedonicum*, but its early history appears to be lost. It is one of the Lilies so well done by the Dutch cultivators. *L. testaceum* is, except *L. candidum*, usually the first to appear above ground, and though the young foliage has a delicate appearance, it is seldom injured by frosts or cutting winds.—T.

PERFUMES FROM PLANTS.*

This list does not profess to be complete, since nearly every plant that grows has odour or fragrance of some sort or other, however slight it may be. Even species and varieties of the same species vary very much in odour, as is abundantly proved by species of, say, *Den-drobium*, *Reseda*, or *Diosma*, and by varieties of H.P. or Tea-scented Roses, Apples, Pears, or Sweet Oranges, no two varieties smelling or tasting precisely alike. This is even true sometimes of individual fruits off the same tree. All that is here attempted is to give a bird's-eye view of the plants most generally grown for fragrance, and especially of those having sweet-scented leaves as well as flowers.

ACACIA.—Shrubs or small trees mostly from Australia and North Africa. *A. Farnesiana* is largely cultivated at Grasse for its flowers.

ACHILLEA MILLEFOLIUM (Yarrow).—Aromatic herb, both foliage and roots being odorous.

ACORUS CALAMUS (Sweet Flag).—Largely grown from time immemorial for its rhizomes in the East. It is cultivated in fen districts in England, on the Continent, and especially on the shores of the Black Sea.

AJOMAN (*Ptychotis ajoman*).

ALLIACEOUS ODOURS.—Characteristic of Onions, Chives, Leeks, Garlic, &c. (*Liliaceae*). As showing that taste and smell do not always agree, we may instance that the taste or flavour of Onions, &c., is enjoyed by many who detest the smell of them. (Shakespeare, "Midsummer Night's Dream," iv., 2)

ALLSPICE (*Pimento officinalis*).

ALOYSIA CITRIODORA (Lemon-scented Verbena).—A well-known shrub from Chili, deservedly much grown in gardens, and hardy in warm and sheltered corners near walls and plant houses. Its leaves retain their odour when dried, and are often placed in the teapot in Spain to add their aroma to the tea.

ANDROPOGON CITRATUS (Lemon Grass).—This and several other species are grown or collected in India, Ceylon, &c., and the essential oil they produce is known as "Indian Geranium" oil. It is grown as a stove plant, and its leaves when fresh are used for flavouring confectionery.

ANGELICA ARCHANGELICA (*A. officinalis*).—A tall herbaceous plant the fleshy stems of which are very aromatic, and are candied or preserved in syrup and used in confections. Oil of Angelica is used in Chartreuse and other liqueurs.

ANGOSTURA (*Galipea cusparia*).—Used as a tonic stimulant.

ANISE (*Pimpinella anisatum*).

ANTHEMIS NOBILIS (Chamomile).—A dwarf ever-green composite plant, grown for its single or double Daisy-like flowers, which are used medicinally.

ANTHONXANTHUM ODORATUM (Sweet Vernal Grass).—This grass belongs to the Commarin series of perfumes, and gives its peculiar fragrance to the hay crop. The essential oil is used in perfuming cheap tobaccos, &c.

ARTABOTRYS (*Artabotrys odoratissima*).—A flowering shrub having aromatic leaves and very sweet Apple-scented flowers, from which a perfume is derived. The leaves have been used in Java as antispasmodic in cholera, as also those of *Melaleuca minor*.

* Paper by Mr. F. W. Burbidge in the Journal of the Royal Horticultural Society.

ARTEMISIA ABROTANUM (Lad's Love, or Old Man).—A well-known plant in most cottage gardens, having finely cut and agreeably aromatic leaves. *A. Absinthium* is "Wormwood" used in rustic medicine and in the manufacture of absinthe in France and Belgium.

ASPERULA ODORATA (Woodruff).—A little rubiaceous woodland plant having whorled leaves and white flowers, deliciously aromatic, somewhat like the Sweet Vernal Grass, used fresh or dried in posies and bouquets, and sweet bags. The flowers infused in Rhine wine yield the "Maitrank" of Germany.

AZARA MICROPHYLLA.—An evergreen shrub or small tree from Chili bearing a profusion of greenish yellow flowers beneath its branchlets in March and April, and yielding a delicious perfume of vanilla.

BALDO (*Peumus fragrans*).—Somewhat like Sweet Gale (*Myrica Gale*).

BALM (*Melissa officinalis*).

BALSAM OF MECCA (*Balsamodendron Opobalsamum*).—Aromatic gum resin, highly valued by the Arabs and Indian Mussulmans.

BALSAM OF PERU (*Pereira myrospermum*).—A leguminous tree, native of Central America; but the balsam is now rarely obtained and little used. It was employed for chronic coughs, ulcers, and in the making of pastilles.

BALSAM OF TOLU (*Myrospermum toluifera*).—Similar to the last and employed in same way, but now rare.

BALSAMITA VULGARIS (Costmary or Alecost).—A hardy herbaceous plant from Italy having balmy or aromatic foliage.

BAROSMA CRENULATA (*Buchu leaves*).—Evergreen shrubs from South Africa.

BASIL (*Ocimum basilicum* and other species).—Basil is a delicious pot-herb much used in the south of Europe.

BDELLIUM (*Boswellia glabra*).—A gum resin from *Balsamodendron africanum* (African Bdelium). *Amyris Bdelium* or *Balsamodendron Roxburghi* is "Indian Bdelium."

BEZOIN (*Styrax Benzoïn*).—Not to be confounded with *Laurus Benzoïn*. It is an aromatic gum resin, not much used except in incense. Native of Borneo and Indian islands. It is sometimes called "Gum Benjamin." False Benzoïn is obtained from two or three species of the genus *Terminalia*.

BERGAMOT (*Monarda didyma*).

BITTER ALMOND.—Yielded also by *Cherry Laurel* (*Cerasus Lauro-Cerasus*).

BLUEBELL (*Scilla nutans*).

BORONIA MEGASTIGMA.—Nearly all the species have aromatic leaves, but in the one named the brown and yellow-lined flowers are deliciously fragrant. It is a well-known Australian plant, largely grown now for its perfume both on the Continent as well as in English gardens.

BOSWELLIA SERRATA (*Frankincense* or *Gum Olibanum*).—An Indian tree yielding an aromatic gum that is one of the principal ingredients in modern as of ancient incense.

BOX TREE (*Buxus sempervirens*).—A well-known native evergreen tree which O. W. Holmes describes as "breathing the fragrance of eternity, for this is one of the odours which carry us out of time into the abysses of the unbeginning past."

BACHU.—The leaves of *Barosma crenulata*.

CAJEPUT (*Melaleuca Cajeputi* and *M. minor*) yields greenish aromatic essential oil, employed as an antispasmodic and stimulant. The leaves are used in China and Malaysia as a tonic in the form of a decoction.

CALIFORNIAN BAY.

CALYCANTHUS FLORIDUS (Carolinian Allspice).—Young and fresh flowers, as also the bark, agreeably scented.

CAMEL GRASS (*Andropogon lanigerum*).—Another scented grass allied to *Lemon Grass*.

CAMPHOR (Kopher, H.).—*Dryobalanops Camphora*, *D. aromatica*, and probably other species, forming large forest trees in Borneo and other Eastern islands, where, as in China, Camphor-wood trunks and boxes are valued as resisting the termites, or white ants.

CAMPHOR is also obtained from *Laurus Camphora*, a tree found wild in Formosa, and it also exists in the common *Rosemary* (*Rosmarinus officinalis*). Antispasmodic.

CAMPHORA (*Laurus*) **OFFICINARUM** (Chinese Camphor Tree).

CANELLA (*Canella alba*) produces an aromatic bark.

CARAWAY (*Carum Carui*).—Seeds used in confectionery, and yield aromatic essential oil.

CARDAMOM (*Elettaria Cardamom*).—Seeds used a stimulant, or to chew after smoking, or they yield an essential oil.

CARNATION (*Dianthus caryophyllus*).

CASSIA CLOVE (*Dicypellium aromaticum*).—The sweet bark is used sparingly.

CEDAR.—*Juniperus bermudiana* and various species of the genus *Cedrela*, of which cigar boxes are often made. The timber of *Cedrus Libani* (*Cedar of Lebanon*) is only of use for building cabinet-work or fuel.

CEDRELA ODORATA (Barbadoes Cedar Tree; *C. sinensis* is Chinese Cedar Tree).

CEREUS GRANDIFLORUS (Night-scented Cactus).—Nearly all night-blooming Cacti or Cerei are perfumed.

CHAMOMILE (*Matricaria Chamomilla*).

CHAMPAC (*Mitchelia Champaca*).—One of the sweetest and most highly prized of all the scented flowers of the East; in appearance like a small *Magnolia*.

CHEIRANTHUS CHEIRI (Wallflower).—Grown by the acre near all large towns for its fragrant flowers. Found on old walls, as at Conway, Nottingham, &c. Everywhere in Britain and Normandy it merits its popular name, and with sweet *Violas* and *Mignonette* sweetens many a cottage garden.

CHRYSANTHEMUM INDICUM (garden *Chrysanthemum*, *Queen of Autumn*).—Both flowers and foliage possess an aromatic *Pyrethrum*-like odour.

CINNAMON (*Cinnamomum zeylanicum*).—This aromatic tree produces bark of a highly aromatic character. This bark in a powdered state is often used as a condiment at meals and in cookery. Oil of Cinnamon is inimical to bacteria. *Cinnamomum Cassia* is most aromatic.

CITRINE ODOURS.—Characteristic of aurantiaceous plants (*Orange family*), leaves and rind of the fruit: also in *Aloysia citriodora* and in many *Eucalypti*. Large quantities of *Orange leaves* as well as flowers and fruits are grown for the perfume industry in Italy, South France, and Spain.

CITRUS AURANTIUM (*Orange*), *C. Limonum* (*Lemon*), and *C. Limetta* (*Lime fruit*), and many other varieties are largely grown for flavours and perfumes in South Europe and North Africa, and in the East (see *Bonavia "Oranges and Lemons of India and Ceylon"*).

CLETHRA ALNIFOLIA (*Mignonette Tree*)—A large shrub or small tree from North America bearing very sweet flowers.

CLOVE (*Caryophyllus aromaticus*).—The young flower-buds dried are the cloves of commerce, yielding a powerful and agreeable essential oil fatal to many putrescent bacilli.

COMPTONIA ASPLENIFOLIA (*Sweet Fern Bush*).—Leaves smell like *Bog Myrtle*.

CORIANDER (*Coriandrum sativum* and other species).

COTTON LAVENDER (see *Santolina*).

COUMARIN.—Hayfield odour, given off by *Sweet Vernal Grass* and *Woodruff* (*Asperula odorata*) when partially dried.

CRATEGUS ONYCANtha (*Hawthorn* or *Sweet May*).

CRINUM ASIATICUM and many other handsome fragrant species.

CUMIN (*Cuminum Cyminum*).

CURCUMA ZEDOARIA, *C. ZERUMBET*, and other species have very aromatic rhizomes, leaves and flowers, or seeds.

CYCLAMEN PERSICUM.

CYPERUS ROTUNDUS (*Sweet Sedge*) and other kinds have aromatic rhizomes or stems, tubers, &c.

CYTISUS FRAGRANS.

DATURA (*Brugmansia*) **SUAVEOLENS**.—A well-known greenhouse shrub bearing large, pendent, bell-shaped flowers, very sweet at night.

DIANTHUS CARYOPHYLLUS (*Carnation*, *July* or *Gillyflower*).—All the family of *Pinks*, *Cloves*, *Carnations*, &c., are most deliciously fragrant. "Sops in Wine" were *Clove* or *Carnation* blooms thrown into wine flagons for the sake of their rich aroma.

DILL (*Anethum graveolens*).

DIOSMA ERICOIDES and many other species have very aromatic foliage, and are well-known greenhouse plants.

DRACENA (*Cordyline*) **FRAGRANS** and other species.

ELEMI (*Canarium commune*).

ELETTARIA CARDAMOMUM (*Cardamoms*).—A warm greenhouse plant resembling *Ginger* in habit, but hardier, and having richly aromatic foliage. It is a good room plant during the summer months, and is easily grown.

ESCALLONIA MACRANTHA (*Shelter Bush*).—With sticky, aromatic foliage. One of the best of all evergreen plants for shelter hedges in wind-swept localities.

EUCALYPTUS.—*Eucalyptus globulus*, *E. citriodora*, and many other (seventy to eighty) species. All the species are aromatic, and yield essential oils, but *E. citriodora* is one of the sweetest. *E. globulus* and others yield "Eucalyptol."

EURANGIUM SUMBUL.—A strong-growing umbelliferous plant of Turkestan and North India used medicinally. The rhizome smells of *angelica* and musk.

FENNEL.—*Feniculum dulce*, *F. officinale*, &c.

FRAGARIA ELATIO (*Strawberry*).—The scent of *dying Strawberry leaves* in the early sunshine of a frosty morning is one of the rarest and most delicious of all the scents or perfumes of the garden.

FRANGIPANI (*Plumeria rubra*, *P. allia*, *P. fragrantissima*, &c.).—Commonly planted on graves in Borneo and Malayan islands. The Italian scent named "Frangipani" is a powder, or sachet, made of equal proportions of all known spices mixed with *Orris-root* and 1 per cent. of *Musk* and *Civet*. An alcoholic extract of this "pot-pourri" is the most enduring scent known.

FRANKINCENSE (*Olibanum*).—*Boswellia serrata*.

FRENCH HONEYSUCKLE (*Hedysarum coronarium*).

FRENSIA REFRACTA (*Freessias*).—All the *Freessias* emit a subtle and delicious perfume, although by some who are partially anosmic their odour cannot be detected.

GALANGALE (*Alpinia officinarum*).—A *Ginger-like* plant having aromatic rhizomes and seeds.

GALBANUM (*Ferula galbaniflua*).—A gum resin resembling that of *F. narthex*, the source of *asafoetida*.

GALIPEA ODORATISSIMA.—A Brazilian tree that yields the *Angostura bark* of commerce, sometimes used as a tonic bitter, especially in the colonies and abroad.

GARDENIA (*Cape Jasmine*) (*Gardenia florida* and *G. radicans*).—Known as the *Cape Jasmine*. These shrubs have highly perfumed flowers, and yield by effluence a delicious perfume.

GERANIUM (see *Pelargonium*).—Many species of *Geranium* and *Erodium* have scented foliage when touched or bruised.

GINGER (*Zingiber officinale*).—Much grown and largely used as a sweetmeat in China and the West Indian islands; also used in cordials and in cookery. For preserving in China species of *Alpinia* and *Hedychium* are often used.

GLECHOMA HEDERACEA (*Ground Ivy*).—An aromatic creeping labiate with balmy odour, formerly infused in ale for its flavour.

GRAINS OF PARADISE (*Amomum Melegueta*, *A. grana Paradisi*, &c.) produce hot aromatic seeds in globose or triquetrous capsules. They are closely related to *Ginger* and *Cardamoms*. The seeds have a camphorated flavour, and have been illegally used in doctoring beer at the risk of a heavy penalty.

GUAVA (*Psidium guava*, *P. pomiferum*, *P. Cattleianum*) is the Chinese purple *Guava*,

generally compounded into a delicious flavoured jelly or pomade.

GUM CISTUS, OR LADANUM (*Cistus creticus*), and many other kinds, such as *C. ladaniferus*, of Spain and Portugal, yield an aromatic gum resin used in perfumery and fumigations by Oriental people.

GYMNEA SYLVESTRIS.—This is an asclepiaceous plant, leaves of which were sent to Kew from Madras. After chewing the leaves, neither sweet nor bitter substances can be distinguished in the mouth. Salts, acids, astringents, and aromatics are unaffected (see *Gard. Chron.*, April 23, 1897, p. 550).

HAWTHORN (*Crataegus Oxycantha*).—A well-known native tree with fragrant, white clustered flowers. There are double, and rose, pink, and crimson forms.

HEARTSEASE (see *Viola*).

HEDYCHUM SPICATUM.—The dried roots or rhizomes are pounded and used in the form of incense, and also as a medicine in India.

HEDYSARUM CORONARIUM (French Honeysuckle).—A crimson-flowered biennial plant well worth culture.

HELIOTROPE (*Heliotropium peruvianum*).—Well-known sweet-scented flowering shrubs from Peru. Their flowers are redolent of "Cherry Pie," and are used in Spanish confectionery, &c.

HENNA (*Lawsonia inermis*).—Much used from Egypt eastward, and mentioned in Song of Solomon. It is a dye tinting the nails red.

HESPERIS MATRONALIS (Sweet Rocket).

HONEYSUCKLE (*Lonicera Periclymenum*).—Native Woodbine.

HOREHOUND (*Marrubium vulgare*).

HUMEA ELEGANS.—A composite greenhouse plant, with leaves scented like Russian leather.

HYACINTH (*Hyacinthus orientalis*).

IBERIS ODORATA (Sweet Candytuft).

ILANG-ILANG (see *Ylang-Ylang*) (Flower of Flowers).

IRIS FLORENTINA (Orris Root).—The dried rhizomes of this and other species of German or Flag Iris are agreeably scented like Violets, and form the basis of violet powders and other dry perfumes for pomanders, bags, or sachets, &c. Orris Root is largely cultivated, dried in the sun, and prepared in S. France and Italy.

JASMINE.—This is one of the most distinct of all natural odours, and the only one that cannot so far be made artificially, afforded by *Jasminum officinale* and other species grown all over tropical and temperate regions. In the East, Jasmine flowers are rolled up in the well-oiled hair of the women at night, so as to scent the hair and skin next day.

JONESSIA (see *Saraca*).

JONQUIL (*Narcissus Jonquilla*) and various forms of *N. tazetta*.—Much grown for perfume at Grasse, Cannes, and elsewhere along the Riviera.

JUGLANS REGIA (Walnut).—The agreeable fragrance of crushed Walnut leaves is much enjoyed by most people, but so far as I am aware it has not gained the attention from perfumers that its distinctness would seem to deserve.

JUNIPER (*Juniperus*).

LASTREA MONTANA, **L. EMULA**, and other species are scented.

LATHYRUS ODORATUS (Sweet Peas).—Well-known and exquisite annuals.

LAURELIA AROMATICA (Sweet Laurelia).—A rare evergreen with fleshy and deliciously fragrant foliage, hardy only in very warm and sheltered localities. It grows 20 feet high in Co. Wicklow.

LAURUS NOBILIS (Sweet Bay).—Foliage aromatic and much used for flavouring confectionery, Figs, sardines, &c. *Laurus Sassafras* is N. American Spice Bush, having perfumed leaves and aromatic bark. The Cherry Laurel is *Cerasus Lauro-Cerasus*, and its prussic acid-like odorous leaves are now and then used in flavouring, also as insecticides.

LAVENDER (*Lavandula vera*, *L. spika*, *L. stachys*).—Very abundant as a wild plant in Spain, where it is called "Romero Santo." Largely grown at Mitcham, Surrey, and elsewhere in England, the oil being exported and

made into lavender water, eau de Cologne, &c. Lavender is now largely cultivated in Australia and New Zealand.

LAWSONIA INERMIS (see *Henna*).

LIGN ALOES (*Aquilaria Agallocha*).—Also known as Wood Aloes.

LILAC (*Syringa persica*).

LILIUM CANDIDUM (White Lily).—This and many other species bear perfumed flowers, some, as *L. auratum*, being too strongly scented for indoor use.

LILY OF THE VALLEY (*Convallaria majalis*).—One of the sweetest and most exquisite of all our native flowers.

LINDERA SERICEA (see *Benzoin*).

MACE (see *Myristica*).

MAGNOLIA (*Magnolia foetida* and other species).—The Yulan or Water Lily Tree of China and Japan, *M. fuscata* and others have highly perfumed flowers.

MALVA MOSCHATA (Musk Mallow).

MARUBIUM VULGARE (Horehound).—Aromatic herb used in cough lozenges and other confections.

MATRICARIA CHAMOMILLA (Chamomile).—The flower-heads are used in medicinal stupes and infusions with advantage.

MATTHIOLA BICORNIS (Night-scented Stock).

MEADOW SWEET (*Spirea Ulmaria*).

MENTHA, various species (see *Mint*).—"Menthol" is a product of this genus.

MIGNONETTE (*Reseda odorata*).—A sweet-scented annual from N. Africa, highly esteemed for its odour. There are many other species, but none so sweet as this.

MIMULUS MOSCHATUS (Musk).—Well-known cottage garden and window herb.

MINT (*Mentha Piperita*, &c.).—Much grown at Mitcham and elsewhere in S. England for distilling. (Black Mint is said to yield 30 lb., and white 20 lb. per acre.) Pennyroyal is *Mentha Pulegium* var. *gibraltarica*, a well-known diuretic; *Mentha odorata* is Bergamot Mint; *Monarda didyma* is Oswego Tea; Balm is *Melissa officinalis*; *Cedronella calamint* is Mountain Balm; Basil Balm or Basil Mint is *Melissa acinos*.

MONARDA DIDYMA (Bergamot, Oswego Tea).—N. America swamp plant, with an agreeable fragrance either fresh or dried.

MYRICA GALE (Sweet Gale or Bog Myrtle).

MYRISTICA OFFICINALIS (*M. moschata*).—A tropical tree yielding Nutmegs and Mace, well-known spices.

MYRRH (*Balsamodendron Myrra*).—Gold, Frankincense, and Myrrh in silk bags are still presented at the offertory in the Chapel Royal, St. James's Palace, on Twelfth Day by two gentlemen of the Lord Chamberlain's Office, but formerly by the Sovereign in person.

MYRRIS ODORATA is a fragrant umbelliferous plant worthy of culture for its aromatic perfume when touched or bruised.

MYRTLE (*Myrtus communis* and many other species).—Well-known aromatic shrubs, easily grown in greenhouses or in sheltered warm localities out of doors.

MUSK (*Mimulus moschatus* and *Delphinium Brunonianum*).—Animal musk is from the musk deer, &c., and ambergris from a kind of whale.

NUTMEGS AND MACE (*Myristica moschata*).—Nutmegs are well-known aromatic fruits grated as a spice. The mace, or arillus, is the inner coat of the nut beneath the orange outer husk, and is also very sweet and grateful as a spice.

OLEA FRAGRANS.—Sweet white flowers, used in China for scenting Tea, &c. (see *Osmanthus*).

OLIBANUM (*Boswellia serrata*).—Supposed to be the frankincense of the ancients.

OPOPONAX (*Opoponax Chironium*).—From the south of Europe, in habit like a Parsnip; 6 feet high; yields a fragrant gum resin, very aromatic, but now not much used.

ORCHIDS.—A large number of tropical species, are very fragrant, the white and green flowered kinds especially at night, others at different periods of the day. A good list is given in Donald McDonald's "Sweet-scented Flowers and Fragrant

Leaves," pp. 85-90. Vanilla is the fruit pods of *Vanilla planifolia*, &c., used in flavouring chocolate and confectionery. Orchids rarely possess a perfume that is not also yielded by other flowers. *Anguloa Clowesi* smells of Fenugreek; *Dendrobium macrophyllum* like Turkey Rhubarb; *Lycaste Harrisoni* smells like roasted Apples; *Odontoglossum Roezli* like Wild Field Rose (*R. arvensis*).

OSMANTHUS (*Osmanthus fragrans*) and other species (see *Olea*).

PANCRATIUM (*Hymenocallis*) **FRAGRANS** (Wedding Lilies) and other species.—Deliciously fragrant.

PATCHOULI (*Pogostemon Patchouli*).—A low, soft-leaved labiate shrub with scented leaves, that were formerly used to scent the Indian shawls.

PELARGONIUM (*Geranium*).—Many species and varieties of the Cape Pelargonium have sweet-scented foliage, and are much grown for the decoration of rooms and conservatories on that account. Their dried leaves are useful for pot-pourri, &c.

PERGULARIA (*P. odoratissima*).—The flowers are deliciously fragrant and yield a choice perfume.

PHILADELPHUS (Mock Orange, *Syringa*).—All the species and varieties bear sweet-scented flowers, similar to Orange blossoms in the bud state. The green leaves possess a flavour similar to that of Cucumber, and may be used sparingly in claret cup as a substitute if Cucumbers are not available.

PIMENTO, OR ALLSPICE TREE (*Pimento officinale* and *P. acris*).—The last-named being largely used in making West Indian bay rum. In 1886 the exports of Pimento from Trinidad = £46,704, and in 1896 they had increased to £90,046. Little Dominica exports £4000 worth of bay leaves and oil; Trinidad grows ten times the quantity, none being utilised for export.

POLIANTHES TUBEROSA (Tuberose).—Largely grown in South France for perfume, native of India. The fading flowers, like those of *Tropaeolum*, have been seen to emit flashes of light at night.

PRIMROSE (*Primula acaulis*).—This genus of many species found nearly all over the world contains many with delicate odours, but none more delicious than our wild Primrose, Oxlip, and Cowslips of the meadows.

ROCKETS (*Hesperis matronalis*).—Well-known fragrant garden plants.

RONDELETIA (*Rondeletia odorata*).

ROSACEOUS ODOURS.—The Eastern Attar or Otto of Roses is one of the most delicious and valuable of perfumes in its pure state, but it is often largely adulterated by the addition of Indian "Geranium" oil (*Andropogon*).

ROSEMARY (*Rosmarinus officinalis*).—A very similar oil is afforded by *Cedrela Rosmarinus* of North China.

ROSES.—An enormous genus, most of which produce deliciously perfumed flowers. Attar de Rose from Persia, Cashmere, Turkestan, &c., when pure is one of the choicest and rarest of perfumes.

SALVIA RUTILANS (Pine-apple Sage).—This is a fragrant greenhouse plant. *Salvia officinalis* is common "garden Sage" used for flavouring.

SAMBUCUS NIGRA (common Elder).—The leaves have an odour that helps to keep away flies, especially if mixed with those of Tansy. Flowers sweet, used for Elder-flower water.

SANTALS.—In 1875 Mr. C. T. Kingzett, after observing the excess of ozone and salubrity of the air near to Pine and Fir tree plantations, and conceiving that this was in part due to their volatile oils producing peroxide of hydrogen and camphoric acid, formed these reagents by a process involving the decomposition of turpentine, and it was made and sold in 1877 under the above name.

SANTAL (*Santalum album*).—Indian sandalwood, much used for cabinet-work and for burning in place of pastilles in India and the East. Said to be one of the ingredients used in making the "joss-sticks" of the Chinese.

SANTOLINA CHAMÆCYPARISSUS (Lavender Cotton).—A woolly-leaved little shrub with aromatic

leaves, useful for edgings or low fences. Grows well in hot and barren places. Sprigs of it are useful for mixing with dried Lavender to keep away moths.

SARACA INDICA (= *Jonesia asoca*).

SASSAFRAS (*Sassafras officinale*).—This and one or two other species have aromatic bark and nuts or seeds which yield a scented oil.

SATUREIA OFFICINALIS (*Savory*).—Pot-herb.

SCILLA NUTANS (*Bluebell*).

SOUCHE (*Cyperus* species).—The dried tubers are used. *C. longus* is "English Galangale" (Gerard).

SPIKENARD (*Nardostachys Jatamansi*).—A dwarf Valerian having an aromatic root, found in North India, and long ago very highly prized. It is now supposed to be the "nard" or "nerd" of the Scriptures, and one of the ingredients in the alabaster box of ointment used by Mary in anointing the feet of our Lord. "Ploughman's Spikenard" is the root of *Inula Conyza*, of which Ben Jonson asks: "Have you smelt the bud of the brier or the nard in the fire?"

SPIRÆA ULMARIA (*Meadowsweet*).—Leaves odorous and quite different from scent of the flowers.

STAR ANISE (*Illicium verum*).

STEPHANOTIS (*Stephanotis floribunda*) Climbing Tuberose.—A well-known stove-climbing shrub having clusters of tubular and highly perfumed flowers.

STOCKS (*Matthiola incarna*, *M. tristis*, &c.).—Several kinds, both day and night bloomers, and highly perfumed.

STORAX (*Styrax officinalis*).—This shrub is found in the Levant, but its balsamic resin is not now easily obtained. The storax now used is from *Liquidambar orientale*, found in Asia Minor. Used in perfumery and as an expectorant.

SWEET BAY (*Laurus nobilis*).—A well known aromatic evergreen, bark, leaves, and fruits being very fragrant. Long grown in European gardens and often used for funeral wreaths.

SWEET FLAG (*Acorus Calamus*).—Long used as a perfume plant. It was the common perfume of the Romans, but they prized more highly the *Roses of Pæstum*, *Spikenard*, *Telinium*, *Medebathrum*, *Onegalum*, *Balm of Gilead*, and *Cinnamon*.

SWEET-SCENTED GOLDEN ROD (*Solidago odora*).

SYRINGA PERSICA, &c. (*Lilac*).—One of the sweetest of hardy garden shrubs. Forced Lilac is deliciously sweet.

TANSY (*Tanacetum vulgare*).—Fern-like foliage aromatically scented, and it is now and then used in order to try and keep flies out of rooms. Used also in cookery, Tansy puddings, &c.

THYME (*Thymus vulgaris*).—A well-known garden herb and the source of "Thymol," &c. *T. citriodorus* is *Lemon Thyme*. There are many species grown as rock plants, all more or less scented.

TODDALIA (*Toddalia aculeata*).

TONGVIN BEAN.—Seeds of *Dipteryx odorata* (Willd.), from Guiana.

TUBEROSE (*Polianthes tuberosa*).

TUSSILAGO FRAGRANS (*Sweet Tussilage*, *Winter Heliotrope*).—An Italian plant naturalised abundantly near Dublin and elsewhere, and flowering freely in January and February, when roads and lanes are redolent with its *Heliotrope*-like perfume. It is a dreadful weed in many Irish gardens.

VALERIAN (*Valeriana Wallichii*).—Now and then used as an aromatic, and in medicine more rarely as a stimulant and antispasmodic. The dried root of *Valeriana officinalis* is very attractive to cats, and is said to be employed by rat-catchers to decoy their victims to their traps. *V. celtica* has fragrant rhizomes used in toilet mysteries like *Sambal*.

VANILLA (*Vanilla planifolia*, *V. aromatica*, and other species).—The fruits or beans are long and dark brown, or chocolate-coloured, and possess a very strong aroma, flavour, and perfume. The essential flavouring principle of *Vanilla* can now be made artificially from Pine-tree sawdust. Both the natural and the chemical products are

used for flavouring chocolate and other sweetmeats. *Vanilla* is sometimes adulterated with *Tonquin Bean* extract.

VEGETABLE WAX or **CANDLEBERRY** (*Myrica cerifera*).—The fruits are coated with a waxy resin from which aromatic candles are, or were, formerly made in America.

VERBENA OFFICINALIS (*Vervain*, *Herb of Grace*).

VETIVER (*Andropogon schenanthus*).—The oil of *Andropogon* is sometimes called "Indian Geranium" oil, having a citrine odour. Used to adulterate *Attar of Roses* and in the manufacture of cheap perfumes. Used in India for screens or "Cuscus tatties."

VIOLET ODOURS.—The well-known Sweet Violet (*Viola odorata*) in all its forms, also present in some Orchids and in *Orris Root* (*Iris florentina* and other species). Violets and *Iris* are largely grown in Italy, Sicily, Sardinia, and South France for the perfume trade. All the garden *Violas* or *Tufted Pansies* are sweet and exquisite garden flowers. *Violetta* and others of Dr. Stuart's race of rayless *Violas* are charmingly dwarf, dainty, and sweet-scented.

VITIS RIPARIA and other wild Grape Vines of North America have sweet-scented flowers.

WALLFLOWER (*Cheiranthus Cheiri*).—One of the hardiest and sweetest of all our native flowers.

Rhododendron multicolor Curtis.

WINTER GREEN (*Gaultheria procumbens*); also from *Betula lenta*.

WINTER SWEET (*Chimonanthus fragrans*).—Waxy yellow flowers produced in winter with a spicy perfume.

WISTARIA SINENSIS (*Chinese Wistaria*, or *Pergola Flower*).—Drooping racemes of deliciously sweet purple or white Pea-like blossoms.

WOODRUFF (*Asperula odorata*).

YARROW (*Achillea Millefolium*).

YLANG-YLANG, **ILANG-ILANG** (*Cananga odorata*).—A tree growing in Java, Borneo, &c., with very fragrant yellowish green flowers. The name literally means "flower of flowers," and the extracted perfume is more valuable than *Attar of Roses*.

ZEDOARIA (*Curcuma*).—*C. Zerumbet* and many other kinds.

Digitalis lanata.—I am obliged to Mr. A. Black for sending me from Carton, Maynooth, a nice spike of this Foxglove. Although not a new plant, it has not come under my notice before. The Woolly Foxglove was introduced in 1789, and on reference to the *Kew Hand-list* it appears to have been in the Royal Gardens when that publication was issued. It cannot be called a showy plant, but one finds that there is a growing inclination on the part of a considerable number of flower growers to embark upon the cul-

tivation of plants of distinct appearance, even if not showy. This Foxglove ought to please such. There is a good, if short, description of it in Nicholson's "Dictionary of Gardening," but such can hardly give an idea of the character of the spike before me. The flowers are small, white, reticulated with brown or purple, and protrude only a little from the woolly bracts. The spike is woolly also, and this constitutes one of the distinct features of this Foxglove. It is a perennial and comes from Eastern Europe. Those who have access to the *Botanical Magazine* will find a plate in that work, tab. 1159.—S. ARNOTT.

GARDEN FLORA.

PLATE 1232.

MALAYAN RHODODENDRONS AND THEIR HYBRIDS.

(WITH A COLOURED PLATE OF R. EXQUISITE.*)

SEVERAL distinct *Rhododendrons* occur on the numerous islands of the *Malayan Archipelago*, and though beautiful in themselves, this is not their greatest claim to recognition, for, thanks to the skill of the hybridist, quite a distinct

section of *Rhododendrons* has been obtained by continuous intercrossing of these original species and of the numerous hybrids raised therefrom. In all, seven species have played a part in the production of this class, which is generally known, besides the name of *Malayan*, as *Tube-flowered*, *Javan*, or *Perpetual-flowering Rhododendrons*. The seven species above referred to are—

RHODODENDRON BROOKEANUM GRACILE.—A loose-growing shrub, native of Borneo, where it often occurs as an epiphyte. The flowers are large and of a pale yellow colour. It was introduced by Messrs. Veitch through their collector, Thomas Lobb, in 1855.

R. JASMINIFLORUM.—This well-known kind, with its small rounded leaves and profusion of long-tubed white flowers, is a native of Mount Ophir, Malacca, and was introduced in 1845. It is particularly interesting as having, in conjunction with the orange-coloured *R. javanicum*, given us the first hybrid of this class, viz., the pink-flowered *Princess Royal*.

R. JAVANICUM.—This is a large, loose-growing shrub, with leaves sometimes nearly 6 inches long and half that in width. The flowers are large and

* Drawn for THE GARDEN by H. G. Moon in Messrs. Veitch and Sons' nursery at Chelsea. Lithographed and printed by J. L. Goffart.

FRANCIS & TAYLOR

vary in colour from deep yellow to reddish orange. This *Rhododendron* is a native of the mountainous regions of Java, and was introduced about 1850.

R. LOBELI.—A good-sized loose-growing bush with peculiar flowers of a bright crimson colour. The tube is narrow, curved, and about 3 inches long, while the expanded mouth of the flower is not more than an inch in diameter. It is a native of Borneo, and was introduced by Messrs. Veitch.

R. MALAYANUM.—A small compact-growing shrub with lanceolate leaves and tiny crimson flowers. It was introduced from Sumatra by Messrs. Veitch.

R. MULTICOLOR.—The most recent introduction of the seven. This is a little shrub with short, almost thimble-shaped blossoms of a pale yellow tint. There is a variety *Curtisi* in which the flowers are crimson. Both were sent home by Mr. Curtis when travelling for Messrs. Veitch in Sumatra.

R. TEYSMANNI.—This, somewhat in the way of *R. javanicum*, has large flowers of a soft yellow colour. A native of Sumatra.

While the name of Veitch occurs largely in this list of imported species, it is even more pronounced among the hybrid kinds, for nearly all those in cultivation have been distributed by the firm in question, and, with the exception of two or three of the oldest, they have all been raised at Chelsea. Mr. Heale is well known for the great improvement he has effected in many classes of plants by a systematic course of hybridising, but if he had done nothing more than raise the numerous charming *Rhododendrons* of this section he would be entitled to the thanks of all plant lovers. The introduction of *R. multicolor* and its variety *Curtisi* in the early eighties was a great boon, and one soon taken advantage of. Since then we have had several varieties showing the influence of *R. multicolor* to a greater or less extent. This is manifest in the dwarf habit of the plant and the shorter tube to the flower.

The species and their varieties have been so frequently intercrossed, that some of the forms now in cultivation are hybrids of the second or third generation, but the subject of the coloured plate—*Exquisite*—is derived from two of the original species, viz., *R. javanicum* and *R. Teysmanni*. The general aspect of the plant is more like the female parent (*R. javanicum*), but the flower shows the paler tint of *R. Teysmanni*. The variety *Ceres* (illustrated in *THE GARDEN*, February 20, 1892) was produced by the reverse cross. The flowers of this are of a distinct shade of rich tawny yellow. Another particularly large-flowered variety, like the two just noted, is *Cloth of Gold*, with bold trusses of light golden yellow blossoms. Other desirable varieties are *Baroness H. Schroeder*, blush; *Brilliant*, scarlet; *Conqueror*, orange-vermilion; *Favourite*, satiny rose; *Jasminiflorum carminatum*, rich carmine; *Luteum roseum*, pink, suffused light yellow; *Ne Plus Ultra*, crimson-scarlet; *President*, buff-yellow, tinged pink; *Primrose*, pale yellow; *Princess Royal*, pink; *Purity*, white; *Scarlet Crown*, orange-scarlet; *Souvenir de J. H. Mangles*, orange, tinged pink. Hybrids of *R. multicolor* characterised by dwarf habit and shorter

flowers are: *Ensign*, salmon-red, tinged scarlet; *Latona*, creamy yellow; *Mrs. Heale*, white; *Neptune*, scarlet; *Nysa*, orange-yellow; *Nestor*, buff, tinted rose; *Rosy Morn*, rose-pink; and *Ruby*, dark coral-red. Besides the above-mentioned there is a small group with double blossoms to which the name of *R. balsaminiflorum* has been given, owing to the resemblance that the flowers bear to those of a Balsam. They were all raised by Mr. Heale from one flower which showed a tendency to become double, and being fertilised with its pollen produced a pod of seed which yielded such happy results. The double varieties are *album*, white; *aureum*, yellow; *carneum*, flesh-coloured; *Rajah*, fawn-yellow, tinted rose; and *roseum*, rose-pink, suffused with orange.

CULTURE.

These *Rhododendrons* are not at all difficult to cultivate, yet they are frequently met with in a far from satisfactory condition. This is often the result of keeping them in too low a temperature during the winter, for they generally occur in catalogues as greenhouse *Rhododendrons*, and the term greenhouse being a very elastic one, they are by some kept in a structure from which frost is just excluded, and

Rhododendron multicolor Mrs. Heale.

nothing more. Such conditions will suit the Himalayan hybrids, but those from the islands of South-eastern Asia require more heat, being best suited by what is usually known as an intermediate temperature, say a minimum during the winter of 50°. Their continuous blooming qualities, which have been often dealt with, result from their manner of growth, for they grow more or less throughout the year, and directly a shoot matures, a flower-bud forms at the apex, and after a time the blossoms expand. From this circumstance even comparatively small plants will have expanded blossoms, flower-buds in various stages of development, and young succulent shoots all at the same time. The *Rhododendrons* are not at all difficult to propagate from cuttings, which are best formed of the young shoots taken soon after they have lost their succulent character and before they are too hard and woody. Unless very vigorous, the entire shoot makes a suitable cutting, roots being readily produced from the slightly swollen base. The pots must be well drained and the compost (about equal parts of silver sand and peat) should be sifted through a sieve with a quarter of an inch mesh. The best place for the cuttings is a close propagating

case in the coolest part of the stove, where, if there is a gentle bottom-heat, they will soon root. When hardened off they may be potted singly, using about two-thirds peat to one-third sand, care being taken that the pots are well drained. As they get larger, the peat may with advantage be rougher, and a little charcoal about the size of beans added to the compost in order to keep it open and sweet. One thing to particularly bear in mind when potting these *Rhododendrons* is, that most of the species from whence these numerous varieties have sprung are in a natural state more or less epiphytes, and on this account dense masses of soil around the roots are very inimical to their welfare. Good fibrous peat, pulled to pieces by hand (not sifted), with a liberal admixture of sand and a little charcoal will suit even large plants. Some cultivators prefer an admixture of fibrous loam with the peat, but it is not necessary; indeed, I would rather dispense with the loam. The soil should at all seasons be kept fairly moist, but not too wet, while the syringe may be freely used nearly throughout the year, the only exception being during very cold, dull weather. While the numerous varieties are occasionally propagated by grafting, but more generally by cuttings, they can also be readily obtained from seed if one is inclined to wait a few years for the results. The seed is extremely minute, and must not be covered at all when sown. Well-drained pots or pans should be filled with sandy peat prepared as for the cuttings, and the surface being levelled and the soil well watered, the seeds may be sown thereon. A good place for them is a close propagating case as recommended for the cuttings, or, failing this, a pane of glass may be laid over each pot or pan in order to maintain an even state of moisture. Of course, the seeds must as well as the cuttings be regularly shaded. As the young plants make their appearance a little more air may be given by degrees, but they make more rapid progress if grown during their earlier stages in a stove temperature. The young plants when large enough must be pricked off into other pots prepared for their reception, and in time potted off singly. In addition to their desirable qualities above enumerated, these *Rhododendrons* possess others, for they are very rarely troubled by insect pests, though aphides at times attack the young shoots, but they can be easily kept in check, while in a dry atmosphere thrips are occasionally troublesome, but a liberal use of the syringe recommended for the welfare of the plants will prevent these pests effecting a lodgment on the leaves. Another point in favour of these *Rhododendrons* is the fact that they are little, if at all, affected by that bane of the plant grower around London, viz., the heavy sulphur-laden fogs, which play havoc with so many plants. As most of the varieties have originated at Chelsea, and Messrs. Veitch sometimes exhibit them nearly throughout the year, a good proof is given of their ability to withstand London fogs.

Some of these *Rhododendrons* have a tendency to run up tall, to obviate which they must be freely stopped during their earlier stages, but where this has not been done the plants may be cut back hard in the spring, for if kept close and freely syringed overhead young shoots will be pushed out from the old wood as readily as in an *Azalea*. Some of the varieties, too, will commence to flower as soon as the young shoots are but a few inches long.

T.

Notes from Baden-Baden.—*Delphinium scopolorum* is striking by the intensity of the

colour of its flowers, which is a glittering ultramarine. It forms a thick root and is a hardy perennial. *D. speciosum macranthum* from original Kurdistan seed has been much admired. It is a stately plant, 4 feet to 5 feet high, flowers deep blue and over $4\frac{1}{2}$ centimetres across in big spikes. *Patrinia hispida* is another desirable perennial; it grows to 2 feet and has large umbels of brilliant deep yellow flowers. *Campanula betulefolia* is a companion to *C. mirabilis* and bears numerous large white flowers. Among seedlings of *Lathyrus latifolius*, a variety has turned up having much larger flowers and spikes. It is much more showy than the type. A strong plant of *Coriaria terminalis* will soon be in great beauty; it has about ten fruiting branches. The robust *Richardia Adlami* is a first-rate novelty, its creamy white flowers having a black blotch extending over half the spathe. A new *Kniphofia* shows good quality; it is not a big plant, but is very free-flowering all the summer until frost; the flowers are sulphur-yellow below and reddish or red at the end of spike. I propose to call it *rufa*, red-headed; it is the most free-flowering I ever have had. My efforts to raise a double variety of *Scabiosa caucasica connata* (syn., *S. caucasica elegans*) seem to draw nearer to realisation, as a beautiful semi-double variety has now appeared. According to the construction of its flowers, I cannot expect to get many seeds, but if evolution goes on in the same direction our gardens will soon be embellished by a double variety.—MAX LEICHTLIN, *Baden-Baden*.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

VINERIES.—Vines which are forced year after year are naturally weakened in the process, and to obviate this as much as possible it is necessary to relieve them of their crop as early as may be, so that their energies can be devoted to finishing up the wood in good condition to go through the same ordeal next year. There are other reasons for early cutting. The Vines used for forcing are generally varieties the fruit of which soon loses its freshness, and in the case of black varieties the bloom disappears and leaves the berries of that red hue so objectionable both to the consumer and the producer. An early clearance gives a chance of syringing and cleansing the foliage, which if well preserved will then ripen off naturally and plump up the buds to which the shoots will eventually be pruned back. If the sub-laterals have been allowed to grow wild during the past few weeks, cut them away to admit all the light possible. Where the fruiting laterals were allowed to grow beyond the orthodox two joints from the bunches, these, too, may be lightly shortened with advantage, especially where the rods are rather close together. Keep the ventilators open night and day, for, given a fair amount of sunshine, the more natural the conditions under which the wood is finished up the better will be the prospects for next year, and to this end also the borders should not be allowed to get dry. It is certain that the under-sized bunches which one so frequently sees in early houses are partly the result of ripening up the growth too early in the season. In midseason houses the Grapes will now be either ripe or fast approaching ripeness, and as some of these must perforce be left hanging for a considerable time, care will be necessary to keep the atmosphere dry and buoyant. Damping down must be suspended entirely or reduced to a very light sprinkling during the forenoon of bright days, and air should always be on the top ventilators at least. Bottom ventilation, being governed by the state of the weather, is not advisable when the air is muggy or in case of rain or high wind. Should wet weather prevail day after day, a little fire-heat must be used during the day to dispel the dampness, but it should be suspended by night, when it would do more harm than good. It really takes very little fire-heat to keep the atmo-

sphere of a house with a fairly rain-proof roof in a sufficiently dry condition to preserve the Grapes from harm—that is, when the ventilators are well managed—and more than this only encourages shrivelling. Look well through the bunches once a week or oftener, according to the weather, and remove any berry which shows signs of damping or which has been injured in any way, as one bad berry will soon taint a whole bunch.

POT VINES.—As these take on the appearance of ripening the wood to the full length of cane which will be allowed to remain at pruning time, more air should be given so as to gradually prepare them for removal to the open when the season's growth is actually completed. Except in the case of pot Vines which are in a backward state, fire-heat may be dispensed with almost entirely, as Vines well forward now will have plenty of time in which to finish up well. Keep the roots in good condition as to moisture, but do not water too freely, or continue to feed the roots over-much, as a firm cane, even if on the small side, will produce a more satisfactory crop than a large, but soft one.

STRAWBERRIES.—The runners when once they have become fairly well rooted in their pots should be cut away and moved to a position where they will be shaded from the mid-day sun, and stood thickly together for the first few days, as the pots then prevent each other becoming too hot and dry, and the young plants are thus inured gradually to the loss of sustenance they incur through being cut away from the parent plants. As they become able to bear it, it is advisable to stand them more thinly preparatory to potting them into their fruiting pots, which should be done by, or very soon after, the end of the month. In the meanwhile a good heap of soil should be prepared, thrown together, and turned over and over again to get thoroughly mixed. There is a gain in preparing the soil beforehand, as if it can be placed under cover and fairly moistened if too dry for use, the ingredients become better incorporated, and anything of a strong and burning nature which may be used will become toned down and harmless to the young roots. The conditions as to moisture also are greatly improved by mixing some days in advance, and those who have had much Strawberry potting to do will readily agree that on the exact condition of the soil in this respect depends a great deal both in the facility with which the work progresses and in the ultimate success with the plants, for soil that has to be damped just before potting never works well. The loam used for Strawberries should be fairly heavy, but with plenty of fibre in it. In such soil good crowns are made, and there is body enough left in it to swell up a crop of fine fruits. I do not advocate the use of much manure in the soil, but I like to give a fair sprinkling of Mushroom-bed manure or horse droppings which have become sufficiently decayed without having gone through the process of "making" in the Mushroom house. A little bone-meal, too, is helpful when the loam is on the poor side, but as a rule loam alone contains sufficient food to carry the plants on till the pots become full of roots, after which they may be fed with liquid manure. Bone-meal is lasting in its effects, so will retain its feeding properties as long as the plants remain in their pots; consequently it is better than any of the quick-acting manures. If the loam is very heavy, mortar rubbish should be added as a corrective and is safe. It is customary to add soot to the mixture, but this varies so much in quality as to be positively dangerous sometimes, even if used in very small quantities, and it is safer to use it through the medium of water in which a bag of soot has been steeped. I like to sprinkle a little on the crocks before putting on the rough soil used underneath the ball, as there it is safe and acts as a worm-preventive. In potting, which should be carried out by the end of the month, see that the plants stand fairly high and that the crowns are not buried in the soil. Pot very firmly, finishing off with about three-quarters of an inch of space from the rims for water. Stand the plants after

potting in the shade for a few days, but do not leave them in shade longer than the time requisite to keep them from flagging after the shift, as they will require as much sunshine as they can get later on. If in good condition as to moisture when potted—an important item to look out for—they should require no water at the roots for a few days, but the syringe should be freely used upon them. Before potting, it is advisable to turn the young plants down on their sides and to syringe them thoroughly on the under-sides with water in which a good quantity of flowers of sulphur has been mixed. This will prevent both red spider and mildew, and is of special benefit to Royal Sovereign, which is always liable to attacks of the latter. CORNUBIAN.

KITCHEN GARDEN.

SECOND EARLY POTATOES.—The whole of these may now be lifted, sorted and stored away in the coolest place procurable. A shed or outhouse having a north aspect is suitable both for seed tubers and those intended for the kitchen. A warm south aspect storage induces loss of weight and quality in those that are to be eaten and shrivelling, coupled with unsatisfactory sprouting in spring. A good sized plot from which this crop has been lifted should now be set apart for early spring Cabbages, and if allowed to remain in a rough condition from now till a fortnight before planting takes place, a sweet condition will be ensured. Where the ground is liable to be infested with slugs in wet winters, it will be well to spread over the surface a good coating of lime and soot, afterward scuffling it in deeply with a fork. Dig and tread the plot well before planting, as a loose root-run, especially in light soil, is not conducive to a growth suitable for standing a severe winter.

YOUNG CARROTS.—Those who have sown small beds as advised from time to time will have realised the value of them, as for soups and flavouring these young tender roots are far preferable to those older and more mature. If the grub has not yet attacked them, it will pay to give another good sprinkling of wood ashes, soot, or burnt garden refuse between the rows, following it by a good soaking of water. Hoe between and hand-weed all young Carrot beds, and in cases where the dreaded grub has actually attacked the crop, procure a large tub capable of holding 100 gallons of water. Into this throw a bushel each of lime and soot, stirring it well round and allowing it to stand for a night. The following day well water the Carrot bed with a rosed watering pot. This will exterminate the pest and promote a healthy growth. Warm soft water is best for the purpose.

SPRING CABBAGE.—Some time ago I cautioned gardeners against making very early sowings of this important vegetable. I make my principal sowing at the end of July, the varieties being Ellam's, Cocoa-nut, Earliest of All, and Mein's No. 1. Provided good seed is used, it need not be sown thickly; in fact, thick sowing is ruinous. I make a second sowing from the middle to the 20th of August, good second early varieties being included in it. As a rule, Cabbage plants that are to be wintered in frames will be quite forward enough if sown at the beginning of September. If sown earlier, large, ungainly plants which lift badly and are prone to run to seed after flagging from removal in spring follow. Sow the red pickling Cabbage at the second sowing and also with the third for frame protection.

LETTUCE.—If another transplanting is now made of various sorts on good moist land, a supply for some weeks to come will be secured. A sowing of good Cabbage varieties may also now be made, which will come in most useful at a period when cooler nights and mornings favour long keeping. The latter do not run to seed so soon as the Cos varieties, and are profitable for growing in shallow, hot soils. When transplanting Lettuces make a slight drill, as then a little soil can be drawn into it around each plant after watering, this preventing evaporation and ex-

cluding parching winds from the roots until well established. In all cases where scarcity is apprehended it should be remembered that by leaving a percentage of plants on the seed-bed and keeping them well watered, Lettuce may be cut a fortnight earlier than from the transplanted rows. Any which have arrived at maturity may be lifted with care and laid in under a north wall, where they will keep for some time in an eatable condition. Of course, where other batches are coming on apace this is not necessary.

LATE-SOWN BEET.—I pointed out some time ago the necessity for a late sowing of Beet in places where this root is eaten by itself at lunch, as large roots are usually objected to for slicing up. If the final thinning has not been given, see to it at once, and keep the rows free from weeds and the intermediate spaces frequently hoed to promote a clean, sweet growth. The coarse varieties, which show white rings in their centres when cut, are not fit for salad, and, unfortunately, this drawback is present in three parts of the so-called table Beets. In case of an uneven plant, Beet does very well if carefully transplanted. I have seen beds which in the earlier stages of growth were very uneven present a perfect appearance later on by transplanting from the other rows. This is worthy of note, as many people might think the experiment worthless.

RHUBARB.—The erroneous idea is often entertained that in order to make the best jam and wine Rhubarb ought to be in a semi-withered condition. Those, however, who desire quality in either will do well to take the sticks which result from a secondary growth which occurs in most vigorous Rhubarb beds and is now at its best. Some varieties, too, are better for jam and wine-making than others, the small-growing Prince Albert and Hawke's Champagne making a delicious preserve. Any seed-stems should be taken off at once, so that the most may be made of the remainder of the season for strengthening and developing the stools for next year.

J. C.

ORCHARD AND FRUIT GARDEN.

FLAVOUR IN FRUIT.

WELL-CONSIDERED culture and careful attention, especially just previous to the finishing stage, have a lot to do with flavour or the want of it in the fruit we grow under glass. In the open we are, of course, entirely at the mercy of the season, and only in certain small details can anything be done to improve the quality when grown. For instance, in the case of Strawberries that have not to be packed, but sent direct to table, there are a few kinds, notably Sir Joseph Paxton, that are much improved by an hour or two in a warm, dry fruit-room or house. Gathered overnight and placed in a vinery where ripe fruit is hanging, this and Royal Sovereign are greatly improved both in colour and flavour by the morning, but nothing that can be done to these varieties can bring them into the first rank for flavour. That handsome Strawberry Monarch has been off and on derided and praised as to quality. I find it rather peculiar, and though it sounds almost impossible, I have always had better-flavoured fruit in a wet season and after a wet time than when opposite conditions prevail. Again, Latest of All and Waterloo have proved of much better quality when grown in a partially shaded aspect than on a bed quite exposed to sun. I think that the want of colour at the tip of the former and some other kinds is always worse when the fruit is hurried along.

But, as I have noticed frequently, what helps us one year fails or hinders in another, and I am looking forward to better coloured, if not better flavoured, fruit of this kind this season, as it has come along more slowly than

usual. Hot sun, with little moisture, is, I am sure, as frequently the cause of deterioration in quality and premature ripening as the opposite conditions are of watery and insipid flavour. Hot, burning days, with bitter cold winds at night when the fruit is forming, constitute a severe strain upon the plant, and cannot do otherwise than hinder the proper development of the fruit, but moister conditions, even if cold, keep the berries swelling gradually, though slowly.

I do not know what is the condition of things generally, but, speaking from my own experience, the present has been a very trying spring for fruit forcing under glass, and the quality of Peaches especially is much below the average. Alexandra Noblesse, usually one of the richest flavoured Peaches in the early house, is far behind its proper form, yet the trees have not been over-cropped, nor have they been hurried, as the house was started at the new year and the fruit is just ripe (July 1). Early Grosse Mignonne is better, but this is an end tree, and has therefore the sunniest and best position, the trees being trained across the house. Even this fine variety is not, I think, quite so good as usual. We have had much less sunshine than usual this year, and this in part doubtless accounts for the lack of flavour. Under these circumstances it is pleasant to turn to a brighter side with the Vines. As long as the right varieties are grown and properly finished there need be little fear on the score of quality. That excellent black variety Madresfield Court is splendid this season. It is a Grape that requires good culture, and to bring out its best points not less than six months' growth from the date the house is closed till the fruit is ripe. This prevents undue haste at any time, and splitting and other evils are more likely to be avoided than if the crop is hurried before stoning is properly finished.

H.

Wall breaks.—On page 420 (last vol.) "A. D." refers to what I should consider an invaluable provision for exposed positions in the form of wall breaks. Would not wind breaks be more descriptive? I have long since wished I could erect such breaks against a wall here having a southern aspect. The projecting walls could be profitably utilised for Morello and dessert Cherries or Plums, but the cost of erection is a barrier. Outdoor Peach growing might be made more easy, because cold cutting draughts, which are so fatal to the tender leaves, would be removed. I have never seen any but the ordinary strengthening buttresses erected, but there are undoubtedly cases where the extra expenditure would be both justifiable and profitable. The need of such is more keenly apparent in gardens of large size where there is a considerable length of unbroken surface of wall. There would not be the same advantage derived from wind breaks on east and west walls as from the south unless they are devoted wholly or in part to such tender trees as Peaches, Apricots, or Nectarines. Plums and Cherries would scarcely justify the expense except in cases where the additional wall space may be required.—W. S.

—I was interested in "A. D.'s" note at page 420 on the wall breaks in the garden at West Hall, Byfleet. One seldom meets with them, but I was employed in two gardens where they existed. In one they were exactly the same in character as those mentioned by "A. D.," having no doubt been built at the same time as the principal wall which was intended for Peach trees. In the other garden they were only of a temporary character, being erected every year by the gardener on the border of the 12 feet high Peach wall. Stout poles and cross rafters were fixed, and the latter furnished with Laurel and Yew boughs. It meant a good deal of trouble, but it was astonishing how it screened the trees from cold, cutting east and west winds while in

flower and until a fair amount of growth was made. These breaks were also of great advantage to early vegetable crops, such as Potatoes, Cauliflowers and Peas, which are more often injured by cold winds than frost. Of course they are not very ornamental, but utility is generally the first thing considered in fruit and kitchen gardens.—C.

STRAWBERRIES IN THE OPEN GROUND.

THE unfavourable weather during the early part of May played sad havoc with the Strawberry bloom in this district, especially with the more forward kinds that had but little foliage. Here on several occasions there were sharp frosts, and on the night of the 5th we registered 7°, which so took hold of the flowers that scarcely one that was expanded escaped. Scarlet Queen, Royal Sovereign, John Ruskin, and others that do not grow so strong on our soil are almost a failure. Some of the later ones, however, escaped, and these are promising. As yet (June 24) I have not been able to gather a fruit from outside, and were it not for a batch of Leader grown in a cold frame I should have been without fruit at the present time. This is unusual in this part of the country, as often the greater portion of the more forward kinds has been gathered. Leader is a grand variety, and in my opinion one that has come to stay. Here on a north border the crop is a heavy one, the flowers not being sufficiently forward in that shaded position to come to any harm by the severe weather. Monarch growing alongside has not half the crop, both being planted at the same time and treated in like manner. In this position Scarlet Queen, too, has suffered less than in the open or on sunny borders, as the blooms were not so forward. Mulching had somewhat to do with the frost taking so much hold of the blooms, for where the ground was not mulched the plants suffered less. While on this subject, may I ask if anyone has ever noticed that the material used causes a difference in the temperature round the plants? Most gardeners experience a difficulty in procuring suitable material for this purpose. Grass from the lawn goes too close together, therefore holds too much moisture for the well-being of the fruit should the weather be damp at the time of ripening. Oat straw, without doubt, is the most useful, particularly if from a farm that is well tilled, as there are then but few weeds of any kind introduced. I noticed that where peat Moss manure was used as a mulch, plants suffered more than they did where there was no mulch at all, and where clean straw was employed less harm was done than with grass. Gardeners in some places are placed at great disadvantages in not being able to procure articles they require, and this is one of those which often puzzle them, particularly where there is no home farm and where the stables are of limited extent. To send Strawberries in the finest possible condition to the table under such conditions entails both a lot of trouble and expense, for where the ground has to be mulched with unsuitable material it is always best to run a piece of bast or raffia round the plants to loop up the fruit.

H. C. P.

Gooseberry Telegraph.—Although at first sight this appears to be a good deal like Berry's Early Kent, it is quite distinct and better in flavour, though not so good in appearance. The berries are very large, but of a clouded green tint when fully ripe, and it is one of those Gooseberries that can be over-ripened. If caught at the right time it is delicious. The tree is a strong but dwarf grower, and makes less headway in a plantation than the kind with which I have compared it. It is good under any form of training.—H. R.

Gooseberry Keepsake.—There is a disposition among growers to decry the larger varieties of this luscious fruit on the score that the quality is poor, but however true this may be of some kinds, it is a libel on others, Keepsake included. It ripens early, forming a good succes-

sion to the Rough Yellow, and is of immense size. The thin, almost transparent skin is pale green with deeper reticulations and less hairy than that of most kinds, while there are ample pulp and few seeds. It is altogether a first-rate kind and a useful addition to the dessert in August. Grown on wire trellises I have an immense crop of fine fruit.—C. H.

Strawberry President.—I am obliged to "West Middlesex" for his reply to my note on this Strawberry, and very glad to hear it is still so largely grown in his neighbourhood. His note bears out my contention that there must be something wrong in the cultivation where it fails, for unless it has deteriorated since I grew it, there are few better. When in the west of England recently, a friend of mine who grows Strawberries rather largely told me he had quite discarded it in favour of the newer kinds, of which Royal Sovereign is a typical variety, and, as I said in my note, I have heard very numerous complaints about it as a forcing kind. I shall try it again this season, but I am afraid in this cold, ungenial soil it will not show its true character. I have some old rows of it in company with Waterloo, as I thought it might improve by being left on the ground, but the growth is weak and the foliage yellow, while the fruit is not at all like the large fine-flavoured berries I have always expected from President. The grower mentioned above used always to leave it on the ground for several seasons, but this was before the plan of clearing off early was so popular as now. Another very useful kind I have lately tried and found wanting is Keens' Seedling.—H. R.

INSECTS AND STRAWBERRIES.

SLUGS and other insects have been very destructive to the Strawberry crop in this neighbourhood, much more so than usual. On one or two occasions it has been really difficult to gather any quantity of fruit without having some blemished ones among them. This is all the more vexatious, as there has been such a splendid crop of large handsome berries. Royal Sovereign has in this neighbourhood been badly attacked by some insect that hardly touches the flesh, but simply eats off the seeds from the outside. I have not noticed that any other variety has been attacked in a similar way, but this kind is picked out from among rows of other kinds. Naturally the appearance of the fruit is much marred, and if any correspondent of THE GARDEN has noticed the same thing in other localities it would be worth mentioning. Even before the fruit is really ripe the seeds disappear, giving the fruit a dull look and of course rendering it quite unfit for dessert. In conversation with a grower on rather a large scale at Sudbury, he attributes the attack to some small insect of the mite order, but I have looked over my rows time after time and can see nothing except a few millipedes, and of course slugs and small snails, and all these marauders were, I think, more active inside the fruit than out. I have looked at night as well as by day, but as yet I am as far from finding out the cause as ever.

Respecting the use of various kinds of litter, I find it makes little difference whether clean straw or that from the stable is used. The slight manurial value of the latter is not worth considering, and if put on early enough to be blanched by rain I find that the slugs can get about on it as easily as on clean wheat straw. Again, the longer the ground between the rows lies open the better, as the moisture caused by the litter is an attraction to slugs. Anything in the way of grass mowings is the worst of all, and I would never use it if I could get good clean straw. When taking layers from a fruiting bed it will be found an advantage to twist the straw into stout bands and lay one of these

round each plant. This not only gives more room and better standing for the pots, but the flower-trusses are lifted clear of the ground out of the way of insects. A little practice soon makes the men adept, and the work then takes less time than strawing the whole of the ground, also using less straw. H. R.

Suffolk.

PEARS ADOPTED BY THE CONGRÈS POMOLOGIQUE OF FRANCE.

(Continued from p. 442, last vol.)

BEURRÉ D'AMANLIS (*synonyms, Delbart, Hubart, Kainsoise, Thainsoise, Wilhelmine*).—As to its origin, M. Jamin (J. L.) found in 1865 the mother plant existing in an orchard at Amanlis, near Rennes. The fruit is fairly large, pyriform, most frequently taking the Bon Chrétien shape. The stalk is short, of normal stoutness, rather curved, set in a small cavity made irregular by a protuberance which is ordinarily very marked. The eye is fairly large, closed or half-closed, irregular, and not deeply set. The skin is a pale green stippled much with grey, sometimes coloured dark red on the sunny side. The flesh is yellowish white, green beneath the skin, melting, juicy, more or less aromatic. A very good or fairly good fruit, ripening in September. The tree is very vigorous on the Quince stock as well as on the natural stock, and very fertile. The branches are thick, long, and bent, greyish red in colour. In cultivation this variety comes well in all soils.

BEURRÉ D'ANGLETERRE (*syns., Bec d'oie, d'Amande, d'Angleterre, de Finois, Gisambert*).—Of ancient and unknown origin. The fruit is smallish, almost medium-sized, regularly pyriform, narrowing almost regularly to the point. The stalk is of variable length, curved, set in the point, and sometimes turned aside by a spur. The eye is large, open, regular, the sepals very short, projecting from a slight depression. The skin is delicate, but rather rough, a light yellow-green, stippled with numerous small brown dots, and often marked with tawny streaks. The flesh is white, rather greenish under the skin, delicate, soft, melting, juicy, more or less aromatic according to locality and season. A good or fairly good fruit, ripening September and October. The tree is of feeble vigour on Quince, very vigorous on the natural stock; of great fertility. The branches are stout, short, spread out and much elbowed. This variety is most suitable for orchards, where it quickly forms a pyramidal and compact head, and bears very freely.

BEURRÉ D'APRÉMONT (*syns., Beurré Bose, Beurré de Humboldt, Cannelle, Carafon de Bose, Paradis d'Autonne*).—Discovered in the forest of Aprémont (Haute-Saône) about 1835. Grafts sent to the Jardin des Plantes of Paris produced excellent fruit, and the variety was dedicated to Bose, although in its native country it still kept the name of Aprémont. The fruit is large or fair sized, a long calebash or pear shape, humpy and swollen at the top, contracted in the lower half and ending in a blunted point. The stalk is longish, woody, straight or curved and set in a small crease. The eye is medium sized, half closed, set in a narrow and shallow and rather wrinkled cavity. The skin is citron-yellow, stained with cinnamon and rather rough, having a pronounced general tint on the sunny side. The flesh is white, delicate, melting, juicy, pleasantly aromatic. A very good fruit, ripening October—November. The tree is of normal growth upon Quince and great fertility on any stock. In cultivation this variety is difficult to control in obtaining regular forms. As a standard on the natural stock it forms a spreading head and quickly becomes fertile.

BEURRÉ DE LUÇON (*syns., Beurré gris de Luçon, Beurré d'hiver, Beurré gris d'hiver nouveau*).—Found in the neighbourhood of Luçon (Vendée), more precise data are wanting. The fruit is large or fair sized, irregularly rounded, generally more swelled on one side than on the other. The stalk

is stout, short, woody, in a broad, shallow and irregularly sided cavity. The eye is small, open, set in a shallow wide cavity, surrounded by obtuse bumps. The skin is not thick, but firm, a grey-green, covered with wide tawny streaks and whitish stipplings, and tinged with light red on the sunny side. The flesh is rather greenish-white, delicate, melting, and aromatic. A good fruit, ripening December—January. The tree is of sufficient vigour on Quince and normal vigour on the Pear; is of great fertility. In cultivation this variety has a tendency to fall and should be trained on a wall.

BEURRÉ DE NIVELLES (*syn., Beurré Parmentier*).—Obtained about 1840 by M. François Parmentier at Nivelles, in Belgium. The fruit is medium or fair-sized, wider than high. The stalk is rather long, slender, curved, set in a narrow shallow cavity and often seamed. The eye is small, often closed, and set in a narrow and shallow cavity. The skin is olive-yellow, spotted and streaked with brown, and broadly marked with a bright reddish-brown on the sunny side. The flesh is yellowish, melting, juicy and aromatic. A good fruit, ripening December to February. The tree is of sufficient vigour on Quince and of great fertility. In cultivation this variety should be grafted on the Pear, and lends itself well to vase forms or large nailed-up palmette forms.

BEURRÉ DE HARDENPONT (*syns., Beurré d'Arenberg, Goulu Morceau, Beurré de Kent, Beurré Lombard*).—Obtained in 1759 by Nicolas Hardenpont on his property of Mont Panisel, near Mons, Hainaut, Belgium. The fruit is of large or fair size, oblong, lumpy, with the form of the Portugal Quince. The stalk is stout and set in a shallow cavity. The eye is open or half open, inserted in an irregular ribbed cavity. The skin is fairly smooth, pale yellow, often yellowish grey-green, stippled grey, washed with tawny at the top and base. The flesh is white, fine, close, melting, very juicy and pleasantly aromatic. A very good fruit, ripening November to February. The tree is vigorous and fairly fertile. The branches are stout, straight, olive-brown shot with ash colour, and covered with very numerous grey lenticelles. The buds are medium sized, short, and at a distance from the branch. In cultivation this variety does well upon Quince and the natural stock, is suitable for all forms, but prefers espalier in a good exposure. The Belgians say that on the natural stock its fruit is much improved.

BEURRÉ DIEU (*syns., Beurré Magnifique, Beurré Incomparable, Beurré des Trois Tours, Beurré Royal, Grosse Dorothée, Melon*).—Found at the commencement of the century on the farm of Trois Tours, near Vilvorde, Belgium, by Meuris, gardener to Van Mons. The fruit is large or very large, obtuse, sometimes as wide as high. The stalk is shortish, stout, swollen at the point of attachment, slightly curved, set rather obliquely in a middle-sized cavity. The eye is medium size or fairly large, half closed, set in a deep, fairly wide cavity, ribbed on the edges. The skin is rather rough, a citron-yellow, much stippled with russet and marked with tawny stains round the stalk and the eye, rarely dashed with a little dark red. The flesh is white, half delicate, half melting, very juicy sugared, acidulate (often too much so), and aromatic. A good fruit, ripening November and December. The tree is vigorous and very fertile. The branches are thick, of medium length, curved, russet colour, with oval grey-brown lenticelles: the eyes large, conical, and distant from the branch. In cultivation, this variety may be grafted upon Quince or upon Pear. It lends itself to all forms of training.

BEURRÉ DILLY (*syns., Beurré Delannoy, Poire de Jollain*).—Obtained about 1848 by M. V. Dilly, a tradesman of Jollain, near Tournay, Belgium. The fruit is of fair size, often almost as wide as high. The stalk is of medium length and slender, swollen at the point of attachment, curved, set obliquely in a shallow, slightly ribbed cavity. The eye is large, half closed or open, set in a fairly wide, shallow cavity slightly ribbed at

the edges. The skin is rather thick, slightly rough, a dull greenish yellow, tinged with dull red on the sunny side, stippled with grey, and washed with tawny round the stalk. Flesh white, slightly greenish, delicate, and melting, juicy, and agreeably acidulate and aromatic in the manner of *Beurré Gris*. A very good fruit, ripening September—October. The tree is of normal vigour and very fertile. The branches are stoutish, short, rather elbowed, a red-brown with small and whitish lenticelles; eyes medium-sized, conical, rather distant from the branch. In cultivation this variety is of good vegetation, and lends itself to all forms.

(To be continued.)

APPLES IN HEREFORD.

I HAD intended to send a note on the subject of the prospects of the Apple crop a week or so ago, but thought it expedient to wait and see how the fruit developed before reporting thereon. Since then the effect of the intensely hot weather we have been experiencing in the west midlands for the past fortnight has been to influence the growth of the fruits on the Apple trees to a marked degree, so that one can now speak with confidence. Apples which a few weeks ago had barely set or only just begun to swell have grown very rapidly, and even the very latest flowering sorts, such as *Court Pendu Plat* and *Sturmer Pippin*, have fruits of a good size on them. The earliest sorts of all, particularly the *Codlins*, such as *Lord Sutfield*, *Keswick Codlin*, and *Potts' Seedling*, are, as may be expected, in a very forward condition for the time of the year, owing, of course, to the forcing nature of the weather. It may be noted in passing that the trees when in bloom had to pass through a rather severe ordeal, as, in addition to there having been frost on several occasions, the wind was most of the time cold and the weather ungenial. As usual in this county, the effect when the trees in gardens and orchards were in full blossom was a fine one, and it well repaid anyone to take the trouble to ascend one of the many hills situated hereabouts for the express purpose of viewing the beautiful picture there presented. Hundreds of acres of orchards were then to be seen, forming beautiful pink and white masses of colour in the landscape, and this not only close at home, but as far as one could see in all directions. I do not remember the blossoming to have been more profuse, and one heard this remark passed on all hands. This is the more remarkable seeing that the trees in the majority of cases carried such heavy crops last year. No doubt we have the fine dry season to thank for this, the wood and fruit-buds in consequence having been so thoroughly matured. The latter were so unusually plentiful, that the wood on trees both young and old fairly bristled with them. The blossoms, it may be remarked, were extremely vigorous and bold looking—always a good augury for a free set—and, what was more, the trees developed a great deal of leafage before and while the buds were opening. Some hold the opinion that when the foliage develops while the blooms are as yet unfolded, or while they are expanding, a good set never results, as an undue proportion of sap is drawn for the support of the leaves which would otherwise go towards nourishing the blossoms and embryo fruits. According to my own observations, but little importance is to be attached to this statement, for last year and on many occasions previously the same thing has happened, and that without the crop being in the least affected. Next comes that important matter which so exercises the minds of all fruit growers in the spring months, viz.,

INSECTS.

I hear of some complaints, but, on the whole, the verdict in this district is that the trees are cleaner than they have been for several years past. By this I do not mean to infer that the trees are free from them altogether, but still one can drive along the main roads and see trees not looking as though they had been riddled with

sparrow shot and in some cases almost defoliated. This is, of course, a matter for congratulation, but it is to be hoped that it will not lull growers into a sense of false security and lead them to imagine that because insects are not so numerous this season, they should relax their efforts in coping with these pests both now and again in the autumn or winter. Personally speaking, I cannot present a clean bill as regards the trees here, but must say they have given less trouble this season than they have done for years. Red spider is present and has been on a few trees, also American blight. The Apple mildew is, I fancy, rather more in evidence this year than usual, as I have noticed it in a great many orchards and gardens the last few weeks. Although not so destructive as caterpillars, it is sufficiently debilitating to the constitution of the tree to call for special means being taken to eradicate it as far as possible. I have also noticed that the brown fungus or mould on the leaves of Apples, which was so prevalent last year in many parts of the country, is still with us, but only to a very limited extent. Of course, we do not yet know to what extent the fruits may be affected by the larvæ of the *Codlin* moth, but so far they look healthy and sound enough. Some growers complain of the Apple cherms or Apple suckers being troublesome, but up to the present I have seen none on the trees here. The Apple-blossom weevil, too, has done but little mischief; in fact, according to my own observations, but few blossoms were infested. I have found a nest or two of the caterpillars of the small ermine moth (*Yponomeuta padella*), but beyond these two instances no more are to be seen. So, taking it altogether, insects which affect Apple trees are, for once, very much less numerous, and in my case this should be so, seeing that no efforts are spared in endeavouring to reduce their numbers throughout the season.

Within the last fortnight trees carrying good crops of fruit have received a fair dressing of manure in the form of chemicals, which has been hoed in in the absence of rain to wash it in. This is of wonderful assistance to the trees, as it keeps them growing and enables them to swell their fruits to a larger size than they would do if left unaided. Liquid would of course be of great benefit when it can be spared and had in quantity, but its application entails more labour at this busy season, while the use of artificial best suited to the Apple and to each particular kind of soil can be applied at very much less cost and trouble. The trees here will have another application of manure when the fruits are about half grown, and this will be sufficient to carry them through. A few hours' steady rain would do the trees an immense amount of good, both in cleansing the leaves and in moistening the soil beneath them, but according to appearances the wish will not at present be realised.

To sum up, the general outlook then as far as the Apple crop is concerned is a bright one, and, judging by present appearances, the yield will be quite as heavy as that of last year. It is pleasing to see old and well-tried sorts such as *Stirling Castle*, *Warner's King*, *Potts' Seedling*, *Ecklinville*, *Ribston*, *Lady Henniker*, *Northern Greening*, *Lord Grosvenor*, *Lord Sutfield* and many others still to the fore as being regular and consistent croppers. Many sorts added to the collection of late years will also afford an opportunity of putting their merits to the test this year.

A. WARD.

Stoke Edith Gardens, Hereford.

Cherry Late Duke.—I have heard *Late Duke* spoken well of for growing in bush form worked on the *Mahaleb* stock, and those who intend planting would do well to give it a trial, as comparatively few varieties give satisfaction so grown. I know from experience that *Late Duke* possesses a capital constitution and will succeed and fruit freely in backward districts if given a wall. Gumming, which injures so many *Cherries*, seems to affect *Late Duke* but little, and even in a light soil, if mulched and occasionally assisted

with liquid manure, the fruit swells to a good size, is of a bright red colour, hangs well and is brisk and pleasant in flavour. An east or north wall suits it well.—N.

Insecticides.—The value of pure water alone in cleaning trees and plants of insects has been well demonstrated by the recent rains, and there is great benefit resulting. What it is thus possible for the rain to do so well may be done with clean water and the syringe, or, better still, force pump, on many things, especially when rains do not prevail. But very much in the direction of cleansing all trees and plants may be done when some simple insecticide is gently syringed over the insects so as to embarrass and clog them, even if not for the moment destroying them. The material, even if it be but soft soap and quassia chips in solution, helps very much to weaken the pests, and then after a few hours of this treatment a thorough washing with clear water effectually disposes of them. Of all trees, wall-trained ones are the greatest sufferers, and these should, because of the rebound furnished by the wall to the projected water, be all the more readily cleansed.—A. D.

Peach Salway.—Although a very fine, handsome-looking Peach, this is not a good variety for private gardens, the flavour when grown in an unsuitable position being very bad, while even in the warmest positions out of doors it ripens too late to get any flavour. The best *Salway* I ever tasted was grown in a mid-season house started at the new year and brought along slowly, but there are many better Peaches at that time, and the principal recommendation *Salway* has is its lateness. In a west of England garden I had it in an unheated house, and with it were *Sea Eagle*, *Prince of Wales*, and a *Nectarine*. The fruit from all these was over before the shooting season had far advanced, but that of *Salway* was often good at the first of October, when naturally it was very useful. The flavour grown thus is far before that of the best out-of-door fruit, and, taken all round, I consider it is the only way that *Salway* is really worth growing, unless under very exceptional circumstances. In many gardens where Peach culture on walls is remarkably well carried out, and other kinds do well and come well flavoured, this either does not ripen, or else when ripe it is poor and watery in flavour and woolly in texture.—H.

GRAPE GROS GUILLAUME.

THIS Grape is not so popular as many others on account of its habit of not finishing properly unless very carefully and well grown. Some consider it an exhibition Grape pure and simple, but as a matter of fact where it succeeds it is a very useful kind for home consumption, and when well ripened late in the season quite equal, if not superior, to *Lady Downe's*. Like *Gros Colman*, it needs a long season to be good, and cannot be rushed along like *Black Hamburg* or even *Madresfield Court* to finish early in the season. If started at the new year it would not be properly ripe before the end of August under ordinary conditions of culture, and from then to the middle of November is undoubtedly its season. Pruned long, *Gros Guillaume* throws large loose bunches that may or may not fill out properly at the shoulders. If by good feeding and careful manipulation they do so, grand bunches result, but the grower of such must beware of how many he leaves upon his rods, for a very few such will constitute a more severe strain upon the Vine than what appears a very heavy crop of smaller bunches. It is better in the ordinary way to prune rather close and be content with smaller bunches, which are usually more solid and preferable in every way, excepting, of course, for exhibition.

Very short or close pruning, on the other hand, will not do for this variety. It should be pruned to a good plump eye. When thinning bunches of *Gros Guillaume*, those who are not acquainted with the variety often make the mistake of thinning the shoulders too much and the

lower part of the bunch too little. The former being in most cases longer than those of most kinds, yet distinct from the long, stiff shoulder characteristic of Gros Coiman, they can be tied out all round and a very fine bunch built up. If too much thinned this upper part will be loose, while the waist of the bunch, owing to the berries having less room, will be tightly packed. Being a very vigorous grower, Gros Guillaume is often inarched upon a weaker growing kind, such as Black Hamburgh, but this is not absolutely necessary. The foliage in autumn takes on very beautiful russet and red tints, and for this reason is much in request for dishing up other fruit upon. This must not be carried to excess, or the Vines will be injured.

EFFECTS OF THE STOCK ON GRAFT.

In the *Country Gentleman* we find some remarks on grafting which show more than usual observation of the effects of the stock on the scion, and are otherwise of interest to fruit-growers although written from observation in American orchards:—

1. DWARFING.—If the stock is a much slower grower than the scion, it may reduce the whole tree in size. Pears grafted on Quince and common Apples grafted on the dwarf Paradise stocks are the most common instances. In certain cases, especially in top-grafting old trees, the slower growing character of the stock does not seem to have so much effect in dwarfing the top. Common varieties of the Apple, like Yellow Transparent, King, or Fameuse, when grafted into Crab tops are not visibly dwarfed. Instead, they overgrow the stock. Frequently they become so top heavy as to break down of their own weight combined with stress of wind and fruit crop.

2. COLOUR OF FRUIT.—The stock sometimes modifies the colour of the fruit borne on the scion. Two cases have recently come to the attention of the writer. In the first, McIntosh was grafted on Siberian Crab, with the result of making the fruit much richer red and darker coloured. The trees from which the scions were taken grew directly beside the Crab trees in which the grafts were set, so there could have been no mistake in the observation. In the second case, Rhode Island Greening was grafted on Talman Sweet, with the result of making the Greenings lighter coloured.

3. FLAVOUR OF FRUIT.—Likewise the flavour is sometimes affected. In both cases cited above this was true. The Greening on the sweet Apple tree was said to have a sweetish taste. The McIntosh on the Crab stock had a more sprightly acid flavour. The latter case was thoroughly investigated by the present writer. Cases of this sort are not rare; but results of this sort are not sufficiently pronounced to be worth working for.

4. MATURITY.—The season of maturity is occasionally modified. The McIntosh Apples on the

Crab stocks kept a full month longer than those from the next row growing on common Apple stocks. Bailey cites the case of Twenty-ounce Apples, which ripened earlier when worked on Early Harvest; also of Winter Nelis Pear, which ripened earlier when grown on Flemish Beauty stocks than when grown on Bloodgood.

5. ADAPTATION TO CLIMATE.—It has been found in Iowa, Quebec, Vermont, and other semi-arctic countries that comparatively tender varieties of Apple, like Greening, King, and Baldwin, can be grown from 100 to 200 miles further north when top-grafted on such "ironclads" as Hibernial, Duchess, or even on Talman. A limited experience seems to show, on the other hand, that certain European varieties of the Pear can be grown further south when worked on such hybrid stocks as Le Conte, Garher, and Kieffer.

6. ADAPTATION TO SOIL.—Plums for light sandy lands should be worked on Peach; for very low, wet lands in the South they may be worked on

Magnolia Lenné at Enys, Penryn, Cornwall. From a photograph sent by Mr. Prestley Hogbin.

Chickasaw stocks; for heavy, cold soils in the North, Americana stocks are best. Peaches for heavy land are best worked on Plum.

The plague of caterpillars.—It was, I think, generally expected that after the extremely mild winter fruit trees would suffer greatly from insect pests. In passing through the principal fruit-growing districts of Kent I have been struck with the ravages caused almost everywhere by the larvæ of the small ermine moth, and in some places they have almost defoliated the trees. This pest is easily distinguished by the web that is formed at the tips of the shoots, where the ravenous caterpillars feed on the succulent leaves and tips till full grown, when they fall or let themselves down to the ground. Both Apples and Plums have been swarmed with the pests,

and now that the caterpillars are gone, the brown and seared tips of the leafless shoots point plainly to their late residence. Strangely enough, the majority of market growers make no effort to destroy the pests, though much damage can be averted by syringing with paraffin emulsion.—H. H.

Flavour in Strawberries.—When recently exhibiting before the fruit committee a plant in fruit of their new Strawberry Veitch's Prolific to show its cropping qualities, Messrs. Jas. Veitch and Sons also sent a box of fruits for tasting. It says a good deal for the excellence of the variety that every fruit soon disappeared. But an odd objection was made to the flavour by one member, and that was that it possessed too much of the Hautbois flavour. So far from being an objection, I thought it to be a strong recommendation. But the general estimate was that without being unduly high the flavour was delicious, and in that respect alone, apart from its other high qualities, the variety is a valuable acquisition. The new Lady Sutfield, shown at the Temple, I had an opportunity to taste with the rest of the fruit committee, but thought that, whilst very nice, flavour had to some extent been lost in transit. Perfume is not always a safe guide, because in fruits too much of it evident to the olfactory nerves seems to indicate some loss of it in the fruit through diffusion in the atmosphere. Melons that are delicious to the nostrils are too often otherwise to the palate. An older Strawberry of very high excellence in respect of flavour is Countess, that was recently in the great trial of varieties at Chiswick the very best in crop and in flavour. It is a variety that should be largely grown by all who prefer medium-sized, delicious fruits to those huge acid fruits that so many think to be the best Strawberries. Countess throws moderate leafage, and may be planted rather closer together than is the rule with ordinary varieties. Some few others merit wide culture because of their high flavour.—A. D.

TREES AND SHRUBS.

MAGNOLIA LENNÉ.

This is undoubtedly one of the best of the deciduous Magnolias and a variety of the white Yulan (*Magnolia conspicua*), but instead of being white the flowers of *Magnolia Lenné* are suffused with a delicate rosy purple. The flowers appear in great abundance and are sweet-scented. Being among the hardiest of early-flowering trees, *Magnolia Lenné* is a most desirable shrub. In Messrs. R. Veitch and Son's nurseries at Exeter and Exminster there are several good-sized trees which have flowered abundantly and are growing in ordinary loam mixed with a little peat. The illustration is from a photograph of a plant in the grounds of Mr. Enys, at Enys, Penryn, Cornwall. Regarding this particular tree, Mr. Prestley Hogbin (who has charge of the gardens) informs me that it is growing on the west terrace in the company of Himalayan *Rhododendrons* and *Camellias*. The height is 20 feet, and it has flowered exceedingly well this year, lasting many weeks. In the autumn it always blooms a second time, and the flowers at that time of the year are darker in colour than the spring flowers. A *Magnolia stellata* planted close by produces yearly a complete mass of its beautiful white, star-shaped flowers. Among the *Rhododendrons*, which constitute the companions of the *Magnolia* here illustrated, are some grand plants raised from seed of *Rhododendron cinabarinum* var. *Roylei*. F. W. MEYER.

Elmside, Exeter.

Periploca græca.—This is a quick-growing liginous climber that is quite distinct from anything else that we have in our gardens. It is a

good wall plant, but is even more suitable for clothing arbours, pergolas, and purposes such as this. The long, slender stems soon form a dense mass, and when furnished with foliage it is very effective and is then a good screen plant, but, being deciduous, it is of little use for this purpose during the winter. The flowers, which are freely borne about midsummer, are star-shaped, an inch or so across, and of a peculiar purplish brown tint. They are somewhat unpleasantly scented; therefore the plant should not be trained to the walls of a dwelling-house, but when growing loosely and, according to its usual custom, profusely laden with blossoms, it presents an attractive and uncommon appearance. It is readily propagated from cuttings.—T.

NOTES ON CURRENT TOPICS.

COLOURING GRAPES.—It is curious to observe how this subject continues to engross the attention of growers without, as the old farmer said to Sir Walter Scott over the claret, "getting any forrader." One feature in the colouring of Grapes I do not remember to have seen often noticed is the tendency of thoroughly well-coloured Black Hamburgs, ripened about midsummer, to turn about as thoroughly foxy as the worst examples of colour on Grapes that have never coloured at all. This very often happens in the case of crops that have to hang long on the Vines, even in the case of Vines in robust health and green foliage. What causes the colouring matter to disappear? Is it because the wood and leaves being matured the circulation has grown sluggish and the supply of colouring matter been arrested? That would imply that the colouring matter, like the chlorophyll of the leaves, is a circulating substance that may fluctuate in quality and quantity, and that when it is in abundance the Grapes are well coloured, and *vice versa*, just as the foliage becomes dark or pale green (anæmic), according to the state of the sap and the supply of chlorophyll. The presumption is that when Grapes do not colour well in a soil that contains all the essentials to good health—and few borders do not—the cause is to be found in the state of health of the subject. Hardy varieties like the Alicante almost invariably colour well when the Madresfield Court, Mrs. Pince and Black Hamburg growing beside it are often red. West's St. Peter's is almost always of a deep black colour under similar circumstances, and so is the old Black Prince that Mr. Hill used years ago to exhibit at Regent's Park. One thing is certain, and that is that the Black Hamburg is the most erratic variety in respect to colouring of any, exhibiting every shade of colour from a reddish green to deep black, and that good colour is always associated with good green foliage and plenty of it, and absent when the foliage is poor from any cause, red spider being most to be feared. Once when among the vineyards of the north of France, where so much of the little black Grape is grown that produces the *vin ordinaire*, I could not help admiring the colour of the little bunches that hung on the Vines among the luxuriant leathery foliage and a tangle of laterals that a gang of women were hacking off in armfuls. The berries were thoroughly black without exception, just as the bunches of Chasselas de Fontainebleau on the open walls were golden. The advice of "H.R." to "very slightly increase the amount of air allowed" when the berries begin to colour is not quite satisfactory. The foliage and colouring agents cannot be maintained in a satisfactory condition if the life-giving air is not always supplied liberally. Neither do I believe that thinning the bunches very early—when the berries are like small peas, for example—does the

least good in the way of relieving the Vines. Physiologists hold, and rightly, that the green berries, previous to stoning, just fulfil the functions of leaves in the elaboration process. Up to that period the laterals grow quite rampantly, but when the critical stoning period arrives there is a distinct pause, and then the task of finishing begins; but if the colouring agents have not accumulated before, then no amount of air will put them there, and if the Vines are overcropped under artificial culture, these agents are sure to be deficient.

THE SPARROW: HOW TO DEAL WITH HIM.—Our friend the sparrow may be fed on insects during the couple of weeks or so of childhood that he remains in the nest, but the moment he leaves there he also leaves the insects and grubs and becomes a denizen of the bushes near the yard where the fowls are fed, and he stays there patronising the feeding trough from early morning till it is nearly dark in the evening. He is a thoroughly demoralised bird with all the vices of civilisation as far as he can acquire them. When he leaves the fowl's, pig's, or dog's feeding-dish it is to carry on operations in the garden. I cannot say that he is such a very bad bud-eater. The silent bullfinch is the arch-offender there. I have known two or three of these birds destroy the whole crop of Currants on a long row of bushes in a short while by eating the buds when they were just swelling and soft and eatable. It is a curious and providential circumstance that he rarely takes the terminal bud, for if he did the shoot would be killed; but he will alight on a shoot and in the most methodical way will pick out each bud alternately to the bottom. The sparrow is a "seedsman." In the garden where I am staying he has nearly made the tenant abandon gardening. Peas, Lettuce, Turnips, Radishes, Spinach, and other things have been an almost hopeless failure. It is in the early morning he gets to work, when no one is about. But I have just put my friend up to a way of reducing his numbers that has proved a success. I deal with him on the Maxim-gun principle, and I learned that from a gamekeeper in shooting wood pigeons. He boasted of killing as many as a dozen pigeons and more at one shot, which I did not credit till I saw it done. His plan was to strew Indian corn in single file in a narrow furrow not far from a turf hut with a hole at the side. Here he waited with the gun well charged with shot, and when the pigeons came and began pecking in a long row in a line with the hole, he sent a shower of shot along the line, killing nearly every pigeon. One exhibition of this sport was enough for me, but afterwards, when I was almost in despair about the sparrows, the idea was useful. I set a board up on about a level with my shoulder—a board at least 6 feet long—and in single line I strewed the most tempting sparrow food. In the morning there was usually an equally long row of sparrows on the board, and one cartridge of sparrow-shot delivered from the shoulder and on to the board used to make a clean sweep, and I waited for the next instalment. One post, a bit of deal, and gun are all that is required, and the plan will have the approval of the philanthropist, inasmuch as extinction is painless and as a rule instantaneous.

FLOWERS AT THE ROYAL ACADEMY.—Who are most to blame for the mistakes of artists such as are described in THE GARDEN of June 17: the artists, or the critics who profess to correct their mistakes? Natural objects, consisting of plants, flowers, and animals, are the stumbling-blocks to those painters of the Alma Tadema school who introduce natural objects

into their pictures as accessories, and which the professional critic whose school is the Academy is almost sure to miss or discreetly leave alone. Here is a story of one famous picture by an equally famous painter, both well known, the former having been often exhibited since it was first "hung," where the critics flattered it, passing over a gross caricature of a natural object occupying a prominent position in the picture. For obvious reasons I can go no nearer. This picture was purchased by a gentleman and taken to his mansion, where it fell under the eye of one who was more of a rustic than an artist, but who at first glance made the remark, "No one ever saw a — like that in Nature." This was repeated to the artist, who had the subject entirely rubbed off the canvas and the amended object restored from an actual example furnished by his critic. The truth is, some artists are like our comparative anatomists, only not so truthful. They procure a bit of a plant or an animal and evolve the rest with the brush.

LORD PENZANCE'S HYBRID ROSES.—These Roses, a new type, should now be about their best. As is well known, they are a cross between the wild Sweet Brier variety and some cultivated kinds, but they inherit the characteristics of the wild form in the greatest degree. I procured the first lot at the beginning, and have found them equal in vigour to the wild Brier, throwing up in good stiff soil tall, vigorous shoots from the crown each season like the common Brier, and producing, in some of the varieties, a profusion of bloom exceeding anything I have seen in the wild Rose. The flowers are single, much resembling the wild Rose, and the colours are varied and rich—brunzy or copper-coloured, deep crimson equal to Crimson Rambler, rich rosy red, delicate pink, and other colours. A group of these Roses mixed or distinct makes one of the most effective masses on a lawn that can be imagined, but the plants must be left alone, untouched by the knife, when they quickly form a thick, dense mass, every part of which is a mass of flowers at this season.

THE ROWAN TREE.—The Rowan tree, or Mountain Ash, is rarely seen to perfection except in cool and moist localities, and its real home is in the valleys and on moist hillsides of the north. Allusion to the brilliant-berried *Cratægus Pyracantha* makes me think of the Rowan tree, which, in my opinion, surpasses all our hardy ornamental-berried trees and shrubs. The tree grows to a good size, and the timber can always be sold for the same purposes as Birch. It never fails to bear an abundant crop of fruit, and the berries are always large and brilliant in colour where the situation suits the tree, which will grow almost anywhere, only the berries are smaller and not so bright in a dry soil or climate. Argyle is one of the homes of this beautiful tree, and in many places there it is to be seen as it is to be seen nowhere else, both foliage and fruit being very beautiful. It is the favourite tree in the gardens and grounds at many of the watering-places on the Clyde, and the tree is often planted to form an archway at the entrances to houses and gardens—"for luck," we suppose, there being an old superstition in the Highlands to that effect. Shepherds used to cause their sheep to jump through a hoop of Rowan tree once a year for luck to the flock. For a similar reason, I presume, there are planted and tended with great care three Rowan trees in one of the courts at the top of Stirling Castle that are specimens in their way as regards health and fertility. I never saw finer, and the trees when I saw them in August a few years back were literally

weighed down with the crop of berries, which were almost as big as marbles, clean, and brilliant. It is surprising how familiarity breeds indifference to things that we would be sure to treasure if they were only rare. When the female variety of the Aucuba was first brought to this country and so much was said about its red berries—the plant being about as stiff and dingy a subject as one could see—I used to compare it to the Rowan tree with its graceful drapery of foliage and profusion of scarlet fruit, much to the disadvantage of the former. The stiff little Solanum capsicastrum has pretty berries, but it is a greenhouse plant and lacks the grandeur of the Rowan tree. The only hardy shrub fit to compare with the Rowan is Rosa rugosa. It has fine and abundant foliage, but it is as a berried plant it is useful. On high and cold exposures the bush is ablaze with its large scarlet berries, and the berries of the white-flowered varieties are by far the finer and more brilliant. Next to this comes the common Barberry, unsurpassed for its brilliant berries borne in great profusion in a cool, moist climate, but seldom seen to perfection in the south. Planted thickly in woods, as I have seen it in Dumfriesshire, the woods seem on fire in October. Last October, in Dundee, one florist's window was draped with it and attracted much attention. I was told that it came from Blairgowrie. I had a branch of it in my room for over a fortnight. In forestry, if we wanted a profitable "nurse"—say, for the Oak—supposing the latter had to be planted where it could not nurse itself, I would plant the Rowan tree. Its few first years' growth is out of all proportion to its later growth, and it generally pushes up from seed with a single straight stem, the annual shoots being, perhaps, a yard long. Planted thickly, therefore, amongst more tender species it shelters them from wind whilst not overtopping them, and when the permanent crop—the Oak, for example—becomes established and can take care of itself, it overtops its nurse, which will then be fit for the timber merchant and may be removed. RAMBLER.

LAW.

MAY V. THYNE.

THE above case was taken in the Sheriff's Court, Glasgow, before the Registrar, W. Guthrie, on June 19 last, but, owing to its importance, judgment was then reserved. The main points in the case are briefly as follows:—

In the early part of 1898, Mr. George May, market grower, Upper Teddington, gave an original personal order to Mr. Thyne McCullum, representing Messrs. J. and R. Thyne, bulb importers, Glasgow, for 10,000 bulbs of *Lilium longiflorum* in two sizes, viz., 5000 of each size. The order, originally a verbal one, was subsequently confirmed by letters passing between the above-named persons. In due course the one part of 5000 bulbs was delivered and paid for, the remaining 5000 bulbs being booked at £6 10s. per 1000, the size being 7 inches to 9 inches. When the time arrived for the delivery of this latter portion, Messrs. Thyne wrote informing Mr. May that they only had some 2000 of the size required, and suggested sending *Lilium speciosum* Krætzleri partly in lieu thereof. To this Mr. May replied by return, asking that the 2000 stated to be in hand should be sent on at once, declining, however, to accept the other Lily named, it being useless at the season. Thereupon the Messrs. Thyne wrote stating that their offer of these two Lilies was made in full and complete settlement of Mr. May's order and must be accepted as such, failing which they declined to supply any portion of the second 5000 lot. Subsequently, Mr. May wrote to the effect that if his order was not executed forthwith, he would be compelled to

purchase against them, which indeed in part was done. The defendants pleaded that the bulbs were not to be purchased in the country, but it was shown that a large consignment was actually sold by auction in London at the time, and, though at greatly increased prices, Mr. May's order could have been executed many times over.

The following is the verbatim judgment in the case:—

Finds that the defenders in spring, 1898, sold to pursuer 5000 bulbs *Lilium longiflorum* 7-9 at £6 10s. per 1000. Finds that in November they found they were unable to supply the said bulbs and intimated this to the pursuer, and that they did not deliver the same. Finds that it is not proved that there was any condition or custom releasing the defenders from their contract in the event of a failure of the foreign crop, or that there was such a crop. Finds that the pursuer has suffered loss by the defenders' breach of contract to the amount sued for. Therefore decrees against the defenders as craved. Finds them liable to the pursuer in expenses, allows an account thereof to be lodged, and remits the same to the auditor of the court to tax and report.

In an appended note the judge remarks:—

The case is very clear. The only obscurity or even question, and indeed the only point really attempted to be made for the defenders, arises out of the manner in which the pursuer has chosen to state what may be called the second part of his claim for damages. He may not have expressed himself in that with exactness and legal accuracy, but I think that the evidence is sufficient to show that the loss "directly and naturally resulting in the ordinary course of events from the sellers' breach of contract" (Sale of Goods Act, s. 51 (2)) is greater than the sum sued for, which is calculated on the footing that all the bulbs could have been replaced in the market by buying in at the price which was actually paid for a part. I cannot agree with the defenders in their attempt to throw back the date of breach till October or November 2, for I think that they did not finally give up hope of fulfilling their contract or put the pursuer on his inquiry for other goods till November 25. One is hardly surprised that the defenders, who appear to have been more generously dealt with by other customers equally disappointed with the pursuer, and whose breach of contract is sufficiently accounted for by circumstances which they could not control, should regard the pursuer as making a heavy or even an exorbitant claim. But it is only what he is entitled to ask for under the contract, and the evidence, such as it is, suggests, though I do not think it proves, that much more might have been demanded.

SOCIETIES AND EXHIBITIONS.

ROYAL GARDENERS' ORPHAN FUND.

THE annual dinner of this fund took place at the Hotel Metropole on Tuesday evening. Alderman Sir R. Hanson, M.P., presided, and among those present were Mr. Sheriff Probyn, Mr. Deputy Sayer, Messrs. N. N. Sherwood, H. J. Veitch, J. H. Veitch, Harry Williams, A. de Chapeaurouge, Arnold Moss, W. Foster, F. Blackwood, H. Turner, J. A. Laing, and Lieut.-Col. Wyndham Hart. The usual loyal toasts having been honoured, the chairman proposed "The Royal Gardeners' Orphan Fund." He said only twelve years had passed since the fund was established. He wished he could say it was only twelve years ago that the necessity for it arose, but since the beginning of the world it had happened to some to be fortunate and others unfortunate. The fund did great credit to those men who had not only the power, but the will to come forward and do something to alleviate the sufferings of the orphans, and he was pleased to see that such a sensible start had been made. He was glad they had not gone in for bricks and mortar, and he hoped that for many years they would keep away from the builder. Let them spend all the money they could on the immediate necessities of the orphans and refrain from setting up a big building with its ever-recurring expenditure on "repairs." It was all very well to put a nice illustration of a building on the top of the subscription list, but it really was not worth doing as an advertisement. He welcomed the establishment

by the London County Council of scholarships in practical gardening as a movement which might be of advantage in promoting the future welfare of the recipients of the fund's bounty. Mr. Wm. Marshall, who responded, referred to the fact that the committee had power to assist in starting orphans in life, and had already dealt with several applications for help of the kind. The executive committee had done him the honour of electing him chairman for the last ten years, and that position had naturally brought him into immediate contact with the late secretary, his old friend Mr. Barron. Nobody but those who were behind the scenes could have any idea of the amount of labour entailed upon the secretary in carrying on the working of a charity of that description. He had been requested to give Mr. Barron a presentation. It had been proposed by Mr. Harry Veitch, and seconded by Dr. Masters, that a testimonial should be engraved and framed and given to Mr. Barron on his retirement from the office of secretary, and that resolution the committee had carried out. He regretted that the name of Miss Barron also had not been submitted to the meeting, for she was entitled to credit for the amount of work she had done on behalf of the society, and for the manner in which she had aided her father in carrying out the secretarial duties. Mr. Marshall then, amid applause, handed the address to Mr. Barron, who briefly acknowledged it. The other toasts included "The Chairman," proposed by Mr. N. N. Sherwood; "Gardeners and Gardening," proposed by Mr. Arnold Moss, and responded to by the Rev. S. B. Mayall; "The Press," proposed by Mr. A. W. G. Weeks, and acknowledged by Mr. George Gordon, who referred to the presence at the dinner of the editor of *American Gardening*, a gentleman trained in England and the son of Mr. Barron; "The Secretary," proposed by Mr. Sherwood and replied to in a very apt speech by Mr. Wynne; and "The Treasurer," proposed by Mr. Marshall. During the evening Mr. Wynne announced that the total amount subscribed was £590 3s. 6d., of which sum the chairman had given 20 guineas, Baron Schroeder 10 guineas, Sir T. Lawrence 10 guineas, Mr. R. Dean 10 guineas, Veitch and Sons 10 guineas, Mr. F. W. Burbidge £5, and Sheriff Probyn £5 5s. The Covent Garden list, included in the total mentioned above, amounted to £100.

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, July 25, in the Drill Hall, James Street, Westminster, 1 to 5 p.m. A lecture on "Seed Dispersal" will be given by Prof. G. S. Boulger at 3 o'clock.

Pot-pourri or Rose jar.—I should be much obliged if you would kindly give me a recipe for Rose pot-pourri, with the exact proportions of things used.—MRS. MILNE-HOME.

** Gather Rose petals early in the morning and place in a cool place for an hour to dry. Toss them lightly, and then put them in layers, with salt freely sprinkled between, in a large glass-covered dish. Add fresh petals to this every morning. When you have sufficient, let the whole stand for ten days, shaking well every morning. In the bottom of a glass fruit jar place 2 ozs. of whole allspice crushed and 2 ozs. of stick cinnamon broken coarsely. Fill the jar with the Rose petals and salt. Let it stand for six weeks, when it may be prepared for the permanent jar. Mix together 1 oz. each of ground cloves, allspice, cinnamon, and mace, 1 oz. of orris root shredded and bruised, and 2 ozs. of lavender flowers. These are the proportions for one quart of Rose petals. Place this mixture in alternate layers with the contents of the glass fruit jar in the permanent jar. From time to time you can add a little lavender water or any other perfume. If the covers are removed for an hour at a time twice a day, your rooms will be filled with sweet odour.

NOTES OF THE WEEK.

Geum Heldreichi is a very pretty addition to our hardy plants, the colour a bright orange, which makes it a conspicuous object. It is free flowering and altogether a very desirable plant.

Mazus Pumilio.—Where a dwarf carpet plant is required in a moist or shady place this can always be strongly recommended. The plant flowers freely, more especially when growing freely. In the drier parts of the artificial bog the plant in question is a good one, and where situated among or near stones is generally content.—E. J.

A double Enothera.—I send you some flowers of a seedling double Enothera I have succeeded in raising. I think it very beautiful with its purple leaves and stem and bright clear yellow flower-heads. It is attracting the attention of every visitor.—M. CUTHBERTSON, *Rothsay, N.B.*

* * A very handsome plant.—Ed.

Lilium Burbanki.—This Lily, which is said to be a hybrid, having *L. Washingtonium* and *L. pardalinum* for its parents, was shown at Chiswick last week by Messrs. Wallace. The former is stated to be the seed parent and the latter the pollen parent. In the flowers alone and the colour and form particularly it has much in common with the somewhat variable *L. pardalinum*.

Hemerocallis Pioneer.—This is a seedling raised between *H. disticha* and *H. Thunbergi*, and a pretty addition to the group in question. In the form of the flower there is much to remind one of Thunberg's Day Lily, and in the colour there is a touch of both parents. A similar remark also applies to the foliage, so that it is quite possible Pioneer will prove a somewhat interesting plant.

Campanula G. F. Wilson.—Very few Campanulas have surpassed this in flowering this year, the blooms, both in colour and numbers, having been all that could be desired. It is, however, one of those that likes a good depth of fairly good soil and, like not a few of its race, a rather heavy or holding soil, at least in part. Given these conditions, it is a capital plant for border or rockwork.

Clarkia elegans Salmon Queen.—This is one of the best forms of the *Clarkia*, and under good cultivation produces fine erect heads of blossoms. To see this variety at its best, clumps of good size should be sown and carefully thinned. The colour, a beautiful salmon, is one of the most pleasing of the whole family. In the borders at Aldenham House, Elstree, good use is made of it, handsome masses just now being at their best.

The Wedding Iris (I. Robinsoniana).—I beg to send you herewith a drawing of *Iris Robinsoniana* (Wedding Flower) sketched from the growing plant in our garden here. The plant stands 4 feet 3 inches from the ground to the top of the flower and is a very conspicuous object. I understand it was introduced to this country from Lord Howe's Island, where it attains a height of 6 feet.—J. C. LINDSAY, 2, *Linn-brane, Alexandria, Dumbartonshire.*

Sweet Pea Emily Eckford.—With so many Sweet Peas the difficulty has been to distinguish the difference between many of them. The variety under notice is quite distinct, and not only so, but also most effective when properly disposed in the garden. When cut the pretty bluish shade, suffused with mauve, enables one to get effects which would not be possible without flowers of these tints. If I were growing a small collection of these plants I should certainly include this variety.—D. B.

Tufted Pansy Magie.—Plants of this variety did exceptionally well last season and raised the hopes of growers in supposing they had found a new sort of a neat and distinct shade of colour—pale rosy mauve. This hope has been dispelled this season, as the blossoms are not nearly so pretty and effective, the colour being much deeper and the plants also have not done so well. This variety does not appear to advantage in exposed situations, a semi-shaded position evidently suiting it better.

Tufted Pansy White Duchess.—This still retains its position as the most refined flower of the type. Stock was very limited with me early in the season, but the few pieces that were got together have developed into large, handsome clumps. The growth of this sort is robust and spreading. In long periods of drought, plants of this type of growth have special advantages. Covering the ground as they do, the soil is kept cooler and moister than is the case with the majority of the Tufted Pansies. The blossoms

are large, irregularly margined, blue, tinted mauve on a white ground, with a faint suspicion of yellow in the rayed centre.

Tufted Pansy Walter B. Child.—The variety under notice is one of the best miniature-flowered kinds, and the blossoms are very effective. Little scraps placed out in the open border in March last are just now blossoming profusely, the dainty little blossoms on stout, erect footstalks and of good length being very showy. The flowers are rayless, broadly margined lavender-blue on a white ground. Small plants arranged about 6 inches apart have already filled in the intervening spaces.

Godetias, self-sown.—There is now in the pink of perfection at Aldenham House a grand mass of Godetias. A capital batch of seedlings, self-sown last autumn, came through the winter without any apparent inconvenience, and these have for some time now been making a wonderfully pleasing display. Rarely indeed does one see such a grand mass of bloom and also so continuously produced. Plenty of room must of course be given these plants to develop, and in so doing one is well repaid by the handsome return given.—B. C.

Iris Kœmpferi.—In moisture-laden places this handsome Iris is now making a fine display, the great flowers in their many and varied colours defying description. Most effective, perhaps, are the rich blue and deep purple-hued kinds, while many of the lighter shades, some of which are nearly pure white and lined with blue or purple, are fine by reason of the contrast they afford. A rich and damp soil is well suited to such things, though not essential, seeing how they succeed in good border soil or even shady ditches.

Campanula persicifolia.—In last issue of THE GARDEN I notice two correspondents drawing attention to variation in size of flower of *Campanula persicifolia alba* Backhousei (syn., *grandiflora*). This variation is caused by carelessness in allowing seedlings to come up round the original plant, the flowers of which seedlings do not maintain the large character of the blooms of the parent plant. I have proved this. I enclose for your inspection a silver-shaded *C. persicifolia* flower which I think is even better than Backhouse's variety.—J. C. LINDSAY.

Lilium Martagon album.—There is something pleasing and satisfying in this pretty white Lily, though it is, unfortunately, not a common plant in all gardens even where good hardy plants receive special care. Some good spikes of it quite 4 feet high were at the Drill Hall the other day. A more everyday plant is the typical form, which often occurs in big clumps in or near to shrubbery borders or the like. Nor is it opposed to the roots of trees, finding in their company an agreeable association and possibly deriving good by the shade such things give.

Tufted Pansy Archie Grant.—It is curious that this excellent and free-flowering kind, after having been in cultivation a dozen years at least, should have remained so long without its merit having been fully recognised. In point of colour, and not less so in the bold, erect carriage of its lengthy flower-stalks, it surpasses quite a large number. For large beds, too, it is invaluable, and equally so in the vigour of its constitution. The fact that its true value has only now been admitted can scarcely do it much good, for the plant has been grown by thousands for years past.

Erigeron speciosus superbus.—This beautiful *Erigeron* does not appear to have thriven in its usual way this season, and in other gardens as well as in my own I observe that it is dwarfer and less free-flowering than in all my experience. This is a disappointment, as one always looks forward to having a superfluity—if such can be—of its charming flowers, which have a lightness not always found among the composites. It is not easy to account for its poor growth this season.—S. ARNOTT, *Cursethorn, by Dumfries, N.B.*

Fuchsias in the greenhouse.—In one of the greenhouses at Chelsea the Messrs. Veitch and Sons have trained a large number of specimen plants of these to the principal rafters from either side. Now that the plants are in flower—and, indeed, they are literally loaded with blossoms—the sight is a very pretty one. At the same time it should be borne in mind that it is not every plant that will thus respond to ordinary treatment, and so near to the heart of London. A year ago some plants were allowed to grow without stopping, and these, given a large shift

early in the present year, are now ablaze with flowers.

Deutzia Lemoinei in S.W. of Scotland.—When I visited the beautiful garden of "W. D. R. D." a few days ago I found your correspondent apologising for an error made regarding this *Deutzia* in his recent note to THE GARDEN. The plant had been received with and planted near *D. discolor purpurascens*, and was, as I saw for myself, plainly marked on the nurseryman's label "Deutzia Lemoinei." The leaves looked very like those of *D. discolor purpurascens*, but when the flowers opened it was observed that they were those of a *Philadelphus*. The plant appears to be *Philadelphus Lemoinei*, and the error on your correspondent's part is one easily made.—S. ARNOTT.

Verbascum Lychnitis.—On p. 52 Mr. Arnott speaks of this as a Caucasian species, but it is also a British species, and is found wild in nearly every country of Europe. It is not a good garden plant, though it has established itself as a common weed in my garden, where I introduced it many years ago, wishing to grow it as a wall plant because it had grown as long as I can recollect on the walls of Haddon Hall, in Derbyshire. In most situations it is coarse and the colour of the flowers dull. However, it contributes its quota to the many ornamental hybrids of *Verbascum* which grow here, and makes a perennial when crossed with *V. nigrum*, though itself only biennial.—C. WOLLEY-DOD, *Edge Hall*

Centaurea moschata alba.—In whatever form or colour, the various kinds of the Sweet Sultan are always popular; indeed, such charming things could scarcely be otherwise. The yellow and sulphur-coloured forms are well known and freely grown—the former especially so, while in the above we have the most recent addition to this lovely group of fragrant flowers. Happily, too, the new-comer is a good and pure white, fully as large, too, as the older kind and quite as delightful in its pleasing fragrance. It is a fragrance, moreover, of which one does not readily tire, and a handful of the blossoms makes a very charming vase. It was recently brought to the Drill Hall by Messrs. Jackman and Sons, Woking.

Trillium declinatum.—Under the provisional name of *T. declinatum* Mr. P. Neill-Fraser grows at Rockville, Murrayfield, N.B., a *Trillium* of exceptional stature and of great beauty. Unfortunately, it was over before I saw it, but there was no mistaking its vigour and free growth. It is not, perhaps, distinguishable from *T. erectum album* in its botanical characters, but from a gardening point of view the two can hardly be looked upon as the same. Growing beside the other Wood Lilies, its great height was very observable, and one could see that its flowers, which were over, had drooped slightly and had been larger than those of the other *Trilliums*. It is to be hoped that Mr. Neill-Fraser may soon have a large clump of this fine variety.—S. ARNOTT.

Acantholimon venustum.—This has been very fine this year, that is in so far as the number of its flower-spikes is concerned. The blooms, however, appear to have been somewhat shorter-lived than usual, doubtless owing to the intense heat and prevailing dryness of the atmosphere. At the same time it is when the majority of good rock plants are past and gone that we value such as this at its full, and in any case were the number of good plants much larger than is actually the case this pretty subject could not fail to be among the most select. Rare to seed, at least in this country, and certainly not easily increased otherwise, it is not likely to be a common plant. It is much less free than is *A. glumaceum* in its growth, for the latter may be increased at will.

Campanula cenisia.—This, though one of the most difficult of the genus to maintain in good condition for long periods, is certainly one of the most pleasing in its delicate colour, a very pale lavender-blue shade. In opposition to many, however, this one appears to detest rich soils, and is more likely to pass the winter safely in

the gravel walk should a scrap become located there than it is in a pot of rich, or even 'good loam. Grit and small stones should always enter largely into the mixture this species is grown in, and where a small plant is being reotted, it will be found a good plan to occupy the space around the old ball largely with crushed brick or small gravel. This rather firmly shaken together appears to meet its requirements better than a good general mixture. Manure should not be employed.

Pæonies.—The herbaceous Pæony is, perhaps, the finest flowering plant of the moment in the hardy plant garden. Particularly pleasing are the pure white kinds, and very chaste and beautiful the delicate shades of flesh and pink. In the garden these things speak for themselves, for then the beauty of their enduring and abundant leafage makes a welcome foil to the great massive blooms. In the exhibition tent and in a cut state their beauty is soon gone. Quite recently Japan has sent us new forms of Pæonies, many of a single or semi-double character, that possess a singularly striking tuft of modified petals in the centre of the flower, short, narrow strap-shaped or twisted filaments, usually tinted with cream or gold, that produce a very pretty effect when seen in the mass. Pæonies are greatly benefited by repeated soakings of water at the approach of the flowering season, which also assist the formation of good crowns for another year.

Veronica salicifolia.—About the Willow-leaved Speedwell there are a grace and elegant bearing that but few plants possess. The dainty white blossoms are borne on nearly horizontal spikelets, as also in erect, terminal, spicate racemes, and both combined produce a really pretty and pleasing result where large bushes obtain. The flowers individually are of a French white, in which is also the faintest suspicion of colour. The plant is also very free-flowering, the axillary spikelets that are usually first to expand their blossoms being disposed alternately in opposite pairs on the more or less erect branches. Compact in habit and free and graceful in its bearing, such a plant is a fitting member for the higher parts of the rock garden, where in mid-summer it will be seen to advantage. The habit is that of the soft-wooded, sub-shrubby type, and the species, which grows about 2½ feet high and about the same through, is among the neatest of its tribe.

Lilium monadelphum.—This fine Lily seems to do remarkably well in the garden of Mr. Robinson-Douglas at Orchardton, Castle Douglas, N.B. It is, perhaps, better known as *L. Szovitzianum* and *L. colchicum* than as *L. monadelphum*, but Bieberstein's name is that now recognised by the authorities. There are two forms at Orchardton. The finer of the two was received as *L. Szovitzianum* and the other as *L. colchicum*. The former bloomed a little later and is finer in colour and a little taller, but there is not difference enough to warrant distinct names. At Orchardton this Lily in a warm bed grows quite 6 feet high and is very handsome with its yellow, spotted, recurved flowers on the tall stems. Like some other Lilies, it is not easy to establish, but when once it has fairly become at home it is certain to please. It has been said to be a prince among early-flowering Lilies, and one can hardly say that the expression is inordinate praise.—S. ARNOTT.

Campanula grandis alba.—This is still one of the best of the white-flowered Bellflowers. It is a plant, too, with a fine constitution, surpassing in this respect at least all the members of the Peach-leaved Bellflower. If the above has a fault it is the inclination to travel somewhat at the root and in good soil to spread too freely and to encroach on smaller subjects. Notwithstanding all this, however, it is a good plant, and with knowledge of its growth and running at the root may be given a place where free scope can be secured it. The blue form is conspicuous when all the Peach-leaved kinds have gone out of flower, and the white in its way is equally valuable. As

the flowers are somewhat closely set on the tall, stiff spikes, a dense and compact head of bloom results. The flowers of *C. grandis* are salver-shaped, and thus display themselves to advantage. No plant is more easily grown, and clumps may often be seen in country gardens where but little attention is ever bestowed upon them.

Dendrobium fimbriatum oculatum.—I beg to enclose you a photograph of a good specimen of *Dendrobium fimbriatum oculatum* in the gardens here. The plant was bought seven years ago in a 6-inch pot and is now in a 15-inch pan. It has about 250 old bulbs and forty-five young growths, and when the photograph was taken it had seventy-three spikes of flower and was a glorious sight, as it is only when one sees a good specimen of Orchid in bloom that the true beauty is fully realised. The plant has been grown for the last two years in a Muscatinery and wintered in a plant stove, as it is too large to be accommodated in the Orchid houses. It is watered freely when growing until growth is completed, then gradually dried off until the flower-spikes appear in spring, when a little water is given. It being an evergreen variety it must not be kept too dry during winter, but given a little water when the young bulbs show signs of shrivelling, or premature loss of foliage will be the result, to the injury of the plant.—W.M. WRIGHT, *Taymouth Castle Gardens, Aberfeldy, N.B.*

Amianthium muscætoxicum.—Yielding to the authority of the "Index Kewensis," we ought in future to drop the late Asa Gray's name of *Amianthium muscætoxicum* and adopt that of *Zygadenus muscætoxicus*, which one is thankful to see is no worse to pronounce than the name by which it is generally known. One is led to mention this member of the Liliaceæ by reason of what may be called a chorus of approval with which several friends have simultaneously spoken of it. One cannot call it a showy, but it is a pretty plant with its racemes of creamy white flowers. It grows in a fairly moist, peaty soil, but is not considered by everyone of great hardiness. It is, however, quite trustworthy in the south-west of Scotland, and the increasing number of growers of hardy flowers in the district seems unanimous on the point. One enemy it has is the slug, which likes to crop it in early spring. *Zygadenus muscætoxicus* is said to bear the unattractive name of Fly Poison. *Helonias læta* is given as one of its synonyms.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Gaillardias.—How very striking and showy are these plants at the present time. Given good soil, firm planting, good seed, and treated as plants of not more than two years' duration, these things create a fine display in the garden. It is worth remarking, however, that old plants transplant badly. Young seedling plants or young plants from cuttings are always best for early planting, as then they take to the soil quickly and well. Seedlings raised now may, with good treatment, be of sufficient size to set out in permanent places during the ensuing autumn, and will flower freely in the summer of next year. Where it is not possible to plant out when ready, it will be found a good plan to bed them out in a reserve garden rather than confine the plants to small pots all the winter. These young plants are quite hardy even in severe winters, and it is only when through flowering month after month that their vitality is reduced that these things are liable to perish in winter. The strains of *G. grandiflora* are of such general excellence, and embrace so many quite as good as the so-called named kinds, that these latter are not worth the additional cost, unless it be a very distinct or exceptional form to be used more or less for saving seed from.

Houstonia cœrulea.—There are some of the most delicate and delightful of dwarf alpines that rightly are termed miffy subjects. Yet, as in all else, there are exceptions. We noted the other day in Mr. Whitehead's garden at Wimbledon a plant given no special care spreading into a veritable carpet, flowering amazingly and with great

freedom. It is the same with the blue as with the white, and of both kinds patches nearly a foot wide and nearly 1½ feet long spread out and flowered in the most charming fashion. Plants, too, that have been put out this spring have done equally well. The plants putting on this unwonted luxuriance are growing in peat and in various aspects. This, however, has nothing to do with the vigour of the plants generally, for they are all alike in each place. Indeed, judging by the progress of plants put out this year, it would be quite easy to cover a few square rods of ground with this delicate and pretty plant, and dozens of growers may place this in peat without getting a patch as large as one's hand for a year's growth. This Wimbledon garden is very high, and if secret there be in the matter, we incline to the notion that it is the outcome of elevation and the pure air that abounds at all times. In any case we have never seen such perfect sheets of growth.

OBITUARY.

MAJOR MASON.

WE regret to announce the death, on July 14, of Major Mason, of The Firs, Warwick, at the age of seventy-eight. He spent the early part of his life in the service of the East India Company. He was the son of Admiral Sir Francis Mason, K.C.B., and the grandson of Viscount Hood. Major Mason at one time was a member of the council of the Royal Horticultural Society, and was a frequent visitor at the meetings in the old South Kensington days.

The weather in West Herts.—Throughout the past fortnight the weather has been very warm, the maximum shade temperature exceeding 75° on ten days and 80° on three of those days. On the warmest day of all (the 19th) it rose to 84°, making this the warmest day as yet of the present summer. The ground is unusually warm, even for the middle of July, the temperature at 2 feet deep being 4°, and at 1 foot deep as much as 6° above the July average. The only fall of rain during the week took place during the night of the 17th, when the measurement amounted to less than a quarter of an inch. At one time during this storm the rain fell for six minutes at the mean rate of an inch an hour. No measurable quantity of rain-water has come through either of my percolation gauges for four days. During the eighteen days ending the 16th the wind came exclusively from some southerly or westerly point of the compass—E. M., *Berkhamsted*.

Iris Kämpferi (H. S.).—See THE GARDEN, July 23, 1898, p. 72, and July 30, 1898, p. 81.

A new open space.—An open space, acquired at the expense of £3400, has been opened in the New Kent Road. One private donation was £1000.

Names of plants.—*Greenwood Pim.*—A form of *Nymphaea pygmaea*.—*Mrs. Monk.*—1, a form of the common Privet; 2, the Garland Rose.—*H. Hallett.*—1, *Escallonia macrantha*; 2, too shrivelled to identify; 3, *E. magnus* sp.—*R. N.*—Blue flower, *Brodiaea laxa*; yellow flower, *Brodiaea gracilis*.—*Mrs. Leveson Gower*—*Reseda alba*; blue flower, *Viper's Bugloss (Echium vulgare)*; *Rose Celestial*, the best of the kinds known as Maiden's Blush.—*Mrs. Wadham.*—The flower sent is *Eriopsis ratidobulbon*. It was first introduced from New Grenada in 1847. It is not a rare plant, but it is seldom met with in flower. Now your plant has reached a flowering stage it will probably bloom regularly every year. It is an interesting plant to botanists, but of no particular value.

"The English Flower Garden."—*Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.*

Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.

ORCHARD AND FRUIT GARDEN.

THE OUTDOOR PEACHES.

OUTDOOR Peach trees have improved wonderfully of late, and all without exception are now making splendid growth. At one time the trees made very slow progress, but lost time was quickly made good once warmer and more genial weather set in. The wood being made is short-jointed and sufficiently vigorous without being at all gross in character. The trees are clothed with young wood from the base to the top of the wall, and the shoots have already been fastened back twice, so rapidly have they grown. The young wood developing so quickly and early in the season is a good augury for the future, as such will, if we have anything like a fine autumn, ripen up thoroughly and develop an abundance of blossom-buds. Another pleasing feature is the very clean condition of the trees generally, for since red spider was got rid of—the which was a legacy left from the droughty season of 1898—and the attacks of aphides mastered, they have given no trouble in this respect. The foliage has, of course, been washed whenever such was deemed advisable, and at intervals of a week or ten days a wash either with soft soap with a little flowers of sulphur added was administered with the idea of keeping them free from attack. Washing will, of course, be continued and as often as appears necessary, but during the last ten days it has been suspended in consequence of a good many showers of rain having passed over the district. Root-watering—always an important item in Peach culture—has so far not absorbed anything like the amount of labour that it has done in the past few years. Up to the time of writing it has only been necessary to give the borders one thorough soaking. Pond-water was used for this. This is conveyed to the gardens in pipes, which are laid along the front of the borders with taps fixed at convenient distances to which a hose pipe can be attached. Under such conditions watering can be done very economically. Immediately after the protection was removed the alleys were sprinkled with artificial manure, then pricked up and

afterwards mulched. The surface was then watered just sufficiently to prevent any undue waste of manure taking place, particularly the potash salts. Another dressing of manure will be given as soon as the fruits have finished stoning (and this has already taken place with regard to Alexander) which is sufficient to carry them through the season. With regard to the crop the trees are carrying, this can be pronounced as being very satisfactory, as there is but one tree which has failed to set. Alexander, Alexandra Noblesse, Royal George, Dr. Hogg, Raymacker's, Crimson Galande, and Dymond set very heavy crops and much thinning has had to be done. Magdala, Violette Hative and other sorts are also carrying a good lot of fruits, while among Nectarines, Lord Napier, Spenser, and Elruge are the best. Taking the trees collectively, the crop is a good average one, and, given warm weather and an abundance of sunshine, the fruits will swell up and be equal in point of size and quality to those obtained in previous years. A. W.

Peach Alexander.—As showing the difference between the two seasons, that of last year and the present, this variety was ready for gathering in 1898 early in July, while at the time of writing (July 5) the fruits on the same tree have only just finished stoning and begun to take their final swelling. This will, however, prove no serious drawback, as the indoor crop will not be finished until they ripen. As time goes on my admiration for this variety increases, it being such a hardy, vigorous grower and sure cropper. This year my tree is carrying a crop of fourteen dozen fruits and is well clothed with young wood, the whole presenting a very thrifty appearance. The roots have just received their final dressing of artificial manure, which has been washed in with a good soaking of soft water. Unless very hot weather should set in, this should suffice to carry them through.—S. E. P.

Fruit trees on north walls.—With a mild winter and one of the worst springs on record, as we registered 17° of frost in May, it is a relief to get a few fruits on a north wall when there are so few on any other. The trees being so much later set their bloom, while that in more favourable positions was quite destroyed. As regards north walls, much of the success obtained in such a

position will in a measure be owing to soil and locality. No one would advise a north aspect in the colder parts of the country or with a heavy, wet, badly drained soil, but in the south and on very light land, northern aspects are not made so good use of as they might be. In my case in the south the trees are so dried up on a south aspect that it is a relief to be able to grow Cherries, Plums and Pears on a cooler wall and with much greater success. For years I failed to obtain Cherries of a good size on a warm wall. I am aware heat and drought were answerable in a measure, but with lack of labour one cannot, even in large gardens, give the necessary attention to watering and cleansing that must be attended to if success is aimed at. It is wonderful in a very thin soil resting on gravel to see how well Cherries thrive on a cooler site, and the same may be said of Plums. On a hot wall the trees are difficult to keep clean and they do not make that close, sturdy growth that gives fruits the next season. My best Pears this year are on a north wall, and they are cropping better than in any other position.—S. H. B.

THE EARLY STRAWBERRIES.

I HAVE read with interest the note from Mr. Wythes on this subject (p. 3), and, considering that he has a warm, light soil to deal with and I a heavy one, I may congratulate myself that I had Strawberries ready for gathering only four days later than he did. Before reading Mr. Wythes's note I was running away with the idea that Strawberries were unusually late here this season, as I have frequently had them ripe on plants set out the previous autumn by the end of May. It seems I am not alone, and if it were possible to obtain the information, I expect a great many more growers are similarly situated. I rely on Royal Sovereign for early supplies. This has never failed me since I first began to grow it. It is a splendid cropper; the individual fruits are large and handsome in appearance, the flavour when the berries are fully ripened very good. This season older plants have produced a superabundance of foliage, which fact may, perhaps, be attributed to the soil having been in an equable state of moisture ever since the plants started into growth. The mulching of litter, too, having been put on early prevented this from evaporating, and that, coupled with the fact of the soil being heavy and rather retentive, has no doubt induced them to make more leaf-growth

than is usual here. This difficulty has been got over by removing the surplus, which has had the desired effect, and the fruits both swelled to a large size and coloured beautifully.

The plants which furnished the earliest fruits outdoors this season were planted last August, and, owing to the drought then prevailing, had to be frequently watered to induce them to start growing. The site they occupy is a warm border at the foot of a south-west wall, and they are in consequence very much sheltered. When in flower they sustained no damage from the frosts mentioned by Mr. Wythes; in fact, none of the Strawberries here suffered from frost effects either then or subsequently. Mr. Wythes's plan of leaving the litter loose amongst the plants until the fruit is set is a good one and worthy of consideration, especially by those living in districts liable to spring frosts. No doubt this would have the effect of saving many of the blossoms from being destroyed, and where the litter can be had, it is a very simple and economical method of affording protection. Sir Joseph Paxton, as may be expected, is also later than usual; in fact, I have one quarter on which the berries are now only beginning to ripen properly. Oxonian has set a heavy crop of fruit, which is swelling away freely and promises to be unusually large. Of the two very late sorts mentioned by Mr. Wythes I have not got Louis Gauthier, but have a small number of St. Joseph. The flower-spikes have been removed from these with a view to induce them to bloom and fruit later on in the season. If this variety proves satisfactory I shall increase the stock considerably this coming autumn, as in that event it will prove invaluable for furnishing fruit for table in the autumn months.

A. W.

APRICOTS.

On looking the trees over a few days ago it was very pleasing to find what a really good average crop of fruit the trees are carrying. This is all the more gratifying, seeing that at one time I was afraid the trees would only have what might be called a nice sprinkling of fruit or a very light crop in consequence of the damage from frost. The same thing has occurred with regard to trees grown by cottagers in this district, and the owners are now very agreeably surprised to find that the trees are carrying quite as many fruits as they legitimately should. I cannot call to mind a similar occasion when all prospects of securing anything approaching a good crop of fruit appeared to be past and gone for the results to turn out so contrary to expectation in the way they have done. The question naturally arises as to why this should be so, but I think the matter may be explained by attributing the results to the fact of a great many of the bloom-buds, especially those nestling close to the wall, being only in a partly expanded condition when the disastrous frosts occurred. The most singular thing is that when these buds opened and set the fruit was such a long time in swelling off; in fact, it remained in a stationary condition so long and seemed to be so weak and wanting in vigour, that I considered the crop a failure. Some few spur-buds escaped, but the number is out of all proportion when compared to those on the young wood; hence my reason for saying as I did at the time that the crop would amount to a good sprinkling of fruit on the trees. By this we learn that the system of laying in a good quantity of young wood annually is a good one, as nearly, if not all the bloom-buds on the spurs, particularly those projecting some distance from the tree, fell victims to the frost. Some growers ignore the spur system and grow their trees much in the same way as we do Peaches. I prefer a modification of both, and like to see the trees furnished with a fair proportion of spurs in addition to laying in young wood wherever practicable.

The fruits are now stoning fast. The final thinning will soon take place, when with the aid of good feeding and abundant supplies of water, should the state of the weather necessitate it, they will swell quickly and should develop into

fine specimens. So far root-waterings have not been a heavy affair, as it has only been necessary to do it twice, the second time during the past week. The alleys being mulched, the rains which fell in the early part of the season were sufficient to maintain them in a moist state until the end of May or thereabouts. The trees have made satisfactory growth, and beyond one or two cases losses in the way of branches dying off have been but few.

S. E. P.

EARLY PEACHES ON OPEN WALLS.

This season I have gathered even earlier than usual. I send you three varieties to note their quality, as in appearance the difference is so slight that if mixed up it would be difficult to separate them. My earliest fruit was Amsden June, and, as you will observe, this has the darkest colour of the three varieties sent. In my opinion, grown in the open the flavour is equal to that of the others—Early Alexander and Waterloo. All three are of American origin, but most valuable, for they give us fruits weeks in advance of the older kinds, and though I have heard their flavour condemned as being second-rate, I think they compare favourably with others. Amsden June was ripe on July 15 on a south aspect and from young trees. Last season I planted the three varieties named on the same wall to test earliness. The trees vary in growth, the Amsden with me being the weakest grower, Waterloo being more robust. With young trees this cannot be relied upon, as they differ much in the working, some going away with more freedom than others. I admit Amsden June has one slight drawback, being a clingstone, but otherwise I fail to see any great difference from Alexander as regards quality, and it is with me a little earlier. Alexander is a brighter-coloured Peach, and this was ripe on July 18. A few days at this season make a great difference often in prices to those who market Peaches. Alexander is a nice-looking Peach and has a brisker flavour than Waterloo, which with me is just softening (July 19), so that it will be seen all three varieties vary little as regards date of ripening. It may be asked, why grow all three? In a private garden it would not be necessary, but there is safety in numbers, as should one fail there are others to fall back upon. My favourite wall Peach is Hale's Early, but this is quite a fortnight later than any of the trio named, and it makes a valuable succession to those kinds, and, what is so valuable, it is of excellent quality and rarely fails to crop. I find Amsden June and Hale's Early much the best for forcing, and they follow each other closely, need little fire heat in comparison to some of the older varieties, and crop grandly. On the open wall Amsden June is the best cropper of the three kinds named.

G. WYTHES.

Pear Fertility.—The fault noted by "J. C." in a recent issue of THE GARDEN—that of sudden and complete rotteness—has been noticed and regretted by most growers. It varies considerably in different soils. A partial cure for the early and complete decay of such Pears as Fertility and Beurré Capiaumont is to grow the trees as dwarf standards on the Quince on moderately poor soil. The fruit should also be gathered before it is quite ripe and sold and eaten with the utmost dispatch. Purchasers should be warned of the specially perishable quality of such varieties, and advised to sell or eat them before they go to sleep into rotteness. Citron des Carmes, another early Pear ripening in July and August, rots rapidly either on or off the tree. But it gives due notice of its approaching doom by changing from green to yellow or yellowish green. Neither does the Jargonelle keep long after it is ripe, but the deepening gold of its yellowish green flesh and its growing aroma warn its possessors to eat it in time.—D. T. FISH.

Gooseberries on trellises.—In many gardens birds have of late been so destructive to the buds of the Gooseberry in the winter months that any efficient means of protection is welcomed.

We see how well the Gooseberry thrives on walls trained in an upright position, and much the same result follows training on wires or wooden supports. The trees grown thus bear more freely and are so easily protected that I wonder this mode of culture is not more often seen in gardens. Few fruit trees are so much troubled by birds as the Gooseberry. I have seen whole quarters cleared, only a few stray buds being left, if no notice has been taken of the birds or attempts to stop their depredations made. I find when the trees are trained as advised birds are much less troublesome. I do not say that they do not touch the trees, but the branches being more exposed they have not the same opportunities as with bush trees. In my case the birds leave the trained trees for the bushes. In the case of trellis-trained trees the size and quality of the fruit are also better, the trees having more light and room. Many of the best kinds of Gooseberries are awkward growers, but if trained from the start they will do well. I admit they require a longer time to make trees, but if these slow growers are treated as cordons or double cordons on a trellis they soon cover a large space, and other growths from the base may be taken later on if desired. The trees grown as advised have a much neater appearance at all times of the year and the fruits can be gathered much more easily.—G. W. S.

OUTDOOR PEACH TREES AND APHIS.

THE condition of open-air Peach trees in many districts this season will, I fear, be very unsatisfactory, though gardeners here and there are able to give a good report. As a rule where the bloom escaped the disastrous frosts of the latter part of March, the cutting winds and generally cold temperature of April and May will have brought colonies of the dreaded aphis. In some gardens not only was the bloom ruined by frost, but the young growths injured also, and all that can now be done is to endeavour to secure a healthy growth for next year. I think many gardeners are too anxious to remove the protecting material from Peach walls. This, especially when consisting of fish netting, would, if allowed to remain, shield the tender growths from the crippling force of spring winds and keep aphis at bay. I knew a very successful Peach grower who used frigi-domo, and even this somewhat thick material was allowed to remain up until growth was considerably advanced, although, of course, in calm weather it was rolled up to the top of the wall. But, take what care one may, aphis will appear, and what makes matters much worse is that gardeners are often afraid of syringing the trees at this comparatively early date. I never found any ill-results from the practice, as during April the sun is not powerful enough for any harm to follow from forenoon syringings. If a fine morning is chosen the trees will dry before night, and one good forcible application from the garden engine is more effectual than all the dusting with tobacco powder, as it is difficult to reach the pest with this when the leaves are at all curled, to say nothing of the time the work takes. Some good growers, however, prefer the latter method, and those who in the matter of insects allow the trees to take care of themselves may as well root them up and throw them away.

Then the question arises, Which is the best insecticide? I think highly of quassia extract, never having found, as some assert, that its application gave the fruit when ripe a bitter taste. Of course, the attacks from aphis being stopped before the fruit commenced to soften, no syringing was needed after that stage was reached, otherwise I am not prepared to say that a bitter flavour would not have been imparted. In my case clear water was always used the following day to cleanse the trees and

fruit from any remaining sediment, which I think advisable whenever insecticides are used. Peach-tree syringing must be done with judgment, as while sufficient force to dislodge insects is necessary, the tender leaves are easily injured and blackened. Soapsuds form an effectual wash and act as a stimulant to the roots. The time it takes to administer say three or four thorough washings is well spent, as if the surface soil is well mulched previously, the roots get moistened and two birds are killed with one stone. The above-named insecticides are equally efficacious in the case of red spider and thrips, which often attack Peach trees in warm situations and shallow soils, and if not promptly checked, soon discolour the foliage and cause it to fall. After all that may be said respecting general cultural treatment, there is far more in situation than many suppose. Some twenty miles from where I write are some Peach trees perhaps forty years old; the garden (a small one) is surrounded on all sides by sheltering woods, and to this fact is attributable the almost perfect immunity from insect pests the trees enjoy, together with the good crops they annually yield.

NORFOLK.

STRAWBERRIES AT NORWICH SHOW.

I CERTAINLY did not expect to see so many or so fine Strawberries exhibited at Norwich. The show was held on the 13th, and from the accounts that had reached me from various parts of the country of the smallness and premature collapse of the Strawberry crop, I was prepared to find only a moderate display. Some parts of Norfolk, however, must have been favoured with a fair amount of rain, otherwise the ground from which these Strawberries were gathered must be in excellent heart and good all round cultural treatment afforded, as they were not only very large, but splendidly coloured. In Mr. Allan's first prize collection Gunton Park and the new Lady Suffield were very conspicuous, the first named being noticeable in most of the lots staged. The judges must have had some difficulty in arriving at their decision, so very near in point of merit did the various lots appear. In proof of the hot weather experienced in the county of late I may mention that both Waterloo and Latest of All were wonderfully well represented. Strange to say, Latest of All, which, by the way, cannot be called a handsome Strawberry, is in some gardens cockscomb and in others wedge-shaped, and sometimes on the same plant this distinction is noticeable. As far, however, as my experience goes, the old Elton Pine is a much later Strawberry, and although, perhaps, rather too acid for some palates, is grand for late supplies grown on a north border. Its colour also is very brilliant. I noticed a nice dish of Macmahon, a Strawberry I have never grown, but which is well spoken of by some. Perhaps some readers of THE GARDEN may have grown it and will relate their experience of it. How seldom now-a-days do we meet with good dishes of British Queen and Doctor Hogg. Why is it? Our forefathers used to grow both well, and they can be induced to colour to the point by propping up the fruit to the sun.

J. CRAWFORD.

Cherries on walls and in the open.—Few fruits suffer sooner than the Cherry in periods of heat and drought if the trees are in a light soil and well laden with fruit. A few years ago a lot of healthy young half-standard Morello Cherry trees was planted by a large grower close to the Thames. In winter and often in early spring the land is covered with water at high tides, yet these trees have given splendid crops yearly. This shows that the Cherry often suffers from drought in gardens, as here there is no sign of gumming or canker, which is so troublesome with wall trees. This year I notice there is a much greater loss of wood than usual, due no doubt to the

drought of last season. I do not care to see the leaves droop in hot sunshine, as is frequently the case when laden with fruit in a light, sandy soil. When planting I find it advisable to give the trees some heavier materials if the natural soil is very light, also to plant so that the border is not too sloping, as is often done, so that by mulching, the moisture given is readily retained. Bush trees I find do well, but are difficult to protect. On the other hand, they are less affected by heat and drought than wall trees. I prefer what are termed half-standards and not too gross growers.—S. M.

BOOKS.

A TEXT-BOOK OF PLANT DISEASES.*

MR. G. MASSEE, the well-known fungologist, has just written a most interesting and useful book on the diseases of plants. It is intended for the practical cultivator of plants of whatever description he may be interested in, and it is written in language that can be understood by anyone who has had an ordinary education. Of course scientific words have to be used, but on the first time of their being used an explanation is given of their meaning. This is quite right, but I think it would have been a great convenience to the non-scientific reader if a glossary had been given as well. Now, if a word occurs not for the first time and the reader wants to know its meaning, he has to look in the index, where on finding the word he is referred to the page on which the explanation is given. This is often done in books at the present time, but I cannot consider it nearly so convenient for the reader as the old-fashioned glossary. While on the grumble, I should like to protest against books of reference like the one now under notice not having their edges cut; the tops catch the dust more, it is not nearly so easy to find the place you want on turning over the pages, and one has the trouble of cutting the book before one can read it. The cost of cutting the edges with a guillotine must be very slight. It is all very well for book collectors, who do not read, but merely collect books, to like the rough edges; but to those who often want to consult a book they are an abomination. The introduction is most interesting and suggestive, and should be read carefully through. Speaking of cures, the author very truly says: "Sometimes the attempt at effecting a cure is a success, frequently not. To the practical man who naturally hopes for a cure at every stage of a disease the result is generally disappointing. In the majority of instances where an annual plant is attacked cure is practically impossible, and in the case of perennials, the prospects of a profitable crop for that year are small. In such instances, however, the disease can be arrested in its course and a recurrence prevented." One reason that cures are not more often effected than they are is, as is pointed out a little later, that often when the first symptoms of an attack are noticed it is too late to do anything to stop it, the plant being internally infested by the parasite for some time before the latter makes its presence known by pushing to the surface of the leaf or stem attacked the spore-bearing portion.

Most readers will be surprised when they learn by how many different agents the spores may be carried from one leaf or plant to another. Great stress is laid on the necessity, if an attack of any fungus is to be prevented from recurring another year, of burning every portion of a diseased crop and not throwing it on to the manure heap, as is so often done. I am quite certain that many of our insect and fungus pests would be almost stamped out if there were no such thing in gardens as a rubbish heap, and if all that otherwise would find its way there were cremated. The author also comments on the folly of taking cuttings or sowing seed from plants infected with any disease, and suggests that "seedsmen should

* "A Text-book of Plant Diseases." By George Massee. Duckworth & Co.

be required to give a guarantee that seed offered for sale was obtained from healthy plants." Several pages are devoted to the consideration of the best fungicides and the proper way to apply them. This chapter cannot fail to be of interest to all horticulturists. Then follows an account of the various injurious fungi and the best means of dealing with them, which is profusely illustrated. The figures are mostly good, but are somewhat diagrammatic, and some of these printed from process blocks are rather faint, but, considering the price at which the book is published, one can only be surprised that they are so good. Several of the descriptions of fungi that are not known in this country seem rather out of place, for such plants as the vanilla, tea, coffee, sugar cane, &c., are never likely to be grown in this country. A scientific description is then given of each of the fungi already noticed, and an index of parasites, fungicides, and botanical terms, and another of host plants complete the volume, which I can most confidently recommend to all who are in any way interested in the parasitic fungi as being the best book I know on this subject written in a popular style. G. S. S.

THE FLORA OF CHESHIRE.*

THIS is one of many books on the flora of counties, but more interesting than usual from being the work of a poet, though Lord de Tabley, we think, has written some more beautiful things than those chosen for this book by his biographer, Sir Mountstuart Grant Duff. As regards the botany in the book, it is of local interest, but it is a pleasure to see anything so lovingly done as this is, and to know that Lord de Tabley had such a wide range of interests. There is a good biographical notice in the book and a list of persons who in the past were connected with Cheshire botany, besides a very good portrait of the author and a map of the county of Cheshire. The book is edited by Mr. Spencer Moore.

KITCHEN GARDEN.

NOTES ON PEAS.

THE dripping season has been very favourable to early and midseason Peas, and though we have had a couple of weeks of intensely hot weather, there is no sign of that failing to grow that often occurs at this time of year, and mildew so far is conspicuously absent. Among the early kinds Harbinger was exceptionally good this year, and gave a long succession of the sweet and well-flavoured Peas, and I should think that eventually this kind will be as popular as William Hurst and Chelsea Gem. As showing how varieties change from year to year, I may mention The Daisy, a really excellent kind that with me has usually done remarkably well. The pods are long and well filled, ten and eleven fine Peas of capital colour and flavour being not at all unusual. But this season I have only one row at all presentable. I always sow this Pea very thinly, as it has a distinct branching habit and is much more free than when drawn owing to thick sowing. I have sown none of the tall-growing, large-podded kinds of the Duke of Albany class this year, as I find that the dwarfer kinds are equally good and more productive and do not give out so quickly in hot weather. Empress of India is a Pea of the class I mean, seldom growing above a yard high, but producing more pods on one row than Duke of Albany would on two, the quality being all that can be desired. It quickly comes to maturity and may almost be classed among the first earlies, yet there could not be a better Pea for gathering now.

I sowed four rows in March, one each of * "The Flora of Cheshire." By Lord de Tabley. London: Longmans, Green and Co.

Empress of India, Yorkshire Hero, Sharpe's Queen and Autocrat, and these have formed a most useful succession, the last being still in bearing. It is a splendid Pea in every way and withstands drought better than any other kind I know. These dwarf kinds all favour rather closer planting than the taller growers I have compared them with, but it is a great mistake to plant even these too closely. Where there is an abundant supply of manure, so that large quarters can be suitably enriched for Peas, I like to grow the rows at 10 feet or 12 feet apart and crop the ground between them, but I do not care for the plan that still obtains of digging a trench and filling in a lot of manure, sowing the Peas just above it. Here I am obliged to keep the Peas by themselves, and the kinds named above are the most suitable for growing under the circumstances. Where rows stand singly at a good distance apart mildew is never so troublesome, as it cannot so easily spread from row to row.

H. R.

Pea Sharpe's Queen.—I think the merits of this very fine Pea are overlooked in many gardens. I grow it rather freely, as I find there is no better flavoured kind, while its appearance and cropping qualities are both well up to the average. It grows about 4 feet high and is of free branching habit. This makes thin sowing necessary. A great many varieties are sown far too thickly, and being crowded fruit poorly and are soon over. I find, too, that these dwarf, strong-growing kinds must be staked very firmly and wide, otherwise they break down the stakes and fall about.—H.

Beet Sutton's Blood Red.—This is a good selection, the roots being of medium size and of perhaps the finest colour of any in existence. Well grown, the roots are very symmetrical, and the plant has a striking and ornamental appearance in the garden. Many stocks of Beet are good for a season or two, but proper care to keep them true is not taken, and in consequence the roots are coarse and flavourless. This I have grown for a number of years, and when the crop is growing the tops are as level as a table, while the roots may almost have been cast in one mould, so uniform are they in shape and size.—H.

Peas and drought.—The early Peas were never better both as regards crop and quality, but I fear the later ones, such as should give us dishes in August, will be less satisfactory, as it is almost impossible to keep the plants healthy. Of course, with a clay soil better results follow. It is strange how badly some varieties suffer from the heat in comparison with others. For the past four or five years the late Pea crop has suffered from heat and drought in light, porous soils, and it is a difficult matter to get regular supplies after July is past in such weather, no matter what culture is given. Much may be done by mulching and watering at night.—S. M.

A peculiar Cabbage pest.—The other day my attention was drawn to a breadth of summer Cabbage the foliage of which was mutilated and disfigured by some insect. At first I thought the enemy must be the Turnip flea, but it turned out otherwise, for the leaves of the Cabbage were swarming with a small black insect of the beetle type, which can jump with all the activity of the domestic flea, and can be detected by the click caused by its movements. A movement among the plants with the foot set hundreds in motion, and the damage done was very apparent, for after the insects have abstracted the sap from the leaves, the latter turn yellow and fall. They are not particular in their tastes, for a little further on I noticed a breadth of Cow Cabbage and a patch of Swede Turnips which had been attacked by the voracious pest.—H. H.

The winter and spring green crops.—In the southern parts of the country, unless we soon get a change of weather, I fear the winter and spring green vegetable supply will suffer, as now

July and early August should see large breadths of green stuff planted. Last season the vegetable supply was short owing to the same cause, as the plants made such poor progress after being planted. I am aware growth is rapid if the rainfall is ample, say, in August or September, but the danger lies in having such poor plants. Here will be seen the utility of ample space in the seed-beds. I have often noticed what a lot of room market growers give their seed to what is often done in gardens. They also sow on the flat and in an open position. A strong plant soon makes headway. I find I get much better results in such seasons by sowing later than usual. For instance, Kales or similar vegetables sown early in June, or say end of May, are much better than those that have been starving in crowded seed-beds for some time.—G. W. S.

FAILURE OF PEAS.

WITHIN the last two or three days some of the Peas in my garden have been attacked by a fungus apparently. As yet only the tops of the plants are affected, the lower part seeming quite healthy and bearing well. I enclose specimens of the parts affected, and should be much obliged if you would tell me what it is and what steps should be taken to lessen the evil or stamp it out. It is the first time that either my gardener or myself have seen it.—J. S. S.

* * * As far as can be gathered from the somewhat bruised top of haulm received, the Peas are infested by thrips, and it is just possible mildew is also partly responsible for the check to growth. Thrips alone would work all the mischief, and these were found active enough on the partially developed pod sent. It is the great heat and dry atmosphere that injuriously affect Peas, rendering them an easy prey to mildew and thrips. If we are to have summers similar to those experienced in America, the cultivation of Indian Corn, the American substitute for Peas, will have to be the rule, as it is very certain our most popular vegetable cannot be successfully grown in a tropical heat. All that "J. S. S." can do is to have the unhealthy tops of haulm removed and a good soaking of water or liquid manure given to the roots, not a mere dribble, but enough to thoroughly moisten the soil to a good depth. This should be followed by a heavy mulching of straw manure, with more water before the soil again becomes dry. If the plants are not too weak, the effect of this treatment will be to cause them to push forth strong side growths which will produce good gatherings of well-filled pods. It would appear that the newer varieties of Peas lack the constitution of the old favourites *Ne Plus Ultra*, *British Queen*, *Champion of England*, and *Veitch's Perfection*, as it is very certain we had fewer failures with Peas when these sorts were principally grown.—Ed.

Pea Prodigy.—"A. W." has a note of praise at page 44 on this fine Pea. I can also speak well of it, having grown it for several years in a light, warm soil. Its strong, vigorous habit of growth enables it to withstand drought well. With me its usual height was 5 feet, and the pods were produced in great profusion over a good long period. I have not grown Boston Unrivalled, named by "A. W." in his note. Those having a warm, shallow soil will do well to select these stout, succulent-haulmed varieties, as they hold out far longer than the less vigorous sorts during a hot summer. All the same, the best results cannot be expected unless a liberal mulch and sufficient root moisture are given. Pure manure is not essential, any loose refuse, such as the clearings of old hotbeds, Mushroom manure, or even grass mowings answering. Timely application is the great thing.—J. C.

Winter Tomatoes.—The present is a good time to sow seed of some free-setting Tomato for producing plants to fruit at Christmas. Sow in single small pots, say 3 inches or 3½ inches in diameter, place in a frame and keep close till the plants appear, then air increasingly until full

exposure is practised, tilting up the lights in rainy weather until the plants are fit for re-potting. Use a good holding loamy compost with some road grit or mortar rubble added, and pot firmly. With full exposure a stocky growth is secured, and if shifts into 6-inch and 9-inch pots are given before the roots become matted, a good supply of bloom trusses will form and set all up the stems. In October they may be removed to a comfortably warm house and a somewhat dry airy atmosphere maintained, this inducing the fruit to swell to a fair size and colour nicely in December.—NORFOLK.

Pea Bountiful.—We have so many good Peas to select from, that to the grower who has a large acreage it may seem out of place to name Bountiful as one of the very best for early supplies. This year Bountiful has been the most productive of the early kinds, and after two seasons' trial I place it at the top of the list for earliness and productiveness combined, the quality also being first-class. This year I grew Bountiful in pots, seeing how well it did previously sown as a first early, and it was quite as early as any other kind. Sown in the open the second week in February and not given protection of any kind, I gathered in May. I had this variety sent me for trial three seasons ago, and it is, I consider, one of the best early Peas recently sent out. In the open it does not exceed 3 feet high, the pods curved and packed with Peas of a good size. This kind, I notice, received an award at Chiswick in 1896.—G. W.

Potato Ninety-fold.—Different seasons bring out some kinds of vegetables to perfection much better than others, and with a late spring early Potatoes were somewhat later than usual. This affected all the early kinds. Though the growth was retarded by the severe cold in the early part of May, I find Ninety-fold was the least affected by the weather. Last year I sent a note on this variety and its excellence in referring to its earliness, and this season I am able to supplement my former remarks, and I think it is the best early Potato we have when its size and quality are considered. Owing to the severe weather in May the Ashleafs were none too early and I find the tubers small, as they have suffered from drought. Ninety-fold having a stronger haulm takes deeper roothold and gives splendid tubers, and being as early as an Ashleaf is most valuable. In future Ninety-fold will be grown largely for first supplies owing to its hardy nature. Being a beautifully shaped kidney with such excellent flavour, it will, I think, become a great favourite with growers who supply the market.—G. W.

Spiral-trained Tomatoes.—A practical gardener recently stated that he found the winding of Tomato stems round five stout stakes fixed in a circle to be productive of much greater crops than is the common rule of tying up vertically to single stakes. With sticks so fixed as to give a diameter to the circle of at least 9 inches it is obvious that at least three plants put out round the stakes 10 inches apart could be wound spirally round the supports, and in such case the product to each column should be very considerable. But beyond the gardener in question I have not heard of any other adopting the plan. There seems to be no doubt that diversion of the plant stems from the erect to the horizontal or oblique does in all things lead to greater fruitfulness. It is specially so in the case of Tomatoes, as plants put out close to the front of a house or frame and then depressed to run up under the roof or lights invariably crop more heavily than do vertical plants. I have seen other plants trained quite horizontally even more prolific. The object of the spiral training as thus referred to is to induce greater fruitfulness, and, so far as tested, it has proved to be very successful. Certainly the plants or fruits on the northern sides of the pillars would not get much sunshine, but then they would be in no worse case than are plants grown partially in the shade. But that would be a trifling obstacle or difficulty, as the fruits would certainly ripen a little later.—A. D.

TREES AND SHRUBS.

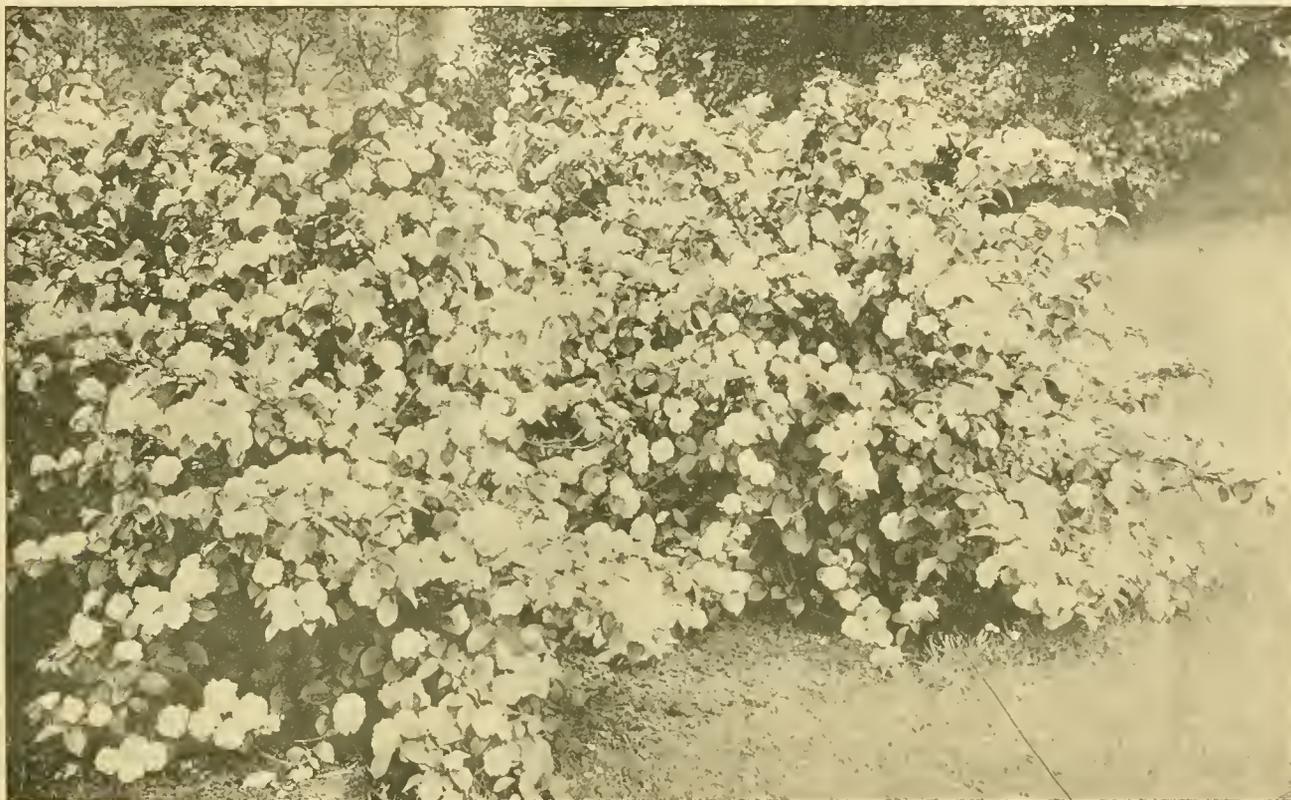

VIBURNUMS.

THE Viburnums are represented in all three of the great areas whence we in Britain obtain the bulk of our hardy trees and shrubs, viz., Europe, North America, and the Indo-Chinese region. It is in the last-named region that Viburnums most abound. Ten years ago, Mr. W. B. Hemsley was able to enumerate twenty-seven species in his "Index Floræ Sinensis" as being found in China alone. This number, as the country becomes more fully explored, will doubtless be considerably increased. Next in point in number of types comes North America; most of these, however, are of garden value more on account of beauty of foliage or fruit

which every flower is large and showy, but sterile. The plants producing the wholly sterile flowers are, of course, not true species, being incapable of self-reproduction. They are purely garden types. In their natural proportion these sterile flowers fulfil an important, although a passive, function in the life-history of the species. Their purpose is that of advertisement. They attract the insects which are necessary to bring about the fertilisation or cross-fertilisation of the less conspicuous perfect flowers. In the great majority of plants fertilised by the agency of insects each flower does its own share in the work of attraction, but some Viburnums, as well as Hydrangeas, attain the same results by devoting a portion of the flowers entirely to this purpose. With not more, perhaps, than one exception, the Viburnums are of the easiest cultivation. They simply need a soil of fair quality and plenty of moisture; the

A group of *Viburnum tomentosum* var. *plicatum* in the Royal Gardens, Kew. From a photograph by Geo. Champion.

than that of the flowers. Of the European species three are cultivated, all of which are extremely valuable hardy shrubs.

The leaves of Viburnums are always opposite on the branches, and, although nearly always lobed or toothed, are invariably simple. The flowers are either white or pale pink and are borne in flattish, cymose clusters, mostly at the ends of the branches, but occasionally in the leaf-axils. The genus *Viburnum* bears one particular resemblance to *Hydrangea*, and this is in some of its species having two kinds of flowers on the same inflorescence, namely, fertile and sterile ones. There are three kinds of inflorescence in *Viburnum*: one in which the flowers are all fertile and of a uniform, comparatively small size; another which has the outer flowers of the cyme much larger and more showy than those of the centre, but sterile; and lastly, there is the inflorescence in

only thing to avoid is planting them in hot, dry positions. They can be easily propagated by cuttings and layers.

The following is a tabulated list of the species and varieties I have seen in cultivation out of doors in this country, but there are several others that require greenhouse treatment. It may possibly be of some use for reference. Not all the species mentioned are alluded to in the notes that follow, but such as are omitted are of quite secondary importance in horticulture, or of which little can yet be said. Those marked * are evergreen.

EUROPE.	
Lantana	* <i>Tinus</i>
Opulus	var. <i>Froebeli</i>
var. <i>fructu-luteo</i>	var. <i>hirtum</i>
var. <i>nanum</i>	var. <i>lucidum</i>
var. <i>sterile</i>	var. <i>purpureum</i>

lobed leaves, which are coarsely toothed and downy beneath, the largest of them 4 inches to 5 inches across. The flowers appear in May and June and they are borne on slender-stalked cymes 2 inches to 3 inches across, and are white, with no large sterile flowers. The fruits are oval and black. Although introduced in 1736, this is not a common species, having but little beauty of flower. Its leaves, however, are very handsome in autumn, dying off as they do a rich claret colour. It is a native of the North-eastern United States, where it chiefly grows on rocky wooded hillsides.

V. CASSINOIDES.—Of the American Viburnums, this is certainly one of the best. It is widely spread over North America, and reaches from Newfoundland to the west of Hudson's Bay in the north and to New Jersey in the south, frequenting swampy places. It grows some 6 feet high, and unless crowded by other things is compact in habit. It has thick, leathery, ovate-oblong leaves, 3 inches to 4 inches long, and yellowish

white flowers produced during the early part of June in compact, flat cymes 4 inches to 5 inches across. It is very handsome in fruit, the berries changing first to rose colour and finally to bluish black. As they do not ripen simultaneously, fruits of both these colours, as well as green ones, occur on a cluster at the same time.

V. NUDUM closely resembles the preceding, but it has thicker and more glossy foliage. In a wild state it does not reach to such northern latitudes. Its flowers are white, and the fruits ultimately blue-black.

V. DENTATUM (the Arrow-wood).—One of the handsomest of *Viburnums* as regards flower, this is also a vigorous grower, forming a shrub 8 feet to 10 feet high, of compact habit and with handsome foliage. The leaves are 1½ inches to 4 inches across, often almost orbicular, or even wider than they are long. They are chiefly noticeable for the very strongly marked venation and for the deep regular teeth. The flowers are all small and fertile, produced in terminal cymes 3 inches to 4 inches across, and are white. Its fruit is very handsome, being dark blue, but, unfortunately, it is only rarely that it ripens in any quantity in this country. The species is a native of the Eastern United States and is very hardy. Very near to this species comes

V. MOLLE, which is also a vigorous shrub, similar in habit to *V. dentatum*. The leaves differ in being very pubescent beneath. The flowers are white, but have more pointed calyx teeth. The fruit is of a similar blue colour, but is larger than in *V. dentatum*. *V. molle* is found from Massachusetts southwards to Florida, &c.

V. DILATATUM.—The first time this plant flowered in this country was in 1875 at the Coombe Wood Nursery. A figure was published the following year in the *Botanical Magazine*, but the species did not extend in cultivation, although it probably did not disappear altogether (it flowered at Kew in 1880). It has, however, been re-introduced in recent years. It is a shrub probably 6 feet to 8 feet high, the young branches, inflorescence, and nerves of leaves clothed with hairs. The leaves are 3 inches to 5 inches in length, often as broad as long, coarsely and unevenly toothed. The flowers are produced in large cymes 4 inches or 5 inches across; they are white, and all of the small fertile kind. As a fruit-bearing shrub this species is, in Japan and America, perhaps the handsomest in the genus, the berries being of a brilliant red, but whether our climate is not suitable, or because the plants are not yet old enough, they have not yet borne out this character here. The species is a native of Japan, where it is widely distributed and also abundant.

V. EROSUM.—More of botanical than horticultural interest, this only needs brief mention here. It is a sturdy bush 5 feet or a little more high, with much-forked branches and ovate, pointed leaves 2 inches to 4 inches long. The flowers are greenish white and borne on small clusters. The fruit is red. Its botanical interest is due to its being one of the few *Viburnums* with small linear stipules. A native of Japan, China, Corea, &c.

V. FURCATUM is a very rare and handsome species, which has recently been "discovered" in Lord Ilchester's interesting garden at Abbotsbury, in Dorsetshire. It is a native of North Japan at low levels, and of the mountains of the more southern portions. Closely allied to the beautiful *V. lantanoides* of North America, it is, like it, one of the finest shrubs for autumn colour. The leaves, which are large and broad, often almost orbicular, turn brilliant scarlet and reddish purple before they fall. In Japan this shrub grows 12 feet to 15 feet in height.

V. LANTANA (the Wayfaring Tree).—One of the commonest of *Viburnums*, this is also one of the handsomest and most useful. It is one of the two species native of Britain, but it is also widely spread not only in Europe, but in temperate Asia. At its best it is almost a small tree, growing as it does 12 feet to 15 feet high. Its

handsome heart-shaped leaves are noteworthy for the thick, pale-coloured down that covers the lower surface and which is also conspicuous on the young wood. The flowers are white and all fertile, being borne during May and June on flat clusters at the ends of the branches. The fruit is red at first, ultimately black, and the leaves often die off a rich red. There is a variegated form of no particular value, but the species itself is a useful shrubby plant.

V. COTINIFOLIUM is a Himalayan plant usually treated as a distinct species, but it is, more probably, only a geographical form of *V. Lantana*. In the case of small plants, at any rate, it is not easy to distinguish them. In *V. cotinifolium* the cyme is smaller and not so flat as that of *V. Lantana* and the tube of the corolla is shorter. Mr. T. Meehan observes that "on some accounts it is the better plant, the flowers, fruit, and foliage being all on a larger scale."

V. STELLULATUM and *V. BUREJÆTICUM* are both of the *Lantana* group. The former is from the Himalaya and is in cultivation at Kew, but I have not seen it in flower. The leaves differ from those of *V. Lantana* in not having a heart-shaped base and in the under-surface having a dark stellular pubescence. *V. burejæticum* is from China.

V. LANTANOIDES (Hobble Bush or Moosewood).—This is one of the few *Viburnums* that are difficult to grow, which is all the more unfortunate, as it is certainly one of the most beautiful, both as regards the fruit and the autumnal colouring of its foliage. It is a North American species, and is a large shrub or almost a small tree at its best. The leaves are almost round or heart-shaped, and, whilst averaging 3 inches to 4 inches across, are sometimes over 6 inches. The truss has its outer flowers sterile, and they are 1 inch or more in diameter; both they and the smaller ones that fill the centre are white. The fruit is at first coral-red, afterwards dark purple or almost black. The foliage dies off a rich claret. It is probable that the best success with this *Viburnum* will be obtained by planting it in a moist, not too sunny spot. American cultivators have the same difficulty with it as we have, but it is said to thrive better when grafted on *V. Lantana*.

V. LENTAGO (Sheep Berry).—More, perhaps, than any *Viburnum* we can grow in this country does this species assume a tree-like form. It has lustrous, ovate or lanceolate leaves, tapering rather abruptly to a fine point, the margins minutely and regularly toothed. They vary from 2 inches to 5 inches long. The flowers are creamy white and appear in large clusters in June or July. The fruit is blue-black and oblong. It is a native of Eastern North America, and is a desirable shrub both for its white trusses and for its handsome habit and foliage. Nearly allied to it is

V. PRUNIFOLIUM (the Black Haw).—This is also American, and also tree-like in habit. The leaves are of a lustrous dark green, resembling somewhat the leaves of a *Prunus* or *Pyrus*. The flowers are of a purer white than in *V. Lentago*, and the blue-black fruit is handsomer. On the whole this is, perhaps, the better species. Its foliage often turns red or purple in autumn. It is a native of the Middle and Southern United States.

V. MACROCEPHALUM.—In recent years this *Viburnum* has been largely used in the greenhouse. Of all the species it is the most showy and bears the largest truss. In this respect it almost rivals *Hydrangea paniculata*, which shrub, indeed, it much resembles, its flowers being all large and sterile and borne on a similarly shaped pyramidal truss. Unfortunately, it is not a very hardy plant and is rarely seen at its best out of doors. Fortune first found it in Shanghai, and sent it to the Horticultural Society in 1844. He mentions having seen it 20 feet high in Chusan. The leaves are ovate, blunt, 2 inches to 4 inches long, and covered beneath with a roughish pubescence. The individual flower is from 1 inch to 1½ inches across and pure white. This plant is, of course, one that does not occur in a wild state, being a product of cultivation. Its flowers being wholly

sterile, it can only be increased by artificial means. The typical or wild plant from which it has been derived is also in cultivation, and is known as

V. KETELEERI (Carrière).—This has the centre of the truss (which is much flatter than in *V. macrocephalum*) filled with fertile flowers, the outer ones only being sterile and like those of *V. macrocephalum*.

V. ODORATISSIMUM (*V. Awafuki*).—As a rule, when grown out of doors this is given a place on a wall, as it is not absolutely hardy in all winters. It is evergreen, its foliage being particularly handsome. Each leaf is 3 inches to 6 inches long, of elliptical outline, leathery, and of a lustrous dark green. The flowers are in corymbs, and although small and dull white, are charming for their fragrance. It is a native of China and was introduced in 1818.

V. OPULUS (the Guelder Rose).—A native of Britain, this species is in gardens the best known of all the *Viburnums*. A vigorous, free-flowering shrub, requiring no special conditions, it makes one of the most useful stock plants for the shrubbery that we possess. This may be said still more emphatically of the sterile form commonly known as the Snowball Tree. *V. Opulus* grows 10 feet to 15 feet high, and its handsome leaves are rather Maple-like in form, being three- (or less frequently five-) lobed and irregularly toothed. The young branches are smooth and four-angled. In the wild form the outer flowers only of the cyme are sterile, and these are about three-quarters of an inch across; the centre is filled with small perfect flowers, both they and the others being white. In autumn this plant is valued for its clusters of fine red fruits and for the rich shades of its decaying leaves. Of its several varieties, the handsomest and most popular is

VAR. STERILE.—This has few or no perfect flowers, the whole truss consisting of the more showy barren ones. This causes it to lose its flatness and makes it much more rounded, which, together with the pure whiteness of the flowers, has led to its being popularly known as the Snowball Tree. It has, of course, none of the beauty of the common Guelder Rose as a fruiting shrub.

VAR. FRUCTU-LUTEO simply differs from the type in the fruits being yellow instead of red when ripe.

VAR. NANUM is a curious dwarf plant, growing only 1 foot or 2 feet high, and forming dense round tufts. It is a neat little plant, but a drawback is that it rarely, if ever, flowers. I, at any rate, have not seen it in bloom.

V. PUBESCENS.—Somewhat resembling *V. dentatum* and *V. molle*, this can, however, be distinguished from them by its dull green leaves. It is 6 feet or more high and of compact growth. The small leaves (1½ inches to 2½ inches long) are only toothed on the terminal part, and are covered with pubescence, especially on the lower surface. The young shoots also are pubescent. In autumn the leaves die off a rich purple colour. The flowers are white, but none of them are of the showy barren sort. The fruits are oval, one-third of an inch long and blue black. A native of Lower Canada and the North United States.

V. SIEBOLDI (*V. reticulatum*).—A Japanese species first collected by Siebold, after whom it was named by Miquel. It is a strong, sturdy bush with distinct foliage. The leaves vary from 2 inches to 5 inches long and are usually broadest towards the apex and tapering towards the stalk; they are strongly veined and coarsely toothed towards the apex, the upper surface being dark green and glossy. The flowers are in flat terminal cymes and are creamy white, the whole of them being fertile. The fruit is black and half an inch long. The name of *V. Sieboldi* is sometimes erroneously given to an evergreen plant—probably *V. odoratissimum* or a variety thereof—whilst the true *V. Sieboldi* may be met with in nurseries as *V. reticulatum*.

V. TINUS (the Laurustinus).—In the southern and milder parts of Britain this species is one of

the most ornamental of evergreens. It is a native of the Mediterranean region, being found not only in the south of Europe, but in North Africa as well. Like many other plants from that region, it has long been cultivated in Britain. More than 300 years ago it was mentioned by Gerard as the Wild Baie Tree. A shrub of compact habit, it grows about 8 feet high, but is usually considerably more in diameter than it is in height. Its evergreen leaves are distinct among hardy Viburnums by the margins being entire. In the bud state and when quite young the flowers are rose tinted, but afterwards become almost pure white. The trusses are flat and some 2 inches or 3 inches across. In sunny positions it usually flowers freely, but not so in shade. Commencing to bloom in December, it will continue till the end of March. Although all its flowers are perfect, it does not ripen fruit regularly, but fruits occasionally occur, the colour being a dark blue. There are several varieties of the Laurustinus, one of which,

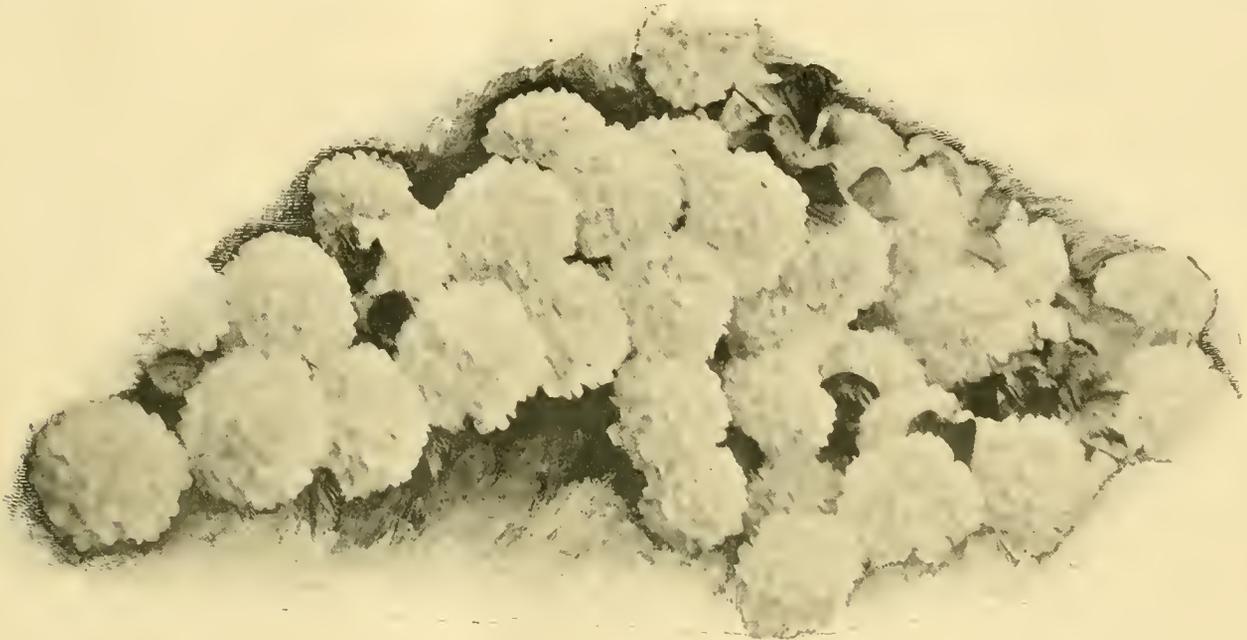

VAR. LUCIDUM, has fine large leaves, shining and almost smooth on both sides. The flowers and flower-trusses also are larger. It is possibly not quite so hardy as some forms of Laurustinus,

prove to be quite hardy in England, its merits as an outdoor shrub have only been appreciated in recent years, owing largely to a fear that it would not stand our climate. I have seen young, newly-rooted plants injured the first year after being put out, but when once established it will stand any frost up to 30° without lasting injury. It is a shrub of neat, yet graceful habit, well clothed with dark green, rather plaited leaves. It bears its fine trusses, 3 inches or more across, on short branches springing from the whole length of the previous year's growth, thus forming magnificent sprays of pure white blossom. As will be seen by the illustration of a bed at Kew, the plants are almost hidden by them at flowering time. The typical seed-bearing plant (*V. tomentosum*) is apparently not quite so sturdy a shrub, neither is it so striking when in flower, only the marginal blooms being of the enlarged sterile kind. It is not common, but was introduced from Japan at least thirty years ago.

V. CORIACEUM.—This is a species new to gardens, and is flowering now—probably for the first time in this country—at Kew. It is a native of N. India, China, &c., the plant at Kew having been received from the Jardin des Plants at Paris

JUNE IN SOUTH DEVON.

In the early days of June the aspect of the landscape was one of exceeding loveliness. In the bright sunshine the varying greens of the deciduous trees, that had not as yet assumed the monotony of tint they exhibit later in the summer, were restful to the eye, the effect of occasional Aspens, striking a note of contrast in the prevailing verdancy, with the amber-brown glow of their young sunlit foliage being especially charming. Fields engirdled by high hedges of flowering Hawthorn were here and there golden with Buttercups, in which the red cattle stood complacently ruminating. The great Chestnuts' broad fan leaves were crowned with white flower-spires. Bean fields filled the air with fragrance, and in still, brown waters floated the yellow Lilies engirt with the tall sword-leaves and golden blossoms of the Flags. Spaces of sloping cliff were white with the Bladder Campion; on rocky crags bloomed the Valerians, pink, deep red and white; Sea Pinks painted with soft hue the ledges of the bluff headlands and spread long stretches of colour above pebble-strewn beaches. As the month advanced the Butterfly Orchis lifted its tall white spires from the shady bank; the Meadow Gera-

Spray of *Viburnum tomentosum plicatum* from a New Jersey garden. From a photograph sent by Mr. J. N. Gerard, Elizabeth, New Jersey.

and should have a sheltered, sunny spot. Another distinct shrub is

VAR. MIRTUM, the distinguishing character of which is the hairiness of the leaves and branches.

VAR. PURPUREUM has the leaves suffused with a dull purple tinge.

All the forms of Laurustinus can be struck from cuttings. They are most useful for forcing, for, coming naturally into bloom before Christmas, they require but little heat. Neat, compact plants in small pots are now sent over by the continental nurserymen for forcing in considerable quantities.

V. TOMENTOSUM (including *V. plicatum*).—Of all the Viburnums now in gardens, the one now figured will by most people be considered the best. It is the sterile form of the Japanese species known as *V. tomentosum*, standing to that species in the same relation that the Snowball Tree does to the common Guelder Rose. It is commonly known as *V. plicatum*; its correct botanical name is *V. tomentosum* var. *plicatum*. It was introduced by Fortune about fifty years ago, but although he said it would doubtless

with the information that it came from Yunnan. It is interesting as an addition to the few evergreen hardy Viburnums. The leaves are of a very dark green, 3 inches to 5 inches long, oblong, pointed, remotely toothed and perfectly glabrous; they are not unlike those of a green Aucuba in texture and general appearance. The flowers are in small terminal corymbs, white, and almost tubular. It does not promise to have many attractions as a flowering shrub.

Arboretum, Kew.

W. J. BEAN.

Catalpa hybrida.—A hybrid Catalpa named as above by M. L. Spath, who obtained it, is the object of a description and coloured plate in *Gartenflora*. It is the outcome of crossing *Catalpa ovata* and *C. bignonioides*. In habit it resembles the former, but the leaves are more irregular in form. The leaf is more or less heart-shaped at the base, then suddenly terminates in a long slender point. The lower side of the leaf is covered with a down similar to that of *C. bignonioides*. Alike in the form and general colour of the flowers it is not perceptibly distinct from *C. bignonioides*.

nium (*G. pratense*), though not admittedly a Devon flower, disclosed its blue blossoms by the lane-side, and the hedges were thickly starred with festoons of Dog Roses, white and shell-pink, with rosy unexpanded buds, while beneath their dark green leafage the Sycamore's pale "keys" hung in countless bunches. In the garden, *Achillea ptarmica* fl.-pl. The Pearl has produced its profusion of white flowers, and the tall blue Monkshood (*Aconitum Napellus*) has mirrored its image in the lakelet by which it grows. The pale blue *Agatheia celestis* has in most cases survived the winter and is now flowering freely, while *Alliums* of sorts, though their pungent odour when bruised detracts considerably from their value, have been decorative in out-of-the-way corners. The pretty little *Anomatheca cruenta* has borne its deep red flowers in a sheltered border of light soil. This pretty Cape bulb should be given a place where *Sparaxis* and *Ixias* can be grown with success. The hybrid *Aquilegias* have been lovely as ever with their graceful contours and suave colour-harmonies, and are especially effective when used in two shades for dinner-table decoration. In heavy soil they should be raised annually from seed, as the plants lose

much of their vigour after their second season, even if they do not perish. *Alstromerias*, especially the hybrid varieties, are among the most charming of June flowers, their range of hues from crimson to cream providing a colour-scheme in which the gradations of tints mingle in a harmonious whole. They are easily raised from seed and are perfectly hardy in the south-west either in light or heavy soil, while they increase in beauty from year to year. It is said that the roots should be planted 8 inches deep, but as a large batch of plants growing in heavy soil passed through the long and severe frost of 1895 without receiving the slightest harm, though their roots were but 3 inches below the surface and they were totally unprotected by mulching, I place but little faith in this recommendation—at all events in this locality. The *Anthericum*s—*St. Bruno's Lily* (*A. Liliastrum*), with its spikes of large white flowers, and *St. Bernard's Lily* (*A. Liliago*), with its smaller-flowered bloom—have been decorative, and in the water the *Cape Pondweed* (*Aponogeton distachyon*) still produces Hawthorn-scented white flowers, while in the wild garden the tall *Anchusa italica* rears its straggling head of small deep blue blossoms. A handsome flower, but rarely seen in gardens, is *Arctotis aspera* var. *arborescens*. Its white, Daisy-like blooms are almost 3 inches in diameter and have an annular band of yellow around the dark eye, while the outer sides of the petals are flushed with crimson. This plant is easily raised from cuttings and succeeds in gardens where *Mesembryanthemum*s are at home. As a cut flower its lasting properties render it valuable, since it retains its freshness for several days after being cut. The *Armerias* are bright in rocky and border, *Astrantia maxima* has developed its quaint flowers, and in shady spots the *Aubrietias* blossomed well into June. *Beschorneria bracteata* in a garden of rare plants has thrown up its tall, branching flower-panicle, bright red in colour. *Brodiaeas* are in bloom, the most conspicuous being *B. coccinea*, with scarlet, yellow-tipped flowers, and the purple-blue *B. laxa*.

THE MARIPOSA LILIES

have been lovely, some of the forms of *Calochortus venustus* being of exquisite beauty. *C. v. Vesta*, a very beautiful variety, appears to be the most vigorous of all, and, besides flowering freely, produces blossoms some of which are 4 inches in diameter. Large plants of the bush *Calceolaria* some 4 feet through are golden with bloom, and of the *Campanulas*, *C. glomerata*, *C. grandis*, and its white variety *C. persicifolia*, its white, double white, and large white form, as well as *C. urticaefolia*, have come into bloom, while the borders are bright with the *Canterbury Bell* (*C. Medium*), and in the rock garden forms of *C. carpatica*, *C. caspitosa*, and other dwarf varieties are flowering. Carnations are commencing to brighten the beds, and the blue *Cornflower* (*Centaurea cyanea*) is producing its deep coloured flowers in quantity from self-sown seedlings that are now bushes 3 feet in height and almost as much in diameter. *C. macrocephala* and *C. rubra* are also in bloom, and walls and rockeries have been white with the flowers of the *Cerastiums*. *Chrysogonum virginianum* is still bearing its golden blossoms. This is a useful plant, easily raised from cuttings, which may be put in any bare spot that may occur through the summer and autumn, and which it will soon furnish. *Convolvulus Cneorum* has produced its pale pink flowers on its silvery foliage, and *C. mauritanicus* its white-throated blue blossoms. *Coreopsis grandiflora* has already commenced to display the bright gold of its large star flowers, and *Coronilla iberica* is showing the same tint in its lowlier blooms. *Crinum capense* has perfected the first of its massive flower-scapes, and gardens are bright with the tall spires of *Delphiniums*. The light, Cambridge blue varieties are decidedly the most attractive, as they are of a colour that is almost unique in the garden; whereas the darker blues and purples are met with in many flowers. *Bella Donna* is an old light blue variety that is not easily beaten for

colour. The dwarf scarlet *D. nudicaule* has been also in flower in a rock garden. *Dianthus Napoleon III.* has made a spot of bright colour in the border, and the tiny pink *D. deltooides* has bloomed on rockeries. *Dictamnus Fraxinella* and its white variety have thrown up handsome spires of bloom, and *Doronicum plantagineum excelsum* Harpur-Crewe has continued to produce its large yellow star flowers through the month, while the mauve, golden centred blossoms of *Erigeron (Stenactis) speciosus* are borne in greater profusion, and the little Mexican Daisy (*E. mucronatus*) is blooming freely wherever the self-sown seedlings have sprung up. The Sea Hollies are now at their best, *Eryngium amethystinum*, *E. Bourgati*, and *E. Oliverianum* being among the most ornamental, the steely blue, metallic lustre of the bracts being most striking.

In the wild garden the white Foxgloves have created a lovely picture, and the Plantain Lilies (*Funkia*) have reared their soft-coloured flower-spikes above their cordate foliage. The best of all the *Funkias* for effect is *F. Sieboldi*, whose glaucous leaves form a pleasing contrast to the foliage of other occupants of the wild garden. Large bushes of *Fuchsia Riccartoni* and *F. gracilis* are in flower; *Gaillardias*, *Gazanias*, and *Geum coccineum* help to brighten the borders; and of *Geraniums*, *G. argenteum*, *G. lancastrisense*, *G. sanguineum*, *G. phæum*, *G. striatum*, and *G. Wallichianum* have been in bloom. The *Edelweiss* (*Gnaphalium Leontopodium*) has been in profuse blossom, and of the family of *Day Lilies*, *Hemerocallis flava*, *H. Dumortieri*, *H. aurantiaca major*, *H. fulva*, and *H. Kwanso* fl.-pl. fol. var. have flowered. These flowers have a far finer effect when massed in breadths of from six to a dozen plants than when grown as single specimens in the border. The *Sun Roses* (*Heli-anthemum*) have been brilliant in rock gardens, *Heuchera sanguinea* has borne its coral-red pyramids of bloom, and the *St. John's Wort* (*Hypericum calycinum*) has studded rough stony banks with its golden flowers, while *H. Moserianum* has also been in bloom. *Iberis gibraltarica* has been flowering well in rockeries, and *Inula glandulosa* has expanded its deep orange, narrow-rayed star flowers. Spanish *Irises* (*I. Xiphium*) have been extremely decorative in the garden—*Golden King*, orange-yellow; *Canary-bird*, pale yellow; *Snow Queen*, white; and *Celestial*, blue, being good of their colours, while the old *Thunderbolt* is of vigorous habit and not unpleasing tints. Of the *English Irises* (*I. xiphoides*), the pure white, deep blue, claret and French-grey shades have all been very attractive, and both in this and the foregoing section the self colours are infinitely to be preferred to the splashed or mottled varieties. *Iris sibirica* has also been in bloom, as has the tall-growing *I. orientalis*, formerly known as *ochroleuca*, and the yellow *I. Monnier* and *I. aurea*. The German *Flags* have furnished an opulent display—*flavescens*, pale yellow; *Princess of Wales*, pure white; *atropurpurea*, dark purple; *pallida*, and *pallida dalmatica*, different shades of lavender, very sweetly scented; *florentina*, white, passing to grey; *Queen of the May*, rosy lilac; *Gracchus*, primrose and crimson; *Mme. Chereau*, white fringed blue; *Victorine*, violet and white, and *Darius*, yellow and netted purple, being all excellent varieties. *Iris variegata* is very similar to *Darius*. *I. setosa*, a comparatively small flower, lilac-blue in colour streaked with white, has also been in bloom, as has the handsome deep yellow *I. juncea*, a bulbous species, not unlike *Golden King* of the Spanish section, but with broader falls. *Jaborosa integrifolia* has lost much of its vigour in the neighbouring garden where it was established some years ago and appears likely to die out altogether, there being only two scented white blossoms this year against a dozen last year. *Lilies of the Valley* have flowered with prodigal lavishness, and *Mariac's Water Lilies* commenced to expand their blossoms by the first week of the month. The *Madonna Lily* (*Lilium candidum*) has been particularly lovely in the majority of gardens, and I have seen less of the disease this

year than for several years past. The *Orange Lily* (*L. croceum*) has also blossomed well, as have varieties of *L. umbellatum* and *L. Thunbergianum*, the variety of the latter known as *Prince of Orange*, of a soft yellow tint, being particularly pleasing. *L. Martagon* and *L. Martagon album*, *L. Hansoni*, the brightly-coloured *L. tenuifolium*, the buff *L. excelsum* or *testaceum*, and the chrome-yellow, red-anthered *L. pyrenaicum*, with its pungent odour, have flowered, as has the beautiful *L. Szovitzianum*, with its pale sulphur blooms, some spotted with minute black spots and some pure in colour. *Libertia grandiflora* has produced sheaves of white bloom-spikes, and in deep, porous soil attains a height of 4 feet. The herbaceous *Lupines*, blue and white, have also been very decorative, as have the tree *Lupines*. Large plants of the latter, 7 feet high and as much through, form striking pictures when loaded with their pale yellow or white flower-trusses. Old plants, however, have a way of dying off without any apparent reason, but a pruning back after the flowering season is past often results in vigorous growth that carries the plant on through the succeeding year. *Linum flavum* and *L. arboreum* were golden with flower early in the month, and towards its close *L. narbonense* opened its blue blossoms, while *Lithospermum prostratum* has borne its deep blue flowers for many weeks past. *Lycnis Viscaria splendens* fl.-pl. has been in bloom, as has the white-flowered *L. Viscaria alba plena*, and the large scarlet flowers of *L. Haageana*, with the brilliant flower-heads of *L. chaecedonica*, brightened the borders before the close of June. *Malva moschata* is white with flower, and the *Night-scented Stock* (*Mathiola bicornis*) has produced its sweetly perfumed blossoms. In the light soil of sunny gardens near the sea *Mesembryanthemum*s have been a blaze of colour. By the waterside the *Mimulus* bears its crimson and gold blooms, and *M. cardinalis* affords a note of vivid colour. The old-fashioned *Bergamot* (*Monarda didyma*) and its white form have expanded their fragrant flowers, and the blue of *Myosotis dissitiflora* is not yet absent from the garden, while the *Marsh Forget-me-not* (*M. palustris*) is in full flower in damp spots. The *Sweet-scented Tobacco plant* (*Nicotiana affinis*), that increases by self-sown seedlings and springs up so plentifully from the old roots in some gardens as to be almost a weed, is becoming starred with its odorous white blossoms, and the pale mauve-white *Nierembergia frutescens* is bearing in a neighbouring garden its pretty fragile flowers. Evening *Primroses* are represented by the lovely white (*E. marginata*) and (*E. speciosa*), both most ornamental plants for the rock garden, and also by the border varieties (*E. fruticosa*) and (*E. Youngi*). *Ononis rotundifolia* has borne its Pea-like, rose-coloured blooms, and *Onosma tauricum* its drooping yellow tube flowers, while *Ornithogalum arabicum* and *O. pyramidale* have blossomed and *Orobus aurantiaca* has been a mass of orange flower-scapes. Many of the *Tree Peonies* suffered so severely by the frosts of the latter days of March, that the flowering season has scarcely been a satisfactory one, but in sheltered situations specimens bloomed well. In this section fine flowers were borne by *Reine Elizabeth*, *Lactea*, *Triomphe de Vandermaelen*, and some unnamed imported semi-doubles, while of the herbaceous section, *Miss Salway*, white and sulphur; *Maria Kelway*, pale blush and white; *Whitley*, lemon-white; the single whites *Emodi* and *albiflora*, and *tenuifolia* were very attractive.

TUFTED PANSIES

are charming flowers, and many very beautiful effects are obtainable through their aid. The following are pleasing varieties: *Border Witch*, pale blue shaded; *Christiana*, cream; *Blush Queen*, pale lilac; *Countess of Hopetoun*, white; *Archie Grant*, indigo-blue; *Duchess of Fife*, primrose, edged blue; *Masterpiece*, pure white; *Virginius*, blush-lilac; *Magnificent*, dark mauve-blue, and *Pembroke*, yellow. The majority of the great *Paris Daisy* bushes were killed by the

March frosts, but such as escaped are now covered with flower. Where the Ivy-leaved Pelargoniums passed through the winter scathless, as they have done in certain favoured nooks, they are now commencing to furnish delightful pictures, and only a few days ago I saw a house the front of which was covered 10 feet high with the salmon-pink Mme. Crousse, that had grown there unharmed since the spring of 1895. In the early days of the month the mauve Pentstemon Scouleri was bright in the rock garden, and now the ordinary herbaceous varieties are in bloom. The white Pinks have filled the air with their sweet scent, flowers of Her Majesty being very large, but splitting the calyx badly. Jacob's Ladder (*Polemonium caeruleum*), both blue and white, is flowering in the cottage gardens, and the Poppies have made a brilliant show, the giant Oriental Poppies (*Papaver bracteatum*) dominating the garden with their blaze of vivid scarlet. The Iceland Poppies, yellow, orange, and white, are beautiful alike in the border or as cut flowers, while the apricot-pink *Papaver pilosum* is of particularly soft colouring, and the Welsh Poppy (*Meconopsis cambrica*) with its drooping yellow blossoms has a pretty effect edging the by-paths of the garden. *Potentillas* are also in bloom, and *Ranondia pyrenaica*, flowering grandly on the shady side of a perpendicular rock wall, presented a pretty sight early in the month. *Ranunculus aconitifolius* fl.-pl. is in bloom, as is the pale blue *Scabiosa caucasica* as well as its white variety, while the tall sulphur-flowered *Scabiosa elata*, 6 feet in height, is proving its excellence as a subject for the wild garden. Sedums are haunted throughout the sunny hours by murmurous companies of the hive bees. The beautiful *Sidalcea Listeri* has expanded the first of its pink flowers upon its branching flower-stems. *Silene alpestris* is covered with white flowers, and of the herbaceous Meadow Sweets, *Spiraea Aruncus*, *S. japonica*, *S. filipendula*, *S. venusta*, and *S. palmata* have come into bloom. *Thalictrum aquilegifolium* and *T. adiantifolium* are in bloom, but the inconspicuous flowers of the latter species are a minor consideration to the beauty of its leafage. The deep violet-purple *Tradescantia virginica* and a handsome white form are in bloom, as are *Verbascum phoeniceum* and *Veronica* in variety. Many annuals are already bright with flower, among which are noticeable the *Nigellas*, *Antirrhinums*, blue *Lobelias*, brilliant yellow *Echscholtzias*, *Lavatera trimestris*, the glowing orange *Erysimum Peroffskianum*, *Omphalodes linifolia*, and the Shirley and Opium Poppies. Of climbing plants a number have been or are blossoming, such as the *Wistaria*, *Honeysuckle*, large-flowered *Clematises*, *Cobaea scandens*, *Jasmine*, *Clianthus puniceus*, *Solanum jasminoides*, *Morning Glory*, the vivid scarlet *Tropaeolum speciosum*, whose vermilion trails light up the sombre foliage of evergreens, the yellow *T. polyphyllum*, the Indian-red *T. pentaphyllum*, and the crimson and black *T. tricolor*, which in the early days of the month I saw rambling over a Rose bush in a sheltered garden. With the heat of the first week of June Roses matured fast, and many have been the basketfuls of exquisitely tinted Teas and deeper coloured Hybrid Perpetuals that have been culled for indoor decoration. Lovely as they all are, perhaps there is no more beautiful Rose than a half-open, shell-pink blossom of *Viscountess Folkestone*, nor a sweeter one than *Socrates*, with its delicate essence. There are several fine specimens in the neighbourhood of the little single white Rose, *R. polyantha simplex*, which is now in full bloom. In one case the Rose has ascended a tree about 15 feet high, which has since died, and has formed an immense head, from which cataracts of bloom fall downwards at every side. The charming little Rose de Meaux is also in flower, and the old *Magnolia* Rose, one of the first introductions of the Teas. *Rosa macrantha* is in bloom, and early in the month a few blossoms still remained on the large single white *Rosa laevigata* at Kingswear, but May is the month when this Rose bears the bulk

of its blooms. Of the Penzance Briers, the pale fawn Lady Penzance is of an extremely delicate tint. In Mr. Archer-Hind's garden at Coombe-fishacre, among many beautiful and rare flowers in bloom the following were included: the pale flesh *Gladiolus carneus*, *Bloomeria aurea*, the lovely, but evil-smelling *Codonopsis ovata*, *Malva Munroana*, the scarlet-flowered *Ourisia coccinea*, a small blue *Lathyrus*, a splendid specimen of *Iris Gatesi*, a foot in diameter; *Hedysarum multijugum*, *Caccinia glauca*, *Geranium sanguineum album*, (*Enothera pumila* with tiny golden flowers, a fine plant of the white *Ostrowskia magnifica* nearly 6 feet in height, *Borago laxiflora* with pretty pale blue pendent flowers of small size, *Gentiana asclepiadea*, which was growing and flowering well by a large patch of Marsh Fern, *Callirhoe Papaver*, *Lindelophia spectabilis*, and a strong colony of *Cypripedium spectabile*, which was blossoming grandly in a spot not far removed from the water. S. W. F.

ROSE GARDEN.

SOME BEAUTIFUL TEA ROSES.

I CANNOT separate many of the so-called Hybrid Tea Roses from the Tea-scented group; therefore if a few are mentioned in these notes that are usually classed with the Hybrid Teas it is because in my opinion they properly belong to the Tea-scented tribe. Why such a dainty Rose as *Kaiserin Augusta Victoria* should be expunged from a box of Teas I fail to see; and surely the exquisite new Rose Mme. Cadeau Ramey, with its lovely high-centred rosy flesh-coloured blossoms and delightful yellow shading so peculiar to many recent novelties, has a right to a place among the Tea Roses. But as this matter only concerns exhibitors, it is of no material consequence to the thousands of individuals who grow Roses to adorn the garden and house.

This has been a glorious season for Tea Roses. I do not remember any year when their innumerable tints were more beautifully developed than this. The quality has also been good. Something like 6000 blooms were staged at the National Rose show at the Crystal Palace this year exclusive of the classes for garden Roses, and of this number nearly one-half were of the Tea-scented section. Of such popular favourites as *Marie van Houtte*, *Anna Ollivier*, *Mme. Lambard*, *Hon. Edith Gifford*, and others I do not propose to speak now, but shall confine these notes to novelties or little-known kinds that if space permitted should be found in every collection. The general public is not cognisant of the bewitching rosy red and glowing lake colours so beautifully blended in the variety *Duc de Luxembourg*, or the demand for it would be very great; and when it is remembered that the growth is equal to that of *La France* or *Viscountess Folkestone*, no further commendation is needed. *Souvenir de Lady Ashburton* is another grand variety. The many hues prevailing here amply justify the phrase *Rainbow Rose* that I have seen applied to this kind. I was convinced from specimens seen last year that the white *Maman Cochet* would be a favourite not only with exhibitors, but with the general Rose-growing public. It does not split in the centre so much as the original kind; at least that is my experience of it so far. As to colour, it is not snowy white, and I am not sorry for it. If anything enhances the beauty of Tea Roses over their more robust relations the Hybrid Perpetuals, it is the delicate hues that they are so frequently suffused with. In this case the three or four outer petals are often wholly pale pink, and

the remaining high-centred, exquisitely-formed part is a beautiful white, with a very slight shading of pink. The immense wing-like outer petals even in the original variety are unsurpassed by any Rose, but when these are of a pink colour and the remainder of the bloom almost pure white, it is not a difficult matter to comprehend the full beauty of the new-comer. Of *Baronne Ada* I have formed a high opinion, and believe it will prove to be a valuable variety. It is somewhat in the way of *Innocente Pirola*, but of a deeper tone of soft creamy yellow. *Empress Alexandra* of Russia was conspicuous both at Colchester and Manchester. It gives just that finish to a box of Teas that was much required. In point of colour we have not had such a distinct Rose for many years. I cannot say I like to see the red Teas, such as *Francis Dubreuil* and *Souvenir de Thérèse Levet*, exhibited among the more delicate hues, but with *Empress Alexandra* it is different. Although high in colour it is more of the *l'Idéal* shade, and of these there is room for many more. *Souvenir de Jeanne Cabaud* is, to say the least, very distinct, but like many of the true Teas its beauty is not revealed until the blossoms are cut, the latter having the bad habit of hanging their heads. The colours, however, are most beautiful, merging from yellowish apricot to a centre of pink and carmine. There is one Rose that if raisers and hybridists could improve in growth and hardness they would confer a lasting boon upon the Rose world. I refer to *Souvenir de Mme. Levet*. Just imagine a perfect flower of *W. A. Richardson*—not those with white edges, but a highly-coloured blossom of a regular form and a little larger, and we have a fair idea of this lovely Rose. *Medea* has been better shown than any other yellow this year, and there is no mistaking its vigour, for it grows as freely as *Marie van Houtte*. The rich old-gold colour of *Mme. E. Helfenbein* and the salmon-white, rosy tint of *Souvenir de Gabriel Drevet* are the predominant features of two really excellent Roses. The beautiful coloured plate of *Souvenir de Catherine Guillot* which appeared in THE GARDEN last year has made the general public familiar with a splendid Rose, and the same may be said of *Mme. Jules Grolez*, a Rose that I prefer to *Mrs. W. J. Grant*. I thought at one time that *Jeanne Forgeot* would be a bad grower. I knew that the flower was superb, the long blooms making it so very distinct, but in vigour it has surprised me, and I now look forward to it becoming a very valuable Rose. *Josephine Dauphin* is really beautiful. It was introduced as a rival to *Niphotos*, but I cannot see that it merits this distinction. It is a different style of flower, and the colour is quite lemon-yellow. I am pleased with the creamy white *Enchantress*. The growths produce such immense trusses of bloom, that each one would be a fair bouquet in itself, and as to vigour, it stands in the first rank. Possibly not since *G. Nabonand* was introduced have we had a finer garden Rose. Mention was recently made of *Mme. René Gerard*, a Rose that has come to stay, and I have also found *Souvenir de J. B. Guillot* to be perfectly distinct in colour.

Among the loveliest of the comparatively recent kinds the following stand out very prominently: *Souvenir de Mme. Eugène Verdier*, *Francis Dubreuil*, in bud most beautiful; *Sylph*, one of the hardiest and best; *Antoine Rivoire*, *Ferdinand Batel*, *Meta*, possibly a seedling of *Luciole*; *Emile Gonin*, in the way of *Mme. de Watteville*; *M. Ada Carmody*, a flower that should be as fine as *Cleopatra*; and *Sweet Little Queen*, a Rose somewhat in

the way of Vicomtesse Decaizes. Of older Roses that merit a word of praise, Mme. Abel Chatenay and Souvenir du President Carnot undoubtedly take first rank, and others following closely are Le Soleil, Mme. Henriette de Beauveau, a lovely yellow, with a suffusion of delicate pink, and a climber combined; and Germaine Trochon, an excellent kind to grow as a bush, although described as a climber. Zephyr is exquisite and a splendid grower, and Dr. Rouges also. What a lovely colour is Mme. Chauvry! I think of all these nankeen or coppery Roses this one is the loveliest. Princesse de Venosa and E. Veyrat Hermanos are both good kinds of the Comtesse de Nadailac type. If they open well in this country (which at present I have found to the contrary) they would be first-class Roses. Rainbow is really a most constant striped Papa Gontier, and for those who like these Roses it will be found an acquisition. Kaiserin Friedrich, a tinted Gloire de Dijon, and Mme. Pierre Cochet, the bud the colour of a Seville Orange, are also worthy of note.

PHILOMEL.

The dearth of dark Roses.—An examination of the long lines of boxes at the recent Crystal Palace show showed that either this year was not suitable for crimson and dark-coloured Roses, or that really they are more difficult to grow than are those of light shades. Abel Carrière, A. K. Williams, Charles LeFebvre, Comte de Raimbaud, Duke of Edinburgh, Dr. Sewell, Earl of Dufferin, General Jacqueminot, Jean Soupert, Horace Vernet, Louis van Houtte, Prince Camille de Rohan, Prince Arthur, Sir Rowland Hill, Sultan of Zanzibar, Victor Hugo, and Xavier Olibo were noted, but were conspicuously rare. I have known some of the above obtain the coveted medal for being the best bloom in a show, and not an exhibit without a fair proportion of them. Certainly they are not the least attractive of Roses either at an exhibition or in the garden. At the exhibition mentioned it was in the nurserymen's classes that the specimens of dark Roses were principally found. Of late years there has not been anything specially good among new Roses of bright deep colours, and people are likely to tire of adding to their collections novelties that vary so little in tint.—H.

Two fine button-hole Roses.—Where neat, long-budded Roses are required for button-holes there are none to surpass Gustave Regis and Mme. Pierre Cochet. The former has a lovely long-pointed bud of a canary-yellow colour with a deeper centre. Many of these buds can be obtained from a single truss. It flowers as freely grown as a bush as it does upon a wall, and as a standard it will make a huge head that when in full bloom is a lovely sight. The other lovely kind in many ways supersedes W. A. Richardson, per-

haps more especially in the regularity of its colour, which is an intensely deep orange-yellow illuminated outside with reddish scarlet. Here again we have a variety serviceable in all forms. It will grow well as a climber preferably on a west wall, and as a standard it is a great success. A peculiar smooth, reddish wood is characteristic of it, and, like many of the Teas, it has fine, richly-coloured foliage. I am afraid it would not be very hardy.—P.

EXHIBITING ROSES DIVESTED OF THEIR BUDS.

FROM frequent remarks overheard at Rose shows, the present style of denuding a show bloom of all its buds is anything but popular

Viburnum macrocephalum. (See p. 78.)

with the general public. Indeed, the attraction of exhibitions always seems to be centred in the garden Roses where a Rose is shown in its natural beauty. Why should not classes be formed wherein so-called show Roses could be exhibited surrounded with their buds? I know this stipulation would have to be enforced, as the rage for large flowers would naturally compel exhibitors to disbud. This difficulty could be surmounted by offering prizes for the best natural truss or trusses of so many distinct kinds. This class would be highly serviceable to would-be purchasers, as they could then see for themselves those kinds which were likely to be most useful to them for the garden, for I take it that it

is only the exhibitor who would be content with one bloom upon one growth when it is possible to obtain two and three and even more. A friend of mine related quite recently a circumstance bearing upon this point. Many years ago when real trusses were shown, he had in his box a truss of Mme. Bravy. This truss consisted of three fine Roses, and some individuals tried to disqualify him, saying that he had more than the specified number. This was not so; he had twenty-four single blooms or trusses, according to the wording of the schedule. Needless to say, this truss considerably helped him to secure the prize. I should like to see this matter taken up by the National Rose Society. More space would be required for such specimens than is now necessary for single blooms, the full beauty of each truss being then brought out more prominently. Exhibitors would do well also to deepen the lids of their boxes in order that such trusses could be cut from 12 inches to 15 inches long. It is absurd to offer prizes for collections of garden Roses and exclude Hybrid Perpetuals. Are not some of these, such as General Jacqueminot, Mrs. John Laing, &c., also our best garden Roses? I maintain that if a Rose is strong to start with and is planted well in good soil, it can support several blooms on a single growth as well as it can one individual specimen, and a great gain is effected by prolonging the season of flowering of some of our very best varieties. P.

GARDEN FLORA.

PLATE 1233.

COLEUS THYRSOIDEUS.

(WITH A COLOURED PLATE.*)

FLORAL attractiveness is not characteristic of the genus *Coleus*; indeed, the only one of the fifty species hitherto known which has any known horticultural merit is *C. Blumei*, a native of Java and the progenitor of the many sorts of ornamental-leaved *Coleus* grown in gardens. By the way, it may be pointed out, *apropos* of the attention garden hybrids, crosses, &c., are now receiving, that *Coleus* as represented in gardens is one of a considerable number of cases of extreme variation, brought about solely by selection and not the result of hybridisation. *C. Blumei* was introduced from Java, through Belgium, by Messrs. Low and Co., of Clapton, about fifty years ago. A figure of it was published in the *Botanical Magazine* in 1853 (t. 4754). *C. Verschaffeltii* is a variety of it.

Although several other species of *Coleus* have been introduced from time to time and tried as garden plants, generally under the name of *Plectranthus*, they have not been favourably received. *C. aromaticus*, with green, succulent, aromatic leaves, is sometimes met with in the gardens of the curious. The species represented in the accompanying plate has several commendable characters. It forms a large, shapely herbaceous shrub under greenhouse treatment and produces its thyrsoideus flower-heads in winter. The colour of the flowers is a bright gentian-blue, and they are produced abundantly and continuously for about a month, unless crippled by a severe London fog. Some of the flower-heads produced last January at Kew were 9 inches long and proportionately wide.

For the discovery of this plant we are indebted to Mr. Alexander Whyte, F.L.S., who sent dried specimens of it from British Central Africa to the Kew herbarium in 1897. A few seeds were secured from these specimens, and the plants thus raised flowered first in January, 1898. Mr. Whyte found it on the Nyika

* Drawn for THE GARDEN by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by J. L. Goffart.

Plateau at 6000 feet elevation, and he described it as "a showy blue labiate, growing in damp situations." Last summer the plants were grown in a greenhouse, where they formed bushes 2 feet high and wide. This year some plants raised from spring-struck cuttings are thriving planted out in a sunny border, the intention being to lift them and plant them in pots in the autumn. This *Coleus* is worth the attention of cultivators who can appreciate an easily-grown plant which produces really attractive bright blue flowers in midwinter.

W. W.

THE WEEK'S WORK.

HARDY FRUITS.

STRAWBERRIES.—Those who wish to have good crops of the finest and earliest fruits next year will have raised a sufficient quantity of plants to put out on wall borders where the soil has been well dug, manured, and prepared for their reception. Early planting has a great influence for good on these plants; indeed, it is the only way in which the maximum of success may be obtained. As the plants on these borders are only expected to give one crop they may be put out thickly, and for the majority of the close-growing varieties 15 inches apart is quite sufficient. Royal Sovereign and others of its habit should be allowed 18 inches, as the extra distance will be required for air, should the season of ripening be a wet one. In planting take care that the ground is firm, either from being well trodden or from having been allowed time to settle naturally. Personally, I like to plant on ground which has been bastard-trenched during the previous winter or spring and from which a light crop has been taken in the meanwhile; indeed, one may take almost any sort of crop, such as early Potatoes, Lettuces, and even Peas, from the ground without doing it any harm, but I avoid using the

Viburnum Tinus. (See p. 78.)

plots as seed-beds for any of the Brassicas, as these leave the ground in a dry and poor condition unless they have been transplanted quite early. Showery weather is the best for carrying out planting on soil which will admit of the necessary treading without becoming pasty, but one cannot always wait for weather and some soils are best left alone when at all wet. See that

the soil about the roots of the young plants is in good condition as to moisture, then they will have what they want in the way of a good start. If, in lining out the ground, the corner of a hoe is used, take care that the drill thus made is not deep or, if it is so, that the plants are kept well up so that the surface of the ball is only just buried when the plant is made firm, for if the crowns are let too far into the soil either when planting or through settling afterwards the plants will be spoiled. Water well in after planting and see that there is no neglect in this while the weather remains dry, or until the plants become established. Having selected for the borders the best of the young stock and planted them, go on planting the main beds or plots. These, being intended to last for three or four seasons, will be planted more thinly than on the borders, the strong growers being given 2½ feet between the rows and 2 feet from plant to plant and the weaker ones 6 inches less each way. These are good average distances, but must not be looked on as arbitrary for every garden, as the character of the growth varies with the soil and must be allowed for to suit individual cases. The crop for the year being over and runners obtained sufficient for all needs, it will be advisable to cut away all superfluous runners and clear them and the roughest of the mulching off the plots on which the plants are intended to remain for another year's fruiting, for nothing looks worse than a weedy and untidy Strawberry bed after it has been stripped of the nets, besides which it is not giving the plants a fair chance to allow the crop of runners to remain on them any longer after the opportunity of clearing them occurs.

SUMMER PRUNING.—Having finished the summer pruning of wall trees, it is well to go right on to the pyramids and all other trained trees in the open garden, getting the work completed as soon as may be, so that the swelling fruits shall have all the advantages of exposure to sun and air. Growths reserved to full length for filling up the bodies of the trees or for extension of the leads should be tied into position before they become hard. They will then acquire the form which it is desirable they should take, and trouble at the winter training will be saved. If any leading growth is not going away so kindly as wished for, the side growths on the branch should be repressed more rigorously to encourage the leading shoot and preserve or obtain a proper balance.

SUCKERS.—On wall trees especially, and on others which occupy ground that is dug over occasionally, suckers often appear and are a great nuisance. If left until now, just as the wood is getting hardened, they can be dealt with more satisfactorily than they can earlier when soft and brittle; they should be opened out and traced downwards until arriving at a single stem, or, better still, at the junction with the root, and then be bodily removed. This will prevent any further trouble with these robbers for the current year. Those trees which are especially persistent in sucker production should be marked down for more drastic treatment during the winter, when it will be safe to open out more thoroughly and trace each bunch of suckers to its origin.

FIGS.—Fig trees, though late in starting growth, grow rapidly, and the soft, pithy wood is easily injured in high winds, so should be secured early to its supports. Surplus shoots may either be stopped or entirely removed, whichever seems to tend most for the benefit of the fruits which need exposure to give them the needed colour. In the extreme south of the country it is usual and wise to allow a considerable amount of latitude to the growth of outdoor Figs, and breast wood may be allowed to hang down the face of the

trees, thereby increasing the number of growths preserved and also the crop given, for these breast-wood shoots acquire a short-jointed and free-fruiting habit in a favourable climate, but in more northern latitudes they have to be rigorously repressed and the trees trained thinly if we are to expect any fruits from outdoor trees.

PEACHES.—These should now be taking on

The Guelder Rose (Viburnum Opulus var. sterile). (See p. 78.)

colour, and, to help them, should be well exposed to the sun by tying back if necessary any leaves which hang over them. The size of the fruits will be greatly increased and the trees benefited by heavy waterings of weak liquid manure during the period when they are taking their final swelling; the mulching, too, should be increased if not thick enough to give a uniformly moist covering to the surface roots. This and the remarks on watering will apply now more forcibly than ever to all fruit trees carrying good crops, and especially to wall trees without a southern exposure.

PESTS.—When the bigger fruits begin to ripen there are pests ready always to attack them, and these are more difficult to deal with in the open air than under glass. One of the worst is the wasp, which comes in such numbers and so suddenly as to fairly nonplus the unwary. I have very little faith in the method of putting various attractive potions, such as beer and sugar or treacle, in bottles to drown or stifle the pests, for, though the numbers which are so killed are great, the baits so provided probably attract by their smell many which would never come to the trees. It is a difficult question to deal with, and one gets to one's wits' ends at times to know what to do for the best, but certainly the most effective measure is to leave nothing undone that will lead to the discovery of all nests within a radius of a mile or so, and to destroy their inmates with a dose of cyanide of potassium solution placed far enough back in the nests to be harmless to all but the wasps, for the cyanide is a deadly poison and must be handled with care. Earwigs often attack stone fruits, but may easily be trapped by the use of Bean stalks or short pieces of Bamboo stuck among the branches and blown out into a bottle of water each morning. Of mice I have given early cautions which can only be borne in mind for present application. Persistent trapping should have reduced them considerably, and there is no wholesale way of dealing with them.

CORNUBIAN.

KITCHEN GARDEN.

EARTHING UP LEEKS.—Where Leeks are required for use early in the autumn, plants which were raised in heat in January will by this time have grown to a good size and may be partially earthed up. If several rows are growing in one wide trench great care will be necessary in order to prevent the soil falling into the hearts. A good

way to accomplish this is first to tie a band of soft matting round the lower part of the plant and then to use a thin board, this being held by one man against the row while a second puts in the soil with a spade, the board being afterwards lifted gently out and the soil worked around the stems with the hand. Where only one row of plants is grown in each trench, it may be earthed up so far similarly to Celery. Leeks are very thirsty subjects; therefore it will be advisable to give the trench a good soaking with farmyard liquid the day previous to earthing up; this will enable the plants to swell at the base during the final stage of growth.

TRANSPLANTING COLEWORKS.—The plants from the first sowing will soon be large enough for putting into their final quarters. Where no rain has fallen, however, it will be best to exercise a little longer patience, as if the plants in the seed-bed were well thinned out when comparatively small no harm will result from the delay. As before stated, I have always planted a quarter from which old Strawberry plants have been cleared, and then drills are not really necessary, as the ground beneath the surface being firm retains the moisture well. Where planting is performed on loose, freshly-turned ground, however, drills will be necessary. Plant 15 inches apart all ways, and water home, keeping a sharp watch for underground grubs, which are often very troublesome amongst newly-planted Coleworks. It is of no use whatever applying lime to the surface for this pest, nothing but searching beneath the surface in the vicinity of the stem being of any avail. It is a good plan to make several transplantings even from this first sowing. As the second-sized plants left in the seed-bed get large enough, the latest sowings, which will be ready for putting out in September, will afford nice useful heads for use during January and February. I like to have the seed-beds in a cool, semi-shaded position.

SCARLET RUNNER BEANS.—Special means must be adopted during absence of rain to induce not only a free, vigorous growth, but also a perfect set of pods. In the first place, the rows on both sides should be well mulched either with manure from the farmyard, or, failing this, a good thickness of old Mushroom manure, or even grass mowings. This will conserve the moisture, which must be applied to the roots with no niggardly hand. A good soaking once a week will be none too much, giving farmyard liquid of good strength. Where practicable I would always give the haulm a good wetting at eventide twice weekly in dry, parching weather. This is best done by means of the hose-pipe or garden engine. Where the pods have arrived at a usable stage they must be kept picked tolerably close. Successional sowings now coming on apace should be treated similarly as regards mulching and watering with liquid manure. On light or porous soils the previously recommended plan of sowing in trenches containing a good layer of rotten manure will this season prove its value. Everyone has not an inexhaustible supply of tall rods, but ordinary 5-foot or 6-foot Pea rods answer well, the haulm being pinched when the top has been reached. The old Scarlet Runner is still hard to beat for freedom of setting and swelling its pods in a dry season.

VEGETABLE MARROWS.—Both bearing and successional plants will now need regular attention, as the young tender Marrows are much appreciated in the dining-room at this season. Marrows as a rule are used in a much younger state than formerly, and it is well that it is so, as by timely easing the plants of their burden growth is strengthened and the season considerably lengthened. Where the earliest planting was made in frames from which new Potatoes had been lifted, the roots being considerably elevated above the ground-level will need an abundant supply of water, or a premature collapse must be expected. Vegetable Marrows will take manure water as strong as the majority of vegetables, but after using liquid manure from the farmyard I like to go over the plants afterwards and wash

the foliage clean with pure water. More recently-planted lots occupying a position on the level or on slightly raised mounds of loamy compost can easily be kept in a growing condition by timely liberal mulching and regular supplies of water. Plants under these conditions produce abundance of fine-flavoured Marrows over a long period, their constitution being hardy. Where available I would always give these successional batches of plants a semi-shaded aspect, having found such to suit them well, especially in hot, dry summers. Plants occupying small pots or boxes may yet be planted out in a good border, as at this date they soon start into free growth and become fruitful, provided the above-named cultural details are carried out. Pen-y-byd is a useful prolific Marrow, and very suitable for amateurs. J. C.

FLOWER GARDEN.

JULY, 1899.

PROBABLY many gardeners have heard the story of Diocletian which is told on good contemporary authority. This emperor, living in the fourth century of the Christian era, had the good and rare fortune after a prosperous reign to retire from the government of the Roman world with his head on his shoulders. He went to his native place in Dalmatia and gave himself up to the pursuits of country life, especially gardening. Things did not go on so well at Rome after he was gone, and an influential deputation waited upon him, begging him to come back and put matters straight again. The ex-emperor pointed to a large garden filled with Cabbages—the gardening of the Romans was mostly kitchen gardening—“All those Cabbages,” he said, “and many more I have planted with my own hands; and I can say this, that no one who has once learnt the pleasure of gardening, as I have, would ever be willing to exchange it for the empire of Rome.” So much for the comparative pleasure of absolute power and gardening in the opinion of one who had tried both. Perhaps there may have been a thought of the sword of Damocles behind Diocletian’s estimate, but if ever there was a month to make gardeners contented and happy it is July, 1899. It is true the year has had its drawbacks for them; the sharp frosts of April and May did much damage to flowers, amongst other mischief destroying the young shoots of the *Fraxinella* and the embryo flower-buds of *Pæonies*. Then came the deluging rains and thunderstorms with hail in June, laying everything flat and starting a vast crop of weeds, but now the weather has settled down—and as St. Swithin’s is past I may say this—into the most splendid July that we have had in Cheshire since 1868. The bright suns and warm nights coming when the soil was well filled with moisture have brought out the finest crop of summer flowers that this garden has ever seen. I can only give a few words to a few of the most conspicuous of them, merely adding that all the others which this soil and climate can grow are here too. *Delphiniums* are past their best and have enjoyed the sun, which has prevented the colours from running, as they are apt to do in sunless seasons. All those at Edge are home-raised seedlings, and nearly all are single. A handful of seed is saved from the best flowers every year and sown broadcast on spare ground. A few of the best are selected to supersede those in the borders either of less merit or worn out. Large flowers of pale Eton blue or of dark sky-blue of the true blue strain and with well-marked white or black centres are aimed at. It is also a merit for the flower-stems to branch nearly to the ground, and a height of 6 feet is

better than one of 3 feet or 10 feet, but I find the general result of this treatment very satisfactory, and seldom see a better set than I grow at home. *Verbascum olympicum*, of which I have at least forty in flower, is not in any danger of being overlooked. They grow 8 feet high, presenting a solid cylinder of flowers 4 feet long and 1½ feet across and pointed at the top. The basal leaves cover a square yard, and, of course, smother anything beneath them, so room must be provided accordingly. A show like the present requires a mild winter preceding, or the large leaves are destroyed and the flowering spoilt. The individual flowers are much smaller than those of their rival *V. phlomoides*, which, however, does not bloom in nearly such a mass. *Eryngiums* are having a grand time. I always prefer amongst these *E. alpinum*. When it does really well, a plant 5 feet high, throwing up several stalks, each holding three or four large heads surrounded with a broad border of soft blue filigrane work, is very ornamental. *Cimicifugas* are stunted in a season of drought and delight in the moisture of the soil this year. Some of the plants of *C. racemosa* have as many as thirty flowering stalks, each with three or four spikes of snow-white flowers rising to a height of 7 feet. Last year the whole genus in my garden was threatened with extinction by a serious blight, the leaves of some of the plants of more than one kind being smothered with black spots, and the flower-stalks curling up and withering in bud. In this and most other mildews I have found dusting with powdered sulphate of copper an excellent remedy. Neglected plants died, but those treated in time recovered. I have found the same treatment very efficacious for the rot in Flag Iris, with which I have been at times much troubled, and never worse than last year. *Spiræas* are unusually fine. *S. Aruncus*, which always grows large here, this year is quite of giant dimensions, and the stalks could hardly hold up the masses of flower. This is a plant in which selection from seed answers well, as in some individuals the panicles are far whiter and more elegant than in others. The roots stand division well, though a hammer and chisel or a saw are required for the operation. *S. kamtschatica* is a coarse plant for a garden border, but good for a pond-side. It becomes fertilised with pollen of some of the pink kinds, and the hybrid seedlings show a great improvement on the parent.

Wherever a piece of ground can be spared I sowed this year Eckford’s Sweet Peas. The superiority of new soil for these may at once be seen over that where they have been grown before, even though well worked and manured. I object to the many forms of this Pea which close their wings like a butterfly at rest. The broadly expanded wings show much better even if the colour is the same on the back and the front of the corolla.

Both *Lilium candidum* and *L. Martagon* are more beautiful than usual. This cannot be all due to the fine July, as the flower-spikes were formed before it came; but so it is. I never before saw *L. candidum* flower here with the stalk covered with leaves, and it is exceptionally good in all the cottage gardens about. As for *Martagons*, they are the mixed offspring of the old pale purple—the white and the dark dalmatic—and, I may add, the *L. Hansoni*, which makes hybrids here and there amongst the others. But as the seedlings of all the varieties are allowed to come up, and the seed is occasionally gathered and scattered, there is every shade of purple and pink, from white to nearly black. I observe that the hybrids of

Hansoni make apparently good seed ; the seed has come up, but none of the seedlings have yet flowered. The abundance of Roses is unprecedented, both in hedges and in gardens. Those most in favour in Edge Garden are old-fashioned kinds which admit of being pruned with hedging shears without resenting it. Such are the old Moss, the Cabbage Rose, the York and Lancaster, the Maiden's Blush, and especially a Rose called Celestial (not Celeste). The most beautiful bush now out in the shaded shrubberies is the giant Syringa (*Philadelphus grandiflorus*), making with its drooping branches a fragrant sheet of white from 10 feet high down to the very ground, upon which the lowest layer is spread.

C. WOLLEY-DOD.

Edge Hall, July 17.

THE PANTHER LILY.

(*LILIJUM PARDALINUM*.)

THIS extremely beautiful and very variable Lily is one of the most amenable to cultivation of all the North American species. Represented by various forms, it has been the subject of three coloured plates in THE GARDEN: firstly in vol. xx., in which there is really little difference between the flowers illustrated; again in vol. xxix., where that distinct unspotted form Warei is shown; and thirdly in vol. xxxviii., the variety luteum is associated with two other North American Lilies, viz., *L. Bolanderi* and *L. maritimum*. The Panther Lily is found spread over a considerable tract of country in California, and is mostly met with in fairly damp spots. This should be the guide for its cultivation here, as in a cool, moist, yet well-drained soil it will soon make itself at home. The consistency of the soil does not appear to be of so much importance, for while, as a rule, if it is of a loamy nature, a mixture of peat or leaf-mould and sand is beneficial, yet I have at times met with it quite at home in a stiff loam. Under these latter conditions, however, the plants did not grow quite so tall, and the creeping bulbs were more compact than in a soil with a considerable proportion of vegetable matter. The bulbs of this Lily just referred to are of a peculiar rhizomatous character, a feature common to a few other North American kinds. When in a thriving condition these creeping rhizomes form quite a dense mass, from whence are pushed up stems of varying vigour, according to the bulbs from whence they spring. Whether the flowers be many or few, they are, however, always disposed in a graceful manner, while the long wand-like shoots, with their whorls of bright green-pointed leaves, are totally distinct from any others, unless it be the nearly-allied *L. superbum*. There is a long list of varieties of *L. pardalinum*, but many of them differ very slightly from each other, and even then intermediate forms are frequently met with. The variety usually known as *Robinsoni* is the most stately of all, while *californicum* is characterised by particularly bright-coloured blossoms. It is, however, in the two above mentioned as having been figured in THE GARDEN that we find the greatest divergence from the normal form, as in *Warei* the flowers are of a warm, unspotted apricot tint, while the blossoms of *luteum* are of a rich yellow, spotted with chocolate. Though the variety *Warei* has been known for some years, it is still, I see, priced in the catalogue of the firm after whom it was named at 50s. per bulb—being, in fact, by far the dearest of all Lilies therein quoted.

T.

Lilium Szovitzianum.—One of the most beautiful of border Lilies when in a flourishing condition is *L. Szovitzianum*, but it is by no means invariably met with in that state, as many bulbs fail to flower, especially the first season or two after planting. The conditions most favourable to its well-doing are a good loamy soil and a position that is not parched up at any time. In the sunken beds near the Palm house at Kew this Lily has flowered well during the present season,

and, as usual, a good deal of individual variation was to be found amongst the numerous plants in bloom. This Lily is a native of the Black Sea region, and quantities of enormous bulbs are often imported therefrom, but they are far more difficult to establish than cultivated bulbs, even though these last may be much smaller. In colour the blooms vary from deep yellow to very pale primrose, almost white, and they differ also to the same extent in their spotting.—H. P.

Tritoma citrina.—This has been very pretty the last few days, the bright clear yellow blooms on the loose spikes being much more graceful than in the larger-flowering, stiffer kinds. On a heavy soil the plants make little headway, and unless special care is taken with them they would get smaller rather than larger. The stouter growers, such as *T. Uvaria* and its varieties, are, of course, well able to take care of themselves, and the tall, handsome spikes look well and hold their own among rough herbage and grass provided they are given a good start, by taking out large holes, filling with good compost, and planting them in large established pieces. The stations must be kept free of weeds for a couple of seasons until they have a good hold, and the spikes should be rubbed out the first season as soon as seen. *T. citrina* has much narrower foliage and is a weaker growing plant altogether, and anyone trying to establish it from the roots sent out from hardy plant nurseries will be wise to pot them up and grow them on a little while in the cool house before finally planting out with the ball entire just as the roots are feeling the pot.—SUFFOLK.

NOTES ON HARDY PLANTS.

Aster diplostephioides.—For seven or eight years I have grown this rare plant, and only now, for the first time, have I got one fine flower. I am sure that for at least two years I grew it in a too shaded position. Where not known it may seem an unpromising flower when opening, and for a week after it has opened; after that time the ray florets straighten out and the disc lightens up with yellow, the whole head (2½ inches to 3 inches across) glistening in yellow and purple. I wonder if it is a variable species? The best description of it would be, perhaps, to compare the foliage to that of *Inula glandulosa*, and the flowers to those of *Aster pyrenæus*, only bigger and yet more refined.

Ostrowskya magnifica.—From five years' experience of this plant, I am satisfied that for success with either big roots or young stock they should be set early—early enough to get the benefit of the warm condition of the soil in the autumn or late summer. For the best results I would plant as early as July. The tuberous roots do not at most make much fibre, but what they do make is essential to sustain the spring growth into summer and to the flowering stage. Such fibrous roots may not be produced in winter or when late planted, because not only is the time less propitious, but the roots have become less responsive from their having become more dry or hide-bound. The results of too late planting are a sudden and complete collapse of the herbage in May or earlier.

Veronica lycopodioides.—It may be worth noting that this pigmy kind, nearly related to the Whipcord section, is flowering profusely this year in the case of a specimen that is 8 inches across and established in its present position for four years. It would be reasonable to suppose that all the Whipcord kinds were shy bloomers, but this points to the possibility of their flowering well in some seasons. The milk-white flowers of this kind are of starry form, have black anthers, and are borne at the apex of the twigs in fives. I grow it in sandy soil and in the fullest sunshine.

Phyteuma comosum (L.).—I believe it is not generally known that this is a very variable species—variable as regards leaves, flowers, colour, and stature, also date of flowering. I have grown it in quantity now for many years,

and my plants came from one place. At present some plants are lovely, others are in seed, while yet others may be two weeks before they flower.

Saxifraga mutata.—I hope your correspondent "S. A." (p. 32) will forgive me if I wrongly assume that from the words he employs in speaking of the living or dying qualities of this plant he may not be aware that the species is of but biennial duration. The plant is a great seed-bearer, and seedlings are more easily raised than in the case of most Saxifrages. You may sometimes keep a plant more than two years, but that will only occur when from some cause the plant has not duly flowered.

J. WOOD.

Woodville, Kirkstall.

FLOWER GARDEN NOTES.

ON hardy plant borders of large size where both species and varieties of the same are strongly represented there are always a coming and going of plants, and at the present time (June 28) many things that were some time ago in full beauty are now past their best and have to be cut over and removed or partially headed back and otherwise attended to with the view to a second display. Pyrethrums come under the latter class, and should receive, if possible, immediate attention. Remove all old flower-stems and any dead foliage, lightly prick the soil about the plants, and give a good soaking of liquid manure, or, if this is not obtainable, mulch with manure and soak with clear water. There was a query recently as to the relative merits of autumn v. spring planting. I should always practise the former, whether in the case of seedlings or plants increased by division, having found that a thorough establishment of the plant for late spring or early summer flowering is thereby better obtained. In removing old flower-spikes on such things as *Campanula persicifolia*, *Verbascum phœniceum*, *Lupinus Foxi* and others, care should be taken not to cut too low, or tiny spikes pushing for successional blooming are apt to be taken away. Much depends on the treatment that can be given them immediately the first flowering is over. Failing rain, they ought to receive, as in the case of the Pyrethrums, a thorough good soaking. Given this and good stuff below for the root-run, the recuperation is rapid and satisfactory. The strain of tall *Antirrhinums* with large spikes and splendid flowers throws out a profusion of side-shoots that will furnish a plentiful supply of bloom of very fair quality if the central portion of the spike is removed before the formation of seed. Pinks like *Anne Boleyn* and *Mrs. Sinkins* are over and flower-stems cut hard down, the plants even without the bloom presenting a bright appearance, especially when contrasted with other things, as, for instance, *Geum coccineum*. Writing of contrasts reminds me to note one of the best things I have this year in bold clumps of *Sisyrinchium striatum*, filled in (in a very large bed) with purple *East Lothian Stocks*. The flower forming the central clumps is not very striking so far as its individual blooms are concerned, but the tall spikes and the abundance of flower that is very well sustained give a bold and very pleasing effect when associated with the purple Stock. It is one of the few plants that can be confidently recommended for very poor soil, although at the same time it pays for good culture, the spikes under such circumstances being much larger and the flowering period much longer sustained.

ANNUALS.—Given thoroughly well-prepared ground with early thinning so that the plants stand well apart (at least 12 inches each way), annuals give a far better display if allowed to bloom where they are sown than if they are transplanted, only in the latter case the flowering is earlier. In outlying beds in pleasure grounds and the wild garden a very fine and enduring display can be obtained by the use of annuals if a good selection is made and the ground is well prepared. Just at present one of my best beds is a mixture in bold clumps of the white spiral Candytuft with *Linum grandiflorum*; the latter

stands well above the Candytuft and the contrast is decidedly pleasing. In cream and orange shades two very effective things just at present are *Calendula Meteor* and *C. Orange King*. Like the perennial *Sisyrinchium* above mentioned, these *Calendulas* are splendid plants for dry soils, and if decaying blooms are nipped off they will flower right away till the advent of frost. Another yellow flower just at present looking remarkably well is *Coreopsis coronaria*. *Godetias* make a fine bed in variety, and look better in this way than when mixed with other things. *Gloriosa*, *Dunnetti* and *The Pearl* are good sorts. *Gaillardias* and *Salpiglossis* also hardly require anything else with them, although in the case of the last named I have had some beautiful beds with occasional plants of *Nicotiana affinis* dotted among them.

LILIUM CANDIDUM.—Some few weeks ago I noted an experiment tried with the above Lily with the view to check the disease that annually appeared in the foliage and practically crippled the plants, viz., shifting the stock to a north order, and am glad to say it has proved a decided success. The plants have not been so good for years; many of the stems are 6 feet in height, and there is an average of twelve blooms to the stem. There is a suspicion of disease occasionally at the extremities of the leaves, but not sufficient to render the foliage at all unsightly.

VASE AND BOX PLANTS have wanted a considerable amount of attention since they were planted, and if from any cause watering was neglected or the water insufficiently applied, they very quickly suffered. *Tropeolum hederifolium* has proved itself an excellent trailer and flowers freely, but, save that it is distinct in foliage, I do not see that it is any improvement on the old *Ball of Fire*, which grows quickly and is very free. These, with *La Florifera* and *Mme. Crousse* Ivy-leaved *Pelargoniums*, with blue and white *Campanulas*, and an occasional bit of *Musk*, are among the best of the trailers. For the back or centre respectively of large boxes or vases an occasional dwarf sturdy *Canna* with plenty of clean, healthy foliage is very attractive among *Marguerites*, *Fuchsias*, *Pelargoniums*, and other things. E. BURRELL.

Claremont.

THE DOUBLE MEADOW SAXIFRAGE.

SAXIFRAGA GRANULATA, which shares with *Ranunculus aconitifolius* fl.-pl. the pretty appellation of *Fair Maids of France*, spreads quickly when planted in the grass. In the spring of 1897 I saw growing beneath some spreading Beech and Chestnut trees on a lawn a plentiful carpeting of white flowers, which proved on nearer inspection to be the double Meadow Saxifrage. I was informed that the spot where they were growing had formerly been a garden, and that some fifty years ago plants of the Saxifrage had been introduced. The garden has disappeared for many years, and its place has been taken by level turf, but the Saxifrages remained and still continue to increase in number. Few plants will grow and flower beneath a Beech tree. Here and there *Wood Hyacinths* may be found doing so, but more often than not the ground beneath the Beeches is bare of flowers, yet these Saxifrages appear to revel in their site and spread from the bole to the outer limits of the branches. I received a small clump from this abundance and planted it beneath a spreading *Hazel* growing on a rough lawn near the wild garden. Last year the clump blossomed well, and this year several plants appeared in the grass about 6 yards distant from the original plant, and flowered freely. These new arrivals are scattered over about 2 yards of ground. A stranger thing than this, however, subsequently happened. I told a neighbour, who resides about a quarter of a mile as the crow flies from my gates, of the beauties of the Meadow Saxifrage for growing on the grass beneath trees and promised a root, which was to be planted beneath a Beech. A

day or so later I received a message saying that there was a strange flower underneath the Beech on the lawn, and would I come and look at it. I went up and found a plant of *Meadow Saxifrage* with two blossoms on it beneath the tree whose branches swept the turf. I presume that the plants which have sprung up in my garden 6 yards away from the first importation owe their position to seed from the first-comer being blown there, but the quarter-of-a-mile journey through thickly-timbered ground, some other agent than the wind must be responsible for, since even *Thistle-down* would scarcely in one case out of a hundred find its way uncaptured through the maze of branches. Doubtless the transportation was effected by a bird, but it seems curious that the bird should so have anticipated the recently-formed intention as to have dropped a seed in 1898 in the exact spot where a year later it was decided to grow the plant, which was then, unknown to the

Heuchera brizoides. From a photograph sent by Mr. H. Staples, Spondon Old Hall, Derby.

parties interested, about coming into flower just where they wished to establish it. How infinitely smoother life would be if some kind providence would but follow the example of this thoughtful bird and arrange things beforehand for us, so that fulfilment might be awaiting our wishes as soon as they assumed form. The plant which I introduced in 1897 was the only one of its sort in the whole valley, and, as far as I know, there are none of the species, single or double, within two miles, so that there is little probability of the germ of the newly-discovered plant having originated elsewhere than in my garden.

S. W. F.

Seedling Pentstemons.—These fine herbaceous plants are very easily raised from seed, and from a collection of named varieties of which I saved the seed two years ago I have some very

pretty and highly-coloured forms. The bright reds, with deep magenta and crimson throats, make a very fine show when they have grown into good clumps a couple of feet or so through them, and these may be kept tidy by thrusting a few branching stakes among them. So treated they are very fine in the herbaceous border, while a group of one variety, especially if it is a good one, makes a splendid and showy bed of itself.—H.

THE HEUCHERAS.

WHEN at Kew some three years ago I was struck with the plants of *Heuchera sanguinea*. I saw in flower there, so I wrote to M. Lemoine for a plant, and at the same time I ordered a plant of *H. alba* and one of a hybrid called *H. brizoides*. These were planted on a border with a gravel subsoil and about 4 feet from a wall facing east in South Derbyshire, where they have since remained undisturbed. In order to explain the state of affairs at the present time I enclose a photograph of the three plants in question, from which you will see that *H. alba* has not flowered at all this year, *H. sanguinea* has put up three or four feeble spikes, while *H. brizoides* is a mass of bloom. This plant seems to me most desirable from every point of view. It requires no protection in winter, and the flower-spikes are more robust and the flowers larger than those of *H. sanguinea*; they are of a pleasant shade of pink. I am afraid to say how long the plant had been in flower when the photograph was taken, but in saying five weeks I am not exaggerating in the least. The flowers last well in water, where their light and graceful style makes them much admired. Even when not in flower the handsome variegated leaves render it a very ornamental plant. The length of the spike is about 2 feet. Spondon Old Hall, Derby. H. S.

Alonsoa Warscewiczii.—This may be grown in a variety of ways, and under whatever conditions it is met with the brilliant orange-scarlet flowers are sure to attract attention. Treated as an annual—that is to say, sown in a gentle heat about March and pricked out in a frame at a sufficient distance apart to allow of the young plants being lifted with a good ball of earth—it may be planted in beds or in mixed borders, while even if sown later on in the open ground it is often decidedly attractive towards the end of the summer. Besides this, effective specimens may be grown in pots and employed for greenhouse decoration and other purposes. It is not often much grown in this way, but I was particularly struck recently with a number of good flowering examples in Covent Garden Market.—H. P.

Murray's double dark Sweet William.—In the garden of Captain Stewart at Shambellie, Dumfries, I was pleased to see a considerable quantity of this old-fashioned border flower. One occasionally meets with it, but it is not often that so many plants are seen. It is very dwarf in habit, of a deep crimson colour, and flowers quite freely. I have seen it used for edgings, for which its dwarf habit makes it very suitable. This little *Sweet William* is practically a hardy perennial and will with the minimum of attention live for several years. It is easily propagated. I have seen it stated that it was raised in Paisley a number of years ago. Those who remember the *Auricula-eyed Sweet William* in its palmy days when it was propagated by layers and sold in

named varieties may think little of this double flower, but it has for years been prized by many who care little for the points of beauty of the florist.—S. A.

A NOTE FROM ORCHARDTON, CASTLE DOUGLAS, N.B.

YEAR by year our Scottish gardens seem to gain in interest to those who admire hardy flowers. Among the gardens which have made remarkable progress in this way is that of Mr. W. D. Robinson-Douglas at Orchardton, Castle Douglas, N.B. Close to the Solway and in a warm corner of Kirkcudbrightshire, it is well adapted for experimenting with plants of doubtful hardiness. Within recent years Mr. Douglas has made a large and pretty rock garden, which gives many useful hints regarding plants suitable for the south-west of Scotland. Some notes taken during a recent visit may be of use to some.

In beds at the back of the house and with an almost south exposure are several Lilies, among these being a fine example of *Lilium monadelphum* about 6 feet high. This is a good form with better coloured flowers than many. *L. Hansoni* is also fine, and several plants of *L. auratum* seem established and increasing. They are upwards of 6 feet high. On the wall is *Rose Crimson Rambler* flowering very freely in a position in which some say it will not succeed. *Gerardia indigofera* on the same wall was very beautiful with its numerous light blue flowers. *Passiflora Constance Elliott* is again covered with buds. *Fabiana imbricata*, *Chionanthus virginica*, *Magnolia grandiflora*, *Ceanothus Gloire de Versailles*, and a nice plant of *Desfontainia spinosa* in full flower are also on the walls with a number of other shrubs. In a bed is a good *Choisya ternata*. In beds by the lawn are many of the best of the hybrid *Rhododendrons* with a large number of choice trees and shrubs. One of these beds consists of *Nabonnand's Tea Roses*, among which *General Schablikine* promises well. These are young plants, and the frosts of March last did them much injury, but they are recovering fast. In another bed one observed *Mitraria coccinea*, which had been badly cut by the same frost, *Deutzia discolor purpurascens* and *Philadelphus Lemoinei*.

Near these beds is a pretty artificial lake formed about three years ago, advantage being taken of a natural depression with a rocky bottom. At one side the natural rock has been artistically used to form a high sloping promontory, and on these rocks *Sempervivums*, *Sedums* and a few hardy *Cacti* have been planted. On the grass above is *Hypericum calycinum majus*, *New Zealand Veronicas*, *Rose species*, such as *R. rubrifolia*, and for spring bloom, *Crocuses* in the grass. With a south exposure *Kämpfer's Irises* thrive admirably in the shallow water here. Several were in bloom and were very fine. *Ranunculus lingua grandiflora* was also in bloom in the shallows with *Villarsia nymphaeoides*. It is not intended that the surface of the lake should be entirely covered with plants, but bold groups of *Nymphaea Marliacea Chromatella*, *N. M. albida* and *N. M. carnea* were really fine with their large handsome flowers. At one side *Gunnera manicata* is making good progress.

From the lake, rocky steps and a path through the grass lead to the extensive rock garden, which is very picturesque with its Japanese Maples and other ornamental shrubs, its rock plants, and its little pools in which are several *Nymphaeas*. Of these, *N. Laydekeri rosea* was the best, its habit adapting it well for a small pool. *N. pygmaea helvola* was not open. *N. Caspary* is in rather too shady a place. In the

rock garden I observed a capital plant of that beautiful *Cytisus*, *C. schipkaensis*, a little *Broom* which ought to be more known, so pleasing are its neat habit and white flowers. A large number of plants of *Ramondia pyrenaica* are thriving beautifully. *R. serbica* is also doing well, and *Jankæa Heldreichi* has been planted with good prospects of success. Good plants of *Codonopsis ovata*, *Potentilla nepalensis*, *Dryas lanata*, *Coronilla varia* (looking well on the large rockwork), *C. iberica*, *Dianthus cinnabarinus*, *Polygonum spherostachyum*, and many others were thriving and happy. *Cotyledon* or *Echeveria glauca* and *Sedum Sieboldi* were very beautiful at the foot of a rock and touching the water of a pool beneath. In a bed was a number of *Irises*, among them being *I. Kämpferi*, and a good colony of *Primula rosea* occupied a place at the margin, while a spike or two of *P. sikkimensis* showed among the *Irises*. There are many good shrubs and plants on the bold and effective rockwork. The *Maples* are remarkably fine specimens, but so luxuriant has been the growth of some of these and other shrubs, that a new rock garden has been built for the smaller plants which might be overgrown. A cosy corner in the grounds has been chosen for a trial planting of some of the *Himalayan Rhododendrons*, most of which ought to do at Orchardton.

A long, broad herbaceous border has the back wall clothed with shrubs, among which was a grand specimen of *Buddleia globosa* covering a wide space. The walled garden is not looking so well as usual, as annuals, which are rather largely grown, have, as in most south-west of Scotland gardens, been a comparative failure this season. Fruit is scarce also. In the houses *Aristolochia elegans* was in bloom with its curious flowers. A capital strain of *Gloxinias* is grown, and one was pleased to see grand plants of several *Abutilons* in the conservatory, with a fine *Bougainvillea* and *Stephanotis* on the roof of the stove. I admired a seedling tuberous *Begonia* with small flowers and leaves, of very compact habit, which was raised at Orchardton and is often coveted.

S. ARNOTT.

SOWING DAFFODIL SEEDS.

IN reply to Mr. W. Ainslie, I may state that I make a point of sowing my seeds early in September, and I have not found that anything is gained by sowing earlier. I sow in 6-inch pots, filling them about one-fourth full with drainage, covering the same with some rough material, and filling up to one half the depth of the pot with light loam, adding thereto a little leaf-mould. I cover this with about an inch of leaf-mould, with a slight addition of silver sand, in which the seeds are sown. The pots are plunged in a cold frame, remaining there until germination takes place, which will be just as *Daffodils* are coming through in the open ground. It is well to allow the young bulbs to remain two years in the pots, filling up the space in the pots the second season with leaf-mould. Very little water will be needed, and it is well to cover the surface with Moss, or put a pane of glass over each pot. Seedlings take from five to seven years to come into bloom, but much depends upon the treatment given the young bulbs. The ground in which they are planted must be very sweet and friable, having been well exposed to atmospheric influences throughout the summer. The bulbs being so small must not be put more than 3 inches or 4 inches deep, and they should be set out early in September. The seeds may be sown in the open ground, and in light soils will frequently germinate very well, but the young plants are liable to be injured by slugs and are apt to be disturbed in some way. In the case therefore of seeds produced by carefully fertilised blooms it is wiser not to run the risk of

loss that open-air sowing entails. Frequently when I have any quantity of seed of the commoner kinds I sow in the open ground, choosing a place that will neither be hoed over nor dug. I have a lot of seedlings, some very good ones, that have been raised in this way. I have a bed of hardy *Cyclamens* under a *Plum* tree, and from time to time I have scattered a pod of seed among them. This last year a very fine double declared itself there, fine in form and coming into bloom when all the doubles were over. J. C. B.

BORDER CARNATIONS AT CHELSEA.

AT the present time the border Carnations in Messrs. Veitch and Sons' nurseries at Chelsea are making a really fine display. The Carnations here are neither unduly disbudded nor unnaturally grown for the mere purpose of securing one big bloom per plant or the like; indeed, to an ordinary grower of such things, who will ever be satisfied with moderate-sized flowers and plenty of them, it is discouraging to see these things so disbudded that only one bloom remains. This is, of course, trying to make a show flower of one of the most valuable of summer border plants, whose very freedom is one of its claims to general notice. Collectively there are some thirty or forty beds of Carnations at Chelsea, the varieties representing only the newest and best, the general collection being grown elsewhere at one or other of the branches. If only as showing what to grow in a town garden for mid-July, these beds of Carnations, teeming with beautiful, and in a large number of instances fragrant flowers, afford a useful, if not indeed a most valuable lesson. Where such things can be associated with a fresh green lawn their beauty is very much enhanced.

Of the large collection grown it is possible only to give a selection, but those named below will be found among the best in flower when our notes were taken. The following are mostly novelties of the present season: *Hampden*, a good buff-yellow, of capital form; *Brodrick*, a fine yellow ground, prettily freckled with rosy red; *Miss Florence*, pure white, faintly touched with rose, a very vigorous grower and very strong on the stem; *Helwood*, a deep maroon self; *Asphedel*, clear rose-pink, a very fine-petalled flower; *Helmsman*, a really splendid pure white of large size and with outspreading shell-like petals, the plant also strong and free. Another fine white is *George Maquay*, though here it appears to suffer from the great heat and scorching sun. As to its form and freedom it is excellent, and doubtless in cooler quarters and purer air it would rank first-class. *Elfin* is another pure white of unusual substance and exquisite in form. *Edith Leadendam* cannot be omitted from the white kinds, and, like others, it is free and a good doer, fine for massing. *Amber Witch* is of a yellow-buff tone, beautiful in form and delicately touched with rosy lilac. In the scarlet selfs, *Amy Robsart* is a fine flower, rather dark-coloured, good in form, fine in calyx, and of splendid habit. *Isinglass*, a strongly-scented flower, is another grand scarlet self almost leathery in the firmness of its petals, the latter broad and outspreading, the fine calyx cup retaining the petals in perfect contour. The *Cadi* is another fine thing of the same rich shade, and *Lady Hindlip*, even if a trifle smaller than some, is really very fine in colour, and certainly too good to be omitted from any list of scarlets. In *Francis Wellesley* we have a rose-carmine, a very distinct flower, free, and of good form. Coming to the fancies, we noted a good and distinct flower in *Artemis*, which is a scarlet, freckled and streaked with lavender. *Czarina* is also a handsome kind, also a yellow ground fancy, heavily edged with bright scarlet. *Haidee* is of a blue-mauve shade, very attractive among the host of good things by reason of its striking shade of colour, and *Saul* is a good addition to the self-yellow class. Some very fine yellow-ground *Picotees* are *Mrs. Tremayne*, *Mohican*, *Miss Violet*, and *His Excellency*, all being of fine form and very full and free. The

vigour of the present-day type of yellow grounds is also a noteworthy feature. These are some of the more important novelties, though there are others, perhaps, equally meritorious, and others, too, not sufficiently forward when these notes were taken to form an opinion of them. Besides these there were either masses or beds wholly devoted to such as Bendigo, perhaps the most remarkable Carnation ever raised in point of colour. It is also a fine grower. Cinnamon is a fine attractive flower, and Garville Gem is the best so far of the so-called heliotrope-shaded kinds. King Arthur, Knight Errant, and Mrs. Macrae are of the finest type of the scarlet selfs, the last named being an improved Hayes' Scarlet, which is saying much of any scarlet kind. Little John is also a splendid scarlet, with full flowers and perfectly smooth petals, while Ness is, perhaps, the brightest of the scarlet kinds. Joe Willet, an old scarlet kind, still finds favour; it is very dwarf and free, and for a companion of similar habit, Mrs. Frank Watts is an excellent white.

These are but a small part of the Chelsea collection of these beautiful flowers, which in their massed and varied colours constitute a most attractive exhibition in the open air at the present time.

German Iris Beauty.—This is an exquisite flower worthy of its name, and one of the prettiest I know. The standards are whitish below, veined with a velvety purple, the upper portion a deep violet-blue with white mottling. The falls are as beautiful as the lip of an Orchid, a soft bluish tinge of white with a reticulated margin of purple and deeper lines of the same colour leading to the beard. It is surprising what a recuperative power the German Iris possesses, small and shrivelled bits of root growing away freely and at once if planted in spring, while if good stout rhizomes are used they make fine flowering plants in one season.—H.

New soil for hardy flowers.—I lately noticed the good effect of new soil on Mignonette and other things in a villa garden near here. The beds appeared to have been filled up with maiden loam taken from building sites and chopped fine, and the roots, judging from the vigorous character of everything in the garden, were revelling in it. I thought private gardeners might well take the hint. Often, of course, flower borders and beds cannot be entirely renewed, but if spare soil of any respectable nature, leaf-mould, burnt refuse, and road scrapings were added in liberal bulk, the effect on growth and bloom would soon be apparent, altering the character of the various occupants much more than the orthodox plan of merely digging or pointing in ordinary manure.—NORWICH.

Gillenia trifoliata.—When it can be left with safety from wind to develop its true habit, this plant is one of the most beautiful of our border or rock garden flowers. A good plant I saw the other day in Mrs. Maxwell-Witham's garden reminds me that one seldom sees any reference to it. Why this is so it seems hard to tell, because its beauty and grace would entitle it to frequent favourable notice. In some other gardens—notably in that of Mr. J. Lotimer, Nithbank, Dumfries, I have seen taller plants than that at Kirkconnel, but none pleased me better because of its neatness combined with elegance and pretty effect. Unhindered by stake or tie it was very beautiful with its flowers so thickly set upon its foliage. It was as if a swarm of small white butterflies had settled down upon it. Unfortunately, some of us cannot, because of wind, grow our plants in so natural and pleasing a way. *Gillenia trifoliata* is a North American plant, and is most at home in a moist but not too wet soil.—S. ARNOTT.

STOVE AND GREENHOUSE.

HELICONIA SANDERI.

THIS distinct and handsome fine-foliaged plant is one of several species which have been introduced within the last twenty years from "South Sea Islands" (wherever they are), and which have been called Heliconias, without having any evident relationship with that genus beyond belonging to the same natural order. True Heliconias are all natives of tropical America. Their leaves are not distichous (arranged fan-like), and they are quite different in texture from these South Sea islanders. Mr. Baker, who recently monographed the genus *Heliconia* and the several other members of *Museae*, says these Asiatics probably belong to a new genus, but nothing can be done with them until the flowers are known. Cultivators who succeed in flowering any of them therefore will do useful botanical service by sending the

leaves, rendering it unique among plants of its kind. It was introduced by Mr. Bull in 1893. A variety named *rubricaulis* differs from the type in having the leaves more richly variegated and the bases of the leaf-stalks coloured vermilion. It was distributed by Messrs. F. Sander and Co. in 1895.

H. SANDERI (see figure) has the habit of *H. illustris*, differing only in being dwarfer, broader in the leaf-blade, and in being marbled with creamy white and rose on a glossy green ground. Messrs. Sander's collector describes it as a robust *Musa*-like plant, with the rich variegation of a tricolor *Pelargonium*. It received a first-class certificate at the recent Temple show.

These plants are all easily grown in a moist stove, and they pay for liberal treatment. The finest examples I have seen were grown by Mr. T. Rochford in his Broxbourne nurseries.

W. W.

Geraniums for winter flowering.—Now is the time to pay special attention to plants of

Heliconia Sanderi. From a photograph by Col. Taylor, Norbiton.

flowers to Kew. Meanwhile we must perforce continue to call them *Heliconias*. The species referred to are as follows:—

HELICONIA AUREO-STRIATA.—This was introduced in 1883 and was figured and described in Mr. Bull's catalogue of new plants for the year following as a noble-looking plant, resembling a dwarf *Musa* in general appearance. The leaf-stalks are striated with green and yellow, and the elongated blade is deep green with the veins marked out by lines of bright yellow. When grown in rich soil the leaves get large and become uniformly green, as may be seen by a large example in a corner of the Victoria Lily tank at Kew.

H. METALLICA was distributed by Mr. Bull in 1882. It closely resembles *H. spectabilis*, which may be only a form of it.

H. SPECTABILIS.—Introduced by M. Linden in 1891. This has large glossy green, ovate leaves, with a dull red midrib and coloured dull purple beneath.

H. ILLUSTRIS, well known to growers of stove plants, has beautifully variegated red and green

zonal *Geraniums* intended for winter flowering. Those struck in January or February will now have received their final potting. Pots 6 inches in diameter are those the majority of growers use, and when once the outsides of the balls are fairly well furnished with roots, judicious feeding must be commenced and followed up right through the flowering season. I do not think any compost surpasses good loam kept open by coarse sand or road grit. Avoiding crowding the plants, as a free circulation of air and sunshine are essential for the building up of a hardy constitution and thorough maturity. A dewing overhead with the syringe at eventide will be beneficial.—NORFOLK.

Clethra alnifolia as a market plant.—This *Clethra*, known as the White Alder of the United States, has been long grown as a hardy shrub in the open ground, and of late Messrs. Veitch have shown us what a pretty thing it is when brought on under glass, for they generally exhibit it in good condition at the Temple show. For all this, it was somewhat of a surprise to meet with it in Covent Garden Market, in the shape of bushes about 4 feet high, which were

plentifully sprinkled with their spikes of white blossoms. Having expanded under glass, the flowers were decidedly whiter than those in the open ground. As an outdoor shrub it is, in a cool, moist soil, decidedly attractive. This *Clethra* flowers, as a rule, during the month of August, but a variety—*tomentosa*—which appears to be rare I have seen at Kew in bloom after the others were all over.—H. P.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JULY 25.

THE meeting on the above date was far better than anyone could have expected after the tropical heat we have lately had. The Orchids were not quite so numerous as on previous occasions, but in the other departments there was a good display, more especially in the fruit, the very fine collection of Gooseberries attracting a deal of attention.

Orchid Committee.

First-class certificates were awarded to the following:—

RENANTHERA IMSCHOOTIANA.—This lovely plant caused some sensation a few years ago when exhibited by Mr. Woodall, of Scarborough. On the present occasion a finer-developed spike was sent. The upper sepal and petals are each about an inch long, orange-yellow, suffused and spotted with purple. The lower sepals are rich purple, mottled and spotted with a dark shade of crimson, the lip deep purple in front, with a clear space of yellow at the base of the front lobe. The side lobes are purple, lined with yellow at the base. The cut spike carried upwards of twenty flowers. From Mr. J. Gurney Fowler, South Woodford.

SOPHRO CATTLEYA QUEEN EMPRESS (*Cattleya Mossiæ* × *Sophrontis grandiflora*).—This is by far the finest of the *Sophrontis* hybrids. The sepals are deep purple at the top and around the margin, shading to light rose towards the base. The petals are similar, of nearly the same colour as the sepals, but veined with a darker shade of purple, the lip reddish purple in front, with some crimson through the centre, the side lobes margined with yellow, the remaining portion purple, shading to yellow at the base, where there is also a suffusion of brown. The plant carried a two-flowered raceme. Mr. Seden is to be congratulated on the production of so fine a hybrid after waiting a period of sixteen years. It is the only plant. From Messrs. J. Veitch and Sons, Chelsea.

DISA CLIO SUPERBA (*D. grandiflora* × *D. Veitchi*).—This differs from the typical hybrid in its having deep magenta segments. The lip is deep yellow, spotted with dark brown. The colour is most distinct and attractive, and the plant should prove a desirable addition to this fine race of hybrid *Disas*. From Messrs. J. Veitch and Sons.

An award of merit was adjudged to—

VANDA TERES (Gunnorsbury Park variety).—This is a distinct and pretty form, the sepals white, the petals slightly tinted with rose-lilac. The front lobe of the lip has a distinct zone of rosy lilac in front of the bright lemon-yellow disc. The side lobes are rose-tinted on the exterior, yellow inside. A cut raceme of five flowers came from Mr. G. Reynolds, Gunnorsbury Park, Acton.

Messrs. J. Veitch and Sons sent a small, but choice group consisting wholly of hybrids. The most prominent among these was a grand dark form of *Lælio-Cattleya callistoglossa ignescens*. The sepals and petals are of fine form and substance, pale rose-lilac, the front lobe of the lip rich velvety crimson, the front of the throat bright lemon-yellow, lined with purple in the centre, shading to purple lined with yellow at the base. The plant carried a three-flowered raceme. *Lælia Olivia* (*xanthina* × *crispa*), with its creamy

white, yellow, and purple flowers, was well represented. *Cattleya Atalanta* (*C. Leopoldi* × *C. Warscewiczii*) with two of its deep rose and rose-purple flowers was most attractive, showing the distinctive characteristics of its parents. *Epilælia Charlesworthi* (*L. cinnabarina* × *Epidendrum radicans*) with its orange-scarlet and yellow spotted purple flowers makes a fine addition to its class. *E.-L. radico-purpurata* with orange and purple-tinted sepals and petals, the large flat lip deep purple, shaded with orange, and a large bright yellow disc, is very quaint and interesting. *Epidendrum elegantulum* has creamy white sepals and petals, the lip white, lined and spotted with violet-purple. *Disa Clio* (*D. grandiflora* × *D. Veitchi*) has rose and lilac-purple flowers. *Disa Veitchi* was also well represented. *Cypripedium Morganae*, with two spikes of three flowers each, was very effective. The true *C. Harrisianum superbum*, *C. Alice*, *C. Astræa*, *C. Euryale*, and a dark form of *C. Orphanum* were also included. A silver Flora medal was awarded. Messrs. Hugh Low and Co., Bush Hill, sent a small group consisting of a fine plant of *Cattleya Leopoldi* with twenty-six flowers on the spike. *C. Eldorado Wallisi* and a light form of *C. Eldorado* were also included. In *C. Prince of Wales* the sepals and petals are greenish white, the lip white, shading to yellow at the base, the whole surface veined and suffused with bright pink. *C. Dowiana* was also well represented. *Dendrobium sanguineum*, with its scarlet, white and yellow flowers, was most attractive. Messrs. F. Sander and Co. sent *Cypripedium Premier*, *C. Lord Derby*, *C. A. de Laiesse*, *C. Garbari* and *C. callo-Rothschildianum*. Most of these were noted at the Chiswick meeting.

Mr. T. B. Haywood sent two spikes of eight flowers each of the almost white *Miltonia vexillaria Daisy Haywood*. A fine form of *M. v. radiata* and other forms came from the same collection. Mr. E. Ashworth sent *Dendrobium formosum Lowi*. In this the flowers were altogether larger than in the plant exhibited by Sir T. Lawrence, the lines on the lip being distinctly marked, showing the intermediate characteristics of the parent species indicated in the name. Sir T. Lawrence sent *Stanhopea aurantiaca*, with deep yellow and brown spotted flowers. Mr. F. A. Rehder sent *Cypripedium Miss Rehder*, having the intermediate characteristics of the two species from which it is derived. Lt.-Col. Shipway sent a good form of *Cattleya Warscewiczii* and a distinct *Gongora* with brown and white flowers.

Floral Committee.

A first-class certificate was awarded to

ABIES DOUGLASSI PUMILA.—This is the Colorado form of this plant, and certainly beautiful in the form seen at the Drill Hall. The pretty, almost pea-green tone of the plant, coupled with the compact bush form, should render it serviceable in any part of the garden. From Mr. Anthony Waterer, Woking, Surrey.

An award of merit was granted to each of the following:—

ACER CALIFORNICUM AUREUM.—Some discussion was raised as to the identity of this, but, apart from its title, the variety in question, if of the same hue permanently, is a very attractive plant, the foliage a pale golden yellow, with perhaps a suspicion of cream. From Hugh Low and Co., Enfield.

CAMPANULA MAYI.—This plant would have been more correctly labelled *C. isophylla* var. *Mayi*; indeed, for all practical purposes it is nearly a repetition of the typical *C. isophylla*. The chief difference is that *C. isophylla* is more distinctly hirsute than the seedling. In other respects, that of habit, freedom of flowering, colour, &c., the two are almost identical. Though the plants were trained erect, it is, of course, like *C. isophylla* in all its variations, a first-class trailing plant. The flowers are pale blue and salver shaped. From Mr. H. B. May, Edmonton.

BEGONIA M. WANNOT.—A double tuberous kind, having handsome flowers of immense size

of a delicate shell-pink shaded with salmon. From Messrs. R. Hartland and Son, Cork.

BEGONIA MR. JOHN CAULFIELD.—Another handsome sort with large flowers of an intense crimson scarlet hue. From Messrs. R. Hartland and Son, Cork.

CORNUS MACROPHYLLA.—A handsome shrub which occurs frequently throughout Japan and Northern India. It is of vigorous growth and bears an abundance of clusters of creamy blossoms. From Messrs. Veitch and Sons, Ltd., Chelsea.

ARUNDO DONAX MACROPHYLLA.—The chief differences between this and the ordinary forms of *A. donax* are its larger stature and decided glaucous colour of the leaves, that render it conspicuous at a distance. It is also called *A. d. glaucus*. From Mr. Anthony Waterer, Woking.

VITIS THUNBERGI.—In so far as size and general appearance go this appears a large form of the well-known *V. Coignetiae*, and quite distinct in garden effect. The leaves are finely coloured in autumn. From Mr. Anthony Waterer, Woking, Surrey.

DELPHINIUM JOSE MARIE DE HEREDIA.—A double—not a semi-double, as most so-called doubles are—with closely arranged flowers of light azure blue and rather deeper on the outer side. From Messrs. James Veitch and Sons, Ltd., Chelsea.

CAMPANULA WARLEYI.—A very distinct and pretty member of the Bellflower family, which attains nearly a foot high in the largest plants shown. The colour is deep violet-blue, the corollas of a semi-double character. The plant is rather free flowering, and slender and elegant in growth rather than vigorous, and though we trust it may prove a true perennial, the examples shown afford some uneasiness in this direction. From Miss Willmott, Warley Place, Essex.

CALADIUM MME. JEAN DABOWSKI.—A striking form with blood-crimson foliage, elegantly bordered with dark green, the leaves large and the plant generally showy. From Messrs. John Laing and Sons, Forest Hill.

ROSE J. B. M. CAMM.—A hybrid Bourbon of considerable promise. The ground colour is nearly white, the tips of the petals shading to rather deep rosy pink, which on the finely recurring petals is seen to advantage. The blossoms are delightfully fragrant. It is a seedling, raised between the H.P. *Mme. Gabriel Luizet* and the H.B. *Mrs. Paul*. From Messrs. Paul and Son, Old Nurseries, Cheshunt.

PHLOX FIANCÉE.—A pure white herbaceous kind, which, considering the intense heat and general dryness, was very good. From Messrs. Paul and Son, Old Nurseries, Cheshunt.

NICOTIANA SYLVESTRIS.—Visitors to the hybrid conference at Chiswick had a good opportunity of noting this plant, a cut spike of which was now shown. The flowers are white, and droop in the daytime while not closing. From Mr. J. Hudson, gardener to Mr. Leopold de Rothschild, Gunnersbury.

From Edmonton Messrs. J. Hill and Son brought a really grand lot of Ferns, many of which were of great size. Some of the more important things were *Leucostegia immersa*, *Cyathea insignis*, *Davallia fijiensis elegans*, a splendid example; *Nephrolepis davallioides furcans*, *Adiantum elegantissimum*, *A. trapeziforme*, both in capital form; *Pteris aspericaulis*, with red-coloured fronds; *P. tremula Smithiana*, very fine; *Davallia tenuifolia Veitchi* and *D. epiphylla*, fully 6 feet across. *Dicksonia davallioides* and several *Gymnogrammas* were also shown, the group occupying a considerable space. A silver-gilt Flora medal was awarded. Another highly meritorious group was that of *Ivies* from Messrs. Wm. Cutbush and Sons, Highgate. These were presented in excellent condition, the plants nicely arranged in baskets, one such being devoted to each kind, which materially assisted the view and equally the group. In all there were some four dozen examples or thereabouts representing very naturally the finest material of this valuable

group. A few kinds are *dentata*, *maderiensis*, *argentea variegata*, *rhomboidea obovata*, *palmata aurea*, &c. A silver-gilt Flora medal was deservedly awarded in this instance. A capital lot of hardy flowers and the hybrid *Rhododendrons* of *jasmiflorum* and *javanicum* were shown by Messrs. Veitch and Sons, Ltd., Chelsea. In the former, *Verbena venosa*, *Platycodon grandiflorum album* and *P. Mariesi*, *Gaura Lindheimeri*, the latter a fine subject for a dry soil; *Romneya Coulteri*, a fine solitary flower of this; (*Enothera speciosa*, *Scabiosa caucasica*, *Liatrix*, *Eryngiums* in variety, *Statice latifolia*, very beautiful; *Cimicifuga racemosa*, with fine spikes of white and creamy white flowers; *Delphinium sulphureum*, a splendid spike of this fine plant; *Harpalum rigidum*, the early form; *Sidalcea candida*, *Monarda didyma*, and others were included, the group being finished off with sprays of *Gypsophila paniculata*. The *Rhododendron* hybrids were a complete set of these so far as then in flower, nothing new or fresh being noted. A silver Flora medal was awarded. A beautiful and interesting gathering of hardy things from Messrs. Wallace and Co., Colchester, contained a variety of Lilies, including *L. Henryi*, *L. Browni*, *L. pardalinum*, many beautiful forms of *L. Thunbergianum*, the brilliant scarlet *L. chalconicum*, much finer than is usually seen, and not least a finely-marked *L. auratum* (*vittatum* variety). Indeed, with the *L. auratum* foliage and growth generally we have a decidedly *L. platyphyllum* flower in many respects, particularly size and breadth of the segments, and with all this we have a flower much richer and more intensely coloured even than *L. rubrovittatum*. At present no distinctive name has been given to this fine Lily, which promises to be an acquisition. Other good things in Messrs. Wallace's group included *Montbretias*, *Alstroemerias*, *Calochorti*, *Liatrix spicata*, *Delphinium cardinale*, *Echinops Ritro*, some lovely Japan Irises, and a few good sorts of garden Carnations (silver Flora medal). The group of Cacti and allied plants from Messrs. Cannell and Sons, Swanley, was among the chief attractions of this meeting. Many of the examples were very rare, others almost unique, and all interesting. A very fine piece of the Golden Cactus (*Echinocactus Grusoni*), with its long gold spines, was in the centre, the not less beautiful *E. cylindricus versicolor*, with reddish spines 4 inches long, being a close companion. Other good things are *E. c. chrysanthus* and the sturdy *E. ingens*. There were also some notable examples of *Cereus*, *Echinocereus*, *Opuntias*, *Pilocereus*, *P. senilis* (the Old Man Cactus) being noticeable in several fine plants. There were also good contributions of *Echinopsis*, *Mammillarias*, and others of this very remarkable group, the whole of which formed an exhibit quite unique in character and material. A silver Flora medal was awarded. From Langport, Messrs. Kelway and Sons sent a large display of *Gladioli*, cut spikes of these being arranged in boxes. As yet it is early for these things, and the kinds staged do not in any sense represent the good things we have seen from this firm. Some seedlings of *G. Kelwayi*, said to be a new race, were also shown, but no information could be obtained as to their origin, though some of them appeared to possess certain characters of the *G. Lemoinei* forms. One of the best of these is *Mr. J. W. Willard*, a large salmon-pink with crimson base. *Max Muller*, *Kipling*, *Lord Ashbourne*, and *Brutus* are good scarlet kinds. *Dr. Woodman*, *Plunket*, salmon shades, and *King of Siam*, a rich crimson-maroon, were also noteworthy. The same firm also had *Gaillardias*, *Hollyhocks*, and a selection of herbaceous things, as *Eryngiums*, *Achilleas*, *Lychnis*, the pretty *Delphinium Belladonna*, and such like (silver Flora medal). *Roses* came from three sources, viz., Messrs. Paul and Son, Cheshunt; *Cooling* and Sons, Bath; and *Mr. W. Rumsey*, Waltham Cross. In the first named, mixed with many beautiful *Roses*, such as *Maman Cochet* and its white form, *Muriel Grahame*, *Ellen Keller*, *Mrs. Grant*, and *Gustave Regis*, were some good heads of *Phloxes*,

such things as *Etna*, *Regulus*, *Coquelicot* being conspicuous among the bright coloured kinds. *Iris*, a purple-mauve, was also noted as distinct from the general collection (silver Banksian medal). In Messrs. *Cooling's* lot, which was arranged in vases in bunches, *Gustave Regis* and *Papa Gontier* were very fine, while more conspicuous even than these were *Duchesse d'Auerstadt*, a clear rich golden, and *Mlle. B. Violette*, a yellow and white kind. *Paul's Single White* and *Macartney Simplex* were also good among single kinds (silver Banksian medal). In *Mr. Rumsey's* lot the most telling thing was a box of the pink *Mrs. Rumsey*, the other boxes containing single blooms of a great variety of kinds (silver Banksian medal). A very fine array of cut *Begonia* blooms from Messrs. *Richard Hartland and Son*, Cork, represented a fine strain of these flowers. Some of the doubles were particularly fine and were selected for awards, the remainder all affording evidence of the highest excellence. The batch was very strong in the pale salmon shades. Flowers of seedling single kinds were also shown, and though by no means the best things to stand so long a journey, came out quite fresh and good, and stood well during the day (silver Banksian medal). The group of *Campanulas* and *Ferns* from *Mr. H. B. May*, Edmonton, was a very attractive one, the former being of the blue and white kinds of *C. isophylla*. The blue kind called *C. Mayi* is obviously a seedling from *C. isophylla alba*, and for all practical purposes a reversion to the typical species. This last, however, is, perhaps, rather more hirsute than the seedling, which is in every respect a free-growing and abundantly flowered plant. It is a coincidence that *Mr. E. H. Jenkins*, Hampton Hill, exhibited a seedling *Campanula* at the recent Chiswick conference which appears identical with the present plant (silver Banksian medal). Messrs. *Hugh Low and Co.*, Enfield, showed a small group of *Acer californicum aureum*, and *Mr. A. Waterer*, Woking, had a variety of interesting trees and climbers, among these *Fagus sylvatica purpurea pendula*, very fine and distinct, *Quercus pedicularis*, *Clethra canescens*, and a fine golden form of *Ulmus campestris* named *Louis van Houtte*. *Koeleruteria paniculata* is a pretty yellow-flowered plant. *Vitis Coignetia* and *V. Thunbergi* were also shown in capital form. *Mr. R. C. Notcutt*, Woodbridge, Ipswich, had an assortment of Sweet Peas. Messrs. *Sander* brought good examples of *Acalypha hispida*, and the pretty *Palm*, *Linospadix Petrickiana*. Messrs. *Dobbie and Co.* had a group of *Victoria Pansies*, a strain of bronzy-red flowers. As usual, the Messrs. *Barr and Sons* had an exhibit of hardy flowers, for the most part the usual subjects that are now in flower, as *Coreopsis*, *Heliopsis*, *Anchusa italica*, the white and mauve *Scabiosa caucasica*, *Phloxes* of the decussata section, beautiful Japanese Irises, *Platycodon Mariesi*, *Francoa*, *Alstroemeria psittacina*, *Lilium*, and one or two forms of *Campanula carpatia*, &c. *Mr. Salter*, gardener to *Mr. T. B. Haywood*, Reigate, showed handsome bunches of *Carnations* *Isinglass* and *Germania*, neither of which can be equalled in their respective shades of colour, the flowers being very finely grown. A most attractive group arranged on the floor was that from *Sir Charles Pigott*, Wexham Park, Slough (gardener, *Mr. J. Flemming*). The chief attraction of the group was some finely-grown *Humeas*, drooping their willowy plumes over some well-grown examples of the blue and white *Chimney Campanula*, the general effect being very distinct and pleasing. The groundwork was composed of the usual plants, *Crotons*, *Carnations*, *Cannas*, *Caladiums*, *Lilium*, *Francoa* and such like being disposed to good advantage from several central or important positions, everything, however, being subordinate to the *Humeas* and the *Bellflower* above-named, and which lent a distinct charm to the whole. More than this, it fully demonstrated the value of tall, graceful and elegant things in the decoration of the conservatory, or indeed any large building, and for such a purpose the plants cited are perhaps difficult to equal.

Fruit Committee.

A meeting was held in the society's gardens on July 24 to examine dwarf Beans, early Potatoes, and Tomatoes on trial. Unfortunately, the committee was one member short, so could only recommend awards, but as these were sanctioned by the larger committee at the Drill Hall the next day, the awards appear in that day's proceedings. Some thirty stocks of early Potatoes were lifted and ten selected for cooking. The crops were excellent for the season, many having been cut down by frost early in May and again in June. Three marks were given *Early Peter*, *Caradoc Seedling*, *Norbury Park*, *Prolific*, and *Hibberd's Seedling*. The others did not pass the cooking test. *St. Lawrence*, *Early Market*, and *Leader* were good in other respects. It is only fair to add some kinds were not sufficiently matured. Dwarf French Beans formed a most exhaustive trial, nearly all the kinds in commerce being grown. The seed was sown on a south border on May 5. About fifty-seven stocks were represented. Some half-dozen kinds were selected as superior, three marks being given. Turnips were examined, but owing to heat and drought were past their best. Tomatoes in pots were next gone through. There was but little novelty, as, though some excellent kinds were on trial, any new variety must be good to be recognised. *Comet*, an old kind, was given three marks for its excellent cropping, and a very pretty variety, *Cherry Ripe*, was given the same award. A new Tomato, a sport from the *Red Peach*, and by selection improved, has handsome fruits of a pale peach colour and of excellent quality. This the committee recommended for a first-class certificate.

This committee had its full share of work at the Drill Hall on Tuesday, there being some excellent exhibits.

First-class certificates were given the following:—

GRAPE LADY HASTINGS.—A sport from *Muscat Hamburg*, but a much stronger variety, having robust, glossy foliage, a roundish large berry with thin skin and of splendid colour. It is very juicy, with a distinct *Muscat* flavour. This is a valuable addition to the *Black Muscat Grapes*. From *Mr. W. Shingles*, The Gardens, Melton Constable, Norfolk.

STRAWBERRY LADY SUFFIELD.—A new variety that has been shown on several occasions of late. It is a dark fruit not unlike *Lord Suffield* in colour, with prominent seeds and of excellent flavour. It is a free cropper and evidently a good keeper, as the fruits sent were of fine quality. From *Mr. Wm. Allan*, Gunton Park Gardens, Norwich.

CHERRY NOBLE.—A very fine late fruit, dark red, not unlike a very fine *Morello* in appearance, but a dessert variety. It is very fleshy, sweet and a great bearer. This will be a welcome addition to the late kinds. From Messrs. *Ray and Co.*, Nurserymen, Teynham, Kent.

Awards of merit were given to the following:—

POTATO EARLY PETER.—A kidney-shaped tuber of fine flavour with a short top, very productive. From *Mr. Bradley*, Church Street, Peterborough.

POTATO CARADOC SEEDLING.—A pebble-shaped tuber of fine quality. It is an early variety and very prolific. From *Mr. Caddick*, Caradoc Court, Ross, Herefordshire.

POTATO NORBURY PARK.—This is a distinct early kidney with a dwarf top and of excellent quality. From *Mr. L. Solomon*, Norbury Park, Dorking.

POTATO PROLIFIC.—A very prolific early variety with a rough skin and of first-class quality. From Messrs. *Johnson and Sons*, Boston, Lincoln.

POTATO HIBBERD'S SEEDLING.—A yellow-fleshed kidney of excellent quality with small top. From *Mr. H. Hibberd*, Edge End, Botley, Hants.

FRENCH BEAN PROGRESS.—An enormous cropper with large fleshy pods of fine shape. It is very early and stands drought well. From Messrs. *Veitch and Sons, Ltd.*, Chelsea.

FRENCH BEAN EVER-BEARING.—This is a distinct Bean with large leafage, the flowers being produced in long racemes above the leaves. The plants continue bearing for a long time. The pods are of a good size and fleshy. The only drawback with this class of Bean is that the plants in wet seasons, owing to the produce being on the top, are liable to be beaten down and get dirty. MM. Vilmorin et Cie., Paris.

FRENCH BEAN STRINGLESS.—In this the pods are devoid of the string portion at the backs. This is a great gain, as much time is saved in preparation. The pods are round, very fleshy, of good quality, and produced freely. The plant is a free grower, and the pods are best if cooked whole.

FRENCH BEAN NE PLUS ULTRA.—This is a well-known variety and very delicate in flavour. It is an excellent cropper and very early. From Messrs. Veitch, Ltd., Chelsea.

FRENCH BEAN PERFECTION.—This has long succulent, narrow pods of a roundish form, very fleshy, of excellent quality, and produced in abundance. From Messrs. Sutton and Sons, Reading.

FRENCH BEAN COVENT GARDEN EARLY NEGRO.—This is a long-podded variety, and though not a very early kind it is remarkable for its cropping. The pods are long and narrow. From Messrs. Watkins and Simpson, Strand, W.C.

TOMATO CHERRY RIPE.—A Plum-shaped fruit, produced on large long clusters, and excellent for salad. It was one of the best flavoured Tomatoes grown at Chiswick out of many kinds. It is very prolific, the fruits of a deep crimson colour. From Messrs. Dobbie and Co., Rothesay, N.B.

TOMATO THE COMET.—An old variety, still one of the best on trial for crop, quality, and shape. The fruits are produced in great profusion and are medium-sized. The Royal Horticultural Society, Chiswick.

Messrs. Veitch, Ltd., sent one hundred varieties of Gooseberries in trays and a goodly number of trees in pots, also in cordon shape, fan-trained and vase or cup-trained. The trees were laden with fruit and the leafage perfect. Mention must be made of such as Langley Beauty and Langley Gage, new kinds of great merit. Industry, Forester, Keepsake, High Sheriff, Clayton, Tom Jones, Jenny Lind, Lancashire Lad and Oldham were also good. In the white section, Alma, Antagonist, King of Tramps and Progress were beautiful fruits. In the greens, such kinds as Fearless, Keepsake, Matchless, Plunder and Surprise were excellent, and in the red section, which was strongly represented, we noted Clayton, Crown Bob, Dan's Mistake, Duke of Sutherland, Highlander, Nottingham and Whinham's Industry, with excellent yellow kinds, such as Drill, Hannah, Loveller, Penn, Pilot and Trumpeter. Bright Venus, Early Red, Ironmonger, Keens' Seedling, Warrington, Champagne and Yellow Sulphur were noteworthy for flavour. A gold medal was deservedly awarded. From Mr. G. Norman, Hatfield House Gardens, Herts, was sent a choice collection of dessert fruit, including Royal George Peaches, Lord Napier Nectarines and Brown Turkey Figs. Grapes in three varieties were the weakest dishes. Cherries were fine, the Bigarreau Napoleon, Frogmore Bigarreau, Black Tartarian and May Duke being splendid. British Queen and Waterloo Strawberries were also good. Raspberries Superlative and Norwich Wonder, with White and Red Currants, were also shown (silver-gilt Knightian medal). Messrs. Harrison and Sons, Leicester, sent eighty varieties of Peas. A few of the older kinds were not true to name. The dishes of Duchess, Gladstone, Telephone, Duke of Rutland, Geo. Clelland, Sharpe's Queen, Stratagem, Optimus, John Harrison, Gradus, Leicester Hero, Emperor of Japan, and several new hybrids were of excellent size and colour (silver Knightian medal). A new Grape stated to be a white early Muscat came from Andover. The committee thought it to be a Frontignan variety. A new Raspberry (Eclipse) came from Mr. Jennings, Barrow-on-Humber, but of no special merit. The same exhibitor sent a new Pea

called Competitor, which was referred to Caiswick for trial. Messrs. Veitch sent the Loganberry, also fruit in a preserved state. Mr. G. Wythes, Syon House, Brentford, sent seedling Melons.

SPECIAL MEETING, JULY 21.

A special meeting was held at 117, Victoria Street on July 21 to consider the proposed alterations in the society's charter. Most of the members of the council attended and about twenty Fellows, Sir Trevor Lawrence, Bt., presiding. The president stated that the council had in the past found some portion of the old charter most difficult to work, and it was feared some of their actions in the past were not quite legal, and though they had all tried to do the right thing, they had taken legal advice and were now endeavouring to make clearer and more workable rules. Much of the confusion in the past arose at the time the society had to vacate South Kensington. This made a lot of the existing charter obsolete, and they were advised it would be far better to get a new charter and add more to the bye-laws than patch up the old one. The council trusted the Fellows would see the need of the proposed alterations. The president, in calling upon the solicitor to read the new charter, said he would be glad to explain any points and reply to questions that arose. Mr. Clark, from the office of Messrs. Garraud, James, and Wolff, solicitors, Pall Mall, then read the new charter. This showed considerable alterations in election of members of the council, and we think even now the process might have been much simplified; but without the new charter to refer to it is difficult to criticise. It is proposed that one-fifth of the number retire yearly, but till and including 1903 the present system is to be followed; afterwards it will be eligible for members to be re-elected. There is still the same cumbrous mode of procedure about notices to nominate a new member from outside. Dr. Masters asked if the new charter would cause a total re-construction of bye laws, and was informed it would. Mr. G. Gordon regretted the smallness of the meeting, and made some suggestions as to election of council and its members. In reply, the president said in the past the difficulty had been to get gentlemen to give their time. Sir J. Llewelyn, Bart., seconded the adoption of the new charter.

National Carnation Society.—The report of this show will appear in our next issue.

NOTES OF THE WEEK.

Pratia angulata.—This is now freely covered with its pretty white flowers, to be later succeeded by equally attractive fruits. In a moist position in peaty soil the plant covers a large space quickly, and is also serviceable in large hanging pans in the greenhouse or cool fernery.

Nymphaea Froebeli.—Others have begun to take part in the good work done by M. Latour-Marliac, among them M. Froebel, of Zurich, whose N. Froebeli is a vigorous and hardy kind. After a trial of two seasons in open water it is now large and free in flower compared with the other highly-coloured kinds, and is a fine deep crimson.

Mazus Pumilio.—This pretty plant, with its Snapdragon-like flowers, is one of the freest of subjects for covering the surface of the ground in any cool or rather shady place. The plant must have one of these if it is to grow at all freely, for it dislikes dry and hot positions. For so dwarf a plant it is quite a vigorous subject and of considerable value by reason of its hardy character.

Delphinium sulphureum.—Some fine sprays of this plant were shown at the Drill Hall meeting on Tuesday last. The term "sprays" is here employed because of the spray-like character of the inflorescence, as a whole as distinct from the usual spike-like raceme of so many Larkspurs. In a group the free-branching character of this plant is very fine, and for this as much as its distinct colour this yellow Larkspur merits wide cultivation.

Geranium cinereum album.—This is one of those charming plants that everyone must admire at

first sight. Not merely for its delicate beauty and grace, but as much for its profuse flowering is it worth the attention of all who delight in dwarf and pretty rock plants. Indeed, it is these very plants which, while not furnishing material for cutting, provide at the present time the most beautiful of material in the rock garden or in the open garden, anywhere if you will.

Oenothera tetraptera rosea.—A very pretty and dainty coloured flower of the Evening Primrose family, a term, however, that in this plant appears a misnomer, particularly so as the blossoms remain fully expanded throughout the day. It is, perhaps, of biennial rather than of perennial duration, though it may survive certain mild winters or even moderately severe ones in somewhat favoured places. Should it prove perennial it will make a most welcome addition to its race.

The Royal Fern (Osmunda regalis).—While fishing on a small loch in the neighbourhood of Arisaig, Inverness-shire, I was surprised to see this beautiful Fern growing in such quantities. The plants were numerous and large, the crowns in many instances very prominent. There are two small islands where this occurs, and they are on the North Morar estate and not more than two miles from Loch Morar itself. On the shores of this beautiful loch I have failed to find *Osmunda regalis*. Can this be the natural home of this Fern, or has it at sometime been planted?—**BLUE HACKLE.**

Prunella grandiflora alba.—The white variety of the well-known *Prunella grandiflora* is a pretty plant, which is only met with occasionally in collections of hardy flowers. The white in the best forms is almost pure. It comes fairly true from seed, and from a batch of seedlings it is easy to select the best forms from which to propagate. Like most other flowers, a continuance of raising seedlings and choosing the best would probably lead to an improvement in the flower.—**S. ARNOTT.**

Synthryis reniformis.—I have to thank Mr. Carl Parry for having been at the trouble to note so carefully the colour of *Synthryis reniformis* as grown at Ukiah, in California. If the white *Synthryis* retains its colour when it is introduced into this country it will be very welcome in our gardens. One always finds white varieties of good flowers much admired. It is not difficult to imagine how pretty would be a good plant of *S. reniformis albus*, and how much such would be coveted by alpine growers.—**S. ARNOTT.**

Prunella Webbiana.—In the welcome "Notes from a Cornish Garden" on p. 52, "C. R." speaks of the pleasing contrast afforded by *Prunella grandiflora* with *Licaria tristis*. This leads one to draw the notice of flower growers to the variety of *P. grandiflora* named *P. g. Webbiana*, but frequently called, as I have done in the heading, *P. Webbiana*. The colouring is much brighter than in the typical *P. grandiflora*, being more scarlet than purple. I grow both here, so can speak of them from comparison on the spot.—**S. ARNOTT.**

Iris tingitana.—Like the other correspondents who have written you, I fear I must express my disappointment with this Iris. Although my experience of it is not nearly so extensive as that of Rev. C. Wolley-Dod, I have had it for several years and have not bloomed it more than once. It grows freely enough and does not appear to mind late frosts or the other enemies to which many flowers are subject. Rev. C. W. Dod's suggestive note may, however, lead to fresh attempts to find out its requirements in our climate.—**S. ARNOTT, Cursethorn, by Dumfries, N.B.**

Carnation Isinglass.—It will be a splendid Carnation that will surpass this lovely crimson-scarlet, if this is the true description of its colour. Perhaps a better colour definition would be deep rich scarlet, though even this conveys no idea of the intensity of the almost velvet hue that predominates the flower. Not only in colour, but equally in the firmness of the petals is it a grand Carnation. It was in good condition at Chelsea the other week, and the other day Mr. Salter brought to the Drill Hall, from Mr. Haywood's garden at Reigate, a lovely gathering of the same

thing. As a scarlet self it will long remain a variety of high excellence.

Campanula Warleyi.—The pretty Campanula bearing this name that secured an award of merit from the floral committee on Tuesday is quite an addition even to this extensive race of blue-flowered plants. In the group as shown the plant gave a pretty picture, though individually the plants do not appear to be endowed with much vigour or even freedom of flowering. A feature of the new-comer is the semi-double corolla, while the foliage gives one the impression here and there of *C. rhomboidalis*. Adverting to the mode of growth from the base, it reminds one of the rather frail and delicate *C. Lefflingi*. This is so in the apparent outspreading character, and equally so in the sparsity of the growth. In these particulars the two plants have much in common, but the flowers are very distinct.

Fritillaria pluriflora.—The valued "Californian Notes," by Mr. Carl Purdy, with the reference to this Fritillary on page 49, lead me to remark how hardy it appears to be and how well it withstands cold weather. Last autumn some bulbs were planted in a rather cold, exposed position facing N.E., and thus exposed to cold winds. The plants were nearly a foot high when the spell of exceptionally severe weather we had in March came. For more than a week the plants were fully exposed to the cold winds, and were so limp from the effects of the frost that they were literally prostrated by it. On the return of milder weather they recovered and seemed none the worse of the ordeal through which they had passed. Perhaps the absence of sun helped them to withstand the frost better than they would otherwise have done.—S. A.

Lilium chalcedonicum.—Few things are finer now in the garden than the rich flowers of the scarlet Turk's-cap Lily. Get sound, healthy bulbs, and, if possible, plant them quite by the end of August, or, if need be, transplant them also about this time, and in a position free, or nearly so, from mid-day sun. A rather stiff, holding soil is much better for this Lily than is the orthodox light, sandy loam so freely recommended for growing many things in. Too often plants suffer badly from soils deficient in body as it were, and the addition of quantities of humus is but a move in a wrong direction. Many Lilies are more vigorous in strong loam than in peat, and of these I am not now referring to those of a swamp-loving character. A sound loam well filtered by sharp grit will grow many things well, and not a few good alpiners may be included in this number.

Ixia viridiflora.—In his notes on "Bulbous Plants at the Temple Show," "S. W. F." (p. 38) speaks in appreciative terms of *Ixia viridiflora*. It is pleasant to find that one's impressions of this flower are the same as those of your correspondent. *I. viridiflora* was the most charming of the many beautiful *Ixias* shown. Most people cannot realise that there can be much beauty in a green flower, but the exquisite sea-green of this *Ixia* would go far to bring them round to another opinion even if it had not the black-purple throat which is so markedly effective. The hardness of the *Ixias* is only comparative, and I should like to know if *I. viridiflora* is not more difficult to protect in winter. Messrs. Wallace's flowers were exquisite in their colouring, but one would presume they had been grown under glass. The green-flowered *Ixia* is not often seen even in glass structures, and it ought not to be so little grown.—S. ARNOTT.

Mr. J. Wood's Scarlet Pea.—This perennial Pea is one of the best and most effective of a valuable genus for garden decoration. The colour is the brightest of any of the varieties of *L. latifolius*, and a large, well-established specimen is very beautiful. The colour is pretty well described by the name of Scarlet Pea. I do not know whether it originated at Kirkstall or not, but if not raised there it was, at least, sent out from Mr. John Wood's garden. Although occasionally seen, it is not often met with in gardens,

and one can only say that it ought to be more largely grown. It is not difficult to find a place in most gardens where a Pea such as this could be made use of with benefit. A light wooden trellis is cheaply and easily made, or can be procured at a low price in lengths. This Scarlet Pea clambering over a trellis is very pretty in its season of bloom. Other ways of growing it will readily occur.—S. A.

Lilium testaceum.—It is with pleasure that an old admirer of this fine Lily sees an appreciative note by "T." in THE GARDEN of July 22. It is one of the most satisfactory of our garden Lilies. Its beauty is enough to make it deserve room, and the ease with which it can be grown entitles it to the notice of those who have a difficulty in growing many other Lilies. On very dry soil, although a little dwarfed, it flowers freely enough, but is all the better for an occasional soaking with water before coming into bloom. As "T." says, the young foliage is seldom injured by frosts or cutting winds. It was in this garden when I came here about fifteen years ago, and has never failed to flower annually. The colour is very pleasing also, and is fairly well indicated by the application to it in some continental nurseries of the name of *L. isabellinum* from its shade of yellow.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Campanula Waldsteiniana.—Among the many beautiful and rare alpine plants, this one is all too rarely seen in good condition. In Mr. Whitehead's garden at Wimbledon the plant is evidently at home. It is perhaps not sufficiently recognised that there are several varieties of this plant, and particularly of the dwarf form. In what I believe is the true plant the lobed divisions of the corolla are almost ovate, and usually this form has a coloured exterior about the ovary. In one or two other forms I have seen the corolla divisions are more pointed, indeed all but acutely pointed, the flowers larger and more generally spreading. Yet in all these there are the same dwarf, compact growth and habit generally, save that in the true plant there is an inclination to a more glaucous tone in the radical leaves. Quite recently I have noted at least two varying forms of this exquisite little plant. In its best form it is nearly 6 inches high, and from June onwards to the middle or end of July it is studded with its pretty blue flowers.

Oenothera Youngi fl.-pl.—Without seeing Mr. Michael Cuthbertson's double (*Oenothera*, mentioned in THE GARDEN of July 22 (p. 71), one cannot tell wherein it differs from the above variety of *O. Youngi*, which is in itself a form of *O. fruticosa*. The double variety of Young's Evening Primrose is not a common plant and may more correctly be called semi-double than double. The cup of the flower is partly filled with smaller petals. The leaves are not purple, but are tinged with that colour, as are portions of the stems. This variety of *O. Youngi* is not very plentiful, but is offered in a few catalogues. When well grown the "doubling" is better than when on very light soil. In the garden it is not so effective as the single form.—S. ARNOTT.

P.S.—Since writing the above I have, through the kindness of the editor, had an opportunity of seeing Mr. Cuthbertson's new variety. The flowers resemble those of *O. Youngi fl.-pl.*, but the deep colouring of the stems, leaves, and buds adds greatly to its beauty. The contrast between this and the bright yellow flowers ought to make it valued. It looks to me as if it were a seedling from the variety of *O. fruticosa* named *Fraseri*.

The weather in West Herts.—The present spell of warm weather has now lasted over three weeks. The hottest days of the period were the 19th, 20th and 21st, when the temperature in shade rose respectively to 84°, 85° (the highest reading as yet registered this summer) and 83°. During the night preceding the 22nd the thermometer exposed on the lawn never fell lower than 58°, making this the warmest night experienced here in July for six years. The temperature of

the ground at 2 feet deep is now 4° higher, and at 1 foot deep 5° degrees higher, than is seasonable. The heavy rainfall of the 22nd and 23rd did not appear to either raise or decrease the temperature of the soil to any appreciable extent. At nine p.m. on the 21st the temperature at 1 foot deep stood at 74°, which, with the exception of June 19, 1893, is the highest reading at that depth as yet recorded here. Rain fell during the night of the 22nd to the depth of nearly an inch, and on the following day to the depth of rather more than a quarter of an inch. To give some idea of the welcome heaviness of these two falls when combined it may be stated that it was equivalent to a watering on each square yard of surface of nearly six gallons of water.—E. M., *Berkhamsted.*

TEACHING HORTICULTURE IN INDUSTRIAL SCHOOLS.

At the present time trained or fairly skilled labourers are very scarce, and market gardeners are greatly handicapped accordingly. To meet this want, and at the same time be doing good service to certain classes of the community, it has been suggested that horticulture be taught at industrial schools, and there is no doubt, I think, about this being a step in the right direction. As far as my experience goes, the idea has only been mooted in horticultural papers, and not put into actual practice other than at ordinary elementary schools, more especially in Surrey and at one industrial school. The managers of the Kingswood Reformatory, near Bristol, have anticipated some of their contemporaries around London by having decided several years ago to utilise their superabundant labour, and at the same time train a certain number of the more promising boys to become working gardeners. Twelve acres or more of poor land have been gradually brought into a fertile, productive state, fruit trees and bushes planted, and a good step made towards forming a fairly remunerative farm. The men who superintend the work are experienced gardeners, and in addition a series of lectures and demonstrations have recently been held under the auspices of the agricultural section of the Gloucestershire County Council. If this comparatively new departure is persevered with, there is every likelihood of a number of strong, active, well-disciplined youths being available either for employment in market gardens in this country or in the colonies. The Kingswood Reformatory is largely supported by voluntary subscriptions, and the philanthropists who take such an active interest in this admirably conducted institution are to be congratulated upon the good work they are doing. There are far too many young reprobates on our streets, and those who succeed in converting even a small portion of them into respectable working men, good soldiers and sailors, deserve our best thanks. SOMERSET VISITOR.

Recreation ground for Finchley.—The Ecclesiastical Commissioners, in view of the large interests they hold in the parish, have agreed to lend the Finchley District Council £5000 at the exceptionally low rate of 2 per cent. interest, for the acquisition of land for a recreation ground.

Names of plants.—*J. A.*—1, *Campanula latifolia pallida*; 2, *C. alliariaefolia*; 3, *C. Hosti alba*, probably; 4, *C. grandis*; 5, *C. carpatica* var.; 6, send again, too far gone. Please send only four specimens in any one week. Others shortly.—*S. H. Boyle*.—1, *Periploca graeca*; 2, *Ailanthus glandulosus*; 3, Black Walnut (*Juglans nigra*).—*G. C.*—1, *Genista aetnensis*; 2, we cannot undertake to name Roses.

"The English Flower Garden."—Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d. Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.

ORCHIDS.

LÆLIA JONGHEANA.

It is pleasing to record the re-introduction in quantity of this distinct and desirable *Lælia*. An importation was offered in the autumn of last year as *Lælia præstans*. This importation was in remarkably fine condition, many of the pieces containing hundreds of bulbs. Some of these plants have since flowered and proved to be the rare *L. Jongheana*, which has been for many years practically extinct. Only two or three plants are recorded as having flowered from the original importation. The species having been determined, no time was lost in procuring the plants in quantity. Thinking a few particulars as to its native habitat might be of interest to readers of THE GARDEN, I sought an interview with Mr. E. Kromer, of Roraima Nurseries, West Croydon, where he has recently established himself as an importer of Orchids, &c., from South America. No one is better acquainted with Brazilian Orchids, and none more ready to give information that may be of use to the cultivator. In answer to my query as to the native habitat of *L. Jongheana*, Mr. Kromer gave me the following information: It comes from Central Brazil, from the State of Minas Geraes, growing on trees at an elevation of over 2000 feet. The conditions required for its successful culture are similar to those under which *L. flava* is found to succeed, but in a brighter and more exposed position, where it can obtain the maximum amount of strong light, shading only when the foliage is likely to become scorched from the direct rays of the sun. The most interesting information as far as the Orchid grower is concerned is the period at which it will flower. This, Mr. Kromer says, will, after the plants have become established, be during the months of January and February. This adds considerably to its usefulness, for it will be found most valuable flowering at one of the duldest seasons of the year. I saw with Mr.

Kromer plants that had recently been taken from the cases in splendid condition, many of them with their flowers expanded, but, opening in the secluded and dark conditions of the packing cases, very little form or colour could be determined. They were sufficient to recognise the plants by and to satisfy the most exacting expert as to their identity. In growth it resembles a gigantic *L. pumila*, but with more oval-oblong bulbs, the leaves also being flatter and thicker. The flowers are always produced on partially developed growths, which reach maturity almost directly after the flower decays. I noticed that the seedling plants do not flower in a very small state, but as soon as maturity is reached they bloom regularly every year afterwards. The small growth suggests its being best accommodated in baskets or shallow pans, so that it can be suspended near the roof glass or in a position where the maximum amount of strong light may be procured. Flowering in winter, as stated above, light will be a great consideration, especially in the neighbourhood of London or other large towns.

L. Jongheana was originally discovered by M. Lebon, who sent plants to M. de Jonghe at Brussels in 1854. It seems to have disappeared afterwards, and nothing was recorded of it until 1872 when a plant flowered in the nurseries of MM. Thibaut and Keteleer at Paris. In the following year a plant flowered in Messrs. J. Veitch and Sons' nurseries at Chelsea, and the following particulars were then given: The sepals and petals and base of the lip are deep amethyst-purple, the throat and centre, including the fine crenulate keels, yellow. In front of this the colour passes into yellowish white, while the crisped margin is more or less suffused with purple, gradually shading off into the white of the centre. Messrs. Veitch remarked in their "Manual of Orchidaceous Plants" (part ii., 1887) that it was then, fortunately, represented in several British collections. This statement is very questionable, and I have never seen it in any collection with the exception of Baron Schroeder's at The

Dell, Egham. One hybrid has been raised from the intercrossing of *Cattleya Trianae* and *L. Jongheana*, and named *Lælio-Cattleya Baroness Schroeder*, which was raised in The Dell collection. It was exhibited at the Royal Horticultural Society's meeting on August 23, 1892, and received a first-class certificate.

H. J. C.

Trichopilia lepida.—This is an uncommon and very beautiful plant not unlike *T. marginata*, but with a deeper margin and pretty wavy lip. In habit it is similar, and it is occasionally imported with it. Its culture is not difficult when once it has been induced to root freely in the compost, and it likes best small pans with no more room than is necessary to easily accommodate the plant. During the season of active growth a fair amount of moisture is necessary, but the roots are very easily injured by over-supplies, especially in winter.

Cypripedium Sedeni candidulum.—In this fine form, which was raised by crossing *C. Schlimi albiflorum* and *C. longifolium*, the sepals and petals are white and the lip bright rose. It is a distinct and free-flowering Orchid of great value. Its relation to *C. Schlimi* is shown by its nearly always being in flower, while from its other parent it has inherited a fine constitution and habit, rendering it one of the easiest Orchids to grow. In an intermediate house lightly shaded the growth is very free, and it requires ample moisture.

Masdevallia muscosa.—This plant with its singular flowers with mobile lips is more plentiful than formerly in collections, and is very interesting. The stems of the flower-spikes seem by Nature intended to prevent the access of crawling insects to the blossoms, the lip of which seems to invite winged ones by its bright bit of colour. The slightest touch only on this is necessary to move the lip, and in a wild state no doubt the plant has its flowers fertilised by these flies or other insects alighting upon it and carrying away the pollen masses. The flowers are somewhat neutral in tint, but graceful and pretty. It is a native of New Grenada.

Cypripedium superbiens.—This is one of the handsomest of *Cypripediums*, and though an

old denizen of our collections, it is well worth a place in the most refined. The foliage is handsomely marked in the way of that of *C. barbatum* and the flowers are also similar in build. The immense dorsal sepal is white with lines of purple and green, the petals are more lightly veined and spotted with blackish purple, while the lip is a rich purple-brown. It likes ample warmth, a shady and moist position while growing, with a very plentiful water supply all the year round. Equal parts of peat, loam, and chopped Sphagnum, with some roughly broken crocks suit it well for compost.

NOTES ON DENDROBIUMS.

MOST of the evergreen section are getting over, *D. Farmeri* being one of the last to flower as a rule, and as there are not many of the Australian kinds in bloom as yet, the house devoted to Dendrobiums is not very gay just now. A few spikes of the useful white-flowering *D. Dearci* may be seen, and I have noticed *D. taurinum* in flower during the week, while a few others could be named that are showing more or less. Growth in almost every case is the order of the day, and where there are nothing but Dendrobes in a house the temperature should be kept well up and a brisk, moist atmosphere maintained. Shading is necessary only to a very limited extent, as the plants are better for all the light. Were it possible indeed to keep the atmosphere moist and at the same time admit plenty of air, there is not the least doubt that the plants would benefit by being exposed to the full sun, especially if the glass was good. Common glass has done a great deal of harm to fruit growers and growers of Orchids, and the presence of starred panes, often unsuspected by those in charge, is the cause of many a case of scalding. As a rule, it is safest to shade a little and close the house wherein they are grown early with ample moisture, at the same time drawing the blinds up. This will create the buoyant and stimulating atmosphere that these Orchids delight in, and the moisture settling on the glass will prevent scalding. Towards evening a little air should again be put on below, as it is not high night readings, but stimulating conditions by day that help the plants. The air at night prevents any likelihood of the growths being soft, and grown under these conditions the stems are more likely to flower freely, and not so liable to produce abortive, mis-shapen flowers as when they are grown soft and then hurriedly ripened. In many modern-built Orchid houses there are shallow tanks with hot-water pipes running through them, and these may now be kept filled, as the moisture given off in the atmosphere cannot possibly do harm at this time of year. A little sulphate of ammonia in these tanks occasionally has been found of great assistance, improving the colour of the foliage and the general health of the plants.

Many of the evergreen kinds of the densiflorum and suavissimum types will by now be finishing up, and may, if convenient, be placed in a cooler temperature. If not, the plants should be arranged near the door of the house, or in some position where the atmosphere is a little drier, for although they may produce and finish up another set of growths this season, the plants that continue longest in health are they that keep to an annual cycle of rest, flowering and growth each in its proper season.

There may still be some of the later-flowering specimens not yet potted, and these should be seen to without delay, for unless they are soon done the roots will not have time to get a good

hold of the new compost by the winter. It has been a good deal the custom in some places to leave these plants to get very badly pot-bound before repotting, under the impression that they flower more freely; but this idea must not be carried to excess, or the plants will get weaker every year and eventually die. This has caused in many cases the troublesome habit the plants have of ceasing to grow at the base. Most of this class of Dendrobiums will be found to do better in rather large receptacles and rougher compost than the deciduous kinds, the latter never being so much at home as when the roots are closely coiled about the inside of a small pan or basket. The manner of potting otherwise and the quality of compost are similar to those required for the other members of the genus. The pretty *D. chrysanthum* will soon be showing its buds and rather less water will be needed as the growths finish, but no attempt must be made to dry off and ripen this plant like the majority of its deciduous relatives. When it flowers, as it frequently does, with the green foliage still fresh upon the stems it is very pretty, and large, old specimens with pendent growths well flowered are grand for a couple of weeks.

Turning to such as *D. Phalenopsis*, *D. Johnsonæ*, and the majority of the showy Australian kinds, it will be noticed that in most cases young growths are starting from the base, and in the case of *D. Phalenopsis* higher up the stems as well. All such must now be brought well up to the light, for although these flower upon the young stems as well as the older ones, the blossoms are not nearly so freely produced in shady positions as they are when growing close to the roof-glass. The earlier deciduous kinds, such as *D. heterocarpum* and *D. crassinode*, will by now in many cases have finished growing, and by their removal by degrees the Australian kinds named will be made room for. Of course, the latter are much better in a position where they get the full light all the year round, but it is absolutely essential now that they are not shaded in the morning and after closing-time. H.

Ronanthera Storiei.—When this plant was first shown by Sir Trevor Lawrence, Bt., some time ago it was awarded a first-class certificate. At the last meeting of the Royal Horticultural Society it was again shown, this time by Mr. Gurney Fowler, and by an oversight was awarded a first-class certificate under the name of *R. Imshoottiana*, which had previously received only an award of merit. At the time that Orchid was shown the rule that all plants which received any award were to be painted and the portraits kept for reference was not in existence, and had it been so, the mistake now mentioned would not have happened. A correction was subsequently made. —J. T. BENNETT-POË.

Dendrobium Dearci.—I consider that this plant is much better grown than formerly, and certainly finer specimens of it are exhibited than used to be the case soon after its introduction. Many hundreds of plants of it must have been lost during the first ten years it was imported, and possibly the rush for it caused it to be collected at an unsuitable time. There are few if any more useful kinds, especially for cutting, its flowers lasting well and coming in when Orchids are getting over. It likes a bright, sunny position towards the end of the growing season, and a thorough ripening and rest afterwards. The flowers are produced on the current year's growth, and sometimes the same stems flower again the next year.—H.

Lælia crispa.—This delightful old species is now finely in bloom, and there are few more beautiful at this time of the year, the contrast between the pure white sepals and petals and the

deeply tinted prettily fringed lip being exquisite. It is one of the best growers, thriving well in company with *L. purpurata*, which it resembles a good deal in habit and also in its other cultural requirements. Like it, the roots are most at home where large lumps of charcoal and crocks are plentiful in the compost and where free drainage is provided. The plants commence to grow in early spring, and at that time need careful watering. When the growths begin to root freely a lot of moisture is required, and this must be kept up until the flowers are past and the pseudo-bulbs finished up, when gradually reduce it a little. *Lælia crispa* is a native of the neighbourhood of Rio de Janeiro, and was introduced in 1826.

Odontoglossum Halli xanthoglossum.—This fine variety is now in good form with me, the spikes upwards of a yard in height and the flowers fine and of great substance. The ground colour is a greenish yellow tint covered with large blotches of chocolate-purple, the lip yellow and finely toothed. It is one of the easiest of all Orchids to grow, and will often thrive where *O. crispum* and similar kinds are a failure. For some reason it does not seem to take a very high position among Odontoglossums, but it is certainly worthy of all care. The roots are fairly persistent, and will thrive with rather more material about them than will those of *O. crispum*, this consisting of equal parts of peat fibre and Moss over good drainage. It is more or less active all the year round and no drying-off season is required, while during growth plenty of moisture may be given without fear. Those who have not the convenience of a cool Orchid house may grow *O. Halli* and its varieties very well in a cool, moist greenhouse or fernery, or even in a cold frame outside during the summer months. From May until the end of August it can hardly be kept too cool or the atmosphere about it too moist and shady.—H. R.

Cattleya Schofieldiana.—The flowers of this species are very striking and distinct, and it may be grown in any collection with advantage. From the top of the stems it produces a number of bold, handsome flowers, the greenish ground colour of which is covered thickly with bright crimson spots. Under cultivation it will be found to do well in company with *C. guttata*, *C. granulosa* and others of this class, preferring a medium-sized pot or basket, with the usual mixture as advised for Cattleyas generally. From the time the flowers are past until the growth again starts only just sufficient moisture should be allowed to prevent shrivelling of the stems and leaves, and even when in growth care is necessary, for if the temperature gets a little low, with undue moisture either in the atmosphere or at the roots, the stems are very apt to decay about half way up. This destroys the chance of flowers, of course, and is weakening to the plant. As with all Cattleyas of a like habit, the soft white scale insect seems particularly fond of *C. Schofieldiana*, and continuous care and repeated spongings are required to keep this pest in check. It is a native of Guatemala and first flowered at Newhall Hey, near Manchester, in 1882.

Stanhopea tigrina.—This quaint yet showy Orchid I have noticed in one or two places lately, and some plants I saw in a neighbouring garden had not been potted for over ten years. They were flowering abundantly none the less, and the blossoms were very fine. As a general rule, however, I should not advise leaving the plants so long without new material, as they are bound to suffer badly when pulled about after being so long in the old material. Provided they are carefully handled and not disturbed more than is really necessary, the plants are not, as is generally supposed, prevented from flowering again for years. I have often given *S. eburnea* a new basket after flowering in spring, and it has bloomed again in the autumn. *S. tigrina* is equally free-blooming, but does not as a rule produce flowers in autumn. The plants both do well in wire baskets in a mixture of Sphagnum Moss and loam, with a little charcoal mixed and some

large pieces of this material about the bottom and sides. These allow of the spikes pushing readily through either way, for in many cases they go straight down and in others they push from the sides. The baskets should be suspended in the warmest house and the plants frequently syringed to keep red spider in check.—H. R.

Epidendrum vitellinum.—This cheap and popular species is one of the best of all for cutting and wonderfully effective when arranged with such kinds as *Odontoglossum Alexandræ* or *O. Pescatorei*. The bright vermilion of the *Epidendrum* shows well against the white of the *Odontoglossums*, and the time the flowers remain in good condition without in any way harming the plants is remarkable. No special house is required for this Orchid, which is well worth a place in a cool fernery, where the bright green of the foliage and the showy blossoms are very pretty against the Ferns. The plants thrive in equal parts of peat and Moss in pots of medium size, and though the roots are not fastidious, they dislike being disturbed oftener than is really necessary. Give the plants a fair shift when they are needing it, preferably in early spring, and remove at the time all decaying roots or sour compost, washing the whole of the roots in a bad case of decay and using pots of smaller diameter than usual. The plants delight in copious moisture when the weather is bright and they are growing freely, always provided the pots are well filled with healthy roots, and light overhead syringings are refreshing and beneficial. The plant should be purchased in bloom when possible, as the flowers vary greatly in point of size.

Wild Orchids.—These have been unusually fine this year, the dripping June having suited such kinds as *Orchis pyramidalis*, certainly one of the most beautiful of the British species. Here it is one of the most common, and one can see the many variations in shape and colouring so noticeable in indigenous species as well as exotics. The species in question varies from a very light mauve to the deepest crimson-rose and is beautiful in all. The spotted *O. maculata*, though less bright than *O. pyramidalis*, is very fine, the long, loose racemes occurring in all sorts of positions, but always finest in shady, moist places. A few spikes of the distinct *O. ustulata* have been noticed this year, but though more rare it is less attractive than the others, and I have picked a few spikes of what appears to be a hybrid between this and *O. pyramidalis*. No doubt there are many hybrid forms in these wildings, and unless I am much mistaken I have noticed traces of *O. mascula* in some of the earlier spikes of *O. maculata*. In a cool, shady wood the British Butterfly Orchid flowers well and late, and I have spikes of it now mixed with other hardy species, and very pretty is the contrast between the creamy white tint of these and the bright red of *O. pyramidalis*. Quite a different style of plant is the Bee Ophrys, and rarely found in this neighbourhood. In the chalky hilly districts in the south of England it is common, but easily overlooked on account of its size.—SUFFOLK.

Vanda Sanderiana.—Quite distinct from all other Vandas—indeed, from every other Orchid—this is a noble and effective plant, and it is a pity that it has not led to cultivators giving the genus more attention. Coming as it does from the Philippine Islands, this *Vanda* delights in ample heat and moisture while making its growth, and all that is necessary is to see that a moderate amount of air and ample light are secured to the plants, so that the growth is in a manner consolidated. Like the *Phalaenopsis* from the same region, it needs heat—sun-heat for choice—and as this cannot be had in this country in conjunction with air in plenty, the best thing we can do is to see that the atmosphere is not kept closer than is really advisable, and that during dull periods even in summer a little warmth is kept on the pipes to keep the air moving. Unlike some Vandas, this species does not seem to push its roots so far in search of moisture, and the healthiest plants I have seen have always been

those that have had their roots packed rather closely together in the baskets. Here they take ample moisture, and are far more healthy and longer lived than they would be in a large receptacle with a lot of wet material about them. For compost, nothing but clean, freshly gathered Sphagnum Moss, kept well apart by the addition of charcoal and crocks, need be used. Keep this very moist during the time growth is active and up to and including the flowering season, but in winter *V. Sanderiana* likes a distinct rest, and at this time at least does well in the Cattleya house. Suspend the plants in a good light, and water only sufficiently to prevent the foliage shrivelling, or the plants will not flower freely.

PARK AND WOODLAND.

THE CORSICAN PINE.

(*PINUS LARICIO.*)

The Corsican Pine attains sometimes to a height of close upon 150 feet and a circumference of 17 feet or 18 feet. The stem, which is much oftener cylindrical than conical, divests itself very slowly of its lower branches when growing in or on the borders of open clumps, but more rapidly when growing in dense masses, and finally becomes quite bare of branches from the summit downwards. In a tree 80 or 100 years old, or older, the summit becomes flattened in consequence of the bending of the leading shoot. Five-sixths of the length of the tree at this age is good timber. The cover afforded is at first thick, and becomes light only after the tree attains its maturity; even then it is not so light as *P. sylvestris*.

The Corsican Pine is found in mountainous regions. It makes its first appearance often along with *P. maritima* at an altitude of 2789 feet, and is found as high as 5578 feet, at which altitude it is only a stunted bush. It does best in a clayey gravel soil, and it attains its fullest development on fairly cool soils. Its growth in diameter is not rapid. The timber of the Corsican Pine is white in very abundant layers, and varies from a rose-red to a brown-red according to its quality. The autumn tissue of each layer is clearly marked and of relatively great thickness. The resin ducts are very plainly seen, and contain a thick turpentine, which by filtering through the tissues and impregnating them with abundant resin often renders the wood as hard and translucent as horn. The wood has a fine close grain. The timber of this Pine is excellent for building. The feebleness and evenness of its annual growths—in which it bears a certain analogy with *P. sylvestris* of the north—joined to the fine dimensions which it attains to, gave rise to a hope that, like *P. sylvestris*, it would furnish masts of the first size. Experience has not justified this hope. The wood of the Corsican Pine is too charged with resin and too heavy; its fibre is short and of little solidity, as is proved by numerous small cracks produced by desiccation and shrinkage; it is wanting in suppleness and is brittle. The French naval authorities have for these reasons refused to use it for masts, for which purpose it is nevertheless used in the Italian marine. This excess of resin where it exists also renders the wood less valuable for industrial purposes. It furnishes, nevertheless, planks for the Toulon Arsenal, and there is no doubt it makes excellent and lasting sleepers for railways.

The qualities of the Corsican Pine are besides very variable, and an attentive study of the circumstances—formerly little known—which determine these qualities will doubtless govern the production. It seems, however, per-

missible to affirm that, considering the slowness of its growth, its value will always be very high, and that to regulate this it will be proper to consult much less the dimensions of trees and the thickness of the last annual layers than the volume and development of the perfect wood which alone is useful. It has yielded essence of turpentine, resin and pitch of good quality, but insufficient to pay for the outlay.—*Flore Forestiere.*

ROSE GARDEN.

ROSE CELINE FORESTIER.

THOSE who are in the habit of closely pruning all their Roses irrespective of kind or habit will have only a moderate opinion of this pretty variety, but when it is allowed to ramble almost at will, simply cutting out any very weak or old wood and stopping extra vigorous shoots, what a beautiful thing it is. It is so distinct in habit and the colour and shape of its flowers as not to be readily mistaken for anything else, and here it is nearly always at its best after the first flush of Roses is over, and consequently fills a gap. A little observation of the way this Rose flowers will show the fault of pruning closely every year. The ends of the new shoots flower it is true, but the majority of the blossoms occur upon laterals produced from the side of the previous year's wood, so the more this is shortened the less flower is produced, and, again, the pretty and distinct habit is lost. Although Celine Forestier flowers well against a wall, I never like to see it in such a position. It is true the young wood may be laid in and retained almost wholly, but unless these shoots can hang naturally, the plant loses a lot of its elegance and grace. It is not so bad when, as frequently seen in cottage gardens, it is nailed up to the wall, the shoots being allowed to push out a yard or more from it. This freedom enhances its appearance materially, but Celine Forestier, like Aimée Vibert and one or two others, never looks so pretty as when allowed to take its natural form, on the grass for choice. The foliage is pretty at all times, and there are nearly always a few flowers to be seen, and, as noted, just when there is a scarcity of bloom in the Rose garden it is usually at its best. Roses as a whole attain their finest proportions on a rather heavy soil, but this variety does best on a medium or light one, and if the position is a fairly sheltered one, so much the better. Light soils need a lot of manure, and it is useless to try and grow a great mass of foliage and flowers in a poor, hungry soil. When the border or station for it is made, the bottom spit where the soil is light should be well enriched with cow manure, this being of a cooler nature than that from the stables or piggeries. Again, if the hose can be laid on and a thorough soaking of water given at the roots in very dry weather, it is well repaid by the increased freshness and vigour of the plant. GROWER.

Rose Mrs. F. W. Landford.—The colour of this beautiful sport of Mrs. J. Laing is all one could desire, a clear pale blush, shading to white. I fear it will turn out to be inferior in substance to the variety it originated from, the chief defect being a hollow centre. Whether it will improve as a cut-back remains to be seen. If it does not, I do not see we shall gain much by its introduction.—P.

Rose Rosetta de la Legion d'Honneur as a standard.—This Rose makes a really handsome standard, as, indeed, will most of the so-called climbing Teas and Hybrid Teas. The shoots are elegantly disposed, there being no crowded or heavy appearance whatever. The flowers when open are not exceptional,

the main attraction being the yellow band down the centre of the petals. The buds are really charming, making a lovely little rosette of a bright carnation-red, with a slight orange shading. Three or four of these tiny buds make a neat and pretty button-hole.

Rose Francois Michelin.—This fine Rose has been somewhat eclipsed by better autumnals of its own colour, such as Helen Keller, for in reality Francois Michelin is but a summer Rose. This should not, however, prevent its inclusion in any good collection, as one does not miss such kinds in autumn when the numerous Hybrid Teas, Teas and Bourbons abound. It is a splendid Rose both in form and colour, and recently received the silver medal as the best Hybrid Perpetual in the show. It makes long slender growths quite distinct from other kinds in habit and also in the peculiar light, greyish green wood. These growths should be left of a good length when pruning, even as much as 18 inches from the last season's pruning. It is well suited where a tall mass is wanted quickly. As is now generally known, Mr. Bennett was fortunate enough to seed this Rose, one result being the superb all-round Hybrid Perpetual Mrs. John Laing. This was a striking proof of the value of cross-fertilisation, for hitherto this variety, so far as I am aware, was never known to produce seed.—P.

ROSES ON PILLARS AND ARCHES.

"H. R." asks for the names of a few Roses that will quickly furnish themselves at the top. Unfortunately, true running Roses that flourish best in this country have in most cases very small flowers. On the Riviera and the Continent generally one often hears of Cloth of Gold, or Chromatella, as it is called, Maréchal Niel, Lamarque, &c., clambering away in wild confusion, but it would be useless attempting to grow such kinds upon trellises in our country unless it were in the south. There one can find Climbing Devonensis, Fortune's Yellow, the Banksians, and similar Roses making most luxuriant growth. "H. R." class becoming thick at the base. I do not look upon this as a fault; rather the reverse. It is from the new growths constantly starting out from the lower parts that the healthy condition of a climbing Rose is maintained. This is far better than seeing long, scraggy growths with just a bloom or two at the top. If a good furnished top is desired to a trellis, I would recommend "H. R." to bud some of the kinds named below upon tall standard Briers, the tallest he can procure. In many old hedges and quarries I have obtained Briers with 7-foot to 8-foot stems. If these were planted in their permanent positions, a good plant would be secured in a year and a half. In the meantime the same variety could be planted at the base. This plant in the period stated would reach up to the standard, and the object desired be partially, if not wholly, gained. As "H. R." truly remarks, a great deal of feeding is necessary for these climbing Roses. I have often urged this in these columns. They really require treatment something after a Vine. It is a great mistake to plant climbing Roses in any ordinary soil. The borders should be well trenched and plenty of manure added. Some bone-meal in addition would be advisable, and where the soil is not particularly good a cartload or so of one-year-old meadow loam would repay the expense. To induce these climbers to break more from the upper part of the growths, much can be done by early stopping of the bottom laterals, and if the growths become too thick at the base, then remove them and divert the sap to the upper buds. By stopping the shoots at the top about this time of year they become more ripened and more likely to come through a winter uninjured and break out at the top the following spring than they would if allowed to continue making a soft growth. It is the injury from spring frosts to the unripened wood that gardeners have so much to fear from the better class of clambering Roses.

As worthy companions to Crimson Rambler there appears no doubt that the three varieties

named after the three Graces—Aglaiia, Euphrosyne, Thalia—will be in much demand. They have the free, rambling habit of the multiflora tribe. Aglaiia is canary-yellow in colour, the flowers produced in large, pyramidal bunches. Euphrosyne has also large bunches of pink bloom, and Thalia is a semi-double form of the Polyantha simplex. These Roses grow well, but they require time to furnish themselves ere one can have much bloom. Claire Jacquier is grand. It makes enormous growths, and when established about three years is smothered with large trusses of pretty double pankeen-yellow flowers something like Perle d'Or. It is, unfortunately, not quite hardy and would need watching in severe weather. For rampant growth the new hybrids of Rosa Wichuriana are unequalled. They are really creeping Roses, but would look equally beautiful on a trellis. The leaves are bright and shiny and the flowers of the newest kinds are said to be of good size, although mostly single. There are about nine varieties of various colours, such as white, cream, blush, pink and carmine. A really splendid grower is Reine Olga de Wurtemberg. I know of no more luxuriant climber than this and it is almost evergreen. The semi-double brilliant red flowers are most showy and picturesque, and I should say that this, together with Mme. Alfred Carrière, would be two first-rate kinds that would meet the requirements of "H. R." I have seen Mme. Alfred Carrière growing as freely as one could possibly desire, and its fragrant creamy white flowers are freely produced.

The Garland is a most vigorous grower, producing when well established immense corymbs of buff coloured flowers that are very pretty in the mass. The Ayrshire and Evergreen Roses, such as Félicité-Perpétue, with its lovely little rosette flowers pure white in colour, furnish some of the fastest growers. It is one of the best companions to Crimson Rambler, blooming about the same time. Ruga, blush-pink, and Flora, shell-pink, are both first-rate rambling kinds. Mme. d'Arblay is a very luxuriant grower, but its semi-double tinted white flowers are not very conspicuous. Daniel Lacombe is a very pretty flower, and, what is more to the purpose, it grows well. The colour is chamois-yellow, tinted with rose. Laure Davoust would doubtless be a kind "H. R." is looking for. Its double flowers are of a very beautiful blush-pink shade. Jaune Desprez is a fine old variety belonging to the Noisette, and will certainly grow well and is almost hardy. Its flowers are a mixture of buff-red and sulphur. Another most useful Noisette is Aimée Vibert. This Rose may be seen in country places completely enveloping cottages with its snowy white blossoms and shiny green foliage.

PHILOMEL.

Rose Marchioness of Londonderry.—Magnificent is a term often applied to this Rose. It well deserves it when about half open, its deep globular ivory white flowers being so clean and beautiful. But the beauty of the flowers is not maintained, the full-blown blooms being anything but pleasing; indeed so repulsive are they, that I would advise anyone growing this Rose to remove the flowers ere they reach this objectionable stage. This year the variety has been grand upon two-year-old plants, and even now the maiden bushes are yielding some delightful flowers that look something like large Magnolia blooms when about to open. Marchioness of Londonderry is evidently of the Victor Verdier race.—P.

Rose Killarney.—In point of colour I know of no Rose with such delightful freshness as the above variety. The term shell-pink is often employed when desiring to describe a peculiar clear pink, and this designation aptly describes Killarney. There is also a faint white edge to the petals. As individual tastes differ so much, this Rose will gain admirers by reason of its semi-double character, but by others, especially exhibitors, this thinness will be deplored, for the lovely petal and conical centre raise one's hopes, only to be dashed to the ground after the bloom

has been boxed up for a few hours. As a garden Rose it will be much esteemed, for it flowers as freely as Mrs. W. J. Grant, from which I should imagine it to be a seedling. Killarney grows well and blossoms abundantly, and I shall not be surprised to see many lovely seedlings emanating from it.—P.

Rose Andersoni.—To term this an improved Dog Rose would not be far wrong. It is indeed a most profuse bloomer. Taking this fact into consideration and also remembering that its flowers are each 3 inches across, it would seem to be worth cultivating, although the line must be drawn somewhere, or our gardens will be overstocked with these pretty, but fugitive varieties. In general appearance the flowers are very much like those of the hybrid Sweet Brier Amy Robsart. Andersoni has an unusual abundance of golden anthers, which gives it a somewhat rich appearance, especially when the variety is planted to form a hedge. It is well adapted for this purpose, its growth being more compact than in many of the single kinds. Almost every exhibit of garden Roses put up this year contained Andersoni, which proves it to be a general favourite.

Exquisite tints of some recent novelties in Roses.—Most interesting is it to learn from such a good authority as M. P. Guillot the history of that charming Rose Mme. Laurette Messimy. As he justly remarks, it has indeed created a new type. Can it be that his later productions are the result of similar crossing? Mme. Eugène Resal is even more delightful in colour than Mme. Laurette Messimy, and there seems to be a wonderful affinity between this latter kind and the newer Tea Roses, such as Souvenir de Catherine Guillot, Mme. René Gerard, Souvenir de J. B. Guillot, Mme. René de St. Marceau, and Margherita di Simone, all of which it is impossible to do full justice to in describing their colours. I should like to see some attempt made to increase the size of this class of Rose. At present the fullest of them is Souvenir de Catherine Guillot, a variety that has been much admired this year, the orange shading making it even a more general favourite than l'Idéal.—P.

Rose Mme. Alfred de Rougemont is a charming little Rose belonging to a most useful group that produces the welcome blooms just when the Hybrid Perpetuals are waning. For free flowering, the Noisette Perpetuals are almost equal to the Tea-scented, but, of course, do not approach that tribe in beauty and refinement of blossom. However, they are valuable garden Roses, although mostly of white or pinkish white colours. Mme. Alfred de Rougemont has pretty red buds, that show up well among the white, delicately tinted flowers. If used in the flower garden, the centre plants should be trained as pillars and the outer row pegged down if necessary. This method is adopted on the Continent, and it certainly has the merit of boldness. Even with such Roses as Camoens and Marquise de Salisbury a less formal effect would be produced if the centre plants were somewhat elevated. Nearly the same results may be achieved if half standards and dwarf standard plants are used for the middle of the bed, but these are not always obtainable. Other good Noisette Perpetuals would be found in Coquette des Blancches, one of the freest and best white Roses, and Mme. Auguste Perrin, a delightful Rose, with light and elegant flowers, pale rose in colour, the reverse of the petals whitish. In Mme. Fanny de Forest, a large Rose for this group, the flowers are a salmon-white, changing to a rosy white. Mme. Francois Pittet has beautiful red buds, which are charming among the small snow-white double flowers. Mme. Blanche Durrschmidt is an exquisite blush-white Rose, with very loose flowers, which are produced in large clusters, often as many as seventeen buds and blossoms upon a single truss. Paul's Single White, a very pure white and withal a free bloomer, is quite at home upon an arch, wall, or pillar, the large white blossoms being very showy.—P.

JAPANESE WAYS OF ARRANGING FLOWERS.

MR. EIDA, a Japanese, well known in London for the introduction of the bronzes of his country, has opened a little exhibition of flowers arranged in the Japanese way at No. 5, Conduit Street, Bond Street, in which one can see—though no doubt to much disadvantage owing to the difficulty of finding the sort of plants the Japanese use most—ways very different from our own of arranging flowers. There is a good deal of very curious and subtle writing about this in a list he publishes, such as the following:—

Several styles are practised—as the Koriu, the Enshiu, the Mishe, and the Ikenobo—and in each of these are various schools, each with its own interpretation of the universal rules, and each with its own secrets of manipulation. And among all of them curious traditional meanings are attached to the parts that go to make a flower composition. Thus, in the general formula of Ten-chi-jin, the three main stems stand for the heavens, earth, and mankind. A tall, almost upright, leaf or stem will represent Ten, the sky; a lower leaf carried in a sweep almost horizontal is Chi, the earth; while a third, on the opposite side and higher than Chi, though lower and smaller than Ten, is Jin, the people of the world. A five-leaved formula represents wood, fire, metal, earth, and water. But none of these formulæ is allowed to disturb in any way the attainment of pure beauty in the result. Indeed, they act rather in the manner of mnemonics, keeping the laws of the art before the eyes of the pupil, just as do the principles of In and Yo, or male and female—a formula recognised through all Japanese art. In the matter of flowers, the upper surface of a leaf is called male, the lower female; buds are female and full blossoms are male; blue is male and yellow female, and so forth; and the proper proportioning of male and female in flower, leaf, stem, and colour ensures harmonious blending in the result.

But when one looks from words to things, the difference of the Japanese way is simply that of recognising the beauty and importance of form, and of showing the whole beauty of the plant, instead of the too common way of jamming things into nose-gays, in shape like a Cauliflower. The result of the latter we all know, and it is a very rooted habit in England. Indeed, it runs through all our flower-market work, and leads the excellent Rose growers of London to send their flowers to the market with the heads cut close off and without a bit of stem, so that one cannot place a Rose in any natural and simple way if we depend on such supplies. In Paris, and also in America, Roses are sent to the market with fine vigorous stems, and there need not be the slightest difficulty in cutting them here in like ways. In our country the beauty of the whole plant is not thought of, but simply the flowering part. The Japanese way is the very opposite of this. They are satisfied with a much less quantity, and even the commonest things, such as a spray of Larch,

a stem of Solomon's Seal, or a tuft of Iris, are arranged so as to show the whole beauty and stature of the plant, form of leaf, bud, and flower, and never too much of it. No doubt it is a very important lesson to learn, though as we see Japanese arrangements done in England it sometimes occurs to us that the same results could be obtained in a simpler way than those of the Japanese. They, in working in their beautiful bronze vases, take an amount of pains which, we think, is not always justified by the result; the more so as in our country we can

A growth of the Parlour Palm (*Aspidistra*) in a Japanese vase.

have a greater variety of vessels, many so shaped as to receive a flower at once and to show its beauty completely. Some of the Japanese skill arises from the need of adapting things to their bronze vases which seem to be most in use with them.

One of these Japanese artists in flowers, looking at some of our pictures of flowers by Mr. Moon, at once said, "Why, these are our ways of arranging flowers!" simply because of the fact that the artist had chosen a very few simple things, and shown them in their full beauty. The Japanese attach, and rightly, much more importance to form than English growers do. Their difficulties of getting plants

in this country to show this are serious, because in our markets, as we said before, all the flowers are cut in quite a different way, and much less attention is given to form, whether of the foliage of flowering plants, often very fine, and reeds, grasses, Bamboos and tree shoots.—*The Field.*

ORCHARD AND FRUIT GARDEN.

THE STRAWBERRY SEASON.

In provincial towns at least how difficult is it to get a dish of Strawberries fit to eat or to put on the dessert table. First they come into the market half ripe, and when they are ripe they are tumbled down even in the respectable fruiterers' shops in a greasy, fermenting heap, unfit to look at, let alone eat. And yet there is no fruit that can be set up more temptingly than the Strawberry when gathered clean and ripe, and no fruit that has a surer sale. Even in country places there is a ready demand for Strawberries, and if they are provided fresh and ripe, the highest price can always be got for them. The curious thing is that people who have good but small gardens seldom grow Strawberries well, simple as their culture is, although for garden parties and dessert there is always a brisk demand during the season when the genuine article can be got. As a rule our outdoor Strawberry culture is not of a high order, and few growers seem to realise what an extraordinary difference culture makes to the Strawberry. No fruit responds more readily to good treatment, and it is almost as easy to have a good crop as a bad one. The best Strawberry grower I ever knew was Mr. McEwan, who long ago used to be at Chiswick, and who died early. He was an enthusiast on Strawberries, and published a pamphlet on the subject, showing what could be done by high culture. His crops of fruit from runners layered only the previous autumn quite surpassed those commonly got from well-established plantations. From the way plantations are usually made, one would think that getting a crop of Strawberries under two years was considered an impossibility; whereas runners layered in July and planted out in August produce the following year the largest fruits and the heaviest crops proportionally. For forcing no one would think of using two-year-old plants; the last year's runners only are used. These in the open quarter may be planted more thickly than they are to remain permanently and be thinned out at the end of the second year. It is not realised that the Strawberry can by good culture be increased to two or three times its normal size and weight, which means an enormous increase over a plantation say an acre in extent.

There is an opening for anyone who would simply supply rooted Strawberry runners early in August for planters at a reasonable price, but nurserymen who go in for Strawberries as a speciality do not seem to understand the business. I have before me a catalogue in which all the sorts are priced at 5s. per 100 rooted runners, such as one can find about this season in any Strawberry quarter without trouble and that have rooted without assistance. I have had samples over and over again of these so-called "prepared" runners—just weeds from which no crop could be expected for two years. Plants of the same age and not much stronger, rooted into pots, are priced at 15s. per 100. As the price of a 2½-inch pot is so infinitesimal as not to affect the price of the Strawberry

plants, one wonders where the value comes in. Not only that, but the pot plan of layering Strawberries for sale is a thoroughly bad one. The pots are rarely plunged, and the layer is parched and stunted from the first. No plant takes to the soil quicker than a Strawberry, and if the runners are layered (as soon as they can be pinched beyond the first joint) in a small ridge of light, good soil laid between rows they will root surprisingly fast, and will lift and transplant without turning a leaf in August.

RAMBLER.

STRAWBERRY VICOMTESSE DE THURY.

I WAS very pleased to see that this useful old Strawberry is thought well of by Mr. Burrell. The larger varieties have ousted this and a few other good old sorts from many gardens, but where ground is limited and the most has to be made of the crop, gardeners cannot afford to dispense with Vicomtesse. As Mr. Burrell remarks, the earliest-formed fruits are quite large enough for dessert, the successional ones, which on fair soil are produced in great quantities, being excellent for preserving. Moreover, I have not yet met with a soil which would grow a Strawberry at all in which Vicomtesse was not at home. Some years ago, having a badly-constructed, ill-ventilated lot of glass houses to deal with, I found it most difficult to secure a decent set of fruit on the majority of forcing varieties. I succeeded very well with Vicomtesse for some time, but was induced to abandon it for other larger sorts. After repeated failures I was glad to go back to the old favourite. In the houses referred to Peaches were grown, and the necessary syringing of the trees kept the atmosphere too close for the Strawberries when in bloom, and, no matter how good the plants or strong the bloom-trusses of most sorts I tried, a satisfactory set seemed impossible. Vicomtesse, however, always set enough and to spare, and with judicious thinning and assistance with liquid manure the fruit swelled to a very good size. The finest forced fruits of Vicomtesse I ever saw were at Gunton Park. The runners, which were secured from young, vigorous stock plants, were potted in a good holding loam, and the fruit when swelling assisted liberally with that best of all Strawberry stimulants—farm-yard liquid. Had I not known for certain what the variety was, I should have taken it for another and much larger variety. Mr. Burrell also mentions Black Prince as a favourite with some for open-air culture, the fruit to be used for stewing or preserving. I can remember when this Strawberry was very generally grown for early forcing, and still think that where earliness is of first importance it is well worth growing in limited quantities. Old growers used to pot up the runners in $\frac{1}{2}$ -inch or 5-inch pots, feed them well, so as to secure good prominent crowns, and start the plants in November by giving the roots the benefit of a gentle bottom-heat of leaves. This had the effect of inducing root-action, while as yet, in consequence of only a moderate top-heat, growth proceeded very slowly. Gardeners with convenience requiring extra early fruit ripe, say, in February would by adopting this plan find any extra labour incurred well repaid. I am glad to find some gardeners still clinging to that good old Strawberry Keens' Seedling, as I have always found it a good setter, though not one of the best for travelling.

B. S. N.

Strawberry Waterloo.—One of the finest dishes of this well-known Strawberry I have seen was staged by Mr. Church, of Milford Hall, at a local show last week. The berries were of quite a deep claret colour, shining as if varnished, and a most regular dish as regards shape and size. Waterloo is not everywhere a success, and at Milford, as elsewhere, it is found to succeed best when allowed to remain on the ground longer than other kinds. The flavour is fairly good, and being late it comes in very useful as a distinct addition to the dessert. It will not thrive in all

soils, and I think is most at home on a light soil planted behind a wall with a north aspect. Another really good Strawberry that makes it a good companion is Eleanor, but this, like many other kinds, seems almost forgotten in many places.

Strawberries President and Keens' Seedling.—Pity "H. R." did not give some indication of locality before telling your readers of his semi-failure with these generally healthy and robust varieties on page 66. Unless on stiff or sodden soils, I never remember the leaves of President getting yellow. Most Strawberries may, however, on clay. Perhaps your correspondent would also say what he found wanting in Keens' Seedling. It could hardly be fruit, for its constant and abundant fertility is proverbial. It could hardly be foliage, though that is neither so high nor wide as that of Royal Sovereign. Neither does Keens' lack quality if eaten at home, where its soft, sweet, sparkling juice satisfies the palate beyond most varieties. Keens' has also the merit of being all and wholly eatable, no green or white hard ends. Not a few readers of THE GARDEN will probably be surprised to hear of Royal Sovereign superseding President or Keens' so generally in the west, for the additional rainfall in the west fosters the tendency to an excess of foliage on Royal Sovereign, which has been noted in most quarters out of doors and under glass as a fault.—D. T. F.

POTTING YOUNG STRAWBERRY PLANTS.

STRAWBERRIES raised in exposed gardens and in hot soils, and which are intended for forcing, will have to be carefully dealt with after the recent spell of hot weather. Even where growth is vigorous and the dreaded spider seldom attacks the foliage, it is not wise to pot up the young stock before cleansing them by the application of sulphur water. Sometimes people make a mistake in leaving the plants fully exposed to sun and wind on the open quarters until time can be spared for potting. It does not take long to sever a few hundreds from the parent plants and remove them to a shaded position behind a north wall. This has always been my practice, and while there I always rid the foliage of any trace of spider by first laying the plants on their sides and then well syringing the under-surface of every leaf with sulphur water of sufficient strength that when dry a thin yellow coating is perceptible. In my opinion there is no application to equal this. Late-rooted plants of backward varieties intended for planting in the open garden or for pricking out into nursery beds in autumn in readiness for final transplanting in spring should also be treated similarly. In potting, be careful to use the soil in a semi-dry state, as when the least wet or clammy the balls often leave the sides of the pots afterwards and cause great trouble. For many years I used to ram in a cube of loam round the roots when planting. This gives them a good start, and is especially to be recommended in light or none too good Strawberry soil. It is astonishing also what benefit is derived from a moderate mulch of, say, leaf-mould or old Mushroom manure. There is no necessity for covering the whole surface of the bed; a foot round each plant will suffice. Some stand all newly-potted Strawberries behind a north wall for a time, and although I do not consider such a course necessary in the case of strong, vigorous plants, a week in that position is very beneficial for weakly plants or those damaged by spider.

B. S. N.

Strawberries in the open ground.—"H. C. P.'s" note (page 65) would prove far more useful were some idea given of locality. It is little wonder, however, that 7° of frost on May 5 should blacken many blooms. That it should have caused such injury to such varieties as Scarlet Queen, Royal Sovereign, and John Ruskin as to make them a failure would no doubt be more intelligible did we know the county they grew in. It will surprise some to hear that

these three sorts do not grow strong on our light soil. Again, locality would explain the fact that no Strawberries had been gathered in the open air till after June 24, which so far was fortunate for your readers, as it enabled your correspondent to tell us all how useful he found Leader from a cold frame. Leader is also said to be a grand variety. Monarch side by side has not half the crop, and Scarlet Queen has suffered less than on sunny borders. I found out years ago that such borders are not the best for either safety or flavour, and by the simple expedient of growing Strawberries on every possible aspect we may not only ensure a better crop, almost double the length of the season, but raise the standard of quality. Fierce sunshine to such fruit as Strawberries is almost as fatal to flavour as frost. I agree in the main with your correspondent's remarks on mulches and their effect on flavour, local temperature, &c., unless in his emphatic preference for Oat straw. One of the best Strawberry growers ever known to me used to mow a portion of the deer park every year, convert it roughly into hay, and then mulch with it.—D. T. F., *Edinburgh.*

PROFITABLE RASPBERRIES.

No doubt Raspberries in many gardens are scarce this season, owing to the injury the canes received last March. Shelter is a most important point when planting Raspberries, the lack of this so often telling most unfavourably against market growers. Even where the new growth escaped uninjured, root drought will have materially affected the crop and the canes for next season's fruiting unless the ground is in good heart and fairly retentive. I have noticed what tall, stout canes Raspberries make in a dripping season, fine fruit and plenty of it resulting the following year provided the autumn is sunny enough to mature the canes. In gardens where labour is limited, timely removal of the old exhausted canes and thinning out the new are often neglected, in fact postponed till winter or spring, but an effort should always be made to perform the work in season, or the loss in all ways is irreparable.

There are, I think, few gardens where hardy fruit is esteemed in which Superlative is not grown. I saw on July 17 at Beeston Park, near Norwich, some grand specimens of this fine Raspberry. They reminded me in size of Vicomtesse Strawberries, and being gathered for dessert with a portion of stem attached looked very handsome. The soil at Beeston is fairly deep and inclined to be strong, and in hot summers retains moisture well; the garden is also well sheltered by surrounding woods and is an ideal home for Raspberries. I do not assert that Superlative is the best flavoured Raspberry, as if it really comes to quality I should say the old Fastolf leads the way, but the vigorous constitution, free bearing, and firmness of the fruit which fit it for travelling a long distance have made it a great favourite, especially with market growers. Baumforth's Seedling is certainly a splendid variety, as, given good all-round treatment, it grows vigorously and yields freely, the fruit being large, round, deeply coloured and of good quality. It did well with me in a light soil, being liberally mulched annually. That it also has a hardy constitution is, I think, proved by its standing almost quite uninjured the terrible frost of February, 1894. Norwich Wonder has been well spoken of several times in THE GARDEN, and is no doubt an excellent all-round variety. I think Mr. Wythes has stated that he has not found it suitable for a shallow, warm soil. Anyone, however, whose root-run is fairly deep and moist may with confidence plant it, as it is a favourite with some market

growers, who do not as a rule grow any fruit the second year that is not profitable. I do not think it wise for gardeners to plant large breadths of any untried Raspberry any more than Strawberries, as soil and general surroundings affect various sorts in different ways. What I recommend is planting a few canes only at first, and if the variety is found satisfactory, to increase it. Northumberland Fillbasket, Carter's Prolific and Hornet are all favourites in some quarters, and in forming large plantations it is decidedly advisable to plant two, three or more varieties, as, like Strawberries, some do better in certain seasons than others. Superlative has perhaps one drawback—it requires to be well ripened before it will leave the stalk, and of course market fruit is best in an under rather than an over-ripe condition. Although I still think that a greater weight of fruit can be obtained from a given area by the old-fashioned mode of training on stakes, yet doubtless finer crops result from tying thinly to cross wires.

B. S. N.

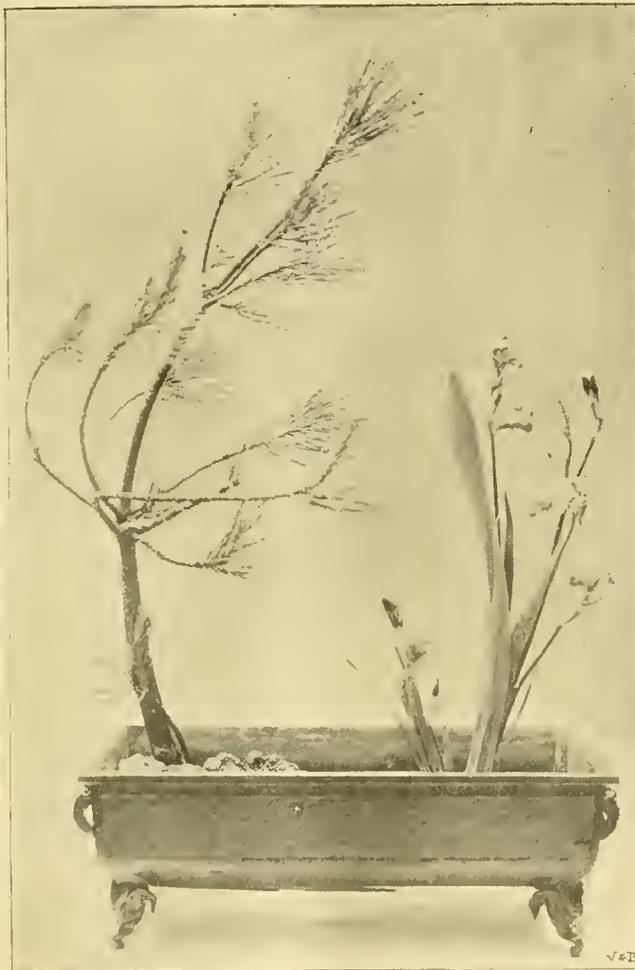

Strawberry Empress of India.—I was pleased to see the note by "H. R." (p. 3) on this delicious Strawberry. "H. R." describes his soil as heavy and stubborn, in which a percentage of his plants of Empress of India collapses during winter. I fancy this Strawberry enjoys a good holding rich loam, and I think that "H. R." could, by incorporating a sufficiency of opening material, render his soil suitable for the Empress. My idea is that one good way of managing it is to grow it in beds well prepared early in the season and to plant good healthy parent plants in spring, selecting three or four runners which spring from it and pegging them down at equal distances round the parent; good results may then be expected the following summer. The flavour of Empress of India is so rich, that any extra trouble taken to make it at home is amply repaid.—C.

Peaches and Nectarines in the south and north.—I think in the south we have much less fruit than in the north. This not only applies to the Peach and Nectarine, but other fruits. This season our Strawberries suffered very much, as when they were in flower we had a cold wave for some ten days, whereas in the north at that period the weather was milder; in fact, though there was snow late in the spring it did less damage than the cutting winds we experienced with heavy rain and frost combined. Of course, growth being from a fortnight to three weeks later in the north, there is a better chance to escape spring frosts, and there is also a much greater rainfall in the growing season. I am surprised to see what good crops there are on walls protected with a thick covering only used at night or in the daytime in severe weather. If we

had had a more efficient protector in the south, in many cases we should, I think, have had more fruit. I am not much in favour of warm coverings in mild seasons, but in a spring like the one just past the trees need protection when in flower. The value of movable copings is here seen, as these could be used to greater advantage and they would also be valuable for protection in wet seasons.—S. M. N.

FLAVOUR IN STRAWBERRIES.

READING "A. D.'s" comments (p. 68) on the above, I must confess I am somewhat surprised that such a practical and observant correspondent did not notice the close relationship of the three varieties he there mentions. He must have over-

A Japanese arrangement of flowers and foliage. (See p. 97.)

looked the fact that Messrs. J. Veitch and Sons obtained Prolific Strawberry by crossing one of my highest flavoured seedlings, viz., Empress of India, with British Queen, and that I obtained Empress of India, Lord Suffield, and Gunton Park by crossing British Queen with Countess, and *vice versa*. British Queen and Empress of India being both pale scarlet in colour, Messrs. J. Veitch and Sons' seedling Prolific must have bred back to its original parent Countess for its dark colour and to some extent for its flavour. To obtain Lady Suffield Strawberry I crossed the early variety Empress of India with the late variety Lord Suffield, this producing a midseason kind combining the richness of flavour of the Empress of India with the delicious sweetness of Lord Suffield. I maintain from a hybridiser's point of view Messrs. J. Veitch and Sons erred in re-crossing Empress of India with British Queen. Prolific thus becomes the progeny of its grandparent on the one side. A distinct step forward in

point of flavour had been gained by me in crossing British Queen and Countess, and the right thing to do was to take two of these high-flavoured seedlings, the one late and the other early, and re-cross them to gain another step forward to that goal of excellence in flavour at which I am aiming. I should like to point out and emphasise here what important results will spring from that lucky cross of British Queen and Countess. It is not fully realised yet.

It has already given us Empress of India, Lord Suffield, Gunton Park, followed by Veitch's Prolific and Lady Suffield. Still higher flavoured seedlings will follow of such exquisite flavour, that the next generation of Strawberry eaters will require neither sugar nor cream to tone down their acidity. I may add here that I grew Countess for years and much appreciated its quality and free-bearing, but it is so entirely superseded, in my opinion, by its superior flavoured progeny that I no longer grow it. "A. D." states that Lady Suffield had lost flavour in transit when exhibited at the Temple. As these Strawberries were grown in pots and had to be retarded a few days to keep them back for May 31, it may be so. "A. D." regards the rapid disappearance of the Prolific Strawberry as a test of great excellence when exhibited before the fruit committee. Granted. Then I will congratulate myself, as no Strawberry in the world ever disappeared more quickly than the two fine dishes of Lady Suffield exhibited at the conference at Chiswick. Not a Strawberry was left on the plates when the committee rose. Perhaps the tropical temperature of the large vinery induced this great need of refreshment, or may I conclude it was the excellence of the Strawberries?

WM. ALLAN.

Gunton Park.

ROTTENNESS IN FRUIT AND MUMMIFICATION IN PEACHES.

YOUNG and growing fruit as well as fruit bordering on maturity are often attacked by various microscopic fungi which stop their growth or cause the destruction of already formed tissues. One such destructive organism is the *Monilia fructigena*, a fungus which especially attacks Apples when these are ripe and causes brown or black rottenness. Circling round the little wound that gave passage to the mycelium, a spot is seen to spread, which from a light brown becomes gradually black. Later, in the affected part appear small ashen-coloured swellings like warts varying in size from a millet seed to that of a very small pea. These are always ranged in concentric circles round the wound. As the rottenness increases new circles appear one after the other to the number of three or four. The mycelium of the fungus pervades the fruit pulp and decomposes it. Beneath the skin the fungi increase rapidly in size and number and crowd upon each other in all directions. Under pressure of them the skin bursts, and from the cracks issue certain aerial projections or ramifications, which become fertile, and it is through them that the parasites are propagated. They are formed of filaments drawn out perpendicularly to the fruit and which are drawn in at intervals, resulting in the formation in a series of cone-shaped spores of a kind of chaplet, and hence the generic name of *Monilia*. These chaplets also are apt more or less to bifurcate in places, and in serried formation they compose the warty protuberances mentioned above. When ripe these spores are easily separated from each other, and, carried away by the wind or rain, they are apt to contaminate other fruit. Each when isolated is seen to be almost lemon shaped. If put in water they germinate with extreme rapidity and quickly ramify and constitute the destructive mycelium.

The *Monilia fructigena* is apt to cause decomposition and rottenness in large quanti-

ties of ripened fruit, and it also frequently attacks and completely arrests the growth of immature fruit, causing a kind of drying up known as mummification. The disease on young fruit has been especially noticeable in America. Peaches especially are affected, and the crop is sometimes entirely destroyed by the action of the *Monilia*. The fruits attacked begin to soften, and frequently cling more or less completely to the branch they are on, or where there are several in proximity cling to each other, mummification quickly follows, and nothing is left but the kernel and the skin. While the mummification is going on in the pulp the mycelium has attained complete development, and outside a large number of groups of spores have been formed identical with those mentioned above, and which cover the fruit almost entirely with a grey efflorescence. The mummified fruit remains attached to the tree during the summer and even the most of the winter. Towards the end of winter and in the spring the fruit falls to the ground. The mycelium which has kept alive vegetates anew and produces an abundance of new spores which may infect the budding fruit. But the fungus does not confine its attacks to the fruit; it may also invade the young shoots (of the Peach at least), which then rapidly wither and decay. The destruction it causes in this way is in America apparently as important as that which it occasions by directly attacking the fruit, because it injures also the vegetation, destroys the fruit crop of the following year, and may, moreover, favour the development of gum.

In France it has not so far made its presence felt to this grave extent, but still it should not be exclusively considered as a parasite of fruit already fully grown. Although it has already been observed upon young fruit, it does not appear to be considered as greatly harmful. This year I have been able to observe the rapid development and the ravages of the *Monilia* among Plums. In a few days almost the whole of the fruit of certain trees was attacked, and the crop thereby almost entirely destroyed. In Plums the disease shows itself when the time of ripening is at hand. The fruits attacked become of a livid colour on one side, then slightly soften and cling together. From a Plum so attacked the mycelium can then pass to one still sound and infect it also. In this way the disease rapidly spreads to a great number of Plums which were not infected by the spores. After softening, the fruit gradually withered, as with the Peach, and the spores of the fungus made their appearance on the outside, but generally much less abundantly than on the Peaches.

Among Peaches in the open also I was able to observe the havoc caused by the *Monilia*, all the fruits of a small tree planted in the open being mummified one after the other. But further—a thing which, I believe, had never been observed before in France—the extremities of the shoots were likewise attacked and a large number of young branches withered up under the influence of the parasite. Upon some branches were observable, protruding through the bark, small excrescences, which at first sight seemed to be identical with the groups of spores that appeared upon the fruit, but which were very small, and subsequent microscopic examination established this identity beyond doubt.

So far the disease has not been observed to be very dangerous, but there is fear that it might be otherwise at a given moment and that it is capable of acquiring importance, as in America. Moreover, it may well have been the

cause of injuries of which the real origin was ignored. Its peculiarities, therefore, are worth the attention of fruit growers, especially as some authors have been inexact in their information as regards it. The *Monilia* has in all probability another form of fructification analogous to that of another *Monilia*, which attacks the young Quince—the *Monilia Linhartiana*—the ultimate fructification of which is a small cup-shaped receptacle, of which the concave part is furnished with a large number of asci, each enclosing eight oval-shaped spores (*Stromatinia Linhartiana*). A form analogous to this ought certainly to exist for the *Monilia fructigena*, as in all its characteristics this fungus resembles the other, but this ascophorous form has not as yet been observed.

PRESERVATION OF THE TREES.

For the protection of fruit trees from this parasite a remedy both easy and general has not yet been found. Cupric sprayings are likely to have some influence, but these require to be frequently repeated in order to protect the lengthening shoots. In America it is thought advisable to collect and burn as fast as they are detected all fruit attacked by the fungus. This process must be repeated at intervals of several days in order not to leave the infected fruit time to give birth to spores or contaminate sound fruit by contact. But, however careful the search, a certain amount of the fruit may well escape by being more or less hidden by the leaves, so that it is necessary in winter when these have fallen to make a fresh search and destroy at the same time fruit still adhering to the branches, those which may have fallen to the ground, and all branches and shoots attacked by the fungus and more or less withered. These are certainly excellent precautions to take, and their application should prevent the spread of the disease. The gathering of the infected fruit is done at the cost of minute search and great expenditure of time. Unfortunately, there exists hardly another way of dealing efficaciously with the disease. Doubtless copious sprayings in winter have a good effect in destroying the spores which may exist upon the branches, but the spores produced in the spring by fallen fruit may easily infest the young fruit, which it is a difficult matter to protect, and the young shoots; hence the importance of destroying all the infected parts. Cupric sprayings during the time of vegetation may, nevertheless, be a protection. —PIERRE PASSY, in the *Journal of the Horticultural Society of France*.

Peaches in Russia.—My earliest Peach house contains three trees—Amsden, Hale's Early and one whose name I do not know. I begin forcing this house about December 25 and force it very slowly, so that the first fruits of Amsden ripen about June 1. The trees, which were planted some six or seven years ago in raised borders, are large and in good health. Amsden bears fruit annually abundantly, Hale's Early very badly. I often read in THE GARDEN that of the early American varieties Amsden is the best. I quite agree that it is prolific, that the fruits are of a nice size and look very promising, but it lacks quality. I think it so poor and flavourless, that I should feel ashamed to offer it to a friend. It is somewhat bitter, and if it hangs a little too long, it gets mealy and quite unfit for the table. If I had instead of three houses five or six, perhaps I should feel obliged to spare room for the Amsden for its earliness, or if the fruits were required for sale. But as this is not the case, I think the most radical way the best, viz, to throw it on the rubbish heap. Hale's Early is not prolific at all with me. The few fruits I get often have split stones. The general constitution of the tree is

very weak. It always loses a greater part of its leaves at the lower end of the shoots than any other variety. The quality is excellent, but considering all its other disadvantages I think it not worth growing. The third tree, the fruit of which, though very good in quality, is by far too late for the earliest house. So I think of clearing the house of its occupants and planting other young trees in other sorts. Following this time the advice given in THE GARDEN by Mr. Iggulden, I shall plant maiden trees. Will you kindly tell me the best sorts to plant instead of the above? I am not obliged to have ripe fruits very early in the season, but nevertheless I should be glad, as it is my earliest house, to be able to gather the first fruits not later than June 25 to July 1, forcing slowly and beginning about December 25. The kinds must be (1) of a vigorous and most prolific habit, (2) the fruits freestone, nice looking, large, and of excellent quality, and (3) early and ripening in succession.—R. K., *St. Petersburg*.

SPRAYING FRUIT TREES.

The spraying of trees to kill and to prevent fungi and insect pests has long since passed an experimental stage, and is now looked on as part of regular orchard work by good fruit growers. From the necessity of making it pay, commercial fruit growers are more advanced in the matter than are private gardeners. Probably the first general use of poisons for the purpose was in the case of the Paris green for the destruction of the Potato bug. This poison was so useful for the purpose, that it awakened many to the value of such means of warfare who had previously paid but little attention to the subject. The use of powdered hellebore for the destruction of the Currant worm is another well-known instance of the value of poisons for such work. Paris green is still the standard remedy for the destruction of leaf-eating insects on fruit and other trees, kerosene emulsion for sucking ones, and Bordeaux mixture for all kinds of fungi. Paris green is made into a mixture for spraying by adding a pound of it to 200 gallons of water, with enough lime to equal the Paris green in bulk. Bordeaux mixture is made by mixing 6 lbs. copper sulphate (bluestone) with 75 gallons of water and 7 lbs. lime. Kerosene emulsion can be made by boiling half a pound hard soap in a gallon of water, and when boiling hot add 2 gallons kerosene. This is to be churned vigorously for ten or fifteen minutes, and then adding ten times as much water before using.

As a matter of fact, all fruit trees are the better for being sprayed, whether usually attacked by insects or not. It prevents blight and other pests; and besides this, experiments carried on by the United States Department of Agriculture some years ago proved that sprayed trees made a better growth than those not so treated, even when no insects or fungi attacked the latter. Later experiments prove that the two mixtures, Bordeaux and Paris green, may be combined and used as one; and it is now quite common to use them in this way. It is recommended to start spraying before the bursting of the leaves, giving another application as soon as flowering is over and two or three more at intervals of three weeks or so. After midsummer there is not much to be feared, and spraying may cease.

Insects and fungi injurious to Apples, Pears, Plums, Cherries, Peaches and like trees are destroyed by a system of spraying. Scale insects and those that suck the juices of trees are to be treated to a spraying of kerosene emulsion. This can be carried on in winter as well as summer, and when persisted in will in time rid the trees of their enemies. Fire blight and black knot cannot be controlled by spraying, though it is believed to act as a preventive. The usual and only plan recognised as efficacious is to cut off the diseased branches and burn them to destroy the fungus spores. As soon as fire blight appears cut off the branch some 9 inches below the dead part, and do the same with branches of Plum or Cherry attacked by black knot. The fungus which pro-

duces the disaster is supposed to be in the sap, hence outside spraying cannot reach it. It is not certain that outside agencies are not at work too, hence the suggestion to spray these trees as well as others.—JOSEPH MEEHAN, in *American Gardening*.

PEARS ADOPTED BY THE CONGRÈS POMOLOGIQUE OF FRANCE.

(Continued from p. 67.)

BEURRÉ DUBUISSON.—This was raised about 1832 by M. Isidore Dubuisson, gardener of Jolain, near Tournay, Belgium. The fruit is of fair size, oblong, truncated at the base, rather ribbed at the base. The stalk is short, stout, straight, set rather obliquely in a small wrinkled cavity. The eye is small, closed, set in a cavity of medium depth, ribbed at the edges. The skin is yellow, much stippled with red, sometimes washed with red on the sunny side. The flesh is whitish, delicate, close, melting, unctuous, juicy, and pleasantly aromatic. A very good fruit, ripening in December—February. The tree is of moderate vigour and fairly fertile. In cultivation the growth is rather weak upon Quince.

BEURRÉ DUMONT.—Obtained in 1831 by M. J. Dumont-Duchy, gardener to the Baron de Joigny, at Esquelmes, near Tournay. The fruit is large, sometimes pyramidal and truncated at the base, sometimes turbinate. The stalk is short, stout, straight, set obliquely in a narrow bumpy cavity. The eye is medium, open or half open, set in a fairly wide wrinkled shallow cavity. The skin is rough, yellow, washed tawny, gilded on the sunny side with some deeper streaks and stippled grey. The flesh is white, delicate, luscious, juicy and delicately aromatic. A good fruit, ripening October—November. The tree is of normal vigour and fertile. In cultivation this variety, suitable for all forms on Quince, is better in regard to length of life and vigour for an intermediary graft.

BEURRÉ DU MORTIER (*syns.*, *Verte du Mortier*, *Beurré Dumonstier*, *Fondante de Tirlumont*).—Obtained in 1818 by Van Mons and named after B. C. du Mortier, a naturalist, of Tournay, Belgium. The fruit is small or medium-sized, turbinate obtuse, taking the shape of Bon Chrétien, bumpy in its contour. The stalk is of medium strength and length, curved, set obliquely in a narrow, wrinkled cavity. The eye is large, open, set in a shallow, wide cavity, wrinkled. The skin is rough, yellow-green, much stippled with grey, streaked with tawny red. The flesh is whitish yellow, fairly delicate, luscious, juicy. A very good fruit, ripening September and October. The tree is of normal vigour and fertile. In cultivation this variety is adapted to small forms upon the Quince; it is a good thing to double-graft it in order to get strong shoots.

BEURRÉ DURONDEAU (*syn.*, *de Tongre*).—Obtained in 1811 by M. Charles Louis Durondeau, a brewer, of Tongre Notre Dame, near Tournay. The fruit is fair sized, pyriform. The stalk is short and stout, set obliquely on the fruit or slightly pushed aside by a small mound. The eye is medium-sized, closed or half closed, set in a shallow, wide, and irregular depression. The skin is smooth, thick, tawny, tinged very slightly with red on the sunny side and stippled all over with small grey points. The flesh is whitish, juicy, and aromatic. A good fruit, ripening in October. The tree is of medium vigour and fertile. In cultivation it is of sufficient vigour upon Quince. This variety lends itself to all forms.

BEURRÉ GAMBIE (*syn.*, *Beurré d'hiver Nouveau*).—Obtained by M. Gambier, of Rhodes Saintes-Genève, near Brussels. The fruit is medium-sized, pyriform; the stalk sometimes long and not very stout, sometimes of middling dimensions, swollen at the point of attachment, set straight in a cavity neither wide nor deep. The eye is medium-sized, half closed, inserted in a depression scarcely marked. The skin is delicate, citron-yellow, stippled russet, slightly streaked with tawny red, and at times washed with red on the sunny side. The flesh is whitish,

delicate, and aromatic in the way of Doyenné Blanc. A good fruit, ripening March—April. In cultivation this variety, too feeble upon Quince, requires to be grafted on the natural stock or double-grafted on a vigorous variety, yet can only form trees of small size. It should be cultivated in a warm exposure and gathered late, otherwise the fruit never attains full maturity.

BEURRÉ GIFFARD.—Originated as a chance seedling with M. Giffard, of Angers, and propagated by him. The fruit is of medium size, pyriform; the stalk of medium length and stoutness, slightly curved, set straight at the top of the fruit. The eye is medium-sized, open, set almost flush with the fruit in a shallow, wrinkled depression. The skin is smooth, delicate, pale yellow, stippled grey, often washed with tawny red round the stalk. The flesh is white and agreeably aromatic. A good fruit, ripening July. The tree is of medium vigour and fertile. In cultivation this variety does not lend itself to regular forms. It is suitable for orchard culture.

BEURRÉ GRIS (*syns.*, *Beurré d'Amboise*, *Beurré Doré*, *Beurré Roux*, and *Beurré d'Isambart*).—Of very ancient and unknown origin. The fruit is medium sized or fairly large, almost as wide as high. The stalk is of middling length, fairly stout, sometimes fleshy at the base, swelling at the point of attachment, set obliquely at the summit of the fruit. The eye is medium sized, open, set in a shallow, wide depression sometimes flush with the fruit. The skin is delicate, pale green or yellow, almost entirely washed with tawny red and stippled grey, rarely tinged with a little rose colour. The flesh is white, very juicy. A very good fruit, ripening October. The tree is of medium vigour and fertile. In cultivation the tree, delicate upon the Quince, ought always to be double grafted. It ought nearly everywhere to be trained as an espalier in order to yield sound fruit.

BEURRÉ HARDY.—This variety was raised from seed by M. Bonnet, of Boulogne-sur-Mer; it was propagated by M. Jean Laurent Jamin. The fruit is of medium or fair size, turbinate. The stalk is of middling length, stout, swollen at the point of attachment, and set obliquely in a small cavity. The eye is fairly large, open, set in a wide, shallow, wrinkled depression. The skin is rough, greenish yellow, washed with tawny red, stippled brown. The flesh is white, luscious, rather gritty about the cells. A very good fruit, ripening September to October. The tree is of medium vigour and fairly fertile. In cultivation this variety comes well on the Quince and is suitable for all forms.

BEURRÉ MILLET.—Originally obtained in 1847 in the garden of the Commice Horticole of Maine-et-Loire, and named after the president of that establishment. The fruit is small or barely medium sized, slightly bumpy in its contour. The stalk is of middling length and stoutness, rather swollen at the point of attachment, curved and set straight in a small bumpy cavity. The eye is large, open, set in a wide, deep cavity. The skin is rather rough, greenish yellow, washed with dull red, streaked carmine, stippled tawny red. The flesh is greenish white, melting, and very pleasantly aromatic. A very good fruit, ripening December—February. The tree is vigorous and very fertile. In cultivation this variety grows badly on the Quince. It should preferably be grafted on the Pear to get trees of medium size without retarding the yield.

BEURRÉ RANCE (*syns.*, *Bon Chrétien de Rance* or *de Rans*, *Beurré de Flandre*, *Beurré de Noirechain*, *Hardenpont de Printemps*).—Obtained originally in 1762 by the Abbé Nicolas d'Hardenpont at Mont Panisel, near Mons, in Belgium. The fruit is of good size, of Bon Chrétien shape. The stalk is fairly long, of medium stoutness, rather swollen at the point of attachment, set obliquely in a narrow cavity. The eye is small or medium-sized, half open, set in a shallow and fairly wide cavity. The skin is roughish, thick, green, slightly tinged brown on the sunny side, stippled grey and streaked sometimes with tawny red. The flesh is white at the centre, greenish

in the outside, sometimes half delicate and half melting, sometimes delicate and luscious, very juicy, and with a peculiar aroma. The fruit is fairly good, ripening January to March. The tree is vigorous and fertile. In cultivation the tree grows vigorously both on Quince and on the natural stock; it lends itself to all regular forms. The fruit is much better if the tree is grafted upon the Quince, and the Belgians say that on the natural stock it is uneatable.

BEURRÉ SIX.—Obtained originally about 1845 by M. Six. The fruit is fair sized, pyriform, and ribbed in contour. The stalk is of middling stoutness, sometimes long and slender, curved, set well at the summit of the fruit. The eye is fairly large, closed, set in a very shallow, wrinkled cavity. The skin is light yellow, finely stippled with russet, mottled with green. The flesh is white, tinged green, especially close to the skin, luscious, and pleasantly aromatic. A good fruit, ripening October, November, and December. The tree is of moderate vigour and fertile. In cultivation the tree prefers the natural stock to the Quince; it is best double-grafted. In certain soils and climates it does best as an espalier.

BEURRÉ SUPERFIN.—Obtained originally in 1844 by M. Goubault, nurseryman, of Millepieds, near Angers. The fruit is of good size, as wide as high. The stalk is shortish, very stout, and fleshy. The eye is large, open, set in a very shallow and wide depression. The skin is smooth, golden-yellow, very slightly washed carmine on the sunny side, stippled with russet, dotted over with some tawny red. The flesh is white, luscious, and delicately aromatic. A very good fruit, ripening September. The tree is vigorous and fertile. In cultivation, grafted on the natural stock the tree is long before fruiting; on the Quince it becomes quickly exhausted. It is best double-grafted. It lends itself to all forms.

BLANCHET CLAUDE.—Obtained originally by M. Claude Blanchet, nurseryman, of Vienne (Isère). The fruit is barely medium-sized. The stalk is long and stout, swollen at the point of attachment, set rather obliquely in a small, lightly-ribbed cavity. The eye is medium-sized, open or half-open, set in a medium and wrinkled depression. The skin is smooth, rather unctuous, tender green, washed yellow, stippled green and tawny red. The flesh is whitish, greenish beneath the skin, gritty near the cells. A fairly good or good fruit, ripening in the middle of June. The tree is vigorous and fertile. In cultivation the tree lends itself to all forms, requires a warm exposure to hasten the ripening of the fruit, the earliness of which is its principal merit.

BON CHRÉTIEN D'HIVER (*syns.*, *Bon Chrétien*, *Bon Chrétien de Tours*, *Poire d'Angoise*, *Poire de Saint Martin*, *dc.*).—A very old variety of unknown origin. The fruit is large, rather calabash in form. The stalk is long, slender, curving, set sometimes straight, sometimes obliquely in a rough cavity. The eye is small, open, set in a deep, wide cavity very lumpy at the edges. The skin is almost smooth, greenish citron-yellow, marked with russet, mottled green and tawny in places. The flesh is white, juicy, and slightly aromatic. A very good cooking and a fair dessert fruit, ripening February—April. The tree is of normal vigour and fertile. In cultivation this variety does not lend itself to regular forms unless trained. Its true place is a south espalier. It is esteemed in warm districts, where it is said to acquire quality.

(To be continued.)

Worn-out fruit trees.—Too much has been made of the good effects of pruning old trees, and nine-tenths of the rubbishy old orchards up and down the country should be cut down, the trees burnt, and the land cleared for some other purpose for a year or two. The poor old trees have been neglected entirely for so many years, that their vigour is gone and only a lingering life remains. Still further check this by cutting faggots out of them, and they are done for in most cases. No matter how carefully the work

s gone about, there comes a time when it is absolutely useless to think of repairing the damage that time and neglect have wrought, and it is best to accept the inevitable and cut them down. A new orchard may, of course, be planted on the same site if really necessary, provided the land is properly prepared, but it is not to be recommended as a rule. One such was replanted by a nurseryman in Gloucestershire and is now a fruitful orchard, but in this case the whole of the old trees and the top 3 inches of soil were burnt, thus doing away with all insect and fungoid life. The ash was kept in heaps and mixed with the top spit when the land was trenched, manure from the scavenger's yard being plentifully incorporated with the lower soil. There is yet plenty of time for preparation of the soil for planting this season, and I would like to urge on those who have these worthless old trees, that the sooner they root them out and plant the young ones the better. Not only is the produce of better quality and more of it, but early Apples of the Codlin types come into use from young trees much earlier than from old ones.

Stone-splitting in Peaches and Nectarines.—One is often asked what causes the stones of these fruits to split, but I think, like many other troubles, it arises either from a poor state of health of the trees or from some error of culture. In forced trees there is little doubt it is often caused by running the temperature up too high, and again, young trees that are not properly established or older ones that have run through the proper border to a bad soil beneath are given to it. There must be a cause undoubtedly, but it is not the same in every case, and those who have been looking after the trees and observing them should be the most likely to know where the culture has gone wrong. There is now time to note any trees that have given trouble in this respect in the past or present seasons and mark them for examination of the roots towards the autumn. If got about early, there need not be any fear of doing them the least harm, and often the secret may be found. There may be a badly-drained part of the border itself or a few strong roots may have got through it entirely, and in either case corrective measures can be carried out. Just as the leaf is turning before it falls is the best time to disturb the roots.—H.

WATERING VINE BORDERS.

It seems to be the opinion of some that Vine borders can scarcely be watered too often or too much, but such an idea is, I believe, erroneous. We sometimes see watering every ten days or so advised, and certainly in the case of extra shallow borders and where the compost is light and sandy, such frequency may be necessary. In well-made borders of ordinary depth I have found a good moistening before the Vines are started, another when the bunches are coming into bloom, a third when the berries have been thinned, with a fourth and fifth when taking their second swelling and commencing to colour to be sufficient. I am afraid many of the so-called waterings are only surface moistenings; whereas they should be thorough soakings from summit to base. Where the borders are shallow, mulching is often neglected. A thick layer of manure is not necessary; nothing answers better than a couple of inches of spent Mushroom manure. This prevents undue evaporation. Some gardeners never seem easy unless constantly soaking their Vine borders, even in autumn and winter. It matters not whether the border is inside or outside, or whether of a sandy or clayey nature; it is all the same to them. I have known copious supplies of manure water poured on to outside borders during winter which if followed by severe frost cannot but prove injurious. The reason why so many outside Vine borders are destitute of roots within a foot or so of the surface is that saturation from heavy rains or deep snow at that period, followed by frost, destroys the delicate fibres. If anyone doubts this, let him examine a

border that has been regularly covered with leaves in autumn. If the Vines are healthy he will find surface roots numerous, because they have been preserved from the perishing effects of wet and frost. Excessive watering washes the nature from Vine borders. I have heard of gardeners using shutters on their Vine borders in winter with a view to throwing off excessive rains and snow, and I think the plan worthy of imitation. A wet autumn is deemed prejudicial to the proper ripening of hardy fruit trees, and that because it influences the roots as well as the branches, and the same remark applies to Vines. A gradual diminution of root as well as atmospheric moisture is necessary in order to

A Japanese arrangement of Irises. (See p. 97.)

secure perfect maturity and rest for the Vine. For Vines in active growth I think nothing equals liquid manure. B. S. N.

Gooseberry Rough Yellow.—Your correspondent (p. 35) does not seem to be aware that this is probably but another and an older name for the Early Sulphur or Golden Ball. The Yellow Amber or Hairy, also well named Yellow Champagne and Yellowsmith, is much of the same character and equally good. All growers will agree that it is worthy of the best possible culture to bring it to the highest perfection. The jam or jelly of the Yellow Sulphur or Rough Yellow has with good cause been named golden honey.—D. T. F.

Apple Mr. Gladstone.—Where Apples are required for dessert very early in the season this is a useful variety, for though the quality is not quite up to the mark, its earliness is undoubted. Judging at a local show recently, I was compelled to give this first place against a dish of Juneating, which was quite unripe, though doubtless in another ten days it would have been much the better dish as regards flavour. Mr. Gladstone is too mealy and soft to ever come much into favour, and its earliness is its best point, though

I am far from thinking that Apples are really needed in July, considering what a lot of really good fruit is to be had at this season.—GROWER.

Air for Vine borders.—No doubt many have been interested in the article by Mr. Riddell on air for Vine borders. I think the practice of supplying air to borders by means of underground tunnels was more common fifty years ago than it is now. Raised borders, as recommended by Mr. Riddell, were also more common. I have several times written in support of elevated borders both for vineries and Peach houses, especially for early forcing. I well remember an old vinery in Essex containing Black Hamburgs which were very successfully forced so as to be ripe at the end of May for twenty-five years. The border was outside the house and raised considerably. At the top near to the front light, and also at the bottom close to the Box edging, were air shafts formed of brickwork communicating with the drainage. The supply of air could be increased or diminished at will simply by means of a lid on the top. The interior of the house was constantly supplied with fresh air through the front wall, the air being made to pass over the hot-water pipes before rising into the house. The border was always covered to a depth of 2 feet with dry leaves in October, these being thatched with reeds. Better early forced Hamburgs I have seldom seen.—NORWICH.

GARDEN FLORA.

PLATE 1234.

NOTES ON TULIPS.

(WITH A COLOURED PLATE OF T. SAXATILIS.*)

THERE is no period of greater importance to the Tulip family than that of the resting period. That period is now well advanced, and those who appreciate their Tulips will not let it pass unheeded. That it concerns the bedding kinds so-called as much as any other section or group, and not unnaturally the many varying and beautiful species of which this valuable genus is composed, is well known to all who have given any thought to the cultivation of the bulbs in question. It may be said that there are known instances of old cottage garden Tulips that have remained in the soil year after year without being lifted, and with but the rest secured to the bulbs by the heat of the summer, and which have flowered freely afterwards. Yet the bulbs that do well under such treatment would without doubt have done infinitely better had the roots been lifted in early summer, and having been carefully dried, cleaned and sorted, replanted in due course in a fresh position and soil. This fact is too well known to large growers of such things. An excellent illustration of the value of resting the bulbs is afforded now and again by the progress under cultivation of some newly-imported species. Frequently, indeed generally, the bulbs by long contact with the soil become very small, and on their first flowering do not impress either the beholder or support the glowing accounts of their beauty or worth that may have gone forth. Much of this, however, is quickly changed under the conditions of culture accorded the bulbs by most European growers, and frequently an offset will be larger in the third year after introduction than was the original bulb when first introduced. Nor is this the result exactly of a forced growth, such indeed as one may expect from land heavily manured or the like, but rather an

TULIPA PANATII

illustration of the general conditions of growth in lowland gardens as compared with those of the higher altitudes at which numbers of these beautiful flowers are found. Doubtless not only a more deeply cultivated soil, but the moist climatic conditions which alone ensure a longer season of growth in the lowlands will in a considerable degree account for this development both of bulb and of stature. In the replanting of such things as Tulips it is always better to make at least two sizes, planting the large flowering roots in one lot and the small or successional bulbs more thickly in a reserve plot. So long as the soil is new to these things they are not particular as to its component parts, seeing they do so well in such variable material as vegetable and peat earth or sandy loam, or even the lighter clay soils. As a rule, however, the more vigorous types will be safe enough in stronger soils, while in the case of a few exceptional sorts, particularly those dwarfed and more dainty in growth, a free sandy soil may be given.

Planting may be done during the early autumn. Meanwhile keep the bulbs in some free, airy place such as a well-ventilated shed or outhouse. It may be worth noting how beautiful are the many dwarf species when grown in groups in the rock garden. Here, small groups or colonies may be planted that at flowering time will create some very pretty effects, the dwarfed sorts being perhaps best suited to this purpose.

The pretty species in the coloured plate to-day, *T. saxatilis*, is among the choicest of the dwarfed sorts, rarely, if ever, attaining a foot in height. The dainty character of the plant is so well shown in the plate, that it would be superfluous to add anything in this respect. It may be remarked, however, that the larger flower is rather highly coloured for this kind, while the expanding blossom gives a good idea of the way the flower is lined externally. The species is a native of Crete and among the earlier sorts to flower. Some good companions for this charming sort may be found in *T. violacea*, a unique species, very dwarf, and probably the earliest known species to flower; the exquisite *T. Leichtlini*, a delightful plant from any point of view; *T. Batalini*, lovely in the soft yellow tone of its flowers; *T. persica*, a dwarf and fragrant kind, beautifully adapted for massing or rockwork; the cream-coloured *T. biflora*, which is also a profuse bloomer and quite early; *T. Clusiana*, which is white with red stripes and conspicuous with violet eye; and the pretty Grecian *T. orphanidea*, the last having orange-yellow flowers and a dark centre. Masses of any of these would be most interesting, and from their earliness as much as dwarfness are well suited for this style of gardening.

THE WEEK'S WORK.

KITCHEN GARDEN.

OPEN-AIR TOMATOES.—Plants, whether occupying warm, sunny walls or grown market fashion in open positions trained to stakes, will now demand close attention. The soil at the base of walls is frequently drier than the cultivator is aware of, and, through the roots suffering, the bloom-trusses fail to set, the weather being blamed for it. Mulching, though generally indispensable, is often somewhat deceptive, as the surface appears moist when 6 inches down the soil is dry. Practically speaking, one can hardly over-water wall Tomatoes, although, of course, much de-

gives a check to the plants generally. The same remarks as to mulching, watering, and applying stimulants as in the case of plants on walls hold good. Mulching may in some soils easily be carried to excess.

CARDOONS.—The earliest transplanted rows of these will now be sufficiently advanced in growth to assimilate liberal supplies of water of a manurial nature. This is the only way to secure sturdy plants, Cardoons being such thirsty subjects. On light, porous soils if artificial watering is neglected in comparatively dry seasons failure is certain. Go over the plants and remove any suckers that may have issued from the base of the plants, also any rough, discoloured leaves, giving a copious drenching with farmyard manure once a fortnight, or where this is not practicable prick over the surface of the soil with a fork and apply a moderate sprinkling of guano, fish manure, or nitrate of soda. The last manure must be used with discretion, as if applied too liberally harm may be apprehended.

CUCUMBERS FOR AUTUMN.—In some gardens where Cucumbers are in constant demand and sufficient glass accommodation exists, it is customary to raise a batch of plants for producing fruit at the latter end of September and onwards. These plants will now be in small pots and in a growing condition. A moist, shady house is essential for the production of vigorous, spider-free plants, which after filling a 6-inch pot with roots will be ready for transferring to their permanent positions early in September. With care in management there will then be no fear of a scarcity of tender, well-flavoured fruit from the time the summer frame and pit supply is exhausted until the winter plants commence to yield. Upon no consideration allow a pot-bound condition to occur, as then an attack of red spider may be expected. I do not advise a too rich compost for autumn-bearing plants which may, perhaps, have to supply fruit throughout November, as a solid, wiry growth rather than a soft, over-sappy one is desirable. I think good sound loam, kept open with a little leaf-mould and some road grit, is a very suitable compost, as it is easy to feed to any extent when the plants commence to carry fruit. A quiet corner in a rather close, moist house is the best position for the plants at present, and they enjoy the moisture arising from a layer of damp Moss. People nowadays, as a rule, prefer large, showy Cucumbers, but, provided a true strain is secured, I do not think there is a more reliable or profitable variety for late autumn or winter use than the old *Syon House*. Next to it, a good variety of *Telegraph* is, perhaps, best.

SPRING-FRUITING TOMATOES.—From the commencement to the middle of August is a suitable time to sow, in as cool a place as possible, seed of some hardy, free-bearing sort, or sorts, of Tomato for furnishing fruit say in April, 1900. Hardiness and non-liability to fungus attack during the dark, dull days of winter being the aim of the cultivator, a cool position from the very first is imperative. A frame turned towards the north and kept moist daily will answer well, airing according to the weather. I think the plan of sowing in small pots and potting on as soon as these are well filled with roots as good as any. Good calcareous loam and road grit, or old mortar rubble, form a good rooting medium. When growing freely, the young plants must have free exposure to sun and air, and in favourable weather the lights must be drawn clean off. Stockiness is the great thing, and in October, before frost sets in, remove the plants to a cool, airy house close to the roof glass, where they will remain till potting time arrives. J. C.

FRUITS UNDER GLASS.

PEACH HOUSES.—Should any replanting of trees or renovation of soil be requisite in the early Peach house, they should be taken in hand at once before the trees lose their leaves, then the roots will become active again immediately and scarcely any check will be felt by the trees. In dealing

Iris in a Japanese bowl. (See p. 97.)

depends on the season. Administering or withholding stimulants must be regulated entirely by the growth the plants are making or the crop they are carrying. I have found nothing better for Tomatoes than farmyard liquid obtained in a fresh condition and diluted to about one-third of its strength. Beware of the still too common practice of wholesale defoliation, nothing tending more to check the plants and reduce both size and quality of the fruit. Keep all side laterals closely pinched out, and in the case of any clusters of fruit being unduly shaded, shorten a few leaves to half their length, or even tie them on one side to admit sun and air. Plants trained on stakes must not be neglected for a moment in the matter of removing side growths, as frequently, if the weather is dull and hazy, a sufficiently free circulation of air is not enjoyed and mildew and other evils result. Pinch the leaders immediately they reach the top of the stakes, as allowing growth to fall downwards excludes air and light from the fruit, and the final removal of a foot or 15 inches

with such trees I have found it advisable to shade the house for the time being, and if the roots have to be kept out of the soil for any length of time they should be kept plump by covering them with damp mats or something equivalent to the latter for the retention of moisture. If the trees are not old and actual replanting is contemplated, I see no need whatever to attempt lifting them with a large ball of soil, for, provided the work is done quickly and well and the roots surrounded with the kind of soil which conduces to activity in the shortest possible period, the preservation of much old soil round the roots is more of a hindrance than a help, besides adding to the danger of fracturing many of the roots by its weight when lifted. Few trees take so kindly to transplanting as does the Peach if given anything like fair treatment and provided it is not old enough to have lost all its recuperative vigour; therefore if the growth or the crop has been in any way unsatisfactory, I strongly advise an overhauling of the roots and re-making the border as the best means of correcting faults of this nature. As re-making does not necessarily mean giving the trees an entirely new border, the expense need not be great. Provided the old soil is not sour, most of it may be retained and will do good service when corrective materials are added to it. When Peach trees which are treated correctly as regards general management go out of health from any cause except that of old age, it is tolerably certain that the fault arises from a deficiency of lime in the soil, and it is to lime that the grower must turn for help in renovation. Many borders which contain a fair amount of mortar rubbish—an excellent ingredient for keeping a border porous—are still deficient in lime, for that in the mortar will have lost all or almost all its virtues, and freshly slaked lime should be added freely to the heap of soil being prepared for the planting. The only other ingredient for which I care is the ashes from the garden smother fire, which will consist of about equal proportions of wood ashes and burnt earth. These two ingredients and some good sound loam provide all the necessary elements to the border, and any feeding which may be necessary later on can then be applied to the surface or in solution when watering. The only case in which I recommend anything further to be added is when the border is wholly inside and very limited in extent, then a liberal allowance of half-inch hones will be of service. In dealing with fruit borders of any description too much care can hardly be spent on the drainage, as this to be effective must be ample and well arranged so that it is capable of carrying off within a reasonable time the large quantities of water that should be given during the time when the fruits are swelling fast. The most unsatisfactory borders are those which remain so wet below after watering as to preclude the possibility of giving the thorough waterings essential at frequent intervals during that period. These borders often crack on the surface and allow the upper roots to become dry while the lower ones are still wet from the previous watering; consequently the border has to have mere dribbles of water just to keep the surface right. On top of the drainage should be placed fibrous turves, which should be made to fit together nicely, and not be broken up by being wheeled upon or trodden heavily. Such a covering over the drainage will remain intact for years and will prevent the fine particles from silting down and choking the drainage. In planting, take care to make the border firm and to set the tree so that its stem will be buried no deeper than it had been previously; then spread out the roots in a natural manner, keeping them well up, and fill in round them with some nice mellow turf from an old stack if possible, keeping the newer soil for the body of the border. After planting, keep the house close, but cool for a few days, leave the shading on, and syringe freely two or three times a day, then the wood will remain plump and hardly any check will be felt. As the mid-season Peach trees are stripped of their fruits, use plenty of water to cleanse the foliage, and leave full air

on night and day, also see that the roots are not allowed to get dry. Late crops must be fed as occasion offers, so that they may attain a good size, and they should be kept well exposed to the light to gain all the colour they can, for with many of the very late varieties appearance goes for much.

PINES.—Though the weather may remain hot by day, we have now got to a time of the year when cool nights may be expected occasionally, so that there should be no laxity as to the heating arrangements, a brisk night and day temperature being necessary to keep the plants going, especially those carrying fruits that are in the swelling stages. These, too, will take water freely, and should be looked over frequently so that none among them will be allowed to get over-dry. Manure-water, preferably that made by steeping good guano and used in a weak form, will be taken freely by all the growing stock that has practically filled the pots with roots and will do the plants a great deal of good, whether they be fruiters or successions. All surplus suckers should be wrung out as they become big enough to be easily got at, retaining not more than one, and that one of the lowest on each plant for stock. Continue to pot up suckers when they become big enough, giving them small pots only in which to start and pot on earlier batches that have filled their pots with roots, so that they may become well established in their new pots before winter. See that the houses and pits are shut up early enough to run up the temperature 15° to 20° by sun-heat, and to counteract the scalding effects of the sun use the syringe freely, especially as regards the walls, linings, &c., to promote abundance of evaporated moisture.

MELONS.—Whatever license may be allowed to early crops, it is certain that one cannot afford to permit any laxity with regard to the latest plants at any time either in the matter of planting or in the general details of management, for it is these late batches that are most likely to become cankered when the weather begins to change for the worse and the nights get long. Perhaps pots are better than beds in which to grow late Melons, but either will do very well, and certainly plants in pots give most trouble in the long run. The beds or hillocks on which to plant should contain less soil than former lots have been given; they should be well raised, made firm, and the plants set out in the soil, which must previously have been well warmed. After planting, ventilate with care and close very early, syringing the plants freely at closing time and keeping up a high night temperature, so that both root and top grow rapidly. If pots are used, they should be so fixed that they cannot sink out of position, a firm pedestal being best for them. When plunged loosely in fermenting material the plants are apt to become strained through its settlement, and this is sure to injure them badly. CORNUBIAN.

KITCHEN GARDEN.

VEGETABLES AND DROUGHT.

This is a very familiar theme just now with everyone who has the charge of a garden and from whom is expected a daily vegetable supply of greater or less variety and bulk. The season has not so far been remarkable for the length of drought as much as for the great damage done in such a short time. For the six months—January to June—there have been in this neighbourhood 6½ inches more rain than in the corresponding six months of last year, and yet there is a much more widespread outcry from the influence of drought on vegetable and fruit crops. Peas and Cauliflowers among vegetables have given the most trouble with me, although others have suffered proportionately. The soil overlying a sandy clay subsoil drains rapidly in summer, and without mulching Peas suffer quickly. Several of the early sowings, which

were made at intervals of ten or fourteen days, seemed to come in all together, although kinds of a successional character were chosen. The evil of this was too clearly manifested in a short supply between these and the maincrop sowings, and at a time when the demand is heavy. The drought, too, showed very clearly the value of trenching the ground for Peas, especially that which has to do duty for them at rather short intervals. No vegetable so soon tires of the same soil as Peas when there is a frequent repetition of sowing, and which must necessarily occur in small gardens in dividing the warm borders between the early and most valued crops. In such cases trenching is invaluable, because it breaks up and incorporates some new and unexhausted soil with the old. Clayey subsoils ought not, of course, to be treated on the same principle as those of a lighter nature. I have known instances where the bringing up of a quantity of clay to the surface has completely spoilt the ground for vegetables, and until re-trenching had been carried out no useful crop could be produced. Straw manure dug into heavy ground is good, but that which is short and decayed is better for light soil. Mulching, as Mr. Wythes remarks, does not add to the appearance of the vegetable quarters, nor does it simplify the work in keeping down weeds. In open soils the hoe can be kept constantly moving among growing crops and the weeds kept well under hand, but this does not take the place of mulching.

In sowing late crops of Peas when the weather is summer-like I am compelled to cover the soil with straw litter as soon as the seeds are put in and allow these to push their heads through it. Needless to say, this must not be very heavy, or they would fail in their effort by being suffocated. Lately, Spinach has given much trouble, some in running early to seed, other and later sowings absolutely refusing to grow. Spinach Beet comes to the rescue, however, and the weather which dealt so severely with the ordinary varieties seemed quite what the other enjoyed. Planting of winter crops was at a standstill for some time, resulting in over-grown and succulent plants in the seed bed and a large percentage blind and useless. Slugs in dry weather are less troublesome among tender salads and young vegetable plants, but the Turnip flea has been more than usually active. In the fruit garden birds have been most daring and destructive. Onions, which are usually good dry-weather plants, showed signs of distress previous to the rain of the 22nd ult. A heavy thunderstorm on that date, when 1¾ inches of rain fell, greatly assisted the swelling of these and stimulated other vegetables into active growth. Early-planted Brussels Sprouts and Runner Beans have made good growth. The break-up of the drought, however, will, it is hoped, soon change the aspect of affairs. W. S.

Wills.

The early Potato crop.—In many districts early and second-early Potatoes have this season had an indifferent time of it, as during the latter half of April and throughout May cold, particularly at night, gave the haulm a severe check. In some districts in the eastern counties the first growth was cut clean back when a few inches high, and all practical gardeners know well what that means so far as the size of tubers is concerned, as the majority of sorts never make up the lost vitality. These late, unexpected frosts ought to teach the necessity of protection, if only of a rough nature, such as loose, dry Bracken or litter. Owing to a lack of rain in this district first and second-early varieties will on most soils

be undersized, and an old gardener told me a few days ago that in the event of a copious rain the probability is that the tubers will grow out. I have not at present heard any complaint as to the disease. This confirms the opinion I have before expressed that the germs of disease may exist, but that they will not develop unless surrounding circumstances are favourable to it. I hope that the rain which fell almost without intermission in this part of East Anglia from 4 a.m. on Saturday until the same time on Monday has come just in the nick of time to save the late field plots on light land. Probably the price at which seed tubers are offered makes it impossible for growers to plant Renown in quantity for market, but I look upon this variety as one of the most useful late-keeping rounds introduced for many years. It is a grand cropper, almost as round as a cricket ball, delicious when cooked, and withstands disease better than many.—NORWICH.

AUTUMN AND WINTER SPINACH.

As regards the dates for sowing late autumn and winter Spinach, much depends upon the locality and the soil. Indeed, the soil in my opinion is the chief cause of failure in many cases, as I have often observed that land that produces a quick, soft growth is not the best for wintering the plant. In all gardens Spinach is not considered a necessity, but it is certainly a valuable addition, and where it does well there will be supplies from October to May. I find for autumn and winter supplies the best results are obtained from the large-leaved kinds, not but that these fail quite as badly as the older prickly and small round-leaved kinds if not given ample room. I am inclined to attribute some of the failures to undue crowding at the start. I fail to see why so many vegetable crops are sown so thickly at the present day, as in nine cases out of ten it is not necessary. By sowing thinly much better results would often follow. In the sowing of winter Spinach I find crowded plants in a rich, close, old garden soil grow so rapidly at the start that failure is nearly certain at a time the plant gets pinched in severe weather and is too weak to bear the strain. For years I sowed on rich or well-manured land specially prepared for the crop. It is necessary to manure in poor land, but I have obtained far better results from less manure at the season of sowing, giving more food in the shape of top-dressings when new growth is needed early in the spring. I also find a light, loose root-run not conducive to sturdy growth. It certainly is advantageous for seed sown say in March or April, but in August and September I find by reversing the conditions of culture a better crop is secured. Having a very light soil resting on gravel, growth is rapid, but not reliable, and to get a better return I sow on land well trodden; in fact, rolled both before and after sowing. One may often see large breadths of winter Spinach in fields when there are none in gardens. With field culture the plant gets what is almost impossible in a garden, that is, change of soil, and this is important. As regards dressing the soil, I would much rather give a good quantity of such aids as soot, lime, and burnt refuse of any kind than heavy coatings of manure. In heavy clay soil I have used road scrapings to advantage, and in a light porous soil cow manure is better than horse manure, and if any heavy materials can be added, so much the better. I am not in favour of sowing in newly-dug land just manured if the soil is very light. Several seasons when short of manure I used fertilisers, and had a much better crop. Lack of moisture is often the cause of failure with Spinach at other seasons, but too much in autumn and winter

soon tells its tale. I think it is of great importance to give plenty of room—18 inches to 2 feet apart in the rows, the plants being thinned to at least 6 inches to 9 inches in the row.

A hard and fast line cannot be drawn as regards date of sowing, as so much depends upon the soil and position. About the middle of August is a safe time, provided ample room is given and early attention paid to thinning. I get better results by making two sowings—one early in August, one a month later. Should the earlier-sown get coarse, the later will be a better crop and not run so quickly in the spring. The late-sown lot will often escape a severe winter when the other is much cut up. The later sowing need not be given so much space. The newer kinds of Spinach are excellent for winter and spring supplies, and a kind much grown abroad—the Viroflay—is very useful, on account of the colour and quality of its large leafage. The Long Standing, the Carter, and the Large-leaved Victoria are all good. In heavy land it may be advisable to sow the Perpetual or Beet Spinach. This lacks the quality of the others named, being more like a Beet-root, but it is a good substitute.

G. WYTHES.

ROOM IN THE KITCHEN GARDEN.

It is very short-sighted policy on the part of those who have the laying out of country places to allow so little room for the culture of good vegetables. The number of things that have to be grown to satisfy the kitchen department and the amount of space necessary to get proper quality in the produce can only be understood by those who have to do it with very limited space at disposal. Close planting is one of the worst evils, leading to want of quality and allowing insects a much better chance than when the rows of various crops can be kept well apart, so that air and light filter freely through them. Closely-planted gardens are and must always be a splendid propagating ground for Potato disease, mildew and other fungoid troubles, and, of course, more seed is used, good rows well apart of almost every crop producing twice the amount that crowded ones do. Again, it is impossible to give the various crops their proper rotation, and land has often to be sown or planted before it is really in a fit condition. I know that in some large gardens where there is only a limited demand the spare plots are sometimes allowed to get into a very bad state, but this need not be. Potatoes might be grown and less room needed for the field crops; and, again, what a boon it would be to be able to dig the plots for Brussels Sprouts and other winter greens and allow them to stand until they were needed instead of having to plant after Potatoes and even in some cases on the late Broccoli quarter of the previous season. There could be no comparison in the quality of the produce grown under such different conditions, while the cultural details could be carried out in suitable weather instead of having to do the work at a time when other important things are waiting attention.

There is, in fact, no end to the advantages that accrue from having ample room, and it is certainly false economy to pinch the kitchen garden for room on estates where the land is let in many cases for a few shillings the acre. Where vegetable quarters have to be cropped several times in the year, it is only reasonable to expect that a lot of feeding with good farm-yard or stable manure will be necessary. It is one thing to grow a single crop in a year and another to take two, or even three, as we must

do when double cropping has to be practised, and good, succulent vegetables take a lot of goodness from the soil. A too small kitchen garden means an endless worry to those in charge of it. A SUFFERER.

Globe Artichokes.—Owing to the limited supply of rain, Globe Artichokes in gardens where the soil is of a shallow or sandy nature will have so far made a none too robust growth. In order, however, to enable the stools to regain their normal strength, liberal treatment from the present date till the leaves and stems begin to decline must be accorded. If any stools are weak, they must not be allowed to mature all the heads they throw up; removing say one half will be of advantage in enabling the plants to build themselves up for another season. Where a good mulch was applied in spring, and this has been washed away by repeated waterings or by birds in search of insects, another must be given, also as frequent and liberal doses of farmyard manure as time and means will allow. Plants raised from small offsets and put out in May should be treated as liberally as possible. These should make good stout-bearing stools for next season.—J.

Pea awards at Chiswick.—I should be glad to know why a variety given three crosses by the fruit committee at Chiswick does not receive an award of merit, as I find, by scanning the gardening journals, several varieties had the same award and were given awards of merit at the next meeting. I fail to understand why Dwarf Triumph was omitted, and I think the reason should be given, as if it was not considered distinct, why give it three marks, or if not good enough in other ways, why bring it forward at all? I do not know Dwarf Triumph, and my contention is that a variety once recognised should receive the proper award. Of late years I notice a different course is adopted by committees of the Royal Horticultural Society, at least by the fruit and vegetable committee. In former days three marks meant a first-class certificate, two an award of merit, and one meant highly commended. The plan was good and everyone knew what these marks meant. Now it appears that three marks do not even carry an award of any kind.—AN OLD FELLOW.

Trouble with the Celery.—This season the Celery fly has been most energetic, and even before the Celery was out of the nursery beds brown and seared leaves were noticeable. On a dull, warm day at the beginning of June I saw a horde of these flies hovering round a trench of early Celery when walking round the garden of a friend. Prompt measures were at once taken, soot was dusted over the foliage, and I have since learnt that scarcely any traces of the maggot were afterwards noticed. But this is just where many people make a mistake. The mutilated leaves point plainly to the work of the grub, and they at once commence to apply soot and other remedies. It is a parallel to the case of locking the stable door when the horse is stolen, for the mischief is then done, and no insecticide is strong enough to kill the grub feeding under the outer tissues of the leaves without destroying the foliage as well. Prevention is better than cure in most cases, emphatically so in this one, and anything that is used should be in the form of a preventive in making the foliage distasteful to the fly. High cultivation is another antidote to Celery fly, for whenever there is any check to the growth of the plant in its early stages, that is the time when the enemy appears to do the most damage. Unfortunately, every grower has not an unlimited water supply, and where this commodity is withheld or supplied sparingly the Celery fly is almost certain to do much damage. One thing is certain—that when once the grub is there the best plan is to at once pick off the mutilated leaves, and by assisting the plants as much as possible with liquid, induce them to make fresh healthy foliage.—G. H. II.

FERNS.

ADIANTUM GLAUCOPHYLLUM.

THERE are few prettier members of the great genus *Adiantum* and probably none more easily grown than the subject of the annexed cut. It resembles a good deal *A. cuneatum*, but is of a lighter and brighter green and the pinnales differ in shape. It has short creeping rhizomes, and seems at home almost anywhere, for it will exist in an absolutely unheated house. It grows luxuriantly in the intermediate fernery where nearly all the other *Adiantums* and *Gymnogrammas* thrive, but probably a shady greenhouse temperature is as good as any. The illustration shows a specimen covering the entire exterior of a porous earthenware pitcher, which is kept filled with water, the Fern being simply tied on with wire, with a very little soil. It envelops the pitcher so completely as to render it quite invisible. The whole is suspended from the roof, the vessel being pointed at the bottom. It can be

Adiantum glaucophyllum in a porous jar. From a photograph by Mr. G. Pim, Dublin.

grown into very pretty little specimens for table decoration in 3-inch pots, and will stand being pot-bound well. *A. glaucophyllum* is a native of Mexico and Guatemala, and probably represents in N. America *A. cuneatum*, which belongs to Brazil, &c. G. PIM.

***Pteris tremula*.**—Where there is much home decoration to do seedlings of this useful Fern ought to be raised frequently, unless, as in many cases, they come up promiscuously about the pots or walls. No Fern is so easily grown or comes so quickly to a useful stage, and it is almost sure to preponderate in any batch of seedlings raised from purchased spores. Grow the plants and use them as long as they are fresh, then throw them away and bring on a clean lot of young stuff.

***Athyrium Goringianum tricolor*.**—This is a very pretty and brightly coloured Fern that is well worth growing, but does not seem to be generally cultivated at the present day. At one time I had a nice lot of it growing in a light, almost unshaded house, and the pretty green, red and silver-grey markings were always commented upon and admired. The plant is herbaceous,

dying down to the ground-line and springing up again in spring, and in a warm, sheltered rockery in Gloucestershire it lived outside through several winters, though the fronds were not so large or nearly so well coloured as under glass. These curve out over the side of the pan in which they are growing almost like those of a *Davallia*.—H.

***Adiantum Wilesianum*.**—The fronds of this fine species have a good deal more substance and are much more handsome than those of the somewhat similar *A. formosum*. Strongly grown it makes an excellent specimen plant, the large, overlapping fronds giving it a fine appearance. It is best grown in a warm greenhouse temperature, and cutting the fronds ought not to be practised at all seasons, but when thoroughly hardened each plant may be cut over. The fronds, however, are of more than annual duration, and if a good plant is wanted they ought not to be cut for decoration at all, simply removing them when they begin to decay to make room for the younger ones to ascend. Being so strong growing, a rather rougher compost than most *Adiantums* like may be given, and when healthy and rooting freely a fairly large shift is quite to its taste. Rough peat and loam, with a little leaf-mould and

a good sprinkling of sharp silver sand, make a good compost, and this should be placed rather firmly in the pots for old-established specimens. Young growing plants may be potted a little more loosely, as the growth will be quicker, though less substantial. Grow it in a good light all the year round, shading only for an hour or two in the middle of the day.

***Gleichenia circinata*.**—This in its varied forms is one of the best of stove Ferns, and neat specimens are very elegant and light-looking. The long graceful pinnae of *G. c. semi-vestita* are even prettier than those of the type, but both should be grown and are worthy of a place in the best collections. The wiry rhizomes seem to delight in surface and atmospheric moisture and where a brisk stove temperature is maintained. It is necessary to prevent injury to the points of these, as when once checked further progress from that individual point is doubtful. For the reason stated above I tried a few small specimens in growing Sphagnum Moss, placing this over the top of the compost as a surfacing. The rhizomes extended in this material very freely, throwing up strong fronds and making very

fine plants. Where possible this *Gleichenia* ought to be grown so far back on the stage that it is not likely to be touched, as the fronds are even more susceptible to damage than the rhizomes. Where the points by any means do get bruised, it is not always necessary to remove the fronds entirely, but they may be cut back to the fresh portion with a pair of scissors. *G. circinata* is a native of various parts of Australia.—GROWER.

WALKS, DRIVES, AND WEED-KILLERS.

PROBABLY the greatest boon that has been conferred upon foresters and gardeners during the present generation at least is the weed-killer. The saving of labour by its application over the kingdom must have been enormous. I can well remember what the keeping of some scores of miles of gravel walks in good order on a large estate in the north meant. The hoeing and raking were very bulky items, but as the work could only be done in dry weather, squads of women and boys were set to hand-weed the walks throughout the whole summer as well. Hoeing and raking were usually abortive, in woods especially, as the walks were green again at one end of the wood before the hoe had reached the other. Later, on another estate where reduction of expenses in gardens had become the order of the day, the private roads and drives had to be tackled, and as the weed-killer had not then become known it was decided, on the advice of the gardener, to draw the line somewhere between gravel and grass, with the result that miles of gravelled walks and drives were allowed to grow green, and only those were "kept" that could be kept. In one season the abandoned roads grew green with grass, but being a hard bottom the roads in the parks never became rank and were cropped close by sheep and cattle, so that in a short time they became soft, yet firm, and some wondered why the idea of leaving them alone had never occurred to anyone before. One of the most perfect grass drives I know of was once a macadamised road, which has now for over thirty years been covered with a dense soft carpet of grass. When the carriage leaves the highway and goes on to this drive one feels as if the wheels had suddenly jumped into pneumatic tyres. This, by the way, to those who care to take the hint. In woods, of course, grass paths have to be gone over once or twice with the scythe, but the grass can usually be disposed of, which defrays the cost of cutting.

The objections to the weed-killer have first to be disposed of. These are a supposed injury to the health of people who frequent paths where the weed-killer has been used, and a danger to cattle, game, &c. I do not know whether or not all weed-killers are alike. I have only used one, Bentley's, and after about six years' trial on garden walks, estate roads, wood walks, and pavements in and about the mansions and dwelling-houses, not a single mishap has occurred, and the parks are full of cattle, sheep, and horses and the woods full of game. The saving in labour will be guessed when it is stated that one man with proper appliances has for the above period done the work of probably ten men, and done it usually in one month, the work being let by contract. The effect upon the weeds was magical. The stirring of the surface of walks has been avoided, and the hacking of the edges of roads, much to their injury, done away with. A besom now does all the work. The first year the full dose was applied according to the directions in May and June. The second year scarcely any application was needed; the third year weeds were still few, and the killer was only applied where

they grew, and since then the annual application has been slight. It has been asserted elsewhere that the health of people in whose gardens the weed-killer has been suffered. My experience where the walks have been saturated up to the doors is that no one has ever complained of the slightest ill-effects. The same man has applied the weed-killer every year, and for a month at least is going with his nose over the can with which he applies the poison, but he has never suffered in any way, and his general appearance would satisfy the most exacting of insurance society doctors. The appliances should be kept by themselves when not in use and be locked up. All the accidents I have heard of have resulted from neglect in this respect. One gentleman wrote to another, "Do you use any of these weed-killers? I have lost three of my prize short-horns through its use." The gardener, not to be stopped, inquired further into the matter, and discovered that the cattle had sipped the liquid out of a pail carelessly left standing in the park by the man during his meal hour.

Much care is necessary in using the weed-killer in gardens where the roots of trees extend under walks. A fine plant that covered a large portion of a mansion died suddenly and inexplicably. The root was sent to a scientific expert in London not a thousand miles from South Kensington, who was as much puzzled as anybody. Later I had a chance of looking at the spot, where it could be seen that the walk sloped towards the place where the plant's roots had been. Into this depression the weed-killer had flowed and soaked, probably assisted by a shower of rain, killing the plant in a short time. I have known three instances of this kind.

RAMBLER.

Pea sticks.—A Pea that would produce heavy late crops of wrinkled marrows of the best quality on a short haul would be a boon to the gardener and his employer. Early crops some gardeners do not stick at all, but late Peas that grow from 7 feet to 9 feet high must be supported in some way, and the sticking of the rows is a laborious and expensive business. I knew a garden where there were about sixty rows of Peas sown annually, each row about 50 yards long, and which could hardly have paid for the sticking done. Each row required about 300 tall sticks, which, collected, trimmed, sharpened and delivered, cost from 5s. to 7s. per hundred, and that, together with the labour of putting them in and removing them in autumn, would bring the amount up to fully £1 per row, or to a total of about £60. Where labour is scarce the Pea crop is a source of anxiety to the gardener, and some few years back I came across one who had reduced the labour and the cost by at least half. Reasoning upon the assumption that the Pea will cling to one stick, where it had not the choice of two, and find all the support it required, he only put one row of sticks to each row of Peas, and as the rows ran north and south, as they usually do, he put the sticks firmly in on the east side of the row, as the prevailing winds were from the west or a point west. I saw these Peas (No Plus Ultra and the like) late in autumn bearing crops, and they certainly did not look as if they needed further support. Ever since he has stuck to the "one-stick plan," as he calls it, saving much precious time thereby. He is not particular about the shape of the sticks, which is another advantage. Beech and other flat-branched sticks have always been the favourites, and there have been plenty of gardeners who would have no other, but my friend takes any kind of stick that is tall enough, stout enough and twiggy enough, that he can stick firmly into the ground, and he nips off the extremities and puts them in at the bottom to thicken it there and lead the young Pea to its supports.—J. S.

FLOWER GARDEN.

A PLEA FOR SIMPLICITY IN THE FLOWER GARDEN.

WITH the advent of more natural methods of laying out gardens which have made such immense strides of late years, there is less need of bedding out—properly so-called—in many places where formerly it was the great attraction. Borders and permanent beds have encroached in the majority of gardens on the space once devoted to flower-beds. But even now, although formal beds are out of fashion, there are some places where they are desirable and indeed necessary, even in small gardens. A few beds, for instance, near the house give a brightness in early spring and late autumn which cannot easily be obtained by the use of hardy flowers, and, of course, in formal gardens such as exist round many large places the bedding-out system must always continue, modified and, as it were, softened by the introduction of hardy and fine-foliaged plants.

It is in laying out these beds that the gardener may show real taste. For instance, it may be allowable in a large Italian garden to have beds edged or carpeted or to plant various species together, and no doubt where this is done artistically, most beautiful combinations may be produced; but in smaller places or in gardens where the main features are the borders of perennials or groups of hardy flowers, nothing looks worse than to see pretentious beds. Even where these are most beautifully done they seem quite out of place. A large simple bed of some freely growing plant will in such a garden harmonise with its surroundings in a way in which the finest combinations of colour and form or perfection of edging and carpeting cannot do. And further than this, in gardens where, as I suggest, the simple form of bedding out should obtain, such plants as Begonias or Calceolarias are, I think, out of place. Beds filled full of Ivy-leaved Geraniums, Heliotrope, Pentstemons, Violas and many other free-growing and spreading plants (one kind only to each bed) lend themselves to association with hardy flowers. I would exclude, indeed, all flowers which suggest by their form an exotic origin. The same remarks apply as well to spring bedding as to summer. We ought not, in a garden such as I have indicated, to have the formal Hyacinths or Tulips in beds. But we can have Polyanthuses, and Primroses, and Forget-me-nots and many other what I may call informal plants which will suggest themselves to everyone, and if these are planted so that the beds are overflowing, as it were, the effect will be charming in combination with the borders and permanent beds around.

We too often allow the gardener to show his skill in planting out and combining plants to the loss of artistic beauty, and although the results are in themselves often most beautiful, we ought not to forget that it is the effect of the whole garden, or what is seen from one point of view, that we ought to consider and not merely a part. Many gardens, more especially small ones, are marred by the incongruity of their set beds, and if a little more restraint were exercised and greater simplicity observed, the whole effect of many a beautiful place would be much enhanced.

S. T.

Cenothera Fraseri.—In my note regarding *C. Youngi* fl. pl. and Mr. Cuthbertson's new Evening Primrose I find that I have been in error in referring *C. Fraseri* to *fruticosa*. I observe in the "Index

Kewensis" that it is said to be synonymous with *C. glauca*.—S. ARNOTT.

Tropæolum speciosum is doing well in Mr. G. F. Wilson's Wisley garden. The slender shoots are almost hidden among the branches of a white Rose, the scarlet blooms peeping out here and there, their bright hue emphasised by the abundant verdure and pure flowers of the Rose. A large Holly gives shade, and other trees hard by create the cool atmosphere which is so necessary to the continued well-being of this delightful hardy flower, in southern gardens at least.—J. C. B.

Double-flowered Martagon Lily.—This must now-a-days be assigned a place among the rare kinds, for it is seldom met with, and the name occurs in very few catalogues, yet some years ago it was quite common. This was brought forcibly home by the perusal of the catalogue of one of our prominent nurserymen, who twenty-eight years ago announced the price of the double-flowered Martagon at 1s. 6d. per bulb, being in fact at that time one of the cheapest Lilies.—H. P.

Pratia angulata.—In various portions of Mr. Wilson's Wisley garden this delightful little hardy flower covers some square yards of ground with its fresh green foliage. The pure white flowers are this year produced in unusual profusion, being shown off to great advantage by the thick carpet of verdure on which they repose. At Oakwood this is grown in a rather moist, sheltered position, but where abundance of light and a fair amount of sunshine come in the growing season.—J. C. B.

Lilium colchicum under trees.—In Mr. Wilson's Wisley garden this Lily is grown in various positions, but always in the shade of deciduous trees. In the subdued light which there prevails, the handsome pale yellow blooms are seen to advantage, and by the vigorous growth made it is evident that the plants rejoice in the shade and shelter they enjoy. Clumps of this Lily throwing up their tall stems among the branches of low-growing Apple trees have a very pleasing appearance.—J. C. B.

CARNATIONS AND PICOTEES AT THE CRYSTAL PALACE.

THE display of these charming flowers on the occasion of the National Carnation Society's annual exhibition (southern section) was as extensive as in previous seasons and the blooms throughout were of nice quality. From the point of a mere visitor I thought the show a good one and by far the most interesting I have seen in respect of new exhibitors. When fourteen take part in competition in the class devoted to novices, I think there is a sign of some enthusiasm. The introduction of new self-coloured Carnations, yellow-ground Picotees, and those of many colours called fancies has given these flowers a great and increasing popularity. They are easy to grow in comparison to the bizzarres generally, although the old school florists do not look upon them with much favour. To an ordinary person, however much one may admire the pretty markings of the old type of flower, there is no getting away from the showiness of the newer flowers. The yellow-ground Picotees appeal to my individual taste, but before I note the varieties of excellence I would point out how confused is the present arrangement of exhibiting them. A very large and handsome kind named Voltaire was placed first in the class for half a dozen fancy Carnation blooms of the same variety, and if my memory serves me, it obtained prizes as a yellow-ground Picotee. There were instances throughout the classes of other sorts being equally mixed. I would suggest that the Carnation Society take this matter in hand, so that complaints will be less rare in the future. It would not be difficult for a small committee to make out a list of what are fancies and what are yellow ground Picotees, the same to be printed in the schedule and revised yearly. An old kind, Mrs. Douglas, is a first-rate type of a yellow ground. The bloom is not over large, well formed, clear coloured, and rich. A new variety was exhibited, which makes a distinct advance in this section, named Childe Harold. It is one of Mr. Martin Smith's latest gains. Another that easily won first prize in its class is Lady St. Oswald. This has a very deep yellow

ground with a true red margin. These two appeared to me most beautiful kinds. Badminton, Dervish, Empress Eugénie, Hygeia, Mrs. Robert Sydenham, Stanley Wrightson, and Heather Bell are among the best of older sorts.

Fancy Carnations belong to a most interesting section, the colours being so rich and varied. Perseus, Monarch, Hidalgo, Lady Ardilaun, Czarina, Geo. Cruickshank, The Dey, and Artemis are very striking among those now in commerce. Khedive, Guinevere, Charles Martel, Falca, and Pagan are new and likely to be popular in time to come. In self-coloured flowers Mrs. Eric Hambro was seen in perfect form. It would hardly be possible to obtain a better white Carnation. Ensign would appear better, as it gained the prize for premier self of the whole exhibition. I did not see a better rose-coloured bloom than Exile. Seagull is the best blush-white bloom, although Her Grace, a lighter bloom, is very fine. Endymion, salmon-red, and Mrs. James Douglas, a deeper tint of red, are magnificent kinds, quite indispensable to exhibitors. A splendid scarlet Carnation is Lady Hindlip. The Cadi is also fine. Sir Bevy's, a crimson-scarlet, somewhat new, is a rich-coloured bloom. Yellow sorts of rare beauty are Germania, Cecilia and Regina, the last, however, being a weakly grower. Apricot or buff blooms always admired were somewhat rare. Mrs. Colby Sharpin is excellent. Benbow is a new light buff kind which should be noted. Another is Winifred, now well known as a good variety. One of the points of a perfect Carnation is smoothness in the petals. In the buff-coloured class there is room for improvement in this direction. At the Crystal Palace show I noticed one thing especially, and it is a point would-be exhibitors should remember. The best prizes go to those who stage young, highly coloured, fresh flowers of medium size and even in preference to those with size as the principal merit to recommend them. The classes devoted to Carnations shown as grown on long stems did not bring out anything remarkable—at least to my taste—although it is of course the most natural way of seeing them. In such classes there seems to be less care in selecting the blooms, which are more or less confused in form and not fully open. A group of plants that contained a large number of Malmaison Mrs. Martin Smith brought out the merits of that beautiful kind. This, a rich rose tint, Nell Gwynne, white, and Lord Rosebery, dark rose, are distinct hybrids of that remarkable type. H. S.

Gypsophila paniculata.—There are few gardens where material suitable for table decoration or for filling vases and glasses in which the above indispensable hardy plant is not grown. Those, however, who do not possess it should do so, as for elegance and lightness I know of nothing to equal it. I saw it used with good effect at a local show, being in both the first and second prize table decoration. In one instance it was mixed with yellow and white Iceland Poppies, and in another with white and yellow Marguerites. Its hardiness is a great recommendation. A bush here and there intermixed with other subjects in the hardy flower border has a telling effect. It is very easily increased by root division.—N. N.

The Great Arrowhead (*Sagittaria variabilis*).—Any of our readers who are concerned with the adornment of pieces of water might find this a precious aid. It has a double flower like a great white Rocket, with very large leaves, not the same as the old double Arrowhead, but twice as large. A few plants we got of it two years ago have spread all round the water in a very rapid way. It cannot be raised by seeds, but by some floating bulbs, perhaps; but we have never seen a plant take hold more quickly, or, to do it justice, produce a better or more distinct effect, the large and handsome leaves telling very well indeed, and forming fine masses by the margin of the water. The effect of water when it is well planted or bare on the margin is singu-

larly different. Pieces of water with hard, water-beaten margins may be in a year or two altered very much in aspect by carefully planting quite hardy things, waterside and bank plants.

RODGERSIA PODOPHYLLA.

For a cool, half-shaded position *Rodgersia podophylla* is one of our handsomest fine-foliaged plants. This giant-leaved Saxifrage was first introduced into the United States by a Captain Rodgers, of the American Navy, after whom it is named. Its native name in Japan is Yagueumasa, but we may be well content to call it the Japan Bronze-leaf. Each leaf is supported on a central petiole or leaf-stalk varying from 1 foot to 3 feet or more in height, and the largest leaves when fully expanded each measure 3 feet across. Leaf-mould and some peat and sand mixed with the soil seem to supply its requirements, which are a cool, free root-run in a moist and partly shaded position, and each November when the leaves have withered and fallen away, a top-dressing of old manure and wood ashes will be found very beneficial. The flower-stalks are

Rodgersia podophylla. From a photograph by Mr. Greenwood Pim, Dublin.

usually few in number, but the plant herewith depicted is bearing ten feathery wands of creamy blossom, which seen against a dark background are delightfully fresh and cool in the hottest hours of leafy June. A. L. L.

Campanula pulla.—This pretty Bellflower has been very effective this year with the large bells of the deepest violet-purple on frail stems only 2 inches or 3 inches high. Of the small kinds, of which *C. pumila* may be taken as typical, it is, perhaps, the best, the richly-coloured flowers being borne singly on the stems. Quite early in July, and frequently in the latter part of June, it is seen finely in flower. Although a charming plant for the rock garden, it is scarcely suited to the border. Grown in the rock garden it requires a good depth of soil, and rich soil, too. In large pots or pans it is a good plan to divide and repot as soon as flowering is over, not merely

because the plant is much more safely handled at that time, but because it forms a large amount of new roots and underground shoots at this time. Those who have doubts of this have only to leave one plant alone and repot another, and await the next flowering to see the increased vigour of the potted plant. It is much the same with established tufts, for by dividing these and either forming new colonies or spreading a tuft out into a patch twice the size, giving fresh soil and manure, a greatly improved flowering and vigour will be maintained. Some growers recommend peat for this plant, but I have no faith in this. In good loam and finely sifted very old manure this plant may be grown to perfection. Too frequently these dwarf kinds with their myriad root fibres are left too long, exhausting the material at hand and at times becoming well-nigh flowerless.—E. J.

WATER LILIES AT WISLEY.

It is in a time of heat and drought that one is best able to appreciate the beauty of those plants that live in the water. The Water Lilies in Mr. Wilson's Wisley garden have for some time past been giving a delightful display. Very prominent among them is *Chromatella*, in which the beautiful rich yellow colour that distinguishes this kind

fades away to soft pink in the outer petals. The way in which several shades of colour imperceptibly mingle in the flowers of these hybrid Water Lilies is one of their distinguishing and most attractive features. This is especially noteworthy in *Laydekeri rosea*, the flowers of which when opening are of a pale pink, with delicately tinted margins, but which eventually in the course of several days assume a deep pink colour in the centre with rather paler edges. The difference in the early immature and perfect stages of expansion is so great, that one might easily be so far deceived as to imagine that the flowers in their different stages of expansion represent two distinct varieties. *Laydekeri purpurea* is, as its varietal name signifies, more richly coloured, but it and the above-mentioned so nearly resemble each other, that one may reasonably suppose that

they come from the same pod of seed. In *Marliacea carnea* we have a handsome bold-habited Lily, apparently as vigorous and as capable of taking care of itself as our own native species. It throws up its abundant leafage on stout stalks well above the water, the fine flesh-coloured blooms, deeper tinted on the reverse of the petals, being very conspicuous. The rich bronzy green foliage of this variety is very taking, and it will undoubtedly in time be as common in cultivation as is the white Water Lily of our streams and rivers. In great contrast to the foregoing are *pygmæa alba* and *pygmæa Helvola*, the latter with sulphur-yellow blooms. These are little gems, all the more precious as being suitable for the miniature lakes and ponds or large tanks which so many have to be contented with. In a very circumscribed area these dainty little Water Lilies are able to develop and assume their true proportions. *Exquisita*, also very pretty, is of moderate growth with narrow petalled flowers, and would be a good

companion to the above. *Odorata rosea* is in the way of *Mariacea rosea*, but with smaller and much brighter flowers. At Oakwood it grows with freedom and is very attractive. J. C.

Byfleet.

NOTES ON HARDY PLANTS.

Streptopus amplexicaulis, also known as *S. distortus*, is a graceful, though distorted plant, and the flowers are greenish white. It is because of the big and handsome berries that I note it now. These are deep orange in colour, and so large and numerous that you cannot miss a group but must stop and admire it. It grows 2 feet or rather more in height, and, like Solomon's Seal, will thrive and fruit between trees that do not cause too much shade.

Primula suffruticosa.—This Californian species is as remarkable for its distinct features as the part of the world whence it comes. As yet it is little known, having been introduced so recently as 1884. I have grown it almost ever since it came to this country, and though some books tell us it blooms in spring, I never saw flowers out of doors except at midsummer. My first opened this year July 16, and such flowers! the brightest rosy-purple intensified with the brightest yellow eye. The tree-like form of the thick and woody stems fully justifies the specific name, and the wedge-shaped leaves clustered into something like a rosette give it an effect that no other *Primula* has.

Cistus alyssioides is at once the earliest to flower, lasts the longest in succession, and the hardiest of the genus excepting *laurifolius*, which, being perfectly hardy, it can do no more than equal.

Lilium californicum.—The richest colour I have had in the garden during July has been from a big group of this Lily. It belongs to the class of Turk's-cap and the rhizomatous-rooted sorts. It is quite one of those flowers that must be seen to know it and duly admire its beauty and intensity of colour and lively marking. I think it may be safely grouped with the few Lilies that will grow in any garden, and which as yet has not been found to be liable to any disease. If it has a preference, it is for light but moist soil. It dislikes disturbance, and may be two years before it flowers after it has been transplanted, which is best done in September.

Kirkstall.

J. WOOD.

Hyacinthus candicans.—To be effective this species should be planted in large broad masses where it can make a good display and be seen from a distance. A plant or two is all very well in the herbaceous border, but it is much finer as indicated, and being one of the cheapest of bulbous plants there is nothing to prevent its being so used. The plant seems pretty well able to take care of itself, and in shrubbery beds and borders, though planted quite late in the season, it is throwing up immense spikes of flower that look very well among the handsome dark green leaves.

Iris Kämpferi.—This must be regarded as one of the finest hardy flowers of the week, and being among the latest of the Irises to flower is all the more welcome. The colours are remarkably varied and good, the flowers of large size, prettily veined and splashed. The plants bloom freely in a suitable spot, one where moisture is abundant for preference, and the flowers are very bold and striking owing to the width and substance of the petals. Those who do not care for the splashed and veined flowers will find plenty of delightful soft self tints among the varieties.

Yellow Sweet Sultan.—This is one of the most useful flowers for cutting, and at a local show I saw it used with great success in table decoration. The bright golden tint is very distinct and beautiful, and it is also one of the most free flowering plants in cultivation, a good dry weather kind and one that lasts well in a cut

state. It grows about 2 feet high and the plants may if convenient be grown where sown, as it is not one of the best to transplant. Not that it will not thrive when moved, but the roots are not of a character to relish disturbance. It is a good town plant and does best in a rather light soil.

Yucca gloriosa.—There is in the public park at Worthing a fine specimen of this noble plant, which is now in its full glory, having a splendid spike of bloom. Measuring from the lower blooms to the top, the bloom-spike is fully 6 feet, and this stands well above the foliage. I have never seen a more vigorous specimen, the plant being well clothed with healthy leaves down to the ground. I am informed by the park superintendent that there were two plants, the other being in full flower at Christmas-time, and though it did not develop such a fine spike of bloom as the present one it proved a great attraction. During a heavy gale this plant was broken off close to the ground, but the roots being left undisturbed have given a nice stock of young plants. Already a good many have been taken off, and there are more to follow. It will probably be some years before these flower. Another good specimen is in bloom in a villa garden near here.—WORTHING.

SOCIETIES AND EXHIBITIONS.

THE NATIONAL CARNATION AND PICOTEE SOCIETY

(SOUTHERN SECTION), JULY 21.

It is difficult to say of the Crystal Palace that it is a fitting place for an exhibition of cut blooms of Carnations. The vastness of the building dwarfs such flowers out of all proportion. Then a huge glass building reflecting the rays of the sun at every angle is scarcely a place in which cut flowers can remain fresh when the temperature is near 95° in the shade. From openings in the awning the sunlight poured in upon some of the tables whereon cut flowers were placed, and partly frizzled them up before they were judged. The heat in the building, large as it is, is great, and many of the blossoms, half scorched when they were brought to the Palace, speedily collapsed. In dull weather, when it is cool, and when the greatest amount of light is required, the Palace affords it, but when the weather is hottest one sighs for a building roofed other than with glass. The bare undraped tables, of a colour that afforded anything but an agreeable contrast to the flowers, brought into view a palpable incongruity. Then there were huge patches of nakedness, as if spaces had been reserved for exhibitors who did not bring their flowers. The tables for such cut blooms as Carnations should not exceed 2 feet in depth from front to back; in consequence of their greater depth there appeared to be as great a bare space as that covered with stands of blooms. Two handy men set to work as soon as the flowers were judged could so have circumscribed the table space as to reduce it fully one-third, and materially added to the attractiveness of the exhibition as a whole. It will doubtless be said that the visitors go to see the flowers, and vacant spaces on tables are of secondary importance. But an effective arrangement materially assists the effectiveness of a competitive exhibition, and is therefore not without its importance. There is no reason why the artistic element should not be more in evidence at flower shows, and it always appears to be lacking at this particular exhibition. The schedule of prizes is now so comprehensive, and as many prizes are offered in all the cut-flower classes, a large number of blooms is certain to be forthcoming. The white ground, bizarre and flaked Carnations and the white ground Picotees fell much below the average. The burning temperature of the few previous days had told severely upon them. Prizes were awarded to flowers really unworthy of them, but then all were more or less mediocre.

One well-known grower spoke of them as rubbish, and he was truthful as well as candid. The selfs, fancies, and yellow ground varieties, being larger in size and fuller in substance, and, consequently, later in development, were of better quality, some of them really very fine.

Despite the weather, there were seven stands of twenty-four blooms of Carnations, not less than twelve distinct varieties. It is interesting to note how some old varieties hold their own. Admiral Curzon and Sarah Payne, two bizarres, have been in cultivation for half a century and are still found in winning stands. Many of the leading flowers shown on this occasion have been in cultivation from ten to thirty years. Mr. Martin Rowan, Clapham, who grows his flowers near the suburban railway lines and under certain hostile conditions, won the first prize in the leading class. Of bizarres he had Admiral Curzon, Robert Houlgrave, Robert Lord, J. S. Hedderley, and William Skirving; and of flaked flowers, Sportsman, Thetis, Merton, John Buxton, Mrs. Rowan, James Douglas, Gordon Lewis, and George Melville, a very good selection. The flowers were small, fairly pure, and correct in their marking. Mr. C. Turner, Royal Nursery, Slough, came second with larger blooms, but showing signs of the heat and dryness of the atmosphere. Among the bizarres were Duke of York, Arline, Thaddeus, and Master Fred; among the flakes, Chas. Henwood, Prince George of Wales, and Guardsman. Mr. James Douglas, Great Bookham, was third, and every stand got a prize. For self Carnations (twenty-four blooms), Mr. Blick, gardener to Mr. M. R. Smith, Hayes Common, staged some of those superb varieties of his own raising, and in their size, fullness, and freshness they were in marked contrast to the bizarres and flakes. In this first prize stand were Ensign, very fine; Much the Miller and Helmsman, white; Cecilia, Miss Edith Harbord, and Michelet, yellow; Blushing Bride and Her Grace, pink and blush; Benbow, buff; Bomba, Mrs. A. Gilbey, Commander, and Conqueror, rose; Etna and Dudley Stuart, scarlet and crimson; Sir Bevy's, very fine; Kira, Proserpine, and Agnes Sorrel, maroon. It is possible some of the foregoing may not be in commerce, but they are a set of splendid varieties. Mr. C. Turner came second also with some fine blooms; differing from the foregoing were Zachara, Zampa, Mrs. Buchanan, Anne Boleyn, and Miss Judith Harbord; third, Mr. J. Douglas. For fancy Carnations, Mr. Smith was again to the fore with twenty-four blooms, and here could be found in very fine character Lily, Duchess, Monarch, Goldilocks, Bedemer, with a singularly deep edging of crimson-maroon; Aglaia, Falka, The Dey, Electra, Galilee, another deeply-edged flower, in this case with crimson-purple; Guinevere, delicate amber, flaked with pink; Heroine, Alexandra, Queen Bess, Hidalgo, Cervantes, yellow, with slightly pencilled lines of carmine; Ossian, Charles Martel, &c. Mr. C. Turner was second.

Mr. Turner was first for Picotees with small flowers, clean and pure; the leading blooms were—red edges, Brunette, Etna, Mrs. Gorton, and Heart's Delight; purple edges, Amelia and Mary; rose edges, Favourite, Little Phil, Mrs. Payne, Lady E. van de Weyer, Mme. Richter, and Duchess of York. Mr. Martin Rowan was second, having red edge Moroa, purple edge Miriam, and rose edge Nellie, differing from the foregoing; the last a beautiful variety, which Mr. Rowan grows to perfection. Third, Mr. F. Hooper, Bath. For Picotees, yellow ground, Mr. Martin Smith came in first this time with twelve blooms, having in very fine character Argosy, Badminton, Dinorah, Duke of Alva, Author, Fenella, Empress Eugénie, Lady Bristol, Childe Harold (a beautiful new wire-edged Picotee of great merit), Busybody, and Alcinous. Mr. C. Turner was again second. Of self Carnations, one variety, in the class for the best six blooms were those of Mrs. Eric Hambro, white, from Mr. F. A. Wellesley, Woking; Mr. C. Phillips, Bracknell, Berks, came second with Britannia, yellow; and Mr. J. Douglas third with Trojan, white. For six

blooms of fancy Carnation, one variety, Messrs. Thomson and Co., florists, Sparkhill, Birmingham, were first with six blooms of Voltaire, Mr. Wellesley coming second with Monarch. In yellow ground Picotees, one variety, Mr. M. R. Smith was again to the fore with six blooms of Lady St. Oswald; Messrs. Thomson and Co. came second with Golden Eagle.

Division 2 consisted of five classes for exhibitors with smaller collections of plants than those exhibiting in Division 1. Messrs. Thomson and Co., Birmingham, won the first prize with twelve blooms of Carnations, bizarres and flakes; Mr. R. Sydenham was second. Messrs. Thomson and Co. were also first with twelve selfs, and Mr. Charles Phillips, Bracknell, was second. Again with twelve fancies Messrs. Thomson and Co. took the lead, Mr. C. Phillips was second; and Messrs. Thomson and Co. first with twelve white ground Picotees, Mr. F. A. Wellesley, Woking, second. With six yellow ground Picotees Messrs. Thomson and Co. were first and Mr. F. A. Wellesley again second. The Birmingham blooms were good all through these classes and reflected great credit upon Mr. C. H. Herbert, the grower.

Division 3 consisted of eight small classes, which gave growers of small collections a chance—a very wise arrangement, especially as exhibitors in Division 2 could not compete in Division 3. Here, as in the previous division, the varieties shown were much the same as those exhibited in Division 1, and therefore there is no need to repeat names. The competition was exceedingly keen. In the class for six bizarres and flakes there were fourteen stands. The first prize was taken by Mr. R. C. Cartwright, an enthusiastic Birmingham amateur, and he was also first with six selfs out of twenty-two stands. Mr. S. A. West was first with six fancies, there being eighteen competitors. Mr. Cartwright was again first with six white ground Picotees, Mr. A. R. Brown first with four yellow grounds, and also with three self Carnations of one variety, having Regina, a yellow. Mr. S. A. West had the best three blooms of a fancy, staging Brodrick, and Mr. H. W. Sillem the best three blooms of a yellow ground Picotee, setting up Mrs. Douglas. There were eight classes for blooms exhibited without dressing or cards, with Carnation foliage attached to each. The competition was good throughout, and with few exceptions the flowers were not named.

There was a class for six blooms of all classes for those who have never won a prize at an exhibition of the society, and Mr. H. W. Sillem was placed first and Mr. C. L. Goodes second. A class was also provided for two cut blooms of a seedling, Mr. M. V. Charrington, Edenbridge, taking the first prize with The Sirdar, a bright rosy red self of good quality. Mr. H. W. Weguelin, Dawlish, was second with a deep rose self, unnamed; while Mr. S. F. Solley, Forest Gate, was third with a promising flesh-coloured self, also unnamed.

Certificates of merit were awarded to the following new varieties: Sir Bevys, a rich dark crimson self; Goldfinch, yellow self; Childe Harold, light-edged yellow Picotee; Hesperia, a heavy-edged yellow Picotee; Erasmus, a fancy; Guinevere, a fancy; and Ensign, a splendid white self, all from Mr. M. R. Smith; to Mrs. Foster, a heavy rose-edged Picotee, from Mr. T. Lord, Todmorden; to yellow self Lady Dora, from Mr. E. Charrington, Chislehurst; and to Sirdar, self, from Mr. M. V. Charrington.

A silver cup was awarded in Division 1 to Mr. C. Blick, gardener to Mr. M. R. Smith, for the greatest number of points. It was declined by Mr. Blick, it being the gift of his employer, and was then awarded to Mr. C. Turner, Slough, as the next in order of merit. A silver cup was awarded in the second division to Messrs. Thomson and Co., and in the third division to Mr. R. C. Cartwright, both of Birmingham.

PLANTS IN POTS.—The best twelve specimens of Carnations came from Mr. M. R. Smith, the plants well grown and bloomed. Mr. J. Douglas was second. Mr. Smith had the best single

specimens; Mr. Douglas again second. In the class for a large group, Mr. M. R. Smith was again first, having a very fine lot indeed. Mr. T. Carruthers, Reigate, was second, and Mr. C. Turner third. The first prize in the smaller group was taken by Mr. J. Douglas. Mr. E. Charrington was second.

TABLE DECORATIONS.—These consisted of a dinner table arranged for twelve persons, there being seven competitors. Miss and Mr. H. Anstey, West Norwood, were placed first, having yellow Carnations and yellowish green foliage, a somewhat heavy arrangement. The Morter Stores, Ltd., were placed second, a somewhat low and formal design, with Miss Jolliffe Carnation and foliage. Mrs. J. Douglas was third, some bright touches being given to this by the use of some coloured Carnations, but it was rather heavy also. Mrs. Hadley, Reigate, had the best vase of Carnations, Mr. A. C. Charrington was second, and Mr. H. Rogers, Woodbridge, third. Mr. Rogers had the best three sprays and Mr. E. C. Gobie the best three button-holes, both of Carnations.

A few miscellaneous collections were staged. Messrs. W. Cutbush and Son, Highgate, had a large group of Malmaison and other Carnations. Mr. F. G. Foster, manager of the Brockhampton Nurseries, Havant, had a fine and varied collection of Sweet Peas, and Mr. G. W. Piper, nurseryman, Uckfield, had examples of his beautiful new Tea-scented Rose Sunrise.

NOTES OF THE WEEK.

Mr. J. Wood's Scarlet Pea.—This fine Pea is in all probability not a variety of *Lathyrus latifolius*, but of *L. rotundifolius*. Further examination and comparison of the latter with Mr. Wood's Pea procured from the garden at Woodville show that the plants are similar in foliage.—S. ARNOTT.

Scabiosa caucasica alba is among the best of good hardy border plants in flower at the moment, and a plant deserving of very extended culture. Indeed, no collection could possibly be complete without it, and good plants flower profusely over a long period. For cutting it is one of the best that could be named.

Cimicifuga racemosa.—While taking some time to form a fine specimen, the above plant is sufficiently distinct to be worth waiting for and to prove attractive meanwhile. In a deep and rather moist soil, or with plenty of moisture in summer, it is usually a success. The pretty white flowers are closely set on long spikes.

Coris monspeliensis.—This interesting little gem is one of those things that, among alpine, will ever be rare. In its growth generally it most closely resembles *Athionema*, itself a pretty plant of more easy culture. Just recently we noted this little thing in flower in the frame ground at Kew, the pretty terminal heads of blue-lilac flowers all the more showy by reason of the conspicuous richness of the orange anthers. The plant is best increased by fresh seeds.

Tufted Pansy Blanche—This is a large rayless white flower, and probably the best of its kind. There is little to choose between this variety and one named White Empress, and under certain conditions they appear to be synonymous. During the hot weather the flowers have stood remarkably well, and this may be attributed to the robust constitution which the plant has. In a large bed of white Tufted Pansies the variety is usually singled out as one of high quality.

Tufted Pansy Mrs. A. H. Beales.—This is a very handsome flower of considerable promise. It is devoid of coarseness, which, unfortunately, characterises many of the larger flowers. The blossoms are circular in shape and of good substance, and may be described as white—almost a pure white. A peculiarity of the blossoms is that they are pleasingly flecked with pale rosy lavender during cool or cold weather, this variation evidently appealing to the taste of some, judging by the remarks made whenever the variety under notice has been exhibited.

Sweet Peas failing.—The premature failure of the Sweet Peas has been most disappointing this season, and this notwithstanding every attention being

given in the way of removing spent blossoms and seed-pods. Copious supplies of water have repeatedly been given and every detail of culture carefully observed. A fortnight since my collection was as good as one could well wish, but now, except in just a few instances, there are very few blossoms indeed. Failure was noticeable much earlier in collections where the ground had not been specially prepared.—A. R.

Tufted Pansies for stock.—These plants have been discarded by many during the past two years owing to the drought having spoilt the display. This can be explained where the soil is hot and dry, but planted in garden soil with a subsoil of clay, or in any fairly heavy loamy soil the character of the plant is most pronounced. Three weeks since a few plants of an ordinary sort were cut hard back, and at the present time these same clumps are bristling with innumerable fresh green young growths, and of a kind calculated to make cuttings for the autumn planting. This severe handling has taken place in a collection of plants which are fully exposed to the sun's influence from early morning until sunset.—D. B.

Michauxia campanuloides.—A portion of a very fine inflorescence of this plant was brought to the Drill Hall last week by Mr. Bain, gardener to Sir Trevor Lawrence, Bart., Dorking. The most remarkable feature of the specimen was the densely flowered part of the upper portion of the raceme as shown. Whether this was due to slight injury in youth or not we are unable to say, but it culminated in a really fine spike of flowers, such as is seldom seen. The spike so often runs up to 8 feet high and but sparsely flowered throughout, that a change to the opposite is welcome.

Romneya Coulteri.—If only a solitary flower, the blossom brought to the last meeting at the Drill Hall by Messrs. Veitch and Sons was welcome. Of the purest white imaginable and fully 5 inches, if not more, in diameter, a shrub would be handsome indeed that was well covered with such flowers as these. It is a plant only for the warmest corners or most secluded spots of our gardens, and with the ripening influences of such seasons as now prevail the plant may become somewhat more content. Unfortunately, it is the undoing influence of the winter season that each year takes so much setting right in such plants as this.

Michauxia Tchihatchewi.—This species is quite removed from the well-known *M. campanuloides*, not merely in its growth, but in the manner and disposition of the flowers. These latter are white and almost sessile, and closely set on a columnar spike fully 2½ feet high. In the young state the flowers are minus the rosy pink tinge that so often characterises the older kind, and from the dense arrangement of the spike, the plant generally is without that striking character which has ever been a marked feature of *M. campanuloides*. The new plant comes from Asia Minor, and the radical leaves, which disappear with the uprising flower-spike, are usually rough and shaggy to the touch.

Campanula Mariesi alba.—The white variety of the beautiful *Campanula* (or *Platycodon*) *Mariesi* is now becoming more plentiful in gardens in which a year or two ago only the blue form was to be found. I am not quite decided as to which of the two to prefer. Both are pretty and attractive either in bud or when fully opened. Seeds saved from the white variety give a proportion of good colour, but others are not so pretty as either the pure white or the deep blue. It is to be hoped that nurserymen will not send out unbloomed seedlings to those who order the white variety. Should they do so, disappointment will often result to the purchaser.—S. ARNOTT.

Anchusa italica.—This is not a choice subject, nor one difficult to grow or increase. All the same, a fine bush laden with the intense blue flowers and so many of them is always an attraction, and being so free flowering it lasts a long time in good condition. The plant is also well known as a good bee plant.

—Mr. Charles Herrin, writing to us from Dropmore of a very beautiful form of *Anchusa*

italica, says as follows: "It is without doubt a true perennial at Dropmore, growing and flowering with great profusion year after year. I have sent it from here to many other gardens, where it has received equal praise. I do not find this variety produce seeds, but it is readily increased by root cuttings (just like Seakale), and every little bit soon forms a good plant and only requires to be buried in the border. Whether this be the correct name for it I cannot say, but I have always understood it to be so." Whether it is a distinct species or a good variety we do not know, but there is no doubt it is an excellent plant.

Zauschneria californica.—A useful discussion on the habit of this plant appeared in THE GARDEN about last March. Some correspondents with whom I sympathised complained that the flowering was so late as soon to be destroyed by cold and damp nights. It became evident that there were several varieties in cultivation. Mr. Burrell, of Cambridge, said he had a variety with large flowers which never failed to bloom before the end of July. I got two or three plants from him, and though cut back severely by the frosts of May, they are now (before the end of July) in full bloom, and the size of the flowers and vigour of the plants are far ahead of anything I have before grown or seen in the species.—C. WOLLEY-DON, *Edge Hall*.

Incarvillea grandiflora.—The comparisons and conclusions of Mr. W. E. Gumbleton are perfectly right, only there is some doubt about Regel's figure, which was made from a dried specimen and shows a rosette of leaves closely surmounted by an umbel of flowers very much resembling those of a Rhododendron. Moreover, *I. compacta* has flowered at St. Petersburg with a spike 30 inches high, and I am informed this was a seedling from collected seeds. Is what Regel figured a sixth new species, or is it an imperfect development of *I. compacta*? In any case *I. compacta* remains a shy bloomer. As to *I. lutea* there can be no doubt, as Messrs. Bureau and Franchet have determined the name, and perchance only wrong seed was gathered.—MAX LEICHTLIN, *Baden-Baden*.

Sweet Peas for table decoration.—As a rule these displays are overdone, not only in the quality of flowers used, but also in the too free use of draping material. Blossoms are frequently crowded into the various receptacles without regard to the effect each spray should have, and as a consequence a most inartistic display is made. A wise choice of colours appears to be the first thing those responsible for their arrangement should aim at, as by so doing many points are thereby gained. If the rule of never inserting a flower in the stands unless it can render a good account of itself were followed, fewer flowers would be used and a more elegant and artistic finish gained. A first prize arrangement at the recent Beckenham show was composed of Sweet Pea Aurora, and probably not more than a double handful of flowers was used altogether. The arrangement was extremely simple and pleasing.—VISITOR.

Notes from a Cornish garden.—*Ipomæa rubra cœrulea* has opened some fifteen flowers in the garden, and is certainly the best sky-blue flower ever grown here. *Gerbera Jamesoni* and *Senecio pulcher* are both flowering well, also *Swainsonia alba*, which has wintered out for two years. In the conservatory *Jacaranda mimosaefolia* has been in flower for three weeks. This plant was grown from a seed brought home eighteen months ago from Australia. *Cestrum aurantiacum* began to bloom a week ago. *Tecomia jasminoides* has been out a long time, and is always grown here now in pots, as I find it so hard to dry off if planted in a bed in the greenhouse. *Campanula Vidalii*, after being killed here regularly, has at last come on, and one plant has eight spikes and fifty-three bells fully open.—C. R.

Hardy annuals in S.W. Scotland.—Even the most enthusiastic admirer of perennial flowers

cannot but admit that annuals have not only great beauty, but also much usefulness. Thus one cannot fail to regret that so many gardens in this district have the misfortune to be losing to a great degree the aid they receive from the many beautiful hardy annuals now at command. As usual there are exceptions, but the greater number have to tell of stunted growth and want of vigour in the plants. This is having its usual effect upon the blooms, and the display of flowers is consequently small. One must attribute the comparative failure to the unfavourable weather in spring and early summer. I have lately been through a good many gardens in the district, and in the larger number of these it has been with disappointment that one has seen such a comparative failure of favourite annuals.—S. ARNOTT.

Saxifraga mutata.—I have to thank Mr. Wood for his remarks on page 85 concerning this Rockfoil. I have never been able to retain a plant of *S. mutata* after flowering, as it has always died off, and it is thus with me, as with your correspondent, practically a biennial. Mr. Wood is, however, fortunate in securing seedlings, as it is not as a rule a good seeder in this country. While the general experience in Britain is that it is a biennial in most gardens, there are exceptions, and I am led to believe that plants which do not flower very profusely do not exhaust themselves to such a degree as to cause their death. This is borne out by the references to it in several works in which it is found classed as a hardy herbaceous or perennial plant. All the same, Mr. Wood has, I think, done us service by detailing his experience. I feel personally obliged to him for so doing, and thus making clearer my reference to the plant.—S. A.

Tufted Pansy Duchess of Fife and its sports.—Notwithstanding the fact that many excellent sorts have been raised within recent years, the members of this family still hold their own. The exceptional heat of the present summer and drought in many districts have severely tried plants of this description, but in the ordeal the creeping-like growth of the Duchess type of plant has much to commend it. A generous mulch of rotten manure has no doubt assisted very materially to keep the plants in a healthy condition and also comparatively cool at the roots. This, combined with the spreading character of the growth, has enabled them to combat the exceptional heat and drought through which they are now passing. At the time of writing, the members of this family, which embrace the Duchess of Fife, Goldfinch, Duchess of Teck, and White Duchess are flowering freely and promise to continue doing so for a long time to come.—A GROWER.

Enothera missouriensis.—While the *Enotheras* which come into bloom in late afternoon or early evening look dowdy and comparatively unattractive by day, and are thus despised by those who see gardens only in the forenoon or early afternoon, they are very pleasing at a later hour. It is amusing, too, to observe the way in which they are looked at by those who know little about flowers, but who are deeply impressed by the idea of a plant refusing to show its beauty in the sunlight, but ready to avail itself of the later hours to display its blooms. Of the Evening Primroses of this habit and of prostrate growth *E. missouriensis* is perhaps the most reliable and satisfactory. It comes easily from seeds and is fairly hardy in light soil. Its prostrate habit makes it a favourite for the rock garden, but it also looks well in the front of the border. Its light green leaves, large yellow blooms, and red-spotted calyces give it considerable beauty.—S. ARNOTT.

Campanula soldanelloïflora fl.-pl.—Your note on *Campanula Warleyi* in THE GARDEN of July 29 reminds me of this pretty little Hairbell, which one does not often meet with now, and *Campanula soldanelloïflora* is understood to be only a variety of *C. rotundifolia*, from which it differs solely in its flowers. When raised from seed it produces some flowers identical in every

way with those of the typical plant. Others, again, assume the form figured in the "Dictionary of Gardening," which has the segments cut up into a number of narrow divisions. This is not, however, the prettiest variety, which is that having semi-double flowers much like what one supposes from your description those of *C. Warleyi* to have. These are very pleasing when lifted up and examined, although on a low rockery their distinct character cannot be seen without doing this. I have raised seedlings from this semi-double variety, and these have varied from the typical rotundifolia to those of the parent with some intermediate forms. The only colour I have seen is dark blue.—S. ARNOTT.

Hardy flowers at Hatfield.—The borders and beds skirting the lawns at Hatfield are just now very beautiful, clump after clump of the best scarlet Phloxes, such as *Etna*, *Boule de Feu*, and *Coquelicot*, being relieved by numerous masses of *Chrysanthemum maximum*, some of a very dwarf form growing no taller than 2 ft. 6 in. In such a season as the present, where the hose can be daily applied, the Phloxes are magnificent in the extreme, and one can fully appreciate the value of M. Lemoine's achievements in giving us these splendid scarlet kinds, although several of his latest productions have anything but pleasing colours. Fine masses of *Bergamot* (*Monarda didyma*) are found here in perfection mingling with groups of *Eryngium Oliverianum* and *Helianthus rigidus*. Whilst a showy effect is aimed at, a continuous display is provided for. Grand, indeed, must have been the noble spikes of *Delphiniums*. At the extreme outer boundary some magnificent specimens of *Crimson Rambler* and *Fellenberg Roses* vie with each other in displaying gorgeous masses of colour. How much nobler herbaceous plants appear when planted boldly and thinly near a good expanse of lawn.—P.

Campanula mirabilis.—The finest form we have yet seen of this most beautiful Bellflower has been a picture of blossom in the hardy plant department at Kew for nearly three weeks. The chief difference in the Kew example is that the tips of the corolla divisions incline inwards rather than the reverse, as in other forms of this fascinating flower. Large, delightful in colour, and most profuse in its flowering are among the chief attributes of this handsome plant. In the Kew specimen between 200 and 300 flower-buds have been counted, to say nothing of scores of miniature buds that at an earlier date could not easily have been traced. At present all the fear centres in the plant being only of biennial duration, and it is certainly a drawback to so fine a flower that it takes three years, more or less varying in individual instances, to reach the flowering stage. All the same, the large, flat table of leaves that is formed is very interesting all this time. Whether biennial or not, all who can should save seeds of this most striking Caucasian Bellflower, and when fully ripe, which should not be hastened prematurely, sow at once. If kept a few months the chances are against ever securing a plant. Sow the seeds on the surface without any soil covering, and place a piece of slate or smeared glass over them to exclude strong light. In three weeks or a month the seedlings should be appearing, when more light will be required.

Ostrowskya magnifica.—Those of us who have paid some attention to the *Ostrowskya* and have experienced some trouble in trying to flower it must have observed with interest Mr. J. Wood's note on page 85. I fear, however, that even the early planting he advocates will not ensure the success anticipated. Were this so, it would follow that plants which had been left in the ground and had survived one or more winters would have a better prospect of doing well. With most people *Ostrowskya magnifica* has proved a very disappointing plant. I have known good strong plants grown from year to year which, despite every care and attention, have never thrown up a flower-stem, and have in some cases dwindled away instead of increasing in vigour. One has, errone-

ously or not, formed the impression that it is a flower which does better in a district where the winters are comparatively dry than in one where there is a good deal of rain. From plants I have seen in bloom, I feel inclined to ask if it is a plant worth a great amount of trouble. Somehow or other even when in flower it looks unhappy, and the colour soon fades if grown in full sun. In this respect the white variety, which was incidentally mentioned in THE GARDEN some time ago, ought to be superior to the blue form. The other day I had a very interesting letter from Mr. W. B. Boyd regarding a white Ostrowska which had flowered in the garden of his brother, Mr. James Boyd, of Cherrytrees, Melrose, N.B. The plant had been carefully nursed in the border for two years and was covered with a glass shade in winter. Last year it produced a single, badly-shaped bloom, but this season it has flowered well. One flower was 5 inches across at the mouth and was pure white. I believe most of us who attempt the Ostrowska will find it necessary to protect it with glass in winter, as was done at Cherrytrees. Even this assistance, as some of us know to our regret, will not always enable us to bloom a plant which it has been one of our ambitions to bring into flower.—S. ARNOTT, *Cursethorn, by Dumfries, N.B.*

PUBLIC GARDENS.

Hampstead Green for the public.—A movement has been initiated in Hampstead for purchasing a part of the old Hampstead Green on Haverstock Hill for the public. A portion was given up for the site of St. Stephen's Church, and another small corner has been dedicated to the public, but the centre portion, about an acre in size, containing some fine trees, has been put up for sale. The whole estate has been bought by a private purchaser. Though the buyer's name has not been mentioned, it is understood that the land was bought with the idea of making the Green public property. The price paid was £7500.

SEED TRIALS AT MORTLAKE.

VERY few perhaps of those who grow and enjoy the produce of a well-stocked kitchen garden have but the faintest idea of the care that is bestowed in the fixing and selecting of the best stocks of vegetables in their several departments or even the space that is needful for the conduct of a great variety of such trials. Of many things in this connection, however, some information was gathered recently by a visit to the trial grounds of Messrs. Carter and Co., seed merchants, High Holborn. The seed trial grounds of the firm are about midway between Putney and Mortlake on the South-western Railway. The plot of land is some ten or a dozen acres in extent probably, and as showing the need of such an extended area, it may be said the whole of the ground was fully occupied by trials of this or that. At the time of our visit, in mid-July, Peas, both cooking and sweet, were among the more conspicuous things—at least, so far as then in condition for undergoing comparative examination. For it is this indeed that is the primary object of such a garden. Primarily, of course, the devoting of such an area to such an object was for the express purpose of testing and recording the value of the many seeds sent out by the Holborn firm. There are some 600 or 700 trials of cooking Peas alone, a row of 12 feet or so being devoted to each. Only four days divided the sowing of the whole. Some were already ripe and the seed gathered, while others were full of promise for a good September crop. Had the planting been otherwise done, the earliness could only be a subject of conjecture. As it is, everything is substantiated by fact. It is worth mentioning, too, that no attempt is made in these trials to grow huge produce—produce for the prize stand, for example—rather is it an endeavour to retain, in so far as possible,

the true characteristics of this or that flower or vegetable. Sports of anything are ever welcomed, and particularly so of the best types of things, but before any such is put into commerce some years must elapse. The "fixing" of any new type is often a long, tedious business, and culminates frequently in a disappointing manner. For example, a new Pea to-day has to pass a variety of tests, and naturally is put into competition with the best of its class, or those most nearly allied to it. It will surprise not a few perhaps to know that a large batch of seeds is grown in the Antipodes expressly for the Holborn seedsmen, and from seeds specially sent thither by the firm. The object of this is a gain in point of time to enable them not merely to cope with foreign orders at an early date, but equally to equalise the rush of business at such a time.

The reader will readily grasp how impossible it is here to give even a summary of so complete a set of trials, but a few of the Peas may be noted. Taking Stratagem, for example, of which there were numerous rows all representing varying stocks as an example of the dwarf kinds, and it is scarcely possible to possess a finer Pea than the strains here noted. A few indeed are select strains. Delicatessé is a small wrinkled Pea valued largely by the French and in demand for canning. Princess of Wales possesses the merit of remaining green even when old-looking. Gladiator is valued by market growers, and Abundance is good on a dry soil. Here it is 3 feet high, and a good doer on dry, sandy soil. Duchess is an improved Duke of Albany, and not only in one respect, for it is more reliable, which is a great gain. Early Morn is a wrinkled Marrow as sweet in flavour as Stratagem. The Duke of Albany was very fine, as, indeed, it ever is where it is a success at all. The Carter is perhaps the giant of all, as was seen from examples brought from one of the Essex seed-growing farms. It is evidently a great success on the heavier soil of Essex, the huge pods full of grand looking Peas. It is a blunt-podded Pea, quite distinct, and very broad and long. John Howard is an early Ne Plus Ultra, which is saying much. Then came Everbearing, a most prolific kind 3 feet high here, pods blunt-ended—in short a much improved sort of the Yorkshire Hero type. Some other good kinds are The Baron, 2½ feet, a fine podded variety, strongly curved, and even on this abnormally light soil well filled with good sweet Peas. Dwarf Monarch has proved earlier than Omega, from which it was selected. It has also a larger pod. Dr. McLean at 2½ feet is very prolific, and Majestic, of the same height, carries frequently nine and even ten Peas of a good wrinkled type, with the fine flavour of Stratagem. It is a curved pod. Among late kinds, Autocrat as well as Michaelmas deserve special mention. The former is 2½ feet and the latter 3 feet high. It is doubtful indeed if, taken all in all, these two kinds can be beaten. That forerunner of many good things—Ne Plus Ultra—was noted in several stocks, and what is as yet known as Ne Plus Ultra Selected is a specially fine strain of this most reliable cropper of all Peas. King of the Marrows and Berkshire Challenge may be noted as of the same tall growth and free-cropping propensities. The last, however, is a rather small-podded Pea, but the sturdy blunt pods are well filled. The whole of the Peas noted were sown on March 28, another set following four days after being a trifle later in flower, &c.

The Broad Beans, though not of the same endless category as regards variety, were very interesting, Leviathan and Masterpiece being two of the finest, though a re-selection of the former surpasses it both in the size and abundance of its pods as well as the Beans they contain. Lettuce again formed a great item in these trials, and represented a really wonderful array of this useful article. One kind, however, Green Fringe, is not merely useful from the edible standpoint, but valuable for its decorative or ornamental character, and another of the Cabbage tribe, though as yet unnamed, has the deeply lacinated character

of the Stag's-horn Fern, a name that would be quite applicable to this well-marked ornamental type. Parsley, again, was very fine, that with the prefix "Fern-leaved" being as near perfection as possible.

The foregoing is but a fragment of the many trials conducted here, the same care and zeal characterising all throughout be they large or small. It is worthy of note, too, on a soil so thin and dry that such excellent results are secured generally. E. J.

OBITUARY.

MRS. RICHARD PARKER.

It is with regret that we have to announce the death of Mrs. Parker, wife of Mr. R. Parker, gardener to the Duke of Richmond and Gordon at Goodwood. Gardening friends throughout the country will, we are sure, sympathise with Mr. Parker in the loss he has sustained.

The weather in West Herts.—The past week was the fourth very warm one that we have had in succession. On four days the shade temperature exceeded 80°. Several nights, however, were cool for the time of year, and on that preceding the 28th ult. the exposed thermometer fell to within 8° of the freezing-point. Consequently, the difference between the highest and lowest readings in the thermometer screen was on several occasions considerable, the difference on two days amounting to 32°. At the present time the ground at 2 feet deep is 6°, and at 1 foot deep as much as 8° warmer than is seasonable. No rain has fallen since the 26th ult., but a little rain-water still continues to pass through the percolation ganges. During the last six days the record of bright sunshine has averaged nearly twelve hours a day. July proved a very warm month throughout. Taking the month as a whole, it was the warmest July yet recorded here during the fourteen years over which my weather records at Berkhamsted extend. On no fewer than seven days the temperature in shade rose above 80°, while several of the nights were as exceptionally warm. Rain fell on only ten days to the aggregate depth of 2½ inches, which is about a quarter of an inch short of the average for the month. The sun shone brightly on an average for eight hours a day, or for a longer period than in any July for twelve years.—E. M., *Berkhamsted.*

Names of plants.—J. A.—7, *Campanula nobilis alba*; 8, *C. grandiflora* (Platyodon); 9, *C. livifolia* (deep coloured var. of); 10, *C. glomerata* var.; 11, *C. carpatica*; 12, *C. persicifolia alba*; 13, *C. pusilla*.—H. B.—a, *Scirpus maritimus*; b, *Scirpus sylvaticus*.—H. Boyle.—1, *Plagiathus Lyalli* (white flowers); 2, *Pyrus Aucuparia fructu-luteo*.—T. Buckerfield.—*Cratagus Douglasi*.—R. H. Ireland.—*Brassia verrucosa*.—T. R. B.—1, *Epidendrum alatum*; 2 and 3 (labels detached). The white and rose-tipped flower is a good form of *Aerides odoratum*. The small clustered spike was past identification. It is a variety of *Pholidota*, probably *P. clypeata*.—Col. Clements.—*Datura* (*Brugmansia*) *Knighti*. We can see nothing amiss with the flowers you send.

Names of fruit.—R. Katzer.—Peaches: 1, *Montagne double* (syn., *Montauban*); 2, *Red Magdalen* (syn., *Madeleine de Courson*); 3, not recognised.

"The English Flower Garden."—*Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d.*

Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.

ORCHARD AND FRUIT GARDEN.

TREATMENT OF PEACH TREES AFTER FRUITING.

THE fact of the crop having been gathered from the early and second early Peach houses does not imply that the work in them is over for the season, and a good deal depends on how the trees are treated. Yet many growers, though they may have watched with regret the first appearance of red spider when the fruit was ripening, will allow this pest to make as much headway as it likes directly the fruit is over and throw open the house to take its chance. In cases where this troublesome insect has obtained a footing, the first thing to do is to see that the borders are thoroughly moist, well soaking every bit of soil in them if they appear to be on the dry side. Then with a garden engine or syringe thoroughly moisten the foliage all over, using a fair amount of force and not sparing the water. This will make the insects uneasy, and before applying any insecticide, whatever pruning is necessary should be done. This in most cases will consist principally of wood that has fruited and any chance bit of new growth that there is not room for. This latter in all cases is best left either its full length or else cut right out, as there is a danger of shoots that are stopped after this date not starting from the upper buds. Indeed, if the trees have been properly attended to with regard to tying and stopping during the season of growth, all that now remains to be done is a little pinching of sub-laterals and the removal of foreright shoots that are not needed when the fruiting wood is cut out. A good home-made remedy for red spider is an emulsion of soft soap and water with a table-spoonful of sulphur added to every gallon. Mix it to the consistency of paint to sink the sulphur, then add a pint of the mixture to a large pail of water and thoroughly wet every part of the tree with it. With patience it is quite possible to clear the trees even when badly attacked, but of course there are many proprietary insecticides that will do the work much more rapidly. Fumigation, too, will

lessen the number of insects in bad cases, but the best and surest means of keeping the trees clean is to be always at them with the syringe when the weather is bright. The idea that it prevents the wood maturing is ridiculous, for it helps rather than hinders this end by keeping the foliage clean and healthy to the last and allowing it to carry on its function of sap-elaboration and bud-development. Air in plenty is an important factor in the due development of the wood and fruit-buds, giving both vigour and strength, that stand them in good stead should the weather prove dull and cold when starting the trees. For this reason both top and bottom ventilation should be left full on night and day as long as the weather is warm, and the cool night temperature will conduce to perfect rest later on. I think under such conditions as these, over-ripening, as it is termed, is almost impossible. It is when the wood is starved from want of root moisture, the atmosphere arid, and the sun pouring down on enfeebled foliage that the trees give way, and bud-dropping and other evils are caused. I am not saying that the former can be prevented by ever so careful treatment, but the more the general tone of the tree is kept up, the less likely is it to go wrong in this or any other particular. With regard to shading after the fruit is gathered, this may be necessary in exceptional cases, but not often. It may be when a very early-ripening kind is in the same house with a much later one that a little shade over the former at the back end of the season may do good, but it may easily be over-done, and should in all cases be removed by degrees as soon as it is deemed advisable. H. R.

Strawberry Waterloo.—I was delighted to see the fine examples of Waterloo Strawberry at the Norwich show on July 13—a rather early date, some will say, for this so-called late sort to be at its best. No doubt the latter fact was to be accounted for by the spell of tropical weather experienced just after the fruit commenced to soften. The same remarks apply to Latest of All, also shown well at Norwich. I had no opportunity of ascertaining whether the noble dishes of Waterloo were gathered from one- or two-year-old plants, but I have found that, besides a larger yield

being forthcoming from two-season plants, the fruit is not so liable to injury from strong sun-heat, which this variety is liable to. It was rather a pity that the fruit shown at Norwich should have had to compete with that of the Queen type in flavour, as the latter, size and finish being present, were of course preferred, though when ripened gradually in partial shade Waterloo is a very refreshing Strawberry, and well worth any extra trouble necessary to secure sturdy growth and fruitfulness.—J. C.

Peach Hale's Early.—This is much the best of the American varieties for flavour and one of the most useful Peaches in cultivation. In an early house it fills the break between Waterloo and Alexander and Early Grosse Mignonne better than any other kind I know, while from the last week in July until the middle of August there are no two more useful kinds than it and that fine Nectarine Early Rivers in an unheated house or Peach case. The habit of the tree is all that could be desired, and on an open wall with very little trouble in training, a round, fan-shaped tree that can easily be picked out from other kinds on the same wall is produced. Those who have tried it and found it wanting in quality when thickly trained I can strongly advise to train the new shoots 5 inches or more apart. It is very free fruiting, and no fear need be felt as regards crop, while the quality when the fruit has plenty of light is distinctly good, though, of course, falling short of that of such kinds as Noblesse and Grosse Mignonne. The colour is very fine, and it thrives equally well as a forcing kind for unheated houses or for culture on a wall.—GROWER.

Grape Madresfield Court.—I was very pleased to see this fine, but not always satisfactory Black Muscat Grape in such fine form at the Norwich show on July 13. I have seen larger bunches and perhaps berries, but the size of bunch and general finish were excellent. Probably the hot, dry atmosphere experienced of late has been all in favour of a perfect finish and freedom from cracking, although, of course, special care is needed in such seasons to keep red spider at bay. Madresfield Court is frequently seen even at exhibitions in a foxy condition. I think the finest examples of it I ever saw were at Blickling Hall some years ago. The rod, if I remember right, was inarched on to either the Black Ham-burgh or Foster's Seedling, the fruit being ripe in September. Even in these perfect bunches a cracked berry would appear here and there. Cracking pure and simple, however, is quite a

different thing to the wholesale decomposition which some gardeners, myself included, have had to contend with. When living in South Notts I had charge of a Vine in a mixed house. It was inarched on the Alicante, a stock which seemed to suit it admirably; indeed, if I may use the expression, too well. The bunches were not only very large and heavily shouldered, but, thin as freely as one might, the berries swelled to such an enormous size, that wherever one pined another in the slightest degree the skin was sure to split and a sort of decomposition set in, which, if not detected at once, speedily ruined other berries and rendered the bunches useless, and this in spite of maintaining as dry an atmosphere as was possible in a mixed vinery. I never thoroughly cooquered the evil, but felt convinced that actual cracking could at any rate be reduced to a minimum if the Grape had a house to itself, which I think all Grape growers will admit it deserves. I should also be inclined to confine the roots entirely to an inside border.—J. C.

PEARS ADOPTED BY THE CONGRÈS POMOLOGIQUE OF FRANCE.

(Continued from p. 101.)

BONNE CHRÉTIEN NAPOLÉON (*syns.*, *Beurré Liard*, *Poire Médaille*, *Beurré Napoléon*, *Captif de Sainte Hélène*, *Charles X.*, *Belle Caennaise*).—Obtained originally in 1808 by M. Nicolas Liard, gardener, of Mons. The fruit is fair-sized, taking the form known as Bon Chrétien. The stalk is sometimes short, sometimes of middling length, stoutish, swollen at the point of attachment, curved or straight, set in a sometimes rough cavity. The eye is medium-sized, closed, set in a shallow, wrinkled depression. The skin is smooth, light yellow, stippled grey, strewn with some tawny stains, rarely washed with a little red on the sunny side. The flesh is white, juicy, and very agreeably aromatic. A very good fruit, maturing October, November, December. The tree is too feeble on the Quince. The tree should be grafted on the Pear, which will scarcely retard its fruiting and will not injure its fertility. It is suitable for all forms, especially for walls.

BON CHRÉTIEN WILLIAMS (*syns.*, *Williams*, *Bartlett de Boston*).—A native of Berkshire. It was raised in the year 1770 by a London nurseryman named Williams. The fruit is large, of turbinate form, slightly ribbed in contour. The stalk is stout, short, straight, set obliquely in a medium-sized, rough cavity. The eye is medium, open, set in a very shallow depression, ribbed at the edges. The skin is smooth, unctuous, golden yellow, stippled russet, with some tawny mottlings especially near the stalk, sometimes streaked with a little light red on the sunny side. The flesh is white, juicy, close, highly aromatic and musky. The fruit ripens in August and September; the tree is of moderate vigour and very fertile. In cultivation, grafted on the Pear, the tree is fertile, vigorous, and easily trained, and bears as early as when grafted upon the Quince.

BONNE DE MALINES (*syns.*, *Colmar Nelis*, *Nelis d'hiver*, *Beurré de Malines*).—Originally obtained by M. Nelis, Consul at the Court of Malines about 1814 or 1815. The fruit is medium-sized, truncated at the base. The stalk is short, stout, straight, set rather obliquely in a narrow cavity. The eye is fairly large, open, set in a wide, shallow cavity. The skin is rather rough, greenish yellow, stained tawny over a large part of its surface, stippled pale grey, rarely and slightly tinged with rosy red. The flesh is white and aromatic. A very good fruit, ripening December—January. In cultivation this variety is weak upon the Quince. On the natural stock it is more vigorous, fairly fertile, and almost as early in bearing.

BONNE D'ÉZÉE (*syns.*, *Bonne des Naies*, *Belle et Bonne d'Ézée*, *Belle des Zees*, *Bulle Excellente*).—Originally discovered in 1838 at Ezée, near Loches (Indre-et-Loire), by M. Dupuy Jamain, of Paris. The fruit is of fair size, swollen at the base. The stalk is short, stout, set obliquely in an irregular

shallow cavity. The eye is small, open, set almost flush with the fruit in a wide and very shallow depression. The skin is roughish, citron-yellow, washed and stippled red on the sunny side, with small tawny mottlings. The flesh is white, delicate, and pleasantly aromatic. A good fruit, ripening September. The tree is not sufficiently vigorous on the Quince. In cultivation this variety requires to be grafted on the Pear, when it is almost as fertile as on the Quince. It lends itself to all forms.

BONSERRE DE SAINT DENIS.—Originally obtained in 1863 by M. André Leroy, and named after M. Bonserre de Saint Denis, author of the "Dictionnaire de Pomologie." The fruit is medium sized, almost spherical, nearly as wide as high. The stalk is short, stoutish, straight, set obliquely in a narrow, shallow cavity. The eye is large, closed or half-closed, set in a wide and shallow depression. The skin is rough, greenish yellow, stained russet and stippled red. The flesh is whitish, delicate, juicy, very sweet, and gritty at the centre. A good fruit, ripening December to January. The tree is of moderate vigour and bears freely. In cultivation this variety is suitable for all forms, as well on the Quince as on the natural stock.

BONTOC (*syn.*, *Notre Dame*).—This has been grown for many years in the Gironde. The fruit is small, the stalk of medium length, slender, curved, set almost straight in a small embossed cavity. The eye is large, open, projecting, placed in the centre of a slight depression. The skin is smooth, pale yellow, rarely tinged with a little red, stippled brown, washed tawny round the stalk. The flesh is greenish, melting, and soon goes off. A good fruit, ripening August to September. The tree is of middling vigour and fertile. In cultivation the tree does not succeed upon the Quince; it is very vigorous on the natural stock. Its proper place is the orchard as a standard tree.

BOUVIER BOURGEMESTRE (*syn.*, *Nouveau Bouvier Bourgmeister*).—Originally obtained from seed in 1824 by M. Bouvier, formerly burgomaster of Jodoigne. It first bore fruit in 1842. The fruit is medium or fair sized, the stalk longish, of medium stoutness, set obliquely in a narrow cavity. The eye is medium-sized, half closed, set in a wrinkled shallow cavity. The skin is rough, golden yellow, stippled red, mottled with dark bronze stains. The flesh is white and aromatic. A good fruit, maturing November. The tree is of moderate vigour and fertile. It prefers a wall.

BRANDYWINE.—Originally found on the farm of Mr. Elie Harvey at Chaddsworth, on the Brandywine River, Delaware, U.S.A. The fruit is of medium size, the stalk of medium length, straight and set obliquely in a slightly embossed and narrow opening. The eye is small, half opened, set in a wide, shallow depression. The skin is firm, citron-yellow, almost entirely covered with bronze, with a dull crimson stippled with light brown on the sunny side. The flesh is white, pleasantly acidulate and aromatic. A good or very good fruit, ripening July and August. The tree is of normal vigour and fertile. In cultivation this variety lends itself to all forms and is at home in all soils.

BROOM PARK (*syn.*, *Brum Park*).—Originally found before 1838 by Mr. Knight, president of the Horticultural Society of London. The fruit is medium sized, spherical, bumpy, depressed at the two ends and wider than high. The stalk is of middling stoutness, curved, set obliquely in a fairly deep, wide and ribbed cavity. The eye is medium sized, open, set in a cavity of medium width and depth, embossed at the edges. The stem is rough, thick, dull yellow, strongly stippled red, mottled with brown. The flesh is whitish or slightly yellow, juicy, and aromatic. A good fruit, ripening December to January. In cultivation this variety requires a wall. It is rather feeble upon the Quince and requires to be double grafted in order to form trees of good dimensions.

BRUNE GASSELIN.—Originally obtained in 1854 by M. Durand Gasselina, an architect, of Nantes.

The fruit is medium sized, ovoid, truncated at the base, rarely pyriform. The stalk is short, stout, and sometimes of medium length, set in a narrow, shallow cavity. The eye is small, open, set in a very shallow, wide, and rather wrinkled depression. The skin is rather rough, yellowish, almost entirely washed with brown, warmer on the sunny side, stippled grey. The flesh is yellowish, juicy, and very agreeably aromatic. A very good fruit, ripening October to November. In cultivation this variety adapts itself to all forms; naturally it takes the pyramidal shape.

CATILLAC (*syns.*, *Cadillac*, *Gros Monarque*, *Chartreuse*).—Of ancient, unknown origin. The fruit is very large, turbinate, almost as wide as high. The stalk is of medium length and curved, set obliquely in a deep, narrow, embossed cavity. The eye is large, closed or half-closed, set in a wide, deepish cavity. The skin is rough, yellow, golden in the sun, washed with brown, and rarely tinged with dull red. The flesh is white, coarse, crisp, gritty, and sour. A good fruit for cooking, ripening January to May. The tree is of normal vigour and fertile. In cultivation this variety adapts itself but little to regular forms; it is best as a standard on the Pear.

(To be continued.)

RED SPIDER ON PEACHES.

As Peach growers are aware, when once red spider becomes established on trees on open wall, it is almost impossible to destroy it. I have no doubt that in many instances this formidable foe commences its operations at a very early date and so escapes the attention of the grower until it is too firmly established to allow of its being effectually dealt with that season. In the gardens of Lake House, Byfleet, it was pointed out to me that spider was present on the young leaves just as the fruit was setting. Mr. P. Bradley, the gardener, is of opinion that Peaches are very liable to the attacks of spider at such an early date when the walls are old or have not been pointed for some time. The walls get hot under the influence of the bright spring sunshine, and the insects, finding the conditions congenial for increase, fasten at once on the immature foliage. I must confess I was surprised to see red spider at work in the open air so early in the year, for in a general way one does not see much trace of it before the turn of the days. The arid atmosphere which frequently characterises the month of July causes this pest to spread with great rapidity, so that where it has been quietly at work for a couple of months previously, infested plants are sure to suffer grievously. Mr. Bradley acts on the stitch-in-time principle, and as soon as he perceives the faintest signs of spider, syringes at frequent intervals with soft soap and sulphur. By doing this, he prevents the insects from getting a firm grip of the trees. They cannot multiply as they otherwise would, and the tender leafage, which would be a rich feast, is thus rendered unpalatable. Red spider, as is well known, only attacks the under sides of the leaves, and when these are but partly developed it is easier to apply the insecticide in a thorough manner. I am inclined to think that nothing suffers more from a severe attack than the Peach. The wood gets into an over-hardened condition, from which it never seems to recover. In an old garden there once existed some good Peach trees which were the owner's pride. They yearly made good growth, and in favourable seasons bore good crops of excellent fruit. For a good many years the walls were not pointed, and then came several very hot, dry summers. The trees were very badly attacked. Various remedies were ineffectually tried, but the result was that entire branches eventually died away. J. C. B.

Packing Raspberries for dessert.—I have had to pack Raspberries several times this season, and no one who has had to do this will, I think, envy me the job. No fruit is more easily damaged. I have tried several plans, but the best of all

is the old-fashioned one of packing with strips of Rhubarb leaves cut about an inch wide and of suitable length, according to that of the boxes. Tin boxes with closely fitting lids are best, and two layers may be sent with pieces of Rhubarb leaf at the bottom, top and between the layers.—GROWER.

Melon Gunton Scarlet.—In all probability this will eventually become as popular as the now well-known Gunton Orange. I do not know any scarlet variety which has a deeper, richer flesh and which can be eaten right down to the skin. The colour is very pronounced, and I think that either *bona-fide* scarlet or green-fleshed varieties are more generally appreciated than the white-fleshed. Many gardeners now-a-days fight shy of the huge varieties, preferring those of medium size, which can be eaten at one meal. In my opinion a Melon should never enter the dining-room a second time after being cut. Scarlet Premier, Blenheim Orange and Read's Scarlet are all good Melons, and Gunton Scarlet is a worthy addition to a none too numerous class.—J. C.

Strawberry M. McMahon.—At page 75 J. Crawford asks for information about the above-named Strawberry. A few days ago I was in W. E. Gumbleton's garden, Belgrove. I asked the gardener what his experience after growing nearly every known variety of Strawberry was, and he said for general cropping and quality he placed McMahon first. This is my experience also, and for market use it has taken the place of all others in the neighbourhood of Cork, showing that it is a general favourite. It is a very compact grower, with short flower-stalks, so that the flowers are protected from spring frost by the leaves. Two or three plants may be grown in the same space as one Sir Joseph Paxton or other strong variety. What is true of this Strawberry here may not be true in any other locality or soil.—W. O., *Fota, Cork.*

Airing vineries in hot weather.—Gardeners recognise the importance of giving a little air to vineries almost as soon as the sun strikes the house or by the time the thermometer has run up 3° or 4°. Of course, the time at which air is needed depends on the position the house occupies. I have known span roofed houses running north and south to be aired at 5 a.m. Although not a believer in the necessity of night air in lean-to vineries facing due south, except, of course, during tropical weather, I think it is safest to leave the ventilators open a little way all night in houses running north and south. The Grape or Peach grower is then on the safe side. This can be increased in good time in the morning. This is the chief point in airing vineries at midsummer. An amateur whose vinery I inspected recently had adopted the wise and effectual plan of securing a current of air through his house by removing the glass door and substituting one made of ordinary wire netting.—C.

Failure of Strawberries.—Seldom has there been such a general failure of the Strawberry crop as during the present year. The failure is set down to that old time-worn theory of late spring frost. I am not prepared to say that spring frost did not do any mischief, but I am sure that if the present spring had been a mild, genial one the Strawberry crop would still have been far below an average. My idea is that the mischief was done twelve months ago, when the drought that prevailed then, as it does now and has done for several years past, continued to increase in severity right up to the end of September, so that the season when the crowns ought to have been formed and ready for going to rest found them just starting into growth with copious autumn rains, which continued right up to the time when the Strawberry plants ought to have been just starting from their winter's rest. In reality they had no rest at all; consequently, as might be expected, the bloom spikes were very poor. Even young plants that almost invariably bloom and swell off some fine fruits were more than half flowerless, and did not finish off the few fruits they had to anything like a full size. Those who have beds suffering from drought now should

lose no time in getting them cleared of runners and thoroughly soaked with water, for unless the crowns are able to perfect their growth at the proper time, viz., before the end of September, no amount of growth made in the dark days of autumn will give a full crop of fruit.—JAMES GROOM, *Gosport.*

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

THIS season so far will be remembered for its absence of rain, at least in the south. I have never known the soil so dry, although for several summers there has been some difficulty in getting proper growth in the plants. In pots, however, Chrysanthemums do not suffer, and sunny weather has the effect of ripening the wood satisfactorily. Where watering has been done with the necessary regularity there is little to complain of in the present look of the plants, and there is no danger of gross growth if over-feeding with manures does not follow. That somewhat intricate detail of selecting flower-buds is one which must engage the attention of those who cultivate for exhibition, or, in fact, desire to obtain what are called big blooms. Growth has taken place so rapidly of late, that many kinds at the time of writing are showing crown buds at the points of the shoots. Some sorts have even grown to the stage and second crown buds are appearing. But the wisest plan in regard to them is to pinch out and allow the points of the growths to proceed to another stage, selecting those flower-buds which appear later. An exception is in the variety Mrs. H. Weeks, the blooms of which take a considerable time to develop. General rules as to bud selection are these: Japanese kinds require a longer time to open the flowers than do the incurved, which grow imperfect in form if buds be retained before the end of August. Japanese kinds, too, of an incurving shape like Oceana must be allowed a longer period for the blooms to open than the loose reflexing forms like Vivand Morel. Again, the great wide, thick-petalled sorts—E. Molyneux, for instance—take a long time to unfold their blossoms, and should be remembered accordingly. Both in colour and form, flowers resulting from buds retained not before the last week in August will be better than from those selected now, although in size alone early buds have the advantage. But the two first-named qualities are to be preferred to the latter. Among new varieties that are likely to be seen pretty frequently this year I know of none requiring such special treatment in the matter of buds as the sort mentioned, Mrs. H. Weeks. John Pockett, J. Chamberlain, Le Grand Dragon, Marie Calvat, Nelly Pockett, Mrs. W. Mease, Chatsworth, Mr. T. Carrington, President Bevan, and Surpasse Admiral are all Japanese kinds to which the above remarks apply. Quite new kinds now on trial for the first time will all be treated to late bud-selection, as this has been found the better plan until a sort becomes known through its peculiarities being watched for one season.

Outdoor Chrysanthemums started well, but they now present rather a sorry appearance. The first blooms struggle to open, and rain is the only thing wanted to bring a satisfactory display. Watering, unless thoroughly done, is useless, and when one has to deal with a number of plants it is out of the question. It is difficult, too, to keep the leaves free from insect pests under the trying conditions of extreme drought. The rust which caused a great amount of concern last year has not been heard of this, and I

fancy it had troubled much before this date a year back, so that one may reasonably hope it was only a periodical fungus. Minute thrips are the most troublesome pest I have to deal with on a hot, sandy soil. Some sorts appear to be especially liked. Australian Gold, Mme. G. Bruant, and J. Chamberlain are kinds which have the points of growth quite stunted in spite of being several times dusted with tobacco powder. Mme. Carnot, with the sports G. J. Warren and Mrs. W. Mease, have caused trouble in the matter of shedding their lower leaves prematurely, but now seem to be growing out of what may be a disease peculiar to the kind. Dwarfness of the growth has fortunately been considered by the raisers of most of the newer kinds, the seedlings of Mr. Weeks, of Derby, being noticeable in this respect. One could name sorts of recent introduction that will soon go out of cultivation because of an ungainly habit. Australia is too tall for ordinary greenhouses to hold it, and Mary Molyneux, in spite of a reputation for being a fine flower, grows so high that it will not be cultivated long. H. S.

FRUIT AND VEGETABLE CROPS.

IN this district the weather during the past spring can hardly be described as favourable to either fruit or vegetable crops. Severe frosts were prevalent during the time many of the fruit trees were in bloom, which resulted in much damage being done, and in many instances only light crops can be recorded, the same conditions being equally against the progress of early vegetables growing in rather exposed positions. During May and June, when warm rains were so much needed to give an impetus to latent or backward growth, dry weather prevailed, which added considerably to the difficulties of the gardener. Here we are situated midway between the coast line and the South Downs, and rain often follows one or the other lines, but other localities may not have suffered so much from early drought.

In connection with fruit, if we take wall trees first, Plums and Pears suffered the most from the frost, the former being practically a failure, while Pears are only a moderate crop with the exception of a few varieties which appear to have escaped its ravages. Morello Cherries, too, are only half a crop, while dessert kinds are scarcer than usual. With Peaches and Nectarines, however, nothing can be complained of, as a good set was not only obtained, but the fruit at the present time is developing kindly. Gatherings of such varieties as Hale's Early and Amsden June were commenced from south walls on July 6, the size and quality of the fruit being all that could be desired. Some of the trees were so thickly set with fruit that severe thinning had to be resorted to. I attribute this success, in spite of repeated frosts while the trees were in flower, to the warm south walls against which they are trained, together with the protection of a double thickness of a Strawberry net suspended loosely about 18 inches from the brickwork. The early mulching of the border with cow manure, followed by copious waterings, has done the rest to ensure heavy crops of Peaches. Both Plums and Pears are also very scarce on standard, pyramid, and bush trees, but, fortunately, Apples are fairly plentiful, and though the trees are not carrying heavy crops, the fruit at the present time promises to be of good even size without the undersized, deformed specimens too plentiful when there is a glut. In respect to

bush fruit, Red Currants may be termed an average crop. Black good in every way, and the bushes free of mite. Gooseberry plantations suffered rather severely in the spring both from the attacks of birds on the buds as well as the frost, but still there have been sufficient berries for all requirements. It is rather curious that while the bushes in the open ground suffered from the above causes, trees trained to wire trellises (upright cordon system) escaped. These are now strung with fine fruit, and being easily netted, they prove both valuable and welcome for dessert. Strawberries appear to have proved disappointing this year generally, but in most instances it is an error to blame the present season altogether for the deficiency. Here, young plantations have yielded a very heavy crop of fine berries, but older ones, that went through the trying ordeal of last summer's drought, failed, and have not compensated for the site devoted to them. This should force the fact upon growers that during dry summers such as we have experienced recently, old plantations cannot be relied upon, and the only sure way of securing a full crop is to plant healthy young stock on rich deep soil not later than the first week in August. This, I am convinced, is the only way of providing the best results annually, and it pays. I believe it is difficult for some growers to realise this, but the enclosed bill of sale will show that, grown in the way described, gatherings from outdoor plants will realise 2s. per lb. wholesale, these being simply an overplus after the home consumption had been supplied, the variety depended upon being Royal Sovereign. Probably in no other locality are Figs grown more successfully in the open than hereabouts. Large standard trees are now swelling off heavy crops of fine fruit which will be ripe in August. Nuts are also grown extensively, but both the large Cob and pink Filbert have only moderate crops this season. Mulberries appear never to fail, as most years these bear freely, but perhaps never more so than this one.

Early Potatoes suffered from the want of moisture; therefore the produce from such kinds as Sharpe's Victor and Ringleader ran small. Second earlies suffered too from a like cause, but not to the same extent, Early Rose for instance proving most satisfactory. All late kinds look promising, especially Up-to-date, which I have planted extensively. Peas are generally one of the first crops to show signs of distress after a few weeks of dry weather, but experience causes one to prepare for this, and I only sow mid-season varieties on deeply prepared ground. Many bushels of the finest quality have to be provided here at the end of July, and to avoid any fear of a famine trenches are prepared in winter or early spring the same as for Celery, and then sowings every ten days are made of one variety—Ne Plus Ultra. It would be useless to expect a succession of heavy crops during a dry summer here unless this method was resorted to. To have Scarlet Runners in at the same time and plenty of them, seed is sown in 6-inch pots early, and the young plants protected in cold frames until it is safe to put them out. Gathering can then commence by the third week in July. Similar means are employed in connection with French Beans and Vegetable Marrows, as there is no demand for either after the first week in August. To keep up a supply of good Lettuce during the heat of summer I have ceased to trouble about transplanting seedlings, as such work cannot be followed without a check being given to growth. Seed is sown thinly on deep, rich ground, the seedlings being afterwards

thinned out to allow room for those retained to develop. The waste of seed is trifling compared to the cost of transplanting and subsequent loss of stock, while certainly finer hearts are obtained by leaving the plants where sown. Onions are very satisfactory, which I attribute to preparing the site early and the use of soot some weeks in advance of sowing the seed, which, by the way, is also put in much earlier than the recognised dates, viz., about the middle of March. I find the beginning of March, or even February, the best time for sowing this important crop, as the plants become strong and can better resist attacks from the grub. Among the different root crops, perhaps Turnips have proved the most disappointing, but now we have had some nice rains, less difficulty will be found in getting a good clean plant, and better hopes are entertained for autumn and winter crops. At the time of writing (July 13) the heat is less intense, which, with occasional showers, favours the main planting of all kinds of winter stuff, such as Broccoli, Kales, Savoys, &c., as well as Celery, and prospects generally are more promising for a full yield of most things. R. PARKER.

Goodwood.

SOUTHERN.

Aldenham House, Elstree, Herts.—The fruit crops in this district are very poor. Apples generally are very thin and the trees badly infested with American blight. I have never before seen them so bad. The varieties which are bearing best are Cox's Orange Pippin, Hanwell Souring, Keswick Codlin, King of the Pippins, Lane's Prince Albert, Court Pendu Plat, and Ecklinville Pippin. Pears are a fair crop on walls, but on pyramids and standards a failure. The whole of the standard Plums and Damsons were ruined by bullfinches just as the buds were swelling, and I was compelled to protect the whole of the wall trees with netting, or these would have suffered in the same way. Fortunately, I have good crops on the walls. Peaches and Nectarines I do not attempt outside, but under glass I never had them better. Apricots are fair and the trees look healthy. Cherries are very fine on walls, except Morellos, which are thin and poor. Nuts are thin. Strawberries have been the most unsatisfactory crop since I have been at Aldenham—fifteen years. Royal Sovereign and Latest of All were the best. I attribute this to late frosts and continued drought. Raspberries very fine and plentiful. Gooseberries very poor. These suffered very much from the late spring frosts. Currants, Red and White fair, Black very fine.

Vegetables of all kinds plentiful and good. The Potato crop promises well and up to this date free from disease.—EDWIN BECKETT.

Claremont, Esher.—The fruit crop, taken as a whole, is below average. Apples are partial—in some cases good, in others very thin indeed, a remark that applies both to dessert and cooking kinds. The quality seems likely to be good and the maggot is not so troublesome. Apricots are very thin, not half a crop. Cherries, both dessert and Morello, are also considerably below average. Peaches and Nectarines are a good average crop, the set nothing like so thick as usual, but enough to furnish the crop. Quality bids fair to be good. Trees of Waterloo and Alexander already (July 17) cleared have given very good fruit. Pears are decidedly below average, but, fortunately, some good and reliable sorts, as Louise Bonne, Baurré Superfin, Doyenné du Comice and Glou Morceau, are carrying very fair crops. Plums on walls (I do not grow them in the open), both dessert and cooking, are well up to the average. Fruit of Early Prolific has been picked to-day (July 17). Small fruits as a whole are a good average crop. Gooseberries and Raspberries are thin, but all kinds of Currants and Strawberries plentiful. I mulched the latter with good holding manure early in the year and protected blossom with a

double thickness of fish netting supported by binders, measures that proved effectual in resisting both drought and frost.

Vegetables are on the whole satisfactory, but in the majority of cases a considerable amount of labour to mulch and water has been necessary to keep them up to the mark. Earliest Potatoes ripened somewhat prematurely and were very small.—E. BURRELL.

Leigh Park Gardens, Havant, Hants.—On the whole the fruit crops about this part are under average. Some sorts of Apples are a fair crop, including Lord Suffield, Keswick Codlin, Duchess of Oldenburgh, Bramley's Seedling, and other free-setting sorts. Pears have suffered much from birds, principally bullfinches, which devoured the buds wholesale, so that the crop will be light. Peaches on walls outdoors are fairly good, but suffered from a severe frost when they were in bloom. Strawberries, notwithstanding the dry season, have been a nice crop where they could be watered before ripening, but where left unwatered are almost a failure; Royal Sovereign and Sir Charles Napier proved the best this season. Small fruits are rather under average, with the exception of Black and Red Currants, which are very good. Morello Cherries are a nice crop. I have a tree planted against a south wall carrying an immense crop. It has done so for several years, and, coming in early, does me good service.

Vegetables are suffering from the prolonged dry weather. I fear early Potatoes will be much under average; late sorts are looking well where there is a good depth of soil. Peas in trenched ground are carrying a magnificent crop. The best sorts with me for main crop are Duke of Albany, Telegraph, Autocrat, and Ne Plus Ultra. Cabbages have not been so good. Early Rainham, when one can get the true sort, is one of the best either for a gentleman's table or for market, as it can be sown early without fear of running to seed; in fact, not one in a hundred will run. It is of good size and comes in very quickly. Should we get rain soon, Onions, Carrots, Scarlet Runner Beans, Cauliflowers, and the different Coleworts will be fairly good.—E. PENFOLD.

Bearwood Gardens, Wokingham.—The fruit crops here and in the neighbourhood are bad. There was abundance of bloom on wall and standard trees, with a good set of fruit on most sorts, but the terrible frost in Whitsun week destroyed Pears, Plums, and most of the Strawberries. Apricots, Peaches, and Nectarines are under average; Apples very good in places; bush fruits very good, only small from want of rain. I never remember a more disastrous season from the severe frosts.

Vegetables are suffering badly from the severe drought.—JAMES TEGG.

The Gardens, Brookwood Asylum, Woking.—Owing to the very dry summer and autumn of 1898 and the frequent spring frosts of the present year, the fruit crops as a whole are rather poor. Apples are about a third of a crop; Pears and Plums very thin; Currants not half a crop (Black are the best). Gooseberries and Raspberries are good; Strawberries not half a crop; Peaches a moderate crop, trees healthy; Apricots very thin; Figs poor.

Potatoes are very much checked in growth owing to the dry weather. The early sorts will not be more than half a crop. The late sorts promise well, and will be good if we get rain enough in time. Cabbages are late and difficult to obtain owing to the bad seed time. I have had plenty, but rather late. Onions are good. Peas and Broad Beans are poor through dry weather. The winter green crops want rain.—R. LLOYD.

Cassiobury Gardens, Watford, Herts.—Generally speaking, the Apple and Pear crop is under average; Plums very poor; Cherries under average; Peaches and Nectarines average; Apricots under average; Strawberries average crop, but short season owing to the drought. Small fruits an average crop.

Vegetable crops looked very promising till end of June, but owing to the continued drought all are suffering very much now.—CHAS. DEANE.

A VIEW IN ROSS-SHIRE, N.B.

THE two promontories are extremities of an amphitheatre enfolding the loch and forming a fine harbour. The southern shore is clothed with Birch wood almost to the water's brink, whilst on the northern coast may be seen the magnificent corries of Applecross and barren precipitous rocks of old red sandstone, still the haunt of golden eagle and peregrine falcon. From the estuary of the river Kishorn, which bounds the Applecross Forest inland, in beautiful contrast lie the limestone lands of Kishorn, rich in pastures and it is said also in minerals. The portion of garden ground represented in the drawing is again not on limestone, but on another formation, a conglomerate, I think, which may account partly for successful culture of Japanese Lilies on this spot when not devoured by rats or mice. Most Japanese plants thrive here on suitable soil. It is possible that being situated on an earthquake line may conduce to warmth and fertility, and the influence of the Gulf stream is felt, although it actually touches the coast further to the northward. We have not, however, the golden rays

Loch Kishorn, Ross, N.B. Engraved for THE GARDEN from a water-colour drawing by F. Stainton.

of the southern sun, so that, for instance, the William Allen Richardson Rose is usually only in various shades of yellow, though in England it is said to be tinted red, and in the south of France is a most brilliant orange.

Kishorn, Ross-shire, N.B. MARY STUART.

A simple table decoration.—The too common practice of adding to tables florally decorated for competition some drapery material, not infrequently also of a somewhat killing colour, should be strongly deprecated. Too seldom do we see in combination with such aids good floral taste. I was very recently much pleased with a table easily placed first, the flowers used being solely those of *Lavatera rosea* and *L. alba*, the dressing being Fern fronds, sparingly used, *Gypsophila paniculata*, and a very few grasses. The flowers kept fresh all the day—long, indeed, after other flowers had flagged. The harmony found in the combination was of the most pleasing kind, and whilst everything was simple and drapery of any description absent, the table yet stood a good way ahead of others shown in which coloration and drapery were mixed. Very recently I saw a table the only flowers employed being those of St. John's Wort, but on the cloth was laid some thin material of a rich florid yellow hue, which quite killed the flowers by contrast.—A. D.

NOTES ON CURRENT TOPICS.

WELL-GROWN TUFTED PANSIES.—The Tufted Pansy, like some other hardy plants, is never seen at its best outdoors. Some of the strong, erect-growing kinds, like Countess of Wharnccliffe, would hardly be recognised grown in a pot of good soil in a perfectly cool frame plunged in ashes and allowed to expand its first crop of flowers unhindered. Under these conditions the flowers are of a size and substance and their foot-stalks of a length and stoutness never seen outdoors in a border. I have seen a large frame full of such plants which if placed on an exhibition table would have produced a sensation. Like the Strawberry, the first flowers are the best and largest, and in frames they are of a purity in colour not seen outdoors. I have seen such plants used for house decoration singly and in masses, in pots, so fine as to excite the admiration of all who saw them. The culture, which is simple and easy, is as follows: Prepare a compost consisting of good strong loam, leaf-mould, and rotten manure in about equal quantities, and in that, in autumn, pot good slips, four or five in a 5 inch pot. Do not put more than one crock in the pot for drainage, a cool, moist rooting medium being what the *Viola* loves. Plunge the plants in a quite cold frame and let them remain there

exactly after the housemaid's carpet-sweeper, an excellent appliance which does its work well, only it is apt to get clogged like the grass-sweeper and has to be cleared out in the same way. The difficulty with the sweeper has been to get it to make as clean a job as the common besom, and deal with worm casts and other obstructions. The lawn-mower sweeps as well as cuts, and need not be followed by the sweeper, which should really come in when the mower is laid up for the winter. Lawn-mowers are supposed to have reached perfection, but what a boon it would be if they could only be made lighter. The idea of the mower was originally derived from the similar little machine employed in the Yorkshire mills to shave the pile of velvet cloths, but weight had to be attached to the grass-mower in order to drive the knives, and the longer the grass the greater the force required. With the lightest lawn-mower in use the work is the hardest that the garden labourer is put to, and constant work at it in summer weather is slavery. The labour is easier when the grass is cut before it gets long, but the exigencies of work drive the cutting to the last minute, and the tugging, backing and pulling involved are laborious. Not so long ago, in a well known Scotch garden, I saw two men, stripped, pulling at a "two-man" machine that a donkey at least ought to have been put to. The weight of the lawn-mower lies chiefly in the roller, the object of the latter originally being to roll the lawn every time it was cut. No lawn, however, needs to be rolled often, and certainly not every time it is cut, and the roller is nothing else than an encumbrance and dead weight in dry weather on a light lawn, when a much less weight would drive the knives. Even the so-called "rollerless" machines are too heavy, the weight being simply transferred elsewhere with no compensating advantage. They are all too heavy to the last screw. A certain amount of weight is wanted to drive the knives, but, that secured, all other parts should be as light as possible. During the past few days I have been trying to operate with a "lady's lawn-mower," the particular name of which indicates that it surpasses all others, and find it to be about as heavy as a modern plough and harder to work. The lady gave it up long ago, and now a stout labourer performs with it and finds it heavy work.

THE GARDEN SPADE.—One day a gardener went into the warehouse of a well-known firm that makes a speciality of garden tools, and, making some inquiries on that head, was told that the firm had everything up-to-date. "Except spades," said the gardener. "Why," responded the shopman, "our patent etcetera spade is very well known." "Who invented it?" said the gardener. "It is our own invention," said the other. "I thought so," said the gardener; "no one who has learned the art of digging would have invented your spade." Then the gardener, taking one of the spades, showed the dealer that the blade and the handle formed a very obtuse angle, and that when the blade stood perpendicularly—as it should do—in the soil when digging, the handle projected forward about 6 inches beyond the blade, and that the digger had to lean forward so far as almost to overbalance himself, while losing power over the implement. The idea of the inventor of this spade was that the bend at the junction of the handle with the spade gave the digger leverage, whereas it is a spade that is wanted, not a lever. The Scotch spade, handle and blade, is nearly straight, and the reason of that shape is that it enables the digger to insert his spade straight down, to the greatest depth, deep digging, like deep ploughing, being of the first importance in the production of garden crops. With the obtuse-handled tool the digger, never inclined to dig as straight and deep at any time as the gardener would like him to do, puts the spade in at an angle, a little less than 45° perhaps, but at any rate at a slope that misses the bottom soil, and 2 or 3 inches may be lost. I remember the editor of THE GARDEN long ago saying that digging was a "lovely art," and so it is when well done. Old Scotch gardeners used to ask "Can you dig?" for they dearly loved a good

LAWN-MOWERS AND SWEEPERS.—The lawn-sweeping machine has taken shape at last, but "it may be dooted," as Jane Eyre's Scotch agent used to say, if it ever will become as useful as the lawn-mower. The first attempt at a sweeper was in the form of a hay-tedding machine, in which the besoms were attached to a skeleton drum and swept the rubbish into a receiver. The latest invention of the kind appears to be modelled

spadesman. I have seen a gardener, who was a martinet, stand at the end of a line of eight or ten young gardeners digging a broad quarter and shout like a drill sergeant if one of them happened to take a too thick slice before his spade, did not insert his spade straight down, or who could not use either hand foremost as might be required and turn the soil upside down in the true artistic style.

TOPIARY WORK IN THE PROVINCES.—Much as this kind of work has been condemned in general gardening, it is still practised more than might be imagined—not so much in gardens in the country, but in gardens in the suburbs of, or near, large towns. At the present time gardening is carried on with more spirit in these places than in many of our old and better known gardens, and such gardens are often extensive and usually well kept. Some have indeed been laid out by the best landscape gardeners with great taste, but where the personal fads of the owner come in we frequently find gardening of the grotesque order. In many cases it takes the form of clipped specimens, almost every Holly, Yew, Laurel, or plant that will bear the shears being trimmed into the stiffest of shapes. In one part of the suburbs of the "Steelopolis" and the "Cottonopolis" this kind of gardening has been contagious, and is evidently meant for show as much as anything else. In certain suburbs both evergreen and deciduous trees and shrubs, conspicuous from the road along which the wealthy citizens drive going or returning from business, are all shorn into the form of cones of different proportions. The general effect is rigid in the extreme, and it puzzles one to understand why such practices are tolerated by people who love Nature and beautiful gardens. One cynical individual suggested that the whole business was borrowed from the foundry, and the castings turned out there and transferred to the garden shrubbery. The practice is, perhaps, adopted thoughtlessly, but it is certain that the owners of such examples pride themselves upon their handiwork, as do also their gardeners, and it is not an uncommon thing to hear both in their respective spheres boasting of their formal Golden Queens, Golden Yews, Portugal Laurels, Laurustinus, and the like.

ALL LIGHT.—This is the title applied, I see, to a new style of fruit and plant house. Of the particular invention I know nothing, but since ever I remember all good gardeners have been striving to reduce the timber and iron in their glass structures with the object first of admitting the greatest amount of light possible to the interior, and secondly reducing the cost, and any design that promotes these ends should be welcomed. The first Crystal Palace of 1851 was all light and looked a fairy structure, and it was designed by a gardener. One has, however, only to look at the advertising pages of any of the horticultural papers to see how unteachable some of our horticultural builders are. "There is nothing like leather," and with the hot-house builder, who is usually no gardener, there is nothing like timber. Only those engaged practically in plant and fruit culture realise how much is lost by every ray of light obstructed or lost in a house devoted to plants. I know a garden where a tall tree outside the walls begins to cast a shadow early in the afternoon over a long glass structure, the shadow gradually lengthening till the whole structure is in gloom. The effects of this tree on the inmates of the house have always been of the most marked description, the flowers becoming fewer and more inferior exactly according to the duration of the shadow. Creepers always suffer worst, being in permanent positions, whereas the portable plants can be changed from one side to another. Heavily-timbered plant and fruit houses produce the same bad effects. Where the rafters are deep and not far apart, the sun is off the plants not long after it passes the meridian, and that is all lost measurable energy. Why a builder should persist in making a conservatory with such cumbersome uprights and roofs, with the sides made up of frames glazed like windows,

involving wood and putty and paint and providing receptacles for dirt in every corner, is a problem. It is next to impossible to keep such structures clean inside. Sludge and dirt accumulate and set on the glass till it becomes obscured, reducing the amount of available light to a minimum, and necessitating much cleaning which can only be done with difficulty at any time. It is also in such houses that vermin find shelter and are worst. Let our plant houses be as nearly like a French cloche or bell-glass in principle as possible.

RAMBLER.

ORCHIDS.

COOL ORCHIDS.

At times during the present summer it has been difficult indeed to keep the cool house at anything like as low a temperature as is usually recommended. No matter how heavy the shading or how free the ventilation, the glass keeps going up, and at midday the house is like a stove. The air, indeed, entering the house through the ventilators is hotter than that inside, and when it is so the best way is to almost close the top ventilators, shade as heavily as possible, and admit air only through the lower side ventilators. Damping the floors and stages becomes an almost constant job, and it is well to lay some ordinary garden mats on the glass and damp these several times daily, as often as they dry in fact. This done, the house will be kept so that on entering the inside atmosphere feels cool and fresh after the hot sun outside, and is the best that can be done. Where the very coolest section, such as the New Grenadan Odontoglots, the Disas, and cool Oncidiums, are placed in frames in summer, those left, such as Anguloas, Lycastes, Cymbidiums of the Lowianum and giganteum types, will find just the conditions they like, as will *Odontoglossum grande*, *O. Schlieperianum*, and various other autumn-flowering kinds that like a little more warmth than *O. crispum*, *O. triumphans*, and the allied kinds. If only for the additional room provided, the removal of the latter class is a great advantage.

After the end of the present month we usually get cooler nights, though during the day it is hot and bright, but the nights get longer and cooler conditions on the whole prevail. It will then soon be time to renew the compost of such as may require this attention. Some of the Oncidiums, for instance, that produce large scandent spikes, such as *O. macranthum*, *O. serratum*, and similar kinds, will be pushing their roots from the new growths, and both in order to protect these from insect attacks and provide them with nutriment the sooner these are covered with new material the better. All may not want repotting; with some it will simply be a little surface-dressing that is needed, but the sooner either operation is carried out after the tips of the roots appear the better, as they are not then so liable to be injured and the better hold they get on the new compost. In preparing the latter due regard must be had to keeping it open by the aid of crocks and charcoal, this being especially necessary when top-dressing. After the plants are done it is not advisable to keep the roots very moist, but as the new material dries much more rapidly than the old, it will probably be necessary to water quite as often as before. The plants that were top-dressed are the more difficult to manage, as sometimes the new material at the surface will be dry, while below it is quite wet. In doubtful cases the weight of the pot is the best guide. A comparatively dry state at the roots and a very moist atmosphere are more conducive to early activity of

the former than the opposite conditions. Roots, as a matter of fact, are put forth in search of moisture; they are not drawn out by it, and at first they need to be coaxed into the compost, as it were.

Far too little attention is given at this time of year to the cleaning of cool and other Orchids, damping, watering, and other details of culture taking up so much time. But if possible time should be spared for a thorough cleansing before the plants are potted or surface-dressed. Well wet the foliage before beginning to use the sponge, and after the plants are finished a light fumigation may be given on a still evening. *Masdevallias* especially should be carefully gone over to destroy yellow thrips, as these ruin the appearance of the blossoms of the showy-flowered section of the genus by the white lines they make all over them.

Cypripedium Sanderianum.—This is a very interesting *Cypripedium* that ought to be grown wherever these useful Orchids are liked. It is one of the finest of the Old World kinds, thriving under cultivation in a hot, moist house with a very substantial compost, the growth when the plants are healthy being very vigorous. The plant has broad, strap-shaped leaves and tall flower-spikes, the latter containing several blossoms, which are remarkable for their long, pendent petals. These are yellowish brown and purple, the same colour being repeated on other parts of the flower.

Oncidium pulvinatum.—The large trusses of flowers produced by this old species are very beautiful, and many rarer and more expensive Orchids are less worth a place. The pseudobulbs are a foot or upwards in height, and from these the flower-spikes spring. It is of the easiest culture, thriving in any moderately warm house in a rather rough and open description of compost. Keep the plants well up to the light and they will be far more free-flowering than if growing in dense shade, though of course the foliage has to be considered. Water is freely required all the year round, more, of course, being necessary in summer, when evaporation is rapid, than in winter.

Oncidium lamelligerum.—The flowers of this *Oncidium* are as striking and handsome as any in the section to which it belongs, the long twining scapes 7 feet or more in length having at intervals fine yellow and brown flowers of characteristic shape. The growth is fairly strong, and the roots, being large and fleshy, push most readily through a compost with which rough lumps of charcoal and crocks are freely mixed. Set the plants only moderately high in the pots, as then top-dressing may be easily done, this being oftener necessary than with kinds of a more tufted habit. It delights in a cool, moist house all the year round, and is rather more liable to insect attacks than most Orchids. Light syringings overhead help to keep these in check, especially thrips, and are refreshing to the plants.

Curious sport on *Dendrobium nobile*.—I noticed a very peculiar malformation of this Orchid the other day, a plant in a local collection having pushed up a young growth from the base, and being by some means checked had pushed its flowers in quite a whorl, or so it seemed until examined closely, when it was apparent that there were several little bunches of two and three flowers each. They were not perfect flowers, but they were not abortive, and the colouring was almost as bright as if they had occurred in the usual way. The check had evidently caused the premature ripening of the shoot and the flowers formed, the fluids pushing these up when they again became active. Such a thing would be likely to occur when using plants with immature growth for decoration when in flower.—H. R.

Epidendrum Brassavolæ.—The likeness to a *Brassavola* is at once seen in the pretty flowers

of this somewhat uncommon *Epidendrum*; the pretty purple tint on the end of the lip contrasts nicely with the yellowish tinge in the sepals and petals, and it is a pity the plant is not more grown. The habit is strong and a large number of flowers is produced on the tall, vigorous scapes. Its culture cannot be called difficult, but it will not flower freely unless grown in a house where ample light and air reach the plants on every side. The lightest position in the *Cattleya* house or a place with the Mexican *Laelias* will be suitable, this tending to a thorough ripening of the growth after the flowers are past and ensuring a free-blooming plant. Plenty of water is necessary while growing, and when at rest sufficient to prevent shrivelling.

NANODES MEDUS.E.

This is certainly a most peculiar Orchid to cultivate, plants in some places doing well under one system, in others under another, and even in the

neighbour. But it is, unfortunately, not always so, and do what one may the plant seems to get smaller instead of larger. It is always worth while to try the plant for a week or two in a rather higher temperature than usual to see if that will give it a start. As regards its growth and flowering, it is one of the most inconstant of Orchids, and usually there are growths upon it in all stages of development, some flowering, others half made up, and young shoots pushing from the base of those in flower. This being so, it is evident that nothing like a regular season of growth and rest can be arranged, but the plants must be kept moist at all times. Less moisture will be needed when the weather is dull and cold than when opposite conditions prevail, and all the year round the plants should be grown in a cool, moist, and shady house such as suits the New Grenadan *Odontoglossums*. The blossoms are very singular, and are produced in terminal racemes of two or three, seldom more, from the distichous-leaved pendent stems. They are

rough blocks with *Sphagnum Moss* about the roots.

TREES AND SHRUBS.

AZALEA VASEYI.

Of not merely botanical interest, but of great value also for the garden, is the handsome *Azalea Vaseyi*, one of the latest of North American discoveries in this line. Belonging to the *Rhodora* group, it appears to be more closely allied to the Japanese representatives of this group than to the American *Azalea (Rhodora) canadensis*, and is thus a new proof of the near relationship between the flora of Eastern North America and that of Japan. As late as 1878 *Azalea Vaseyi* was unknown until in the spring of that year it was discovered by G. R. Vasey, son of the well-known botanist, Dr.

George Vasey, in North Carolina, in the neighbourhood of Webster; since then it has been met with in other localities, not, however, outside the boundaries of the North Carolinas, and, moreover, only in two districts, viz., Jackson and Mitchell, where it thrives to an altitude of nearly 7560 feet. A report that it was also to be found in South Carolina was based upon an error.

Azalea Vaseyi is a handsome shrub, which in April or the beginning of May begins to put forth its blooms, not much later than those of *A. canadensis*, which, however, it far exceeds in beauty, not merely as regards the abundance and size of its blooms, but also in their tender rose-pink colour. A fair specimen of this shrub is to be seen in the Arnold arboretum. After twenty years this plant is now about 5 feet in height, yet shows no visible inclination to attain to the height to which in its native habitat it often grows, namely, 13 feet or thereabouts. This, however, may be accounted for by the fact that there it is found in close association

Azalea Vaseyi.

with other and loftier growing vegetation and in greater moisture, whereas in the arboretum it has greater scope for lateral development. In European gardens this handsome *Azalea* is yet almost unknown. *Azalea Vaseyi* is in its native North Carolina a bush 13 feet or so in height with tall smooth branches. The blooms appear before the leaves in umbels of five or six, borne upon stems about a centimetre in length. Like the other hardy *Azaleas*, as *A. canadensis* and *A. viscosa*, it loves a moist situation. In all parts of Germany it is hardy. According to Herr von St. Paul, who owns an estate at Fischbach, in the Riesen Mountains, it has often been exposed to a temperature as low as 30° C. without hurt. As in all *Azaleas*, the bloom is most abundant on old shrubs, and the older these are so much the richer in bloom. This is particularly characteristic of the American kinds, in contrast to which *A. sinensis* blooms best as a young plant.

usually about 2 inches across, the sepals and petals yellowish green, the lip broad and deeply fringed deep maroon-purple. They last a long time in good condition. H. R.

Dendrobium cucullatum.—Flowering rather later than *D. Pierardi*, this is useful in keeping up a display, and it is a very pretty and graceful Orchid when in bloom. From the long semi-pendent shoots the blossoms appear at intervals in short racemes of two or three, the colour being a soft mauve or rose on the sepals and petals, the lip yellow and white, with streaks of purple. *D. cucullatum*, in company with one or two others that make late growths, likes a position where in summer and early autumn it catches every ray of sunshine and the warmth is well maintained till the end of the season. Then the pseudobulbs are well developed to the point, and, being well rested after the foliage is off, flower abundantly along their whole length. The plant is not so strong-growing as *D. Pierardi*, and does best in pots or baskets of limited size or even on

with other and loftier growing vegetation and in greater moisture, whereas in the arboretum it has greater scope for lateral development. In European gardens this handsome *Azalea* is yet almost unknown. *Azalea Vaseyi* is in its native North Carolina a bush 13 feet or so in height with tall smooth branches. The blooms appear before the leaves in umbels of five or six, borne upon stems about a centimetre in length. Like the other hardy *Azaleas*, as *A. canadensis* and *A. viscosa*, it loves a moist situation. In all parts of Germany it is hardy. According to Herr von St. Paul, who owns an estate at Fischbach, in the Riesen Mountains, it has often been exposed to a temperature as low as 30° C. without hurt. As in all *Azaleas*, the bloom is most abundant on old shrubs, and the older these are so much the richer in bloom. This is particularly characteristic of the American kinds, in contrast to which *A. sinensis* blooms best as a young plant.

The foliage, as in most Azaleas, is not particularly striking, yet in autumn it acquires a dark red colour which is very handsome. The great value of *A. Vaseyi*, however, lies in its early blooming and in the abundance of its delicately coloured blossoms, and, furthermore, in its hardiness. The flowers themselves appear to be little susceptible to night frosts, and I have never known them to suffer from this cause.—*A. REHDER, in Deutsche Gartner Zeitung.*

The Spanish Broom (*Spartium junceum*).—In soils and positions where the ordinary Broom and its varieties are not a success, this may be tried, as it is more easily suited as regards soil and very free-growing and flowering. The blossoms are large and in colour a very bright clear yellow, a fairly large plant in bloom having a very fine appearance from a little distance. It should not be planted where hares and rabbits abound, or if planted it should be protected, but for the front of shrubberies or for making distinct bits of colour in the distance it is certainly one of the best of plants. As showing its free habit, plants of it here cut nearly to the ground-line during the present spring are now over a yard high and flowering. Propagation of this species from seeds is easy, and these are usually very freely produced after flowering. The pods should be gathered before they show signs of bursting and laid on trays in a warm, sunny place until quite ripened. Sow in autumn in fairly wide drills and the seedlings will appear in spring, when they may be left to grow into a thicket or be transplanted. Cuttings of half-ripened shoots root freely if covered with a handlight.—*Suffolk.*

JULY IN SOUTH DEVON.

THE past month has been a period of perfect summer weather. In the early mornings the waters of the adjacent bay were darkened by a cool air from the north-east, which, as the sun mounted the heavens, faltered and changed in direction, coming in fitful breaths from the south over the horizon-line that marks the open channel and gradually veering until, as the sunset hour approached, it blew crisply from over the western shore. Occasional local thunder-showers served to keep the grass fairly green and the hedges free from accumulations of dust until the closing days of the month, when vegetation at length began to assume a parched appearance. During July the corn ripened with great rapidity, many fields being harvested before the end of the month. Stretches of distant moorland and ledges of sea-girt cliffs are purple with blossoming Heather. The lanes are full of the luscious scent of the Meadowsweets that grow amongst the rank herbage which clothes their banks, interspersed with numberless wild flowers, lavender Scabious, yellow St. John's Wort, Bedstraw, Milfoil, Chicory, Crane's-bills, Enchanter's Nightshade, Agrimony, Rest-harrow, and a host of others. The Bryony's tangled skein wreathes the now flowerless sprays of Eglantine; the first Thistle seed, wafted by an impalpable zephyr, floats slowly down the winding lane, and the voice of the stream that laves the Sedges, amid whose seclusion the reed-warblers have reared their brood, is silent. Save for the screaming of the swifts, as they sweep with lightning like speed round the old tower, ere circling aloft for their evening flight until they are mere specks in the clear sky, the occasional laugh of the green woodpecker or the calling of the brown owls from the wood on moonlight nights, the feathered tribes are mute. The blithesome time of singing birds is past—the time of hudding branch and opening blossom—and Nature stands full-foliaged and content calmly awaiting the next act of the drama—the pageant of her autumnal transfiguration.

In the rock garden *Acena microphylla* bears its long-spined crimson flower-globes, and in rich soil the stately *Acanthus* spreads its noble cur-

ing leafage of glossy green, surmounted by lofty purple and white flower-wands fully 7 feet in height. *Achillea ptarmica* fl.-pl. The Pearl is still bearing a profusion of its double white rosettes, and the Monkshood (*Aconitum Napellus*) is perfecting a second crop of flower-spikes. The blue African Lily (*Agapanthus umbellatus*) and its white variety are objects of great beauty where large clumps have thrown up a dozen or more great umbels of flower from the green sward. At the commencement of the month the hybrid *Alstroemerias* were in the zenith of their loveliness, the golden-orange *A. aurantiaca* being also very attractive, yet lacking the suave gradations of colour that are presented by a breadth of the hybrids, where the tints blend harmoniously one with another, ranging from palest cream to rich crimson, with half-shades of yellow, orange, and pink, and dark pencillings. These hybrid *Alstroemerias* should always be planted in masses and not singly, since it is only when the former method is adopted and patches 2 yards or so in length and half as much in breadth are formed that the association of the varied tints becomes really effective. *A. psittacina* has also been in flower, as has the white *A. pelegrina alba*, sometimes called the Lily of the Incas, but this latter apparently does not possess the constitution of the before-mentioned varieties, since its growth has been feeble and its flowers few. Hollyhocks (*Althea rosea*) have generally done well this year, several collections that I have seen showing little or no trace of the Hollyhock disease. They are particularly handsome flowers for the back row of the herbaceous border or for planting where their flower-spikes are thrown into strong relief by a setting of evergreens. These are often seen growing vigorously in cottage gardens, where deep red or rose-coloured varieties are very effective when gaining the contrast of a whitewashed wall. Many of the double forms are massive and grand, but the singles with their simple blossoms are, perhaps, the more attractive. A single yellow, with deeply-cut foliage almost resembling a Fig leaf (*A. ficifolia*), is a very taking plant. Hollyhocks should be provided with rich and deep soil and liberally treated in the matter of liquid manure and mulchings, when they will attain a height of 8 feet or 9 feet. When in perfect health they have an air of robust comeliness that renders them most decorative in the garden. *Anchusa italica* is a handsome plant for the wild garden, the deep blue of its flowers being very telling. Its somewhat straggling habit and the comparatively small size of the blooms prevent its becoming a general favourite, though there is a form with flowers quite double the size of those of the type that is well worth a place in the border. *Anemone japonica alba* Honorine Jobert heralded the approach of autumn by expanding the first of its blossoms before the close of the month, and the white-flowered Pearly Everlasting (*Antennaria margaritacea*) produced its clusters of double blossoms. St. Bruno's Lily (*Anthericum Liliastrum*) and St. Bernard's Lily (*A. Liliago*) bore their spikes of white flowers, the former being by far the more effective, owing to the much larger size of its flowers, both in the border and when used for indoor decoration, though the scapes of the latter are graceful. The pure white *Antirrhinum* have borne a profusion of flowers, old plants two years old having formed quite large bushes. A fair proportion of the seedlings come true to colour, but, since this cannot be depended upon, it is always advisable to propagate from cuttings. Hybrid *Aquilegias* were at their best in June, but were still flowering in the early part of this month. *Armeria bracteata rosea* blossomed well into July, and the Prophet Flower (*Arnebia echioides*) produced its primrose-yellow bloom-heads with the deep maroon-purple spots on the petals that have the curious property of disappearing entirely after the blossom has been open a day or so and leaving the flower entirely yellow. *Arum Lilies* (*Richardia*) have been blooming freely where they are planted around ornamental water, and in some cases below the water level, and in exceptionally sheltered positions will carry blooms until the close of the

year unless unusually severe weather should set in. *Astrantia maxima* has borne its quaint double blossoms, and *Arundo conspicua* has produced its white plumes on their slender shafts. These latter are so frail, that if the plumes become saturated with rain before the shafts have attained their maximum consistency they break, and thus spoil the effect of the clump. This month during heavy rain, in an absolute calm, many shafts broke on a fine clump with the weight of their plumes. Tying and staking the shafts are, even if practicable, too inartistic a method to be pursued, and the only remedy is to cut out and remove the broken shafts. This New Zealand Reed is of far more graceful habit than the Pampas Grass (*Gynerium argenteum*), with which it is often confounded, but the latter has certainly an advantage in possessing shafts that are not so readily broken by the action of the rain and wind. In light soil in sunny gardens *Babianias* have been in flower, and the tuberous *Begonias* are weak by week making a more effective display. The great Plume Poppies (*Bocconia cordata*), 8 feet high and more in good deep soil, are holding aloft their branching panicles of inflorescence, ivory-white and ruddy brown in colour, above their wide-spread scolloped leaves, blue-green on the upper surface and silvery white beneath, their reverses showing fitful gleams of light as the breeze momentarily lifts their edges. *Brodiaea californica* and *B. laxa* have been in bloom, and many of the *Campanulas* have brightened the garden with their flowers. In the herbaceous border *C. grandis* and its white variety, *C. latifolia*, purple and white, over 5 feet in height, *C. persicifolia* in all its forms, *C. lactiflora*, with the biennial Canterbury Bell (*C. Medium*) in varied colours, and the tall Chimney *Campanula* (*C. pyramidalis*) expanding the blossoms on its earliest flower-spikes. Of this species, the pale lavender variety, presumably a cross between the purple and the white forms, is perhaps the most attractive. Of the dwarf habit species and varieties, *C. carpatica* and its varied forms, *C. cæspitosa*, *C. pusilla*, *C. garganica*, *C. cenisia*, *C. isophylla alba*, which is used so extensively for hanging baskets, *C. Raineri*, and *C. G. F. Wilson*, as well as many others of the same family, have been in flower in various rock gardens. *Calandrinia umbellata* has produced its corymbs of magenta-crimson blooms, and is certainly one of the showiest of dwarf biennials. *Callirhoe involucrata* has borne its crimson flowers, and *C. Papaver* its violet-red blossoms.

The large-flowered *Cannas* are commencing their showy reign in many gardens, and the comparatively old *C. Ehmanni iridiflora* is bearing its arching bloom-scapes of cerise-pink. This *Canna* lives out through the whole winter in sheltered gardens where the soil is not too retentive of moisture. Carnations have given a lovely display in some places, two-year and three-year-old plants providing a multitude of bloom, while in other soils they are rarely satisfactory after their first season. The Cretan Mullein (*Celsia cretica*) has borne its tall yellow flower-spires, and of the *Centaureas*, *C. macrocephala*, *C. babilonica* and *C. montana* have been in bloom, as well as the annual blue Cornflower (*C. cyanus*) and Sweet Sultan (*C. moschata*). *Chelone barbata* has borne its tall flower-spikes set at intervals with drooping orange-red blooms, and the larger-flowered dwarf form of *Chrysanthemum maximum*, styled *C. m. grandiflorum*, has expanded its wide star flowers, while *Cimicifuga racemosa* has perfected its long, pendent trails of snowy blossoms. Two bushy *Clematises*, *C. Davidiana* and *C. recta*, have produced their blossoms of pale purple and white respectively, and *Codonopsis ovata* has continued to expand its lovely but ill-scented flowers. *Convolvulus Cneorum* and *C. mauritanicus* have been in bloom, the latter exhibiting the most vigorous health and flowering profusely when planted between the stones of a retaining wall. *Coreopsis grandiflora* is a blaze of gold, and the white *Cosmos hippinatus* is already in bloom where seedlings have been raised under glass and subsequently planted out. Treated in this manner the plants come into flower at a comparatively early

date: whereas if the seed is sown in the open in rich ground the plants often attain a height of 6 feet before forming flower-buds, which are then not produced until October, when the weather rarely admits of their satisfactory expansion. *Crinum capense* and the deeper coloured *C. Powellii* have both opened their flowers, and one solitary bloom has appeared on a plant of *Cypella Herberti*, which, however, has never recovered the check it received by being eaten down level with the ground by a rabbit just as it was coming into good growth in the late spring.

At the commencement of July the *Delphiniums* presented a majestic appearance, many specimens being 8 feet in height and carrying numerous flower-spikes. Those with pale blue flowers are by far the most effective, the comparatively smaller-growing *Belladonna* being of a shade of blue hard to beat. *Cactus Dahlias* are daily becoming more decorative, and in a neighbouring garden *Desmodium penduliflorum*, also known as *Lespedeza bicolor*, has been in bloom. *Dianthus Napoleon III.* has produced a succession of its bright blossoms, and the Burning Bush (*Dictamnus Fraxinella*) has borne its many-flowered bloom-spikes. The white variety of this plant is more beautiful than the dark-flowered type, but it appears to be less hardy, as I have known it die out in not a few gardens. The blooming season proper of *Dorenicum plantagineum excelsum* Harpur-Crewe passed away with the preceding month, but now and again a few giant golden stars are produced. The Globe Thistles have been distinctly ornamental, *Echinops Ritro* having borne numbers of its blue globular flower-heads, and the Rocky Mountain Willow Herb (*Epilobium obcordatum*) has been bright with its rosy blossoms. The common Willow Herb (*E. angustifolium*) is very attractive when seen growing by the thousand at some little distance in marshy spots, a space two or three acres in extent creating a fine colour-effect in the landscape. The Mexican Daisy (*Erigeron mucronatus*) is blooming as prodigally as ever, and *E. speciosus* is producing its lavender-gold-centred blossoms in quantity. This flower associates charmingly with the white *Gladiolus* The Bride for indoor decoration, and another flower that lends itself to artistic floral arrangement is the metallic-blue Sea Holly, which when allied with the orange *Alstromeria aurantiaca* creates a charming colour contrast. Of these Sea Hollies, *Eryngium Oliverianum* is one of the best, and is often sold for *E. amethystinum*, which is rarely to be met with true in gardens. *E. Bourgati* is another handsome kind. The lovely steely-blue lustre on the bracts of the flowers when these have reached perfection is quite a unique colour in the garden. Great bushes of *Fuchsia Riccartoni* and *F. gracilis* are in full flower in cottage plots, and in the wild garden the white Foxgloves made a chaste picture at the commencement of the month, while the Plantain Lilies displayed their cordate leaves and inconspicuous flower-scapes. Of these by far the most effective is *Funkia Sieboldi* with its large cool-coloured, blue-green foliage. The *Gaillardias* are gay in their crimson and gold, and the *Galegas* have been clothed with a multitude of their Pea-like blossoms. The white variety is the most effective in the garden, but the mauve type is not unpleasing when used with pale yellow flowers for decoration. The tall Cape Hyacinths have held aloft their spires of pendent white bells, and are particularly effective when associated in the garden with the scarlet *Gladiolus brenchleyensis* or the deep blue of *Salvia patens*. Some of the lovely hybrids of the *Gladiolus Lemoinei* and *G. Nanceianus* sections have been in bloom, and the rarely seen *Gaura Lindheimeri*, 4 feet in height, has been studded with rose-flushed white blossoms. In a rock garden the Partridge Berry (*Gaultheria procumbens*) has been thickly set with its drooping white flowers, and the *Gazanias* make a show in many a sunny border. *Gentiana asclepiadea*, *G. cruciata*, and *G. septemfida* are all in bloom, as have been many of the *Geraniums*, and I noticed a plant of *Gerbera Jamesoni* in flower early in the month. The bright crimson

blossoms of *Geum coccineum* are still in evidence, and the charming *Gypsophila paniculata* has perfected its billowy clouds of flower-lace. *Helenium pumilum* is golden with bloom, the annual Sunflowers hang their heavy discs by many a cottage path, and the earliest of the perennial Sunflowers are already becoming yellow with flower. Old plants of *Heliotrope* that have passed through the winter unharmed are odorous with blossom, and of the Day Lilies, *Hemerocallis fulva*, *H. Kwanso* fol. var. and *H. aurantiaca major* are in flower, while the common St. John's Wort (*Hypericum calycinum*) has swathed a steep bank, 40 feet long and 15 feet high, with an evanescent mantle of gold, and *H. Moserianum* and *H. olympicum* are also in bloom. *Inula glandulosa* has produced its large, narrow-rayed orange stars, and in the wild garden the coarse-growing *I. Helenium* has borne its yellow flowers.

By the water-side the many-tinted blooms of *Iris Kämpferi* have created a striking effect in gardens where this manner of planting them is possible, and the tall *I. orientalis*, or *ochroleuca*, with its white and yellow blossoms, and *I. aurea* and *I. Monnieri* with their rich golden flowers have formed a handsome picture. In the early days of the month a particularly beautiful variety of the English Iris was in bloom in a cottage garden, a pale French grey self. As far as I am aware this form is not mentioned in any bulb list, and personally I have been unable to procure this colour free from markings of a darker shade. *Jaborosa integrifolia* has continued to produce its fragrant white flowers in a sunny garden, and the *Kniphofias* have perfected their brilliant spear-heads of bloom. The Everlasting Pea (*Lathyrus latifolius*) is in full beauty, both the pink and white varieties being favourites with the cottagers. *Lavatera trimestris* brightens the garden with its blossoms of pink, white, and red, *Linaria repens alba* has been blooming in the rock garden, as have the golden-flowered *Linum arboreum* and *L. flavum*, while *L. narbonense* has displayed its blue flowers from the border. *Lindelfia spectabilis* has borne its clusters of purple flowers, and *Lychnis chalconica* and *L. Haagana* their vivid scarlet bloom-heads, while *L. diurna rosea* and *L. vespertina alba plena* have both been in flower. The true green-leaved *Lobelia cardinalis* has perfected its vermilion flower-spike long before the purple-leaved *L. fulgens* has expanded a blossom, and by the margin of ponds the Loosestripe (*Lythrum*) has borne its rosy purple flowers. The Musk Mallow (*Malva moschata*) is white with bloom, and *M. lateritia* and *M. Munroana* have been in blossom. *Matricaria inodora fl.-pl.* bears its double white flowers above its Fennel-like foliage, and *Matthiola bicornis* (the Night-scented Stock) has produced its fragrant, sober-coloured blooms, while *Menziesias*, white and pink, have flowered, and in light soil in sheltered gardens near the sea the *Mesembryanthemums* have created an indescribable brilliance. *M. tenuifolium* is the brightest of all the genus, being of an absolute scarlet that gleams with dazzling effulgence in the sun. By a streamlet the *Mimulus* is bright with its yellow and chestnut, and where *M. cardinalis* is grown the crimson blossoms are most effective by the water's verge. The old-fashioned Bergamot (*Monarda didyma*), also known as Bee-balm, since in days of yore the interiors of the straw skeps were rubbed with it in order to induce bees to take kindly to their new home, has borne its crimson flower-heads. When naturalised in large masses this plant has an excellent distant effect. *Mediola geranioides* has produced its bright red flowers and *Morina longifolia* its crimson bloom-heads.

In ornamental water the *Nymphaeas* have been particularly charming, the pale yellow *N. Marliacea Chromatella* and the large white *N. M. albida* being perhaps the most beautiful of all. The sweet-scented Tobacco plant (*Nicotiana affinis*), although by no means attractive in the daytime, perfumes the warm twilight with its white star flowers and of the Evening Primrose, (*Oenothera marginata*, a sweetly fragrant flower,

O. speciosa, *O. Youngi*, *O. fruticosa*, *O. macrocarpa*, *O. pumila* and *O. Lamarekiana* have been in bloom. The splendid white *Ostrowskia magnifica* has blossomed well in some gardens, growing to a height of over 5 feet. *Oxalis floribunda rosea* is still bright with flower, as are many of the Tufted Pansies in situations not too burnt up; of these the delicately tinted Border Witch, the lavender-blue *Ariel*, *Sylvia*, cream-white, *Florizel*, lilac-blue, and *Pensée d'Or*, bright gold, are especially pleasing varieties. The Paris Daisies are covered with bloom, one enormous bush of the yellow form that has braved three winters in the open being a fine sight, while some of the Ivy-leaved *Pelargoniums* have also seen three seasons in the same site and are now covered with a wealth of blossom that stretches 10 feet or more up the walls of houses. *Penstemons* are flowering, as are the herbaceous *Phloxes*. Of these by far the brightest is *Etna*, a variety even more effective at a distance than near at hand, the truest test of a good border flower. *Phygelius capensis* has produced its tall spikes of scarlet flowers, and *Platycodon grandiflorum*, *P. g. album*, and *P. Mariesi* have blossomed, while *Plumbago Larpentæ* has commenced to disclose the tint of its soft blue flowers. *Polemoniums*, blue and white, have also been in bloom, as has also *Polygonum capitatum*; while of the Poppies, the giant *Oriental*, the Iceland and Welsh, *Papaver pilosum* and the annual *Shirley* and single white *Opium* Poppies have graced the garden. *Prunella grandiflora* has borne its violet blooms, and *Pyrethrum*, single and double, have brightened the borders. Fair Maids of France (*Ranunculus aconitifolius fl.-pl.*) have bloomed, as have the golden *R. acris fl.-pl.* and *R. lingua* in shallow ponds. The double white *Rockets* have been odorous as ever, and the exquisite *Romneya Coulteri* has borne its large, white, crêpe-like blossoms with their central boss of golden stamens and their delicious fragrance. *Rudbeckia purpurea* and *R. Newmani* are in bloom, and *Scabiosa caucasica*, *S. lutea* and *S. elata* are flowering, as are *Scutellaria alpina*, *Sedum album*, *Senecio pulcher* and *Sidalcea Listeri*. In the rock garden *Silene alpestris* is a mass of minute white stars, while in a sheltered border *Sparaxis pulcherrima* holds its drooping bells poised on slender arching shoots 6 feet in length. Of the Meadow-sweets, *Spirea Aruncus*, *S. palmata*, *S. venusta*, *S. filipendula* and *Astilbe japonica* have been in flower. *Statice latifolia* has commenced to bloom, and the *Tigridias* in various colours have expanded their glorious Orchid-like blossoms. *Telekia speciosa* in the wild garden is bearing its yellow flowers, *Thalictrum aquilegifolium* was in full beauty at the commencement of the month, and *Tradescantia virginica*, both in its purple and white varieties, is still in bloom, as are the Globe Flowers (*Trollius*). *Tunica Saxifraga* is blooming in the rock garden, and *Verbascum phoeniceum*, *Veronica Lyalli* and many of the *Yuccas* are in flower, while of annuals the beautiful Sweet Peas in all their delicately tinted new varieties, the *Salpiglossis* with its wondrous shot-silk hues, and scarlet *Zinnias*, that already make a breadth of bright colour in the border, and the deep blue *Phacelia campanularis* are amongst the most attractive. S. W. F.

Two new Richardias.—*Richardia Nelsoni* is a vigorous plant 30 inches to over 3 feet high, the erect scape rising a good deal beyond the leaves. These are arrow-shaped and a deep green, marked on the surface with pellucid stains, as in *R. Elliottiana*. In colour it is pale yellow, with a broad purple stain at the base. This species, which seems to be vigorous and free flowering, nearly resembles *R. albo-maculata*, figured in the *Botanical Magazine*, t. 5140 (1859). *Richardia Adami*, distributed by M. Max Leichtlin in 1898, is a strong-growing form, with arrow-shaped leaves of a handsome, brilliant green. The spathe, which is shorter and more open than in the foregoing species, is white, and is likewise marked with a broad purple stain at the base. The species

is quite distinct, nor can I connect it with any other. It appears to be really new. Less decorative than *R. Nelsoni*, it is yet interesting for its vigour and the colour of its blooms.—M. MICHELI, in *Revue Horticole*.

Euphorbia splendens.—As a rule in most private gardens there is a plant of this old stove flowering shrub, but usually of a poor variety. There is a great difference in the flowers of these and the better larger forms, and although when badly cultivated and starved the latter almost sink to the level of the former, they are quite distinct. The growth of the variety *grandiflora* is stouter with paler bark than that of the old kind, while the blossoms occur on larger corymbs and are brighter. It is in bloom nearly all the year round, and if a specimen can be planted in an out-of-the-way corner of a stove or warm greenhouse, there is usually a flower for a button-hole when other blooms are scarce.

FERNS.

FERNS ON CORK.

VIRGIN CORK may be used in various ways. It is the best material for growing all the Stag's-horn Ferns on. Pockets may be formed which hold some soil and Moss, and when the young plants are fixed on these they do better than when grown on wood or tree stumps, where they do not get so much soil to root into. Although under favourable conditions these will subsist entirely on atmospheric moisture and the decaying basal or shell-like fronds among which the roots spread freely, by providing a little suitable compost for the roots to penetrate into it is much easier to keep them in a healthy, vigorous state. Many other Ferns may also be grown in these cork pockets. *Asplenium caudatum* and *A. longissimum* do well, and when hung against a moist wall their long drooping fronds are seen to the best advantage. The pockets should be made as large as possible for these, and any openings may be stopped with Sphagnum Moss. I find if treated well the above do better than when grown in suspended pots. *Adiantum Edgworthi* (*ciliatum*), *A. caudatum*, *A. dolabriforme*, and *A. lunulatum*, also any of the *Capillus-veneris* section, do well. Most of the *Davallias* are particularly adapted for the purpose, also the *Nephrolepis*, and many others might be enumerated. Where shady walls have to be covered, a suitable selection well arranged is most effective. In making the pockets, broad, flat pieces should be selected to form the backs, and the cup or pocket may be formed with pieces that curl round more. In using up a bale of cork, pockets of various sizes will have to be made, and these can be used for the various Ferns according to their habits of growth, but even if small plants of the large-growing sorts are used, large pockets should be given, as there is not much danger of over-watering, and it is not so convenient to transfer them to larger sizes as it is to repot from one size to the other. A similar compost may be used as is given for the various sorts when grown in pots. I like to use Sphagnum Moss for all. In joining the cork there are sure to be some spaces which require stopping, and by using Sphagnum a certain amount of moisture can be kept up without risk of the soil getting sour. In filling the pockets, care should be taken that the soil is well worked into all the narrow crevices.

If well managed, many Ferns will do much better in these pockets than when grown in pots, besides which they can be given positions where they are seen to the best advantage. Cork may also be used for forming stems, using wood for a foundation. The stems may be

made of any size, and being hollow in the centre more soil can be used than when tree stumps are employed. For the larger stems a flat board 4 to 6 inches wide may be used. A fillet should be firmly nailed on either side. The width will depend upon the height the stem is to be made. It should be broad at the base and fixed firmly to a broad flat board. In covering the woodwork the cork can be selected so as to form pockets at various distances, and the cork can be nailed firmly to the wood, or wire may be used to fix the cork where the nails will not reach the wood. Stems that are intended to be moved about should be made more than 5 feet high, and these should be at least 18 inches square at the base. To avoid making them too heavy the larger spaces may be partly filled up with any rough light material. The coarse siftings from peat will answer the purpose well,

for a few days. It requires care in watering to start with, as some of the balls may dry while the surface appears moist, but after the roots have well penetrated there will be little difficulty, and in most instances Ferns treated in this way will give less trouble than when grown in pots.

GARDEN FLORA.

PLATE 1235.

CHIMONANTHUS FRAGRANS.

(WITH A COLOURED PLATE OF *C. FRAGRANS* VAR. *GRANDIFLORUS*.)

THERE are two virtues in particular that belong to this plant and its varieties; these are the date at which it flowers, and the exceptional

Flowers of *Azalea Vaseyi*. (See p. 119.)

but they must be pressed in firmly and care taken that all the spaces are filled to prevent the soil falling away from the roots. Smaller stems may be made by using a single piece of wood to fix the cork on, or tree stems covered with cork may be recommended. I have seen the smaller stems fixed in pots, but I prefer a wooden base for all sizes, as there is no danger of breakage. It must be understood that they all require firmly fixing, for the weight is considerable when filled and watered. If there are a few cracks or crevices open they should be filled with moss, and if this does not grow, the roots of the Ferns will penetrate and hold the soil together after they are well established.

For the large stems various Ferns may be used, and small plants of *Ficus repens* help to make a nice groundwork. In filling the stems it may be necessary to disturb the roots of the Ferns, but they will soon recover if kept close

charm of the perfume of its blossoms. The first flowers are open as a rule in December, often even in November, and they continue to appear till February or, it may be, March. In the strictest sense of the word the flowers are not showy; still, they are very pretty, especially for the season at which they appear, and, what is perhaps more pleasing, they diffuse around them one of the most delightful of flower perfumes.

The species, the finest variety of which is now figured, is a native of China, and was introduced to Europe in 1766. It is sometimes called the Japanese Allspice, but although it has, like so many of the finest Chinese plants, been long cultivated in Japan, it is believed not to be a true native of that country. It belongs

* Drawn for THE GARDEN by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by J. L. Goffart.

to the same family as the Carolina Allspice (*Calycanthus floridus*), but its leaves and bark have not the same aromatic fragrance. The *Chimonanthus* is represented in gardens by three forms: there is the one now figured, which has the largest flowers and is known as *grandiflorus*; there is the typical plant, whose flowers although smaller are more fragrant and have the base of the petals more distinctly marked with purplish-brown; and, finally, there is a third and rarer form known as *luteus*, which is, I believe, at Glasnevin and whose flowers are more purely yellow than any. As a rule the shrub is quite leafless at flowering time, but the leaves are lance-shaped, 3 inches to 5 inches long, drawn out to a long fine point, of a very lustrous dark green, and curiously rough to the touch on the upper surface. Near London it is perfectly hardy as a bush in the open, but I have never seen it so charming as when grown on a wall. In the freedom of its flowering there is no comparison. When grown on a wall the shoots should be pruned well back, any weak shoots removed, and whatever re-nailing may be necessary done towards the end of February. The new growths ought then to be allowed full freedom, and no further pruning or tying done till February again. The object should be to obtain strong shoots of good length and not so crowded as to prevent their thorough ripening. Such branches when in bloom are very charming for cutting and associating with sprays of some evergreen like the common *Malonia*. This plant is one of the most difficult shrubs to propagate by cuttings. I have heard a story that Dr. Lindley when connected with the Horticultural Society's garden at Chiswick made a standing offer of a guinea for a rooted cutting, which he never had to pay. Still, cuttings have been rooted. It can be increased by layers or by seed (which it not infrequently produces in this country). For the named varieties layering will be necessary to get them absolutely true.

It is to the old walls of long-established gardens that this shrub seems more particularly to belong. Claremont, Glasnevin, Belvoir, all have noteworthy specimens. Newer establishments, I fear, often ignore it. One reason for which, perhaps, is that there are more claimants for wall space now-a-days than there were sixty or eighty years ago. Yet there is nothing more delightful than to meet with this and similar old things that have grown where they now stand almost since the days when first they reached this country. There is an additional pleasure to be got from trees and plants beyond the gratification their size, beauty, or fragrance give, which comes from a knowledge of their history and the associations that cluster round them. The name that one associates most with the present plant is that of Engelbert Kämpfer. He was one of the first naturalists who travelled to the far East. Japan he visited 200 years ago, and he was one of the first to make known the floral treasures of that country to European eyes. He was the first to figure and describe this shrub in his "*Amœnitatum Exoticarum*," p. 878.

CHIMONANTHUS NITENS.—Till within quite a recent date the genus *Chimonanthus* was supposed to be monotypic. Within the last few years, however, a second quite distinct species has been discovered in Ichang, China, by Dr. A. Henry. Professor Oliver named it *C. nitens*, and it is described as a shrub 5 feet to 6 feet high, with white flowers three-quarters of an inch across. The foliage appears to be similar to that of our cultivated species. This new species is not yet in cultivation, but it is interesting as an indication of the wealth of new plants which

await discovery and introduction in the central and western parts of China. W. J. BEAN.

THE WEEK'S WORK.

HARDY FRUITS.

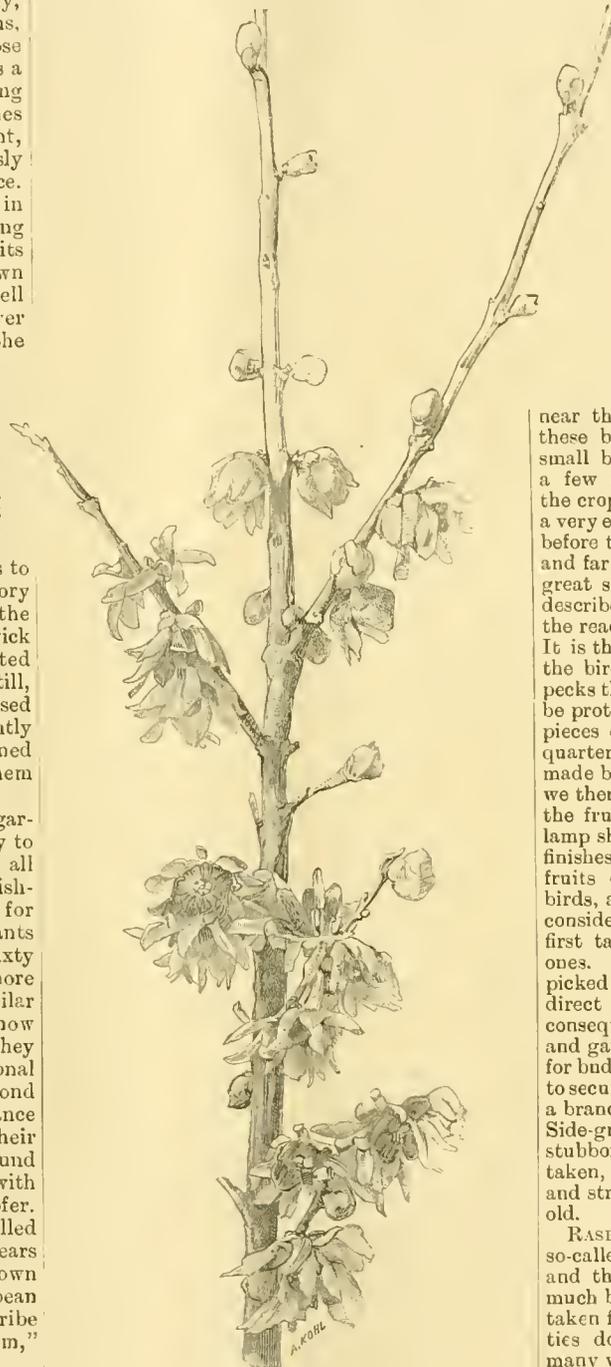

APRICOTS.—It should not be forgotten that the Apricot is a moisture-loving tree, and attention

from the soil, without any further assistance than that given by the natural fall of water, which is generally inadequate to the requirements of trees, especially those grown on walls. Occasional soakings of the soil, accompanied by frequent drenchings of the foliage, are quite the best things that can be given to ensure healthy and fruitful trees, and many people who have to bewail the fact of non-success in Apricot culture would be agreeably surprised with the result of giving more generous treatment in the way of affording moisture in dry seasons.

PEARS.—To Pear trees on the Quince stock the notes above dealing with Apricots will apply with equal force, for the Quince is equally a lover of moisture and cannot exist without it. It cannot be doubted that the fruits of Pears on the Quince are, except in rare instances and with some special varieties, much finer than those grown on the free stock, but they must be well supplied with water to attain both size and quality, and those who are not prepared to go to the trouble of giving it in plenty had better leave the Quince as a stock severely alone, except in soils that are naturally moisture holding. In many gardens the titmice do great

damage to Pears by pecking holes near the stalk of the fruit, a very trying habit these birds have, for they consume such a very small bit of each fruit and visit so many, that a few of them are sufficient to spoil most of the crop. To circumvent these and other enemies, a very elaborate protection has lately been brought before the public, but there is an equally efficient and far less costly method which I have used with great success, and which I will here attempt to describe, as its simplicity brings it well within the reach of all who care to preserve their fruits. It is the base of the fruit only which is attacked, the bird clasp the stem with one foot while it pecks the holes; consequently only this part need be protected. This is done by cutting out circular pieces of tough brown paper, folding these into quarters, then cutting off a small bit of the corner made by folding, and slitting up one of the folds; we then have a protection which can be placed on the fruit and drawn into shape something like a lamp shade. A pin thrust into each of these caps finishes the work, and with these on the best fruits one need not fear the attentions of the birds, and the danger of attacks from wasps is considerably lessened, as these latter get their first taste of the fruit by finding out the pecked ones. Some of the earliest Pears require to be picked just at the right moment and eaten almost direct from the tree to have them at their best, consequently they require to be well looked after and gathered as they ripen. This is a good time for budding Pears, and budding is the best method to secure growths on any portion of the stem where a branch is needed to keep the balance of the tree. Side-grafted pieces of wood frequently become stubborn and fail to furnish, but once a bud has taken, one can be pretty sure of getting a healthy and strong growth, provided the stock is not too old.

RASPBERRIES.—Personally I like to confine the so-called double-bearing Raspberries to one crop, and that the autumn one, as I think we get a much better crop than we do if one has been taken from last year's canes, so I cut these varieties down to the ground in spring. There are many who still allow the two crops to form, and in cases of this sort no time should be lost in removing all last year's canes which have now done fruiting and securing the young canes to the wires or whatever support is provided for them; they should also be well fed with liquid manure on every possible opportunity, as Raspberries enjoy and well repay for good feeding. There is a great difference in opinion as to the wisdom of removing the old canes from the ordinary summer-bearing Raspberries directly the fruiting period is over, but I incline to the opinion that no harm is done by leaving them for a few weeks longer, and that

Chimonanthus fragrans.

to this fact after the crop is gathered is important in plumping up the fruit-buds for the ensuing season, the result being fine blossoms, which are more capable of resisting the weather influences than are those of a more flimsy nature. Too often no account is taken of the trees after they have yielded their crop, and they are allowed to languish for the remainder of the summer, at a time when most of the moisture has been drawn

they form some sort of protection for the young and tender canes. The best ways of dealing with them would be either to leave them or only to remove a few at a time, so that the exposure may be gradual. If the plot has been netted over, the net should be taken off before the points of the young canes push their heads through it. It is no uncommon thing to see quite a struggle between the nets and the shoots at the end of the season through neglect in taking off the nets as soon as the crop is over, and the canes are frequently injured by the defoliation of their tips which then takes place.

BLACKBERRIES.—These promise to perfect an enormous crop here, and will be much appreciated if they come up well; consequently they are being well fed during the drought; and one of the results of this feeding is to produce new canes of enormous length, and which it will be necessary to secure from injury by fastening them back to the wood fence on which they are growing. There is no doubt that these Blackberries are a very paying crop where they do well, but my experience is that they only do so on a soil that is inclined to be heavy. On a light soil I had great difficulty in keeping them alive.

WOODLICE.—In my recent notes on pests to fruits I did not allude to the woodlice, but these often do much mischief among Nectarines and Peaches in some gardens, and should be trapped persistently by using small pots loosely filled with dry moss covering a piece of freshly-cut Potato, and placed among the branches and on the ground at the foot of the wall. These pots should be examined every morning and cleared of the insects. If there are any earwigs about, these pot traps answer the double purpose of catching these as well as the woodlice. CORNUBIAN.

KITCHEN GARDEN.

GENERAL WORK.—Although the general absence of rain will have prevented the growth of weeds, the Dutch hoe must be used frequently between growing crops, this moving of the surface being very beneficial during tropical weather, especially where the soil is liable to get into a caked condition; it also preserves the moisture. Now is the time to give Broccoli and the various sorts of Kales that have become established liberal supplies of liquid manure, the same remarks applying to Peas, dwarf and runner Beans, Vegetable Marrows and Celery. In exposed gardens it is always a good plan to earth up such things as Brussels Sprouts, Broccoli and general winter stuff, as this not only steadies the plants and renders them proof against high autumn winds, but the ridge of soil acts as a mulch and keeps the roots in a moist, growing condition. Acting on the maxim of better late than never, mulching moisture-loving crops, such as late Peas, Beans, ridge Cucumbers and Marrows, should, if not already done, at once be performed. One good soaking over a good mulch will be of greater benefit to such subjects than two or three administered on the bare ground. Mulching is always regarded as so much wasted time in the vegetable garden, whereas in reality it is a great economiser and saves no end of worry. Only those who have been accustomed to cater for a large kitchen know the value of early mulching, copiously watering and closely picking such exhausting crops as those above named. By mulching alone on hot soils can they be induced to bear till frost cuts them down and other early winter crops take their place. Nothing pays better for liquid manure and plenty of it than Globe Artichokes. The best way is to form a kind of basin around each stool by means of short manure, so that the roots get the benefit of every drop of water which leaves the cans. Remove all seed-heads, as they have an exhausting effect on the plants. In midland and northerly gardens from the 10th to the middle of the present month is a good time to make the first sowing of Turnips intended for winter use. Were I confined to one kind only, I would choose the old favourite Chirk Castle Black Stone as being the most hardy and

best doer generally. Orange Jelly is also good for autumn use where a yellow flesh is not objected to. If former advice was carried out and advantage taken of the clearance of summer crops to prepare the ground, it ought now to be in good condition for receiving the seed. The broadcast method of sowing is the best, distributing it not too thickly, a surface sowing of guano or some other approved fertiliser being given as soon as the crop is fit for thinning. I recommend a second sowing to be made about the first week in September, as when once established, Chirk Castle will even during frosty weather increase slowly in size and prove most useful in spring. Where the soil is light and strong, it is a good plan to run the garden roller over the surface after sowing. Keep a sharp watch as soon as the plants appear, as should September turn out hot and dry, fly will sometimes put in an appearance even at this advanced date. Dusting the plants over with lime and soot or wood ashes will check the pest and also assist the crop to make a free growth. The most open position need not necessarily be selected for this crop, as Turnips will succeed even in the partial shade of trees.

MAIN-CROP COLEWORTS.—If the date recommended in a previous calendar, namely, July 7, was adhered to for sowing the principal lot of hardy Rosette Coleworts, they should where rain has fallen now be in a fit state for transferring to their permanent positions. I consider this crop well worth any extra care to ensure for the plants a good start, as nothing, so far as my experience goes, stands a trying winter so well. Besides, after a few brisk frosts in November their tenderness and good quality are equalled by those of few other winter greens. Being small they may be planted from a foot to 15 inches apart all ways, and there is very little waste in preparing them for cooking. As, however, no time has as yet been lost, if the ground intended for their reception is insufficiently moist a week or so more may elapse before planting takes place, always, of course, provided the young plants are not crowding each other or are overgrown. As previously stated, I have always made it a rule to plant vacant plots from which Strawberry plants have been cleared off. I find that in the solid root-run the plants if lifted from the seed-bed carefully and put in with a trowel speedily become established, and evaporation is less speedy than in ground recently turned up with the spade. After watering home, it is a good plan to draw a little fine soil round the plants with the hoe. This encloses the moisture and prevents a caked or cracked condition. Any early batches just commencing to grow must be occasionally treated to supplies of liquid manure, nothing responding so quickly to this stimulant as Coleworts.

SOWING TRIPOLI ONIONS.—As a rule, from the 15th to the 20th of this month is a good date to get in seed of the various sorts of Tripoli Onions, and if the site was prepared a few weeks ago so much the better, as a firm root-run is one of the surest guarantees of a satisfactory growth both in autumn and spring-sown beds. Beware of thick sowing, as the removal of so many young plants loosens those which are to remain; consequently they get blown about by autumn winds and crippled by frost at the base. After the seed is sown sprinkle a liberal supply of burnt refuse or wood ashes in the drills previous to filling in, after which tread and re-tread, and on light soils use the garden roller. Those who require bulbs early next season should sow the small but useful old White Queen, which does its work in a much less time than other sorts, and is very mild and agreeable in flavour. There are also several varieties of the ordinary Spanish type well suited for autumn sowing, often surviving a sharp winter even better than the Tripolis, Trebons and Cranston's Excelsior being amongst the best. Those who are likely to require small Onions in autumn for the salad bowl had better sow a row rather thickly for the purpose.

SPRING-SOWN ONIONS.—The last cleaning by means of hand-weeding should now be given to spring-sown beds, also one more broadcast

sprinkling of artificial manure. This will carry the crop on to maturity. If any of the bulbs have thick necks, go over the bed with a wooden rake and bend down the tops to check the flow of sap and assist in swelling out the bulbs. These, after storing, must be used first, as they never keep so well as bulbs with thinner necks. On wet days the Onion and root rooms generally should be thoroughly cleared out and made ready for the present season's produce. Onions always keep best where a free current of air can pass through the bulbs; anything approaching a heated condition is ruinous. J. C.

AN ADDITIONAL PAGE FOR "OUR GARDENS." *

THERE is one aspect of a garden which is not always dwelt upon, but which seems to me as important as any other, or I might even go so far as to say it is the most important of all—in point of interest it cannot be exceeded. I refer to its fitness for becoming a receptacle for the mementoes of absent friends, or the reminders of bygone days, or the vivid remembrancer of places that are far away. All this must be intelligible enough when once it has occurred to the mind, but the pleasure that comes from it—the bright, sparkling satisfaction—cannot be estimated aright until it is fully known. My garden is to me like an open book, full of pages which are dedicated to friends who are with us still, or who have in some instances passed away, or it brings before me scenes in my life which nothing else can freshen up in at all the same degree, and makes them live again in a way which nothing else can do; and the reason for all this is very plain—it comes from those laws of association† in the mind on which we act, it may be insensibly, but still inevitably every day of our lives. If I may prose for a minute or two I would say that there is such a thing as a law of succession in the mind, and also a law of co-existence, which move us powerfully. If we have been in the way of seeing two things together, the mere presentation of one will suggest the other; or if one thing has followed another, then the occurrence of the first will be sure almost to bring before us the existence of the second as by a sudden flash. I need not dwell on this, but it certainly is the groundwork of all which I have to say on this head about the garden I love, and plants and flowers in a very remarkable degree lend themselves to the sort of suggestion I am now speaking of. Anything about which you have to take trouble always has a voice for you which nothing else possesses; and because flowers come and go—and they are with us at one season and we lose them at another—they speak to us when they reappear with a

* Soon after this paper had been completed I came across the following interesting passage in "Our Gardens," by Dean Hole, p. 285; it exactly expresses what I have endeavoured to say at greater length. It runs thus: "Some arrange in a quiet nook their memorial garden in which they are happily reminded of their friends who have planted or sent to them shrubs or flowers, and also of the places, some of them far away, from which they have brought the same souvenirs—the sweetest and prettiest of all. Such associations of our friendships and admirations of those we have loved the best, and of the scenes which have charmed us the most, with a life of beauty which endures for ever, keep the memory of our attachments ever green and our faith in the future always strong. There is a touching and a teaching pathos in a record by Alphonse Karr: 'I had in a solitary corner of my garden three Hyacinths which my father had planted. He died before they came into bloom, but now every year the period of their flowering is to me a solemnity, a funeral and religious festival.'"

† See Dr. McCosh's treatise on "The Association of Ideas," page 6.

distinctness which they certainly would not have if they were with us at every season of the year. Let anyone busy himself about the cultivation of some particular flower, and take pains about it, and give his mind to it, and use all the means he can think of for ensuring its success, and then it is quite certain when that flower comes into blossom and is seen just once in the year in all its pride and beauty, that slumbering associations will be instantly waked up, and absent people and things will live again for us for a little space, as they could not possibly do if no reminder were given to us. I love beyond everything to walk about carelessly in my garden, and very often in some secluded nook, or in some well-dressed border, or in some little compartment of the rockery to light upon a gem which is valuable not merely on its own account, but because of the voice it has about people and places which live for me and ever will live deeply engraven on the tablets of my mind.

But some concrete instances will bring all this out in a way which no theorising can effect. Let me speak of a few places and then of some persons out of many which are suggested to me from time to time by the treasures of which my garden is full. A long time ago—five and twenty years it may be, or even more—I was able to carry out the dream of my youth and to visit Palestine in the spring. The month of April is the season of all seasons for a visit to the Holy Land, and I saw nearly all the spots of most sacred interest and which are usually visited. All the way through I had one great desire in my mind, which was to procure the seed of some interesting plant or plants and to bring it away with me, but I was there so early in the year the time of harvest was not yet, and I had almost given up my quest as unavailing when one day as I sat beside Jacob's well, and must have been at the very spot which the Saviour of the world had visited, I espied an Anemone seeding in a most unmistakable manner and just giving to me the opportunity for which I was looking. It was the only one which I met with in Palestine from first to last, and it was speedily and avariciously embraced. The seed soon found its way into a small receptacle which was kept in my waistcoat pocket, and was treasured up and brought safely home to be used in due time. There is, luckily, not the smallest difficulty in growing Anemones from seed, and this did so well that I soon had quite a large crop of *Anemone coronaria* and fine specimens on hand. Some of these were given away and some were kept here, but for a long term of years, when *Anemone coronaria* came regularly into blossoming, I could fancy myself, and I did fancy myself, once more in the vicinity of Jacob's well, and that memorable scene—one of the only two or three which can be identified with absolute certainty in the land—lived again before me with a clearness which nothing can obliterate, and which lasts while life lasts with me. It is, of course, true that the first succession of Anemones were itself out and then passed away, and in altering the beds my gardener was not quite so particular about the matter as I should have liked him to be, but the lineal descendants of the one plant in Palestine which I saw in seed are, I believe, with me still, and the Saviour's blood-drops, as they are so expressively called, suggest to me very much more than a mere patch of red, and they quicken thoughts which only a journey to Palestine can give, and which are best kept alive by some reminder of it. Or, to take another instance, though not from the Holy Land. The greatest shave which I ever had in my life was in visiting the temples at Poestum

—those magnificent Doric temples which once seen can never be forgotten. They stand alone on the solitary beach without a vestige nigh of any power that could have reared them, and they look almost supernatural in their splendid magnificence. Their grandeur, their gloom, their size, their isolation make an effect upon the mind surpassing anything I have seen before or since. It is not now either difficult or dangerous to visit these temples. The railway takes you within five minutes of the spot where they are situated, and there are signs of human habitation not far off, which proclaim safety at once. But it was a very different thing some thirty or thirty-five years ago. There was then not a more blood-stained spot than Poestum through the length and breadth of Italy. It was the favourite haunt of banditti, and dark deeds were done there which are remembered to this day. It was my fortune to go there on one occasion when things were at their worst, and so little did I realise that there was any special danger at Poestum, that I spent a great part of a day there wandering about inspecting the temples and looking for flowers without any misgiving of any kind. But that very day the brigands were at work in the place; one of their most notable captures was made, and the unfortunate victim was raced about over the mountains of Italy for three long months, and, finally, he had to pay an enormous sum for his ransom. Why I got off so easily I could never exactly tell, but I must either have been unnoticed or else held to be too small game for their attentions, and so they left me alone. But the mere mention of the word Poestum brings not Roses but Asphodels to my mind. I never came across a single Rose in Poestum, but Asphodels and Cyclamens abound there on every hand. When I paid a second visit to the temples the other day I came across them by hundreds, and Asphodelus ramosus is to me a kind of memorial of my escape beyond everything else. It has grown well and easily in my garden for many years last past, and I sent home some the other day which travelled safely by post and are flourishing here. I have come across the plant on the hills around Baalbec, but it has more to do with Poestum in my mind than any other place, and its pretty white blossoms with a reddish white line in the middle of each segment, which spring from the axils of large bracts in very long racemes, spell the word "preservation" for me in a way which nothing else can do. The ground all around the Temple of Neptune is simply carpeted with Asphodels and Cyclamens, and they grow there without any interruption from generation to generation. But as long as I live so long will Asphodelus ramosus be a plant of the greatest interest in my eyes. It would not be difficult to dilate on the beauty and luxuriance of Banksian Roses during the month of May, but they are nothing here when compared with the freedom and the delightful abandon with which they grow all over Athens, and Athens is as though its chiefest glory, the Parthenon, were brought full into sight. Banksian Roses are always connected in my mind with the place where I have seen them at their best. They seem to quicken a remembrance which else might die out of itself, but which is freshened up and revived, so to say, by a yearly reminder. Let me notice only one plant more which has a very great attraction for me. This is

CAPPARIS SPINOSA,

which is not a child of civilisation at all. It eschews the haunts of men, but in the south of Europe and some parts of Asia Minor, and,

it may be, in other places wheresoever desolation has set its seal and everything seems given over to aridity and death, there it is wont to luxuriate and grow, and it flings itself over broken arches and streams along the empty colonnades, and grows out of the dry wall as if it positively chose out some woebegone spot rather than were in the habit of seeking for any fertility at all. I consider it to be one of the most beautiful of flowers. The large white cup with the long purple stamens and long-stalked ovary has a kind of plaintiveness about it, and it is in the very strictest harmony with the surroundings which it loves to adopt. I have generally had this plant in my garden during the last twelve or fifteen years and I have it still, and now and then it has blossomed, and there are few things on which I set greater store than I do upon it. For does it not tell of places and of buildings whose interest cannot be surpassed? It loves, for instance, the Palace of the Cæsars in Rome; it grew luxuriantly in the old Colosseum; and beyond everything else I have seen it quite lately adorning what is left of Tiberius' Villa in Capri, and starting out from some solid Roman masonry which is as hard as the rock itself. How any plant could live at all and look so happy in such an unpromising situation seemed to me to be one of the greatest of mysteries, but there it was apparently feeding upon nothing, and in some strange and very inexplicable way deriving what nutriment it required from the solid Roman cement in which it was fixed as firmly as if it were held in a vice, or had become by some mysterious agency an integral part of the time-worn ruins themselves. It would be an utter impossibility to tear that plant bodily out of the location it had found for itself, and it only can have got there by some chance seed which was dropped by a bird or wafted by the winds. It had then managed to anchor itself in this way. But when I have come across it in my garden, as I very frequently have done, and can do now, *Capparis spinosa* seems to me to be a protest against many of the ways and wishes of Ryde, or of any other watering-place under the sun. It tells of the mutability of all human affairs, and speaks of deterioration and loss, and is a corrective of the vanity which so often abounds, as if we had to live here for ever. Ephesus, Babylon, Rome, these are the sort of reminders it has for us, and which should not be forgotten. But I have no intention to sermonise just now. Let me only point out how plants very often carry deeper meanings with them than may seem to some persons. I never can look on *Capparis spinosa* without being carried out far and away beyond this place, and taken in thought to scenes which are not in the least represented here.

But now let me turn in an exactly opposite direction. There are very many plants in my garden which only have voices that are full of happiness and delight—indeed, only gladness can be associated with them; for if there is one thing more than another that is exhilarating and fitted to lift one up, is not a mountain excursion in Switzerland an occurrence of just that description, and does it not take one away from all the anxieties and troubles to which we are liable? The blue vault of heaven above, the exhilarating air, the hum of innumerable insects on the wing, the bustle of getting ready, the upward climb along the mountain's side, the companionship of friends, all conspire together to make an effort of this sort as unlike anything that we have here in the towns as can by any possibility be conceived, and it always seems to me that if we

want to live this over again for however brief a space, there is no better way of doing it than that of letting those flowers speak to us which remind us of this sort of thing. It may be but a whiff that we get of our old Swiss experiences, but a whiff is better than nothing, and Switzerland seems in a way to be brought to our very doors when its well-known denizens greet us. *Gentiana verna* is not doing so well with me now as it has done in former days, but whenever I have it here it has an unmistakable message with it from Chamounix or some such place. What myriads of it have I not seen in the Breven or the Flegère! It carries me to the Jardin at once, and I remember the climb I once had to that sort of island in ice, which in August is enamelled over with flowers; or when *Dryas octopetala* fills, as it does now, several pockets in my rockery, and its pleasant creamy-white yellow-stamened blooms are attractive in the highest degree, is it possible to forget the frequent walks one has had across some long moraine where it flourished exceedingly? The leaves are here, as in its own home, shining above and white and downy beneath, and the fruit has a sort of feathery appendage about an inch long. Or take *Anthericum liliastrum majus*, which is such a recommendable plant, how it speaks to you of the grateful warmth and freshness of many a Swiss valley which you have traversed in setting out for an expedition and before any ascent is made. You can see it standing about level with the tips of the blades of grass and mixed up along with them—look at *Anemone alpina*, or *A. sulphurea*, which is really the same thing only in a different colour; it does not differ here so much as it does in its own habitat in point of size and vigour. There, as Mr. Robinson says in "Alpine Flowers," you will find it near some alpine range, a few inches high and humbly holding up its velvety cups; but in descending through the rich green meadows to reach the roofs of men you will brush against many of the stems nearly as tall as the knee, each bearing a soft round head of silken bearded seeds. It grows in a border in this garden with the greatest facility and assumes a magnitude which I have scarcely ever seen to belong to it in any other place. But *Anemone sulphurea* carries me straight away to Pontresina and to excursions about it, or, even more emphatically than this, to the Pic de Nancy, in the Auvergne district in France, where I am sure I have seen millions all nodding together on the mountain slopes and giving a grace and beauty to the whole picture which I cannot attempt to describe. I somehow believe that the French examples of *Anemone sulphurea* were more striking than any even in Switzerland itself, and I believe this has been noticed by others. To mention the mere names of *Aquilegia alpina*, *Hedysarum obscurum*, *Campanula barbata*, *Aster alpinus*, *Astragalus hypoglottis* and many other things of the same sort is to speak of the mountains at once; they all can be grown in an English garden without any trouble at all, and they gladden me here whensoever I see them doing well as though they were old friends come on purpose to visit me and to bring pleasure into my life.

I have said that flowers serve to bring mementoes of absent friends as much as of places to those who look for them, and I am quite sure that it is so in a very remarkable degree. We want nothing to keep warm in our minds the names of friends who are with us here, or of those whom we have lost and who have passed away, but still there is a kind of touch of themselves, the reminders in the latter case of a voice that is still which can be despised

by no one and is sure to be cherished exceedingly. Of all my horticultural friends—by which I mean friends who would not have become such but for a fellowship in the culture of flowers—I place first and foremost among those who are gone the late Harpur Crewe, whose name used to appear so often in THE GARDEN twenty years ago. I knew him very well indeed, and to this day I miss him in my garden in all sorts of ways. He was ready to answer any question that might be put to him, and so well able to do it. He so markedly loved flowers for their own sakes, and so lived amongst them, that nothing has made up for the void which his death caused for me, and causes still. That he loved flowers for their own sakes and nothing else at all may perhaps become apparent to others if I just mention two curious things which I often noticed about him. One is that his encomiums were as often given to some small and perhaps very humble thing as to a more striking object which would take other people instead of it. I have seen this noticed by his friends, and when he used to praise a thing very much indeed in his letters I insensibly discounted his praise, for he loved and praised every flower that grows. The other point about him was more curious still. Not only was he well acquainted with the natural habitats of a very large number of plants, but from going about a good deal and from a quick eye to business he had registered up in his mind where any scarce or good plant could be found in the country and who was in possession of it. I had a strange illustration of this in the following way. Years ago there was a quest in the pages of THE GARDEN for *Fuchsia lycioides*, which was an unknown plant to most persons and could not be heard of at all. It did not occur to me that I was in possession of it myself. I do not know where it came from or how it got into my hands, but Harpur Crewe wrote at once to the editor of THE GARDEN to say he had come across it in my greenhouse, and there it certainly was and there it is now. The plant is not of much account in itself and it is certainly not handsome, but *Fuchsia lycioides* will always have a place on my shelves because of the occurrence I speak of.

Another plant also gives me a strange sort of reminder of my old friend. A very long time ago I had a consignment of things from America, and Mr. Falconer, of Harvard University, sent me several good plants, which I have to this day. Among them was *Iris Hartwegi*, which came into my possession in April and grew and did well. It multiplied very much in the course of the summer and blossomed accordingly. I sent a blossom to Harpur Crewe, and he was immensely delighted with it because he had never seen it before, and begged me to give him a growing bit of the plant. I took it up in autumn and cut the plant into three or four pieces, and gave one piece to him, replanting the rest of it and taking it to be a mere matter of course that all would do well. But, instead of that, both the plant which Harpur Crewe had and those which I kept here very soon died, and for more than twenty years I am sure last past I have never done well with *Iris Hartwegi* again. I either got hold of the wrong thing or, when the right one was given to me, it was given to me at the wrong season of the year. I never knew till quite lately, when I was so informed by Herr Max Leichtlin at Baden-Baden, that *Iris Hartwegi* refuses to be established at any other time of the year besides the spring, and that it prefers April to any other month for a move. Now at last, after this long lapse of time, I have it in my

garden again because it came to me in April of last year. It has just now blossomed profusely, but "touch me not" is written all over it, and I would not meddle with it for any consideration whatever. But these two plants—*Fuchsia lycioides* and *Iris Hartwegi*—are speaking reminders to me of the late Harpur Crewe, because of the very great interest he took in them, and so is also an insignificant little thing, viz., *Ficaria ranunculoides alba*, and that because of the inordinate praise with which it was sent to me. It comes out in this garden anyhow in the spring if allowed to live on because of the commendation which was once lavished upon it. But his knowledge of plants and bulbs was, I should think, unique in itself, and few could compete with it. The postman used to bring him at breakfast-time a pile of letters about flowers as though some regular business were carried on, and he used to correspond with directors of botanic gardens, with nurserymen, and others in very large numbers. I remember on one occasion going to see him at Drayton Beauchamp very late in the month of March. We went out into the garden at once to look at the flowers, but the east wind cut us like a knife, and we simultaneously proposed that we should retire into the house. This was accordingly done, and we talked about flowers to a very late hour, but during the night I heard a sort of pitter-patter constantly going on against my window-pane, and in the morning I found that the whole place was deeply covered with snow, and it was very difficult to get away. Not a sight could be got of any flower at all, and I never was able to pay him a visit again. I stand in need of no mementoes to keep his memory quite fresh in my mind, but I am still glad that *Fuchsia lycioides*, *Ficaria ranunculoides alba*, and *Iris Hartwegi* in a way were so much connected with him and that he took such great interest in all of them.

Another plant I would mention because it brings before me one who was perfectly devoted to his garden and the cultivation of flowers is

VERBASCUM LYCHNITIS.

Between twenty and twenty-five years ago an old gentleman used to migrate from Derbyshire to the Isle of Wight as each winter came round. He generally took a house close to St. John's Church, and we got to know a great deal of each other. The common tie was flowers, and it is wonderful what a strong tie it can become even between two persons who have never till then known anything at all about each other. Mr. H. very soon found out that there were objects of interest in my hands, and very soon he had a *carte blanche* to go through the garden gate as much as he liked and to inspect the place at his leisure. How often have I seen him poring over my beds and examining this plant and examining that with the utmost attentiveness! I remember his seeing *Tulipa Greigi* for the first time and how he was struck with its gorgeous array and the splendid exhibition it makes. He was never tired of looking at my plants, and he stayed here just long enough in the early spring to see a good many. What amazed me as it came from his lips was the oft-repeated lament that he never could find a place in England where he could get good fly fishing and cultivate flowers with success. He was obliged to choose between the two. I should imagine that he had met with a good deal of this world's enjoyment in his life, and certainly he was able to do just what he liked and to live in any place that might fall in with his fancy. But he could not make impossi-

bilities possible and fly-fishing won the day, and flowers had by comparison to go to the wall, for he pitched his tent in Derbyshire, becoming a tenant of the late Duke of Devonshire, and living there to the end of his life; and though he did all that he possibly could do in his garden he was never satisfied with it, nor were a great many of his favourites, notably *Narcissi*, for they could not stand the cold, wet soil at all. He most kindly asked me to visit him near Hassop, and I spent an enjoyable time in his house, being made acquainted by him with many objects of interest and seeing while I was with him a great deal of that very beautiful part of the world. Among other things he took me to visit Haddon Hall, and one could realise there in a measure what mediæval glory must once have been and how captivating the relics of it still are. But this is now my point and that which bears on the paper I have in hand. For the first time in my life I came across *Verbascum Lychnitis*, and I was much struck with it as it grows on tower or wall; it seemed to suit Haddon Hall to perfection and was rampant all over the place. It was easy enough to secure a pinch of seed, and easier still to throw it down on my border, and one had no fear at all about the result, nor doubt as to the crop which would be sure to result on it. As a matter of fact, I have had *Verbascum Lychnitis* well in my garden from that time to this, and if there is any difficulty at all about it, it is the difficulty of keeping it under and of not having too much of a very good thing. But *Verbascum Lychnitis* is entirely owed by me to the kindness of Mr. H. more than twenty years ago, and it is inseparably connected with Haddon Hall in my mind, and seems a part of it. My old friend, not very long after I had been to stay with him, passed away and entered into his rest at a good old age. I was grieved to hear of failing strength and of his imprisonment in his house, and when the end was drawing nigh I was told that his ruling passion was then as strong as ever—the love of flowers was with him still, and he had them all over his bed in profusion to inspect. I know I sent my own contribution, which was the best of the best I could find, and was glad that he was able to notice it. *Verbascum Lychnitis* is valued by me for his sake, and always will be so. Another acquaintance of much the same sort was made in the Isle of Wight, and it began in rather a curious way. The Rev. D. F. had a parish in the north of England, which he was obliged to give up in his declining years, and he came to settle in Sandown. He was, I believe, a good naturalist, and a botanist of some little distinction. He one day took it into his head to write to one of the local papers about gardens in general, and specially about those in the Isle of Wight, and the expression he used was that he did not think there was a single garden which was worth looking at between Sandown and London. He put a black mark over all. It should be said that just at that time he was making war against red *Geraniums* and yellow *Calceolarias*, and the villa gardens on the south side of the island were not such as to give him any pleasure at all. But when I came across such a sweeping condemnation as that which I knew to be undeserved, it was rather difficult to sit down quietly under it, so I wrote to my friend and asked him to come over to Ryde and to see if his words could be mitigated. He accordingly came very soon, and he could hardly have had a better day for a first visit than that which he met with. It was on a beautiful September afternoon that I saw him first, and there were in the air all

that clearness and crispness which belong to the season, but beyond everything else a most dear little favourite of mine was then in full blossom, and *Oxalis lobata* was in its prime in one of my borders which is given up to bulbs. There were many other things of course noted, but this *Oxalis* attracted Mr. D. F. on the moment, and he could not say too much for it. Very soon his sweeping condemnation of all southern gardens was retracted in full, and he found plenty of interest in Ryde, both here and elsewhere, of which he never was tired. I quite agree with him as to the extraordinary beauty of *Oxalis lobata*. It inverts the ordinary process of jewellery, and instead of being an emerald set in gold, it is gold set in emeralds; the fresh green foliage so charmingly surrounds the bright yellow flowers, the whole plant sparkles in the ground. If any flower is ever fit to be called a gem it surely is worthy of it. It is a most dear little thing, one of September's chiefest ornaments, which does very well in sandy loam in Isle of Wight, and which I would not be without on any account. The Rev. D. F. on his first visit of course inspected the *Asters*, the *Sternbergias* and other things of which the place was full at that time of year, but his first choice was his last. I never remember anyone taking a liking to a plant so strongly and so soon. After this I saw him over and over again as long as he lived, and I was always so glad to have a friend near me whom I could consult on any horticultural subject, and from whom there was so much to be learnt, but the time when I think of him most is on some bright September day, and to *Oxalis lobata* I very much indeed owe an acquaintance which came to an end far too soon.

It is always a matter of very great interest to me to have a gardening talk with some old experienced nurseryman who has lived among plants for many years, loved them and cultivated them. I do not by any means intend to say that all nurserymen are on a level in this respect, for they differ exceedingly, and it is easy to tell that £ s. d. is the sole consideration of some of them, while with others it comes in as a sort of necessity, but, incidentally and by the way, I am sure that I have had many friends in that line of life who are as fond and as proud of their plants as I am of my own, and during their long experience they have accumulated treasures of knowledge which they are generally so ready to impart. Of this latter and wide-embracing class let me give three notable instances, all of whom I knew quite well and to whom I looked up. The first that I would mention is old Wheeler, of Warminster. He was always so called, and Wheeler seemed to belong to Warminster; Warminster without him would have been nothing in my eyes. How many visits have I not paid to him, and mostly in the spring when the cold, cutting winds came off the Wiltshire downs and served to shrivel one up. The establishment of Wheeler was like an old curiosity shop which was run upon horticultural lines, and he was himself the greatest curiosity of all—an enthusiast if there has ever been one in this world. I can call to mind now what a pleasure it used to be to me to pay him a visit. There was generally some special plant in blossom exposed for admiration in his little bureau, and outside in his premises there were numbers of old-fashioned and very familiar subjects as well as some that were new. It was in this way that one autumn I came across *Oxalis lobata* and brought it away with me. I had never seen it before till I saw it with him, and I have never been without that most delicious little thing from that day to this. But what I

prized most of everything I have bought from old Wheeler was a delightful and very scarce gem, and which now cannot be got at all for love or money. I refer to *Pulmonaria dahurica*, which I should think very few persons in England have seen and about which they know nothing. Mr. George Paul had it some years ago in his nursery at Broxbourne, but I know he has lost it, and I had it here for some time, but, alas! I have long ceased to be able to say so. It is very difficult to describe a little plant which you have not seen for a long time, but I know it was of the most heavenly blue, and its habit was very neat and, I think, drooping as well. I did not know at first what a priceless treasure had come into my hands, but I took great care of it, and, of course, gave it a pocket on my rockery all to itself and light, rich soil, and I put a glass over its head in winter, the sides being left open. In this way it did quite well for several years, and when others lost it I had it still, thanks, I imagined, to the climate of the Isle of Wight. But my time came in due course for a great disappointment. *Pulmonaria dahurica* dies down in the winter, and it was always a pleasurable excitement to me to watch for it in the spring and to see it come up. This it did for a good many springs in succession, and I seemed to be in possession of quite a large stock of this daintiest of all dainty flowers. But one year, alas! there was no response to my wishes. The little pocket showed no sign of having a tenant at all, the ground was unbroken, and *Pulmonaria dahurica* had passed out of my hands for ever and ever. I mourned over its absence very much indeed, and I attributed its departure to this thing and that. But when spring was over and summer-time had arrived the true cause of the disaster was revealed. Up came one of the most striking of all summer flowers in great strength and self-assertion as well, and *Oenothera marginata* showed, I think, that it had murdered my most precious flower of all and that it had taken its place. One of its strong stolons had run a long way under ground, and then it had most cruelly come up, usurping the premises which were never meant to belong to it. Pure and attractive as *Oenothera marginata* always is, I confess I can never see it without a pang because of this circumstance I have described. You can get the *Oenothera* any day you like for a shilling, but who will bring back *Pulmonaria dahurica* into my hands for pounds upon pounds? It would surprise me now to be told that there is one single specimen of it in the whole country. Where Wheeler got it or how he got it I do not know at all, but the plant is so very delicate and it requires such careful cultivation, that I am not at all surprised that it has been lost. I have written shoals of letters about it to many likely persons both in this country and on the Continent, but it has always been without any success. No one knows anything at all about it now, and I fear its very name is forgotten. Herr Max Leichtlin told me the other day that he did not think it ever would be recovered till a special collector had been sent out on the errand, and this is not likely to come off at all so far as I know. Old Wheeler has long since passed away. To see him was a pleasure; to have a long talk with him was a privilege of no common kind. *Pulmonaria dahurica* and Wheeler of Warminster were always connected together in my mind as long as it lived.

There was another old nurseryman some years ago who should in nowise be forgotten by me. When I first came across Green he was conducting a business at Redhill, and

seemingly doing well in it. I remember his showing me a potful of *Saxifraga valdensis* of which he seemed to be excessively proud, and it was certainly a triumph of most skilful cultivation. *Saxifraga valdensis* is of the crustaceous division of Saxifrages, and very pretty to look at. Its little fleshy grey leaves are arranged in tufted irregularly branching rosettes; their blunt points, crowned with a white tip, are erect and slightly expanding, and the whole forms a very compact and dense mass, from the more prominent of whose rosettes arise the flower-stalks to the height of about 2 inches, clothed with short glandular hairs and crowned with three or four white flowers of great purity. This was the plant that he was carrying in his hands when I first made his acquaintance, and he treated it to as much devotion as if it had been a child, bending over it and being apparently as fond of it as if it had been a member of his own family, and certainly he acted also in that sort of way. He told me that

came to preside over. The grounds of the late Sir G. Macleay were delightful in the highest degree, and not only in one department, but in many the extraordinary skill of his head man in the way of growing plants was allowed to display itself. Every encouragement was given to him by his employer and he had full scope for his powers, but I always thought that the excessive interest of the glass houses, of the herbaceous borders, and indeed of everything else would have been far less than it was if a less capable person had directed the affair. Green was a nurseryman and afterwards a head gardener who lavished great stores of affection upon every plant that ever came into his hands, and *Saxifraga valdensis*, as it was shown to me first of all by him, is a type of the sort of thing which I associate with his name. There was another fine old nurseryman in days that are gone by, and I must not omit some mention of him. I did not know him so well as the other two because he lived far away, but I once

donor to whom I am beholden for them, and with whom they are inseparably connected in my mind. The one brings before me the other, and quite as much as for any beauty of form or colour, or for anything else they have value in my eyes because of the source from which they were derived. Is it nothing that a Myrtle, which will soon be so large that the fowls of the air can lodge under the branches of it, originally came from a small cutting which was a part of the bridal wreath that was worn by one's wife? I think it is a Myrtle and something more—it always has a voice for me additionally to the voice which other Myrtles possess. And so also has a Rose which I have had under my care for nearly fifty years. It belonged to my mother, and, being on its own roots, it has lived on with me all this long time and is now as strong as ever. *Souvenir de Malmaison* is a capital Rose for this sort of continuance, and I would almost guarantee it a spell of another fifty years if it is taken care of by someone and no accident happens to it. It never should be allowed to blossom in the summer, and then in autumn, and even in early winter in the Isle of Wight, it displays itself to perfection. My Rose has followed me wherever I have been since the year 1851, and when I had a garden in the centre of Maidstone of about the size of a pocket handkerchief it was my pride and delight. I can easily sympathise with what Alphonse Karr has said about his three Hyacinths—they were to him what my Rose has been to me since it came into my possession.

There is just one point, of no very great importance however, about which I do not quite follow what the Dean of Rochester has said. A memorial garden, as he terms it, is sure to be a very interesting spot, but it is likely to be small, and I think a visit to it would be of a stiffer and less pleasant description than is the alighting upon memorial plants which are grown in a less restricted, and therefore a more natural way; but this is only a matter of opinion. I like to have my memorial plants scattered here and there all over the greatest possible space, and to come across them at odd times and in odd ways, and the difficulty of cultivating some of them seems almost to demand it. I can only say in conclusion that I advise all those who have not looked at their garden from the above point of view to begin it at once. It does not detract from any other objects they may have in view, but it adds a new and very great interest to what was so interesting before. One's garden becomes the record of a lifetime, and the past can be lived over again in it when it is conducted in this manner.

HENRY EWBANK.

Group of *Lilium giganteum* at Haddon Hill, near Bournemouth.

it was quite impossible for him to go on with his nursery at Redhill because it broke his heart to be obliged to part with objects of great interest, and that he could not do it any more with flowers that had grown up under his care. Accordingly I was not in the very least degree surprised when I heard that the nursery, the stock-in-trade and everything else had been abandoned, that he had parted with all of it, and that he had accepted the situation of head gardener in Sir George Macleay's splendid garden near Redhill. There may have been other reasons at work of which I knew nothing, but I always thought that the one that was assigned to the move was sufficient, and that Green did take a step lower down, so to say, because he wanted to keep the plants under his own eye and in his own hands on which so much care had been lavished. And what a very beautiful and most interesting place he

paid him a long visit at Darley Dale, near Matlock, and he showed me all over his store. The name of Whittaker was a familiar one in those days to the lovers of plants in Derbyshire, and my first acquaintance with *Tropeolum speciosum* in anything like the splendour which I know it can acquire was, I think, made with him.

And here I am sure my long paper may as well come to an end. I hope I have done something to show that, additionally to the question of species and genera, additionally to that of the harmonies of colour, additionally to all tricks of cultivation, a garden may be stored with many objects of great interest if it reminds us of by-gone days, of far-away places and of persons with whom we have been closely bound up. I might add a page or two about friends who are with us still, but there is no occasion to do that. I have scores of plants which tell me of some

FLOWER GARDEN.

LILIUM GIGANTEUM.

I AM sending you a photograph of a famous clump of this glorious *Lilium*. The bulbs are growing in the garden of the Rev. Mr. Hopkins, Rector of Holderness, near Bournemouth. The *locale* is not the rectory, but a beautiful place called Haddon Hill, near Holderness. A more beautiful and peaceful spot I have never seen. The house is modern, and the grounds have not been laid out for more than thirty years. The present head gardener, Mr. Osborne, has planted or superintended planting every conifer and tree except one on the whole estate. The grounds are very extensive, and the *Rhododendrons* and *Pines* and conifers are magnificent. This Lily bed is at the end of a large and beautifully kept lawn surrounded by

Pines. There were eighteen *Lilium giganteum* in bloom. Most of these had about fourteen flowers on them. There are about forty bulbs planted, and the gardener informs me that he generally has about fifteen in bloom each year. The tallest one was 10 feet high, and a more magnificent spectacle I have never seen. All these bulbs were got from one bulb, and, strange to say, this was given to Mr. Osborne, so that the whole of this splendid stock cost the raiser nothing at all. I shall not soon forget the impression these Lilies made on me. The grower plants these bulbs very shallow indeed, and takes off all the suckers and plants these in pots. He keeps the young bulbs in pots for about five years, after which he plants them out when all fear of spring frosts is over. He gives one heavy dressing of sewage water and then leaves them alone. He agrees with me that a bulb of this Lily flowers once in five years.

JOHN B. M. CAMM.

Burnham Grange, Bournemouth.

Campanula isophylla.—The pretty pale blue *Campanula* shown recently at the Drill Hall as *Mayi* has been in your columns commented upon adversely in relation to its name with perfect justice. But I could not help remarking the other day, when passing a cottage window at Carshalton where both the true blue *C. isophylla* and the white variety were flowering charmingly, that in this case the type plant had flowers apparently exactly alike in form and colour to those on Mr. May's plants, but the leafage was rather darker and smaller and somewhat serrated. The leafage of the white variety, the most beautiful of the section, is larger, paler, and smoother. I should therefore regard the Edmonton variety as being a pale blue-flowered sport from *isophylla alba*. It should be said of these *Campanulas* that we have no hardy pot plants that are more beautiful for hanging in windows or anywhere than these are.—A. D.

* * We fear that the variety to which "A. D." refers as having seen in the cottage window is *C. fragilis*, which often does duty for the blue form of *C. isophylla*. The two are quite distinct in every way.—Ed.

Single Hollyhocks.—An able florist recently asked me to mention where he could obtain seed of a good and varied strain of single Hollyhocks, as he felt they offered wide room for improvement, and he would like to take them in hand for that purpose. I gave him the information, but at the same time strongly urged that in no case should any attempt be made to double them. I do not say that the introduction of a second layer of petals would be objectionable, as we see in a kindred spike-bearing flower, the *Delphinium*, how in such way the singles have been improved, whilst the creation of doubles has proved singularly objectionable. Double Hollyhocks have their admirers—not so much perhaps because of the rotundity or massiveness of their flowers as for their fine spikes, for it is a happy characteristic of doubles that they remain on the stems, and thus produce fine spikes so much longer than the singles do. But, on the other hand, the singles seem to be more robust, more readily raised from seed, and they do produce flowers in a wonderful variety of colour, many of the hues being singularly beautiful. Only a few days since, riding by rail from Croydon down the Oxted line, I observed near Selsdon Road a most charming selection in flower in a couple of small back gardens, presenting just the form of material my florist friend wished to secure. Certainly it would not be difficult to find in these flowers quite diverse colours or markings. Generally the flowers are large enough and they are of excellent form. The chief defect of the single strain lies in the too great facility on the part of the blooms to fall, and thus a good spike of flowers is rarely seen. We could very well do with a rather dwarfer strain, having more retentive

capacity. Possibly the flowers attract insects too readily, hence rapid pollination and falling. With these defects corrected, single Hollyhocks might be converted into singularly beautiful garden plants.—A. D.

HARDY PLANTS AT NEWSTEAD, WIMBLEDON.

QUITE recently, when looking round Mr. Whitehead's garden at Newstead, Wimbledon, the following plants were in good condition. It should be noted as marking the success of some plants here that the position is on the high road adjacent to the common, and there is little doubt that the elevation and the purer and more bracing air have much to do with the success of some of the plants. The chief part of the garden, so far as the hardy plants are concerned, is one continuous slope that culminates in a spacious pond acting as a receiver for much of the water that flows thitherward in times of heavy rain. In like manner it forms a good receptacle for all superfluous moisture in winter, thus leaving the plants high and dry. Indeed, my own impressions of such a slope are sufficiently good that I would not hesitate to plant many of the rarer alpine plants. The staple soil of the garden is of a clayey nature that in summer resolves into hard, nutty particles—a soil of course that requires not a little modifying to grow good alpinists with success. To this end peat is employed in some instances, while rock chippings are freely added to the bulk. At the same time, its obviously holding nature is of great benefit to the stronger kinds, and equally so to the success of tree and shrub alike that in the lighter and drier soils languish and die in times of great heat or prolonged drought.

Among the most contented of subjects was the *Edelweiss*, represented both by the Swiss and Himalayan forms, yet while the latter is much the stronger, both kinds are furnished abundantly with their woolly heads, and growing quite freely spread out into patches that in some of the larger tufts would have at least twenty or thirty heads of flowers. Nor is there any idea of diminished vigour, even with this number in the tufts themselves, for these latter really clothe the ground in their immediate vicinity. In several instances these plants were much the same, no special position being selected in planting. *Houstonia cerulea* is another plant that is so free in this garden as to verge upon being a weed; yet its growth is so free and abundant and its blossoms so profuse as to be quite a revelation. It was the same in several positions, and the plants were only in peat, that has more than once been tried for it, though with very indifferent results. Spring-planted pieces, though smaller, give the same promise of success, which is such that the entire slope may soon be covered with this delightful plant. *Omphalodes Luciliae* is also doing well, though as yet represented by only small plants. These, however, have got hold, and in a shady spot, which the plant does not really require, is quite happy, and producing its exquisitely coloured blossoms profusely. Seeds, no doubt, of it will be saved this year and an attempt made to increase this alpine gem.

Very happy and free-growing is the Hungarian *Campanula Waldsteiniana*. One tuft was flowering abundantly. This, I believe, is the typical plant of this rather variable species, having the radical leaves slightly notched and of nearly a glaucous hue. It is a charming plant when in good condition, and is about 5 inches high. Another pretty *Campanula* is *C. Zoysi*, a singularly dwarf species and a miffy plant in not a few localities. This kind has the constricted corolla which is best known in the *Dielytra*, while in the pale blue flowers it is distinctly pleasing. *Veronica salicifolia* (the Willow-leaved Speedwell) is here a very graceful and elegant plant full of its pretty spikes of closely arranged flowers. One capital example was about 2 feet high and the same through, and the position it occupied rendered it a conspicuous and pleasing object. The blossoms are white with just a suspicion of rose

colour when closely examined, though at a short distance this looks much like a French grey. It is worthy of being seen much more frequently. *Erythraea diffusa* is a pretty dwarf plant of deep rose-pink hue, which in small patches gave a warm glow here and there, the tufts flowering freely in various positions. This is quite an easily grown plant in many gardens. *Campanula Tommasiniana*, one of the most distinct of the bell-flowered family, and indeed a true Bell-flower, is represented by quite a strong established plant. It is a pretty species of slender, elegant habit of growth from the Italian Alps. The flowers are pale blue, distinctly tubular in outline, and each about three-quarters of an inch or rather more long. The slender growth renders it a graceful plant, and for its distinct character it is worthy of being more freely cultivated. It is a good perennial and attains a foot or more high, producing a numerous array of stems from the crown.

A new Russian *Gentian*, *G. Prizewalski*—a ponderous name for any plant, quite sufficient alone to deter it from general cultivation—is flowering for the first time. The plant is distinct from the fact that it is a white-flowered kind, though not a pure or even a good white. The inflorescences are procumbent, the flowers produced in pairs one on either side the stem, some eight or so of these forming the total. Two flower-stems had been produced from a single crown, the few leaves forming the latter lying close to the soil. Individually the blossoms are as large as those of the white *G. asclepiadea*, though perhaps a trifle firmer in texture. Only one flower was open, and this did not impress one with its superiority—rather the reverse. In another spot the Bavarian *Gentian* gave promise of being quite a success, and this though only a few months planted, while the tufts of *G. verna* bear ample testimony to the value and free flowering of this fine plant. A capital bush of *Moltkia petraea*, or *Lithospermum petraeum*, as it is sometimes called, had just finished blooming. The flowers, produced in dense terminal cymes, droop slightly and at first appear of a pinkish hue, but gradually put on a violet-tinted blue shade. The plant is bushy and free, and comes from Dalmatia. A good patch of *Campanula G. F. Wilson* is giving the last few blooms, having already covered a good space, while an apparent seedling form of this is a promising plant. Other things, such as *Primulas*, *Ramondias*, and the like, are doing well, and patches of *Sempervivums* are pretty and interesting. Of the latter, several of the *S. arachnoideum* group are well established, *S. a. Hookeri* in particular being a fine patch.

Around the pond, *Iris levigata*, *Spiraea palmata*, and *S. p. alba* are at home. In a good position on the lawn is one of the finest plants of the *Umbrella Pine* (*Sciadopitys verticillata*) I have seen. It is a fine pyramid fully 15 feet high, possibly more, and some 9 feet or 10 feet through at the base. The plant is evidently at home on the sloping ground here, and finds ample nourishment in the deep clayey material at hand, which, however, is less cold than would otherwise be the case, owing to the sharp incline on this side of the garden. There is a second plant of this at Newstead, but this is not so good.

A VISITOR.

***Lilium auratum vittatum* variety.**—This beautiful Lily, referred to in the report of the last meeting of the Royal Horticultural Society, and which was shown in good condition by Messrs. Wallace, of Colchester, appeared to me the same as one I obtained from Japan last year under the name of *L. auratum rubro-vittatum platyphyllum*. The bulbs flowered magnificently, but most of them perished afterwards, while those obtained early this year have not proved so satisfactory. In the first place the bulbs differ from those of the ordinary form of *rubro-vittatum* in the scales being wider and more suffused with red; indeed, in the general appearance of the bulb there is a slight leaning towards *L. speciosum rubrum*. The leaves are a little wider than in *rubro-vitta-*

tum, while in the case of the flowers the crimson-purple band is more intense and wider than in the other; indeed, it extends over such a large portion of the petals that they appear to be simply edged with white. It is to be met with in some of the Japanese catalogues, and the bulbs always command a good price.—H. P.

NOTES ON HARDY PLANTS.

Meconopsis aculeata is a little plant with big flowers, and a lot of them of the most lovely turquoise-blue colour. At a height of from 6 inches to 8 inches, two-year-old plants have numerous branched stems bedecked with more than ordinary durable flowers for a Poppywort, and the colour is very striking. As implied by the name, the foliage is prickly. The upper surface of the radical leaves has erect, rigid, horn-like spines each nearly a quarter of an inch long. I imagine this will be a flower of the future. I have tested it and found it quite hardy. It seems to enjoy a rich soil and plenty of moisture when growing, and I have hitherto given it full sunshine, but possibly it may do as well or better in an east or west aspect.

The Scarlet Pea to which "S. A." (p. 92) refers was raised here. It may be of interest to give a few particulars of it, for though not, perhaps, in trade lists, it is a favourite plant in many private collections. Many years ago the late Mr. Thos. Williams, of Ormskirk, during our frequent correspondence, sent me some seed. We were then both hunting for Lord Anson's Blue Pea, and he had got this particularly fine scarlet from someone, I think, abroad. I got two plants from my seed. I grew both for some years, and did not think much more of them than scores of other new things at the time being introduced to these gardens until I had the pleasure of a visit from the Rev. Henry Ewhank, when one plant happened to be in flower. He noticed it, and said the colour and size of bunches for *Lathyrus rotundifolius* were unusual. I then compared it with all the red or reddish tints I could, and my plants proved vastly superior. One correspondent could see in it a metallic sheen changing in its scarlet shades with the varied points from which it might be viewed. "S. A." does well to mention that established specimens should be seen, or, in other words, until the plants are strong the colour and size of flowers are not at their best. I believe there is both the blood of *rotundifolius* and *latifolius* in it. Anyhow, there are the features of both to be seen in it, and a total conformity to neither type.

Campanula Waldsteiniana.—It is very true that there are various plants going under this name. It is equally true that, once the typical plant has been seen through all its annual stages of growth and flowering, it will always be impressed on the mind as not only a most distinct *Campanula*, but as a thing of beauty. One form at least that one can readily lay hold of by reason of its having an authenticated name is *Tommasiniana* of Koch—no doubt an Italian form of or a nearly related variety of this species. It is, however, a greener plant, also taller, the thicker stems laxer flowered, and the flowers themselves more tubular and less bell-shaped. I know that the plants in Mr. Whitehead's Wimbledon garden are not likely to exist there long under wrong names, but it may be useful to show that one wrong plant going under the name of *Waldsteiniana* need not do so when it has both distinct features and an authorised name of its own. There is no time better than the present to see the differences and put the names right (July 31). The most marked distinctions are the relatively less glaucous foliage and longer and stouter stems of *Tommasiniana*.

Campanula Wanneri.—I have lost sight of this plant for the last year or two. It is known to be but an indifferent perennial in some gardens, but I kept it here for years (the same plant) on the drier part of a rock garden, and it gave me seed for my friends. I have tried to get

it from seedsmen, but the seed proved not to be true.

Campanula Raineri (Perpent).—This grey creeper with thick leaves and big flowers almost startles one with its delicate beauty. Once you get the true plant and make it do well, you have an alpine and an achievement to be proud of.

Campanula patula is a scarce British plant, but there can be no more charming Bellflower either for rocks, borders, or the vase. The variety of shade from blue-purple to red-purple and the half starry, half bell-like flowers glisten like glazed wax. Altogether it is a flower to see and to watch from day to day to find out its beautiful features. J. Wood.

Woodville, Kirkstall.

IS THE SWEDISH RED WATER LILY A VARIETY OF *NYPHÆA ALBA*?

HAVING had the above Water Lilies growing side by side for five or six years, the differences appear to be so great and so constant that it is very difficult to believe the former to be a natural variety or sport from the other. The differences consist in the size and shape of the leaf, the size, shape, and number of the petals, and the colour of both leaves and flowers. These differences are as great as, if not greater than, those between most of the recognised species of the genus *Nymphaea*.

I will briefly enumerate these differences. The leaves of *N. alba* are somewhat longer than broad; those of *N. rosea* are broader than long. A full-sized leaf of each chosen at random measured as follows: *N. alba*, 10½ inches long, 8¾ inches broad; *N. rosea*, 6 inches long, 6¾ inches broad. Of course, both vary somewhat in proportions, but this difference seems fairly constant and gives a distinct character to the two groups of leaves. Accompanying this difference of proportion is a marked difference of outline, especially of the base of the leaf. In the white species the lobes usually overlap for more than half their length, and the lower termination of each lobe is a very slightly pointed oval. In the red form the lobes open at a very wide angle, and the termination is an oblique unequal-sided blunt point. Out of more than 100 leaves on my red Lily I can see none that approach the overlapping form of the white species, of which it is a specific character, Babington indicating it by the words "notch in the leaves with parallel sides." A Siberian species, *N. nitida*, is described in Hemsley's "Hardy Plants" as having "deeply lobed leaves with spreading lobes," which exactly describes those of the red-flowered form. Equally distinct is the colouring of the two leaves, which differ as follows: *N. alba*, above, clear bright green, below, yellowish green; *N. rosea*, above, an olive-green, very distinct; below, a full dull red, faintly tinged with green.

Coming to the flowers, the differences are equally great. The botanical books give from sixteen to twenty-four as the number of petals in *N. alba*, but in *N. rosea* they are much more numerous—usually about forty. They are also broader and blunter; hence the flowers of *N. rosea* are smaller, with a more regular rosette of petals, often as perfect and compact as in a well-formed double *Dahlia*. Now it appears to me that these various and well-marked differences in form, size, proportions, and coloration of the leaves, as well as in the size, shape, and number of the petals and the coloration of the complete flower—differences which in their entirety are as great as between any two species of the genus inhabiting the same continent—do in themselves constitute *prima facie* evidence that the two forms are distinct species. Of course such evidence must give way if there is

direct proof that the one form is produced from the other by seed without the possibility of any crossing having taken place. The words in italics indicate the essential point needed to constitute such a proof, and I send these notes in the hope of eliciting from some of your readers what is the nature of the evidence that has led botanists, apparently without any hesitation, to class two such very different plants as belonging to the same species.

I may add that I am now growing and flowering in a small tank out of doors, but warmed by a lamp, two blue Water Lilies—*Nymphaea scutata*, from Port Elizabeth, and what appears to be *Nymphaea stellata*, the roots of which were obtained from Diep River, about ten miles from Capetown, where they were probably introduced, though now apparently growing wild.

Dorset.

ALFRED R. WALLACE.

JULY LILIES.

THE white Madonna Lily (*L. candidum*) has this season kept in vigorous health and blossomed well, and has seemingly been freer from the disease than for some years past in this locality, certain groups that have in former years lost their foliage completely before their flowers expanded carrying their stem-leaves unwithered until after their blooms had faded. *L. croceum* is a Lily that nothing seems to harm, blooming as well in seasons when the Madonna Lily is badly affected with the disease as when the latter enjoys comparative immunity. Though not so frequently met with in cottage gardens as *L. candidum*, which, curiously enough, when growing in such spots always appears to enjoy the most excellent health, whether grown in the sun or shade, in damp or dry ground, it is far from being uncommon, and clumps of bulbs that have remained in the same position for years may be seen carrying their erect flowers on stems 7 feet and more in height. *L. Martagon* and *L. M. album* have been in flower, the latter when strongly grown being very effective in the garden, while *L. M. dalmaticum*, with its deep purple flowers, and its variety *L. M. d. Catani*, with even darker coloured blooms, are very vigorous, attaining a stature of from 5 feet to 6 feet, and carrying in some cases as many as two dozen flowers. *L. excelsum*, or *testaceum*, with its crown of pale apricot-buff blossoms, said to be a hybrid between *L. candidum* and *L. chalconicum*, is a beautiful garden Lily, and one that apparently appreciates rich food, as a few bulbs planted in some heavily manured ground have far overtopped their less liberally treated relatives. Of the Swamp Lilies, the Panther Lily (*L. pardalinum*) appears to be the most sturdy in constitution, since this sometimes succeeds where *L. canadense* and *L. superbum* fail to prosper. When it does well it is a striking feature in the garden, growing to a height of 7 feet and bearing as many as forty blooms. *L. superbum* and *L. canadense* are also two beautiful Lilies, and with *L. pardalinum* succeed best in peat or leaf-mould in a partially sheltered bed where their roots may be kept moist during their period of growth. These Swamp Lilies are the most graceful of all their race, with slender graceful stems and reflexed spotted flowers swaying to every zephyr, delicately poised at the extremities of long, slight footstalks. *L. Humboldtii* is another handsome Lily, with blossoms of a yellow-fawn tint, blotched with lake. It succeeds well in a mixture of loam and leaf-mould. *L. Szovitzianum*, with its citron-coloured flowers, some self-coloured and some spotted with minute black dots, is a charming flower, and was in bloom during the early days of the month, as was the golden-yellow *L. Hansoni*. The great Himalayan Lily, *L. giganteum*, with its towering stem 9 feet and more in height, and its long ivory-white tubular blooms, stained with purple in the interior, is quite the feature of the Lily bed when in the zenith of its beauty, and on dewy evenings distils its vanilla-like essence on the passing

breezes and renders all the garden odorous. This Lily is partial to deep, but not heavy soil, and is said to be not averse to manurial assistance. After flowering the bulb dies, but a few bulbets are usually to be found round the base of the stem, which if grown on under favourable conditions should flower in the course of from three to four years. In heavy, damp soil, however, the bulbs will often decrease instead of increase in size. Towards the close of the month the brightest of all Lilies, the scarlet Turk's-cap (*L. chalcedonicum*), came into flower, its blossoms of a vivid vermilion hue. Like the Martagons, it grows well in ordinary garden soil, and is a Lily that no collection should lack. The splendid *L. auratum* commenced to bloom as the month was ending. It is marvellously handsome with its wide-spreading, showily-tinted flowers, and it is a pity that it is not more to be depended on. In some soils it may be possible to count on its becoming permanently established, but in the majority it appears to die out after blossoming well for a season or two, which entails yearly planting if its presence in the garden is to be assured. S. W. F.

Torquay.

YELLOW GROUND AND FANCY CARNATIONS.

THE confusion in the yellow ground Carnations alluded to by "H. S." on page 107 arises from the circumstance that this section is a comparatively new one, and that no serious attempt has as yet been made to classify them. The fact is, that with, perhaps, the exception of Mr. J. Douglas, no leading grower is found advocating classification, the general desire being to defer it for the present. I am with Mr. Douglas in the desire that out of the material already possessed a section of yellow ground Picotees should be formed, and so separate them from the yellow grounds. It is objected that there is not enough material to commence with, but I hold that there is. Mr. Martin R. Smith created something in the way of a sensation by producing at the Crystal Palace show a beautiful wire-edged yellow ground Picotee in Childe Harold, and as it does not now take long for a new Carnation to get into commerce, this fine variety will doubtless be in the hands of growers two years hence. On the occasion of the recent annual exhibition of the National Carnation Society at the Crystal Palace there were classes for the best bloom of a yellow ground Picotee, heavy edge, and also light edge. In the former class Gertrude was placed first and Aldeforan second, both new varieties of Mr. M. R. Smith's raising, and Mrs. R. Sydenham was third. The two former are not yet in commerce, but soon will be, no doubt. In the light-edged class Childe Harold was placed first and Speranza (Mr. M. R. Smith) second; Mrs. Douglas was third and Fanfuella (Mr. Smith) fourth. The society thus recognises a distinct section of yellow ground Picotees, and what the committee should next do should be to form a class for six blooms in not less than three varieties. The following are clearly admissible to compete in addition to those named above: His Excellency, Effie Deans, Badminton, and Empress Eugénie. It cannot be expected that the edge of colour, whether heavy or light, will be as perfect as is the case with some of the white-edged Picotees, but it is expedient to make a beginning, and the sooner it is made the sooner will a high standard of quality be set up, such as that observed in Childe Harold. Mrs. Gordon, Mrs. Tremayne, Florrie Henwood, Eldorado, May Queen, The Gift, Dervish, Voltaire, Ladas, and Golden Eagle are all classed as yellow ground Picotees, though they are more or less marked with slight bars of colour breaking through the petal edge into the ground of the flower. It is clearly the duty of the judges to select those flowers freest from these bars, and the very act of forming such a class would give a new impetus to the raising of the highest types. In present competitions for fancy Carnations yellow grounds

are admissible, and that is why Voltaire was found shown as a yellow Picotee and also as a fancy Carnation. If the committee of the National Carnation Society were to form a section of yellow ground Picotees and name certain varieties as admissible to be shown as such this confusion would practically cease. A fancy Carnation is anything which cannot be classified in any other section. It is a convenient term, if not very intelligible. It comprises a large number of very handsome and striking flowers, the which when shown in their best character are always attractive. The ground colours and the marginal colours alike may be of any combination or tint, and the term is thus able to comprehend much that would otherwise be lost to the exhibition table. R. D.

Geranium Henry Jacoby.—Probably this is the most generally grown bedding Geranium in existence. It matters not in what direction one looks he finds it, it being easily distinguishable by its free growth and bold dark crimson flower-truss. One thing, however, needing observance is not to give Jacoby a too rich root run, as in such the plants have a tendency to grow rankly, and consequently produce bloom sparingly. This I have noticed over and over again. Some others, on the other hand, notably Vesuvius, are the better for a rich larder, being in ordinary soil prone to make too stubby a growth and undersized blooms. Given the right treatment, however, Vesuvius is still hard to beat by any Geranium of its colour. It seems to me that much greater strides have been made in zonal Geraniums suitable for indoor or pot culture than in the bedding section, this being proved by the fact that not a few varieties raised twenty or thirty years ago are still first favourites with many.—J. C.

Cactus Dahlia Magnificent.—This is one of Mr. J. Stredwick's introductions, and was last year regarded when shown as one of the best of the season, new in colour, and of the most approved Cactus shape, while in respect of habit it exhibits a marked improvement upon some other new varieties. It grows about 4½ feet, it produces freely lateral growths, and the flower-stems are well thrown out beyond the foliage, while it is very free of bloom. As far as my own experience of this variety goes, Magnificent gives good blooms early in the season, and one has not to wait for flowers true to character until the end is nearly reached, as is the case with some sorts. In this respect it is satisfactory to note a decided improvement in the case of Magnificent, and it becomes a welcome addition to the number of Cactus Dahlias which are early to bloom, free, and throw their flowers well above the foliage, and thus adapted for flower garden decoration. Our raisers of Cactus Dahlias are giving much attention to the improvement of the habit of growth.—R. D.

NOTES AND QUESTIONS.—FLOWER.

Cactus Dahlia Britannia.—Not the least in merit among the newer kinds is this. The plant is less than a yard high and covered with bloom. Each flower opens perfectly. The colour, a nice shade of salmon-buff, is distinct and pleasing.—H.

Cactus Dahlia Mrs. John Goddard.—This has blooms of a deep rich red and has the good quality of lightness in the form of its petals. Not a tall grower and very free-flowering, it is among others very distinct. The blooms, too, are more lasting than is the case with sorts generally.—H.

Tricolor Pelargoniums.—Almost the only one of this once very popular section of bedding plants now employed for that purpose is Mrs. Pollock, always the most popular of the golden tricolors. But there is one variety yet far from common that either as a pot or bedding plant is a great advance on Mrs. Pollock, and that is Mrs. Harry Cox. This is a bold, robust grower, with stout, rounded, highly coloured leaves, and does wonderfully well outdoors. I have seen this variety occasionally, and but the other day came across a few plants in a flower garden when with Mr. Burrell, of Claremont, who also was greatly taken with it. No

tricolor put into commerce that I have seen at all equals this one as a desirable bedding plant, especially when put out thinly.—A. D.

NOTES OF THE WEEK.

Statice latifolia.—The large heads of this fine Sea Lavender have made a good display of late, and even now are not wholly devoid of colour. Among good perennials this should always be well to the front, being easy of culture, dwarf in habit and requiring but little care to maintain it in good condition.

Sidalcea Lieteri.—The fringed or deeply cut blossoms of this plant render it a pleasing feature in the border, and even in a small group it is in consequence rendered attractive. The colour too is pleasing, and the plant, which is about 3 feet high, deserves more attention generally. It succeeds well in ordinary soils.

Geranium cinereum album.—Few plants so well suited to rockwork are possessed of more dainty blossoms than this. Its competitors in this respect are nearly allied subjects, viz., the *Erodiums*. In the above there is a purity of tone not always seen in these dwarf plants, and the delicate tinge of colour as the flowers increase in age has a singularly pretty and pleasing effect.

Passiflora Constance Elliott in S.W. Scotland.—Last year I referred to this Passion Flower as being hardy at Orchardton, Castle Douglas. This season I have come across a good plant which has been on the front of the office at Kerr Brothers' nursery at Dumfries for some years. The climate at Orchardton is rather milder than that of the town of Dumfries, which is further inland, and it is encouraging to see a good specimen of *Passiflora Constance Elliott* in this latter locality.—S. A.

Adenophora liliifolia.—This is, perhaps, one of the most graceful of summer-flowering plants, notwithstanding it is rather tall, and perhaps too sparse in habit of growth for some. Yet it is here that its grace and beauty are so apparent. By some it would be regarded as too tall for the rock garden, yet it is in some such place that one catches the transparent beauty and charm such elegant subjects provide. Particularly pleasing is this from a side view as well, and the many pale blue flowers borne on a good-sized plant render it among the most useful of summer plants.

Campanula betulæfolia is a distinct member of the Bellflower family, in which the foliage is distinctly as well as deeply cut, the flowers, which are of a pinkish hue, being equally distinct. This is so indeed in form as much as in colour, for while the latter is comparatively rare, it is not unknown altogether, though the form of the flower, a sort of expanding bell, say from a quarter of an inch wide at the stalk end, to nearly an inch across at the tip of the corolla, is a characteristic almost unique in the group. Even from this point of view the kind should be worth cultivating.

Campanula carpatica pelviformis.—So far as the flowers of this handsome kind are concerned, there is nothing to indicate in the least that it belongs to the Carpathian Harebell, which in reality is the case. The resemblance is easily seen in the leafage of the plant, which is almost identical with that of the parent. The flowers of this distinct kind are almost, if not quite, unique even among the varied forms of which this group is composed. Less vigorous, too, it appears generally and much dwarfer, the plant is even more suited to the rock garden than the original species, which, by the way, is quite at home in both. This beautiful kind is seen but very seldom in good plants despite the fact that it has been some years now known to hardy plant growers.

Mr. J. Wood's Scarlet Pea.—*Lathyrus Drummondii* answers to this description. I obtained it many years ago from Mr. C. Green when gardener at Pendell Court, Bletchingley. It is related to *L. rotundifolius*, but Mr. Green always

held—and my experience of it confirms his statement—that it is quite distinct. It is both earlier and much more prolific of bloom, seeding as a rule somewhat sparingly. Its earliness is seen from the fact that its perennial root-stock breaks into growth much earlier than that of any perennial Pea I am acquainted with. It grows to a height of about 5 feet, and when supported by a few ordinary Pea stakes and looked after in the matter of water, it shows an extraordinary surface of bloom. It should be planted in rich soil, be well mulched and watered, and then it becomes a splendid object in the border. I find it does best in an open, sunny position.—R. D.

Eremurus Elwesianus in Westmoreland.—This Eremurus flowered in my garden at Wanefell Holme, Windermere, early in June, and was photographed by my daughter when at its best. The plant was bought in October, 1898, and planted in one of my herbaceous borders. During the winter and early spring the roots were protected to prevent injury from frost. In spite of all protection the points of the large leaves were touched by the cold winds and slightly disfigured, but no material harm happened to the plant, for it grew strongly and began to show its flower-spike early in the month of April. The following measurements may be of interest, viz.: Length of spike, 7 feet 3 inches; diameter of flowering portion, $4\frac{1}{2}$ inches. Three branches were produced, 20 inches, 19 inches, and about 6 inches in length. The Eremurus was planted on October 7, 1898, and the photo was taken on June 7, 1899.—O. O. WRIGLEY, *Bridge Hall, Bury, Lancashire.*

Campanula Vidalii.—Several times some interesting notes have appeared in THE GARDEN respecting this Campanula and its hardiness. Others, like myself, appear to have been in hope that it might prove hardy in our gardens even when it has been too tender in similar places. I think it was Mr. Wood who referred to it in hopeful terms last year, and one would be glad to hear how Campanula Vidalii has done with him. Your Cornish correspondent, "C. R.," does not, in the note on page 111, give us much encouragement, as it appears it has been killed regularly until this year. When this occurs in Cornwall it is to be feared that there is not much prospect of success for us in the north. With me it has failed in as warm and sheltered a place as I could find. One is not surprised that this distinct Bellflower should be tender, but as plants from even warmer places than the Azores have proved hardy here, a little experiment has been desirable.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Gutierrezia Euthamiae.—Sometimes when one has grown a plant for some years it acquires in our eyes a beauty which could not at first be realised. This peculiarly named plant may be one of those, and may improve much upon acquaintance. I came across it the other day and was not particularly impressed with it, although it may have been due to want of taste. The foliage is light-looking, but the small flowers are of a greenish yellow, which is not very attractive. It seems to be an inferior plant to some others of somewhat similar appearance. The owner of the garden in which it was grown did not think highly of this Gutierrezia, but it is quite possible that one might admire it when it develops into a mass. Perhaps someone who has had experience of it may give us some information about its worth and requirements. It is, I learn from the "Kew Index," a native of Western North America, and belongs to the Natural Order Compositæ.—S. ARNOTT.

Rodgersia podophylla.—One is glad to observe the pleasant notes on the Japan Bronze Leaf by "A. L. L." in THE GARDEN of August 5. As no special mention is made of the bronzy colouring which adds so much to the beauty of the plant and has given it the popular name of Bronze Leaf, one may be pardoned for referring to it now. It is one of the most attractive features of the plant, and anything which prevents

its development cannot fail to be worthy of observation so as to avoid the cause which hinders it from assuming its distinctive bronzy tints. Both in my own garden and in others I find that plants which are in a wet position, such as on the margin of a pond where the soil is constantly saturated with water, are not nearly so well coloured as are those which are in drier places. While this is what I have observed, I hope it is not imagined that I advocate keeping it dry, as it likes a liberal supply of water. It is an excess of moisture which appears to keep the leaves green.—S. A.

Veratrum nigrum.—As an August flowering plant this Veratrum is highly desirable, although its worth does not lie in brilliancy or effect of colour. Usually at flowering time its fine ribbed, massive leaves have also lost part of the beauty which is their marked characteristic in the earlier months, so that they are less attractive. Yet the tall spike is very fine with its array of blackish purple flowers. We are told that the spike is from 1 foot to 3 feet high, but it is occasionally higher than that, and one I saw the other day had a grand spike which could not be much less than 5 feet in height. This was at Summer-ville, Dumfries. The Black Veratrum is not, unfortunately, a very free bloomer, and one has known plants which have not given flowers for some years. Still, a spike or two of these flowers, whose beauty consists in their deep colouring, will compensate for years of waiting. Nearly all the Veratrum are noble plants either when they unfold their plaited leaves, which, as Gerard says, are "folded into pleats like a garment pleated to be laied up in a chest," or when in flower.—S. A.

Spigelia marilandica (Worm Grass).—This is, perhaps, one of the most delightful of North American plants, and one all too rarely seen in anything approaching established plants in British gardens. The flowers, too, are possessed of a rare colour combination—crimson and gold—the former, which is perhaps of a blood-crimson hue rather than otherwise, enveloping the exterior of the corolla, while inwardly and also on the reflexed lobes of the corolla the golden hue prevails. The nearly tubular flowers, which are erect, are about 2 inches long and appear at the summit of the growth, which is rarely more than 8 inches high and frequently much less. In good tufts the stems spring up quite thickly, and when these are crowned with flowers the plant is very brilliant. In the rich and often moist woods of Pennsylvania and Florida this plant is found abundantly, and could it be but induced to flourish in like manner in British gardens, it would certainly prove most welcome. Planted in moist peat and where shade is more or less permanent, the real value of the Worm Grass is seen. In the drier portions of the artificial bog garden this plant should find a congenial home.

Ostrowskya magnifica in Kent.—From the occasional accounts that have appeared in THE GARDEN about Ostrowskya magnifica it seems to be very far from fulfilling the great future that was supposed to be before it at the time of its introduction. My experience with the plant, however, has been more fortunate than that of others, and this season I can record an unqualified success. My plant is close to a very thick and high Box hedge facing almost due south and moderately protected from the east. The soil is a deep, but light loam, and in the exceptionally dry seasons we have had for some years past becomes baked and dust-dry for the greater part of the summer. This year my plant attained a height of between 5 feet and 6 feet, and bore on four stems thirty-two flowers of a pure white save for a faint bluish tinge; at all times of the day the flowers faced slightly west of south. I have never missed having a few flowers for some years past, but late May frosts have usually crippled most of the buds; this year I used a light covering of tiffany whenever frost seemed likely. I keep a large sheet of glass over the roots during the winter; this is only removed when growth has well started. In its earlier stages even severe frost seems to have no effect on the unprotected

foliage. I send herewith a sketch which gives a good idea of the habit of the plant, but the lower leaves have usually turned yellow by the time the flowers are expanded.—R. A. TODD, *Honeydon, North Cray, Kent.*

Lilium chalcedonicum.—The Chalcedonian Lily is generally a favourite with most people, its bright flowers of what is often called "sealing-wax scarlet" being very effective. Although it is in some gardens a little difficult to establish and sometimes takes a few years before it reaches a flowering stage, it is not generally a troublesome subject. In the border it is a very attractive Lily, and in wild gardening it has been used with fine effect. In the south-west of Scotland it is comparatively common, but is never too often seen. Like many other plants, it has several varieties, and one would like to know how many of these there are. Your contributor "H. P.," who has a special knowledge of Lilies, may perhaps be able to help us. From the "Dictionary of Gardening" one would gather that there are plants with yellowish flowers, and that in addition to the type there are the varieties majus and græcum. The varieties I have come across are, first, the usual form, of medium height, with scarlet flowers with small blackish dots; second, the tall form with small flowers, called græcum; third, a variety without the black dots; and fourth, a tall, deep-coloured form with broad segments, which I take to be the one named majus. This was very fine the other day in the garden of Mr. John Maxwell, Maxwelltown, Dumfries, where was also a fine plant of the type bearing eleven flowers, although the usual number is only given as from one to six. One finds that these Turk's-cap Lilies, as those of the section with recurved segments are usually called, are general favourites.—S. ARNOTT.

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, Aug. 15, in the Drill Hall, James Street, Westminster, 1—5 p.m. At 3 o'clock a lecture on "Pruning" will be given by Mr. R. P. Brotherston.

The weather in West Herts.—Another very warm week and the fifth in succession. On three days the highest temperature in shade exceeded 80°, while nearly all the nights were also very warm. Both at 1 foot and 2 feet deep the ground is now about 6° warmer than is seasonable. At 9 p.m. on the 4th the temperature at 2 feet deep stood at 69°, and at 1 foot deep 74°, both of which are the highest readings I have yet registered here at these depths at any period of the year. A little rain fell on two days, but only sufficient to lay the dust, and no measurable quantity of rain-water has now come through either of the percolation gauges for a week. The winds were, as a rule, light, and came mostly from some northerly or easterly point of the compass.—E. M., *Berkhamsted.*

Chrysanthemums unhealthy.—Will you kindly say if it is the Chrysanthemum rust which affects the enclosed leaves? It occurs on single varieties which I have had for some years.—E. ALLEN.

** The leaves sent are not affected with rust, but have been eaten by the leaf-mining fly known to be troublesome to Celery. The holes in the same appear to have been made by small caterpillars.—Ed.

Names of plants.—J. A.—14, Campanula pumila alba; 16, C. persicifolia (type); 19, C. muralis (syn., Portenschlagiana); 20 and 23, forms of C. Trachelium; 21, C. grandis; 24, C. garganica.—B.—Veratrum nigrum (False or Black Hellebore).—Ireland.—1, looks like Rosa lucida, but should like to see flowers; 2, Andromeda floribunda; 3, Escallonia Philippiana; others next week.—Rowe Lewis.—Flowers shrivelled up.

"The English Flower Garden."—Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d.

Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, 8s.

ORCHARD AND FRUIT GARDEN.

BLIGHT-PROOF STOCKS.

TO THE EDITOR OF THE GARDEN.

SIR,—I read with interest the correspondence re Northern Spy Apple for stocks on page 248, April No. of THE GARDEN, and your request for further information upon the subject. Here, in the North Island of New Zealand, the woolly aphid is our greatest trouble in Apple growing, and as necessity is the mother of invention, our growers had to devise some means of alleviating, if not overcoming the difficulty altogether. This has been done, as far as the roots are concerned, by working the different varieties upon the Northern Spy stock. The Northern Spy Apple is absolutely proof against the woolly aphid. To obtain a supply of stocks, the Spy itself must be produced upon its own roots, which can be done by layering the branches, or by the system of root grafting, that is, by inserting a small piece of root of an ordinary stock say 2 inches above the base of the Northern Spy scion. The root thus inserted and properly tied will enable the scion to grow, and in time roots will be produced at the base of the scion, when the side root may be removed, and the whole tree will be upon its own roots. When once a few dozen trees are produced upon their own roots it is a simple matter to work up a stock by root grafting, obtaining only Spy roots; by this means Northern Spy stocks are produced. There are other varieties that are non-blighting and suitable for stocks, but the Northern Spy is the best, being fibrous-rooted, and brings the trees into bearing early. In America the State Board of Horticulture is experimenting with most satisfactory results. Some fifty trees were obtained from Australia on Northern Spy roots and planted in an old nursery where trees that were badly affected with woolly aphid had been recently growing, the ground being full of roots that were covered with the aphid. Upon the results of the examination, the trees on blight-proof Spy stocks were dug up and found absolutely free from aphid. Roots were cut off and distributed to all who desired to experiment with them, using the roots as stock and Northern Spy as scion.

The resistance of the Northern Spy to woolly aphid is thoroughly established, and has been demonstrated in Australia and New Zealand for over thirty years. In this Auckland province of New Zealand attention is directed to the raising of varieties of Apples that resist the woolly aphid, and with such success, that our growers will be able to discard the sorts that blight badly. Cox's Orange Pippin, Ribston Pippin, King of the Pippins, Blenheim Orange, and the majority of the best of European varieties blight so badly, that they are hardly worth growing, even although we are able to keep the roots perfectly clean by working them upon the blight-proof Northern Spy stock. It seems incredible that the aphid should attack some varieties and not others, but such is the indisputable fact with the N. Spy. It has not yet been found out why the insect discriminates, yet it is a fact that it does. As an instance, take the Grape Vine. The Phylloxera destroys the roots of some varieties, but will not attack others. The same thing occurs throughout the insect world. To my mind, it is surprising that the Northern Spy has not been made use of in Europe as a stock for the Apple.

Being a constant reader of your valuable paper during the last two years, I have noticed that attention has been frequently called to the prevalence of woolly aphid upon Apple trees, and that various remedies have been suggested, but never any mention made of using resistant stocks. I can assure you that it can be entirely got rid of by working upon the resistant stocks. Nurserymen here would never think of working their trees upon any other, as they would immediately lose their business. I hope the Spy will come into prominence as a stock for the Apple in localities where woolly aphid is troublesome.

D. A. HAY.

Auckland.

Apple Beauty of Bath.—This will eventually take a high place among early dessert Apples, for it is a very pretty and attractive variety, ready early in August and of far better quality than the majority of early kinds. A dish of it on coloured Vine leaves looks extremely pretty, the fruit being flattish round, russet yellow, with

streaks of green and very bright red. The tree is a free bearer and of fairly vigorous habit, and on the free stock makes a fine healthy-looking bush or pyramid. The flesh is white, juicy and tender, sub-acid at first and sweeter afterwards.

The Myrobalan Plum.—This pretty little Plum should be grown in the pleasure grounds or in parts of the garden where room can be spared, and in a season of scarcity of other Plums the fruit would be very welcome for tarts and preserving. Not only this, but the plants are very pretty whether in fruit or flower, and would be well worth growing for the sake of appearance only. The growth is very free and vigorous, and it would make an attractive and excellent fence if kept low for a year or two and then allowed to thicken out. Nurserymen still persist in using it for a stock for Peaches, and many early failures of fine trees may be traced to it.

Grape Lady Downe's.—Although usually grown only as a late Grape, I find a rod or two of this very useful in the intermediate house where it makes a useful succession to the Black Hamburgh, and its brisk pleasant flavour is liked as a change. The additional time given the wood to ripen is in its favour, as the bunches from well-ripened Vines are always more compact and have better shoulders than those from canes that are started late and have to develop their wood late in autumn. This, of course, is true of all varieties, but I think that the loose bunches with a long bare neck sometimes seen on Lady Downe's are very often the result of badly ripened wood. Where a little fire-heat is allowed and plenty of air kept on, as it should be in all well-managed late houses of Vines, this failing is less apparent. This variety colours perfectly under the conditions named above, and does not show the same disposition to turn foxy as Gros Colman.—H.

Peach Crimson Galande.—There is no question about this being a fine handsome Peach to look at and good for exhibition for this reason. But I was bound to condole with a fellow exhibitor recently when he was beaten by it, his own dish being a very fine one of Alexandra Noblesse. There is no doubt that had the judges tasted the fruits and awarded the prize for flavour, the Noblesse would have won easily, but the fruit has not the colour and appearance, and for this reason had to go under. When ripened under the very best conditions Crimson Galande is only fair in flavour, and if hurried at the finish quite poor. Its season is about the same as that of Violette

Hâtive, which is a far better Peach in every way, a sure cropper, a fairly handsome Peach for exhibition, and of excellent flavour. The best fruits of Crimson Galande I ever tasted were grown on a south-west aspect in a Wiltshire garden, where the soil was rather light with a little chalk in it. In such soils as this, if the roots are well looked after as to moisture and manure, I believe Peaches show their very best points as regards colour and flavour.—H.

The Japanese Wineberry.—It is strange that this showy and useful autumn fruit should not be more generally grown, especially in gardens where choice preserves are appreciated. It is now some twenty years since its introduction, yet it is in few gardens one meets with it. It is perhaps rather more tender than the Raspberry, but it stands ordinary winters uninjured in most localities. By some the well-ripened fruit is preferred to Raspberries, even in a raw state, but the majority, I think, value it principally for jam. The bushes enjoy a deep, moist root-run, and in dry seasons a good mulch, together with a couple of thorough soakings of farmyard liquid, will improve the size and quality of the fruit and also strengthen growth. I believe this Wineberry would pay if grown for market, as so many people like preserves having a slight acidity.—C. N.

YOUNG & OLD PEACH AND NECTARINE TREES.

THERE can be no doubt that a great deal of valuable space under glass and on walls is wasted owing to the trees thereon having grown out of the profitable stage. Very little wood is made annually, and if perchance a branch dies the trees have not enough vigour to make up the deficiency with good wood. The shoots are very short and weak, the fruit naturally suffering in point of size and quality. The contrast between these and young, vigorous trees is very marked, for a mistake in culture with the latter is much more easily rectified, and if allowed their head and properly attended to at the roots they will bear without injury a remarkably heavy crop. Indeed, a heavy crop is necessary to their well-being, for if the crop is light and the trees rooting freely in a new border, they are very apt to grow too strongly and get into an unfruitful habit. Many growers object to planting large trained trees, and where one can afford to wait for results, possibly maidens one year from the bud are best. But with careful planting in proper season of good, well-rooted trees, there is no reason why a limited number of good fruits could not be gathered the season after planting. One point must be insisted on. The trees must be obtained from nurserymen of standing who make a speciality of fruit culture, and, if possible, personal selection of the trees should be made. There is no mistaking the well-balanced fruitful tree with its even and not too strong growth. It is perfectly distinct from a tree that, owing to careless culture in the early stages, has formed a quantity of gross sappy wood. Again, the trees must be carefully lifted in suitable weather just as the leaf is turning to fall and planted immediately they are received. The best plan I know to quickly furnish a house is to obtain maiden trees a couple of seasons before they are required and plant them against a suitable wall for the two seasons. Then they are at hand when they are wanted, and, no matter how early in the season, the roots may be thoroughly soaked and the trees lifted and replanted with no delay whatever. Such trees do not feel the removal, and the slight check given the roots is an advantage in nearly every case, as it corrects the tendency to strong wood that is sometimes observed in healthy young trees. If a few young trees were purchased occasionally and grown on, they would come in very useful for filling up blanks when a tree dies or is removed owing to lack of quality in the fruit.

The subject of border-making need not here be gone into further than to say that it is often shelved on account of the supposed trouble involved, and old trees are kept for that reason.

But, properly set about, it is neither a long nor a tedious job, and should not be neglected. This being so, it is all the more unaccountable that old and worthless trees are allowed to remain instead of being cleared out and replaced with young and fruitful ones. H. R.

PEARS ADOPTED BY THE CONGRÈS POMOLOGIQUE OF FRANCE.

(Continued from p. 114.)

CERTEAU D'AUTOMNE (*syns.*, *Petit Certain*, *Belleime d'Automne*, *Vermillon Poire de Fusée*—*Cuisse Dome*, by mistake).—The fruit is small, long, pyriform. The stalk is fairly long, slender, curved, set at the summit of the fruit, sometimes straight, sometimes obliquely. The eye is open, set almost level with the fruit in a scarcely perceptible depression. The skin is rather rough, golden yellow, a little tinged and streaked with carmine-red, stippled grey. The flesh is white, crisp, not juicy. The fruit is very good for cooking, and ripens October to December. The tree is vigorous, fertile, but uncertain. In cultivation the tree is vigorous both on the Quince and on the natural stock. It adapts itself to all forms, but its true place is as a standard on the Pear.

CITRON DES CARMES (*syns.*, *Madeleine*, *Poire Précoce*, *Gros Saint Jean*, *Sainte Madeleine*, *Saint Jean*).—Of ancient, unknown origin. The fruit is small, nearly spherical and almost as wide as high. The stalk is fairly long and stout, swollen at the base, curved, set in a wrinkled and scarcely perceptible cavity. The eye is of fair size, open, set level with the fruit in a small wrinkled depression. The skin is smooth, yellowish-green, stippled grey, with some tawny stains. The flesh is white, juicy, and slightly aromatic. A fairly good fruit, ripening July. The tree is of moderate vigour and very fertile. In cultivation this variety is ill adapted to regular forms; it is specially recommended as a standard on the Pear.

CLAPP'S FAVOURITE (*syn.*, *Favorite de Clapp*).—Originally obtained by Mr. Thaddeus Clapp, of Dorchester, Massachusetts, U.S.A. The fruit is large, rarely pyriform, the stalk short, stout, fleshy, set obliquely in a slight fold; the eye medium sized, half closed, set in a narrow, shallow cavity, wrinkled and ribbed at the edges; the skin smooth, greenish yellow, strongly washed with purple-red, carmine on the sunny side, stippled with red; the flesh is white, juicy, and aromatic. A very good fruit, ripening August. In cultivation this variety can be grafted on the Quince and the natural stock, and adapts itself to all forms; nevertheless, double grafting is advisable if established on the Quince.

COMTE DE CHAMBORD.—Originally found a few years ago by M. Eugène des Nonhes at Nantes. The fruit is medium sized, as wide as high, the stalk of medium length, stout, the eye closed or half open, in a wide and rather wrinkled depression; the skin yellow, slightly mottled dull red on the sunny side, much mottled with smooth brown, the flesh white, juicy and aromatic. A very good fruit, ripening from September 15 to October 15. In cultivation this variety should be grafted on the Pear for preference, and lends itself to all forms.

COMTE LELIEUR.—Originally found in 1865 by MM. Baltet frères. The fruit is of fair size, often embossed at the insertion of the stalk; the stalk is long and not greatly swollen at the point of attachment; the eye medium sized, with sepals small and connivent and set in a shallow cavity; skin water-green, stippled brown and changing to yellow, always washed with rose-carmine, with tawny spots on the sunny side; the flesh white, delicate, very juicy. A very good fruit, keeping ripe for several weeks without turning off or losing its qualities. Ripens September to October. The tree is vigorous and fertile. In cultivation this variety is well adapted for medium and small forms in a good exposure.

CONSEILLER À LA COUR (*syns.*, *Conseiller de la Cour*, *Maréchal de la Cour*, *Duc d'Orléans*).—Obtained originally by Van Mons in 1840 and

dedicated by him to his son. The fruit is of fair or medium size, the stalk long, slender, curved, set almost straight on a small, rather bumpy cavity. The eye is small, open, set in a regular shallow and wide cavity; the skin rough, thick, yellow-green, stippled grey on the sunny side, which is washed with dull tawny red. The flesh is white, juicy, acidulate (sometimes too much), passably aromatic. A fairly good fruit, ripening October. The tree is vigorous and fertile. In cultivation this variety, almost as vigorous on the Quince as on the natural stock, is suitable for all forms upon both stocks. It is rarely that the soil suits it sufficiently to produce a good fruit.

CURÉ (*syns.*, *Belle de Berry*, *Belle Eloise*, *Bon Papa*, *Comice de Toulon*, *Vicaire de Winkfield*).—Found originally in 1760 by M. Leroy, curé of Villiers-en-Brenne, near Clion (Indre). The fruit is large or fair sized, elongated, the surface irregular, taking the Saint Germain or calabash shape. The stalk is stoutish, of medium length, swollen at the base, curved, set rather obliquely. The eye is large, open, filling a narrow and bumpy cavity. The skin is smooth, thick, yellow-green, mottled black and green, slightly tinged pale red on the sunny side, slightly mottled with russet, forming a line from the base to the summit of the fruit. The flesh is white, juicy, and sometimes endowed with an agreeable aroma. The fruit fairly good, and for cooking very good; ripens November, December, and January. The tree is very vigorous and of great and sustained fertility. In cultivation this variety may be grown on the Quince and on the Pear, and trained to all forms, even standards. It likes a warm soil and exposure in order that the fruit may acquire good quality.

DE L'ASSOMPTION (*syn.*, *Beurré de l'Assomption*).—Originally got in 1863 by M. Riullé de Beauchamps near Nantes. The fruit is large or very large, variable in shape, sometimes turbinate, long and obtuse at the base, sometimes rather cylindrical and narrowed. The stalk is stout and fleshy, set in a narrow cavity and surrounded by bumps. The eye is fairly large, open, regular, in a fairly deep wide cavity, surrounded by unequal bumps. The skin is brilliant yellow, abundantly mottled with light tawny red. The flesh is whitish, rather green under the skin, tender, very juicy, and fairly aromatic. A good fruit, ripening August. The tree is vigorous and fertile on the Pear and on the Quince. In cultivation this Pear grows well on the Quince, and forms handsome, regular pyramids.

DELICES DE LOWENJOU (*syns.*, *Dr. Gall*, *Jules Bivort*).—Obtained originally by Van Mons about 1836. The fruit is medium or fair-sized, pyriform, rather higher than wide. The stalk is fairly long, slender, swollen at the two extremities, often set obliquely in a shallow and irregular cavity. The eye is medium sized, open, set in a wide shallow cavity. The skin is delicate, at first a bronzy green, changing to golden-yellow at maturity, spotted and stippled brown-red, washed orange on the sunny side. The flesh is whitish, very juicy, and richly aromatic. A very good fruit, ripening October—November. The tree is of normal vigour on the Quince, of great and sustained fertility. In cultivation this variety bears very freely. It is good for the sake of a lasting tree to graft it on the natural stock. It may be cultivated in all forms.

DELICES D'HARDENPONT (*syn.*, *Archiduc Charles*).—Obtained by the Abbé d'Hardenpont in 1759 in his garden at Porte d'Avré, Mons, Belgium. The fruit is fairly large, of Bon Chrétien shape, rather narrowed towards the base, where it is slightly hollowed, widely depressed at the top. The stalk is of medium strength and length, set rather obliquely in a little cavity. The eye is very variable, sometimes medium, regular, and set in a superficial cavity, sometimes smaller or larger, irregular, in a cavity more or less large. The skin is citron-yellow, with brown stippings and stains, very slightly stained light red on the sunny side. The flesh is white, unctuous, very juicy, and more or less aromatic according to soil. A good or very good fruit, ripening Oc-

tober—November. In cultivation this variety is generally at home in cool soils, in which the fruit acquires more sugar and aroma.

DES CANOURGUES.—Originally found by M. Lauzeral, of Monastrer, Tarn, in a hedge of his domain. Des Canourgues, more than sixty years ago. The fruit is small. The stalk is short, weak, curved, set in a not strongly marked crease. The eye is small, closed, in a slightly wrinkled depression. The skin is straw colour, strewn with small dots, shaded or streaked with pale rose colour at the sunny side. The flesh is white and very agreeably aromatic. A very good fruit, ripening July—August. In cultivation this variety on the Quince may be trained to small forms, but it is specially good as a standard on the natural stock, on which it is vigorous. The fruit should be gathered at intervals.

DES URBANISTES (*syns.*, *Beurré Drapiez*, *Beurré Picquery*, *Coloma d'Automne*, *Louis Dupont*, *Louise d'Orléans*, *Urbaniste*).—Obtained originally in the garden of the Urbanists at Malines about 1783. The fruit is medium sized, turbinate and regular in contour. The stem is thick, unctuous, light green, passing to bright yellow, stippled and mottled and slightly stained bronze, sometimes rosy on the sunny side. The stalk is of medium length and stout, especially at the extremities, set in an oblique crease. The eye is medium sized, open, in a narrow shallow cavity. The flesh is white, juicy, and agreeably aromatic. A very good fruit, ripening October—November. In cultivation this variety grows well on the Quince. It is useless to graft it on the natural stock, as then it grows too strongly.

DOCTEUR JULES GUYOT.—Obtained in 1870 by MM. Baltet frères. The fruit is large, pyriform, or rather a calabash shape, often ribbed near the eye. The stalk is of average stoutness, turned aside by a pronounced spur. The eye is medium-sized, open, in a little perceptible depression. The skin is green, quickly changing to citron-yellow, finely stippled, often tinged rose on the sunny side. The flesh is juicy, refreshing, and agreeably aromatic. A very good fruit, ripening the second fortnight of August. The tree is moderately vigorous on the Quince, very fertile even in early age. In cultivation this variety, vigorous on the natural stock, is suitable for the fruit garden under all forms and in all exposures.

DOYENÉ BLANC (*syns.*, *Beurré Blanc*, *Beurré Blanc d'Automne*, *Bonne Ete*, *Carlisle*, *Citron de Septembre*, *De Linton*, *De Neige*, *Doyenné du Seigneur*, *Saint Michel*, *Valencia*).—Of ancient and unknown origin. The fruit is medium-sized, rounded, the stalk stoutish, short, straight, slightly inclined in a shallow cavity. The eye is medium-sized with connivent sepals set in a shallow, wide, and regular cavity. The skin is thin, unctuous, very smooth, citron-yellow, stippled and spotted brown, shaded orange on the sunny side. The flesh is white and distinct in aroma. A very good fruit, ripening September—October. The tree is of medium vigour on the Quince, of great and sustained fertility. In cultivation, though delicate, this variety succeeds in all forms, but requires a rich, well-drained soil and a good exposure, east or west for preference.

(To be continued.)

Strawberries President and Keens' Seedling.—The criticism on my note by "D. T. F." is more captious than useful, I think, for I mentioned the fact that my soil was "cold and ungenial." The precise locality I write from has little to do with the question, but if it interests "D. T. F." or any other reader, it is in West Suffolk, not far from the old town of Bury St. Edmunds, and very close to where my critic spent many years of his career. "D. T. F." wishes to know also what I found wanting in Keens' Seedling. First, it is not free bearing enough, plenty of fruit numerically being produced, but they are too small for my requirements, and I have to make the most of my ground. Again, though "D. T. F." apparently thinks otherwise, the flavour is not good, falling very far behind two favourite varie-

ties of mine—Monarch and Leader. Its constitution is not of the best, so though I regret to have to disagree with "D. T. F.," I must still go on growing what I find suits my soil best. I did not say that Royal Sovereign had superseded President and Keens' Seedling generally in the west. I said that a grower of my acquaintance had discarded President in favour of the large kinds, of which Royal Sovereign is typical. "D. T. F." seems to have read in my note some things that were not there and to have missed other sentences that were.—H. R.

ROSE GARDEN.

ROSES IN AUGUST.

GENERALLY speaking, August is a very dull month in the Rose season, but during the last two or three dry summers it has been more than usually wanting. It is true the Teas and Hybrid Teas and Chinas are rarely out of flower from June to November, but yet even with these there is a lull as it were during these dog days. It is not to place on record what is patent to every gardener that these lines are penned, but rather to offer a suggestion to remedy to a certain extent this dearth of blossom between the summer and autumnal display. What I would advocate is that a goodly number of the Tea-scented and Monthly Roses be planted as late in the spring as possible. I have found the third week in April none too late provided the plants had been, as it were, prepared for such planting. This preparation consists in either lifting plants already in one's possession or purchasing some new stock, and then carefully heeling them in under a north wall or hedge until the time for replanting, as already alluded to above. The heeling in must be carried out thoroughly. A trench should be opened about 1 foot deep and some nice fine soil must be in readiness to shake amongst the fibrous roots of the Roses. The roots, which are usually those of the seedling Brier, are often as long as Parsnips. It is a great mistake to mutilate them at this time of the year, reserving this operation until the spring. In heeling in, the roots must not be cramped in any way; consequently a good deep trench is advisable. Apart from the advantages accruing from this transplanting, we have the plants under our control more effectually should a severe winter set in. Nothing is better than earth as a protection from frost. I should not object to bury the plants in it if I could be sure when a hard frost was coming, but, unfortunately, one has such little warning; consequently the fine soil necessary is not always procurable. Where conditions of soil and climate are favourable to those Roses emanating from *R. indica*, I would not advise the whole quantity to be annually transplanted, but in order to obtain a goodly number of blooms in August, it would be better to purchase a sufficiency of plants for the purpose early in autumn and heel them in as advised, the established plants being taken in hand every third year; or, what is better, transplant a third of the total number every year, not for what I will term the August display, but in order to keep the plants in a healthy condition. I have great faith in this transplanting both for standards as well as bushes. It enables the grower to properly enrich the ground, and the aëration the soil perforce must receive is also beneficial. What a boon trenched land is in dry seasons! I have had ample evidence of it this summer, and I feel convinced that many of the insect and fungus pests would be in a great measure obliterated from our gardens if our Roses were more often rejuvenated by

triennial transplanting. No better evidence could be obtainable than a specimen pot Rose. In this case it is annually disturbed when repotted, and what fine specimens such plants will make, yielding quantities of good exhibition blossoms.

To be successful with late planting three points must be remembered. (1) Never allow the roots to be exposed to wind or sun. When about to plant take a few from the trench as required, keeping the roots well covered with soil or mats until wanted. (2) Trim the roots slightly, then dip them into some thin mud or, as it is technically termed, puddle. This puddle can be prepared by digging out a hole in the ground close by; throw into it some fine loamy soil, then add water until a moderately thin mud is produced. (3) Plant these Roses on a really good piece of land that has either been trenched not more than twelve months before or a few weeks previous to April, and when planting, work in some well-decayed cow manure. The plants are moderately pruned before planting. Beyond this little pruning is needed, and as soon as roots become active some fine strong growths will commence to break from the base of the plants that about the time stated are crowned with lovely heads of bloom, the more so if the surface is kept constantly hoed to conserve the moisture and occasional doses of water and liquid manure afforded. PHLOMEL.

Rose Celine Forestier.—I was very glad to see "Grower's" note (p. 95). Like him, I have often wondered Celine Forestier is not more grown. We have no Rose like it in colour, none more useful in season, and the free-and-easy method of culture and training seldom fails in producing a long succession of fresh and pleasing blossoms. It looks superb in a sheltered border or lawn, with plants of white Aimée Vibert in tall bushes or pyramids behind. I agree with "Grower" that it is often a mistake to grow Celine Forestier on a wall. It is often grown there because of its supposed tenderness. As a Noisette there is something in that, but it is less tender than the Maréchal or Lamarque, and with a free head to protect it it seldom takes any harm. In exposed localities Celine Forestier does well, and looks, perhaps, its very best running wild up Yew trees, the soft sulphur-yellow contrasting well with the dark green supporting branches of the Yew. In warmer beds and borders dwarf bushes, little or not at all pruned, yield a rich and long succession of soft golden blossoms.—D. T. F.

Rose Caroline Testout.—Those who have only seen this Rose at shows shorn of its buds are probably at a loss to understand why it is praised so much, but they have only to see it growing as a bush, pillar, or standard when they will come to the conclusion that not one word too much has been advanced in its favour. I have never seen a really good bloom of it staged. Its form is somewhat against its general adoption as an exhibition flower, although it was much in evidence this year at the Crystal Palace Rose show, there being on that occasion something like 170 blooms exhibited. Only one other Rose was shown in greater numbers, and that was Mrs. John Laing, with 370 blossoms to its credit. The lover of garden Roses cares very little about form. He can appreciate the vigour of growth, the delightful tint of salmon-pink colour, the easy disposal of the exquisite and immense shell-like petals, and the profusion and continuity of blossom. It is a pity this Rose is not more fragrant. There is a perfume, but nothing like that of our ideal sweet-scented variety La France. Caroline Testout is grand as a pot Rose. Under cool treatment its blooms develop so slowly that they assume very large proportions, equal in this respect to any variety cultivated. It will probably stand out as the Rose of the decade, and is

likely to have many descendants, for raisers are already obtaining from it some interesting hybrids.—P.

NOTES AND QUESTIONS.—ROSES.

Rose Tennyson.—I was pleased with this fine novelty as shown at the hybrid conference at Chiswick. Not even in the torrid heat or the extra trial of being staged in a conservatory did its flowers exhibit signs of fading. Towards evening they appeared almost as fresh as they did in the morning. There are not many Roses that can stand such extreme heat, and it speaks volumes for the value of this Rose to the exhibitor. The flowers are of a lovely pearly white shade and the form superb, the outer petals pointed and the centre high and globular.—VISITOR.

Rosa anemonæflora.—Distinct both in leaf and flower, this is certain to have many admirers. The foliage is elegant, long, lance-shaped and of an ashy-green colour. There are many Roses worth growing for their foliage alone, such as *R. lucida*, *R. Watsoniana*, &c., and the above kind might be included, but it has also a very interesting Anemone-shaped flower, pure white in colour but very small, not larger than a sixpence. This variety grows well and is almost a climber. I cannot pronounce upon its hardiness. Coming from China, it may be too tender for our climate outdoors in winter.—P.

Rose Robert Duncan.—The weakest point in this is perhaps colour. This is usually a shade known as rosy lake, but at times, especially early in the season, the older flowers assume a rather objectionable dull magenta tint. Perhaps this defect is owing to the season. This Rose grows well and produces a splendid truss of bloom upon each shoot, averaging as many as ten buds and blossoms. This is rather unusual for a Hybrid Perpetual, and I imagine that there must be some Tea blood in the variety, for at the base of the petals a distinct yellow shading is visible. As to form, Robert Duncan resembles a *Camellia*.

Rosa Wichuriana.—Although this is a creeping Rose, it nevertheless makes a delightful pillar variety. During the first fortnight of August the plants flowered most beautifully, having the appearance of the pretty single white Macartney Rose. A lovely feature would be to train *Rosa Wichuriana* over an old tree stump or conical-formed mound of roots in a conspicuous part of the grounds. The tiny shining Berberis-like foliage looks cheerful at any time, but when the white star-like flowers are open the foliage and flowers contrast most happily. It is yet too early to speak of the hybrids of this Rose. They grow most luxuriantly, and if they only flower as well they will be valuable.

Rose Sir Rowland Hill.—This sport from Charles Lefebvre was thought much of when it received the gold medal of the National Rose Society about ten years ago. It is true the colour is very novel, a rich velvety plum shade, but there is a tendency in the older blooms to die off a dull purple that is not at all pleasing. Towards autumn, however, this variety becomes less purple, then it is most beautiful. If one cares for this shade of colour I think he would find Jean Cherpin more interesting, and it yields some lovely buds when it first opens. For exhibition Sir R. Hill is useful, being very distinct, and when the season is suitable to that grand dark variety Charles Lefebvre, the Rose under notice is sure to be in fine form.—P.

Red Rosee for Christmas.—These would certainly be highly valued at such a season, and it is quite possible to have some provided one has plants established in pots. The best kind to grow to give long stems is Ulrich Brunner. The plants should now be dried off for five weeks and pruned at the expiration of that time. A steady temperature should be maintained at first, increasing it as the plants advance in growth. Do not set the plants too thickly together, for during November and December all the light available must be given, removing the plants to a lean-to house with a southern aspect for this purpose. Gardeners should put up a lot of this Rose in October. They would come in useful at different periods of the year, but at no time are red Roses so much prized as at Christmas.—A GROWER.

Rose Duchesse d'Auerstadt.—This splendid climber, more vigorous than *Rève d'Or* if that were possible, although not such a profuse bloomer, is very valuable for its intense yellow colour. The buds are pure yellow when opening, but the full-blown flowers have a large amount of nankeen-yellow pervading the centre petals, and the outer ones are of a

peculiar shade known as citron-yellow. When growing luxuriantly the foliage is very handsome and glossy. In favourable localities this fine Rose should find a place either on a south or west wall, preferably the latter, but I fear it would be too tender for a very cold district. Mons. Pernet-Ducher has utilised Duchesse d'Auerstadt as pollen parent for his new Rose Billiard at Burré. It seems a very promising climber, the seed parent being the Hybrid Tea Alice Furon.—P.

KITCHEN GARDEN.

WINTER CUCUMBERS IN POTS

MANY are unable to grow winter Cucumbers, and if they are grown for profit it is certainly a crop I would fight shy of, as the produce is uncertain. Having to provide Cucumbers all the year round, I have tried various ways, but so far my greatest success has been obtained by pot culture. I do not advise pots in all cases. Mine succeed because I have a peculiar climate in the winter and much moisture in the shape of fogs, and very little sunshine. By getting the pots full of roots by say the end of October I can in a measure be independent of the weather. No matter how winter Cucumbers are grown, I find it essential to secure a strong plant before the short days come in.

For winter work there is less choice of varieties than in summer, and so far I have found Syon House and Telegraph reliable. The latter is the better shaped fruit, longer and smoother, but not superior as regards cropping or quality. This year I hope to give the new Every Day Cucumber a trial. This was shown well last winter and promises to beat the useful Telegraph. Cardiff Castle is also an excellent winter fruiter and very prolific. Many prefer it. Some large growers have selections or crosses from good kinds that are known to do well. The raising of the plants should not be deferred long after August is in, as there should be a fair season's growth before fruiting commences. I raise two sets of plants. One I crop freely in the early autumn, and from the other I take but few fruits till November. This allows of the trellis being well filled with wood. When I begin to feed in the late autumn the plants respond quickly and fruit through December to March—the most critical period of the year. Of course, for the early autumn supply pot culture is not advised, but much depends upon the locality and the houses. I do not use large pots; 12-inch are sufficient. These I plunge in a warm manure-bed in addition to hot-water pipes, as I find the manure encourages new surface-roots, and so long as these are produced freely the growth is strong and fruitful. The plants raised now will be ready to place in their fruiting pots a month hence—that is early in September. The pots are stood in position over the pipes on some thick turf-sods, and a little rough rubble placed directly over the pipes. The pots are about half filled at the start, and the materials are added to as growth increases. This is much better than having the soil nearly up to the rims, as the new roots made are surface-roots. By the end of October some rough turf may be placed round the pot rims just on the edge and new materials or surface-dressings given. I also grow some plants on a shelf at the back of the house. These have no bottom-heat whatever. The crop from these is valuable, as when fruits are needed daily they are acceptable. Strange to say, these plants near the roof with much less heat pull through a long period of fog better than those in a better position. This I attribute to their having been grown with more exposure and more air. For

these I use 10-inch pots, this size being ample. I find a high night temperature harmful, especially in foggy weather; indeed then I lower the day temperature also. Seventy degrees is a good day temperature in midwinter, with 5° to 10° lower at night in severe weather. In pots a short-jointed growth is secured. The best food I find is liquid manure, with alternate supplies of soot water. Avoid crowding the growth at the start, it being an important point to get well regulated leaders to cover the allotted space, as from these later shoots in abundance will be needed to keep up a succession of fruits. G. WYTHES.

Pea Sharpe's Queen.—I fully agree with the remarks of "H." (page 76) on the merits of this fine, but I think by no means generally known Pea. When living in South Notts I used to see very fine samples of it at the various local exhibitions. It was very much grown by cottagers, which is pretty good proof of its profitability. I grew it myself, and found it not only first rate as regards cropping, size and handsomeness of pod and flavour, but of just the height and habit of growth most gardeners like. As "H." says, it is of very branching growth and must not be sown too thickly. Sharpe's Queen is, I believe, a great favourite throughout Lincolnshire, and I remember judging at one cottagers' show where there were probably a couple of dozen dishes of it exhibited.—J. C.

Tomatoes for market.—The present season has thus far been very favourable for the Tomato. I do not remember a season when the demand has been so brisk, that is, if the Tomatoes are of the right kind for sale. Unlike many other crops, the very large fruits are not nearly so much in demand as the medium-sized fruits. The purchasers want bright crimson Tomatoes, of smooth outline, rather under than over a quarter of a pound each. Those who have this class of Tomato have lately had a difficulty in supplying customers, while those who have large, coarse fruits have a difficulty to find purchasers even at a lower rate. Those who have grown the much-vaunted Peach Tomatoes, or yellow-skinned ones, can hardly get purchasers at all. The one thing that Tomatoes need to ensure good crops, in addition to bright sunshine, is fresh soil, for they do certainly take all the nourishment out of it to such an extent that simply digging in a lot of manure, as one does for other crops, does not have the desired effect. Outdoor crops are doing well, and I am getting some well-coloured fruit from warm spots. I find that Tomatoes set their fruit and keep much healthier, even in such dry seasons as the present, with very little artificial watering, for they have such voracious roots, that they seem able to extract every particle of nourishment from the soil for some long distance around the stem, the roots being nearly as strong as whipcord.—J. G., Gosport.

NOTES AND QUESTIONS.—KITCHEN.

Potato Carter's First Crop.—Anyone requiring a first-class short-topped early Potato should try the above. I have grown it for two seasons and have been highly pleased with it. Another season I intend it to take the place of Ringleader.—T. COCKERILL.

Potato Ninety-fold.—This Potato is turning out well with me this season. There is an excellent crop of large tubers, and when cooked they are everything that could be desired. The only fault that I have to find with Ninety-fold is its having such a strong t.p. This season it has made a growth 3 feet high.—THOS. COCKERILL, Wirksworth, Derbyshire.

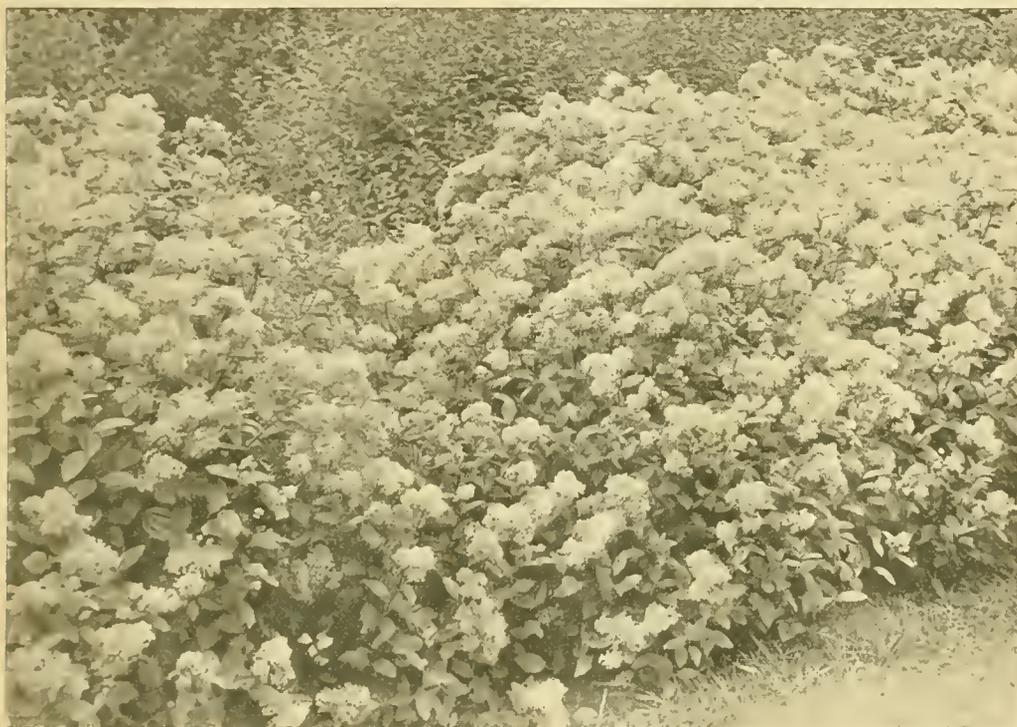

A dwarf Ne Plus Ultra Pea.—"J. S." and no doubt other readers will be glad to hear that there is a dwarf wrinkled Marrow Pea—the East Anglian, growing about 2½ feet—yielding capital Peas equal to Ne Plus Ultra, a Pea that has not been beaten for produce or quality. Any East Anglian seedsman could supply it true, and in fertility and quality it is so identical with Ne Plus Ultra as to be sold for the dwarf strain of the same.—D. T. F.

TREES AND SHRUBS.

CEANOTHUSES.

ALTOGETHER there are between thirty and forty species of *Ceanothus* known, all of which come from the New World and to the north of the Isthmus of Panama. The greatest aggregation of species occurs in California, whence most of the showier species at present cultivated in the British Isles have been obtained. There the *Ceanothuses*—according to Professor Greene, a well-known authority on the flora of Western North America—constitute a large part of that “almost impenetrably dense brush-wood called ‘chapparal’ which covers the middle elevations of the Coast Range and forms a distinct belt between the herbaceous vegetation of the foot-hills and the forest growth of the highest ridges and summits.” Thus they constitute, especially when in flower, one of the most striking and characteristic features of

The flowers of all the *Ceanothuses* are individually very small, but they are densely crowded on numerous racemes. A curious feature of the flower is the petals. These are narrowed to a stalk at the base, but the outer portion has the shape of a hood. *Ceanothus* is one of the comparatively few genera in which species with alternate and others with opposite leaves occur. The venation of the leaves is also a character that is used to differentiate the species; in one set the leaf is feather (or pinnately) veined, whilst in another it is distinguished by three prominent veins running lengthwise. The greater part of the *Ceanothuses* are not strictly hardy even as far south as Kew, but all those mentioned below can be grown on a sunny wall. Even then a winter occasionally comes which severely injures the more tender ones. The requirements of *Ceanothuses* under cultivation may, indeed, be inferred from the fact that most of them come from California. They revel in abundant warmth and sunlight, which is why under our

A group of *Ceanothus americanus* in the Royal Gardens, Kew. From a photograph by Geo. Champion.

the Californian flora. But the genus is represented also on the eastern side of the continent, and reaches as far south as Guatemala. What is, perhaps, the most useful of all the species (*C. azureus*) is one of the few shrubs native of Mexico that can be grown in the open air in England. All the cultivated species are shrubby, although two species (*thyrsiflorus* and *arboreus*) are occasionally met with in a wild state as trees, and they are included as such in Sargent's “*Silva of North America*.” As garden plants *Ceanothuses* are valuable for the distinct and delicate beauty of their flowers; being mostly of some shade of blue, they provide us with one of the rarest colours among hardy shrubs. They are valuable also for the season at which some of them flower. Of the shrubs in bloom at the present time (early August), the genus *Ceanothus* certainly furnishes some of the most beautiful ones.

duller skies they are seen at their best on a sunny wall. At the same time, *C. azureus* and *C. americanus*, as well as the valuable race of garden forms that have been raised from them by selection and intercrossing, thrive admirably in the open, and are very useful for planting in large beds or masses. Those species and varieties that flower in spring or early summer should be pruned back as soon as they are out of bloom. The later autumn-flowering ones should be pruned in February. All of them can be increased by cuttings or layers.

The following is a list of the species here mentioned. It includes most or all of those likely to be of value in gardens here, although others have been introduced. All except those marked * should be given wall treatment in districts with a winter climate similar to that of Kew.

I.—OPPOSITE LEAVES.

**Cuneatus* *Rigidus*

II.—ALTERNATE, THREE-VEINED LEAVES.

**Americanus* **Ovatus*
**Azureus* *Thyrsiflorus*
Divaricatus *Velutinus*
Integerrimus

III.—ALTERNATE, PINNATE-VEINED LEAVES.

Dentatus *Veitchianus*
Papillosus

C. AMERICANUS (New Jersey Tea).—Coming from the eastern side of North America, this species naturally became known to European cultivators sooner than those of the western side. It was, indeed, the first *Ceanothus* seen in Europe, and, according to Aiton, was introduced in 1713. As an ornamental shrub it does not equal the best of the garden varieties and hybrids, which have, however, been partly derived from it. Still it is not without beauty, flowers freely, and is quite hardy. It grows 3 feet to 4 feet high, and has ovate or heart-shaped, three-veined leaves 2 inches to 3 inches long, downy beneath, and toothed at the margin. The flowers are of a rather dull white, and are crowded on long-stalked racemes that spring from the leaf-axils near the ends of the branches. It flowers from the latter part of June till the beginning of September, and has an extensive distribution in Canada and the Eastern United States, frequenting open woods. During the revolutionary war the American troops drank an infusion of its leaves, which possibly gave rise to the popular name by which it is known. *C. ovatus* (or *C. ovalis*) is nearly allied to *C. americanus*, but has smaller, more glabrous leaves, these being each 1 inch to 2 inches long, narrow oval, and not heart-shaped at the base. Flowers white. A native of Eastern N. America.

C. AZUREUS.—On the whole it may safely be said that this species, if not the handsomest, has proved in Europe to be the most useful and important of all the wild *Ceanothuses*. It is quite hardy in the south of England, and to its influence more than to that of any other species is owing the beauty of the numerous garden varieties that have been raised, chiefly by the continental growers. It is a native of Mexico, where it is widely spread, one of its sites being the slopes of the volcano Popocatepetl. It is said to attain a height of 10 feet, but I have not seen it so high in the open ground; as a rule it ranges from 3 feet to 5 feet, forming a compact bush. The flowers, of a charming light blue, are densely arranged on long racemes. In general appearance it bears a resemblance to *C. americanus*, but even when out of flower it can be distinguished from it by the smaller oblong leaves, those of *C. americanus* being ovate and much the broadest towards the base. Under this species may be mentioned the garden varieties, which, as stated, have been in a great measure raised from it and *C. americanus*, either by selection or by hybridising with each other or the Californian species. Many of these varieties (of which there are scores already named) are great improvements on either *azureus* or *americanus*, and the flowers vary in colour from white to blue and rose. Some are dwarfier; others have finer foliage. They flower between June and September.

C. GLOIRE DE VERSAILLES.—This is one of the best and hardiest of *Ceanothus*, and at present perhaps the most popular. It is a seedling from *C. azureus* raised by Mons. Christine, of Versailles. It bears large clusters of rich blue flowers over a long season, and has fine foliage and a vigorous habit.

C. VIRGINAL.—Not so strong a grower as some, this is useful for the whiteness of its flowers, which are purer than in any other variety I know.

C. SCEPTRE D'AZUR.—A strong grower, with fine foliage and spikes; blue.

C. CERES AND *C. CARMEN*.—Both raised by Lemoine, of Nancy; rose coloured.

The names of Lemoine, of Nancy, and Simon-Louis frères, of Metz, are most prominent in connection with the raising of new *Ceanothuses*. Their catalogues should be consulted by intending planters.

C. CUNEATUS.—Except that it is quite hardy and evergreen, there is little to be said in praise of this species as a shrub for our gardens. In those parts of California where it most abundantly appears to be a pest. According to a Californian writer in *Garden and Forest* (Mr. G. Hansen), "it clothes hillsides for miles and gives them a greyish green tint. Wherever man has done any cultivating, cleared an old wood-road, cut a trail, ploughed a furrow in years past, or still keeps cultivating, this *Ceanothus* follows him like the Nettle or Chickweed." In a similar way *Coriaria myrtifolia* (which needs some care in this country) is the first plant to overrun the terraced vineyards of Southern France when they are abandoned. *Ceanothus cuneatus* is an erect, rather straggly-branched shrub 4 feet to 6 feet high. The leaves are opposite (one of the few instances in this genus), half an inch or so long, wedge-shaped, rounded at the apex, and of leathery texture. The flowers are in short corymbs and are dull white or slightly tinged with blue.

C. DENTATUS.—Although allied to *C. papillosus* (being one of the species whose leaves are alternate and pinnately veined), this is distinguished by its leaves being smaller (quarter of an inch to 1 inch long), not warty, and in their margins being more revolute. The flowers, of a somewhat brighter blue, are in smaller roundish clusters. It blooms in May and June. William Lobb introduced it from California for Messrs. Veitch about fifty years ago, and it was figured in the *Botanical Magazine*, t. 5810, as *C. Lobbianus*, but as in several other instances where plants were named in honour of that fine collector, this name had to give place to an earlier one.

C. DIVARICATUS.—Like several other fine *Ceanothuses*, this species first reached cultivation by means of the Horticultural Society, seeds having been sent to the garden in 1841 by Mr. R. B. Hinds, at one time a surgeon in the Royal Navy. It is a native of California, from the extreme south of which State it extends northwards up to Oregon. It is a nearly glabrous plant, and has oblong-ovate, three-nerved, very glossy leaves that are half an inch to 1½ inches long. The flowers appear in slender racemes 1 inch to 4 inches long, and are pale blue or almost white. It is said to grow 10 feet high at Monterey, in California. In this country it has to be given the shelter of a wall. On an old wall at Kew it is quite 10 feet high, and its stem near the ground is quite 6 inches in diameter. It blossoms in May and June.

C. INTEGERRIMUS.—Discovered by David Douglas in 1833, this species appears not to have reached cultivation until about twenty years after. It was, at any rate, raised from seed by the Royal Horticultural Society, and flowered at Chiswick in 1856. It is a native of the Sierra Nevada of California and other parts of Western North America. It is said to average about 10 feet high in California; here on a wall it is somewhat dwarfed at present. Its branches are terete (in some of the *Ceanothuses* they are distinctly angled), and the short-stalked, dull, glaucous leaves are each 1 inch to 3 inches long, three-nerved, ovate or oblong, the margins not toothed. The flowers are in cylindrical or roundish clusters, a number of which go to form a large panicle, terminating each branch; they are white or tinged with blue, and appear in June. It is not so hardy as *azureus*, but still survives all but the very hardest frosts if given a sheltered spot. In some parts of California it is known as the Deer Bush, owing to the deer-feeding on it when driven down from higher altitudes by stress of weather.

C. PAPILLOSUS.—Like the preceding species, this was discovered by Douglas in California, but it was later introduced by Wm. Lobb when collecting for Messrs. Veitch. It is a very distinct *Ceanothus*, and although not hardy in the open it is a singularly beautiful plant for a wall. There is on a wall at Kew a magnificent specimen 10 feet high and 20 feet in diameter, which is a glorious picture every year in May and June. Its branches are very downy and hairy, and its leaves are pinnate-veined, narrow-oblong, half an inch to 2 inches long, and render the species distinct by the numerous wart-like excrescences on the upper surface. Their dark green and very lustrous upper surface makes the shrub handsome and striking at all times. The flowers are clustered densely on short racemes and they are of a charmingly delicate blue. The species inhabits the coast ranges of California from Monterey to San Francisco.

C. RIGIDUS.—Although belonging to the same group as *C. cuneatus* and having, like that species, opposite leaves, this is a much more beautiful shrub. On the other hand, it is not so hardy and needs the shelter of a wall. It is a plant of erect growth with rigid, woolly branches and short, stiff, wedge-shaped or obovate leaves a quarter of an inch to half an inch long, coarsely toothed at the broad apex. The flowers are of a fine purplish-lilac, and appear on short, but numerous clusters during April, May, and June. Hartweg when collecting for the Horticultural Society was the first to introduce this *Ceanothus*. It had, however, been previously noticed by David Douglas. It is a Californian species, and, like several others, is abundant near Monterey. It is one of the most distinct in general appearance. At Kew it is represented by a specimen 7 feet high growing against a wall.

C. THYRSIFLORUS (Californian Lilac).—Of all the species that we can grow out of doors in England this is the one that attains the greatest size in a state of Nature. It is described as sometimes a shapely tree 25 feet or more in height. Climatic conditions will prevent it assuming more than shrubby dimensions in this country (except perhaps in Cornwall and such like places), but it will cover a high wall, and even in the open grows with remarkable freedom till a frost comes that is too much for it. It was discovered by Eschscholtz in 1816, and was introduced in 1837 by the Mr. R. B. Hinds already mentioned. It is a native of the coast ranges of California from Humboldt County to Monterey. Its branches are distinctly angled, and the leaves each three quarters of an inch to 1½ inches long, three-veined, strongly toothed, smooth and glossy above, greyish beneath. The flowers, of a charming bright blue, make a display from June till autumn; they are borne densely on compound racemes. To be safe, wall space should be afforded this plant.

C. VEITCHIANUS.—This is one of the very finest of the Californian *Ceanothuses*, but seems to be one of the rarest, for although introduced by W. Lobb when collecting for Messrs. Veitch upwards of fifty years ago, it is still unknown in a wild state. Of the other species here mentioned it comes nearest to *C. papillosus* and *C. dentatus*, having alternate, pinnate-veined leaves. These are, however, shorter and comparatively broader than in *papillosus*, not warty, and from half an inch to 1 inch long. The upper surface is smooth and lustrous. The flowers are of a bright blue, and come in dense clusters on the end of the short lateral branchlets. So abundant are they, that on a plant in full flower scarcely any leaves are visible. A wall is needed to grow this species satisfactorily.

C. VELUTINUS.—A species rare in gardens, but grown and flowered by Mr. Gumbleton near Cork. It has large ovate leaves, whitish beneath and three-veined. The flowers are whitish and borne in large panicles. It comes from California and Oregon, and is one of the more tender species. Both Douglas and Lobb sent it home.

Arboretum, Kew.

W. J. BEAN.

TREES AND SHRUBS IN BLOOM IN JULY.

ABUTILON VENILLARIUM grown against a wall has been bearing a profusion of its crimson, yellow-centred flowers, from which the maroon anthers protrude, on its slender arching shoots, and at the commencement of the month *A. vitifolium* had not entirely passed out of bloom. When grown in sheltered spots, as large pyramids 8 feet and more in height, the lavender and white-flowered varieties form charming pictures in the zenith of their beauty. The common Barberry has been thickly set with its golden blossoms, and the Strawberry Tree (*Benthamia fragifera*) was covered with its pale yellow flowers in the early days of July. The Allspice Tree (*Calycanthus*) has also come into bloom, and *Carpenteria californica* has borne its fragrant white blossoms well into the second week of the month. *Ceanothus Gloire de Versailles* is a cloud of palest blue, and many of the *Cistuses* have expanded hosts of their too fleeting flowers. *Crategus Pyracantha*, trained on cottage walls, has been covered with its white flower clusters, and the Golden Broom has gleamed brightly from the shrubberies throughout the month. *Desfontainea spinosa* has borne its pendent scarlet tube flowers amongst its Holly-like leafage, and the double *Deutzia crenata* has been white with blossom. Tall specimens 10 feet in height situated among deciduous trees along the margins of drives or standing in open glades are charming sights when enveloped in their snowy flower mantles. *Dracena australis*, though usually perfecting its inflorescence in June, was in some cases in full beauty at the commencement of July. Its fragrant flower-spikes are much appreciated by the bees, whose murmurous song pervades the surrounding air throughout the sunny hours. The Fire Bush (*Embothrium coccineum*) retained a few vermilion flower-clusters until the second week of the month, and plants of the Heath-like *Fabiana imbricata* have been pyramids of white bloom. Bushes of the *Habrothamnus* have flowered in the open, and *Hydrangea paniculata* is perfecting its massive, cone-shaped blossoms. In a particularly favoured garden *Indigofera Gerardiana*, *Metrosideros robusta*, *Piptanthus nepalensis* and *Swainsonia albiflora* have flowered. *Kalmia latifolia* has borne its clusters of flesh-white, cupped blossoms, and the Jew's Mallow (*Kerria japonica*), both single and double, are still producing flower. The double form is the general favourite, and may be seen blooming in mild winters almost up to the close of the year in cottage gardens, but the single variety carries off the palm in the grace of its simple flowers. Myrtles are white with blossom and the Daisy Bush (*Olearia Haasti*) is rapidly hiding its foliage beneath its myriad expanding star flowers. An Oleander that has lived for three winters in a sheltered nook in the open is bearing its first rosy blossoms. A specimen of *Ozothamnus* that I received a few years back as *O. thyrsoides*, but which appears identical with *O. rosmarinifolius*, has now grown to a height of over 6 feet and has been a mass of fragrant white blossom, so thickly set that in the upper portion of the bush no leafage was discernible. Its flowers have the merit of retaining their freshness for a lengthened period, the inflorescence of the subject in question remaining decorative for quite three weeks.

Of the Syringas, the charming *Philadelphus mexicanus* perfected its small cupped blossoms early in July, when the large-flowered *P. speciosus* with snowy flowers over 2 inches in diameter was at its best. The New Zealand Flaxes (*Phormium tenax*), both in the green-leaved and variegated forms, have thrown up their giant flower-stems in many gardens, and in a sheltered spot the odorous *Rhynchospermum jasminoides* has been in bloom. The *Kerria*-like *Rhodotypos kerrioides* has continued to produce its single white blossoms, and the Venetian Sumach or Smoke Bush (*Rhus Cotinus*) is in bloom, and will soon enter upon the period when the feather-like

clusters that succeed the inconspicuous flowers will assume their attractive purple tint. Of the shrubby Spiræas, *S. Lindleyana* came into bloom in the third week of the month, followed before its close by *S. arifolia*, whose blossoms last in perfection a much longer period than do those of the former species. It is only when these subjects are allowed to assume their rightful proportions and to grow, unhampered by encroaching evergreens or other shrubs or trees, in deep, moist soil that a just appreciation of their natural beauty can be arrived at. When growing in isolated positions under favourable conditions they will, in the course of a few years, attain a height of 12 feet with a branch spread of 18 feet or 20 feet, and form exquisite pictures when every spray is tipped with an ivory-white plume. *S. flagelliformis*, a much earlier bloomer, was passing out of flower at the commencement of the month, when *S. bella* and varieties of *S. japonica*, such as *Bumalda* and others, were at their best. Great trees of Portugal Laurel, between 20 feet and 30 feet in height and more in diameter, were early in July smothered in their sickly sweet, white bloom-sprays, and are now decorated with flowering trails of Traveller's Joy (*Clematis Vitalba*). The Tulip Tree (*Liriodendron tulipifera*) in the early days of the month still held a few fresh blossoms of tender fawn and green, and the Weigelas were then still flower-laden. *Veronica Traversi* is a mass of pale lavender bloom spikes, while early in July the Japanese Guelder Rose (*Viburnum plicatum*) in partially shaded spots still held its snowy flower-balls. The great standard Magnolia is daily producing a fresh supply of its ivory-white perfumed chalice, and while it sweeps the ground with its lower branches has made such growth in its top-most boughs as to obliterate the disastrous effect of the blizzard of 1891 to all but those cognisant of its appearance anterior to that date.

Torquay.

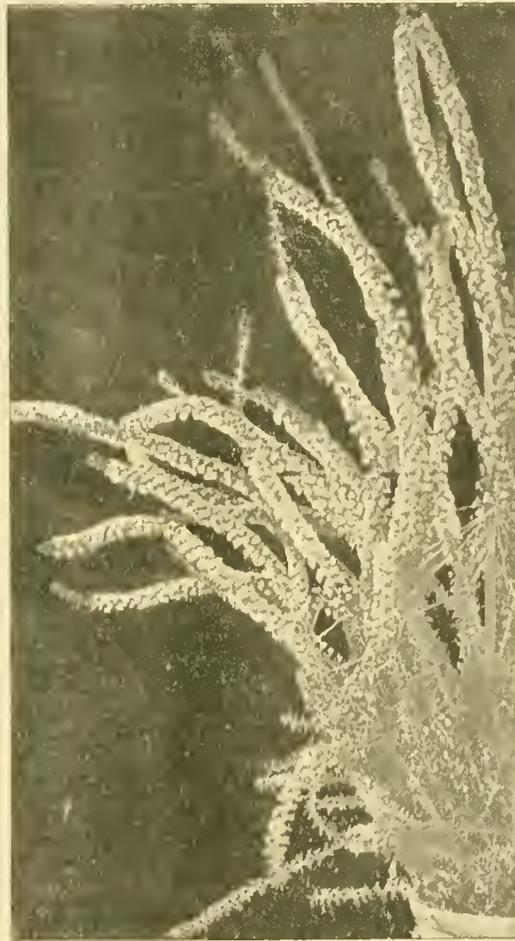

S. W. F.

BUDDLEIA VARIABILIS.

IN 1894 M. Maurice de Vilmorin first introduced this shrub to the National Society of Horticulture of France as the result of some seed he had received from China, the sender being the Abbé Soulié. In the same year the species was described under the name of *Buddleia variabilis* by Mr. Hemsley, of Kew, in the Bulletin of the Linnean Society. In 1895 the *Revue Horticole* described in terms of eulogy a specimen cultivated at the City of Paris School of Arboriculture at Saint-Mandé. In the same journal in 1896, in describing some flowering specimens I had seen at Barres belonging to M. de Vilmorin and in M. Micheli's garden at Crest, I foretold that the plant would quickly make its way. Its vigour, fine leaf, and its numerous clusters of pale lilac flowers, lasting in succession throughout the summer, have, in fact, won for it favour. In 1898 an article appeared by M. de Vilmorin, accompanied by a coloured plate and an engraving, which enabled one to form a definite idea of the plant.

B. variabilis, despite the vigour of its vegetation, continuity of its bloom and the facility with which it is propagated by cuttings, is not so frequently met with in gardens as it deserves to be. One of the principal causes of this is that the flowers are open to the reproach of being a little pale. Nevertheless, I consider them to be more delicate in form and tone than those of *B. curviflora*; the habit also is more elegant. Without having the fine deep violet of the flowers of *B. Lindleyana*, as a shrub it is decidedly superior to it. The branches of *B. Lindleyana* are too fragile and often ungainly. Some recommend a rather short pruning for *B. variabilis* in order to obtain larger leaves and finer flower-clusters. With my own plants at Lacroix I have tried the direct contrary plan, *i.e.*, not pruning at all. The result has been a great number of branches and of blooms. At the extremity of every branch a well-formed cluster develops and flowers from base to summit. The flowers wither without falling. The faded cluster is cut away and is immediately replaced

by those of the two lateral branches which accompany the terminal inflorescence. This is a sort of dichotomous pruning, to be carefully renewed every time the flowers fade. My object now is to call the attention of gardeners to the possibility of hybridising this shrub with another, a description of which and coloured plate have appeared in the *Revue Horticole*. I refer to *B. Colvillei*, without doubt the handsomest species of the race; its large rose-coloured corolla has the happiest influence upon species hybridised by its means. The plant is now in my possession. I received some from Mr. Gumbleton, and have distributed them among a few friends. The plant which I gave to M. Micheli is now superb, but it has yet to flower. He will not fail after it has flowered to cross it with *B. variabilis*, which is so perpetual flowering. M. V. Lemoine likewise possesses, or should possess, a plant, and no

Part of a plant of *Acacia cordata*. From a photograph by Mr. G. Pim, Dublin.

doubt will strive to be the first in this hybridising race. I once saw in the Cordilleras of the Andes, on the high plateaux of Ecuador and Columbia, in soil said to be fairly cold, numerous fine species of *Buddleia* not as yet introduced into Europe. What handsome shrubs they would make in our gardens were it only on the Mediterranean coast! *Buddleia verbascifolia*, *B. hullata*, *B. calycina*, *B. Jamesoni* inhabit those regions, and then there are the *B. grandiflora* of Brazil and those of Chili and of Peru, the native land of *B. globosa*; those of Argentina, and even of Madagascar, which gave us the beautiful *B. madagascariensis*. Let us hope we shall one day see all these handsome shrubs in our collections.—ED. ANDRÉ, in *Revue Horticole*.

STOVE AND GREENHOUSE.

ACACIA CORDATA.

THE pretty little *Acacia* here depicted does not seem to be very much known, but is, I think, destined to become a favourite. It blooms profusely in a very small state, and can be readily kept in bounds by cutting back, although naturally the shoots are somewhat long. The flowers differ from those of most of its congeners in being nearly white, so pale is the yellow. The leaves are very curiously shaped, cordate, with sharp, almost prickly points, and closely set along the stems. G. PIM.

Cyrtanthi in flower.—Treated as greenhouse bulbs, many of the small-growing species of *Cyrtanthus* flower freely quite early in the year. Of these small kinds, especially mention must be made of *C. Mackeni*, white; *C. lutescens*, pale yellow; *C. angustifolius*, light red; and *C. Macowani*, crimson-scarlet. They all need the same treatment, that is, growing in deep, well-drained pans or pots, the soil consisting of a good sandy loam. They do not require any drying off, as many bulbs do, though, of course, during the winter less water is required than at any other time. They will stand for years without being rotted, and given much the same treatment as a *Pelargonium* will do well. Seeds ripen freely, and seedlings make such headway, that if grown on without a check, many of them will flower in about eighteen months.—H. P.

Ivy-leaved Pelargoniums for cutting.—I find some of the newer varieties of this section very useful for furnishing cut blooms. If they are grown along freely through the summer, getting them into 6-inch pots by the middle of August, they will furnish a lot of bloom in the following spring if wintered in a temperature of from 45° to 55° according to the weather. If shifted into 8-inch pots in May they will make large specimens, and it is surprising what a quantity of fine trusses can be taken from them if they are supplied with liquid manure once or twice a week from the time they become root-bound. The older kinds had foot-stalks too short to allow of their being serviceable for cutting, but varieties that have been raised within the last few years have foot-stalks long and stout enough for any purpose for which cut flowers are required. The double kinds are, of course, much the best.—J. C. B.

Clerodendron fallax.—Young plants of this *Clerodendron* grown on freely without stopping, and each carrying one large head of bloom, make a goodly show at any season of the year. It is a native of Java, and is consequently a stove plant, but at this time of the year it may be kept in a cooler structure. In the greenhouse the flowers last longer than under any other conditions. It is very easy of increase, as cuttings strike root readily, while seeds are often produced. They germinate quickly, and treated liberally make rapid progress afterwards. A nearly allied species whose ornamental qualities are about on a par with those of that just mentioned is *C. Kämpferi*, of which a coloured plate was given in THE GARDEN, December 24, 1892. This is quite an old plant in gardens, having been introduced about 100 years ago.—H. P.

Streptosolen Jamesoni.—This is a fine plant either for the conservatory or for summer bedding. To flower it well it requires to be grown

where it is well exposed to the sun, and it is not until the wood is well matured that it will bloom well. Old cut-back plants started early in the spring soon come into bloom, and continue well through the season. Some time ago I saw several good plants in bloom in the conservatory at Offington, and I find it has been flowering well in the Worthing Park. These plants are about 3 feet high, and when I saw them a few days ago they were full of flower and seemed likely to continue for the rest of the season. I understand they have been flowering for upwards of a month. This useful plant is easily propagated from cuttings, but these do not flower well the first year; at least that has been my experience. Given the same treatment as Bouvardias they grow freely, but give very little flower the first year, while the older cut-back plants bloom freely from every shoot.—H.

Hedychium coronarium.—This is now flowering in the stove at Mr. Goodliffe's nursery, Worthing. The plants are grown in 8-inch pots and have several strong growths in each, most of which are flowering this season. The terminal clusters of pure white flowers are very pretty, and emit a most pleasant perfume. The above and *H. Gardnerianum* are both well worth a place where room can be given. They succeed best perhaps when planted out, and to ensure flowering when grown in pots they must be divided from time to time before they get too much crowded, otherwise they do not make growths strong enough for flowering. They may be potted or planted in good rich loam with leaf mould and manure added, and during the time they are making their growth they should be liberally supplied with water. They may be kept cool and dry during the winter. When given a period of rest they flower better than when kept in heat throughout the year. The flowers, though not long-lived, are very beautiful.—SUSSEX.

Allamanda grandiflora.—The habit of this species is quite different from that of *A. Schottii* and similar kinds, and it is better fitted for growing into loose bushes than for climbing over roofs or trellises. The shoots are more twiggy and shorter, the flowers smaller and paler yellow, making a welcome change from the deep yellow large blossoms of *A. Schottii*. The plants do best in a good sound yellow loam with a little peat and half-decayed manure added and a liberal sprinkling of sharp silver sand, all made very firm at potting time. This ensures a hard, solid growth that is more easily matured by sun and air than when the soil is very loose and rich. All through the growing season—indeed all the year round—this *Allamanda* likes to be exposed to the full sun and will never be free-flowering if kept in a shaded stove. Heat it likes in abundance and a moist atmosphere, but it must not be shaded. When starting in the spring the shoots should be allowed to make a little growth before being repotted, or it may be difficult to induce free root action, and a slight bottom-heat is useful in the same direction. Cuttings of half-ripened wood root readily in a brisk bottom-heat.

Cassia corymbosa.—Many greenhouse shrubs are greatly benefited by being placed out of doors during the summer, and those that bloom at that period may be employed for various decorative purposes. The practice seems to be greatly on the increase, especially in some of the public gardens, of plunging large plants either on the turf or in beds, where in the summer they yield a display of blossom or of foliage totally distinct from any hardy subjects. The *Cassia* in question readily lends itself to this mode of treatment, as if kept during the winter in a greenhouse or conservatory just free from frost and treated much as *Fuchsias* are, it will grow and flower profusely when turned outside in the summer, more particularly during such a season as we are having. The prettily divided leaves, which are of a bright shining green, are very attractive, and serve as an admirable setting to the clusters of rich golden coloured blossoms. It is a native of Brazil, but has been grown in this country for over 100 years.

Many other subjects are available for the same mode of treatment, prominent among them being *Fuchsias*, *Pelargoniums*, *Heliotropa*, *Bougainvillea glabra*, *Browallia* (*Streptosolen*) *Jamesoni*, *Erythrina Crista-galli*, *Plumbago capensis*, and others, many of which are so employed in Hyde Park.—H. P.

BOUVARDIA HUMBOLDTI CORYMBI- FLORA.

This is in many particulars widely removed from the numerous garden forms of *Bouvardia* that are so largely grown in many places. The flowers, which are borne in loose corymbs on the ends of the shoots and principal side branches, are as much as 3 inches long and over an inch across, pure white, and deliciously scented. It also flowers much earlier than any of the others, numerous examples of it being now beautifully in bloom, their Jasmine-like perfume being much admired. Good plants may be grown in 5-inch pots, but they must not be stopped too much, the object being to obtain a few stout, sturdy shoots, each of which will carry a huge head of bloom rather than a great number of weaker branches. It is difficult to obtain good flowering examples of a less height than 18 inches to 2 feet. The exceedingly long tube is rather weak; hence when the plants are employed for decoration, care must be taken in moving them about, otherwise the tubes will break. This *Bouvardia* will flower well if planted out of doors during the summer, as if the plants are large enough they will commence to bloom soon after midsummer and continue till the frost. This, of course, does not apply to those planted out during the summer and lifted in the autumn to flower in pots. There is a comparatively new form of *B. Humboldtii* known as *grandiflora*, in which both the foliage and flowers are of greater substance and somewhat larger than in the variety *corymbiflora*. It is a really good plant, and attracted a considerable amount of attention last autumn when it was several times exhibited. It received an award of merit from the Royal Horticultural Society on November 9, 1897. H. P.

Rhododendron Falconeri.—This fine greenhouse species is not usually a success in gardens, as many persist in giving it too much heat during the growing season and after, this combined with a dry atmosphere predisposing the plant to insect attacks as well as causing it to grow out of season. Of course, in the small state that we are compelled to grow it to bring it within the limited capacity of our glasshouses it is not likely to be as free as the smaller growing kinds, but by judicious treatment it may be had in flower annually. Where possible it should be grown in a house that is never entirely closed excepting at night during very severe weather, but such structures are not always to be had. Rather than keep it cooped up in an ordinary greenhouse the year through it should be placed in the open air and well hardened after its growth is complete, and the most airy and cool quarters at command must be given in winter. This gives the buds time to form and develop properly, and even then it must not be hastened, but allowed to come on quite naturally and gradually, placing the plants in the open air again in April if no convenience exists for them under glass. Slight frosts do not harm the plants, especially in autumn; in spring the foliage may be damaged by cold winds.

Campanula Vidali.—This *Campanula* forms a very attractive feature in the greenhouse, and is also particularly interesting as being very distinct from any other species. It is a native of the Azores, from whence it was introduced in 1851, and requires the protection of a greenhouse during the winter. It may, however, be planted out in the summer, under which treatment it will flower for a long time. In this way I have seen it very attractive in some of the London parks. A prominent feature of this *Campanula* is its half-shrubby character, as it forms a stout stem, which

divides, as a rule, into several branches a little way from the ground. The leaves, which are principally clustered towards the points of the shoots, are narrow, deep green, and fleshy in texture. Standing well above the foliage, the long spikes of drooping wax-like blossoms are seen to great advantage. They also remain fresh for a considerable time, while numerous buds develop from the same spike. It forms a few stout roots with little or no fibres; hence it is very impatient of removal, as if shaken clear of soil and repotted it will frequently stand a long time before it makes a start. A single plant will produce a large quantity of seed, and as it germinates freely, this is the best method of increasing this *Campanula*. Being of a somewhat succulent character, it must, especially when young, be kept moderately dry during the winter months. A good illustration showing this *Campanula* flowering in the open border with great freedom at Ardcairn, Co. Cork, appeared in vol. liv. of THE GARDEN, page 290.—T.

Propagating Pelargoniums.—The regal *Pelargoniums* ought not to be kept any longer under glass, as they are best for a week or two in the open before propagating, especially where they have been shaded while in flower. The plants in this case must not be turned out directly to the full sun, but hardened a little previously. I always stand mine under the shade of an old Mulberry tree in the garden, where the wood hardens before being placed in the full sun in front of a Peach house. The roots are dried a little by degrees, but the water supply is never totally withheld as long as the growth is upon them. The cuttings are taken the first week in August, and the old plants stood quite in the full sun and kept quite dry until new shoots appear. When these are an inch or so in length they are thinned to the requisite number and the plants repotted into very firm soil. All flower-stems should be rejected as cuttings, and only half-ripened, hard wood with good leaves used. Three cuttings may be placed in a 4 inch pot, first removing the sheaths at the leaf bases and cutting clean with a sharp knife just below a joint. Stand the cutting pots in the full sun out of doors, and at first keep them well soaked with water. As the roots appear gradually give them less, and it is easy to see when they are well rooted by the leaves picking up. Any shoots with young points may be pinched at this stage, but a good many of the cuttings will not need this, as they will branch naturally. It is not often they can again be placed outside after potting singly, but with the old plants should be given a place on a light stage in the greenhouse and kept gently moving through the winter.—H.

Hydrangea Hortensia in pots.—I was pleased to see the illustration of the fine specimen of this showy plant at p. 19 of THE GARDEN and to read Mr. Young's cultural notes. Many years ago I was employed in a garden where *Hydrangeas* were well grown in pots, very large bushes being required for standing in the front hall of the mansion. In three seasons from the cutting the plants attained to a large size and were objects of great beauty. The great point is, as Mr. Young says, to get the growths well matured by exposure to sun and air. When the plants have arrived at the desired size they may be kept in good health and vigour without repotting by annual mulching and liberal feeding with liquid manure. At this age it is not advisable to allow all the new growths to remain. Judicious thinning should be practised, this ensuring plump terminal buds and large trusses of bloom. A good holding yellow loam, a sixth part well rotted manure, and some coarse sand or road grit suit them well, ample drainage being indispensable, as established plants will take copious supplies of water during growth. The plants under notice had the protection of a cool pit or home-made unheated glass structure during winter, the pots being plunged in leaf-mould to protect from frost. It is best also to be cautious in exposing the new growths to the open air in spring, a very sheltered corner being best,

or damage may be apprehended. When flowering is past the old stems should be clean cut out in order to give the new shoots the best chance of development.—J. C.

NOTES AND QUESTIONS.—STOVE.

Alpinia mutica.—This may be treated in the same way as the Hedychium. As a fine-foliaged plant it is worthy of a place where room can be given. The tall succulent growths attain to from 5 feet to 6 feet high, and when surmounted with large panicles of bloom they are very attractive. In a batch of plants grown in the stove there have been some flowers throughout the spring.—A.

Ivy-leaved Pelargonium Mme. Crousse.—Despite the number of new kinds annually sent out, this old kind still maintains its hold. Window boxes filled with it and white Marguerites are still common, and it is largely grown for the purpose both by market men and private growers. Like Souvenir de Chas. Turner in its colour, it seems to be impossible to get a better flower with the same excellent habit of growth and free-flowering characteristics, and it will be long before either is ousted from its position.—H.

Costus igneus from seed.—This showy plant may easily be raised from seed. It should be gathered when nearly ripe and placed in a sunny, dry place to finish, eventually sowing at about a couple of inches apart in well-drained pans or pots of loose, rich soil. The seeds germinate quickly and surely. The seedlings should be lifted with a little soil attached to the roots, potting into 3-inch pots, and growing on as rapidly as possible in a warm greenhouse temperature. The pretty fresh leafage of seedling plants alone makes them worth growing, being much deeper in colour than old leaves.

THE MARKET GARDEN.

THE BANANA IN CULTIVATION AND COMMERCE.

THE Banana is, as is well known, one of the principal articles of food of the people that inhabit the intertropical zones. A pound weight of Bananas, according to Humboldt, contains as much nutritive matter as 44 lbs. of Potatoes. Crichton Campbell, "one of its greatest advocates in the United States, estimates the nutritive value of 1 lb. of Bananas to be equal to 25 lbs. of wheat bread. The Americans import immense quantities of Bananas at the present day. The number of clusters imported in 1896 through the ports of the Mexican Gulf, New Orleans, Mobile, New York, Charleston, &c., was not less than 25 millions, which were immediately absorbed by the markets. Each cluster brought from Central America bears 120 to 180 fingers, and weighs from 2 qrs. 5·8 lbs. to 3 qrs. 4·3 lbs., so that it is easy to comprehend what an extraordinary development must have taken place in the cultivation of the Banana in order to supply a consumption of such magnitude. For the present I will consider the regions of the east and centre of the United States only, California and the other Pacific States obtaining their supplies from the southern coast of Mexico and the Hawaiian Isles.

In all the favourable parts of the north coast of Central America, from the colony of Belize in 19° of lat. N. down to Santa Marta, in Colombia, immense breadths of Bananas have sprung up. Jamaica, San Domingo, Cuba and the Bahamas also produce great quantities, but of inferior quality. Large centres have been formed, towns even have arisen in tropical centres such as La Ceiba, Rama, and Bocas del Toro. The last, which I knew in 1883 only as a miserable, straggling, isolated village

at the entrance of Admiralty Bay, in Northern Chiriqui, is to-day an important town, in direct communication twice a month with New Orleans. In 1883 the district counted barely 500 inhabitants; to-day it has close upon 10,000. The department of Zélaya, in Nicaragua, the ancient realm of mosquitoes, and not long ago quite overlooked by geographers, has now its Banana plantations, with a service of steamers putting Rama and Bluefields in constant communication with New Orleans. And what of Port Sinion and Costa Rica? On both sides of the railway which unites the port with the capital, along the latter end of the route, is a forest of Banana plants, and to meet the steamer at the port there is an endless succession of trains, discharging hundreds and thousands of tons of the fruit for conveyance to New Orleans. More south still, Colon, Carthagena, and Santa Marta furnish also a considerable contingent; but as at these ports the traffic is chiefly with New York, there is a considerable slackening off during the winter months, owing to the frosts that are met in transit beyond Cape Hatteras, which sometimes destroy whole cargoes of fruit. North there is Honduras, Guatemala, and the English colony of Belize served by a weekly line of steamers plying between Belize, Livingston, Puerto Barrios, Puerto Cortez, and New Orleans. On each voyage there is a complete cargo of Bananas. Another line communicates twice a month with the ports of Ceiba, Truxillo, and Roaton, and once a month another line places these ports in touch with New York. Another port of call for fruit vessels arriving is that of Galveston, Texas, which will eventually become a very important place owing to its direct communication with the interior of the United States in the south-west, it being the terminus at the Gulf of Mexico for the South Pacific Company's railway.

VARIETIES.

The Banana belongs to the family of Musa, of which the species are very numerous. That cultivated in the regions under discussion is *M. Paradisiaca*; this includes many varieties which have not, so far as we know, yet been scientifically classed, even Horaninow in his "Prodromus Scitaminearum" (Petersburg, 1862) having renounced the task. The only variety which is now cultivated to a large extent, however, and the only one admitted without dispute in the American markets, is the variety *M. sapientum*, called Taita, or Tahitian. This is said to have been introduced to the southern coast of Mexico, at San Blas and Acapulco, by the galleons from Manila, and to have been increased there first until it was transported to the north-west, where to-day it reigns supreme. It has the advantage of being more robust than the other varieties, of being easily increased by suckers, of the fruit clusters being compact, regular, and almost always equal in weight, thereby bearing carriage for long distances better than any of the others, and lastly, of the fruit being well formed, fat and succulent, and as fit for cooking as for eating raw. As in all the numberless plantations of the regions under discussion it is the only one grown for exportation, and we shall therefore consider only this variety. In the markets of New Orleans, Mobile, and generally in the Mexican Gulf there is a large species of Banana often met with called *Plut-au-ciel*, or *Dieu le veuille*, cultivated especially at San Domingo, which is only fit to be eaten cooked, and is rather insipid. The clusters contain only a few fingers, from ten to twenty-five, but each of the fruits weighs as much as 2 kilogrammes. At New York there is also

introduced, but in very small quantities, the Banana Fig (*M. mensuaria*, or *Neina*), a delicious fruit well known in the Antilles and in Central America, but the clusters are very small and barely exceed 2 kilogrammes; it is a fruit *de luxe*. Here it would be superfluous to describe the Banana from the botanic point of view. The elegance of its form, the beauty of its port, the size and the emerald of its leaves grouped around the graceful and supple stem, and moved by every motion of the breeze cause it to be used as an ornamental plant in our country. Rarely, however, do we see the Banana in bloom, its flower emerging first as a vigorous scarlet-rose bud from amongst the smaller leaf and more delicate green of the terminal shoot, next bursting into bloom, and displaying the concentric rows of little yellow-white flowers surrounding its floral axis, and shortly to be transformed into Banana fruit. In this particular variety it is rare that the sterile flowers, which first appear on the style or floral axis, are numerous, and hence those fine, compact clusters so much prized in the United States. The flowers are quickly over and the fruit appears, tiny at first, as it emerges from the ovulus, but it increases in length and grows in girth almost under the eye. Its weight causes the cluster to droop more and more from the soft bower of leaf that shelters it from the heat of the sun. The fruit thickens and the skin is now firm and light, and though not yet quite ripe, it is the time to cut away the cluster and despatch it to the port. Cut at the right time the Banana ripens easily in eleven or fifteen days. If, however, it is to be eaten on the place, it is left for some days more until the fruit has taken on the golden colour which is proper to the Taita Banana. The cluster having been cut away, it is the custom in all rightly managed plantations to cut down the plant which produced it to make way for another which in a few months will also produce its cluster of fruit. On the northern coast of Central America one Banana plant produces every year two, three, and even four or five different fruit-bearing shoots. This particular Banana varies in height according as the soil is more or less favourable to it.

USES OF THE BANANA.

The Banana is used in different ways, raw or cooked. Raw, it is a savoury, floury, slightly saccharine, agreeable, rather astringent fruit, not easily digested by some stomachs unused to it, especially children, in whom it is apt to cause gastric troubles if not quite ripe or over-ripe. It is more commonly eaten raw in the United States. Cooked, it is prepared in a number of ways. In the tropics they cut it before maturity and remove the skin, which in this state is very acrid, and cook in the oven or under the ashes. Prepared thus it serves for bread. Also, after desiccation it is made into a flour by pounding in a mortar and kept in sacks or jars in a dry place: in this state it keeps for a long time. This flour, which is very nourishing, is carried by travellers, who make from it a very healthy and refreshing drink and a sort of thick gruel, which is sometimes eaten with sugar to deprive it of a certain insipidity. Cut into slices it is used in soups, and is one of the resources of the *ménage*, just as the Potato is with us. The ripe fruit baked in the oven is a very healthy and nourishing and at the same time very agreeable food. It is also made into fritters, cakes, *bon-bons*, &c. Its price in New York (one cent) places it within the means of all. Out of ripe Bananas fermented *au eau de vie* is distilled, but the amount of essential oil it contains imparts to it a disagreeable flavour, and being comparatively wanting in strength it

is rather despised by toppers and only used failing other and stronger liquors. Its

CULTIVATION

on a large scale as practised on the north coast of Central America is the simplest and most rudimentary. The only obstacle to the European who should risk to embark in it is the climate. The Banana, in fact, requires for its development and easy production a climate at once warm and moist. The lowest temperature it will stand is 22° Cent. In looking for the soils that are proper to it, the choice must be made in the littoral zone, where life for the European is certainly passed under unhealthy conditions; but, given certain precautions easy to be observed, it may be affirmed that the fears which are generally expressed in regard to this are, as a rule, greatly exaggerated. The choice of soil is of great importance; it should neither be too dry nor too moist. A black loam or a red ferruginous soil is preferable, and a site raised rather above a river so as to be out of reach of the inundations that occur periodically. The best choice would be that of a site stretching for some distance along the banks of a river and where there is no great depth of soil. It would then be easy and not costly to convey the clusters to the riverside for putting on board boats and barges for conveyance to the port of despatch. The chosen site should be protected from the north winds, which often blow in tempests on this coast from November to January. It is the custom in clearing land for plantations to leave on the northern side a belt of forest to give the necessary protection. The effect of violent winds is to deprive the fruit-cluster of the adequate protection of the young leaves at the commencement of its growth and expose it to the fierce rays of the sun, under which it withers and becomes useless. After the choice of a site the next thing is to clear the ground, which in certain spots is no easy matter, owing to the forest being choked with the free growth of creepers, dwarf prickly Palms, and all the exuberance of tropical undergrowth, which, in the neighbourhood of rivers especially, often makes it a very laborious task. The axe and the knife are used to hew down all but the forest trees of mature growth, which it would be too costly to attack directly, and which are presently to be reduced to ashes by means of fire. The work of making clearings is undertaken at the beginning of the dry season—that is, November or December—after which the felled trees being sufficiently dry, the opportunity is taken of a rather strong wind in the quarter most favourable for leaving intact the belt of forest left for the protection of the plantation from northerly winds to throw petroleum over the first of the felled trees and set it alight. The fire rages with the utmost violence and swallows up everything in a very short time, leaving nothing whatever of the great forest trees but the half-calced stems, in which the fire continues to smoulder for several days. The work of clearing is generally done by contract with the natives of the country, who are used to it, and whose services are always at hand. The cost of clearing a single hectare of land is about 80 pesos, or a little less than 200 francs. The cost of the purchase or occupation of lands, whether government or private property, is so trifling as to be not worth mentioning here. The site having been cleared, the first light rains are waited for, when the planting of young plants can be carried out. Young plants of the species or variety preferred can easily be had in the district, and ought not to cost more than 5 pesos the hundred. The ground having been pre-

pared for them, the plants are set out, the space between each varying according to the locality and temperature. I think a space of about 10 feet between each is the best, yet I have seen plantations in which it did not exceed 7 feet and even 5 feet. In this case, however, after the first year or two there is the certain fear of overcrowding, which can only be avoided by sacrificing a number of the plants each year. That being so, I adhere to my opinion that a space of 10 feet is preferable, and this avoids overcrowding, and at the same time the plants are close enough to each other to prevent the sun drying up the adjacent soil.

A plantation of one hectare under such conditions should contain 999 plants, but as in all these lands, even the best cleared, there remains a certain number of burnt stumps of old trees, I am inclined to put the real number of plants to the hectare as 800 only. The young plant is set in a hole prepared in advance, about 20 inches deep; the hole is then covered up, and care taken to collect a sufficient depth of soil about the young plant to prevent as much as possible the action of the sun on the roots. The plantation having been made, it is necessary at the outset to keep down the growth of weeds and underwood which would otherwise choke off the young plants. This work is not of long duration, as the Banana grows very quickly and itself overwhelms everything that grows underneath it.

FRUITING PERIOD.

Generally eight months elapse before the Banana furnishes its first cluster of fruit; this is generally of small dimensions, as not before the second year does the plant begin the regular production of clusters large enough for the American markets. From this stage onwards the plantation may be left to look after itself, except that care must be taken to cut the fruit at the right moment. When cut the fruit is taken down to the riverside, put aboard the boats and carried off to the port of despatch. The fruit is generally sold at the port of despatch, sometimes on the steamers themselves, sometimes to agents, according to quality and weight at the rate of 30, 60, and even 80 centimes the cluster, those of Bocas del Toro fetching the highest price. The labour needed for

WORKING A PLANTATION

of one hectare in extent in the producing stage is a very small item, and I advise anyone who thinks of taking up the business not to plant less than 10 hectares. In the latter case two gangs of ten men each are sufficient at the most, each gang being under a supervisor. The price of labour is generally 1 peso for a workman and 2 pesos or 2 pesos 50 for the supervisor. Labour is relatively very easy to get for this kind of work. On the other hand, the cost of transport by boat or canoe from the plantation to the port is rather high, whether the plantation possesses its own means of transport—which is the most practical way, but involves at the outset a considerable outlay—or whether the work is done by contract, which is quite possible. On all accounts, therefore, it is preferable to set up the plantation near to a port. On the Mosquito or Nicaragua side, on the river Rama, the steamers run as far as the plantations, the river being navigable for a long distance. At Port Barrios, Port Cortez, Port Simón, Colon and Santa Marta the trains fetch the Bananas down to the wharves, nearly all the plantations being situated in these regions alongside the railway. In this case great economy is secured in transport. In any case and whatever the cost of transport, I consider the

cultivation of the Banana as one fraught with the greatest profit to whoever devotes himself to it. It is necessary that someone should devote himself, like Crichton Campbell and others in the United States, to the diffusion of the Banana as an article of food. What is wanted in our markets is a Banana at once cheap and of good quality. The Banana as we know it in the Paris markets, for example, is small, flavourless and very dear in price. It occurs to me that in our colony of Senegal, and especially Rivières du Sud, where the climate is analogous to that of the northern coast of Central America, the Banana known as Taita could be grown with excellent results; and as its fruit is capable of standing a considerable length of sea voyage, it would be easy to bring it to our ports at a reasonable cost.—A. L. PINART, in *Bulletin de la Société d'Acclimatation*.

GARDEN FLORA.

PLATE 1236.

LÆLIO-CATTLEYA DOMINIANA LANGLEYENSIS.

(WITH A COLOURED PLATE.*)

IN THE GARDEN, vol. liv., p. 465, will be found a figure of *Lælio-Cattleya Dominiana langleyensis*. Accompanying it will also be found particulars of the origin of *L.-C. Dominiana* and its varieties, including particulars of the accompanying coloured plate. It was raised by Mr. Seden in the nurseries of Messrs. J. Veitch and Sons, Ltd., at Langley, and was exhibited at the Drill Hall meeting of the Royal Horticultural Society on October 11, 1898, when it was awarded a first-class certificate. One of the most interesting points in connection with this beautiful hybrid was the fact of clearing up the uncertainty which had previously existed with regard to its parentage, proving it to be the result of intercrossing *Lælia purpurata* and *Cattleya Dowiana*. As stated in the notes referred to above, there had been four varieties previously raised of this hybrid. *L.-C. D. rosea* was certificated in 1884. Mr. Law-Schofield exhibited the variety *L.-C. D. tyntesfieldiensis* at the Temple show of 1897, and Mr. J. Douglas exhibited a form as *L.-C. Appollonia* in 1896. This variety was very much inferior in colour and distinct in many ways from the other forms of *L.-C. Dominiana*. I have not the slightest doubt that this distinction has been brought about by using *C. Dowiana* var. *aurea* instead of the old *C. Dowiana* from Costa Rica. Though much sought after, *C. D. aurea* has not the substance or the intense colouring that are found in the older species, though it will be found to possess a better constitution, and may be kept in perfection for an indefinite period, a desirable feature which cannot generally be claimed for the old variety. Since the article referred to above appeared some other additions have been made by plants flowering in collections in this country that have been raised on the Continent. One received a first-class certificate at the Drill Hall meeting of June 27 last as *L.-C. Dominiana* var. *Fire King*, coming from the collection of Mrs. Briggs-Bury, Bank House, Accrington. A full description will be found in THE GARDEN of July 1 containing the report of that meeting. Mr. J. Seden agreed to its being a form of *L.-C. Dominiana* in a conversation I had with

* Drawn for THE GARDEN by H. G. MOON in Messrs. Veitch and Sons' nursery at Chelsea. Lithographed and printed by J. L. Goffart.

SAPPELIA DOMINICANA LANKESTER

him afterwards. On the following Thursday (June 29) another form of this hybrid, from the same continental origin, was exhibited at the Manchester and North of England Orchid Society's meeting by Mr. G. W. Law-Schofield, and was awarded a first-class certificate as L.-C. Fire King var. Frances Mary. Surely such a name as L.-C. Dominiana Fire King var. Frances Mary is unnecessary. If the one had previously been recognised as a form of L.-C. Dominiana, the other must be a form also of that hybrid. The complications are already sufficient in the nomenclature of hybrid Orchids. Such a system as herein illustrated can easily be avoided, and in this instance might have been. The fact of its being recognised as Fire King leaves no excuse for dropping the name of L.-C. Dominiana. That Mr. Law-Schofield's plant was a distinct form I am ready to admit, for I saw this in good condition. Its principal distinction was in the base of the lip and through the throat. Instead of the usual yellow and purple longitudinal lines, the whole of

as to be an ungraceful mass, which of course detracts from their elegant form. The exhibit in question required but one thing, namely, a bud peeping out here and there, which would have added to its natural appearance.—H. S.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

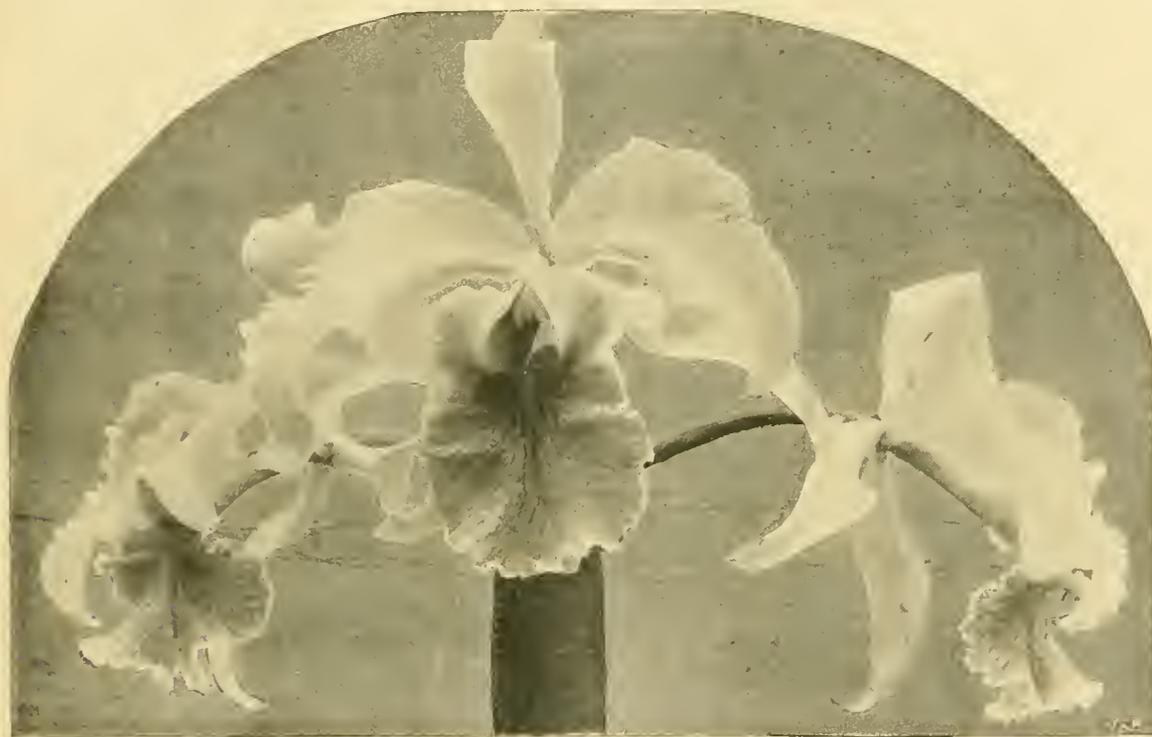

ORCHARD HOUSE.—In the orchard house there will now be need of constant attention with the watering pot, for the limited size of the receptacles, combined with the crammed state of the roots, makes frequent watering, with some things as often as three times a day, quite necessary, and stimulants in the form of liquid manure should be given almost at each watering to those trees still carrying fruits, and once a day to such as have been cleared of their crop, for these will still require help to plump up next year's fruit buds. As fast as the orchard-house trees are cleared of fruit they should be removed to the open, or, in the case of trees that have been plunged and have

quantity of fruit if allowed access to it, and a stray blackbird getting into the house is also capable of doing much mischief to fruit, which from the limited capacity of the system of production costs a great deal to produce. Apples and Pears certainly finish up best if they can be removed to the open to ripen after they have reached full size, as they derive benefit from the night dews. Of course such removal is only advised where the trees have not been allowed to root into the inside borders, for cutting off the supply of nourishment by disturbing these roots would more than counteract the benefits above spoken of. Trees put outside in this way will have to be protected from birds and wasps. It is late now to speak of top-dressing, but there is still time to renew it in the case of the latest crop, and it is astonishing how soon the roots and the fruits respond to a little generous treatment in this way, and I do not hesitate to recommend a further dressing of malt dust to any pot tree which appears backward in swelling its fruits.

VINERIES.—Early Vines, from the great differences in outside and inside temperature during the time they are making their growth, are more subject to mildew than are the later ones, and wherever there has been the least sign of this pest during the season, I strongly advise now that the fruit is off, two or three good syringings at intervals of a week of water in which half an ounce of soft soap has been dissolved and two ounces of flowers of sulphur mixed to the gallon of water. This will be useful as an insecticide and will kill the germs of mildew that may be left behind.

MUSCATS.—Muscat of Alexandria Grapes which are not well coloured by the end of August stand a very poor chance of taking on the clear amber hue so much appreciated by lovers of this Grape: consequently the treatment afforded from this time onward must tend to putting on this colour. Where the bunches run small there is very little difficulty in getting them to colour up well, but it is the finest bunches that give the most trouble, and if these are now at all on the green side it is advisable to increase the fire-heat given by night and to remove any shading that may have been given in those few places in which it is found necessary to shade at all. The

Vines themselves will be none the worse for this additional fire-heat provided the necessary precautions have been taken to keep down red spider. The above conditions will be an advantage also to that excellent Grape Mrs. Pince's Black Muscat, one of the finest Grapes we have when it is well finished. Among other Grapes which derive much benefit from fire-heat is Gros Colman, as under the influence of artificial heat in which to finish it loses much of the flatness and muddiness of flavour which have brought it into disrepute among real lovers of Grapes. It will be necessary to look frequently over all bunches that have passed the colouring stage for damaged berries, as these should be removed before they carry decay to their neighbours. This is especially necessary with those varieties which are prone to berry-splitting, and in the case of Madresfield Court only a couple of days or so should be allowed to elapse between each visit, for if this is not attended to the evils of splitting will be more than doubled. In extreme cases where the splitting is very bad it may be necessary to cut partly through the laterals

Laëlio-Cattleya Dominiana langleyensis.

the basal portion had a suffusion of a peculiar shade of brownish purple. The remaining segments also appeared to be deeper in colour than in Mrs. Briggs-Bury's plant.

Since writing the above, I hear from Mr. Law-Schofield that the raiser asserts that the above-mentioned hybrids are derived from the intercrossing of *L. purpurata* and *C. Mossiae*. This would bring them to forms of *L.-C. Canhamiana*, which they certainly are not.

C. J. H.

Exhibiting Sweet Peas.—At the Birmingham Carnation show recently I noted a particularly fine exhibit of these flowers from Mr. J. B. Johnstone, Tettenhall. Not only were the individual flowers remarkable for their richness of colour and fine development, but they afforded a good lesson in arrangement. The blooms were cut with long stems and loosely tied at bottom in bunches, so that the whole had a very light appearance. Mostly one sees them tied so close

rooted through, prepared for removal by severing the main roots which have escaped their bounds. This may be done by running a spade round the pots or by twisting the pots around and dislodging the roots, which may be cut back afterwards. On removing the trees to the open, they should not be neglected either for watering or syringing, the latter being very helpful in retaining the leaves in good condition as long as possible. A good position should be found for the trees in the open—that is to say, they should not be crammed together in any out-of-the-way corner. Give them plenty of room and a good exposure to the light, but provide some means of shading the pots either by plunging them or by surrounding them with litter. In the house, to do the best by late Peaches, Pears, Apples, Plums, &c., ample ventilation must be given day and night, and where birds, rats or mice are plentiful, this necessitates covering the front ventilating spaces at least with galvanised netting of sufficiently small mesh to exclude these vermin, though the mice are able to get through very small openings. Rats are most troublesome with Plums, and will soon spoil a

to lessen the flow of sap, but the care in ventilating and other details which I advised in a former calendar note when dealing with such Grapes as these will probably have obviated the necessity of going to this extreme.

POT VINES.—Pot Vines for next year's fruiting will now have finished their growth and will have become firm in the wood. Some growers who have plenty of glass at command can afford to allow these Vines to continue in the pits where they have been grown, and expose them by simply leaving the lights off night and day whenever the weather is fine, but practically the same results will be obtained by moving them now to a south wall and providing a few pieces of slate or board laid sloping on the pots to carry off any excessive rainfall. From this time onward the water-pot must be less freely used, but it is a great mistake to withhold water altogether. Lessen the supply and give up the use of liquid manure, then well-ripened canes will be sure to result. Early ripening not being so necessary for younger stock, which will be cut back to the pots later on, these should still be kept growing and well fed for some time to come.

Figs.—Keep the points of shoots on those trees trained near the roof well tied down to the wires, as the points extend much better when prevented from turning up to the glass. With the Fig it is possible to get the growths too short-jointed, and this will certainly follow if the shoots are not kept a moderate distance from the glass. Feed up those trees which are carrying fruit and ply the syringe freely on those which are without ripe fruit for the time being. The crop may be hastened at any time by closing the house early in the afternoon, but this should not be done when there is ripe fruit on the trees, more especially if this has to be packed for travelling, as only Figs which have been grown in a house well ventilated night and day are fit for such a purpose.

CORNUBIAN.

KITCHEN GARDEN.

WINTER CUCUMBERS.—It is now time seed of hardy reliable cropping sorts of Cucumbers was sown for yielding fruit during November and December. Some gardeners sow a little later and are satisfied so long as the plants arrive at a fruiting stage by the beginning of the first-named month, but I think, however, timely sowing is preferable, as although by reason of fine sunny weather the plants commence bearing before the fruits are really needed, the latter can be removed, and thus the plants are able to stand against the trying ordeal of cropping through the short, dull days. Syon House or a good strain of the old Telegraph cannot, I think, be surpassed for winter work, and the seeds should be sown in small pots, the plants being potted on in due course. Give them a light, airy position close to the roof-glass, yet out of draught, and by no means raise the seedlings in a house infested with either spider or mealy bug. Once allow this pest to get on the leaves of young Cucumber plants, they might as well be thrown away. If the house in which the plants are to fruit has had Melons or Cucumbers growing in it, a thorough cleansing must be given, well washing all woodwork with soapy water and coating the walls with limewash into which a little sulphur has been stirred. Plants now cropping and which are to keep up a supply of fruit till the winter batch comes into bearing must be well attended to, and as the summer declines and demand for salad lessens, these plants should only be allowed to carry a moderate quantity of fruit and receive a good, rich top-dressing of loam, bone-meal and road grit, followed by liberal supplies of liquid manure the colour of pale ale. Seed for supplying plants intended for fruiting at the new year may be sown from the middle to the end of September. A very light position while in a young state must be accorded them.

EARLIEST MUSHROOMS.—The season has now arrived for all those who require Mushrooms at the end of October and early in November to

collect manure for making the first bed. It is not advisable to use manure from grass-fed horses, such not being comparable to that obtained from corn-fed animals. Do not throw the manure into a heap as collected; rather spread it out thinly in an open shed where it can be moved about now and then to keep it sweet. When thrown together carelessly or from lack of convenience, it frequently heats unduly before being noticed. A large bed is not imperative for a start; therefore where material is scarce, a full-sized bed may be reduced to one half its dimensions by placing a board across the middle. As soon as sufficient manure has been collected let it be thrown into a heap and allowed to remain so for a few days, after which turn it over every morning, allowing the outside portions to come into the middle of the heap. When the bulk of the steam is dispelled, mound it up once more and allow it to remain untouched for a few days, then wheel it in to form the bed. Deep beds are not so necessary early in the season, shallow ones retaining sufficient heat and ammonia to induce the spawn to run, and when once young Mushrooms appear a gentle warmth should be allowed in the hot-water pipes. When making up beds lay on only a thin layer at a time so as to secure thorough firmness. Where sufficient head room exists I prefer treading the bed first of all, finally beating it very firmly with the back of a five-tined fork. Making completed, those who do not possess a bottom-heat thermometer may thrust in a stout testing stick. Examine this occasionally, and when the temperature has risen to its maximum, prepare a quantity of fine soil for surfacing. When the heat has declined to 90°, spawning may safely be performed, there being no fear of any reaction in these shallow beds. When spawned at this figure and covered down the heat is retained; whereas, when left to fall to say 80°, it will frequently run down to 60° and a considerable time elapse before young Mushrooms appear. After soiling, firm with the back of a spade, using a little chilled water if at all dry. Cover with a moderate thickness of oat-straw if obtainable, this being preferable to hay refuse, which so often becomes mouldy and offensive, making the surface actually colder than if it were not covered at all. As no fire-heat will be necessary for a time, so neither will be floor and wall moistening, these being commenced as soon as the pipes are warmed and a less moist atmosphere prevails. For inserting the spawn I prefer a flat-ended dibber, as a sharp-pointed one is apt to leave a cavity under the spawn. Some use no tool, merely making a hole with the hand about 1½ inches deep and pushing in the spawn, which should be in pieces about the size of a pigeon's egg. Re-beating the surface is necessary when spawning is completed. Some growers place the spawn in a moist plant stove for a few days previous to use, thinking that it then breaks up more readily. I have known a few good early Mushrooms secured by levelling and moistening the surface of old exhausted beds in Cucumber and Melon houses, inserting the spawn, and covering with crossbars and mats or even loose litter, but this can of course only be done when the house is not required for young plants in winter. Amateurs who have only a Cucumber or Melon frame may, after the crop is over, moisten the interior, insert spawn, and duly darken, keeping up the heat when colder nights appear by building up linings of fermenting material round the frames.

J. C.

Cactus Dahlia Lucius.—The first flower of this sort is open, and it quite comes up to the high expectations formed of it when seen last year at the exhibitions. It is an advance in form, being of light spiky arrangement. The colour is orange-yellow, rich and taking. In growth it is excellent, throwing the flowers well out of the foliage. The variety is one which should be noted as an improvement and one which is certain to become popular when less scarce.—S.

FRUIT AND VEGETABLE CROPS.

SOUTHERN.

Royal Gardens, Windsor.—Apples a good average crop, some trees heavy, others scarcely any. Same applies to Pears; many fell off, especially on walls, during drought and great heat from May 24 to June 18. Cherries a very heavy crop, clean, and of fine quality. I commenced picking outside on June 10. Peaches and Nectarines heavy crops. These are thinned and crop left according to age, vigour of tree, and variety. I ought to state that our Peach walls are covered with canvas blinds on rollers; this protection from spring frosts and wet invariably ensures a good set of fruit. Apricots rather thin; they were in full flower early in March, and 10° of frost on March 5 and 6 thinned them considerably. Plums about half a crop. Raspberries a heavy crop, and finest fruit I have seen, Hornet and Superlative especially. The Raspberry is much appreciated here as a dessert fruit, and with cream is by many preferred to Strawberries. Strawberries generally a poor crop. This, I conclude, is owing to the dry season last year, the foliage almost burnt up and crowns failing to mature. One variety that can always be relied on for cropping well here is Aromatic; the flavour is good, but the colour might be better. The Countess, Waterloo, and V. Héricart de Thury are also good this year. Many of the new varieties are very poor, though Royal Sovereign and Noble were valuable as early crops, and being a dry time (middle of June) the flavour was delicious and colour very bright. Bush fruits are abundant; Walnuts cropping heavily; Filberts under average.

So far vegetables have done well, though late, as the nights were very cold till nearly mid-summer. Peas (early) were good, Gradus or Early Giant, Chelsea Gem, and Telegraph the best; main crops of Peas and late varieties want more rain. Cauliflowers very fine from autumn-sown plants wintered in cold pits in single pots. Onions are looking well; so are vegetables generally since heavy rain on June 30. Potatoes looking well. Ne Plus Ultra is a good early outdoor variety. Windsor Castle (now being lifted in fine condition) and late sorts are very promising.—OWEN THOMAS.

Buxted Park, Uckfield.—This has been the most unfavourable season that I can remember for the production of first-class fruit and vegetables. The winter was a mild one, the average maximum temperature for January being 50° in the shade. This, together with the heavy rainfall, which was about 3½ inches, caused things to commence growth. All, however, went fairly well till the third week in March, when winter set in with a vengeance, and from March 18 to 25 the weather was more like what is usually experienced in January, for on one occasion we registered as many as 24° of frost. This put an end to all fruit blossom that was at all forward. Peaches, Nectarines, and Apricots suffered seriously, the former being less than a tenth of a crop, while there is none of the latter. Pears also suffered badly, and with the exception of two or three varieties I have no fruit. Plums, except those on a north wall, are a failure, for where I could gather a bushel last season I cannot find a fruit this. Strawberries are a very poor crop; in fact, the worst I have known for the last twenty years. Raspberries, on the other hand, are abundant, particularly Superlative, the fruit being both plentiful and good. Black Currants are a fair crop, but Red are very scarce, and the same may be said of Gooseberries. Cherries, both on standards and north walls, are good, but those on other aspects are very scarce indeed. Apples are partial, some varieties having an abundant crop, others none at all. This remark applies alike to standards and bush trees.

Vegetables of all kinds have done fairly well, with the exception of early Peas, which with me were quite a failure, having been cut down by the frosts in March. It is too early to say anything

about Potatoes, except the early kinds. These suffered so seriously from the frosts in May that they scarcely paid for lifting. The late ones, so far, are looking well. All other crops, considering the dry weather, are looking well and promise abundant returns. The weather has been very hot and dry of late, very little rain having fallen in this neighbourhood since April, so that the soil has become parched, and unless rain comes soon, all late crops will suffer.—H. C. PRINSEP.

Syon House, Brentford.—I fear the report of the fruit crops in this part of the country will not be a cheering one. Apples are a variable crop as far as I can ascertain. In some places there is an abundance of Codrus and early kinds; in others the crop is very poor. I have not a heavy crop of any one kind. My best trees are the late-flowering varieties. These escaped the severe weather the others experienced early in May. Such kinds as Prince Albert, Alfriston, Newton Wonder, Sandringham and a few others have average crops. Of dessert kinds there are none too many. I notice the newer Allington and James Grieve have full crops. The Pear crop is far more unsatisfactory, and this I much regret, as this is such a useful fruit. I have a few Beurré Diel, Marie Louise, Conference, Louise Bonne of Jersey and others, but so few with so many trees that the results are most disheartening. I never remember a better promise of fruit. The previous season having been a bad one, I expected different results in every way. Even on walls the same loss is felt. Cordon trees on all aspects are failures in spite of protection. This season my best crops are on a north wall, so that doubtless late blooming of the trees saved the crop. Plums are a total failure. I do not think I have half a bushel of fruit in the whole garden. I admit this is not a Plum soil, but rarely has such a total failure been recorded. The trees were white with bloom; this dropped in shoals after the fruit should have begun to swell. I am unable to name a single variety with a quarter of a crop. Damsons are very scarce; all the trees are alike. Apricots with me are a poor crop; the trees promised well, but 17° of frost when in bloom was too much for them. This with hail and sleet combined destroyed all the first bloom. A few of the late buds that were close to the wall escaped. Peaches and Nectarines usually set so well with me on open walls that the difficulty is mostly in thinning sufficiently to give the fruits a chance. But that is not the difficulty this season; indeed some of the earliest trees have not a single fruit; others, such as Dymond, the Nectarine Peach, Sea Eagle, Golden Eagle, and late kinds, are fair. Midseason kinds have a very thin crop. Nectarines are under the average. The trees of both Peaches and Nectarines look remarkably well and should make good fruiting wood for another season. Early Rivers Nectarine promises well, but this year such kinds as Pine-apple and late kinds have better crops than that useful variety Lord Napier. Cherries have been good. Doubtless owing to the protracted drought last season the trees have this year suffered more from loss of branches than usual, but in my light soil I always lose some in spite of frequent renewal of trees and assisting the roots. Most of the dessert Cherries were very good, and such kinds as Governor Wood, the Bigarreus in variety, Early Rivers and Black Tartarian were the best in the black section. Morellos this year are not so good. They showed plenty of bloom, but being late the severe weather affected them. As regards Strawberries, this is my worst year on record. Bloom was abundant, the promise good, but not a quarter of a crop, as frost at the blooming period killed the earliest and, of course, the strongest flowers, and severe drought with a light soil prevented later bloom giving the results it would have done, and I fear the crop in this neighbourhood may be classed as a quarter of the usual yield. In my own case I have been able on a single occasion to gather by the hundredweight; this year only by the pound. Raspberries are good, but need moisture badly to swell up the fruit. Superlative

I find far ahead of all others for crop. Gooseberries and Currants have been good, the latter being more abundant than the former. The Gooseberries though late were doubtless affected by the late frost.

Vegetables have been plentiful. Potatoes were much later than usual, owing to the cold weather. At the end of May growth was at a standstill, and it is surprising how cold affects some, such as the Ashleafs, more than the stronger growers. My earliest kind this year was Ringleader, but the best, though a few days later, was Ninetyfold. Most of the Ashleaf varieties are splendid this year as regards quality, but the tubers are rather smaller than usual. The late kinds look well and promise a large yield, and there is so far no sign of disease. Broccoli this spring, owing to a mild winter, was over sooner than usual. Cauliflowers were excellent, and though the heat and drought have affected later supplies, by having plants in diverse positions there has been no break in the supply. The early Pea crop was the best I have had, and in spite of cold weather when in bloom I gathered Chelsea Gem in May from open borders. Bountiful I find a splendid variety for sowing in pots and planting out. The plants of later kinds have been attacked badly with thrips, but so far I have kept pace with the pest and only a small portion of the plants suffered. Later crops will need the same care, and should be watered overhead in the evening to check the spread of insect pests. There was a bountiful supply of French Beans from pot plants, and those sown in the open are doing well, but need moisture to keep red spider at bay. I find the new climbing Beans of great value, as they are more robust than the dwarf kinds and not so quickly affected by drought and heat and nearly as early with fine pods. I consider this new Bean of great value where quantities are needed. Other vegetables have been plentiful and good; salads abundant till mid-July. Since then special culture has been necessary to provide successional supplies. Most crops in this district at the time of writing need rain badly, and I fear in many gardens it will be a difficult matter to get out the winter crops. Every chance should be taken to do so, as when change of weather occurs the plants will soon make up for lost time.—G. WYTHES.

Swanmore Park, Hants.—The fruit crops here and in this neighbourhood generally are unsatisfactory. Apples are a very thin crop, and this notwithstanding the abundance of bloom. The late frosts experienced at the time they were in flower proved very destructive. Then, again, later on (June 28) a severe hailstorm visited the district, doing much damage, knocking some of the fruit off and bruising the remainder that were not protected by branches. Pears are likewise a thin crop. Plums are also a scanty crop. One of the largest growers in this district estimates his crop at about a quarter of the average. Here we have a poor crop with the exception of the variety Belle de Louvain, which is heavy. This appears to be a most consistent bearer. It is early, the quality good, and I should say worthy of more extensive cultivation. Damsons about here are almost a failure. Dessert Cherries have been fairly good; Morellos promise well, but black fly has been troublesome and requires constant attention to keep it under. Peaches on outside walls are good considering the severe test they were put to from March 20 to March 24, when they were in full bloom, no less than 16° of frost being registered at that time. Fish netting placed four thicknesses proved only a slight protection, but where canvas was employed and kept a considerable distance from the wall a much fuller crop was ensured. Blister has again been prevalent, but not quite so bad as last season. Strawberries, although looking so strong and healthy in the spring and showing an abundance of bloom later, have been poor and much below the average. Prices have ruled high. Last season, when plentiful, good fruit was selling at 1s. per gallon, while this season 1s. 6d. and 2s. are asked for fruit of inferior quality. Royal

Sovereign is the variety chiefly grown. Raspberries are a fair crop. These seem to withstand the drought better than many kinds of fruit. Superlative is the favourite variety, and it well sustains its reputation of being a consistent and good bearer. Gooseberries, White, Black, and Red Currants are heavy, especially some trees trained to a north wall, which will keep up the supply after those in the open are done. Filberts are an average crop.

Vegetables on the whole are a very good crop. Early Peas have been good, but rain is much needed to help forward the later kinds. Potatoes are excellent where the ground is in good tilth; otherwise they have suffered from the drought. Greens have been much infested with green fly, an unique experience probably caused by the drought.—J. LEWIS.

Wrest Park, Beds.—The fruit crop this season is anything but a satisfactory one, owing no doubt to the frosts we had when most of the fruit trees were in full blossom. The late Peaches and Nectarines suffered very much from the severe frosts experienced about March 20. Apples are not an average crop here this season, and will be small owing to the dry weather. The Strawberry crop was of very short duration. As far as I can ascertain it has been the same nearly all over Bedfordshire.

The vegetable crops are very satisfactory on the whole, and good crops have been gathered of all kinds of early vegetables. The drought is beginning to be felt very much in this neighbourhood, as the rainfall has been very poor since May; consequently all kinds of late vegetables are showing signs of the drought, and Potatoes and a great many other crops will suffer accordingly.—GEORGE MACKINLEY.

Battle Abbey.—Apples very good. Pears average on walls, none in open ground; dropped during frost and winds in May. Plums light; Peaches and Nectarines light; Quinces and Medlars heavy; Cherries light; Strawberries heavy crop, very fine fruit, especially Royal Sovereign and Latest of All, which I find treated as annuals are much the best for dessert. Raspberries, Currants, and Gooseberries heavy crop. Most of the stone fruit dropped during the cold we had in May. We had 4° of frost each morning from May 23 to 29. Strawberries were all covered up or we should have had none.

Vegetables are remarkably good all round, especially Peas and Potatoes, which I have not seen better. The ground here being very heavy and deeply worked, dry weather suits it the best.—WM. CAMM.

Coombe Park, Whitchurch, Reading.—Fruit crops in this neighbourhood suffered very much from late spring frost, especially on the lower ground. Strawberries, except some of the late kinds, are quite a failure. Gooseberries, Currants and Raspberries are fair. Cherries are good, especially on the higher ground. Apples, Plums and Pears are poor with the exception of a tree here and there. Filberts and Walnuts are good. Trees and all kinds of vegetation in this neighbourhood suffered very much last season from drought, from which many have not recovered.—E. TROLLOPE.

Widmore Court, Bromley.—Apples on bushes and trained trees are a very good crop; orchard trees are rather light. Cherries in this garden are only a moderate crop, but there are splendid crops in the neighbourhood. Black Currants are a very fair crop and fruit fine. I think by what I have seen they are rather above the average. The mite is bad here. Red and White Currants are a splendid crop; in fact, one of the heaviest I have seen in this district. Figs outside are a very fair crop. Gooseberries are a fair crop and fruit fine. We seldom get extra heavy crops in this locality now, as the sparrow claims his share in the early spring. Plums on walls are a very fine crop; on bushes and standards there is a light crop. Peaches outside are very poor. Raspberries very good fruit. Strawberries have been very disappointing in this

locality this year; in private places the crops have been very fair.

VEGETABLES.—Spring Cabbages have not been so good here, nor, in fact, in the whole neighbourhood this year. Potatoes are only a moderate crop here, but very fine in the fields.—ALEX. MCGLASHAN.

Walhampton Park, near Lymington.—I find Apples a good crop in general, Pears a fair crop, Plums bad, Peaches and Nectarines bad, Cherries fair, Figs good, especially Brown Turkey, which always does well here. All small fruit a good crop.

Vegetables have been in general a good crop, but owing to the long severe drought in this part are now almost a failure.—J. SOUZA.

Beckett Gardens, Shrivenham, Berks.—The fruit crop in this neighbourhood is below the average. Apples and Pears are very scarce, Plums good, Damsons poor, Apricots (outside) moderate, Cherries good, Figs (outside) good, Currants, Gooseberries and Raspberries very good; Strawberries have been a failure.

Vegetables are good. Early Potatoes are small, second earlies good. The main crops are looking well, but are in want of rain; the same also can be said of the Peas and Beans. The Onion crops are very good and quite free from maggot. The root crops are especially good. The winter greens are in want of rain to strengthen them, or else they will get another attack of the caterpillar, which did so much damage to them last year.—H. WRIGHT.

Loseley Park Gardens, Guildford.—All bush fruits are abundant. Gooseberries, Currants and Raspberries are a full crop. Strawberries are almost a failure, owing no doubt to frost in May. Plums are better than for some years past, but cannot be considered a full crop. Pears are much below the average. Apples are very satisfactory, although not up to the average. Nuts are plentiful.

The vegetable quarters have suffered much from the drought and excessive heat. Peas are fairly good, but the season was soon over. Potatoes are looking well.—H. SAWYER.

Colworth, Sharnbrook, Beds.—Apples are a good crop; Apricots none; Currants very heavy; Cherries good; Damsons light; Gooseberries abundant; Mulberries good; Pears medium; Plums good; Peaches none outside; Raspberries very good; Strawberries very light.

VEGETABLES.—Peas very good, but promise to fail soon from want of rain. Potatoes promise well.—J. HOAD.

Bayham Abbey Gardens, Lamberhurst, Kent.—The fruit crops are on the whole satisfactory. Apples with us are thin, but better with others near. Pears are an average crop, and will, I think, be good. Plums are average. Peaches and Nectarines suffered very severely from frost and later from blister: Apricots are thin; Nuts a fair crop. Strawberries, with the exception of Royal Sovereign and Waterloo, are not very good. Raspberries are an immense crop, as are also Gooseberries. Currants of all sorts are good. Cherries thin, except Morellos, which are a heavy crop.

Vegetables are as a whole good. Early Peas are good, but main-crop ones are infested with thrips, which is very prevalent here, and if not checked entirely spoils the crop. Carrots are very scarce, a great part of the crop going off when quite young. Onions, Potatoes, Celery, &c., are good.—G. H. SAGE.

Kingston House Gardens, near Abingdon.—Apricots are poor; Peaches and Nectarines average; Cherries and Plums poor; Apples average, the earliest blooming trees loaded, later flowering sorts a complete blank; Pears poor; Strawberries a light crop and soon over; Raspberries good; Gooseberries very light; Currants enormous crops; Nuts fair; Walnuts thin, a good set, but the majority have since fallen.

Vegetables have been, and still promise to be, grand; in fact, during the ten years I have had

charge of these gardens I have never had such crops, though I must say we have been very fortunate as regards rain, many of our neighbours not having had a drop when we have had heavy thunderstorms.—A. J. MORRIS.

ORCHIDS.

SOME RECENT ODONTOGLOSSUMS.

THE number of really good *Odontoglossums* that have made their appearance during the past six months is remarkable. Recent importations have been undoubtedly rich in superior forms of *O. crispum*. I recently visited a collection where *Odontoglossums* are a speciality, and I was surprised, among the number of plants blooming for the first time in this country, to find scarcely a poor-shaped flower or one wanting in substance. There were some hundreds of spikes expanded at the

Odontoglossum crispum Franz Masereel. From a photograph sent by Mr. H. J. Chapman.

time. The high prices also which good forms realise when offered for sale give every encouragement both to the importer and grower. *Odontoglossums* were never in greater demand than at the present day and sensational prices are often obtained for the best of the typical form, more particularly for distinctly spotted varieties. I propose noting some of the best forms that have been exhibited during the present year.

One of the first to make its appearance was the subject of the accompanying illustration, *Odontoglossum crispum* var. *Franz Masereel*. This plant was exhibited at the Royal Horticultural Society's meeting on February 28 last by M. Jules Hyc, of Ghent, when the Orchid committee awarded it the society's silver Flora medal. It had previously been certificated

when shown by M. Vervaeet on November 13, 1894. It is certainly one of the most distinct and lovely varieties that has ever been seen. The outside of the sepals and petals is beautifully blotched with bright rose-purple, marbled with white, the front of these segments having a ground colour of white, through which is reflected the purple from the back, giving each the appearance of having a rose suffusion. The sepals are blotched and marbled with rich maroon markings. The petals, as shown in the illustration, are more evenly marked, and the large blotch which covers nearly the whole of the centre area is slightly deeper in colour than are the markings of the sepals; the band around the toothed white edges is of a similar colour, as are also the smaller lines and spots towards the base. The lip is white, shading to yellow on the disc. The large spot in the centre and the smaller ones towards the base are bright brown. The cut raceme

carried three flowers. On March 14 a lovely form was exhibited by M. Jules Hyc as *O. c. Sultan*. It is a very brilliant form, and one in which the white, tinted rose ground colour has been almost obliterated by the deep reddish purple, large irregular blotches. All the segments have a very narrow margin of rose, tinted white. Through the big blotches the ground colour runs in irregular narrow lines. The lip is large, white, with deep yellow disc and bright purple spots in front. The flowers were nearly 3 inches in diameter, but the shape was somewhat loose, the segments not overlapping each other, as in the better shaped forms.

It would be interesting if some of our *Odontoglossum* experts would give us the distinctive characteristics by which we might distinguish the difference between *O. c. Sultan*, *O. c. Sanderianum*, and *O. c. Hyeatum*. Mr. de B. Crawshay will, perhaps, be kind enough to give us what is desired here. On April 18 Mr. E. Ashworth exhibited and received a first-class certificate for *O. c. Ashworthianum*. In this the sepals and petals are almost wholly rich brown, marbled and margined with white. The broad lip has a wide margin of white, centre deep brown, mottled with white and having some yellow on the disc. The plant carried a raceme of six flowers. It resembles *O. c. Baroness Schröder* to a great extent. The only distinction between the two is that the markings in Mr. Ashworth's plant are brown; whereas in *O. c. Baroness Schröder* the spotting is of a deep purple. At the meeting on May 16 Mr. T. B. Haywood exhibited *O. c. Purity*. In this the flowers are almost pure white, only a slight trace of rose in the sepals and the yellow on the disc of the lip being apparent. The flowers are of remarkable form and substance. At the same meeting was also shown *O. c. Raymond Crawshay*. This promises to be one of the finest forms of *O. crispum* in cultivation. It was not expanded when shown, but on seeing the flowers later, I was surprised at its attractive and distinct characteristics. Particulars of this were given on page 446 of the last volume of *THE GARDEN*. *O. c. Arthur Brisco* was exhibited by Mr. W. Thompson, of Stone, Stafford, at the Temple show. It is a distinct variety of fine form and substance. The sepals are white, with some

indistinct purple through the centre. The centre area has several rich, large purplish spots. The petals, much toothed at the margin, have a pure white ground and several large blotches of purple in the centre. The lip is white, shading to yellow on the disc, the centre area having several large brown spots. At the same meeting M. Jules Hye showed *O. c. Etoile du Congo*, a pretty form. The sepals are white, having large blotches of brown in the centre area, the petals also white, with spottings of the same colour as the sepals towards the base, the lip white, with a yellow disc and some brown spottings in the centre.

In M. Linden's group at this show was *O. c. var. Miss Linden*, in which the sepals are white, suffused with rose, and thickly covered with numerous small brown spots. The petals are white with some purple in the centre, where there are also numerous small brown spots. The lip is white, shading to yellow on the disc, with some brown spots in the centre. At the Drill Hall meeting of June 27 two remarkable forms were exhibited. The variety *O. c. Seraphim* from Mr. de B. Crawshay is almost white; only the faintest tint of colour could be traced on the bottom sepals of the lowest flower on the spike and the yellow disc of the lip. It also had some brown spottings on the column. The flowers were each considerably over 4 in. in diameter. *O. c. purpurascens* came from the collection of Sir T. Lawrence, Burford Lodge, Dorking. It is a distinct and desirable form of the *O. c. Starlight* section, the flowers being white, tinted with rose, the segments thickly covered with miniature lilac-purple spots, the lip having some large brown spots in the centre.

Odontoglossum crispum Rochfordianum was recently noted in flower in the nurseries of Mr. T. Rochford at Turnford Hall, Broxbourne. It is by far the best of the many good things that has flowered among Mr. Rochford's imported plants. It may be well to mention that there are 100,000 plants of *Odontoglossum crispum* in cultivation here, and as the majority of these are unflowered there will no doubt be found many fine and valuable varieties among them. The sepals are about an inch wide, the ground colour white, heavily suffused around the outer margins with deep violet-purple, the central area thickly covered with large yellowish tinted brown spots. The petals are of beautiful form, $1\frac{1}{2}$ inches across, much toothed on the margins, the ground colour white, with some violet-purple at the apex and spottings of the same colour near the margin at the base. The whole of the central area is one large blotch of yellowish brown, marbled and mottled with white. The broad lip is white at the apex and around the margin, the centre area covered with one large blotch of chestnut-brown, the bright yellow disc having several spots and lines of the same colour on it. The plant carried a three-flowered raceme. As in *O. c. Franz Masereel*, the remarkable coloration of the segments can be seen from the exterior of the flowers. H. J. C.

Masdevallia radiosa.—I consider this one of the best of the *Masdevallias* of the *Chimera* section and a very distinct and interesting plant. The leaves are tall and strong, and the spikes push out over the sides of the basket or pan in which it grows. These produce several blossoms in succession, one falling and another taking its place, so that it is often in flower. The tube part of the flower is bell-shaped, open in front, and in colour a brownish yellow, this part being covered with deep purple hairs, the tails purple. The lip is small, white, spotted with rose and black. A native of New Grenada, it should be grown in a house where the tempera-

ture does not fall below 50° in winter, with very cool quarters in summer.—H.

Chysis bractescens.—This plant is certainly much better grown than it used to be, and the improvement in the materials used in fumigation has helped towards this end. The ease with which insects can be kept at bay has much more to do with improved culture than many people are aware of, and I was reminded of this on seeing a lot of very healthy plants of this *Chysis* recently. The plant does best in a fairly strong compost in which good loam figures largely. The structure of the roots seems to point to a lot of moisture being necessary both in the atmosphere and in the compost. Not very much heat is needed, but the temperature must be high enough to induce free growth, which must be well ripened by exposure to sun and air in autumn, or flowers will not be forthcoming in spring.—H.

SACCOLABIUMS.

JUST at this time of year all Orchids with distichous leaves from a single stem are growing very freely and require considerable care. The principal difference between these and the pseudo-bulbous division is that the latter may be dried off and ripened, so to speak, this process taking place more or less suddenly according to the likes of individual species. With distichous-leaved plants this sudden change would not do, and in consequence the ripening must go on during the whole of the growing season, the leaves being consolidated as they are produced by the action of sun and air. No genus in this section likes more light and sun than *Saccolabiums*, and it is especially necessary now to all the winter-flowering kinds, such as *S. giganteum* and its varieties and allied kinds. In the depth of winter, when the conditions under which the plants are grown are at their very worst, these plants have to perfect and produce long racemes containing an enormous number of flowers, and, if allowed, to carry them for several weeks. Unless the plant has plenty of stamina in it it will not stand this strain, and now is the time to prepare for it by exposing every leaf to the light and allowing as much as possible of the health-giving air to play about them. In winter this cannot be done, of course, and the fact of the plants mentioned flowering at that season is one of the most difficult points to get over in their cultivation. If this consolidating treatment is neglected now, it is very probable the plants will not flower at all; while if they do, the blossoms will be poor and washy in colour and thin in texture. Again, the plants will show their weakness by the foliage dropping in spring, a certain sign that something is wrong and the most reliable symptom of distress.

Turning to the *S. Blumei* section, the plants here are somewhat different. They have not the same great fleshy foliage that the kinds I have mentioned above have, and anyone unacquainted with Orchids may think that they were more difficult to grow on account of this seemingly weak habit. But it is not so, and with fairly good treatment *S. Blumei* and its allies can be grown on year after year in comparative certainty of arriving at large specimen size, a very uncertain goal for *S. giganteum* or *S. violaceum*. At the time this ripening process is going on it is not feasible to reduce the atmospheric moisture as we do for *Dendrobiums* and other tropical Orchids. Doubtless in their native habitats they are exposed to conditions of climate quite as severe as the *Dendrobies*, but under cultivation this will not do, and it is necessary to keep up the atmospheric moisture or lose the foliage. All through the summer light dewings from the syringe may be given

daily over the foliage, but these should now be discontinued, excepting on very bright days. The house being closed early, the temperature will run up rather high, producing just the conditions the plants like, especially the dwarf kinds, like *S. Hendersonianum*, *S. miniatum*, and *S. curvifolium*. These are usually grown in small baskets or pans quite close to the roof-glass, and though the larger kinds mentioned above like equally as much light, the receptacles should be rather larger, especially for *S. giganteum*, the immense roots of which will push through a fairly large amount of rough, open compost and drainage. *S. Blumei* does not require quite so much root-run, though when the plants are large and healthy they make a fair amount of root. All are beautiful plants that may with advantage be added to any collection of Orchids however select, and many of them flower during a dull season for Orchids.

Lycaste lanipes.—This is one of the most free-flowering of *Lycastes*, and a good plant of it in bloom has a very fine appearance. The spikes crowd up around the large bulbs and each bears a single flower. The sepals and petals are rather narrow, the former greenish, the latter ivory-white, as is also the singularly shaped lip. In a cool, moist house it may be grown in rather large pots, equal parts of peat, loam fibre, and Moss finely chopped making a good compost. Rather liberal supplies of moisture are necessary at the roots, especially, of course, when the growth is most active.

Oncidium prætextum.—Grown in a light part of the Cattleya house this fine *Oncidium* flowers well and freely, and is one of the best of the autumn-flowering members of the genus. In habit and manner of flowering it resembles *O. crispum* rather closely, the flower racemes arching and often branched, containing when strong a large number of bright yellow and brown flowers. A raft or very shallow basket suits it well, so that the roots may not be hampered by a lot of compost, but push readily through it and into the air of the house. Plenty of moisture both at the roots and in the atmosphere is necessary, and in order to avoid distressing the plant, it is wise to cut the flowers after a week or so. The bulbs are not particularly large for the immense spikes that they produce, and it is a pity to weaken the plant just for the sake of another week's display. In order to avoid disturbance of the roots, it is well when placing the plants in the baskets or on the rafts to keep the leads as near the centre as possible, using also the best description of peat and Moss for compost. These materials, in conjunction with a few crocks and a little charcoal, will grow it well.

Watering Cattleyas.—Little as I believe in overwatering these Orchids at any time of the year, I am convinced that in quite a number of cases they get far too little now that the pseudo-bulbs are finishing and the roots very active. The effect of lack of water at this time of the year is that the bulbs finish up prematurely, and in consequence break weakly in spring. These growths are more apt to damp off than are those that start from fully developed buds and pseudo-bulbs, and though it seems somewhat of a contradiction, the lack of moisture leads to damping. Water with freedom, then, until the pseudo-bulbs are fully matured, and not until then reduce the supply a little. I have never seen the good effects that are supposed to follow the drying-off of *Cattleyas* in winter to such an extent that both leaves and pseudo-bulbs shrivel, and in the majority of cases the plants are quite free flowering without any such proceeding. It is as wrong to go to one extreme as the other, and the shrivelling can but detract from the beauty and strength of the flowers when they do appear. When it is done with such kinds as *C. aurea* or *C. gigas*, certain plants of which do not always flower as freely as desirable, it is worse than useless, as

weakens the plant with no corresponding benefit.—H. R.

Dendrobium Aphrodite.—In its native country this plant is found growing high up on the branches of tall trees in company with *D. albo-sanguineum*. It is useful in making a pretty show after the usual deciduous Dendrobies are over, and is rather more difficult to keep in health than the majority of these. The pseudobulbs are stem-like, swollen at the nodes like those of *D. Findlayanum*, and the blossoms look extremely pretty towards the upper ends of these. The sepals and petals are creamy white, and the lip has two maroon blotches, one on either side. In growing *D. Aphrodite*, it is well to see that whatever is used as compost is not likely to quickly decay, and very good results have been obtained by growing it on blocks of Tree Fern stems. Here, of course, the plants can remain for a number of years without disturbance, and this suits them much better than pot or basket culture. Baskets and composts decay and the roots sicken, but the natural roughness of the Fern stems suits the roots well. They are very light, too, and may be suspended as easily as a basket. Ample light is essential all the year round, and a good deal of care is necessary to keep yellow thrips in check.

ANÆCTOCHILI.

EXCEPT in a few well-known places, the culture of these singularly beautiful Orchids is not attempted, some at least being extremely difficult to grow. But the beauty of the foliage, unsurpassed in some cases by any other plants, should tempt more amateurs to try and grow them, starting with some of the least expensive and strongest-growing kinds, and gaining a little experience before going in for them largely. It is usual to grow them in a stove temperature under hand-glasses in order to retain atmospheric moisture, and a great deal depends upon the temperature being kept regular and always moist. The plan of watering overhead has been the cause of many plants dying. Although they like the atmosphere absolutely saturated with moisture, this in the morning settling in the form of dew all over the plants or at any time when the glasses are not tilted, still they do not like water poured on them from a syringe or even a sprayer. The roots, in fact, would probably be better not watered from the top provided sufficient moisture could be brought to them in any other way, say by plunging in Sphagnum Moss and keeping this always moist. But this makes the Moss grow so rapidly that it is difficult to keep it in place, and by far the nicest specimens I have seen were grown in small pots simply standing on a bed of finely broken coke. The position was a light stove, and no sunshine could reach the cases in which the plants were grown. The lights were tilted a little for a couple of hours daily, and the air of the house kept as moist as possible while this was done. Beyond this the plants had no air except what filtered through the joints of the glass and woodwork. No peat was used, simply chopped Moss and a little half-decayed leaf soil, these materials being apparently sprinkled among broken pieces of crocks and bricks, which formed the bulk of the compost. A very small fine rosed can was used twice daily, so that the coke was always moist, and the roots were only watered at long intervals, the moisture rising and keeping the crocks and Moss moist.

The propagation of these plants is extremely easy when the rhizomes are strong enough to bear it, and simply consists in cutting off the tops or any part that has a tuft of leaves and a few roots and setting the cuttings going on their own account. The temperature most suitable is about 70° by day and 65° night in winter, raising these 10° in summer and keeping them very regular. One would think in such a case as that described insects could not live, but thrips occasionally put in appearance and give a lot of trouble. Fumigation is out of the question, and very careful

sponging with a weak solution of tobacco water is the only safe remedy. H.

FLOWER GARDEN.

RUDBECKIA GOLDEN GLOW.

We are all familiar with the Black-eyed Susan, the *Rudbeckia hirta* of the botanists. *R. laciniata* is a near relative, and in its typical form somewhat resembles it, except that the disc flowers, those minute blooms covering the cone, are of a dull greenish colour instead of yellow, and the whole flower larger. In the doubling up of the Golden Glow, these disc flowers have

it a double *R. laciniata*. Mr. Childs gave it the name Golden Glow, and I bought from him in order to compare it with those received from Mr. Jensen. They proved identical. Mr. Jensen had seen in the autumn of 1895 a large clump of it in the garden of a German in Chicago, who had received it a year or so before from a relative, and traded some Geraniums for a few roots. This traces it back to 1893 or 1894. At this latter date it was blooming both in Mr. Child's place and in Chicago.

A writer in an English paper about a year ago claimed that it was introduced to English gardens nearly twenty years ago under the name *R. lævigata*. Mr. Wm. Falconer, of Schenley Park, Pittsburg, Pa., dispelled this

Rudbeckia laciniata flore-pleno (syn., *R. Golden Glow*).

changed into ray flowers. The Black-eyed Susan will thrive in dry soil, but the other, being indigenous to the borders of swamps and low meadows, requires a fair amount of moisture. The origin of this double form is yet unsolved. About 1894 John Lewis Childs found it in his grounds among some unknown plants sent him by some of his customers. From it he increased the stock that has, in the main, reached the gardens of the United States and Europe.

While I bought three plants in the spring of 1896 from Mr. Childs, I had three given me in the autumn of 1895 by Mr. Jensen, the superintendent of Humboldt Park, Chicago, who called

illusion in a clear and forcible manner. The mere fact that a plant so attractive in all its parts, so hardy in constitution, so readily grown and rapidly increased, was unknown in this country until within the past few years, even in the largest collections and among the most intelligent professionals and amateurs, is evidence enough that it was not known in English gardens twenty years ago.

The group illustrated is composed of the three plants obtained from Mr. Childs which were placed in their present position in the spring of 1896. Some young plants from the outside of the group have been taken away. The group is supported and protected from

damage by the winds by an iron hoop 4 feet in diameter, placed about 4 feet from the ground, and fastened to four strong stakes set among the plants. This is put in place when the plants are some 5 feet high. The hoop—which is of round iron—is slipped over nearly all the plants. Enough of the outer row of stalks is left outside the hoop to hide it and the stakes; these are then distributed evenly along the hoop and tied loosely, allowing each stalk 3 inches or 4 inches play. When a heavy rain accompanied by winds comes they are apt to become top-heavy and may break. In such cases I run temporarily a heavy but soft string around the whole group, well up towards the top, and draw it in quite closely, thus bunching it as one would a sheaf of wheat. This is removed when the storm is over and the blooms dried off. In this way one stalk supports the other and damage is seldom done. It forms such a strikingly ornamental group upon the lawn that it pays to devote some extra care to it. The drip from a lawn hose connection is carried under this group by tiles, thus affording it an extra amount of moisture. Where plants are not given enough water the blooms are smaller.—W. C. E., in *American Florist*.

Acanthus mollis latifolius.—Buried among other perennials, each fighting for the mastery, this is not particularly showy, but give it room to properly develop its fine foliage and sufficient moisture and food to produce large, vigorous spikes, and its beauty is beyond question. The rosy-tinted form is always a noble plant when grown in this way, and any of the varieties are singularly striking and effective in large, bold clumps. They also make a welcome change from Delphiniums and other well-known herbaceous plants, besides which they flower late in July and August when many of these are getting past their best.

Tritoma grandiflora.—This is one of the few herbaceous plants that have a good effect in the landscape, the broad, handsome Aloe-like foliage and very bright red spikes of blossom showing up at a great distance and sure to attract attention. The upper portion is of the brightest red imaginable, then a golden yellow, and lastly green. To grow it well, stations should be cleared, and if the soil is poor, removed, filling up with good rich compost. This will allow of its making ample growth and throwing up spikes of noble proportions 6 feet or more high. The stations should be kept weeded for a time, and good manual support in some form or another supplied annually.

NOTES AND QUESTIONS.—FLOWER.

Galega officinalis.—This and its white variety *G. o. albidiflora* are useful for cutting at this time of year. Although in many cases they are left in the ground for a number of years, it is better to take up the plants occasionally, divide them, and replant in fresh positions. An open, sunny position backed by evergreens is best for them, as when in flower almost the whole of their own foliage is hidden.

Potentilla formosa.—Very beautiful just now are large, loose clumps of this fine herbaceous plant. There are hundreds of flowers produced in loose heads, the colour a pretty crimson, and it is as useful for cutting as it is pretty in the open. *P. formosa* likes a fairly stiff, not too rich soil, in which case it may be planted near the front, where in late summer and autumn flower is scarce, most dwarf plants being over.

Iris Straussi.—This was first found in the environs of Sultabad, in Persia, by M. Th. Strauss, and grown by Herr Max Leichtlin. This little Iris belongs to the section *Pogoniris* (*Iris barbatus*). It is of low stature (under 3 inches), with narrow leaves and a two-flowered stem. The flower is of fair size and of a brown-violet colour. It is well adapted, from its dwarf size, for the rock garden.—*Revue Horticole*.

Iris aegyriaca.—Native of the Euphrates valley, this was described by Hausknecht in 1896. It is a very handsome plant, 20 inches in height, leaves a fine

green and undulating, sometimes 12 inches in breadth. The six or eight flowers, opening from the summit of the stem downwards, are close upon 4 inches in diameter, and generally of a very pale uniform lilac colour. It is robust and free-flowering. Out of doors under a frame it flowers about the end of March. Like all frises of the Juno group, it requires to be protected in winter, and, above all, requires a period of rest and absolute drought in summer.—*Revue Horticole*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 15.

FOR a mid-August gathering, the display both of fruit and of flowers brought to the Drill Hall on Tuesday last was highly creditable. The open-air flowers were excellent considering the excessive heat and drought. The fine collections of herbaceous Phloxes shown at this meeting merited all praise; indeed, had it been one of those moist or dripping seasons they could hardly have been better. Dahlias were on this occasion noteworthy for their freshness and general good form. Gladioli too were good, some especially so, yet here we would fain see what has long been needed in these things, a different mode of exhibiting them, even though the change were but a modification of the present straight-laced method, which is quite unrelieved by aught else, thus presenting a never-ending glare of rich colours to the eye. Some fine *Caladiums* too were shown, though these would appear to have reached a point of excellence beyond which they cannot pass. Roses also were very good, and the Orchids if not numerous contained some beautiful and interesting things. Some excellent fruit was also shown.

Orchid Committee.

A first-class certificate was awarded to—

LÆLIO-CATTLEYA WIGANE (*L. purpurata* × *C. Dominiana*).—This is a lovely hybrid surpassing in beauty the lovely *L.-C. Dominiana*. The sepals and petals are of fine form and substance, deep rosy lilac in colour, the lip, upwards of 2½ inches across, of a deep crimson-purple, veined with a darker shade of colour at the base. In front of the throat there is a large blotch of deeper purple, from which there run numerous veins of the same colour extending over the whole of the front surface. The side lobes are similar in colour to the front lobe, becoming suffused with a bronzy yellow at the base and through the throat. The plant carried a three-flowered raceme. From the collection of Sir F. Wigan, Clare Lawn, East Sheen.

Awards of merit were adjudged to the following:—

CATTLEYA WHITEI.—A supposed natural hybrid between *C. Warneri* and *C. Schilleriana*. The sepals are deep bronzy, tinted and suffused with rose, the petals deep rose, of fine form and substance, the lip flat as in *C. Schilleriana*, deep rose-purple, much fringed on the margin, the side lobes rose tinted with purple, shading to yellow at the base. It is in every way superior to the original form, each flower being upwards of 8 inches across. From Sir F. Wigan.

SCHOMBURGKIA LYONSI.—In this the flowers are each about 2 inches in diameter, the ground colour white, thickly covered over the sepals and petals with deep plum-purple. The lip has some yellow around the margin, the central and basal portion white, suffused with purple. The plant carried a raceme of fourteen flowers. From Lord Rothschild, Tring Park.

LÆLIO-CATTLEYA BERTHA FOURNIER (*L. elegans Schilleriana* × *C. Dowiana*).—The sepals are of fine form and substance, creamy white, tinted with rose, the petals white, mottled and tinted with rose, the broad lip rich crimson-purple in front, lighter on the side lobes, which are thickly covered towards the base with numerous yellow longitudinal lines. A cut flower came from Mrs. Mason, The Firs, Warwick.

STAUROPSIS LISSOCHILOIDES VAR.—This resembles the better-known *Vanda Batemaniana*, but it has smaller flowers. The sepals are yellow, spotted and mottled with dark brown, the petals more heavily suffused with brown and with fewer spots. The lip is rosy purple, shading to yellow at the base. The whole of the exterior of the flowers is deep rose-purple. A cut raceme of some two dozen flowers came from Lord Rothschild's collection.

Messrs. Hugh Low and Co. sent a very nice group. In the back row were several finely-flowered plants of *Vanda cœrulea*, a nice variety of *Oncidium varicosum*, and *O. Krameri*. *Dendrobium Leeanum enfieldense* is a delicate form with buff-yellow and rose-tinted flowers. *Cattleyas* were well represented by fine forms of *C. Warszewiczii* (*gigas*) and several good forms of *C. Loddigesii*. The beautiful *C. superba* was well represented. A good form of *C. Dowiana* and *C. Eldorado* were also included. *C. Gaskelliana* in both light and dark forms, the most attractive being *C. Gaskelliana pallida*, whose flowers had only the faintest tint of rose in the segments, was also shown. *Odontoglossum crispum*, *O. Pescatorei*, and *Cochlidia Noezliana* were well represented. In the rare *Vanda Charlesworthii*, which is supposed to be a natural hybrid between *V. cœrulea* and *V. Bensonæ*, the upper sepal is rose, mottled with white, the lower sepals whiter, with only the faintest tint of rose. The petals are similar in colour to the upper sepal, the lip deep rose-purple, with some lines of white at the base. *Lælia Amanda*, *Lælio-Cattleya elegans*, and *L.-C. Novelty* (*C. Turnerii* × *L. Dayana*) were well represented. A silver Flora medal was awarded.

Mrs. Mason, The Firs, Warwick, sent *Cypripedium Frau Ida Brandt* (*C. Io* × *C. Youngianum*), *Dendrobium McCarthiae* with three flowers, a good form of *C. Warszewiczii* and *C. Fowleri*, in which the sepals and petals are deep purple, the lip, as in *C. Leopoldi*, deep rose-purple in colour. Captain S. Julian, Plymouth, sent a light form of *Cattleya Eldorado* and the beautiful dark *C. Harrisoniæ violacea*. The Rev. F. Paynter showed *Lælio-Cattleya Henry Greenwood* (*L. elegans Schilleriana* × *C. Hardyana*), in which the sepals and petals are very pale lilac, the lip crimson-purple, the side lobes rose, shading to yellow at the base; *Cattleya Harrisoniæ*, *C. Gaskelliana*, and a new hybrid, said to be between *Cattleya crispa* and *C. Warneri*, but no trace of the parents could be discerned. M. Jules Hye, Ghent, sent a fine form of *Cypripedium Mossianum*. Mr. McDonald, Pitlochry, had a new hybrid belonging to the *Cypripedium Rothschildianum* section. Mr. Norman, gardener to Lord Salisbury, sent a finely-grown plant of *Aerides Lawrenceæ* var. *Sanderiana* with four spikes of flower, and Mr. de B. Crawshaw showed *Odontoglossum crispum Trianae*, *O. c. Miss F. M. Bovill*, and a light form of *O. Uro-Skinneri* with an exceptionally large lip. Sir F. Wigan showed a distinct form of *Cattleya Aclandiae* and *Cattleya Atalanta*, in which the sepals and petals are bronzy yellow, suffused with rose, the whole of the front lobe bright crimson, the side lobes of the same colour at the apex, shading to white towards the base. The plant carried a raceme of seven flowers, each about 5 inches in diameter. *L.-C. Aurora* was also included.

Floral Committee.

A first-class certificate was awarded to

NEPENTHES BALFOURIANA.—A handsome form, having *N. Mastersiana* and *N. mixta* for its parents. In the new-comer the pitchers are very bold and well coloured, the inclination, particularly in respect to size, being towards *N. Mastersiana*.

The following obtained the award of merit:—

PHLOX LE MAHDI.—A very distinct kind with violet-purple flowers, quite the best of this shade that has yet appeared. From Messrs. W. Paul and Son, Waltham Cross.

ROSE GROSS AU TOPLITZ.—A beautiful and showy Hybrid Tea, the flowers of a rich crimson-scarlet hue, in trusses containing twenty to thirty

buds. As a garden Rose this should prove of much value. From Messrs. W. Paul and Son.

GLADIOLUS BURNE-JONES.—A very fine scarlet, with flowers of immense size. From Messrs. Kelway and Son.

GLADIOLUS F. PAYNTER.—The finest orange-scarlet we have seen; indeed, it is more vermilion in its intensity, and in the compact spike is showy in the extreme. From Messrs. Kelway and Son.

GLADIOLUS LADY MONTAGU.—Here we have a lovely tone of yellow in a rather poor spike, yet a flower of great beauty and worth, the lower petals marked with crimson spots. From Messrs. Kelway and Son.

GLADIOLUS HENRI VAUDRIER.—A striking flower of the *G. Nanceianus* type, or this mingling with some other form. The blossoms are of large size, spreading widely and crossing the tips of the segments to the next bloom. It is of a distinct amaranth tone, though the throat is white spotted. From Messrs. James Veitch and Sons, Chelsea.

GLADIOLUS JANE DIEULAFOY.—This belongs to the *Lemoinei* section and is of a rose-salmon shade, the lower petals margined with the same colour and spotted with crimson on a white ground. From Messrs. Wallace and Co., Colchester.

CUPRESSUS LAWSONIANA WISSELL.—A distinct and pretty plant, for which it is difficult to find any comparison. It is removed from the ordinary forms of this plant by the forked tendency of the branches that assume opposite directions. It is quite neat and compact in growth and of a semi-glaucous tone. From Messrs. J. Veitch and Sons, Chelsea.

DAHLIA (CACTUS) ANTLER.—A very handsome flower of a crimson-amaranth hue throughout. From Messrs. Burrell and Co., Cambridge.

DAHLIA (CACTUS) SYLPH.—A brilliant orange-red kind, the tips of the florets well incurved. From Messrs. Burrell and Co.

DAHLIA (CACTUS) AJAX.—This is of a salmon-orange hue, and not only distinct in shade from the last, but generally a larger and bolder flower. From Messrs. Burrell and Co.

HOLLYHOCK BLACK KNIGHT IMPROVED.—This is a descriptive term, the flowers being of a glossy maroon and very full. From Messrs. Webb and Brand, Saffron Walden.

CENTAUREA AMERICANA ALBA.—A very large and white-headed Cornflower of the annual class, though quite removed in size and appearance generally from anything we have before seen. The flower heads are each about 4 inches across and composed of long thread-like filaments, which are very numerous. From Messrs. Cannell and Sons, Swanley.

The *Caladiums* from Messrs. Laing and Co., Forest Hill, arranged on the floor, covered a very considerable space and contained all that is worth growing among these plants. Edith Lotter, bronzy pink, with silvery blotches; Charlotte Hoffman, small pure white foliage, with pale green stems; Rt. Hon. Jos. Chamberlain, blood-crimson, with green border; Souvenir de Louis Thibaut, reddish rose, a long and distinct oval leaf; W. E. Gladstone, rich crimson, grass-green margin, very fine; Aureole Boreale, dark red, spotted bronzy green, leaves of great size; and Barillet, green, crimson centre, were among the best. The entire group had a background of tall Palms, and was margined with the pretty *C. argyrites* and small Ferns (silver Flora medal). Messrs. J. Cheal and Sons, Crawley, had a fine lot of the newer Cactus Dahlias, many of which were remarkable for their beauty and colour. Of these, Ebony, blackish maroon; Countess of Lonsdale, rich salmon-red; Exquisite, a reddish apricot with long, claw-like petals; Ranji, deep rich maroon; Viscountess Sherbrook, terra-cotta, with apricot, were noteworthy. Among other things, *Veronica salicifolia*, *Colutea arborescens*, *Glyceria spectabilis* fol. var. and several *Eulalias* were noted. Messrs. Webb and Brand, Saffron Walden, had a superb lot of flowers of their well-known strain of double Hollyhocks, of which Leander, buff; Purity,

amaranth; Alf. Chater, rose; Hercules, buff and rose; and Black Knight, rich and glossy, were among the best (silver Banksian medal). A splendid lot of Dahlias came from Mr. Mortimer, Farnham, Surrey, the group containing the finest of the Cactus and show and fancy kinds. Of the Cactus kinds, Countess of Lonsdale, Captain Broad, Ebony, Magnificent, Lucius, Firebrand, Ranji, The Clown, Radiance, E. J. Deal (the finest scarlet yet raised), Wallace (a bright amber), Arachne, Mrs. J. Goddard, Starfish, Britannic, and Keyne's White were good. The show and fancy sorts were beautifully finished flowers, and were arranged on either side the Cactus forms (silver Flora medal). The group of *Campanula isophylla* Mayi from Mr. H. B. May, Dyson's Lane, Edmonton, was particularly fine, the plants even larger and better flowered than they appeared on a former occasion. More than this, the flowers now appear to have assumed their true character, as was seen in the more mature blossoms, which had a flush of reddish mauve at the tips of the lobes. The plants were splendidly grown, being a mass of flowers fully 18 inches high and nearly the same through. The plants were arranged amid a groundwork of Ferns, and in the mass made a very decided and attractive group (silver Banksian medal). The group of Ferns from Messrs. J. Hill and Son, Edmonton, was one of the finest ever brought to the Drill Hall, and was composed entirely of *Adiantums*, some sixty species and varieties being staged all beautifully fresh and clean looking; indeed, it was remarked in several quarters how well the plants were grown. Some of the finest and most distinct are *Reginae*, *cuneatum grandiceps*, *elegans*, *Faulkneri*, *Victoriae*, *Capillus-venenis imbricatum* (very fine in colour and in pinnae), *curvatum*, *roseum* (a pretty dwarf plant with rose-tinted fronds), *Hendersoni*, *asarifolium*, *tinctum*, *Fergusonii* (perhaps one of the handsomest of all), *tetraphyllum*, *Bessonianum* (also a very distinct form), and many more of the better-known kinds, all in capital condition and certainly meriting great praise (silver Flora medal). A considerable attraction too was the group of cut spikes of *Gladiolus*, though here we would prefer to see some change in the method of setting up, even if fewer spikes were shown and some other material introduced to act as a foil to the endless array of bright and beautiful colours. These latter too frequently cut each other, as it were, by the contrast of the flowers, and however beautiful in beds alone on the grass, scarcely show to the same advantage on the exhibition stand as now employed. Messrs. Kelway and Son, Langport, were large exhibitors of these, and though the flowers were good we do not hesitate to say we have in the past seen much finer spikes from the same source. Some attractive kinds were Sir M. Hicks Beach (salmon and white), *Raladora* (cerise and white), *St. Gation* (crimson with lines of white), *Bullion* (yellow), *Gallia* (rosy white, freckled with scarlet), *Princess Royal* (satin rose and white), *Zoe* (blood-crimson), *Wellington* (maroon), *Chopin* (salmon-scarlet), *Colonel Morgan* (soft pink with spots). A silver Flora medal was awarded. A very great attraction, too, was the Roses and herbaceous Phloxes from Messrs. Wm. Paul and Son, Waltham Cross, the former in vases and baskets arranged in groups, and the Phloxes in tall vases, in their great variety making a really fine display. Of the Phloxes alone some forty kinds were shown, and it certainly speaks volumes for the suitability of the soil and the district around Waltham Cross that in a season phenomenally dry these moisture-loving plants should appear so fine. Of these, the following are some of the best: *Lumineux*, salmon-scarlet; *Droiche*, deep lilac; *Meteore*, salmon, white eye; *Beranger*, soft salmon; *Etna*, brilliant scarlet, very fine; *Esperance*, rose, lilac, and white; *Coquelicot*, orange-scarlet, a splendid colour; *Iris*, violet; *Fiancée*, pure white; *Embracement*, scarlet, &c. The Roses, too, were very beautiful, baskets and boxes of these in great variety, and indeed fine quality also (silver Flora medal). Another

capital lot of Roses and Phloxes came from Messrs. Paul and Son, The Old Nurseries, Cheshunt. Here many of the same kinds were noted, though of the Phloxes one or two excellent kinds call for mention. These are *Bayudere*, pure white; *Broxbourne Star*, white and rose; *Jocelyn*, very bright, colour of Etna; *Miss Pemberton*, fine salmon; *Feodora*, pale salmon; and *Mrs. Croft Murray*, salmon-rose. *Rudbeckia purpurea*, *Statice latifolia*, and a splendid spike of *Veratrum nigrum* quite 6 feet high were also here (silver Banksian medal). From Tottenham Mr. T. S. Ware sent a good batch of mixed hardy things, such as *Tritomas*, *Tiger Lilies*, *Statice*, *Sundflowers*, *Agapanthus umbellatus albus*, *Delphinium chinensis album*, *Eryngiums* of sorts, *Cactus* and *pompon Dahlias*, together with a fine lot of single and double *Begonias*, which, so far as single flowers are concerned, would take some beating (silver Banksian medal). Hardy flowers from Messrs. Wallace and Co., Colchester, were very fine, particularly the *Liliums*, which formed so large a part of their group. Of *L. auratum* and *L. a. platyphyllum* there was indeed a grand display, the spikes of flowers very fine and the blossoms massive in appearance. *L. longiflorum giganteum*, *L. tigrinum*, and *L. rubro-vittatum* were equally good. Apart from these, a well-nigh complete collection of *Montbretias* was set up, these including the double-flowered form, though we confess to see more beauty in the single kinds. Some capital *Echinops Ritro*, blue and white *Caucasian Scabious*, *Anemone japonica alba*, *Gaillardias* in plenty, *Coreopsis*, and the finely-coloured *Platycodon Mariesi*, which is ever an attraction in any group, were also shown. Charming, too, is *Sidalcea malvaeflora Listeri*, a pink flower deeply cut at the margin. It is a capital subject in the open or in a cut state. Besides these were hosts of *Gladioli*, many of which are very fine, those in particular which belong to the *G. Nanceianus*, *Lemoinei*, or *Childsi* groups being especially strong, and, so far as the outdoor garden is concerned, valuable by reason of their greater general hardiness and freedom (silver Banksian medal). Another group of hardy flowers came from Messrs. Barr and Sons, Covent Garden, though in large degree it was apparent these things had suffered from the great heat of the year in conjunction with a soil hot, sandy, and dry. *Lilies*, *Phloxes*, *Aconites*, *Sunflowers*, *Gaillardias*, *Pentstemon barbatus coccineus*, *Hyacinthus candicans*, and such things were freely shown. A small collection of flowers of single and double *Begonias* came from Mr. H. J. Jones, and testified to the fine strain of these flowers. Messrs. Hugh Low and Co. had a small group of the golden Acer (*A. californicum aureum*), a fine golden-leaved plant quite distinct from *A. Negundo* forms. Messrs. J. Veitch and Sons had a variety of interesting things, among which a huge example of *Clerodendron trichotomum* with white flowers attracted some attention, being of considerable age and a mass of its flowers. *Pentstemons* in pots well grown and in great variety were also shown, together with *Clematis Davidiana*, *Apera arundinacea*, *Andromeda arborea* (small white blossoms), *Pharus guianensis albo-striata*, a set of the *Javanico-jasminiflorum Rhododendrons*, and several more or less double varieties of *Begonia semperflorens*, representing white, rose, and scarlet shades.

A very handsome group arranged on the floor of plants grown within three or four miles of Charing Cross came from Mrs. Abbott, South View, Regent's Park (Mr. G. Kelf, gardener). The group in question was one of the usual order of such things, being composed of Palms, tall and dwarf, *Crotons*, *Dracenas*, *Tiger* and *auratum Lilies*, *Pandanus*, together with a great variety of *Celosias* in pots, the whole being margined with Ferns and other small plants. The group was of considerable size, too much and too densely crowded, as is most usual in such exhibits. A silver-gilt Flora medal was awarded. Another group of plants arranged on the stage came from Mr. P. Purnell, Streatham Hill. Here *Fuchsias*,

single and double Begonias, Ferns, and small Palms predominated (bronze Banksian medal). Capital plants and blooms of Nerium Oleander, red and white, were shown by Mr. F. W. Champion, Cowley Manor, Reigate (gardener, Mr. J. Fitt), for which a vote of thanks was accorded.

Fruit Committee.

There were some excellent exhibits before this committee in the shape of collections of fruit, but we fail to see why exhibitors should now stage Apples that are in season in winter.

A first-class certificate was awarded to—

TOMATO THE CHISWICK PEACH.—A very pretty fruit and of equally good quality. It is a sport from the Red Peach and originated in the society's gardens. This was recommended for a first-class certificate by the committee at Chiswick some time ago. There being a full crop of fruit, seed of this new variety will be sent to the Fellows of the society.

Awards of merit were given to—

APPLE EARLY VICTORIA.—A very early Codlin with great bearing qualities. This will be a profitable market fruit, being firmer than the Keswick or Manks, but quite as early. This is the result of crossing Lord Grosvenor with Keswick Codlin. From Mr. J. W. Cross, Wisbech.

MELON (UNNAMED VAR.).—This, a small, round, scarlet, netted fruit, was given an award of merit conditionally. It was stated to have been grown out of doors. On previous occasions the committee have refused to give an award to an unnamed fruit. They did so in this case and asked for a name and particulars. From Mr. D. Harrison, Merrow House, Guildford.

RASPBERRY BLACKBERRY HYBRID.—A dark fruit, very much like a Raspberry in shape, but different in colour. It is the result of crossing Raspberry Belle de Fontenay with the common Blackberry, and should make a delicious preserve, being of a brisk, pleasant flavour. The plant is a free bearer and grower. From Messrs. Veitch and Sons, Chelsea.

A very fine collection of fruit in pots and dishes came from Mr. G. Kelf, The Gardens, South Villa, Regent's Park, N.W., the background being Plum trees well laden with fruit, the varieties Early Transparent, Cox's Emperor, and Jefferson. The same kinds were also staged in dishes, with the addition of Kirke's, Golden Drop, but not ripe, fine Reine Claude d'Athene and Green Gages in variety, excellent Melons, Barrington Peaches very finely coloured, good Black Hamburg and Buckland Sweetwater Grapes, Tomatoes in variety, and some dishes of cooking Apples (silver-gilt Banksian medal). Messrs. Veitch, Ltd., Chelsea, had a varied collection of fruits, mostly early Apples and Pears, with Cherries and Currants, some three dozen dishes being staged. The best Apples were Lady Sudeley, Mr. Gladstone, Kerry Pippin, Duchess of Oldenburg, Yellow Ingestre, Duchess Favourite, Devonshire Quarrenden, Oslin, Red Astrachan, White Transparent (a pretty fruit), Early Julien, with several varieties of cooking Apples, such as Lord Grosvenor, Stirling Castle, Potts' Seedling, Dutch Codlin and Lord Suffield. Among the Pears were Summer Thorle, Doyonné d'Été and Beurré Giffard; La Versaillaise and Lee's Prolific Black Currant, with Morello Cherries, were also included (silver Knightian medal). Messrs. G. Bunyard and Co., The Royal Nurseries, Maidstone, staged twenty-five dishes of early Apples. There were five fruits of Beauty of Bath, Early Julien, Duchess of Oldenburg, Ecklinville Seedling, Gold Medal, Golden Spire, Grenadier, Lady Sudeley, Lord Suffield, Potts' Seedling, The Queen, Stirling Castle and White Transparent (silver Knightian medal). Messrs. Spooner, Hounslow, also staged a collection of Apples, but there were more late varieties than in the other collections. Red Astrachan, Irish Peach, Yellow Ingestre, Stirling Castle, Ecklinville, Grenadier, Lord Suffield and Royal Jubilee were the best (silver Banksian medal). Mr. J. Miller, The Gardens, Ruxley Lodge, Esher, staged a very nice lot of fruit, including

a splendid dish of Early Rivers Nectarine from open walls, Royal George, Alexandra Noblesse, and Violette Hâtive Peaches, Kirke's Plum, Brown Turkey Figs, Cherries in variety, including Bigarreau Blanc d'Espagne, a late white variety; Apricots, Pears, Gooseberries, and a new Melon of nice appearance named A. Henderson (silver Knightian medal). Mr. H. Walters, Eastwell Park Gardens, Ashford, put up a nice collection of fruit, including Melons, Black Hamburg and Foster's Seedling Grapes, Pine-apple and Downton Nectarines, Sea Eagle and Violette Hâtive Peaches, well deserving the silver Knightian medal awarded. Some very fine Oranges came from Mr. S. E. Lamb, Forest Hill, S.E. Three new varieties of scarlet-fleshed Melons came from Mr. Wiles, The Rookery, Farnborough. Dwarf Beans Progress, Early Wonder, and Veitch's Hybrid were sent by Messrs. Veitch and Sons, Chelsea, and Tomato A. H. Gibson by Mr. Gibson, Ben Moore, Pinner.

The Royal Horticultural Society's certificates.—We were astonished to find on perusing the official list of the awards of the fruit committee on Tuesday last to find that an award of merit had been given to a Melon without a name. Having known something of the working of the various committees for the past twenty-five years, we understood that in no case could an award be given to any flower, fruit, or vegetable which was not, on being submitted to the committee, named. This rule has now been broken in the case of the above Melon, and we should be glad to know the reason. If any doubts were entertained as to the Melon, why not, as has often been done, ask the exhibitor to submit it again, the secretary of the committee informing him in the meantime that it is necessary that a name should be given and that all particulars as to the culture should be sent. This in bygone days was always the case, and why not so now?

NOTES OF THE WEEK.

Nymphaea stellata in the open air.—*Nymphaea stellata*, the sweet-scented blue Water Lily, has flowered in a lake at Carton, Kildare, this year. It had four open flowers the other day and was much admired as seen along with the best of M. Marliac's seedlings. This is the first time I have heard of its flowering without added heat or shelter, and think the fact worth noting. — F. W. BERTRIDGE.

Platycodon Mariesi.—This is undoubtedly of the first rank among the whole host of hardy plants. In no sense is it an every-day-looking plant even prior to its flowering, and still less so when the richly coloured blossoms expand, for then it is one of the most valuable, as it is desirable and ornamental in any garden of choice hardy flowers. Any such plant is an acquisition and as such worthy of all care, as it is deserving of all praise.

Sweet Peas.—A week or two since the present season's display of these flowers seemed to have come to an untimely end, but the cooler evenings and early morning dews of late, coupled with the cooler breezes recently experienced, have given us a further supply of their welcome blossoms. Emily Eckford, Blanche Burpee, Aurora, Her Majesty, Blanche Perry, and Countess of Radnor have been and are still making a brave show, and if only still more suitable conditions prevail there is every prospect of this display continuing.

Herbaceous Phloxes.—These usually hard some flowering plants have during the last two years or so had but a sorry time, not one good head per plant resulting where the plants have had to shift for themselves, and where, too, they exist under quite ordinary conditions in the border. Spring-planted pieces have fared even worse in spite of the soil being deeply trenched and heavily manured. Root-watering, unless brought frequently to saturation point, is of but little avail so long as the atmosphere remains parched and dry.

Gentiana tibetica.—Though not one of the tallest or boldest of the Gentian family, this is yet one of the most vigorous and robust for its size.

It is a strong-rooted kind, and noteworthy rather for its vigour and distinctness than for its showy character. It is a white-flowered species, too, and in common with other whites of this family does not impress one in the same degree as do the beautiful and ever-welcome kinds possessing blue flowers varying in their shades of colour and richness.

Campanula excisa.—In this pretty species from Switzerland we have a well-marked kind, particularly distinct in the finely-cut foliage and frail stems that support the dainty and rather pale blue bells. The plant is but a few inches high, and certainly worth a good position in the rock garden, where in a pocket or snug recess it will be content in a mixture of soil and stones or grit. Frequently a capital substitute for grit is the sandy or loamy gravel that abounds in many parts, while in others burnt clay earth forms a capital substitute and is frequently quite easily obtained.

Tufted Pansy King of the Blues.—This has been one of the most pleasing and effective sorts throughout the recent dry weather, and at the present time it still remains in good form. This is one of the few good miniature flowered Tufted Pansies, and will prove effective where a Pansy with a deep blue colour is required. Unfortunately, the variety is little known, but those disposed to take it in hand may do so with every confidence. The constitution is robust, and although the plant has a good habit, it is not quite so compact as some others. It is also a free-flowering sort. — D. B. C.

Campanula isophylla Mayi.—Mr. May made a really fine display on Tuesday last with his new trailing *Campanula* when he staged a group of splendidly-grown plants, a veritable mass of flowers, at the meeting of the Royal Horticultural Society. The plants, too, appeared in better form than previously, the flowers having attained their full tone of colour, a charming shade of blue, with perhaps the merest suspicion of red-mauve towards the extremities of the lobe divisions of the corolla. This, however, is only visible in a certain light, while the mass of heliotrope-grey, rather than blue, flowers makes it showy indeed.

Heuchera brizoides.—I was pleased to read the note at p. 86 by "H. S." on the above, as I recently saw it in splendid condition in the garden of Mr. Hindmarsh, Alnbank, Alnwick. Mr. Hindmarsh, who is a great lover of hardy plants and who has got a very fine collection, grows many of the beautiful alpines much better than we see in the south. *Heuchera brizoides* promises to make a splendid decorative subject, as the increased length of spike makes it more useful, and it remains good so long after being cut. The colour, though somewhat paler than in *H. sanguinea*, is of a pleasing shade and most effective in the mass. It is quite hardy, as Mr. Hindmarsh's plants are fully exposed on high ground. — G. WYTHES.

Acer californicum aureum.—It is perhaps a drawback to such plants as attain to tree-like dimensions ultimately that they are exhibited in a small and, so to speak, immature state. This Golden Acer is a case in point. The exhibitors knowing and appreciating its worth, and having knowledge of the more established original examples, have the highest opinion of the value of the plant from a garden point of view. At the same time it is scarcely possible in such a case to do justice to the plant by exhibiting it in pots about 7 inches or so across. That it is quite distinct from the well-known Japanese *Acer Negundo* forms is certain, and, provided the present colour is maintained when the plants are in the open ground, this Acer will be a decided gain to our gardens in the future.

Tufted Pansy Howard H. Crane.—The miniature-flowered Tufted Pansies for some reason have failed to create the interest that they deserve. First class sorts, it is well known, are limited in quantity, probably because so few of the novelties sent out a few years since came up

to the standard set by the parent variety—Violetta. The variety under notice has a robust constitution, is dwarf and compact, and at the present time is studded with its charming little blossoms, which are rayless and fragrant. The lower petals are rich yellow in colour, the upper ones being of a pale canary-yellow. Those who value Pembroke, one of the newer rayless sorts, will better understand the beauty of the variety under notice when it is stated it may be described as a miniature-flowered Pembroke.—C. A. H.

Gentiana asclepiadea alba.—While I think the blue Gentians superior to those with white flowers, I suppose that taste for something out of the common run, which we all possess in a greater or less degree, makes us prize the white-flowered varieties. The white Swallow-wort Gentian is, although not absolutely rare, so little seen, that it is doubtful if it is known except to those with a wide acquaintance with hardy flowers. Here I find it a little less robust and scarcely so free in producing its blooms as the typical blue form, but it is free enough and robust enough to justify one in mentioning it and in bringing it before the notice of those who like such flowers. I grow *G. asclepiadea* and its white variety in sunny places, and they flower well in such, even if not so tall as one sees them in some gardens. I do not like to see the Swallow-wort Gentian grown to an excessive height such as I have observed in some places.—S. ARNOTT.

Gentiana linearis.—The Gentians are such universal favourites, that any information regarding easily-grown species may be of service to some who have been baffled when trying to grow others less amenable to cultivation in our gardens. If I have this plant true to name, it is one which may be recommended as giving little trouble in the light dry soil here, and as likely to do well under similar conditions. I make the reservation as to name because, although I had the plant from a good source, the synonym of *G. linearis* in Nicholson's "Dictionary of Gardening," i.e., *G. pseudo-pneumonanthe*, makes one a little doubtful. The plant I have more nearly resembles *G. asclepiadea* than any other I can think of at present. It is, however, dwarfer in habit and deeper green in leaf-colouring. It is here a good bloomer, and now that it has bloomed once more it looks pretty with its blue flowers lined with white in the interior. I have had it on a rockery here for some time, where in sandy peat it does well with a large amount of sunshine until about 5 p.m. *G. linearis* is an American species.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Sempervivum Hookeri.—This is by no means one of the least beautiful or distinct of the Cobweb Houseleeks, of which *S. arachnoideum* is the type. Its claims to distinctness are in the shorter, thicker, and more decidedly blunt leaves, which, as in *S. Laggeri*, are of a pale green tint, and the inclination in the growing rosettes at least to spread in a sort of reflexing way. This, however, is more or less transient, and with age, as also in the small offsets, a more compact rosette is formed. All the same, the plant is a well-marked form of this group, and I am not sure that the web itself is not even more white and dense than is usually seen. This I hope to prove another year with three forms side by side, one of these being a plant that some twenty years ago created some discussion by being named *S. Pomelli*. This name was, however, given conditionally, the plant to which it referred having reddish coloured leaves for a long time in spring. This, underlying the white web that adorns all these kinds, resulted in a pretty effect when in a mass on rockwork. The difference in the colour of the flowers in these webbed forms is not great, pink and reddish pink predominating in the hardy kinds at least.

Echinacea purpurea.—This handsome Cone-flower is now very beautiful, and at the same time distinct in its way. Such really good and finely coloured things are by no means plentiful, for it has no equal in its own race and no competitor from any point of view. Being slow in growth and also in its spread at the root, are

among the reasons why this fine plant cannot so quickly be formed into groups. Happily, however, the plant offers few if any difficulties from a cultural standpoint, and in quite strong loamy soil as well as in light, richly manured ground it grows well and flowers freely. As may be expected, there are inferior forms of this plant, possibly originally the result of raising seedlings, and those seeking a reliable stock may do well to see the plant in flower. Perhaps the Winchmore Hill variety of this plant is one of the finest forms, not merely in the size and breadth generally of the flower-heads, but equally in the richer colouring in the ray florets. Three feet or rather more in height and usually quite self-supporting, this is a telling subject in any garden. At a short distance, or even at a distance of 100 yards, the richly-coloured heads will not fail to attract attention.

Campanula carpatica pelviformis.—As one who has grown this very beautiful Harebell for a number of years I may be permitted to express the pleasure with which I read the short note which appeared in THE GARDEN of August 12. It is one of the flowers of which one would like to know where it originated, if a chance find or a seedling raised by some one. One feature about it is its stiff, firm habit which is noticeable even among the varied forms of the Carpathian Harebell. I know that some growers have been disposed to consider it either a distinct species or a hybrid, but there seems to be little but mere surmise to support this view. It seeds fairly well here, but I have never been able to carry out my wish to raise a number of seedlings to see what results would follow. A chance seedling which has appeared has, however, gone back to the normal form of *C. carpatica*, not only in form, but also in the colouring, which is much deeper than the china-blue of *C. c. pelviformis*. I have here another variety of *C. carpatica* with saucer-shaped flowers. It was sent to me from Lanarkshire. The flowers of this variety are deep blue, such as we generally associate with the typical *C. carpatica*, and the plant is of a decidedly prostrate and not erect habit. The flowers are, perhaps, hardly so flat as those of the usual pelviform variety, but are much more so than those of the typical or other forms.—S. A.

Veratrum nigrum.—Attention is directed by "S. A." to this striking plant as a flowering subject for the present month. As justly observed, the value of the plant does not rest in the brilliancy of its flowers, nor is it one of those every-day plants that can be strongly recommended for cutting, a point which appears to carry great weight in the minds of not a few at the present time. Happily for the garden, there are some things that are more or less ill-suited to cutting, and this handsome plant is one of the number. "S. A." also refers to the continued attractions of the plant, when from its early days the handsome leaves can scarcely be seen without being admired. The reference to its non-flowering over a period of years would appear to suggest either an unsuitable spot or a soil too light and possibly too dry. Any such plants should now receive very heavy soakings of water if such be at all possible. Bold in aspect and possibly a trifle gross naturally, a rich and deep bed of fairly strong soil and abundance of moisture from the time growth begins are among the best aids to quickly form it into a flowering plant. Disturbance of the root should only be countenanced of necessity, as it causes a check that leaves its mark for a full season at least. Some years ago a group of this, planted in a semi-wild spot where the root fibres wandered into a trickling streamlet on its way to an artificial bog bed, attained fully 5 feet high, and after the third year flowered regularly for the most part. There is in the flowers a peculiar odour which is by no means disagreeable.

Market gardens.—Judgment was recently given in the House of Lords in an appeal which raised the question whether market and nursery

gardens, upon which are greenhouses and other structures used for productive purposes, can claim the benefit of the Agricultural Rating Act of 1896. At Worthing the overseers returned a market garden and the structures upon it as agricultural land, but the surveyor of taxes treated them as buildings. The question was carried by way of appeal through the Courts, and the Lords now affirmed the judgment of the Court of Appeal that a market garden with its buildings is not agricultural land within the meaning of the Act.

The weather in West Herts.—Throughout the past week the days' temperatures have again been very high, but several of the nights proved cold for the time of year. On the 15th the shade temperature rose to 87°, which is the highest reading in shade as yet recorded here this year. On the other hand, on two nights the thermometer exposed on the lawn fell to within 8° of the freezing-point. The ground still remains very warm, the readings at 2 feet deep being 7°, and at 1 foot deep as much as 8° warmer than their respective averages for August. Half an inch of rain fell during a thunderstorm which took place on the afternoon of the 15th, and during the height of this storm rain was falling for three minutes at the mean rate of 2 inches an hour. No measurable quantity of rain-water has, however, as yet come through either of the percolation gauges. The winds were again light, and came mostly from some point of the compass between north and east. During the four days ending the 13th the sun shone brightly on an average for nearly twelve hours a day.—E. M., *Berkhamsted.*

Open space for Hammersmith.—In the Consistory Court, Hammersmith, Dr. Tristram, Chancellor of the Diocese of London, granted a faculty authorising the improvement and use as an open space of the portion of the old churchyard of St. Paul's, Hammersmith, which has been closed since 1854.

The Dutchman's Pipe.—I enclose a leaf of *Aristolochia Siphio*, or Dutchman's Pipe, which seems unusually large. Several other leaves on the same plant are of much the same size. The plant is growing against a house wall.—J. H. W. THOMAS, *Belmont, Carlou.*

* * * The leaf sent measured 13½ inches across its widest part, the length from the stalk to the tip being 1 foot.—E. D.

Caterpillars on Dahlias.—There is no royal road by which you can destroy all kinds of caterpillars except by hand-picking. From your letter I should imagine that your garden was infested by a great variety of different sorts, but, unless I know the kind of caterpillars, it is impossible to tell you the best means of destroying them now or of preventing an attack next year. I can only suggest that you should spray or syringe your plants with solution of paraffin emulsion, or a mixture of Paris green, lime, and water might be used in the same way with plants that were not intended for food in any way, as the Paris green is a rank poison, but if your garden is a large one this is no light task. If you will send up a few specimens of the different kinds, giving the names of the plants on which they feed, I might be able to suggest something more practical.—G. S. S.

Names of fruit.—*J. W. Shaw.*—Your Apple is French Crab. The fruit looks as if it had been scorched, no doubt owing to the trying weather we have had of late. We should imagine the trees are dry at the roots.—*C. West.*—1, Devonshire Quarrenden; 2, Early Julien.—*N. Kaznakoff.*—Quite impossible to name fruit from leaves only.

Names of plants.—*Subscriber.*—Your Rose is Fellenberg.—*J. R. P.*—1 (if a small tree), Acer Negundo; 2, must be sent when in flower and with fuller material; 3, Sedum Sieboldi; 4, Aloe fruticosum.—*G. B. B.*—1, Bet Balm (*Monarda didyma*); 2, Solidago aurea (*Golden Rod*); 3, Echinops ruthenicus; 4, Anemone japonica; 5, Stenactis speciosa.—*F. Hampson.*—1, Sedum Lydium; 2, the Thorn Apple (*Datura Stramonium*).—*Quercus.*—1, Rudbeckia maxima; 2, Aster Shorti; 3, Hypericum sp.; 4, Statiche latifolia; 5, Ophiopogon Jaburan variegatum; 6, send better specimen.—*Watkins and Simpson.*—1, probably a seedling of *Chrysanthemum frutescens*; 2, *Pellionia Daveana.*—*T. Nowell.*—*Burlingtonia candida.*

FLOWER GARDEN.

CARNATIONS, 1899.

Now that the exhibitions are over for the year, a few suggestions may not be out of place, which, if followed, would, I think, tend to increase the interest in these annual competitions.

YELLOW GROUNDS AND YELLOW GROUND PICOTEES.—I agree with every word that "R. D." says in your issue of the 12th inst. on the subject of the classification of yellow ground Picotees. A meeting was held upon this very subject two or three years ago, but it came to nothing. I have always advocated that some hard and fast rule should be formed as to what is and what is not a yellow ground Picotee. I should like to add to "R. D.'s" interesting notes that if the National Carnation Society laid down that such and such varieties were yellow ground Picotees, there should be power to add to their number, as, for instance, there are a few yellow ground Picotees extant that are as good as any that "R. D." mentions, but they are not in commerce, and owing to the fact that these varieties, or at least some of them, make very little grass, it may be some years before they are seen in public. These, if passed by the judges of the society as worthy, should be admitted into the charmed circle of true yellow ground Picotees and be certified by the society as being so.

SCENTED CARNATIONS.—We all know how the entire absence of scent detracts from the most beautiful of Carnations, and that we could put up with a less perfect form if the flower were only possessed of that exquisite aroma of Cloves that is so delightful. For some years the form has been improving, the edge has become more symmetrical, the petal flatter, and the small centre petals eradicated, but there are few of the best varieties that have any scent. How would it be if the National Carnation Society established a class in which one of the principal qualifications should be that the flowers should be all strongly Clove-scented, say of one dozen self-coloured varieties, all different, three blooms of each, not dressed, but as cut from the plants in the open air on a

9-inch stalk? This brings me to my third suggestion.

GLASS versus OPEN-AIR CULTURE.—Now that the Martin-Smith prizes have been withdrawn for plants grown exclusively in the open air and replaced by cups to be won by exhibitors who accumulate the greatest number of marks in the aggregate a different class of exhibitors is likely to win them; whoever has the largest and best collection under glass is bound to win year after year. Now, is it quite fair that the grower in the open border should be placed upon the same level as the exhibitor that grows exclusively under glass? The former has to contend against all variations of climate (a violent thunderstorm was this year fatal to most good blooms in this district that would have been cut for the Crystal Palace); whereas the grower under glass is subject to no such trials; he waters and ventilates his plants as they require it, and can send up his blooms in a clean and compact state which the out-of-door grower cannot hope to rival. Should there not, therefore, be classes for both exhibitors? I presume that a first-class judge would be able to see at a glance whether a bloom had been grown in or out of doors. In any case the out-of-door grower would have to sign a certificate, such as was in vogue at the time of late out-of-door prizes given by Mr. Martin Smith, that the exhibits were grown exclusively out of doors, and these should compete against each other, and the growers under glass should do the same thing amongst themselves.

THE QUESTION OF THE AMATEUR is also in a very unsatisfactory condition. I was under the impression that, from want of a better, the line was drawn at anybody who published a catalogue or excess list should exhibit only in the professional classes, but this rule does not seem to hold good in some places, and I think also that any grower of over and above a certain number of plants should be compelled to exhibit and take his chance in the larger classes—I mean those of twenty-four blooms—and not be permitted to sweep the decks of the twelves and sixes, thereby discouraging smaller growers.

I have occupied already too much of your valuable space, so I will not enlarge upon the

circumstance that it is quite possible to run up a larger score of marks by exhibiting a few single blooms at the National than can be attained by the more difficult exhibition of good boxes of blooms in the twenty-fours or twelves.

H. W. WEGUELIN.

Dutch.

Ranunculus Lyalli.—Back volumes of THE GARDEN will show how keen was the interest taken in this fine plant when it was introduced to British flower growers. Yet one is, I think, almost safe in hazarding the remark that few plants have given rise to more disappointment from our inability to establish it in our gardens. This note is suggested by a conversation on the occasion of a recent visit paid to me by an authority on hardy flowers who has wider opportunities than I have of finding out plants. We were talking about troublesome plants when I introduced the subject of this Ranunculus and said, "Where is it now?" The reply was, "In New Zealand," and was, if not literally, practically correct so far as regards its being found in British gardens. About a week or so ago another hardy plant grower, who is in the trade, when visiting me told me that he had it and hoped to succeed. I have never seen this Ranunculus in bloom, but saw it in the seedling stage after blooming in the garden of the late Mr. Charles Jenner, near Edinburgh, soon after the death of that regretted lover of flowers. I have never been able to learn what became of that plant, but can recollect that I was told that it had been there during the previous winter, and that it had been very fine while in bloom. Perhaps this note may catch the eye of some who are working with R. Lyalli and who may have been more successful than others.

—S. ARNOTT.

Begonias—where they grow.—I see a writer complaining of the climate of the south of England not being genial enough for these plants—I mean the tuberous-rooted section used for bedding. To see the Begonia in perfection in England one must go to the cool uplands of Yorkshire, but the Highlands of Scotland is their home. The first time I saw them in real perfection was at Fisher's Hotel at Pitlochry, where they were simply magnificent, and the curious thing is that out of the south of England I never saw such fine examples for size of plant and flower as the *Lilium auratum* growing there also, planted out permanently in the open ground. The Be-

gonia is a great favourite in the north in gardens where a bright display is wanted late in autumn. Last year in October at Halyburton House, near Dundee, I saw more Begonias in one garden than I have ever seen before. They were all seedlings, home-raised I believe, and nothing that I have ever seen in the London parks or elsewhere surpassed the gorgeous display of colour which they produced. Geraniums and Verbenas never approached the Begonia for mere bedding purposes, the colours are so numerous and varied, ranging from the softest whites, yellows, and pinks to the most intense scarlet-purple and crimson, and yet none of the shades are exactly alike. I have known the plant to generally flower best after midsummer, and mulching the beds in hot weather and dry soils is indispensable. Coolness and moisture are what the Begonia loves, but not too much shade. The tubers should be kept in sand in a cool shed free from frost during winter, and either planted out in the bed in April and well mulched or brought on in a cool frame and put out later. The Begonia is becoming a popular window plant, and is exceedingly easy to grow in such positions. I lately saw it in cottage windows in a smoky town in fine condition.—S.

HARDY FLOWERS AT SUMMERVILLE, DUMFRIES.

THERE is at Summerville, Dumfries, N.B., a nice collection of hardy flowers. A recent visit gave a considerable amount of pleasure, as not only were there a good many plants in bloom, but much could be seen of the comparative behaviour of those grown under other conditions than in one's own garden. There are a number of good alpine, although there are no elaborate rockeries, but only several raised beds divided into pockets. The welfare of the plants is the first consideration, and this is more frequently secured under such conditions than in ordinary rock gardens. The number of plants was too large to admit of much detail, but one may note some as either in flower or as showing some unusually good features. *Onosma tauricum* (the Golden Drop) was doing well, and a pretty little *Statice* named *S. minuta* was neat and pleasing. *Oxytropis Halleri* was also observed, with *Anthemis Aizoon*, the *Edelweiss*, and *Tunica Saxifraga*, pretty with its mass of lightly arranged little flowers. There is at Summerville an unusually fine plant of the quiet-coloured, yet pretty *Teucrium pyrenaicum*, a neat alpine, not easily kept everywhere and now little seen. *Dianthus Napoleon III.* was unusually good, and plants in bloom were making a quantity of "grass" which would cause many to envy Mr. Davidson his success with this brilliant mule Pink. Another flower doing unusually well was *Mazus Pumilio*, whose little flowers looked well above their dwarf carpet of leaves. *Gentiana Pneumonanthe* was just coming into bloom, and the somewhat difficult-to-grow *Polygonum sphaerostachyum* looked flourishing with its spikes of bright red flowers. *Erodium Reichardi* was also good, and one saw nice plants of *Aster Stracheyi* and the supposed hybrid *Bryanthus erectus*, the latter an exceptionally fine example. At Summerville the encrusted *Saxifrage* and the alpine *Dianthus* are always remarkably healthy. The border flowers were fine, although the effects of the drought were beginning to be apparent in such moisture-loving subjects as *Spiraea palmata alba*. There were good plants of the effective *Veratrum album* and *V. nigrum*, while the large-leaved *Groundsel* (*Senecio macrophylla*) was very showy. The favourite *Spiraea bullata* was good, and *Heuchera brizoides* pleased one much with its sprays of graceful flowers. *Coreopsis verticillata* is always elegant, its light looking foliage associating well with its bright flowers. At Summerville there is also the fine variety of *C. ariculata* named *monstrosa*. Mr. Wolley-Dod's variety of *Heliopsis laevis* was also very good, while *Eryngium alpinum*, a good plant in the district, was very attractive with its wonderfully carved and col-

oured heads of blue. *Spiraea gigantea* was not so fine as I once saw it in Rev. C. Wolley-Dod's garden at Edge, but still it was an effective subject at the back of a border. Not showy, yet pleasing in its own way, was *Asclepias incarnata*, another plant for the back of the border. Always good in this garden is *Maries' Balloon Flower* (*Platycodon grandiflorum Mariesi*). The stock is unusually select, and one capital pure white form was specially noted. Some *Liatris* were fine, and although out of bloom, one observed a good plant of the old double Siberian Larkspur which has been in the border for about eight years. An effective *Rhubarb* (*Rheum sanguineum*) looked very handsome in a broad border. *Helianthus orgyalis*, which, however, seldom flowers at Summerville, is one of the most elegant plants of the season. It comes into bloom so late in this district, that it may only be counted upon as a plant of fine effect because of its grace and lightness, combined with tallness of stature.

My time was rather limited to take a note of the many good border flowers, but those named will give an idea of the variety cultivated in Mr. Davidson's garden. S. ARNOTT.

INCARVILLEAS.

I STATED in the note that accompanied the plate of *I. grandiflora* (page 22) that the plant figured might be only a form of *I. compacta*. In the Kew herbarium there are specimens labelled *I. compacta* var. *longipedunculata* which agree both in leaf and flower characters with *I. grandiflora*. The type has leaves scarcely 3 inches long with pinnae a quarter of an inch long, whilst the flowers are borne singly on very short stems, the corolla being 2 inches across and rose-purple in colour. There are forms with larger leaves and longer flower-stalks up to the dimensions of *I. grandiflora* as represented in THE GARDEN plate. Had I seen the plate in *Gartenflora* referred to by Mr. Gumbleton (p. 59), I should have been of the same opinion as Herr Max Leichtlin, viz., that there was some doubt as to the correctness of that figure. It certainly has no resemblance to *I. compacta* as represented at Kew. I have not, however, seen living examples of the last-named, which, according to the information given by Herr Max Leichtlin, has produced a flower-stem 30 inches high. Probably these variations in size are due to the conditions under which the plant grows. For garden purposes we may, I suppose, stick to the names *grandiflora* and *Delavayi* for the two plants represented in THE GARDEN plates. Surely Mr. Gumbleton recognises the difference in foliage and in the shape and size of the calyx in these two as drawn by Mr. Meon?

There are, according to French botanists, several other large-flowered species of *Incarvillea* worth attention. They are: *I. lutea*, leaves 10 inches long, flower-stems 30 inches high, flowers about 2 inches across, yellow; *I. principis*, general dimensions as in *I. lutea*, with flowers in racemes, coloured bright red; *I. Beresowski*, with tuberous root-stock, leaves pinnate, pinnae an inch long, flower-stem 9 inches, bearing a racemose cluster of about nine flowers. It looks like a form of *I. Delavayi*. *I. Bonvaloti* has the appearance of a small form of *I. compacta*, the leaves being scarcely 2 inches long, whilst the flowers are about 2 inches. The flowers in most of the species are borne sometimes singly, sometimes several on a stem. These are all natives of Thibet and Western China. W. W.

The old *Crimson Clove*.—I was as pleased as surprised recently to see in an amateur's garden quite close to Norwich several handsome beds of the fragrant old *Crimson Clove*. There were literally hundreds of full-sized, richly coloured blooms. I thought how many gardeners in private places where the air is pure and quite unimpregnated with smoke would only be too glad could they but induce this old favourite to grow and flower so well. As is well known, this *Carnation* in many soils goes off wholesale either

with spot, fungus, or dry rot. So much so is this the case, that many have substituted *Uriah Pike*, which, though a bright variety of strong constitution, is not, I think, equal to the *Crimson Clove*. I know some gardeners entertain the idea that to do the latter justice a rather strong loamy soil is necessary, but in the neighbourhood of Yarmouth both it and the white variety, *Gloire de Nancy*, grow and flower with great freedom in a very sandy soil, disease seldom showing itself. Many amateurs and cottagers, though passionately fond of their *Carnations*, do not seem to know their wants. One recently told me that he propagated his stock from cuttings taken off and inserted in the garden, but that a large percentage of them collapsed. He seemed gratified when I explained to him the layering system. Many of the choice, yet none too robust *Carnations* throw but few flowers and make only a limited quantity of grass the first season. The best way, in my opinion, is to layer the whole of the growths, when rooted transplanting a few, but leaving the rest untouched for flowering next season; a good display of bloom will then be secured. These shy bloomers ought also to be planted in twos or threes. Three of the most vigorous free-flowering *Carnations* in existence, and which ought to be included in every collection, are *Pride of the Garden*, bright rose; *Celia*, deep pink; and *Burn Pink*.—N. N.

SINGLE HOLLYHOCKS.

"A. D.'s" interesting notes on these good, but much neglected old-fashioned flowers remind me of a capital strain of single varieties I recently saw in a roadside garden. I could not help thinking what a pity it was they did not occupy a position in which their beauty could have been longer preserved, as close by a dusty road near a busy town is about the very worst place to plant *Hollyhocks*. The single strains are, I think, the more showy, but as "A. D." truly remarks, the lowermost blooms, or those which expand first, often collapse ere those higher up the spike are open. I think this evil may to a very great extent be prevented by good culture, as old growers who used to exhibit preserved the long, gorgeous spikes intact. A deep, rich root-run and general all-round good culture produce corresponding stout stems and flowers, the latter having sufficient substance to enable them to withstand wind and wet, so that the entire spike is in good condition at once. It is certainly strange that *Hollyhocks* should not occupy a more prominent place in private gardens generally where labour is sufficiently plentiful to afford them every attention. Both the singles and doubles—for the latter are very attractive also—are surpassed by very few subjects for mixed border adornment or for massing in separate beds. What can possibly be more showy than a good-sized bed of choice *Hollyhocks*, thoroughly well grown, properly staked, and in full beauty, occupying a site on a well-kept grass lawn? There is something so stately as well as handsome, that even a novice is sure to admire them. But *Hollyhocks* want growing. Probably nothing will take so much rich food either in the form of soil or liquid; indeed, I knew of one old grower who gave to his *Hollyhocks* a larder that he would have been frightened to give to his *Vines*. The ground, if the finest spikes of bloom are desired, should be prepared in good time, say several months previous to planting. This would mean January or early in February, as I am in favour of March or April planting, according to the weather—I mean transferring them from the nursery beds where they as seedlings were pricked out the previous summer. I know some maintain that large and good enough plants for flowering the same season can be produced by sowing in warmth in spring, but my experience is that in the majority of cases such plants only carry indifferent spikes the first year, and are thereby greatly stunted for all time coming. I do not think there is a better way than sowing the seed in a cold frame in a semi-shaded position about the first or second week in May.

A bed of rather fine soil with merely a glass light resting on four flower-pots placed over it will answer as well, protection from heavy rains and parching winds being the main thing. Full exposure when able to take care of themselves and liberal supplies of moisture must be accorded. When sufficiently large, transplant to a well enriched piece of ground where protection can be given should the winter prove severe, putting them out very carefully the following spring. By this means grand plants and towering bloom-spikes will reward the cultivator. Frequently mulching is neglected, and the plants, which are very thirsty subjects, are insufficiently watered. It is unwise to plant Hollyhocks in exposed positions, as high winds play havoc even if firmly staked. Rustic stakes answer the purpose, but the plants are set off to the best advantage when secured to strong deal stakes painted green. Since the dreaded disease made such inroads the majority of growers depend on seedlings.

NORFOLK.

WHITE LILY DISEASE.

AN experiment made at Oakwood goes some way to prove that the disease which is so destructive to the old white Lily may be to a large extent conquered by liberal culture. In this locality it was this season difficult to find a plant that was free from disease, and in most instances the foliage was completely withered, although in some places there was a fair show of bloom, as the disease was late this year in declaring itself. The appearance of such long stems, however, clothed with rusty leaves, crowned with a few flowers, is by no means ornamental, and I would much rather cultivate some other kind, such as pardalinum or tigrinum, which can be relied on to remain in good condition through the flowering period. At Oakwood every plant was when in bloom remarkably healthy, being well flowered and furnished with fresh foliage to the ground, large clumps having the fine ornamental appearance which in former days characterised this Lily in gardens generally. This healthy appearance is attributed to judicious feeding in various stages of growth. The plants were top-dressed with manure when they came into free growth, and later on they were again dressed with guano, which was well washed in. It would be well if those who are desirous of having this grand old Lily in good condition would experiment in the same way. It stands to reason that a well-nourished plant will resist disease better than one that has been starved into a state of weakness.

J. C. B.

Varieties of *Lilium chalcedonicum*.—Though appealed to on p. 132, it is, I am afraid, impossible for me to throw much light on the forms of *L. chalcedonicum*, concerning which a certain amount of confusion prevails. The forms I have met with are just as your correspondent describes, while the variety *Heldreichi* appears to be the same as *majus*. The yellow-flowered form suggested in the "Dictionary of Gardening," I am afraid, does not exist, and I have always thought that the idea of it originated in confusing *L. chalcedonicum* and *L. pyrenaicum*. Such was also the opinion of M. J. d'Hoop, of Ghent, who some years ago compiled a most exhaustive and valuable list of Lilies. This was published in THE GARDEN, February 25, 1885.—H. P.

***Lilium Batemannæ*.**—This Japanese Lily has been particularly attractive this season, as it has not only flowered freely, but the unspotted apricot tint of its blossoms has been even more brilliant than usual, probably owing to the almost tropical weather experienced during its flowering period, which, however, had the effect of quickly shrivelling up the blossoms after expansion. Though it flowers, as a rule, in a satisfactory manner, yet the same cannot be said of the foliage, as many of the leaves frequently turn yellow before the blossoms expand. This is not invariably the case, but at the same time it is quite an exception to find the foliage retained uninjured

till the flowering period. *L. Batemannæ* succeeds best in a sandy loam, and in heavy soils or in those of a peaty nature it is seldom satisfactory. It is also not at all a good Lily for growing in pots, the foliage then suffering even more than in the open ground. Apart from its beauty, it is also of interest as being the last of the upright-flowered Lilies to bloom. *L. Batemannæ* is usually sent here in considerable numbers from Japan, the Dutch growers having apparently not taken it in hand in quantity. The bulbs travel well in their clay covering and can be depended upon to flower in a satisfactory manner the first season, many of the largest pushing up two or three stems.—T.

FLOWER GARDEN NOTES.

BAMBOOS.—Although there may be some doubt as to the value of Bamboos for a prolonged spell of house decoration, they are certainly valuable for occasional work in this direction and also (I refer to pot plants) to assist in forming high and attractive groups for out of doors during the summer months. An intimation that a considerable amount of church decoration would be required this season led me to purchase early in the spring a batch of nice clumps of *B. Metake*. They were well delivered, that is they were very carefully lifted, matted, and had received a thorough soaking, and on arrival were severally potted into 14-inch pots and placed at the back of some sheds, where, given a spell of hot weather, they were not likely to dry out quickly. Since and including Easter these plants have been used in the church four times besides playing their part in occasional house decoration and forming out-door groups in company with Fuchsias, Heliotropes, zonal Pelargoniums and other things. They are now consigned to the old quarters under a north wall and are in the best of health. The leaf dropping is over and the young growths are clean and vigorous. In all cases where a considerable amount of decoration is required and there is not sufficient glass to allow of the storing of large Palms, these Bamboos will be found very useful. I said above that they were effective when grouped with large Fuchsias or zonal Pelargoniums, and both the latter have been exceptionally good this year, fan- and balloon-trained specimens and naturally grown plants all flowering remarkably well, although a considerable amount of attention in the way of watering and feeding has been necessary to keep them up to the mark. When large plants are once secured, they can be kept going for several years by liberal feeding, and it is a good plan as soon as they start in the spring to turn them out of the pots, break off say a couple of inches from the base of the plants, and the same from the surface, replacing in each case by a compost of cow manure and good loam in the proportion of three to one. This is a wonderful help in dry seasons, because when thoroughly soaked such a compost is very retentive of moisture. Capital plants to mix with Bamboos, Fuchsias and Pelargoniums for outdoor grouping are *Campanula pyramidalis alba* and *Francoa ramosa*. I generally retain a batch of the last-named plant for this special purpose, and these throwing as they do eight, nine and ten spikes, make individually a very fine display. The remarks above as to the effectiveness of Fuchsias and Pelargoniums from a pot plant standpoint are equally applicable to open beds; indeed, the much-maligned Pelargonium is at the present moment decidedly the brightest of garden flowers and has been so for some time, and this, too, at a minimum of trouble, for they have only received one soaking and that directly after planting. The plants were well rooted stuff in 4-inch pots and the beds were well prepared for their reception. It has always been my impression that if a little more care and discrimination had been used in the planting of Pelargoniums we should have heard little or nothing of the outcry raised against them. They were used, as many of us remember, in dense, flat masses with absolutely nothing to relieve them, or if anything else was employed, it had

often a tendency to accentuate rather than relieve the stiffness, as, for instance, Golden Privet, variegated Abutilons, or small coniferæ of severely symmetrical appearance. Instead of such things I would advocate occasional plants of *Gypsophila*, which, even when seedling, is light and graceful; *Stative*, lightly staked to prevent the big heads from falling about; nicely-grown plants of *Eucalyptus citriodora*, or for larger beds, *Tamarix gallica* or *Hydrangea paniculata*. Associate with these, as the contrast may need, such Geraniums as *Jacoby*, *Raspail*, *King of Bedders*, *Surprise*, *Olive Carr*, *Amaranth*, or some of the best of the Ivy-leaved section, and I do not think there will be anything to complain of as to a bright display or an effective combination.

E. BURRELL.

Claremont.

Lifting *Lilium candidum*.—I lifted a large number of my stock of this fine Lily last season; indeed, I am gradually drifting to the opinion that it is not lifted sufficiently often in the majority of gardens. I picked out last year a lot of small trashy bulbs that certainly did not look strong enough to bloom and planted them cut very thickly, thinking that they may at least live and in time make flowering bulbs. Many of these have pushed up fine flowering stems, and others have made nice bulbs. This they would not have done if crowded in clumps, but being able to reach new soil all the way round the roots have become more active and fed the new bulbs well. A good baking in the full sun is undoubtedly a help towards keeping disease in check, but is not a cure for it, unfortunately.—H. R.

Carnation Leopold de Rothschild.—Though scarcely up to the standard of merit laid down by many fanciers and growers of the Carnation, this is not only of vigorous growth, but free flowering as well. It would appear also to have some leaning towards the Tree or perpetual section, notwithstanding that it is at its best at this time. The large and showy flowers create a fine display. Mr. G. Reynolds brought a large basket of well-flowered plants to the Drill Hall on Tuesday from Gunnersbury Park. The colour is a sort of rose-magenta, the petals large and the pod well formed. Far too many of our finest Carnations are lacking in vigour if possessing beautifully refined flowers, while here we appear to have a plant which, if lacking refinement, is neither wanting in freedom nor vigour, and therefore would be welcomed by not a few gardeners whose chief object is to maintain a long succession of flowers in the open beds.

NOTES AND QUESTIONS.—FLOWER.

***Monarda didyma*.**—The pretty bright red flower-heads of this old-fashioned plant are now in good condition, and there are many among hardy plants that are thought a lot more of but are not more worth a place in the garden. The leaves when bruised emit a pleasant aromatic fragrance, and it is from this circumstance that its name of Bergamot has been given. It is of the easiest possible culture, thriving in almost any description of soil or situation.

Yellow ground and fancy Carnations.—Referring to the letter from "R. D." in your issue of the 12th inst., I am glad to be able to assure him that steps will certainly be taken this year by the committee of the National Carnation and Picotee Society in the direction suggested by his letter. The inaction of the society in the past concerning this matter has been the result of a well-considered policy, not of indifference or supineness.—MARTIN R. SMITH, *Warren House, Hayes, Kent*.

***Tulipa Lownei*.**—This small Syrian species, described by Baker in 1874, was only lately introduced in a living state. The plant is 8 inches high and has leaves of a yellow-green, which is rare among Tulips, the leaves of which are mostly glaucous. The flowers are of a peculiar shade, which arrests attention. The petals are of a light and brilliant lilac colour, and marked at the base with a broad bright yellow stain. I know no other Tulip so coloured, and though not among the most beautiful, it certainly deserves attention. This year under a frame it flowered in April.—M. MICHELL, in *Revue Horticole*.

KITCHEN GARDEN.

ASPARAGUS—RAISING, GROWING, AND FORCING.*

THE chief districts of England famous for growing Asparagus are Cambridgeshire, Worcestershire (especially the Evesham district), Essex (about Colchester), and in the Thames valley near London. The best home-grown outdoor Asparagus that is sent to Covent Garden Market is produced in these districts. In Scotland, the south-western parts, comprising the counties of Ayr, Wigton, and Kirkcudbright, are specially favourable. The soil in many places is a rich sandy loam, and the maritime situation, together with the influence of the moisture-laden atmosphere from the Gulf Stream, has a very beneficial effect. Its cultivation is, however, almost entirely confined to private gardens. On the cultivation of Asparagus in Scotland, it may be here interesting to quote from a paper on the supply of vegetables to the Edinburgh and Glasgow markets, read before the Scottish Horticultural Association by Mr. J. Scarlett, of Inveresk. He says, "There is practically no Asparagus grown in Scotland for market. English, French, and Spanish have ousted home-grown to such an extent, that the one or two growers who used to bring anything like a quantity have discontinued its cultivation. This is due probably more to the lateness of the home crop, compared with that of other countries, than to any unsuitableness of soil or climate."

SOIL.

Rich sandy soil of good depth is naturally the best adapted for Asparagus, and in such its cultivation is an easy matter. But in these days, whatever the nature of the soil of a garden may be, the cultivation of Asparagus is looked upon as an absolute necessity, and the fact is often lost sight of that if the soil be of a clayey nature and shallow, the produce under such conditions cannot possibly bear comparison with that from ground naturally suitable for the growth of this plant. With labour and materials at command, heavy, clayey soil may be in time brought into a light, porous condition by the addition of sand of the best kind procurable—sea, river, or grit, sandy deposits from drains, road scrapings, burned earth, and lime, brick, and rubble from old buildings, all these are excellent for rendering soil permanently porous. Whatever the soil may be, leaf-mould, peat, light fibrous loam, old hotbed material, seaweed, and farmyard manure (especially that from cows), I have found to be the best fertilisers. The last-named is practically indispensable, for the soil can scarcely be too highly manured, as good quality depends on quickness of growth, which is assisted by richness of soil. Asparagus is a deep-rooting plant. Frequently after doing away with old beds I have found the soil permeated with roots to the depth of 30 inches; consequently in preparing the soil for planting it should be made 30 inches deep by trenching, adding, and mixing in the materials already named, from the bottom to the surface as the trenching proceeds, in quantities as required according to the nature of the soil. The advantages of deep trenching and increased depth of rooting medium are that the roots descend so that they do not suffer so much from want of moisture in dry seasons, and they also assist the free percolation of water in wet seasons. Although Asparagus is a seaside plant, it will not thrive in stagnant ground, and if the subsoil is

of a clayey, impervious nature, insufficiently drained, this defect must be remedied by drains, put in before doing the trenching, or a layer of a few inches of old brick rubble or cinders will form an effective drainage if placed at the bottom at the time of trenching. In considering the situation of the ground, the best is that with a slight fall to the south, well sheltered on the side whence come the prevailing winds. For climate, the southern parts of the country are the most favoured.

Asparagus, like other things, to be in the fashion must be large; size, which does not sacrifice quality, is due to soil, cultivation, and situation, and not to any special varieties, as there is believed to be but one. Red Topped or Dutch, and Green Topped, and the names of places famous for its cultivation have been given to supposed varieties of it, but variations in size and in colour are, in my opinion, due entirely to the conditions under which it is grown. The month of March, when the surface of the ground is dry, is the best time to sow the seed, thinly, in drills an inch deep, the drills a foot apart, at the rate of half an ounce to 15 yards run of drill. The trenching of the ground should be completed in autumn, six months before the time of planting, so that the ground has time to settle, and in March, when it is in a suitable condition to work on, the surface should be forked over and made even, after which it will become friable and settled by planting time. Asparagus is a plant that is amenable to transplanting, provided it is done at the right time and reasonable precautions taken not to let the roots become dry. When the shoots have grown to a length of 3 inches or 4 inches is the best time to transplant, but the young shoots had better be longer than this than transplant before the vital powers have become active. Some growers continue the old beds, and some have introduced the plot system, adopting it from the French; but, whatever the system, the rows should run in the direction of north and south. I have tried various modes of

PLANTING.

The one I have found the best and most expeditious is to cut out a trench with a spade by the side of a line, 6 inches deep and slanting, in the same way as for laying Box. The roots should then be spread out quickly and carefully covered with soil, leaving the crown of each plant about 2 inches beneath the surface. Care should be taken to separate the plants so as not to have two crowns where there should be but one. After planting, a good watering should be given to settle the soil, and further waterings must be given as often as required, according to the weather, until the plants are well established. The distance apart of the plants depends on the system followed. Both have their peculiar advantages. The bed system is the one generally employed, and it is the best where the soil is shallow and the subsoil is of a cold, clayey nature; but where the soil is light and rests on a dry subsoil the plot system is the best, particularly in dry seasons. A width of 5 feet for a bed, and 2½-feet alley between beds, is very suitable for the growth of the plants and for carrying out the necessary work in the different seasons. Three rows are planted in each bed, one in the centre and one on either side, leaving 18 inches between them. The distance between the plants in the rows should be 2½ feet. With the plot system the distances between the rows should be 4 feet, and 18 inches between the plants in the rows. These distances by some may be considered unnecessarily wide, but they are not so, for if good results are to be obtained the plants must have room for the tops to fully develop without

crowding. The French give even more space than this; they allow 4 feet from row to row and 3 feet in the rows. One-year-old plants are much the best; if older, they do not transplant so well. Some recommend the sowing of seeds in the permanent beds or plot; by so doing, the ground, according to my experience, is occupied by it one year unnecessarily, as one-year-old plants do equally well. During the season of growth, besides watering, attention to weeding is all that is required. In the autumn or early winter, after the tops are dead and cleared off, a dressing of decayed manure should be spread on the beds, a stake driven in the corner of each bed, the sides marked off, and about 3 inches of soil from the alleys placed over the manure; or, in the case of the plot, the manure is dug in between the rows. About the same time in each year afterwards a dressing of manure or sea-weed is required to be dug in and the surface left rough. In the spring, before the shoots begin to push, the surface should be made smooth with a rake, and this is the best time to apply a dressing of salt, not only for its saline qualities as a manure, but it also kills insects and weeds. Of artificial manures, I have found nitrate of soda to produce a marked effect when applied early in the spring to old beds past their best. Where the soil is not of so calcareous a nature as desired, a dressing of fresh lime applied early in the spring will supply the defect. On the

CUTTING OF THE CROP

there is but one opinion of the time to begin on a new plantation, and that is not until the third season of growth; and my advice is to cut but very sparingly, only taking about two early cuttings of the strongest shoots. After the third year the plants may be considered in bearing order, and, with liberal and careful management, will continue so for a dozen years or more. Of how to cut, different rules have been advocated by different growers; some cut all that rises above ground until the middle or end of June, others only take the strongest shoots and leave the others to grow up, and no doubt this latter is the best rule, only then more ground must be devoted to Asparagus, a matter which all growers cannot afford. Personally, I adopt a medium rule, by cutting all that rises till the middle of the season, *i.e.*, about the middle of May, and after that only the strongest shoots till June 15, and if by any chance emergency demands a cutting later, it is very reluctantly supplied. After the cutting season, growth must have time to develop and ripen before the autumn. On the vigour of the growth to a large extent depends not only the size of the shoots the following year, but even the life of the plants. Many beds are ruined through over-cutting. I have even heard a gardener say that to have good Asparagus, beds should be cut from only in alternate seasons. As so much depends on the maturing of strong growths, care must be taken to protect them against wind. A few Pea stakes stuck into the ground amongst them for the tops to lean against form a good wind guard. The taste in England hitherto has been for green Asparagus, and to have it in this condition it is allowed to grow 3 inches or 4 inches above the surface of the ground, and then cut 2 inches or 3 inches below it. The French prefer it blanched, and their method seems to be gaining favour in England. To have it in the French style a greater depth of soil is required over the roots, and the shoots must be cut when they are seen to be heaving up the surface of the soil. The plot system is the best for this; the soil may be drawn over the rows on both sides, in the way in which Potatoes are earthed up, and the

* Paper read by Mr. Geo. Norman, Hatfield, before the Royal Horticultural Society, April 18.

time to do this is just before the shoots begin to push. At Hatfield I usually begin to cut Asparagus outdoors about April 15, a few days earlier or later according to the season.

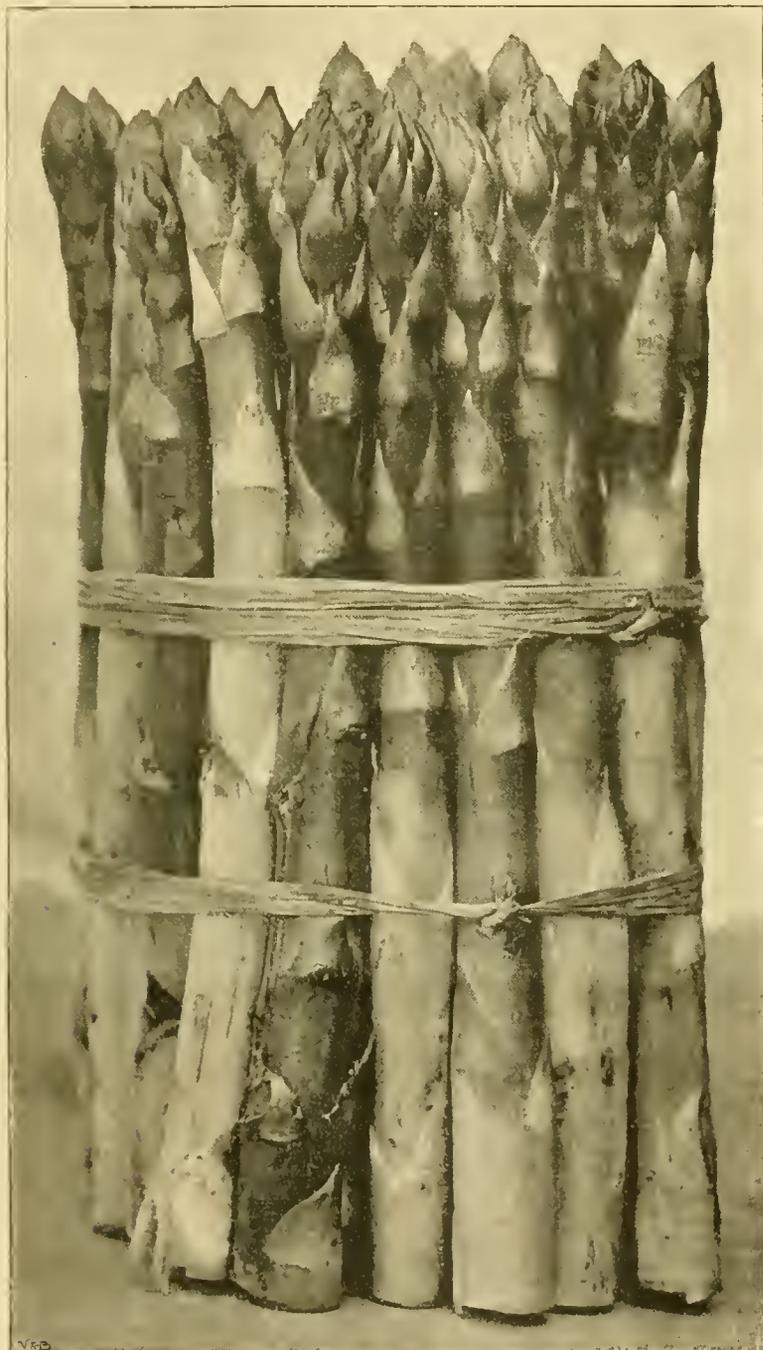

FORCING ASPARAGUS.

There are two systems in vogue in this country: one is to grow the roots outdoors for three years or more, and then to lift them and

spring months. In fact it is looked upon as one of the gardener's necessary duties to provide it. I have forced it in many different structures and positions—in garden frames, with the usual hotbed heat; in houses over heated chambers, while Strawberries over them have occupied their usual position near the glass; and under stages with plants upon

these temperatures cutting begins in from three to four weeks from the start. The quality from the beginning of cutting onward for a month is about the same, after which time it rapidly declines. To keep up a supply from December till the outdoor cutting begins, batches of roots must be lifted monthly, beginning early in November. When putting the roots into the forcing quarters, about 4 inches of light soil are laid over the chamber; on this the roots are placed closely together, and about 4 inches of light sifted soil are spread over them. Liberal supplies of water must be given during forcing. The production of very early Asparagus does not so much lie in the forcing as in strong, healthy, well-grown roots, sown and planted out specially for the purpose, when one year old, on a plot of ground prepared in the same way as recommended for the permanent beds, or plot, in rows 2 feet apart, and the plants 1 foot distant in the rows. After being planted the treatment is the same as for the permanent beds. In the spring of the second season after planting a dressing of salt is given; afterwards weeds are removed that have escaped the effects of the salt, but no cutting whatever must be allowed. During the second season after planting a sound watering occasionally during dry weather does a great deal of good, but, unfortunately, the water supply at Hatfield will not allow of this. When doing away with old beds and using up the roots for forcing, a few of the shoots produced may be stronger than those from the three-year-old plants, but they are not nearly so numerous, and, taken as a whole, they are not so satisfactory. The brick bed system has now been in use for many years, and the fact that it is so seldom met with is, I think, a proof that it has not many or great advantages. At the outset it is expensive to construct. One of its few advantages is that the shoots are thicker than from lifted roots, and they are in season for two months before the outdoor. The beds are usually about 6 feet wide and 4 feet deep, to allow a foot for drainage and 3 feet for soil. The alleys are 18 inches between, and the brickwork is 4½ inches pigeon-holed, with piers for strengthening it. Before forcing begins the beds are covered with several inches of leaf-mould and covered over with shutters. The alleys are generally filled with leaves for heating the beds. Mr. Wythes, at Syon House, forces Asparagus on this system, as also does Mr. Owen Thomas, the Queen's gardener at Windsor, only that he has hot-water pipes to heat the beds instead of leaves. Asparagus is considered by some the finest vegetable grown. It is not only pleasant to the palate and can be used in so many different ways in cooking, but it can also with ease, by forcing and outdoor cultivation, be had in season for seven months out of the twelve—from December to June. The most usual way to send it up to table is as a vegetable pure and simple, and for this purpose only the largest shoots are used, the small ones finding their way into the soup tureen and into many fancy dishes. Every shoot that rises to the surface of the ground can be utilised in some way.

My remarks are, of course, more generally applicable to private growers than to market gardeners; and whatever disadvantages some private gardens may have in producing it, they ought certainly to be surmounted, for to have Asparagus at its best it should be cooked and eaten as soon as possible after being cut, as it very quickly deteriorates in flavour when once cut. For market in this country it can only be grown at a profit under the most favourable conditions of position, soil, and climate. Where growers are so happily situated and

Market bunch of Asparagus. From a photograph sent by Mrs. Wakeman-Newport, Sandbourne, Bewdley.

force them under glass. The other method is to plant the roots permanently in brick-built beds, pigeon-holed. The former plan is the one most generally followed. Lifted roots are quickly excited into growth with very gentle forcing. This renders Asparagus very suitable for forcing, and it is most valuable as a choice vegetable during the winter and early

them. These are but makeshifts; nevertheless they have answered the purpose, and show how easy Asparagus is to force. The best structures in which to force it are pits or low houses, with hotbed material or pipes for bottom-heat and pipes for top-heat. Suitable temperatures are 65° to 70° Fahrenheit for bottom-heat, and 55° to 60° above. In

have experience in growing it, I believe they find it a paying crop; but from time to time many have begun to grow it in places where soil and situation have not been suitable, and have been obliged to give it up. It is very largely imported into this country from the south of France, Italy, and Spain. In the early months of the year the largest and best comes from France. Prices vary according to size and demand, some giant shoots fetching as much in Covent Garden Market as from 10s. and 12s. to 15s. per 100. Many thousands of bundles are brought over daily, and every year the communication from the south of France is quicker, and brings it over in better condition. The best home-grown outdoor Asparagus is sold in Covent Garden at from 1s. to 4s. per 100.

Peas.—The hot, dry weather that we have been having of late in this district has been all against Peas, which are simply eaten up with thrips. I commenced gathering the second week in June, the variety being Carter's Lightning. I have grown it along with other sorts since it was first sent out, but nothing can equal it for earliness. Chelsea Gem came in ten days later. English Wonder I have grown for the first time, but it will have to go. Dickson's Fertility is the best midseason variety, height 2½ feet, a tremendous cropper, with nine and ten large deep green peas in each pod. It has resisted the drought the best of any Pea in the garden. Another good dry season Pea is Daisy. Dr. McLean has likewise done well. Autocrat, Duke of Albany, The Duchess, Dickson's First and Best, William I., and Ne Plus Ultra have been very poor.—THOS. COCKERILL, *Wirksworth, Derbyshire.*

Potato Sutton's Seedling.—I am inclined to think that newer varieties are pushing this grand Potato out of cultivation, although I think that anyone who has thoroughly proved its merits will not readily discard it. For years after its introduction it secured more first prizes, I should say, than any other variety coming into use at the same season, but perhaps for this particular purpose Windsor Castle has superseded it. I am, however, speaking of it as an all-round useful Potato, and maintain that, given good treatment, it will for cropping, flavour, and symmetry combined take a lot of beating. To those who prefer a particularly mealy, nutty-flavoured Potato I would say grow Sutton's Seedling. My land was on the light side, and in dry summers none too moist on account of its porous subsoil, but this Potato invariably did well, its stout, vigorous haulm withstanding drought well. I used to grow it for a secondary supply in frames, and by pegging the tops down found it answer well.—NORFOLK.

Sowing spring Cabbages.—If this useful crop were sown a little later than usual and more pains taken to ensure the health and vigour of the plants after they are up, I think we should hear less of plants being lost in winter, if not of bolting in spring. A hard, well-developed plant is all right, but this is not secured by starvation treatment. I sow towards the end of July Ellam's Early and April, the latter a useful kind for succession. The seed-bed is made firm and not over-rich, and well soaked with water previous to sowing in drills 6 inches apart. If there is any doubt as to the staple of the border, a little of a good quick-acting fertiliser may be sown with the seeds. A piece of ground cleared of early Potatoes is well trodden, and the plants are pricked out in this as soon as ready, going into their permanent quarters towards the end of September. Localities differ, and what is the correct time in one may not suit another, but there are few places where the seed need be sown before the end of July. Larger and later kinds are not sown here until the middle of August, and every care is taken of the plants by hoeing and watering in dry weather. The firm soil and

open position ensure their being hard and well consolidated.—H., *Suffolk.*

Pea sticks and dwarf Ne Plus Ultra.—"J. S.'s" note (p. 107) is suggestive, and his one stick to a plant deserves a trial where Pea sticks and labour are scarce. By keeping Pea tendrils so long idle, I fear we may have weakened their grasping or hold-fast capacity. There are other means of economising Pea sticks, which I practised for years, and which reduces the number one-half and renders the stakes more efficient alike for support and protection. Instead of placing the stakes vertically, give them a long oblique angle with the ground. The stakes are stronger, too, if not placed opposite in pairs, but the stakes on one side to halve the distance between the stakes on the other. Of course, this oblique system of staking lowers the height, but this may save the labour of topping the stakes and render them available for shelter and support along the entire length of the row. Generally far too many stakes are used for staking Peas and the two rows are crowded far too closely together. More room and an occasional stake to connect the two lines reduce the quantity of timber used and give the growing Peas more light.—D. T. F.

BROAD BEANS.

How is it that our hybridisers cannot produce a long-podded Broad Windsor Bean? Broad Beans are amongst the most useful and nutritious of vegetables, and anyone acquainted with the qualities of our garden Beans knows that the Broad Windsor is as superior to all other varieties as the true wrinkled Marrowfat Pea is to the little hard, early garden Pea which is so soon over. All the varieties of the common garden Bean are derived from one species, *Faba vulgaris*, but for garden purposes there are only two sorts in the nurseryman's catalogue—Long-pod and Windsor. The Long-pod is the exhibitor's favourite, and for a long period all the energies of raisers of new varieties have been concentrated on the lengthening of the pod and increasing the number of Beans within it. The Broad Windsor has not altered in any respect since I can remember. Long ago, Thomson described this variety as containing two or three very large Beans in a pod, as an excellent sort, highly esteemed, best for summer crop, and remaining fit for use longer than most others. This character is deserved, only that there are usually as many pods with only one Bean in them as there are pods with the maximum number—three. Yet there is no reason, I believe, why the pods of this variety should not be lengthened and the Beans increased in number. If we could only get an average of three Beans to a pod it would be a distinct advance, and that would appear to be only a matter of careful selection. It is certain that the first man who can produce a long-podded Windsor Broad Bean will make a good thing of it. J. S.

Watering Celery.—I never had more promising rows of Celery than this season, and this I attribute partly to early preparation of the trenches and partly to pricking the young plants straight from the seed beds into the trenches. The quick and vigorous growth made will have taken a good deal of the nourishment from the soil, so that watering and, where possible, feeding with liquid or other manures will be taken in hand at once. Old soot strewed about the rows and watered in is an excellent stimulant to Celery, and more lasting in its effect than quick-acting chemicals. Water in abundance must be given if the produce is to be good, and though it necessitates a lot of labour, this is well repaid by the increased quality and weight of the crop. If this is neglected now the outer stems and foliage that are so useful for protection to the hearts

later on are rendered soft and pippy. Insects, such as slugs, can more readily pass to the hearts, which, of course, will be less solid in character. Feed Celery well and keep the roots moist, and a stout, vigorous plant results. Watering should if possible be carried out in the late afternoon, or preferably on dull days. One thorough soaking of the trenches is better than half a dozen dribbles.—A GROWER.

Constitution in Peas.—I was interested in reading your reply to a correspondent in respect to thrips and mildew attacks on Peas, because you aver that the newer Peas lack the constitution of the older ones. I should very much hesitate to support that statement, because in ordinary seasons I have seen plenty of the more recently raised Peas doing splendidly. All the same, in such a season as the present, when not so much mildew but thrips is rife, and great quantities of Pea plants are almost eaten up by these pests, it is evident that any variety passing through such an ordeal well and quite uninjured, fruiting freely, would seem to retain qualities not possessed by most other varieties. Very recently, going over a group of allotments on which I was called upon to select the best row of Peas, I found it in an admirable one, over 5 feet in height, of the good old Champion of England. This was clean, fresh and podding finely, although the pods were not large. Now it may be a question whether such a variety may not in some respects have more plant stamina because not required to expend so much force in pod production. Then again in this particular instance the row of Peas in question was found on one of the very best cultivated plots, where the soil had been deeply worked and well manured. The worst Peas I have seen this season were on rather poor, thin ground. But universally Peas seem to have been far more affected with heat and drought than last year. I have found in my own trials that the growth was very moderate, the crop short and the plants soon dried up. They are better in deep, rich soils, but in few cases are satisfactory, and unless rain soon comes the customary fine examples seen in August will, at least in the south, be missing.—A D.

Tomato Laxton's Open Air.—One important thing in the cultivation of Tomatoes in the open garden is the selection of hardy varieties. Like Apples and Pears, some are much more hardy in the bloom than others and set their fruit in spite of cold winds and inclement weather. Many a fine batch of plants has been put out as late as the first week in June, and although having the shelter of a south wall they have been sorely crippled by harsh winds. A variety that may safely be recommended for open-air culture generally is Laxton's Open Air. Though by no means handsome in appearance, being much corrugated, it is nevertheless well deserving of wall space, while for training market grower's fashion to stakes, I know of no better. At Earham Hall, near Norwich, I saw on August 11 a grand lot of fruit in various stages of development, some of the lowermost trusses needing support to prevent their weight from breaking them off. At almost every joint for the entire length of the plants was a heavy cluster of fruit. The gardener stated that it was without doubt excellent for outdoor work where fine shape was not the chief consideration. The flavour, too, was very good. Amateurs should give this variety a trial. Even with the freest, most hardy sorts certain simple, though all-important, points must be observed in order to gain success. A weak, puny plant to start with is bound to disappoint. Dwarf, sturdy, gradually hardened plants are imperative. They may then be planted in their permanent quarters the first of June. Shelter from cutting winds from all points is another necessity. Then a few evergreen boughs should be inserted in the ground amongst the plants after planting, removing them say in the course of three weeks. They should be arranged so that while screening they do not unduly shade the plants. Amateurs and new beginners generally often err as to the root-run. Some give too

much rich food, others too little, planting perhaps in the same soil two years running. A good plan is to take out a couple of spits of the old and replace it with fresh compost. Actual feeding is best done when the plants begin to feel the strain of the crop.—NORFOLK.

Transplanting Celery.—Opinions differ a good deal as to the merits or otherwise of pricking off Celery plants before they are transferred to their permanent positions in the trenches. Where the trenches can be prepared early there is a great advantage in pricking straight from the seed-beds to them, but it is quite different in soils difficult to work where the trenches have to be prepared almost directly before planting. I much prefer pricking out in this case. As a rule I have had to hasten on the trenches and plant immediately, with the result that the Celery has been one of the most unsatisfactory of crops, but this season I had a piece of ground to spare and had it out at the beginning of the year. Rotten manure was dug into the bottom and abundance of burnt refuse forked and hoed into the surface-soil, with the result that at the end

sibly safely use some poisonous compounds on Turnips for the insects' destruction, but they could not be so employed on the Cabbage tribe. The best remedy would be found in good rains and ample moisture in the soil, as the beetle does not thrive in moisture.—A. D.

Lettuce Continuity.—In face of the numerous and very favourable references recently made in THE GARDEN by growers as to the excellence of the above Lettuce, all I can say is that either soil or situation, climate or treatment accorded it here fails to develop the extremely high quality it evidently obtains generally. Mr. Burrell suggests I may, unfortunately, have got hold of an inferior strain of this variety. Possibly it may be so, but in my case not, I think, very probable, for Messrs. Daniels Bros. (who were the introducers, I believe) very kindly sent it me for trial, and those I again grew last year were similar in every respect to the original stock, and both were discarded for the same defects, viz., lack of crispness and quality. The heat being so great, the journey long, and the rough usage which seems inseparable from

Turnip seed in drills, as then well broken, but fresh gaslime may be sown between the drills just as the seeds are germinating, and the smell will drive the insects away. Sand or sawdust soaked in paraffin will also emit a very offensive perfume. Still, it is doubtful whether the insects are troubled with discriminating olfactory nerves. Probably they are more susceptible to taste; hence sprinkling the rows of seedlings with soapy water, then dusting with soot, is likely to be more effective. But whilst smotherings of soot, lime, or dust may be freely employed with Turnips, such may not be used over well-developed Cabbages. Nothing is better for these than liberal overhead waterings, as then the roots benefit and growth is greater. It is the experience of most gardeners that the beetle does most harm on poor or shallow soils, as with deeply worked soils well manured the growth is rapid.—A. D.

TREES AND SHRUBS.

RHODODENDRON MYRTIFOLIUM.

THE true species was discovered during the travels of Schott and Kotschy in Transylvania. The plant figured comes from a mountain near Kronstadt, in Transylvania, where it covers the north-western hillsides, flowering abundantly. The species does not grow to a large size. The largest plant I know is about 2 feet through, and grows on chalk in a sandy loam about 10 inches to 15 inches deep. The individual flowers are rather larger than in *R. ferrugineum* and *hirsutum*, and are of a pleasing rosy red, pure white varieties not being very common.—O. FORSTER.

Mr. W. Watson, writing to us about this *Rhododendron*, of which there is a specimen at Kew, says:—

Herr O. Forster's *Rhododendron* is one of the forms of *R. ferrugineum*. (See Kew Hand-list of Trees and Shrubs, p. 61.) We have never succeeded with it at Kew. The other *R. myrtifolium* is a garden hybrid between *hirsutum* and *ponticum*. It is also known as *ovatum* and *ovalifolium*. This grows freely at Kew.

Hypericum Moserianum.—This has been long enough now in cultivation to be well known, and it is fairly cheap as well. It is such a beautiful and useful shrub, that it ought to be planted freely in prominent positions. The trees and shrubs that flower at this end of the summer are all too few, and anyone planting cannot afford to do without one of this kind, which produces plenty of bloom over a much longer season than most things. In shrubberies fringed with herbaceous borders the lack of brightness is not so noticeable now, but between the early summer-flowering and late autumn leaf-colouring there is rather an uninteresting time in shrubberies pure and simple, and anything that blooms late, or by keeping in flower a long time keeps a bit of colour now, should be given a prominent place therein.

Althæa frutex.—This in its many varieties is a showy and free-growing shrub that with ordinary care may be established, and will grow freely in any but the very worst of soils. The plan in vogue in many places of planting it against a warm wall is a good one, for it is very pretty, especially the bright red forms, and if given good soil at the roots will make a lot of growth in a season, thus covering a wall thickly and rapidly. Its only fault is the somewhat bare appearance until quite late in spring, and this is almost compensated for by the delightful fresh foliage and pretty blossoms at this season. Very pretty effects may be had by planting in round or other beds, allowing the plants to take quite their own way, pushing out an extra strong shoot here and there that later on is covered with flower. The lighter forms are not so striking as the deeply-

Rhododendron myrtifolium. From a photograph sent by Herr Otto Forster.

of May the trenches were in splendid order, and, notwithstanding the hot, dry weather since then, the plants have obtained a capital hold, the late welcome rains having given them a good start again. I have never, in fact, had the plants look so promising. I am referring, of course, to maincrop Celery, as Celery is rarely needed here before the end of October, and I do not grow any for early supplies. Under these circumstances the balance is all in favour of not pricking out the plants, but I can well understand that there are times when this is almost a necessity.—H. R.

Turnips.—Unless there is an abundant rainfall during the present month, the prospect of getting Turnips good or plentiful during the winter is indeed a poor one. Not only is the soil so parched and dry that seed germinates badly, but all Brassicæ are terribly infested with the Turnip beetle, which is doing immense mischief to Cabbages, Cauliflowers, winter greens of all descriptions, and is decimating seedling Turnips wholesale. Remedies are not easy to find in face of the abundance of the insect and the existence in any garden of so many host plants. We might pos-

postal parcel service, together with the extremely brittle nature of the foliage, prevents my sending you a sample of what proves here an ideal summer Cabbage Lettuce, to wit, New York. Even in this tropical and droughty season it is large, solid, and crisp.—JOHN ROBERTS, *The Gardens, Tan-y-bwlch.*

The Turnip beetle.—This tiny black insect, and one of the most active, is identical with the insect referred to by "H. H." as doing such harm to Cabbages. It is entomologically *Haltica nemorum*. It is also called the black flea, but is in reality a very tiny beetle. I have seen it very active largely this season on all the Cabbage tribe, including Turnips, especially where the soil is dry. The prevailing heat and drought assist to propagate the insect rapidly, whilst vegetation under these influences becomes stunted and incapable of resisting the insect attacks. Turnips suffer more than Cabbages generally because the leaf is thinner and softer; indeed, it is most difficult to secure growth at all, as the moment the cotyledons appear they are eaten up. It has been recommended to sow the

tinted ones, but still they are very pretty, especially when they become large enough to be effective in the landscape. For this reason when planting is in progress the colours ought to be kept in groups, this being a far more effective plan than mixing them indiscriminately.

FRUIT AND VEGETABLE CROPS.

SOUTHERN.

Worth Park, Crawley.—On account of the severe frost that we had in the early spring, certain classes of fruit, Pears especially, are almost a failure. Of Strawberries and Raspberries there are fair crops, but not so large in size as in previous years. Gooseberries and Cherries are moderate, also Apples and Plums. Those who were fortunate to have their Peach wall outside well covered, thereby preventing the sharp frost from injuring the bloom, no doubt have a fair amount of fruit.

It has been a very trying time for all kinds of vegetation, the nights being so cold through April and May when Peas and all other spring crops were in a young state. With heavy watering and a good mulching of rotten manure, Peas and Beans are very good. I find Chelsea Gem the best Pea for early work, being a very prolific bearer, of good size and flavour, and doing well on a warm south border. The Onion crops are very good, having escaped the disease which was very prevalent in many places last season. Carrots, Beet, Parsnips, and all kinds of Brassicas are very good taking into consideration the hot weather that we are having at the present time.—C. ALLEN.

Castle Gardens, Arundel.—Fruit trees of all kinds bloomed very profusely. I also think the trees were very deficient of moisture, owing to the drought of last year. We had cold easterly winds during that period, which of course were detrimental to the fruit setting. Apples are below the average. The following varieties are bearing crops here: Lord Suffield, Koswick Codlin, Ecklinville Seedling, Wellington, Beauty of Kent, Lane's Prince Albert, Mère de Ménage, Cox's Orange Pippin, Ribston Pippin, and Hambleton Deux Ans. Pears are very thin, as are Apricots. Peaches and Nectarines are an average crop, but owing to the excessive heat it is difficult to keep the trees healthy. Cherries are an average; Morellos heavy. Plums are thin. Early Rivers, Early Orleans, Green Gage, Transparent Gage, Pond's Seedling, and Victoria are bearing good crops. Bush fruits are an average crop; Raspberries good; Strawberries had crop; in some cases a total failure. The season in our light soil was very short. Nuts are an average; Medlars abundant.

Vegetable are suffering very much from want of moisture. I have only registered 1½ inches of rain since May 25. Peas are getting badly infested with mildew. I think highly of Gradus as an early variety to follow Chelsea Gem.—E. BURBURY.

Addington Manor, Winslow.—The fruit crop is a very poor one. Apples on old orchard trees are a failure, on young espaliers a moderate crop. Both Pears and Plums are light. Gooseberries and Currants are scarce, the blossom having been destroyed by frost. Strawberries are the worst crop I have had for years in this garden. In one of our gardens a quarter of a mile distant and 20 feet or 30 feet higher, sloping to the north and in an open situation, cultural conditions the same, I had an abundant and good crop. The first-named garden has a south aspect.

Vegetable crops so far not so very much to complain of. Among Brassicas more plants have gone blind than usual and are in great need of rain. The different successions of Peas are soon over, and Scarlet Runner Beans do not set well owing to the great heat and drought. Early Potatoes are plentiful, but small. Sharpe's Victor is excellent in quality, and so is Snowdrop

at the present moment and a fine crop. Late Potatoes in the field look healthy and strong and promise well for a good crop.—J. MATHISON.

Wentworth Gardens, Virginia Water, Surrey.—Of the fruit and vegetable crops in this neighbourhood I am sorry not to be able to give you a very glowing account, which I attribute to the very late spring frost and cold winds which have been succeeded by unusual great heat and drought. The fruit crop, taken as a whole, is about the lightest I ever recollect. Apples are very light; Apricots none; Peaches fair, but the trees have been badly attacked by blight; Plums are almost a blank; Pears the same; Strawberries about half a crop; Morello Cherries average crop; bush fruits, excepting Gooseberries, average.

Vegetables have been fairly good and plentiful up to the present. Potatoes are small and the late varieties have come very uneven. Late Peas, owing to the dry, hot weather, are looking very indifferent. Root crops are looking fairly well under the adverse circumstances.—W. MARCHAM.

Clophill, Ampthill.—From what I can gather and what I have seen the following is how fruit and vegetables stand this year in Beds: Fruit of all kinds is very scarce, no doubt owing to the late and very severe frosts we had.

Carrots and Onions are good. There is a good supply, and all kinds promise well, but a good soaking rain is needed for the light soils, or the drought will do mischief. Early Potatoes and Peas suffered owing to the dry weather.—W. JOYCE.

The Gardens, Panshanger, Hertford.—In the gardens here Strawberries were very much under crop; Black, Red, and White Currants are a heavy crop; Gooseberries a fair average; Sweet Cherries fair average; Morellos over average; Raspberries over average; Peaches and Nectarines poor; Apricots few; Plums on wall fair average; on standards few; Apples fair average; Pears on wall under average; as standards under average; Cobs are a heavy crop.

Vegetables have been fairly plentiful, and with rain (which is badly wanted) will continue to give a good supply.—JAMES ANDERSON.

The Gardens, Laleham House, Staines.—The late spring frost was most injurious to Strawberry blossom. We registered 17° of frost on March 21. This proved too much for the blossoms of Peaches, although I had a double covering of fish nets.

I have had a good all-round crop of vegetables up to this date. With the short rainfall we have had crops are more or less at a standstill now.—T. ANDERSON.

The Gardens, Wildernesse, Sevenoaks.—The fruit crop in this garden and neighbourhood is not so good as usual. Apricot blossom was spoiled by frost. Peaches are about half a crop; Plums very few indeed; Pears about half a crop; Apples very good and very plentiful. Strawberries are a very thin crop, which I attribute to last year's dry weather rather than to this year's frost. Other small fruits are very good and plentiful.

Vegetables are very good and plentiful, though Peas and Potatoes suffered somewhat from the dry weather in the early part of June and again in the middle of July.—H. ELLIOTT.

Kingston, Surrey.—My numerous visits to all parts of the county enable me to say that, so far as Surrey is concerned, fruit generally is but a moderate crop. The best of tree produce is no doubt found in Apples, of which there seems to be, if not a heavy crop, at least a plentiful one. Some trees are abundantly laden; some are thinly so; not a few have none. But with more rain the Apple crop should, all the same, be a very good one. All sorts are bearing, the season not having favoured one over another. Pears are very thin, the best crops being found on somewhat inferior varieties, such as Autumn Bergamot, Hessele, Windsor, and similar ones. The popular Williams' Bon Chrétien has few fruits. Trees in gardens, whether bush or trained, have

but few fruits generally. Plums are even scarcer. Judging by what I have seen, I should infer that Plums were very scarce indeed, whilst Damsons are almost *nil*. Cherries, both sweet and Morello, have been very good, as they have also been cheap, but Surrey is not a great Cherry county. Bush fruits have been a capital crop, Red, White, and Black Currents and Gooseberries having been very abundant and good. The great value of bush fruits for furnishing crops has been once more demonstrated. Raspberries were excellent at the outset, but the great heat and drought of July told upon them severely in shallow or dry soils. Strawberries were generally hardly more than half a crop. The frost destroyed much of the early bloom, and that was not too abundant, whilst the drought told upon the plants and caused the fruit season to be a short one. Walnuts are very abundant on some trees, and on others there is not a fruit. Small Nuts are not plentiful; indeed, the crop will be but a very partial one.

Vegetable crops are very fair generally, but not all are satisfactory. Potatoes have seldom come so weak and irregular as this season, and in all directions both large and small breadths are seen that show great unevenness and weakness of growth. This is largely due to a mild winter first exciting undue tuber growth, followed on the planting by a spell of cold, ungenial weather, combined with numerous sharp frosts, that greatly checked and weakened top growth. Early Potatoes, though small, have so far been very clean, and little evidence of the usual disease is visible. Peas were, when at their best, a good crop, but still too short an one. The recent hot weather greatly promoted blindness and trips, and late Peas have been scarce. Broad or Long-pod Beans were good earlier in the season, but became much blighted later. It is a poor crop for light, porous or shallow soils when heat sets in. Cauliflowers have not been satisfactory, the great heat and drought evidently much conducing to club. Cabbages were excellent earlier, but now have become hard and blue. Still, there is little evidence of caterpillar. Parsnips seldom have looked cleaner or better than now. The maggot on that and on Celery has so far been little seen. Carrots have suffered much from aphid, arising from spring cold and July heat. Beets are excellent; so, too, generally are Onions, but on light soils the plants are not strong, although autumn-sown bulbs are good. Vegetable Marrows where well done look well and are fruiting freely. In some few cases Lettuces have been found good, but in most instances inferior stocks have soon bolted off to flower. Dwarf Kidney and Runner Beans look well everywhere, but all need rain to induce free setting of the flowers. On the whole the season for vegetables is a very fair one.—A. DEAN.

The Gardens, Haynes Park, Bedford.—The fruit crops in this garden and neighbourhood are very light. Peaches, Apricots, Pears, and Plums are failures owing to early and late frosts in May; Cherries on walls fair crop; Strawberries a failure; Apples are very light; Gooseberries, Raspberries, and Currants of sorts are fair; Filberts a failure.

Early crops of Peas, Cauliflowers, Beans, &c., are fair; Potatoes very light. Autumn crops promise well if rain comes soon. Onions and Carrots are poor. This has been the worst season I have experienced here during the last ten years.—C. STEWART.

Hanger Hill House, Ealing.—Apples and Pears, taking them generally, are a good average crop. The fruit is clean, and promises to finish well. All stone fruit trees bloomed freely, but owing to the spring frosts suffered severely, especially Peaches and Nectarines. These with me have barely one-third of a crop. The trees, however, are looking well, and were subjected less to insect pests than usual. Plums are a small average crop. The same remark applies to Damsons. Apricots are nearly a failure; Walnuts a fair crop. Strawberries were rather under the average. These, too, suffered from spring frosts.

The crop was very disappointing after promising so well in early spring. Bush fruit of all kinds, especially Raspberries, is abundant.

All kinds of vegetables are plentiful and good, and are looking well for a good supply for autumn and winter. The late spring Broccoli was exceptionally good this year and easily overlapped the early Cauliflower, thus ensuring a supply of one or the other—thanks to the mild winter.—D. COOPER.

The Gardens, Englefield, Reading.—Apples, Pears, Apricot, and Peaches are fair; Plums poor; Gooseberries and Currants good; Raspberries poor. Strawberries were not at all good, the soil about here being too light to produce good crops of fruit. I find the second year after planting I have the best crops. The dry season of late has greatly affected our Strawberry crops.

The vegetables in general look well, but are badly in want of rain.—J. COOMBS.

Wycombe Abbey, High Wycombe.—Collectively the fruit crops will be below the ordinary average, and will, without doubt, be of a partial character. With the exception of Cherries, Currants, Raspberries, Walnuts, and Nuts, all other kinds are under the average, and Strawberries never so scarce as they are this year within my remembrance. The lighter crops of such fruits as Apples, Pears, Plums, Peaches, and Nectarines promise to be good, which they ought to be under existing conditions.

The dry state of the weather at certain periods in this year has in some degree, where watering has not been carried out, shortened the season and supply of some subjects as Peas, Beans, Cauliflower, Lettuce, &c., but on the whole the crops look exceedingly well and generally are abundant and good. Potatoes are turning out well and good, with no disease hereabouts. Although not so large or so plentiful as in some seasons, there is at present but little cause for complaint. The early kinds are ripening off very satisfactorily, and the main-crop of these should soon be lifted.—GEO. T. MILES.

Dropmore, Bucks.—Fruit crops are fairly up to the average in this district. Apples promise to be very good, but require now some soaking rains to swell up the fruits. The majority of varieties both as orchard and bush trees are carrying full crops. Orchard trees of Blenheim Orange carried very heavy crops last year, and are consequently very thin this; but, on the other hand, bush trees on the Paradise stock are cropping remarkably well. Nearly all other varieties are bearing freely; therefore it is needless to give many names. Pears are almost a complete failure on wall, bush, and orchard trees. In a few instances some varieties—Williams' Bon Chrétien, Souvenir du Congrès, Doyenné du Comice, Louise Bonne de Jersey, and a few others—are thinly cropped. Apricots are also a very poor crop. Peaches and Nectarines suffered somewhat from a week of severe frost while in bloom, but sufficient of the latter escaped to set good average crops. Waterloo and Amsden June produced ripe fruits in the open by the middle of July. Other varieties promise well and the trees are healthy. Plums are a good crop on wall trees, but almost a total failure in the open on standard and bush trees. Cherries have done well; the crops on orchard trees much above the average and wall trees were also good. Strawberries were only about half a crop and the fruits smaller than usual, owing no doubt to the extreme drought of last summer and the late spring frosts experienced while in bloom. Raspberries are altogether a good and full crop; the fruits of the variety Superlative have been and are unusually fine. Bush fruits generally are good; Filberts and Walnuts abundant.

Vegetable crops are now suffering somewhat from the continued heat and drought. This refers especially to Peas and Cauliflowers. An unusual number of the latter have gone blind and require pulling out and replanting. Peas are affected with maggot, although up to the present

date the yield has been very good. No disease has yet been seen among Potatoes, and the crop is generally good.—C. HERRIN.

WESTERN.

Stoke Edith, Hereford.—The circulars issued and sent out annually by the editor are of great benefit, and result in a mass of very valuable information being obtained from reliable sources, which when published affords very instructive reading. By perusing the reports thus sent in the reader gleans a great deal of valuable information regarding the various kinds of fruits and vegetables found to succeed in various localities in different parts of the kingdom. Besides this, these reports also form a kind of *vade mecum* to many, especially those who refrain from giving newly-introduced varieties a trial, and who prefer to wait until they can ascertain how such succeed in the hands of those who make the growing of novelties a speciality. I think the season of 1899 will long be remembered for the profuse blooming of fruit trees, thanks to the heat of the previous season having so thoroughly ripened up the wood. The blooms were also strong and well developed, and had it not been for frost and cold winds, the crop, as far as this locality is concerned, would have been one of the heaviest on record. As it is, I think we have—judging by what I have seen elsewhere and from what I hear—good reason to be well satisfied with the results. The shortest crop will be that of Plums, trees in orchards and in exposed positions having suffered more from the effects of cold winds than frost, the cold north-east winds seeming to have paralysed the blossoms and prevented them from setting. Early kinds have suffered more in this respect than the late ones, but I have seen good crops of both, and, apart from market gardens and fruit farms, trees carrying quite heavy loads of fruit are to be seen in cottage gardens. I put the average for the district at about one half of what it should be. Here I have good crops of both early, mid-season, and late sorts, those worthy of special mention being Early Prolific, Czar, Magnum Bonum, Kirke's, Belle de Septembre, Coe's Golden Drop, Jefferson, and Late Orleans. With regard to Apples, this crop is an excellent one, and so well are orchard trees bearing, that even old and decrepit specimens are to be seen with a good deal of fruit on them. So far as my observations go, Blenheim Orange promises to be plentiful, and I was looking at some trees of this variety the other day which have now carried heavy crops four years in succession. In these gardens Ecklinville, Potts' Seedling, Lord Suffolk, Keswick Codlin, Stirling Castle, Loddington, New and Old Northern Greenings, Lord Derby, Reinette du Canada, Warner's King, Cox's Pomona, The Queen, Peasgood's Nonsuch, Lady Henniker, Ribston Pippin, Old Nonpareil, King of the Pippins, Court Pendu Plat, and Tyler's Kernel are bearing heavily. Trees of Cox's Orange Pippin, although not bearing full crops, have a nice lot of fruit on them, and the same may be said with regard to many other choice kinds. Taken altogether, Apples will be quite as plentiful and the yield just as heavy as that of last year. Pears are not such a heavy crop as they at one period promised to be, in consequence of the Pear gnat midge having spoilt so many of them. The trees set an abundance of fruit which swelled off well, but through the attacks of the before-mentioned insidious insect they have been much thinned down on trees out in the open. On walls the attack has been but slight and the trees are carrying good crops. Pears calling for special mention are Marie Louise, Beurré Superfin, Marie Louise d'Uccle, Colmar d'Été, Knight's Monarch, Easter Beurré, Hacon's Incomparable, Beurré Baltet père, Flemish Beauty, Doyenné du Comice, Gratioli of Jersey, Glou Moreau, Easter Beurré, Prince Consort, Seckle, Thompson's, Josephine de Malines, Beurré d'Aremberg and Beurré d'Anjou. The fruits are clean, they are swelling apace, and promise to be very fine, especially those that escaped

the attention of the Pear midge. Growers will have to deal very energetically with this last-named foe and make great efforts to stamp it out, otherwise Pear growing will soon become almost impossible in many localities. Next come Cherries. These have been and are most satisfactory, this remark applying both to sweet and cooking kinds. The trees have made capital growth and have on the whole kept wonderfully clean. Apricots, contrary to expectation, have turned out to be a good average crop both in these gardens and in the neighbourhood. Cottagers will in consequence, unless I am much mistaken, realise excellent prices for their fruit. Peaches and Nectarines are also excellent crops. The trees have made splendid growth and are altogether in a very satisfactory condition. The best laden trees of these are Alexander, Alexandra Noblesse, Dr. Hogg, Crimson Galande, Raymacker's, Royal George, Magdala, Prince of Wales, Barrington, Lord Napier, Elruge and Spencer. Bush fruits, such as Currants in variety, Gooseberries and Raspberries, are extremely heavy crops and most satisfactory in every way; insects in all cases are conspicuous by their absence. Strawberries, too, have done well, and very fine fruit, and that of excellent quality, has been gathered of both Royal Sovereign and Sir J. Paxton. At the present time Oxonian on an east border is affording supplies of splendid fruit, the crop being a heavy one. In the neighbourhood the field Strawberry crop has on the whole been very satisfactory, and, according to report, very remunerative. Strawberry growing for market has become a very important industry in this locality, and the quantities of fruit despatched from here would compare very favourably with the output from many of the Strawberry gardens in the south of England. The fruit crops on the whole are, therefore, very satisfactory, and with the two exceptions, Plums and Pears, being short—the one from adverse weather influences, and the other from insect attacks—fruit has been and will be very plentiful.

Vegetable crops are much better than they have been the past few seasons, just sufficient rain having fallen to keep everything growing without check. Early Peas were much later than usual, Cauliflowers also, but as a counterbalance to this the yield has been excellent in both cases. With regard to Potatoes, there was little if any difference in point of time. Famous was again the earliest variety, the crop being good and tubers large. Sharpe's Victor is rather small, but the crop is a plentiful one. Early Regent and English Beauty are splendid and quite as early as Sharpe's Victor. Second early, medium and late sorts are looking remarkably well, and up to the present there is no sign of disease. As might be expected, successional crops of Peas are first rate both in yield and quality, and late sorts just moulded up and staked look very promising. The first sowings of French Beans have borne earlier than last year, the crop being a good one. For this sowing, Early Favourite and Superb Early were the kinds selected, with the result that there is no difference between them in point of earliness, but for heavy cropping the former takes the palm. Successional batches are very healthy, and consist of such varieties as Fulmer's, Best of All, and Ne Plus Ultra, in the order named. Scarlet Runners—that most productive of all kitchen garden crops—have revelled in the heat and moisture, and will in due course yield well. Spring Cabbages were much later in coming into use. These are now very plentiful, and will be right through the season as batch after batch becomes ready for cutting. A large breadth of Coleworts will be got out in the course of a few days for late autumn and winter supply. The Brassicas generally have been got out under more favourable conditions than of late years, and are as a result looking well. Turnips have given a great deal of trouble in consequence of fly having attacked the young plants as soon as they appeared above ground, but by dint of damping them daily and dusting them occasionally with lime, the enemy has been mastered. Carrots,

Parsnips, and Beet, and both the autumn and spring-sown Onions could not possibly be looking better. Broad Beans are heavily cropped and the quality is good. Celery is growing and looking well, the latest batch having been got out a few days ago. Asparagus has done exceedingly well this season, the produce being very fine, tender and succulent, while growth is all one could wish for. Vegetable Marrows will be very plentiful in the course of a few days; these are being grown on old hotbeds. Salading has been plentiful and good, and later supplies on a north border are equally promising. Outdoor Tomatoes look well, but as these are to form the subject of a separate note, further comment here is unnecessary. Very hot weather has set in during the past week, and should it continue, all vegetables that root near the surface will require water to enable them to keep growing before long.—A. WARD.

Badminton Gardens.—The fruit crop in this garden and immediate neighbourhood is, generally speaking, very poor indeed. Apples, Pears, and Plums are almost failures. The trees bloomed well, but the continued severe frosts in May wrought much destruction, and I think the poorest crop I ever remember of these kinds is the result. Apricots are fairly good, but Peaches and Nectarines are very thin. Small fruits have been a good crop and Strawberries abundant and very good, although the dry weather made the season for them somewhat short.

Vegetables up to now have been good; Peas and Beans especially so, but the drought is now beginning to tell on them, and rain with cooler weather is much wanted.—WILLIAM NASH.

The Gardens, Bosahan, St. Martin, R.S.O.—There is a good average of all kinds of fruit with the exception of Plums, which appear to be very poor generally. Peaches on walls are very good.

Vegetables are also very good with one or two exceptions. Spring-sown Onions took the rust very early, with the result that the bulbs will be rather small, and Peas here and in other gardens have been troubled very much with thrips. Early Cauliflowers have also suffered from wireworm and maggot. There are fine crops of Potatoes, but disease has made its appearance.—J. RUNDLE.

Toddington, Winchcombe, R.S.O., Glos.—The following, I think, represents the state of the fruit crop in this district. Apples, Pears, Plums, and Apricots are very thin; Cherries a good crop and quality good; Peaches and Nectarines poor; Strawberries the worst crop for many years; Gooseberries and Currants fair; Raspberries good. Much damage was done by the frosts in May, and the subsequent drought made the Strawberry crop a very poor one. Fruit trees and bushes look healthy and are free of insect pests than usual.—J. CLEARE.

Wilton House, Salisbury.—Apples are a moderate crop; the foliage of the more tender kinds, such as Lord Suffield, Hawthornden, and Cornish Gilliflower, suffered severely from the frosts that occurred at the end of March, middle of April, and the beginning and end of May. Apricots are scarce. A splendid crop had set, but the three successive frosts of all night duration that occurred on March 22, 23, and 24, 14° of frost being registered each night, proved destructive, although the trees were protected by glass coping and suspended netting in front of the walls. Cherries are fair where trees had been protected. Gooseberries and Currants are abundant, excepting Black Currants, which are scarce. Figs are a light crop. Nectarines and Peaches are abundant crops where the trees had been well protected. The trees were just unfolding their blossoms at the time the severe frosts occurred in the month of March, before alluded to, so did not suffer to such an extent as did the Apricots. Nuts and Filberts are fair crops; Walnuts moderate. Pears partial crop; the foliage of the more tender sorts suffered severely, similarly to that of the Apples and from the same cause. Plums a failure, except on walls well protected, where the

crop is fair. Raspberries are a full crop. Strawberries moderate; fruit small owing to dry weather during the swelling period.

Of Potatoes the early varieties are healthy, but light in consequence of prolonged drought; quality good. Later kinds are looking well, except in very dry positions or where the land is poor. No disease is visible either in the early or late kinds. All the other vegetable crops are looking well. I have observed that vegetables and salads have been singularly free from the attacks of slugs and other insect pests this year. Probably the sudden and severe spring frosts caught them, not napping, but on the move, and so proved to be a blessing on the one hand, if not quite so beneficial on the other.—T. CHALLIS.

Westonbirt, Tetbury, Gloucester.—There was every prospect of its being a good fruit year, but in the last week of April and the early part of May the cold east winds and frost crippled the bloom, and on May 4 and 5 we registered 10° degrees of frost, which destroyed the embryo fruit of Peaches and Nectarines. On the whole the hardy fruits are below the average. Apples, dessert, are bad; cooking, one tree in ten good; Apricots bad, Plums under average, Peaches and Nectarines under average, Cherries, especially Morellos, good, Pears under average, Strawberries good, Raspberries good, Currants average, Gooseberries average, Walnuts where trees escaped frost above the average, in exposed places bad; Nuts, Filberts and Cobs under average.

This is the best season we have had for vegetables for years. Potatoes are good, and up to the present free from disease. The haulm both of second earlies and the late field and allotment crops is looking healthy. Soil has so much to do with Potatoes, I hardly care to recommend any special kinds. Ringleader, Sharpe's Victor, and the old Ash and Walnut-leaved varieties are the principal early kinds grown. Paritan, Early Regent, and Harbinger, an excellent Potato, are the principal second earlies, and Snowflake, Windsor Castle, Up to Date, Magnum Bonum, and White Elephant the principal late ones. Peas have been a good crop. William Hurst is largely grown here as a first early, and holds its own against any newly introduced ones both for hardness, dwarfness, productiveness and eating quality. Gradus, Daisy and Prodigy are the three second earlies. Duke of Albany, Telephone and Maincrop, midseason; Autocrat and Ne Plus Ultra to follow. Other later varieties than these suffer from mildew in this district. All green crops for autumn and those to stand the winter look very promising. Onions are good and free from maggot. Celery is strong. I find an application of moderately strong tobacco juice mixed with water syringed over and underneath the leaves will keep the plants free from the maggot in the leaves.—A. CHAPMAN.

Goodrich Court, Ross.—Fruit crops generally are very good. Apples are over an average crop and are very clean. Among dessert varieties the best are Beauty of Bath, Blenheim Orange, Kerry Pippin, King of Pippins, American Mother, Gascoigne's Scarlet, Worcester Pearmain, and White Transparent. Kitchen varieties carrying heavy crops with me are Alfriston, Bess Pool, Bismarck, Bramley's Seedling, Dumelow's Seedling, Ecklinville, Emperor Alexander, New Hawthornden, Hanwell Soring, Lord Grosvenor, Lady Henniker, Lane's Prince Albert, Peasgood's Nonsuch, Sandringham, Schoolmaster, Seaton House, Stirling Castle, and The Queen. Pears, too, are very satisfactory; those carrying best crops are Beurré Bachelier, B. Diel, B. Clairgeau, B. Sterckmans, Benedictine, Doyenné du Comice, Durondeau, Duchesse d'Angoulême, General Todleben, Knight's Monarch, Hacon's Incomparable, Marie Louise, Marie Louise d'Uccle, and Pitmaston Duchess. Plums are in many places a failure; ours are a good crop on walls, but lighter on bush trees. Those carrying good crops with me are Coe's Golden Drop, Bryanston, Green Gage, Belgian Purple, Denniston's Superb, Jefferson, Kirke's, Prince Englebert, Pond's Seedling, and

Victoria. Cherries are a full crop, excepting Morellos, which are rather light. The fruit is smaller than usual on account of the drought, which has affected the size of fruit in general. The sorts doing best here are Bigarreau Napoleon, B. Schreter, Black Tartarian, Elton, Knight's Early Black, and May Duke. Apricots are a thin crop, owing to the unfavourable weather when the trees were in bloom. Small fruits are plentiful and good. Strawberries were a poor crop, the only satisfactory sorts being Royal Sovereign and Sir Joseph Paxton. Nuts are a full crop.

The hot, dry weather has been much against vegetables on our dry sandy soil. Among the early dwarf Peas the following have been particularly good: Chelsea Gem, Earliest Forcing, and Harbinger, the last-named being the earliest. Among mid-season varieties, Peerless, Exhibition Marrow, and Main-crop have been much the best here, carrying heavy crops of large, well-filled pods; the Peas are of excellent flavour when cooked. For later crops, the only one I grow is Autocrat, a magnificent variety and one that is hard to beat, bearing well right into the autumn, and one that resists mildew to a considerable extent. Potatoes are rather small, but good. The best I have here are Ninety-fold, a splendid cropper and of excellent flavour, much the best early variety this season; Early Ashleaf, and Puritan; the last-named will be discarded in favour of Ninety-fold. Among second earlies, Ideal, Epicure, Supreme, Satisfaction, and Windsor Castle are the best. For a late variety I depend on Syon House Prolific, a first-rate variety.—F. SPENCER.

GARDEN FLORA.

PLATE 1237.

NEW NARCISSI.

(WITH A COLOURED PLATE OF—1, MONARCH; 2, WEARDALE PERFECTION; 3, LULWORTH.*)

THE illustration faithfully portrays two of the best of all the new Daffodils now in commerce, viz., (1) Monarch and (2) Weardale Perfection, while (3) Lulworth, although much longer known and cheaper, still remains one of the most desirable in the division of the Incomparables to which it belongs.

As shown in the coloured plate, Monarch (1895) is a glorified Emperor of great substance, and perhaps a trifle brighter in colour. Some cultivators have said that it more resembles a golden enlargement of N. Grandee, but in any case it is abundantly distinct and the most beautiful of all the golden Daffodils now grown. So far it has been but sparsely distributed, as the catalogue price has been £12 12s. to £15 15s. per bulb. Weardale Perfection (1894) somewhat resembles a gigantic N. pallidus præcox, and is assuredly one of the best of modern sulphur Daffodils, its list price being £10 10s. Both these noble kinds have been certificated by the Royal Horticultural Society, as also at Birmingham and elsewhere, and there is nothing but the price to prevent their taking a leading place in our gardens. Weardale Perfection is one of the last and best of all the noble set of seedlings raised by the late Mr. Backhouse.

N. Lulworth is a chance seedling brought to notice some years ago by the late Rev. Mr. Kendall, of East Lulworth, but its culture was always restricted until a year or two ago, when a stock which the Rev. G. H. Engleheart had accumulated was distributed by Messrs. Sutton and Sons, of Reading. There are now a good many newer and, in one or two cases, better things in its way, but, nevertheless, Lulworth

* Drawn for THE GARDEN in Messrs Barr's nursery by H. G. Moon. Lithographed and printed by J. L. Goffart.

well grown is a bright and showy flower and one that has a telling effect in a stand of mixed varieties. Another advantage is that it is now fairly reasonable in price.

All the three varieties now figured are of fairly robust constitution and bid fair to retain their pre-eminence in the winning stands at our Daffodil exhibitions for some time to come.

F. W. BURBIDGE.

THE WEEK'S WORK.

KITCHEN GARDEN.

SCARLET RUNNERS.—In very few gardens indeed has rain fallen in sufficient quantity to penetrate to the lowermost roots of crops which carry abundant leafage, and as few things draw the moisture out of the soil sooner than Runner Beans or feel drought sooner, liberal mulching must on no account be neglected. Where washed away by repeated waterings or dispersed by birds in search of food it must now be renewed, both in the case of full-bearing rows and those only just coming into bloom. Peas will each week become more scarce; therefore their nearest substitute, Beans, will become more and more valuable. Close pickings, liberal manual soakings, and occasional baths from the garden hose at eventide must be given even if some such work as hoeing and cleaning have for a time to be abandoned. Those grown on the pinching system must be topped and re-topped if fresh growth is made, and where it is intended to save seed, pods should now be reserved for the purpose, as later produce often does not develop and mature the seed properly, especially if the autumn is wet and sunless.

ASPARAGUS.—There is yet time enough for giving another good soaking of liquid manure or to apply some approved artificial fertiliser to this important vegetable intended for lifting during winter for forcing, and if the advice given earlier in the season, viz., to leave a space of 2 feet between each three or four rows, was acted upon, there should be no difficulty in carrying out the work. If a mulch was applied when the roots were small there should still be sufficient of it left to preserve the moisture about the roots, and should there now be any weeds visible, a little salt added to the manure will assist in eradicating them. Old permanent beds of Asparagus have now become too dense to allow of getting amongst them, but with care a little manure may be distributed broadcast, and will find its way down to the roots through the force of autumn rains. This will also have the effect of enticing a number of new fibrous roots to the surface. These if slightly protected with any rough short litter in winter will quickly lay hold of an actual top-dressing of loamy compost in spring.

TOMATOES.—Midseason plants now bearing semi-ripe fruit will now require a little more care in order to give the fruit a good opportunity of finishing off with a good flavour and to prevent cracking. Especially is this care necessary where the fruit is eaten raw. As the nights are gradually becoming colder, turn on a little warmth in the hot-water pipes in order to create a buoyancy in the atmosphere and abandon afternoon damping down. Neglect of these simple but important details is apt to result in mildew and wholesale cracking. Provided the plants are fairly strong, the use of manure water, and indeed all stimulants, had now better be discontinued. Excessive foliage may well be shortened back to admit of a free circulation of air.

SUCCESSIONAL TOMATOES.—Where frequent sowings have been made there will in some cases now be a batch of plants bearing very small green fruit and bloom trusses. These are usually grown in limited-sized pots, which are the most suitable for plants so late in the season. These should occupy if possible a light, airy, span-roofed structure until the end of September, when removal to an intermediate house will be

necessary, affording a light position. Here they will yield a useful lot of fruit until the winter proper batch comes into use. If at all pot-bound a little feeding may be practised, but let it be in strict moderation for the same reasons as given above. Small plants now being brought on for actual winter cropping must have all the light and air possible, the object being to secure a sturdy, but not rank growth at this advanced season.

EARLY SEAKALE.—With some gardeners the practice is to give a sunny warm border to that batch of Seakale which is to be lifted for very early forcing, say in November. The plants should now be looked over and any weeds which exist pulled out, so as to admit all the air and sun-heat possible, these agents being indispensable for the thorough ripening up of the stools for early forcing. If, by reason of occupying a sunny, sloping position, the plants show signs of distress through lack of moisture, care will be necessary in applying moisture, as an overdose in such a warm root-run may induce a secondary growth, which would be an evil. All ordinary plots of Seakale ought also to be looked through with a view to clearing away all weeds, discoloured leaves, and whatever impedes the entrance of a maximum amount of sunshine, air, and light.

ASSISTING CROPS.—Whatever spare time there may be may well be utilised in administering liberal supplies of liquid manure to all growing crops except where, through a too rich root-run, over-luxuriance is noticeable. Attend first to newly-planted plots of Coleworts, following on with late Brussels Sprouts, Kales, and Broccoli. Celery will respond quickly to a supply of rich food given in liquid form from the farmyard; this immediately preceding the first earthing up, Marrows, Globe Artichokes, Autumn Giant, Walcheren and Self-protecting Broccoli, also pickling Cabbages, deriving much good from one or more liberal soakings. Pickling silver-skinned Onions grown on a thin plot that are now showing signs of maturing may be pulled up and placed in flat hampers to dry, these being easily removed under cover in case of rain. J. C.

FRUITS OUTDOOR.

PEACHES AND NECTARINES.—The bright and warm weather we have experienced during the past few weeks has done much to bring on in good time the early Peaches, &c., that promised at one time to be so backward, and they have come up well in colour and size. The earliest varieties, and these are certainly the best for outdoor work, will have ripened up by the time these notes appear, but later ones will still be in a backward state, and will pay for further feeding at the roots right up to the time of ripening—that is to say, if the border is in good condition and the trees not gross. In writing of the early varieties I include that, to my thinking, best of all Peaches for outside, Hale's Early, for though it is not the very earliest to ripen, it comes well in advance of the main-crop varieties, and compares well with the best of them from almost any point of view. I mention it particularly here, as I notice a note in a recent issue of THE GARDEN giving it a bad name as a poor grower and not prolific. This is so opposed to my experience, that I think the writer must be mistaken in the variety, and I would certainly urge any of my readers who do not possess this valuable Peach to be sure and grow it. Now is the time to make plans for future operations on trees that have not been quite satisfactory. For instance, a defect often noticed and deplored is that of stone-splitting, which is not only a bad thing in itself, but it admits ear-wigs to the inside of the stone, these rendering the fruit totally unfit for table. A very simple remedy for this is to add a good supply of lime to the soil around the roots, as I believe that the splitting is entirely caused by a deficiency of lime, and have rectified the defect more than once by its use. Old trees or any that have been badly blistered during the past year or two, and which

have not made any clean growth this year, would be best grubbed up and thrown away and their places taken later on by thrifty young trees. See that all swelling fruits are well exposed to the light by tying back any overhanging shoots or leaves from them. Trees cleared of their fruit should be gone over and all surplus wood removed after the same fashion as recommended for trees under glass; indeed, I think this autumn pruning is even more important outdoors than it is indoors, and that the less pruning there is to be done after the trees have lost their leaves the better. Of course, in advising this I am supposing that the system used is the extension system, and that no shortening back of the young wood is permitted, the only thing done being to remove all the shoots that have borne fruit and which can be spared from the trees.

STRAWBERRIES.—Young plantations have had rather a trying time, as there have been but few showers to help them on, and artificial watering never appears to do the amount of good that one might expect from the amount of water used. The greatest help appears to be given by keeping the surface open by using the Dutch hoe and by keeping the runners cut hard back. Having had to make a new plantation of Strawberries in April, I took the opportunity of dibbling out between some of the rows some Onions which had been raised under glass, and I am rather agreeably surprised to find that instead of robbing the Strawberries, the Onions, probably from the slight shade they have given, appear to have helped them, as the plants where the two crops are growing together are well ahead of the others. In using the hoe, take care not to bury the crowns nor to stir the soil deeply, it being quite sufficient to keep the surface in a powdered condition. I advised some months back the early planting out of forced Strawberries with the view of getting some autumn fruit. From a batch of Royal Sovereign treated in this way I am now getting some nice dishes. These will be succeeded by some St. Joseph, which I have had planted in bed fashion, so that they might be covered by frames, and the plants have now a nice crop set on them. Whether this variety will prove an acquisition or not must be proved later, but it is of nice flavour, and a few dishes will be acceptable. Alpines are showing very well this autumn, Belle de Meaux raised from seed being the best grown. It is necessary to look out for mice with these late fruits and to persistently trap them.

GRAPES.—Continue to stop the sub-laterals of those Vines which are vigorous in growth, but do not expose the fruit too much to the light by tying back leaves or bringing the bunches forward, for this would probably encourage mildew, which it would be impossible to eradicate at this late date without ruining the bunches. The Sweetwaters will in the case of old Vines on which the canes have not been renewed lately have almost stopped growing, but Hamburgs and sometimes the little Black Cluster, an excellent little Grape for outdoor culture on the gables of old-fashioned houses, will continue rampant, and if allowed to carry their entire growth after the first stopping the fruits do not get a chance to ripen.

WALL TREES.—On wall trees generally there will be still some fastening back to the walls to be done in the case of growths wanted for extension, and this should not be overlooked, as they are very liable to get broken off through high winds and sometimes from other causes. Trees that are netted should also be looked to in this way to prevent the tips of the growths pushing through the nets and becoming crippled.

CORNUBIAN.

A remedy for the disease in Clematises.—A remedy for black disease which for many years has been the cause of much loss among Clematises and which had of late been attributed to a nematode of the Heterodera species, is described by M. Emile Rodigas in an article in

the *Bulletin d'Arboriculture de Gaul.* He says that when visiting the nurseries of M. Coster at Boskop he saw thousands of plants of Clematis protected at the base of the stem with a kind of sleeve of stout paper, rather wide at the bottom and narrower at the top. These sleeves, he was told, were intended to protect the stems of the young plants from spring frosts and the consequent deterioration which renders them suitable as media for the development of the nematode. M. Rodigas here remarks, by the way, that it is a mistake to attribute to this parasite the decomposition of tissue in Clematises, which is really due to a microbe analogous to the *Bacillus caulivorus*. Among Pelargoniums, Petatoes, Cauliflowers and many other plants as well these bacilli find a medium eminently favourable to their increase in the lower part of the stems when these are in contact with stagnant moisture or disorganised by alternations of frost and thaw. The nematodes come after the bacteria and only when decomposition of the tissues is accomplished. M. Coster affirmed that since he began to make use of the sleeves in the manner above described he has lost none of his Clematises. He has made no change in the method of culture in ordinary use. It may be assumed, therefore, that his plan is one to be recommended.

ORCHARD AND FRUIT GARDEN.

BUDDING PEACHES AND NECTARINES.

THE practice of budding two or more varieties of either Peaches or Nectarines on one tree is not followed so generally as it might be, neither is the advantage gained by doing so fully recognised, especially by owners of small or medium-sized gardens. Even in large gardens with every convenience I have found wide-spreading trees may be made more serviceable by having their branches studded or intermixed with others producing fruit somewhat later, thereby reducing the risk of a glut of ripe fruit at one time and encouraging a more even and regular supply over a longer period, so necessary for private consumption. The same method when resorted to is also appreciated by those growers who compete at the different fruit exhibitions and whose convenience for producing several varieties is somewhat restricted. With a view to getting the greatest possible yield from, perhaps, one medium-sized Peach house, several trees of different varieties are crowded in where really there is only sufficient space to extend one properly. It should be a well-known fact that the heaviest crops of the finest fruit are obtained from strong-growing, unrestricted trees rather than several that have perforce to be restricted unnaturally owing to the want of space. How much better then would it be to rely upon one healthy free-growing specimen to fill the house and use its branches as stocks for different varieties.

The first and most important thing to study is that the trees are quite healthy and sound, and that there is no reason to fear a collapse of roots through an ungenial border or the dying off of branches by gumming for a good number of years at least. Over twenty years ago I was deputed to insert buds of Humboldt Nectarine on the branches of Princess of Wales Peach. For many years, since the varieties are about equally balanced on the same stock, the produce has been in many winning collections at our largest shows, and, so far as I know, will continue to be so. Other trees were treated in the same way with different sorts, affording, as was the desideratum, a large collection of varieties and a continuous supply of fruit. Moreover, many growers are anxious at times to add some new or good old variety to their

existing collection, but are reluctant to discard trees that have proved satisfactory in the past. The latter resource may be avoided by budding the kinds it is the desire to include, establishing them on the young branches of the different trees, and so the object will be gained without loss of time or crop, which must to a certain extent follow where established trees are replaced by young ones.

I have referred to the subject now as the season is with us when the work can be performed with the greatest degree of success, the buds and wood being in a suitable condition for the operation. The details of budding need not be described here, as any intelligent youth who is fond of gardening can bud deftly and successfully. It might be pointed out, however, that care should be taken in selecting the shoots for receiving the buds. These, of course, will be the current season's growth, and preference should be given to those of medium size, rejecting very gross ones, as the latter are apt to gum by the wound made in the bark. It is also wise to choose such shoots as are near to the base of the main branches, so that plenty of room for extending the new variety is secured. The bud, too, should be inserted on the top side of the shoot and also near the base. Care must be exercised in using the knife not to cut or damage the young wood below the bark. This would arrest the proper flow of sap, the bud would shrink from the want of moisture, and a speedy and perfect union would not take place. Where the bark is cut clean with a sharp knife it soon heals, but if bruised in any way it dies back and the inserted bud being exposed to the air fails to grow. In securing the bud in position use broad strips of matting, making the latter moderately firm, but after about a fortnight each one should be examined and the matting slightly loosened if it is found that the bark is swelling above it at either end, which invariably it does. The latter is an important matter and must not be neglected, or the young growth will be strangled as it were, when bad results would follow. Any number of buds may be inserted according to the size of the tree and the wish of the operator, but I advise that a too free use of buds should not be made of any new variety that has not been properly tested. No one would be wrong for instance in budding Early Rivers Nectarine on a healthy tree of a later variety, by which means fruit would be obtained several weeks earlier than formerly from the same trees and treatment, and the season would also be prolonged. The same variety might also be budded on to healthy trees of Early Alexander Peach, the two fruits thereby ripening about the same time, which would add considerably to the dessert table early in the season. Again, healthy trees of some varieties are often a source of trouble to the grower through casting their buds. This, provided cultural details are properly carried out, undoubtedly is the fault of the variety in most instances. Such trees would make first-class stocks for other varieties that do not have this unsatisfactory habit. The position of the buds should be marked by suspending a neat label bearing the name of the variety, which will also warn the pruner later on and prevent the cutting out of the new kinds which it is the desire of the grower to extend.

RICHARD PARKER.

Goodwood.

Apple White Juneating.—More than once I have had occasion to refer to this little dessert Apple, and I do not think it can be planted in the wrong place. I have seen trees towering very high as standards in Essex, their delicate pale-coloured fruit hanging in great profusion, and on

trees trained under the restrictive espalier form it crops equally well. I think all amateurs who cannot afford to experiment with uncertain varieties ought to grow a tree or two of Juneating, as, unless the spring is unusually severe, there is sure to be fruit on the tree, thinning freely being a necessity in more seasons than not. Of course it will not keep long after being fully ripe—in fact, is best eaten from the tree—but if picking is performed when slightly under-ripe and cool storage given, the fruit may be had in good condition for say ten days or a fortnight. Owing to its brisk juicy nature it is very refreshing in hot weather.—B. S. N.

Raspberry Baumforth's Seedling.—There are few Raspberries, I think, to beat this kind. The habit is strong, but dwarf; it is very prolific, and the fruit large, handsome, and excellent. Its firm texture renders it especially suitable for packing or for gathering for home use, some of the newer kinds being too soft. It remains in a profitable condition for a number of years in the same quarters if duly manured and surface-hoed. It would, I think, be comparatively easy to select from Baumforth's Seedling an autumn-fruiting kind, as numbers of the young canes will fruit the first season if allowed, and after the old canes have been cut out there are often several canes that fruit or would do if left. For this reason I usually leave the canes rather thick at first, not thick enough to crowd each other, but sufficiently so that I can afford to cut out a few which show this proclivity to autumn fruiting. Many more sucker growths than are required are annually produced, and this makes propagation very easy and rapid. Any that are not required for forming new quarters should be hand-drawn, as when cut off with the hoe the thickened root-stock gives trouble afterwards.—H.

Insects and Strawberries.—In answer to "H. R.'s" inquiry as to the insect that eats off his Strawberry seeds to the marring of their freshness and beauty, I beg to say this enemy is the common mouse. I found this out first under glass in the case of a house full of the Black Prince. For a few nights a litter of mice overhauled and picked out the seeds from the majority of the fruits, entirely spoiling their appearance. Varieties vary considerably in the size and character of their seeds, Royal Sovereign, Latcast of All, and others having more prominent seeds. Those with large seeds are the first and most severely mauled. The most provoking part of the business is that the Strawberries are not eaten; only their seeds. The only exception I have known to this was in the case of a Pine stove with no ripe Pines for the mice to feed upon. It contained two other growing crops—forced Strawberries and Capsicums—and both were badly eaten. But as a rule, both out of doors and in, mice skim off the seeds and leave the flesh of the Strawberries severely alone. It is difficult to get bait sufficiently alluring to decoy the mice from the Strawberry seeds once they have got a taste of their nutty flavour. Notwithstanding all that has been written against the use of short grass, I heard of a bad case here in Edinburgh to-day (July 22) of a good crop crippled and virtually ruined for the season through a heavy mulch of grass with the usual violent fermentation and consequent decomposition.—D. T. FISHER.

—At page 66 "H. R.," Suffolk, complains of many of his Strawberries having been damaged by, he supposes, some kind of insect. When living in South Notts I was for several seasons much troubled by the destruction of many of the finest fruit of President. The seeds only were taken, exactly as described by "H. R.," and the singular feature of the case was that I could not discover any insect at work in the daytime. I believe the damage was done by mice, not the ordinary field or garden mouse, but the tiny black shrew, or sow mouse as it is called in the eastern counties on account of its long pointed nose. The attack on my fruit happened some years ago, so that I almost forget particulars, but

I believe the runs of the mice were discovered among the mulching when the beds were cleared in autumn. I feel sure the damage was done in the night. Varieties having the seeds on the surface, such as Loxford Hall, seem to be preferred by mice.—J. C.

PEARS ADOPTED BY THE CONGRÈS POMOLOGIQUE OF FRANCE.

(Continued from p. 135.)

DOYENNÉ D'ALENÇON (*syns.*, *Doyenné d'hiver Nouveau*, *Doyenné gris d'hiver Nouveau*, *Doyenné marbré*, *Saint Michel d'hiver*).—The fruit is medium-sized, often lumpy towards the stalk, the stalk short, stout, swollen at the point of attachment, set almost straight in a small cavity or depression. The eye is medium-sized, almost closed, in a cavity sometimes narrow and sometimes wide. The skin is rough, greenish, mottled and spotted brown and grey, passing to yellow at maturity. The flesh is yellowish white. A very good fruit, ripening January—March. The tree is of rather insufficient vigour on the Quince and is free-bearing. In cultivation this variety succeeds in all forms and exposures. It does best grafted upon the Pear.

DOYENNÉ DE JUILLET (*syns.*, *Doyenné d'hiver*, *Jolimont précoce*, *Leroy Jolimont*, *Saint Michel d'Eté*).—Its origin is attributed to the Capucins of Mons, Belgium, about the year 1700. The fruit is small, the stalk fairly stout, fleshy at the point of attachment, fairly long, set straight almost flush with the fruit. The eye is medium-sized, compressed, almost closed by superficial gibbositities. The skin is thick, yellow, freely shaded carmine-red on the sunny side. The flesh is white, half melting, sweet, aromatic, and refreshing. A good fruit, ripening end of June and commencement of July. The tree is of rather insufficient vigour; on the Quince its fertility is great and sustained. In cultivation on the Quince this variety will take small forms, which can be grown against a south wall. On the natural stock as a standard it gives fruit of better flavour.

DOYENNÉ DE MÉRODE (*syns.*, *Burré de Mérode*, *Double Philippe*, *Doyenné Boussoch*, *Nouvelle Boussoch*).—Originally obtained by Van Mons about 1800, and named after Comte de Mérode de Waterloo. The fruit is large or fair sized, with a bumpy surface. The stalk is stout, set straight in an open deep cavity. The eye is medium, open, in a broad shallow cavity. The skin is thin, delicate, without being smooth, bright yellow, stippled and mottled grey-brown, streaked red on the sunny side. The flesh is white, delicate, tender and melting. A good fruit, ripening September. In cultivation this hardy variety is better adapted for grafting on the natural stock, where it is more vigorous and as early as upon the Quince.

DOYENNÉ DE MONTJEAN (*syns.*, *Doyenné gris de Montjean*, *Doyenné Perrault* or *Perrault*).—Obtained originally by M. Trottier at Montjean, arrondissement of Cholet (Maine-et-Loire). It first fruited in 1858. The fruit is large, almost equally rounded at the two ends. The stalk is shortish, fairly stout, swollen at the point of attachment, set straight in a bumpy cavity. The eye is medium-sized, open in a regular and normal cavity. The skin is thin, rough, yellow, abundantly mottled tawny red. The flesh is white, delicate, very juicy, and agreeably flavoured. A very good fruit, ripening January—March. The tree is of continuous vigour on the Quince and of great fertility. In cultivation this variety should be grafted upon the natural stock. By double grafting, shoots over a yard in length have been obtained.

DOYENNÉ D'HIVER (*syns.*, *Burré de Piques*, *Bergamote de Pentecôte*, *Pastorale de Louvain*).—The origin of this variety is disputed. It is probable that it was found first in the old garden of the Capucins at Louvain, Belgium. The fruit is large or of fair size, having most frequently the Doyenné conformation. The stalk is stout,

straight, very swollen at the point of attachment, set rather obliquely in a fairly deep and irregular cavity. The eye is medium-sized or large, open, in a shallow cavity. The skin is smooth, tender, green and yellowish, spotted tawny at the eye, rarely tinged dull red on the sunny side. The flesh is whitish, luscious, and juicy, agreeably aromatic, sometimes gritty at the core. A very good fruit, ripening December to April. The tree is of middling vigour on the Quince, very fertile on the natural stock, as also on the Quince. In cultivation this tree does best as an espalier, and on a good exposure east or south, the fruit generally cracking in the open.

DOYENNÉ DU COMICE.—Originally obtained in the garden of the Comice Horticole of Angers. It first bore fruit in 1840. The fruit is large, sometimes very large, variable in form, which is generally that of a Doyenné, the surface bumpy, especially towards the ends. The stalk is stout, rather fleshy, of medium length, set obliquely in a narrow cavity, irregularly embossed. The eye is medium-sized, almost closed in a deep cavity. The skin is smooth, light yellow, mottled and stained red, washed vermilion-red on the sunny side. The flesh is whitish, delicate, very juicy, and aromatic. A very good fruit, ripening October—November. The tree is vigorous on the Quince, of medium and sustained fertility. In cultivation this variety is easy to train, and forms handsome pyramids on the Quince.

DOYENNÉ GOUBAULT.—Obtained originally by M. Goubault, nurseryman, of Angers. It first fruited in 1842. The fruit is medium-sized, more or less turbinate, often more wide than high, bumpy in surface. The stalk is short, of medium stoutness, set in a broad, fairly deep cavity. The eye is medium-sized, open, in a deep, wide, and ribbed cavity. The skin is rough, orange-yellow, mottled and marbled with deep red. The flesh is white, sweet, and highly aromatic. A good fruit, ripening January to March. The tree is of continuous vigour on the Quince, of middling and sustained fertility. This variety should be grafted on the Pear if lasting and good-bearing trees are required.

DOYENNÉ GRIS (*syns.*, *Doyenné crotté*, *Doyenné galeux*, *Doyenné rouge*, *Doyenné roux*, *Neige grise*, *Philippe strié*, *Saint Michel crotté*, *Saint Michel doré*, *Saint Michel gris*).—Of ancient, unknown origin. The fruit is medium sized, with the exact form of Doyenné blanc, sometimes, however, a little narrower at the base. The stalk is fairly stout, short, straight or slightly inclined, in a rather deep cavity. The eye is medium-sized, half closed, in a normal cavity, the skin delicate, thin, rather rough, deep yellow, much stained and marbled with reddish grey, heightened by small black spots. The flesh is white, very delicate, and even more pleasantly marked than that of Doyenné blanc. A very good fruit, ripening October to November. The tree is of continuous vigour on the Quince, of great and sustained fertility. In cultivation this variety requires the same care and position as Doyenné blanc.

DUCHESSÉ D'ANGOULÈME (*syns.*, *de Pénas*, *des Esparonnais*).—Originated as a chance seedling on the farm des Esparonnais, in the commune of Cherré (Maine-et-Loire). The parent plant, which died in 1862, may have been a hundred years old. The fruit is large, of Bon Chrétien shape; the stalk is shortish, stout, more swollen towards the point of attachment, set in a bumpy depression. The eye is small, close, in a deep irregularly creased and embossed cavity. The skin is fairly thick, rough, greenish yellow, strewn with red-brown and green spots, stippled and slightly marbled with red. The flesh is white, luscious and agreeable. A good fruit, ripening October, November and sometimes December. The tree is vigorous on the Quince, of very great and well-sustained fertility. In cultivation this variety is as early to yield on the natural stock as on the Quince. It is easy to train and adaptable to all forms. The Pear Duchesse d'Angoulême has produced two sub-varieties, which are only distinguishable from the type by the colour of the wood and of the fruit.

DUCHESSÉ PANACHÉE.—This variety is distinguishable by its variegation of wood and fruit. It was obtained and fixed about 1840 in the nurseries of André Leroy at Angers.

DUCHESSÉ BRONZÉE.—This variety is distinguished by its fruit, of which the skin is bronzed and rather rough; this tint is olive-coloured in the digressions and prominences. It was obtained and fixed in the Côte d'Or.

DUCHESSÉ DE BÉRY D'ÉTÉ.—Found in 1827 at Saint Herbelain (Loire Inférieure) by M. Gabriel Bruneau, nurseryman, of Nantes. It is a fruit of medium size, rounded, and rather bumpy towards the stalk, which is of medium length, fairly stout, set almost straight in a slight depression. The eye is medium, half closed, in a wide, shallow cavity, the skin delicate, straw coloured, stippled tawny, mottled and shaded rose on the sunny side. The flesh is white, delicate and melting. A very good fruit, ripening in August. The tree is vigorous on the Quince and of good and constant fertility. In cultivation this variety, feeble at the commencement, acquires with age vigour on the natural stock. It forms satisfactory pyramids and may even be established as a standard.

DUCHESSÉ DE BORDEAUX (*syns.*, *Burré Perrault*).—Obtained originally about 1850 by M. A. Secher, proprietor of La Gobardière in the commune of Montjean (Maine-et-Loire).—It first bore fruit in 1859. The fruit is fair-sized, sometimes more high than wide, uniform in surface, and hollowed towards the stalk, which is of medium length, stout, thickened at the two ends, especially at the stalk end, and set in a wide cavity. The eye is small, half closed in a wide cavity. The skin is thick, light yellow, finely stippled red-brown, abundantly streaked tawny-red. The flesh is white, luscious, and highly aromatic. A good fruit, ripening December—February. The tree is vigorous on the Quince and fairly fertile. In cultivation this variety is easily trained, but grows less well on the Quince than on the natural stock.

DUVERGNIES (*syns.*, *Burré Duvernoy*, *Belle Duvernois*, *Prince de Ligne*).—Originally obtained by M. Duvergnies at Mons, Belgium. The fruit is medium-sized, variable in form, most frequently turbinate, rather higher than wide. The stalk is fairly slender, shortish, straight or curved, set slightly inclined upon the base of the fruit or in a small cavity. The eye is small, open or closed in a regular depression. The skin is delicate, thin, light yellow, finely stippled tawny-red, washed pale red on the sunny side. The flesh is white, very melting, and very pleasant. A very good fruit, ripening September—October. A delicate tree and not vigorous upon the Quince, of great and sustained fertility. In cultivation this variety is best grafted on the Pear. Too dry and burning soils appear unsuited to it.

ECHASSÉRY (*syns.*, *Besi de l'Echusserie*, *Besi Landrin*, *Epine longue d'hiver*, *Verte longue d'hiver*).—Its origin is ancient and disputed, but is believed to come originally from Anjou. The fruit is small or scarcely medium-sized. The stalk is stout, rather fleshy, sometimes shorter, sometimes longer, set between small gibbositities. The eye is small, half-open, almost projecting. The skin is fairly thin, rather rough, citron-yellow, stippled and also slightly stained tawny red. The flesh is white, delicate, juicy, melting, and pleasantly aromatic. A very good fruit, ripening January—April. The tree is of continuous vigour on the Quince, of very great and constant fertility. In cultivation this variety is easy to train, and forms regular pyramids. It is especially adapted to exposed situations.

EPARGNE (*syns.*, *A la suite*, *Beau présent*, *Beau présent d'Eté*, *Chopine*, *Courge*, *Cucillette*, *Grosse cuisse damc*, *Grosse Madeleine*, *Jargonelle*).—It is of ancient and unknown origin. The fruit is medium-sized, long, pyriform. The stalk is of medium stoutness, long, arching, set obliquely on the inclined point of the fruit. The eye is medium-sized, open, projecting, or set in a very slight depression. The skin is rather thick and rough, yellow, mottled and slightly spotted russet, often

tinged red on the sunny side. The flesh is white, half delicate, juicy, and pleasantly marked in flavour. It is a good fruit, maturing July—August. The tree is vigorous on the Quince, of very great and constant fertility. In cultivation this variety is of rather untidy growth and ill adapted for regular forms. It is specially adapted for standards, when it attains to great dimensions.

EPINE DU MAS (*syns., Belle épine du Mas, Belle épine de Limoges, Beurré de Rochechouart, Colmar du Lot, Duc de Bordeaux*).—Originally found in the forest of Rochechouart, on the Du Mas territory (Haute-Vienne), where the parent tree still existed in 1856. The fruit is medium-sized, pyriform, and regular. The stalk is straight or oblique, slightly curved, set upon the blunted base of the fruit. The eye is medium-sized, open, regular in a normal and irregular cavity. The skin is thick, smooth, citron-yellow, stained rose on the sunny side, with strongly marked grey-black stipplings. The flesh is white and very juicy and agreeably aromatic. A good fruit, ripening November—December. The tree is of medium vigour on the Quince, as early to bear on the natural stock, of great and sustained fertility. In cultivation this variety is hardy, easily trained, and may be grown in all forms, even standard.

(To be continued.)

NOTES ON APRICOTS.

JUDGING from the unfavourable reports which appeared in THE GARDEN towards the end of March when the terribly severe frost visited so many districts, Apricots will be few and far between in many gardens. One is apt to get disheartened under such circumstances, and, so to speak, begrudge the trees the necessary attention for the remainder of the summer. But such a course is very unwise; indeed, if anything a little extra care should be shown the trees, as these occasional failures are in reality a blessing in disguise. If the cultivator has courage enough to meet such disappointment, with the determination to mulch liberally and soak the roots as often as practicable with farmyard liquid, trees weakened by a series of too heavy crops recoup, and are better for years to come. Generally speaking, given fair springs, Apricot trees flower and set so abundantly, that gardeners, after removing perhaps thousands of tiny fruit, sometimes imagine they have overthinned them, when really, as time proves, almost as many more could have been spared. No other wall fruit is so long-suffering as the Apricot, or capable of bearing the strain of excessive cropping, hence the abuse it is often subjected to. But it tells in time. With due feeding and, in the absence of rain, occasional drenching baths to the foliage from the hose, strong wood and stout fruit and wood buds will be formed for the coming season. It must be remembered that a dry root run, even though the trees are barren, is about the most harmful condition Apricots can be found in from March to November.

J. C.

Cropping under fruit trees.—The long protracted drought that has brought moisture-loving crops to a standstill is now seriously affecting the fruit trees, and those that are carrying full crops are either shedding the fruit or it is shrivelling on the tree. In looking over several fruit plantations lately, I have been very much struck by the healthy vigorous look of the trees that have the soil as far as their roots extend kept solely to their own use. Those that are under-cropped with coarse growing vegetables or bush fruits are suffering very much indeed, as the roots of the bush fruits monopolise all the nutriment and moisture from the soil. Unless the staple is exceptionally deep and good, the fruit trees should have the soil for at least 10 feet or 12 feet round the base kept quite clear of every other crop and well mulched with manure. Although the old excuse of spring frost is made year after year and doubtless is sometimes the

cause of loss of crop, I am confident dryness at the root causes far more losses than all spring frosts put together. Strawberries were nearly a complete failure all round here, and no wonder, for last year they were simply parched up until the end of September, when rain started them into growth, too late to perfect their flowering crowns. If the present drought holds on as late as it did last year, the Strawberry crop next year will be sure to suffer.—J. G., Gosport.

The Strawberry season.—At p. 97 an excellent note appears on the Strawberry season with some pertinent remarks as to the sale and growth of the plants. I was pleased to see the note referring to the Chiswick treatment of the Strawberry many years ago, and certainly "Rambler" hits the nail on the head when he states we get better results from young plants than otherwise. For some years I have advocated in these pages the culture of what I term yearlings, and have always had splendid crops till this year. Though the fruits were early there were few. I do not attribute the failure of the crop to the system of cultivation, but to the poor growth the plants made

plants were in their fruiting quarters the third week in July, and owing to heat and drought have needed much attention. I fear unless we get a change of weather this attention will be needed for some time, as unless moisture is given the crop will be poor next season. It is useless to fruit plants in such a season as this and get runners also, I mean if annual culture is carried out. If the grower can follow out "Rambler's" ideas he will get much finer fruit and the land will be in better condition for the crops that follow.—G. WYTHES.

APPLE CELLINI.

THIS Apple, now an old inhabitant of our gardens, is, judging by the frequency with which one meets with it both in orchards and gardens, quite as popular as ever. Its value for growing and training in all the recognised forms of tree in this country, together with its free-fruiting and the handsome appearance of the fruit when ripe, is mainly accountable for it having gained this popularity. Whether grown as a standard, bush, pyramid, or espalier, it crops equally well, and it is therefore a suitable kind for the market grower, cottager, amateur, as well as for the professional gardener to plant. The highest coloured fruits, as may be naturally supposed, are yielded by standard trees. Very fine-coloured specimens may also be had from bush trees, which, if they lack the brilliant crimson hue of the former, are quite equal both in size and cooking qualities. As a market Apple it is largely sought after by dealers, and no doubt great quantities are sold for eating in the populous mining and large industrial centres. When fully ripe it is a pleasantly flavoured, juicy Apple, and just such an one as many prefer for eating. As a cooker it is first rate. Its proper season is October and November, but it will keep until the end of the year in good condition; after this it begins to deteriorate. The accompanying illustration conveys a good idea as to the shape of the fruit and its cropping, and will, perhaps, enable intending planters to form an opinion of their own on the subject if they have been at all in doubt about including Cellini in their list of sorts that are to be planted this forthcoming autumn.

Stoke Edith, Hereford.

A. WARD.

Apple Cellini. From a photograph sent by Mr. J. Eddie, Freefield Gardens, Insh, Aberdeen.

last autumn. Not only was there a failure of the plants treated as "Rambler" advises, but the older plants likewise failed, so that it was the worst season I have had for many years. There is no loss by growing young plants; indeed, there is a great gain. In many gardens one often sees patchy beds. The young plants give a heavier weight of fruit per acre, at least fruit that commands a better price, owing to its quality, and fewer fruits fill the basket. The variety to grow is a question of soil and culture. Of course, I would not advise such slow growers as Latest of All, Waterloo, or some of the Pine family, some of which make later growth, the runners are less strong, and do not grow away so freely. With what may be termed annual culture there must be strong, early runners. I fear "Rambler's" indictment as to the poor material supplied when young plants are purchased is near the mark. Plants sent at the end of August or even early in September are useless for the next season if heavy crops of fruit are needed. This year all my young

Plum The Czar.—Owing no doubt to the great heat of the past few weeks this Plum has ripened abreast of Early Prolific this season. As a rule it is generally a week or ten days later, and therefore forms a good succession to the variety just noted. However, it is a good sort to hang after it is ripe, and provided birds and insects can be kept from attacking the fruits, the fact of their maturing somewhat earlier than usual will make no material difference in my case. From a market point of view this earlier ripening will be an advantage, as I think from what I have both seen and heard that the crop of Early Prolific is rather a short one, while the reverse is the case with regard to Czar. It is a fine looking Plum and larger than Early Prolific, while its cropping leaves nothing to be desired. The tree is a hardy vigorous grower. It may be grown either as a standard, bush or cordon, and is a first rate sort

to grow either for private or market gardens.—A. W.

Strawberries Dr. Hogg and British Queen.—At p. 75 Mr. Crawford asks why we do not grow the above varieties equal to those grown many years ago. I fear in many cases quantity is preferred to quality, as they are not such heavy croppers as, for instance, Royal Sovereign. Another point is that British Queen will not thrive in all soils. I am aware this objection may be met by making the soil suitable for the Strawberry, but it cannot always be done at the time of planting, and growers have to fall back on those kinds that are prolific, and when great quantities are needed, no one can do otherwise with a deficiency of labour. It may be said that this is a step backward, but I am sure Mr. Crawford understands the difficulties of the situation. By all means grow the best kinds if it can be done.—G. WYTHES.

Strawberry Macmahon.—It is strange how fruits differ in diverse localities. I find the above variety poor in quality and somewhat soft if needed to be sent any distance. When I was living in the eastern counties Macmahon was looked upon as the best, and it bore enormous crops. In the south it does not crop so freely, and I have not the high opinion of it that I once had. I have this season seen a good breadth of it in the north, and doubtless "W. O." may have a similar soil and sufficient moisture. In the south this has been the worst season for many years, no matter what the variety. Of course, in such a season it is not fair to condemn any kind. Macmahon is not often catalogued in the south. I find Aberdeen Favourite a much better kind, and though late, it does grandly in a light soil. Doubtless there was much more moisture last season in the district "W. O." writes from, this building up the crowns for this season's crop.—G. W. S.

COLOURING GRAPES.

I READ with great interest the notes on "Current Topics" by "Rambler" on p. 69, but I think he has misread me when he considers my advice to "slightly increase the air when colouring commences" to be not satisfactory. All practical growers must be aware that the life-giving air is necessary at all times, and my argument, plainly expressed, was against the principle of throwing the house widely open as soon as the berries begin to colour. It is not the amount of air that does the harm; it is the upsetting of a proper balance of air and moisture which is bound to occur when the air is suddenly changed. This leads, as I there said, to cracking of the skins of tender varieties, and anyone who has grown say Foster's Seedling or Madresfield Court in company with Black Hamburgh knows how difficult it is, on the one hand, to give sufficient air for the latter without at the same time damaging the former. My note was not written without due consideration, and I may mention that in the house where I have grown my early Grapes this year cracking of Foster's Seedling began simultaneously with the increased air at the commencement of colouring—not badly, for the bunches were still good enough to win first place in strong competition, but enough to warn any careful grower to be on his guard.

It is difficult to know what "Rambler" means in regard to thinning. He does not think that thinning at the time the berries are the size of small Peas relieves the Vines. Perhaps not, but they are certainly not needed, for, as he is careful to point out, lateral growth at that stage is very free, and sap elaboration is amply provided for by the daily increasing number of young leaves. Again, he points out that if the colouring agents are not there by stoning time and the Vines are then overcropped, "these

agents are sure to be deficient." When then must we thin? The more I have to do with fruit culture the more I am impressed with the fact that the earlier the trees—be they Vines, Peach trees, bush fruits or what not—are divested of fruit not required, the less risk there is of damage to that left and the better for the trees. I cannot claim to be versed in physiology, but that which I find leads to good results in culture I practise as far as possible, and can only advise others to do the same. I thoroughly agree with the pithy and concise remarks by "Rambler," and would like to see more of them in THE GARDEN. H. R.

Gooseberry Pitmaston Greengage.—This is, I think, the richest flavoured of all Gooseberries, at least I find the fruits of this variety to be so much appreciated here for the dessert, that no other sorts meet with any favour so long as they are to be had. The fruits are but small I must admit, but this is no serious drawback, if any, as they are quite large enough for dessert. When fully ripe the berries are pale or greenish yellow, semi-transparent, and roundish in shape, and they hang a long time after arriving at maturity. The skins are tender and break easily, the pulp being juicy, sugary and richly flavoured. It is a strong growing sort, the bushes make plenty of wood, and they bear most abundantly. I grow a good many bushes of it, and would advise all who have to send quantities of Gooseberries to their employer's table daily for the dessert to give the above variety a trial.—A. W.

A moist root-run for Black Currants.—An old gardener once said to me that, were he planting Black Currants for profit, he would, if possible, choose a somewhat low-lying situation close to a rivulet or marshes. He further added he would have two sets of trees, cutting one clean down one year and the other the next, such was his faith in young wood for producing heavy crops of fine fruit. I was reminded of his words recently by seeing, I think, the finest lot of Black Currant trees I have ever seen. They were growing in the garden of a farmhouse in Norfolk, the position a low-lying one and not many yards from a narrow river. Moreover, the top soil, which was by no means deep, rested on a subsoil of white marl, with which this part of Norfolk abounds. No doubt the Currant tree roots had gone down into this cool moisture-retaining substance, which seemed to suit them. The crops these trees yielded in average seasons, or when late spring frosts do not cripple growth, are astonishing, the fruit being extra large and of grand quality. The farmer, however, admitted that owing to the low, moist position late frosts did occasionally work mischief with the crop, and that is just what I thought might occur when a similar site was recommended by the old gardener already referred to. I impressed upon my farming friend that he would reap still greater and richer harvests of fruit if he would get out of the old groove and use the pruning-knife more freely, letting in sunlight and air, especially keeping the centres of the trees open. When, however, trees have been permitted to grow for years with but little pruning, the reduction of the wood must be gradual. The right way is to moderate growth from the tree's earliest days.—J. C.

Canker in Melons.—Among the several causes responsible for canker in Melons I should put a rank root-run, coupled with insufficient room to enable the plants to go well away, as decidedly the most to blame. There is very little head-room in the pits in which my Melons are grown—only sufficient to enable them to get a length of 42 inches from the collar of the plant, and, as a consequence, considerable curtailment is necessary to keep them within bounds. No bottom-heat in the shape of hot-water pipes is available, and so to procure this a bed of manure has to be made up. For some seasons I made mounds of earth on this bed of manure and

planted the Melons thereon. The result was not altogether satisfactory, as the plants rooted into the manure before the fruit was sufficiently large to check the growth. Very rank growth followed, and the curtailment of the same was invariably the prelude to canker, this being, I take it, the result of the inability of the plant under restriction to assimilate the ingredients taken in from the manure. This was the theory, and I resolved this year to put it in practice with the view of keeping the roots within bounds rather than allowing them to stray into the half-decomposed manure. So the pit was filled as usual with a well-worked heating material of leaves and manure, and as the work progressed a large pot (inverted) used in Rhubarb forcing was inserted in the centre of each light. Clinkers, with coal ashes over the same, were put in the bottom and rammed fairly tight, the pot afterwards being filled up to within an inch of the brim with soil. I am glad to say that the experiment has proved an unqualified success in the prevention of canker, and now that two crops are over and cleared away I find on an examination of the bottom of the pots that the roots were only just appearing through the clinkers. Naturally this mode of cultivation necessitated a considerable amount of artificial feeding from the time the fruit attained a fair size until the ripening stage. I adhered to my old favourites Blenheim and Gunton Orange, with the addition of Gunton Scarlet, obtained through the courtesy of Mr. Allen, the raiser. It is a very fine Melon.—E. BURRELL, *Claremont.*

PÉACH AMSDEN JUNE ON OPEN WALLS.

MR. WYTHES'S notes on early Peaches on open walls at p. 74 will have been read with interest, more particularly so, as without doubt open-air culture is again receiving a considerable share of attention. My opinion is that if gardeners would only deal with the trees in the nick of time in spring, so as to prevent aphid from gaining a footing, the chief barrier to success would be removed. I know one gardener as far north as Retford who grows Peaches on walls with no other protection than that afforded by a narrow glass coping, and yet his trees are the picture of health and produce fruit of high excellence. Aphid is not allowed a moment's grace in spring, as he contends that if once the terminal leaves become curled it takes a whole season for the tree to recover. Mr. Wythes mentions the three American varieties, Amsden June, Waterloo, and Alexander. I can recommend the first as a hardy, sure, and free-cropping outdoor Peach for first early supplies. On a south wall in a midland garden I grew it in company with Hale's Early. Amsden June never failed me, the fruit being large, rather flattened in shape, with a slight furrow. The colour was a black-red, and the flavour, if the fruit was eaten in time, good. I found it necessary to pick them directly they would part from the tree by the use of a little force. If left on until they dropped or left the wood with the least touch they soon turned mealy. If this last point is observed, Amsden June may safely be planted by those who have failed with Alexander and Waterloo. Indoors, if forced gently, this early Peach succeeds well, but it will not stand high pressure until stoned. Like Mr. Wythes, I found it a somewhat weakly grower, but nearly every bloom set, and, what is more, the fruit did not fall. C. N.

Grape Lady Hastings.—I was pleased to read that a first-class certificate had been awarded to the new Grape Lady Hastings. When at Melton several years ago I saw Vines of it in a bearing state and tasted several berries. I thought them delicious: indeed, after tasting both Lady Hastings and Muscat Hamburgh I pronounced the former the better. This is saying a good deal. The Vine is a good grower with luxuriant foliage, and the bunches, which are of good size, colour beautifully, having that Damson hue which all Grape growers like to see. It is particularly gratifying to know that this new Grape belongs

to the Muscat section, as additions of this kind have been few and far between of late years, the majority of the new Grapes having been of a somewhat coarse, thick-skinned nature. Quality is what is mainly wanted, and this in the highest degree is characteristic of Lady Hastings.—J. CRAWFORD.

GRAPE GROS GUILLAUME.

THAT is an interesting note (p. 67) on the above-named Grape. I have sometimes been surprised to see this Grape described as coarse and ill-flavoured. No doubt this description is true when the crop is brought on in too low a temperature and ripens foxy, but when treated to sufficient warmth and well coloured it is, I maintain, quite equal to Lady Downe's, as stated in the note referred to. Gros Guillaume is one of the few Grapes which improve by hanging in the fruit room after being bottled, and I have had it in January more like the Hamburg in flavour than anything else, although best when ripened in August or early in September. It must not be thought that it will do with little or no heat. A maximum amount of heat, with abundance of fresh air, is what is wanted to do this fine Grape justice. A friend of mine near Epping grew the finest crops of Gros Guillaume I ever saw. Beneath that portion of the border in which the Vine grew ran the hot-water pipes. This was compulsory, and the gardener feared failure in consequence, but, strange to say, that particular Vine outstripped all the others both as regards vigour and fruitfulness. If Gros Guillaume is planted in a rich border, growth is liable to be gross and bunches few, these being long, loose, and ill-furnished. On the other hand, given a rather poor root-run, growth is moderate, firm, and productive, bunches being borne on nearly every lateral, their size also being such as can be appreciated at table. Some little care is needed to secure a perfect set of berries, and in order that the bunches may be plump, the shoulders must not be thinned too much. N. N.

Pear Doyenne d'Ete.—For very early use, before the choicer kinds come in, this is one of the best and far superior in point of flavour and keeping to others in the early section. I saw some fine little trees of it recently covered with the pretty bright fruits, which are certainly very sweet. It does not possess the failing common to many early kinds of decaying at the core almost before it is properly ripe. With a view to hastening it, some growers give it the protection of a wall, but, unless very well fed, the fruit is smaller and inferior in quality to that grown in the open.—GROWER.

Bush Morello Cherry trees.—These have borne heavy crops of fruit this season, the produce being of fine size and exceedingly juicy. Of course, the fruits on such trees ripen in advance of those grown on north and east walls, but are none the less welcome on that account, as they come in extremely useful for cooking after the Kentish Cherries are over. It is astonishing the great quantity of fruit bush trees are capable of producing if they are only kept well up to their work by judiciously feeding the roots from the surface. If this is not done they soon exhaust themselves unless the natural soil is very fertile in itself. If worked on the Mahaleb stock and planted from 6 feet to 9 feet apart, bush trees will, in the course of from two to three seasons, form quite a hedge, and will for years produce great quantities of fruit if given an annual mulching of partly decayed manure.—A. W.

Plum Dymond.—Although this is a very large and most useful cooking Plum, we do not hear about it so often as we might expect. Perhaps the fact of its being rather tender in the bloom has caused planters to fight shy of it. Like the majority of Plums, it is prone to make rank growth if planted in a rich, deep larder, barrenness for a number of years resulting. I should choose for it a soil rather poor than otherwise, attention being paid to surface mulching during the hot summer months. It then bears freely and

continues to do so annually. In the midlands Dymond is a favourite both amongst farmers and cottagers. The finest fruit I have grown has been from a tree on a due south wall. Here, if the tree is well nourished, the fruit swells to a great size and lays on a bloom of great depth and beauty. All who have room should plant at least one tree of Dymond. It makes a delicious preserve.—N.

ROSE GARDEN.

ROSES IN NEW ZEALAND.

I HAD hoped to be able to send you some photographs of New Zealand flora, but, although I have made several attempts, the wind, which is the photographer's pest here, has made the subjects but counterfeit presentments of their proper selves. I send you one of the failures, showing Manuka, Flax, and Cabbage Tree. The Manuka has flowered in great profusion this summer. The hillsides have been white

and where button-hole bouquets are in request it is worth growing for this purpose alone, besides which it makes a very pretty bush in the garden. The plant is of a clean habit of growth and throws up large handsome clusters of flowers that are bouquets in themselves, and very fine for filling large vases or bowls about the house. It is one of the very few Roses that look well arranged with Maiden-hair or other Fern in lieu of its own foliage.

Rose Marie d'Orleans.—During the months of August, September, and October, and even if mild until Christmas, this beautiful Rose never fails to produce quantities of its charming flowers. Just now when many kinds appear scorched up this variety is very fine. If ever the Tea Roses are sub-divided into groups according to their vigour (and it would seem to be necessary for a proper arrangement when planting), then Marie d'Orleans will rank as one of the most sturdy non-climbing kinds. As to hardiness, it is equal to any Hybrid Perpetual, and as a garden Rose it stands unrivalled among the coloured Roses. Unlike some of these, it is not a great success

Roses Solfaterre and Climbing Devoniensis in a New Zealand garden. From a photograph sent by Mr. J. D. Crooke, Lawrence, Otago, New Zealand.

with it. Most of the hardy kinds of flowers do well in this district. The soil and climate seem to suit bulbs admirably, especially Narcissi, Hyacinths, Gladioli, Anemones, and Ranunculuses; Roses and Asters also do well. The Rose season is from the middle of November to the middle of May. How one cherishes the May Roses! The view sent shows a Climbing Devoniensis and a Solfaterre in my garden.

I fancy that birds sing longer here than in England. On June 26, 1898, a thrush began to sing at daybreak from the top of a Deodar in my garden, and sang from that same spot every morning, starting at daybreak, no matter what the weather was like, continuing for an hour or more each morning; and he kept this practice up until July 31. White, in his "Naturalist's Calendar," mentions January 6 as the earliest date at which the song thrush sang with him.

J. D. CROOKE.

Lawrence, Otago, New Zealand.

Rose Mme. de Watteville.—There are few prettier Roses when in the bud stage than this,

under glass, the colour then being rather dull, but outdoors as hush or standard or on a low wall the charming tints of rosy crimson and salmon-pink, together with the pointed and reflexed petals, make it a most attractive variety. When planting, a space of 2 feet each way should be allowed, even more if it can be spared. Do not attempt to prune it. Retain plenty of the new wood, thin out some of the growths more than two years old, and a fine healthy plant will be the result. It is far better to have a good-sized specimen plant of this Rose than a collection of pretty Roses that will not grow well without a lot of coddling.

Rose Souvenir de Mme. Joseph Metral (Tea-scented).—It is possible that the cumbersome name is partly responsible for this Rose remaining in obscurity. I wonder exhibitors have not made good use of it ere now, for really the blossoms are quite up to their standard of perfection. The flower is so heavy and so double that the stem is too weak to support the bloom. The colour is pleasing; just that soft rosy cerise tint that is far too rare among Roses. Bush plants flower freely at the ends of the long shoots. I believe many of these extra vigorous Rose

known as climbers would give much more satisfaction if grown as bushes about 4 feet or 5 feet apart than they do when placed close to a south wall. I have this season a quantity of *Maréchal Niel* plants growing as bushes, and they are now flowering grandly. At first sight one cannot see a bloom, but a search among the foliage will reveal some beautiful golden-yellow flowers, perhaps not so rich in colour as we obtain in spring under glass, but quite good enough for ordinary use. Gardeners would find this and other Roses such as *l'Idéal*, *Belle Lyonnaise*, *Mme. Moreau*, *Kaiserin Friedrich*, *Dr. Rouges*, *W. A. Richardson*, *Mme. Pierre Cochet*, *Germaine Trochon*, and even the old *Gloire de Dijon* very useful if grown as stated. Where the flower garden is too small, a row or so of each variety across the kitchen garden, planted upon land recently trenched and in good condition, would yield abundance of flowers, and as they come in when the other Roses are waning their value is obvious. Doubtless more bloom would be obtained if the growths were pegged down or left alone, but I believe the best plan is to prune the shoots each year to within about 2 feet of the ground, then the quality of the bloom is well maintained. As the bushes increase in size some of the older growths may be entirely removed, endeavouring as far as possible to retain none more than two years old.—*PHILOMEL.*

ROSES UNDER GLASS.

NOTHING is so charming as fine flowers of Roses in early spring, and yet one may go into scores of gardens without seeing a single plant under glass unless it is an insect-infested old roof plant that is hardly looked at except to cut a few flowers when they appear. There are not many gardeners, unfortunately, who can afford a house for Roses only, and their only chance is either to grow a few pot plants with other things in a greenhouse, or else to grow climbing kinds on the roof of a conservatory. Neither plan is really satisfactory, but the latter is preferable, for not only do Roses in pots do badly in company with other greenhouse plants, but they never look so nice as when growing alone. On the roof or side lights one may grow any of the stronger Teas as climbers and excellent results may be obtained; or a few plants may be forwarded in early fruit houses, such as vineries or Peach houses, the gradual increase of temperature practised for the fruit suiting the Roses also, though great care will be necessary with the ventilation to avoid mildew and insects. Where a small span-roofed house can be spared for their culture it will prove most interesting in spring. The roof should not be heavily covered with climbing kinds, but a few will do no harm. *Maréchal Niel* is usually looked on as the best climbing Rose under glass; perhaps it is, but we do not want all *Maréchal Niel*. and such lovely kinds as *Catherine Mermet*, with its large and beautifully tinted blossoms, or the charming small flowers of such kinds as *Isabella Sprunt*, *Mme. Guinoisseau*, or even *Mme. Lambard* ought not to be forgotten. *Niphotos* again and *l'Idéal* are two eminently suitable kinds, and more than as many again could be named equally worthy. Any of these kinds that are not to be represented on the roof should be grown in pots, and as it is a well-known fact that many Teas do remarkably well on standard stems, a few of these should be included. Trained a little they have a better appearance than when allowed to grow wild, but tight training spoils their beauty and should be avoided. The time of year is rapidly approaching when it will be safe to lift plants from the open for potting up. By the middle of September have all in readiness for the purpose—some compost consisting of good fibrous loam and partially decayed cow manure, with some lumps of limestone, charcoal or some hard substance to prevent it running closely together and becoming sour. A good sprinkling of coarse drift sand is also a help in this direction. Lift the plants carefully and pot firmly, using a blunt potting stick, and after all are potted, stand in a sheltered and rather shady

place for a few days, sprinkling them overhead twice daily in fine weather as long as the leaves keep on. They should be well established and may go under glass by the middle of November, and a little pruning may be necessary. The amount of this will vary according to the kind of Rose grown. Hybrid Perpetuals and Hybrid Teas may be cut fairly hard back, and, when starting, disbudded to what seems the requisite number of shoots, according to the strength of the plant. Teas, on the other hand, need only be cut into good firm wood and the small spray entirely cut out. A thorough fumigation may be given before the plants are started, the house thoroughly cleaned, and a low temperature kept up at first with plenty of air. The routine treatment is simplicity itself, and the Teas will go on flowering more or less until the outdoor Roses are plentiful. Then—say the middle of July—the plants may be thoroughly cleaned and re-potted, cut back a little and put into shape for their season's growth. They will flower strongly and well for a number of years.

Roses on pillars and arches.—I would like to thank "Philomel" for his courteous and instructive reply to my note on this subject. I did not wish to decry *Crimson Rambler* on account of its habit of pushing strong shoots at the base, but simply to point out that this class is not quite suitable for the object I had in view. *Crimson Rambler* has been remarkably fine this year, and very beautiful are the great masses of brilliant blossoms, but I want something that will climb posts 10 feet high and run along a trellis another 10 feet or more without the thickening out at the bottom I spoke of.—*H. R.*

Pillar Roses.—Will anyone give me the names of six pillar Roses of any class that will bloom freely in autumn; also the names of three light crimson and three very dark H.P. Roses for bedding which are free autumn bloomers?—*B.*

* * * We think you will find the following first-rate for late-flowering: *Longworth Rambler*, *Kaiserin Friedrich*, *Mme. Marie Lavallée*, *Mme. Georges Bruant*, *Gruss au Topfütz*, *Ulrich Bruner*, and the following for bedding at that season: *Light crimson*: *Alfred Colomb*, *Duke of Albany*, *Dupuy Jamain*. *Very dark*: *Xavier Olibo*, *Charles Lefebvre*, and *Victor Hugo*.—*Ed.*

A beautiful climber.—A rambling variety with exquisitely shaped flowers each 3 inches to 4 inches in diameter, very double, and of the charming tint of *Comtesse de Nadailac* would well describe that very fine Rose *E. Veyrat Hermanos*. It is not much known, for it is rarely if ever exhibited, being rather late. This partly accounts for so many of the delightful climbing Teas and *Noisettes* remaining in partial obscurity. Perhaps wall space is limited and what there is is already occupied, but one can resort to standards for this class of Rose. Worked on tall stems, say from 3½ feet to 4 feet in height, they form grand heads, and in the case of the variety under notice the pendulous shoots produce fine blossoms at the extreme end and often some distance up the growth.

Rose Souvenir de Therese Levet.—This is a useful variety for cutting. Its pretty brownish-crimson buds have a very telling effect in a bouquet, especially when interspersed among a variety like *Maréchal Niel*. It is sometimes seen in exhibition boxes, for it may, by severely thinning the shoots and buds, be had of a good size. The average blooms upon plants not thinned are very little larger than *China* Roses, although of much more beautiful shape and of course very double. *Souvenir de Thérèse Levet* is a very free bloomer. Just now upon standards there are large numbers appearing. It was when introduced some seventeen years ago called the *Red Niphotos*, and in the bud state it has a certain resemblance to that fine old kind, but the flowers are certainly not so deep in petal. It is a pure Tea with all the slender wiry growth that distinguishes this tribe from Hybrid Teas. For forcing it is very good, but not so useful as *Papa*

Gontier, though of richer colour, and perhaps *Francis Dubrioul* is superior in size. The flowers of the last unfortunately droop.

Roses in July.—Although, perhaps, the finest Rose blooms could have been cut towards the end of June, the bushes were loaded with fair flowers and buds in the early days of July. Hybrid Perpetuals, Teas, Hybrid Teas, and *Chinas* vied with each other for precedence, and, lovely as are the blossoms of all sections, the Hybrid Tea *Viscountess Folkestone* still bears the palm for exquisite beauty, the shell-pink petals of a half-expanded flower seeming to admit of no nearer approach to perfection. *La France* has borne some charming flowers, but the silvery pink blooms of *Caroline Testout* have been even more delightful. Adjectives are soon used up in writing of these fair blossoms, and as one studies them they all appear to merit superlatives; at least this is the case with *Souvenir de Catherine Guillot*, *Augustine Guinoisseau*, *G. Nabonnand*, and *Archduchess Marie Immaculata*, Roses whose delicate gradations of colouring catalogue descriptions entirely fail to suggest. The large semi-double white, or almost white, Hybrid Tea *Mme. Pernet-Ducher* is a most attractive garden Rose, while the velvety crimson *Princesse de Sagan*, the deliciously scented *Socrates*, the glowing crimson single *Bardou Job*, and the *China* Roses *Irene Watts*, *Laurette Messimy*, and *Queen Mab*, flowers in which shades of rose, pink, salmon, bronze, orange, apricot, chrome, and sulphur are indescribably blended in varied proportions, are all of undoubted excellence. The white *Mme. Plantier* is a Rose not often met with now-a-days, but a standard 5 feet in diameter in full bloom has a striking effect. The single white *Macartney* Rose commenced to flower during the third week in July, and will now continue to produce its golden centred blooms, with their faint ripe-pear perfume, without intermission until October or November, so that, though it is late in coming into flower, it fully atones for that disadvantage by the lengthened period during which it produces its blossoms. The single whites *R. moschata nivea* and *R. m. nepalensis* have also been in flower.—*S. W. F., Torquay.*

BOOKS.

THE SOLITARY SUMMER.*

AFTER the lapse of a few months the authoress of "Elizabeth and her German Garden" has published another little volume, dealing with the same garden and its surroundings and written in the same fresh and spontaneous style. The solitary summer was spent in the many-gabled house set within the confines of the picturesque German pleasaunce, and although, according to the writer, the seclusion, as far as the anticipated growth of soul was concerned, was a failure, that it afforded scope for an appreciative study of Nature the pages abundantly testify.

When "Elizabeth," for thus the authoress elects to be known to her readers, first introduced the public to her garden, she was struggling, and in the main successfully, to direct the doings of an incompetent gardener, but three years' untiring supervision proved too much for even her equanimity of temperament, and we accordingly now find the garden under the charge of an efficient head, supported by an adequate staff of helpers. This, from the flower-loving reader's point of view, is perhaps to be regretted, since there is less concerning the garden proper than was the case when the writer had to rely on her own unaided discretion, and many questions one would like to ask remain unanswered. As regards Roses, we hear nothing of *Laurette Messimy* or *Viscountess Folkestone*, or whether *Dr. Grill* eventually became established. The contemplated yellow border with its background of Pines is not alluded to, nor are we told if the *Primroses* ever became naturalised, while the *Bird*

* "The Solitary Summer." London: Macmillan and Co.

Cherries, that were such a feature in the opening pages of the former book, are unmentioned. There is, however, much to charm the lover of Nature, and not a few delicately-limned garden-pictures are presented to the reader's view. The following description of the evening of May Day is particularly felicitous:—

The sky was full of stars and the garden of scents and the borders of Wallflowers and sweet, shy Pansies. All day there had been a breeze, and all day slow masses of white clouds had been sailing across the blue. Now it was so still, so motionless, so breathless, that it seemed as though a quiet hand had been laid on the garden, soothing and hushing it into silence. The flowers shone in the twilight like pale stars and the air was full of fragrance, and I envied the bats fluttering through such a bath of scent with the real stars above them and the Pansy stars beneath.

Elizabeth's idea of a garden is that it should be beautiful from end to end, and in the one of which she writes the endeavour has been made, and evidently with the best results, from the many peeps we are allowed at its charms, to make it "increase in loveliness, if not in tidiness," the further it recedes from the house until its boundary is reached, where, by the Silver Birch plantation, the Azaleas spread their blaze of colour in the early summer. The sentence "In a garden Nature ought to come first, and Art with her brooms and clipping-shears follow humbly behind," is one that will commend itself to all lovers of the informal in the flower garden, and one can enter into the writer's feelings when she prefers the blue Hepaticas overflowing the shrubberies and the Anemones twinkling in the spring like stars in all the corners to the faultlessly trim and scrupulously correct attractions of the conventional garden. The account of the chosen plot of fertile land of irregular breadth with its wealth of hardy flowers conveys the idea of a delightful mixed border, for here are the chaste Madonna Lilies, the tall blue spires of Delphiniums, towering Hollyhocks of tenderest pink, Irises, Carnations, Evening Primroses, glowing Oriental Poppies, and white Lupines, while in the dampest corner, hard by a trickling streamlet, the lovely Japanese Irises hold aloft their spreading falls. The surface of the ground is covered with Mignonette, Stocks, Pansies, white Pinks, and many other flowers, and groups of Sweet Peas, the writer's favourite flowers after Roses, provide a suave colour-harmony. We are told of the Tea Roses with their undergrowth of Pansies, and of the Tulip beds surfaced with Forget-me-not, of the masses of China Roses and groups of Foxgloves, and of the spring garden in the glade round the old Oak, alluded to in the former volume, with the double white Cherries and Japanese Crabs, and with the surrounding sward filled with Narcissi and Tulips that have taken the place of the purple Crocuses. The garden is rich in Lilacs, white, purple, pink, and mauve, planted in far-off years by a former owner, whose memory is ever kept green in Elizabeth's heart by the living beauty that appears with each succeeding spring, and which leads her to wish to substitute for the lengthy Latin platitudes that face this benefactor's monument the simple epitaph, "He was a good man, for he loved his garden."

The aspect of the September garden in the golden autumn weather, when its mistress is prevented, by the presence of thirty officers who are quartered in the house during manœuvres, from paying it her accustomed visit, is feelingly suggested.

I know how the placid hours are slipping by in uncharmed peace, how strong the scent of the Roses and the ripe fruit is, how the sleepy bees drone round the flowers, how still it is down there in my Fir wood, where the insects hum undisturbed in the warm, quiet air; I know what the plain looks like from under the Oak, how beautiful, with its rolling green waves burning to gold under the afternoon sky, how the hawks circle over it and the larks sing above it.

Perhaps, however, the most sympathetic touch is given in the portrayal of a mid-June dawn.

Yesterday morning I got up at three o'clock and passed out into a wonderful unknown world. It was

quite light, yet a bright moon hung in the cloudless grey-blue sky. The flowers were all awake, saturating the air with scent, and a nightingale sang on a Hornbeam quite close to me in loud raptures at the coming of the sun. There in front of me was the sundial, there were the Rose bushes, but how strange and unfamiliar it all looked and how hush. I went down the path leading to the stream, brushing aside the Rockets that were bending across it drowsy with dew, the Larkspurs on either side of me rearing their spikes of heavenly blue against the steely blue of the sky, and the huge Poppies like splashes of blood amongst the greys and blues and pearly whites of the innocent, new-born day. On the garden side of the stream there is a long row of Silver Birches, and on the other a Rye field reaching across in powdery grey waves to the part of the sky where a solemn glow was already burning. There were no clouds, and presently, while I watched, the sun came up quickly out of the Rye, a great, bare, red ball, and the grey of the field turned yellow and long shadows lay along the grass, and the wet flowers flashed out diamonds. What a smell of freshly-mown grass there was, and how the little heaps, into which it had been raked the evening before, sparkled with dewdrops as the sun caught them, and over there how hot the Poppies were already beginning to look—blazing back boldly in the face of the sun, flashing back fire for fire. Then I went down to the Fir wood at the bottom of the garden, where the light was streaming through green stems, and everywhere was the same mystery and emptiness and wonder. Now here I have had an experience that I shall not soon forget—a feeling as though I had taken the world by surprise and seen it as it really is when off its guard—as though I had been quite near to the very core of things.

A vivid picture is drawn of the gorgeous display afforded in the month of August by the yellow Lupines that clothe the surrounding hills with gold and at sunset are dazzling in their splendour, and the writer's love of and sympathy with Nature is exemplified in many passages. Talking of the delights that await the receptive mind capable of reading and understanding the Earth mother's secrets, she says:—

I am sorry for all the people in the world who miss such keen pleasure. It is one that each person who opens his eyes and heart may have. Anyone who chooses to take a country walk may have them, and there are thousands thrust upon us by Nature, who is for ever giving and blessing at every turn as we walk. The sight of the first pale flowers starring the copses; an Anemone held up against the blue sky with the sun shining through it towards you; the first fall of snow in autumn, the first thaw of snow in spring; the blustering, busy winds blowing the winter away and scurrying the dead, untidy leaves into the corners; the hot smell of the Pines when the sun is on them; the first February evening that is fine enough to show how the days are lengthening, with its pale yellow strip of sky behind the black trees whose branches are pearly with rain-drops; the swift pang of realisation that winter is gone and the spring is coming; the smell of the young Larches a few weeks later; the bunch of Cowslips . . .

Elizabeth loves books, and we are permitted to glance at the contents of the shelves that hold her especial favourites. All gardening books and books about gardens of recent publication are there, and "are an unfailing delight," while the wider aspects of Nature have Thoreau, White's *Selborne*, and Izak Walton for interpreters. In this category one is surprised and almost pained to miss the name of Richard Jefferies, the man who, to reproduce the appreciative and truthful epitaph inscribed upon the pedestal of his marble bust in Salisbury Cathedral, "Observing the work of Almighty God with a poet's eye, has enriched the literature of his country and won for himself a place amongst those who have made men happier and wiser"—the man whose touching "Eulogy" was written by Sir Walter Besant, and who, to quote another writer, was "no mere artist in literary expression, but a prose poet singing in the great temple of Nature."

Elizabeth professes herself enamoured of the charms of poverty, and in one paragraph avers that if she were poor she would content herself with "a piece of bread, a pot of Geranium and a book," and if the weather was fine enough for her to consume her repast under a tree and she could give a robin some crumbs, there would

be "no creature in the world so happy," while in another she descants on the delights appertaining to the occupation of goose-tending, and, imagining herself filling the rôle of goose-girl, declares

For six months of the year I would be happier than any queen I ever heard of. I would begin in April with the King-cups and leave off in September with the Blackberries, and I would keep one eye on the geese and one on the volume of Wordsworth I should have with me, and I would be present this way at the procession of the months, the first three all white and yellow and the last three gorgeous with the Lupine fields and the blues and purples and crimson that clothe the hedges and ditches in a wonderful variety of shades and dye the grass near the water in great patches.

Musing on the attractions of a penury that can never be experienced is a harmless and fascinating conceit, and doubtless Elizabeth herself is fully alive to the fact that in this case, as in many others, "distance lends enchantment to the view." Ability to see the emotional side of things does not blind her to the practical, for did she not remark in a moment of candour in her earlier volume, "It is so sweet to be sad when there is nothing to be sad about." S. W. F.

SOCIETIES AND EXHIBITIONS.

"ONE AND ALL" FLOWER SHOW.

THIS extensive exhibition, which forms an important part of a great co-operative festival, took place at the Crystal Palace, Sydenham, on August 18 and 19. Horticulture played a somewhat prominent part all the week, for, commencing with Monday the 14th, lectures were delivered daily by Messrs. T. W. Sanders, George Gordon, D. T. Fish, Richard Dean, and W. Iggulden on some aspects of popular gardening, and in addition there was a somewhat extensive exhibition of photographs relating to the garden, and prizes were awarded in several instances to these.

The first two co-operative flower shows were held in the conservatory of the Royal Horticultural Society in 1888 and 1889, and the first exhibitors, drawn mainly from working men in different parts of the country, had at the outset somewhat imperfect notions of what constituted quality in flowers, vegetables, and plants. But they were quick to note the preferences of the judges as shown by their awards, and on the first occasion of the exhibition being held at the Crystal Palace in 1890 a considerable increase in quality was observed, and now with but few exceptions the level of quality is so generally good that keen competition ensues. New exhibitors are constantly being attracted, and though some may have hazy notions of quality in vegetables they are furnished with a series of instructive object-lessons of a valuable character. Despite the generally hot, dry character of the summer the entries, which in 1898 amounted to 4138, this year rose to 4703, constituting the largest show yet held. Only one half of the nave was available, but lines of tables had to be placed in side walks. Altogether it is computed a mile of tabling was set up.

The schedule of prizes contained some 300 classes, and is divided into two competitions, one on Friday when the competitors are members and customers of the Agricultural and Horticultural Association, or their gardeners and employés. This being so, a somewhat higher quality in some of the leading produce can be perceived because grown under glass. Collections of vegetables are invited from four different districts. Salop sent some good produce, and so did Oxford; one individual in particular named J. Holton being particularly successful. Runner Beans were very fine, the varieties known as Oxonian and Ne Plus Ultra were to the fore; a dish of the former from J. Holton seemed to suggest the highest possibilities in this popular Bean. Canadian Wonder in good character was the leading dwarf variety. Longpod and Broad Windsor Beans were, owing to the drought, past their best, and the long Beet

was wanting in shape, but the Turnip-rooted type was seen to good advantage. Cabbages, red and white, were few and sunburnt, but Carrots of the Intermediate type were long and shapely, J. Holton again coming to the fore with handsome roots. Cauliflowers were scarce, Celery, red and white, was of fine quality. There was plenty of Cucumbers, frame and ridge. Collections of herbs were good and varied; Lettuce poor owing to the heat. Onions were good, but there can be seen a tendency on the part of some exhibitors to evade the schedule by staging types which are not admissible in certain classes. Some very fine Tripoli Onions were exhibited, and Ailsa Craig and Improved Wroxton were of large size. Parsnips in a few instances were very fine, but the majority, probably owing to the drought, lacked symmetry. Peas were largely represented by Autocrat, which is a valuable late variety. Potatoes were generally clean and bright. Satisfaction, Windsor Castle, &c., were the best rounds; in the white kidney classes, International Kidney, Snowdrop, and Up-to-date were the best; coloured kidneys were represented by Lord Raglan, Mr. Bresee, and Reading Ruby; coloured rounds by Lord Tennyson, Reading Russet, and Vicar of Laleham. In the way of salading there were collections, also Radishes, Shallots, &c. Vegetable Marrows were in plenty, both white and green, though many of them too old. Turnips were somewhat poor and tough. Tomatoes in some instances were very fine.

Bunches of annuals were very showy; the favourites are Helichrysum, Lavatera, Mignonne, Zinnias, Phlox Drummondii, Asters, Stocks, Sweet Peas, Scabions, Lupines, Coreopsis, Larkspur, &c. It seems necessary for judges to allow a little latitude in this respect, especially in the case of the working-men exhibitors, as they appear to be under the impression that Snapdragons, Petunias, and such like biennials and perennials, if they can be sown in spring and had in bloom by August, are annuals for the purposes of the schedule. Some judges appeared to take this view, and admitted them; others disqualified them. Bunches of annuals in colours were invited; blue was represented by Peony-flowered Asters, blue Cornflower, Larkspur, &c.; red annuals by Nasturtiums, Sweet Peas, Zinnias, and others; yellow by Sweet Sultan, African Marigolds, Eschscholtzia and annual Sunflowers. Indian Pinks were very good, especially the double forms of Heddeewigi and laciniatus. Phlox Drummondii and Sweet Peas made charming bunches, so did Zinnias and Asters. Among the Dahlias the pompon and Cactus varieties were remarkably good, the best types of the latter being shown.

Pot plants of annuals were fairly good; the difficulty appears to be to have them in good condition by a certain date. Asters in pots were good, and Petunias, both double and single, especially so, and there were good specimens of Musk, both the common and Harrison's. Begonias of the tuberous section, double and single, were represented by a few praiseworthy specimens; Coleus was fair. Ferns, both as single specimens and in collections, were represented by well-grown examples of greenhouse Adiantums and hardy varieties. The best Pelargoniums were the zonal and Ivy-leaved, and there were nicely grown and flowered Fuchsias of good bush shape. In the way of fruit there were some very fine kitchen Apples, the best three dishes came from W. T. Stowers, and consisted of Peasgood's Non-such, Lord Sulfield and Ecklinville Seedling, all very fine. The same exhibitor had the best three dishes of dessert Apples in Lady Sudeley, Hunt's Early (?) and Beauty of Bath. The best six dishes of fruit came from Mr. T. Osman, who had Alicante and Muscat of Alexandria Grapes, Peaches, Nectarines, Plums and Melons. Open air fruits consisted of Plums, Cherries, Gooseberries, Currants, &c., and they were also shown as single dishes.

Floral decorations were represented more largely on Saturday than on Friday, as many of the exhibitors on Saturday came from long

distances. Plants were not so numerous as flowers, fruits and vegetables, which can be conveyed long distances more cheaply than plants. Saturday's exhibitors may be taken as very largely representative of an entirely new section of cultivators called into existence through the agency of co-operative societies. They come from all parts of the country, travelling long distances by night, bringing their exhibits with them and taking them back in the same manner. One can see by the garb and talk of these people that they are not dwellers in the metropolitan area. The ordinary tripper is not there and there is no noise or confusion. An intense human interest seems to hedge about this second day's show. The exhibits probably exceeded in quantity those shown on the first day by one half, but they were all arranged and ready for the inspection of the judges by eleven o'clock. Generally the subjects were similar in character to those shown on the previous day. Flowers and vegetables preponderated, and in many cases the quality was equal to that exhibited by gardeners. There are so many entries in some of the classes that it is an onerous task to select the three best out of thirty or forty. Many of the exhibitors do not study their schedules of prizes as they should, and in cases where only two dozen bunches of Currants should be staged they put fifty on the plate, and judges were similarly at fault, for they awarded prizes to these. But in the case of so gigantic a show some oversight is natural, and in all cases the best subjects appeared to gain the highest awards. Some modifications appear to be required in the schedule of prizes, and it can be truly said of the promoters that they are always ready to receive suggestions of a practical and useful character.

Royal Horticultural Society.—The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, August 29, in the Drill Hall, James Street, Westminster, 1 to 5 p.m. At 3 o'clock a paper on "The Soil considered as Plant Food, and its Exhaustion," by M. Georges Truffaut, will be read.

NOTES OF THE WEEK.

Hyacinthus candicans.—The bold spikes of this fine bulbous plant are now making a capital display in the garden, and if grown in deep and rich soil the plant will well repay it by the vigour and by the increased show of flowers. It is a capital subject for mixing in a bed of dark Dahlias or the like.

Clematis Viticella alba.—For freedom of flowering and purity of colour, it would be difficult to find the equal of this charming summer-flowering Clematis. Of course, it is a well-known plant, though it is not every day in a hot season such as the present that it is seen covered with a perfect sheet of blossoms. Quite recently in a shaded recess against a dwelling-house we noted this in the finest possible condition, and were struck by the great display of flowers, a space some 5 feet wide and 20 feet high being covered by the plant.

Campanula Profusion.—When a large number of the dwarf Bellflowers are past, this pretty plant is one of the most conspicuous in the garden or in any position in which it may be placed. Nothing can surpass it for its profuse flowering. It is not a rambler, but a really charming and beautiful addition to a group already rich in good and free-flowering plants. In its colour it is also quite distinct, a sort of slate-grey with little blue in its composition. Yet it is this very shade of colour that catches the eye and makes it quite a welcome plant in the garden at this season.

Rose Gruss au Toplitz.—Notwithstanding there is a goodly number of choice and free-flowering Roses in gardens to-day, there yet appears room for others that are as good, if not indeed better. The above is at least of decided merit, and the rich crimson or almost velvet crimson flowers are very effective. It is of the Hybrid Tea section, sending up shoots with a couple of dozen buds at the top in a more or less branching raceme. It was conspicuous when shown

at the Drill Hall last week by Messrs. Wm. Paul and Son, Waltham Cross.

Gladiolus Lady Montague.—This novelty in so far as colour is concerned, is one of the finest that has yet appeared. It is in the main a good shade of yellow, primrose rather internally and shading to a deeper more strictly yellow tone, while externally it is of a more decided yellow and more uniform. The spike unfortunately is not a good one, but as this is more a matter of the corn from whence the spike was taken, and of the moment, so far as being ready for exhibition, little notice was taken, and an award of merit was secured. It is worthy novelties such as this that quickly catch the eye.

Campanula Hendersoni.—The flowering each year of this plant, certainly one of the best of the tufted Campanulas, is worthy of note. There is something so much better than the usual run of the turbinate forms, to which at least it is most nearly related, that at least it must be regarded as superior to most of them. It comes later, too. It is in its way quite distinct, and it is no drawback to it to add that in some gardens it is of slow growth. Good plants possessing this character are the more appreciated, for it is nothing in favour of any plant, however good in flower, if it is destined shortly to become a weed.

Veratrum nigrum.—One quite agrees with the mode of treatment advocated in the note on page 152 of THE GARDEN. In many cases the non-flowering for years of this Black Hellebore is due to unsuitable conditions. Yet it is, I think, naturally less free in blooming than *V. viride* or *V. album*, both of which I have observed to flower more frequently—more regularly one should, perhaps, say—than *V. nigrum*, even in the same gardens and with similar treatment. There is a dwarf *Veratrum*, which I have not met with, named *V. Maackii*, which has dark brown flowers, but is dwarfer than *V. nigrum*. Perhaps someone who has grown this may be able to tell us something more about it and its ways.—S. A.

Kniphofia hybrida Lachesis.—Flame Flowers or Torch Lilies are generally appreciated, although the manner in which they are often staged at autumn shows does not tend to favourably impress the observer. Personally, I have a liking for the scarlet varieties, as we have usually enough of yellow given by other late-flowering plants. There has, however, apparently been a sustained effort to produce yellow-flowered *Kniphofias*, and the success attained has been wonderfully good. The hybrid *K. Lachesis*—if hybrid it is—is very beautiful, besides having in its favour what is to many an important quality, that of being now moderate in price. The flowers are of a bright orange-yellow, and the heads are both large and symmetrical.—S. ARNOTT.

Ordinary bedding plants and the drought.—A score of years ago or rather more, when the tuberous Begonia was coming into greater notice for the flower garden, it was freely predicted that the end of the scarlet Geranium or zonal Pelargonium was very near at hand. But if the unbiased mind will inquire carefully into the matter, it will readily be seen how utterly the Begonia fails as a summer bedding plant in these very dry seasons, and how abundantly the elder plant flowers. The drawback to either one or the other is when the whole garden is given up to the one thing, and when we see only a glare of intense colour on all sides. There is yet room for a little of the scarlet Geranium when this is used in moderation, while the Begonia may still make a display in early autumn.

Anomatheca cruenta.—This pretty plant, while deserving attention from those who grow miscellaneous bulbous things, is not seen so often as its merits justify. The specific name, suggestive as it is of a highly coloured flower, is not in the least degree misleading, seeing the blooms are of a rich crimson-carmine with a dark spot at the base of the lower segments. It is a charming plant, quite out of the common way, and flowers quite late in summer each year. It is one of the numerous introductions from South Africa, and

though not hardy in the open ground, requires but little care to keep it safely through the winter. The care bestowed on the plant to ensure its safety is fully repaid when one is rewarded by a nice potful in full blossom. A cool greenhouse is all it needs to grow it well during summer.

Clerodendron trichotomum.—This, which came to this country from Japan in the dawning of the present century, was represented at the Drill Hall last week by a fully-developed tree, or at least a very large portion of such, which had been severed at the ground or quite low down. In any case the example must have been 9 feet high and possibly 18 feet through its widest part, and to say that it was literally loaded with its clusters of white flowers is only bare justice to the plant. Why such a fine piece had been taken was a matter of inquiry, and it was not unnaturally decided that unfortunately the specimen had to be removed of necessity. As the example in question had far exceeded all measurements usually given of the tree, it is but fair to assume the tree to be one of the first to reach this country.

In reading your report of the last fortnightly meeting of the Royal Horticultural Society a reference to this hardy *Clerodendron* was observed. It leads one to think that a little comparison of the experience of growers who have tried it might be of service. One is not disposed to raise the question of its hardiness, as observation and inquiry have made one satisfied that it is hardy in these islands except in extremely unfavourable conditions. As a hardy flowering plant I have, however, seen reason to think that it is worthless except in some highly-favoured places. This is due to the late season at which it comes into bloom. I have had occasional opportunities of meeting with it in gardens in England, Ireland and Scotland, and in nearly every case the same remark has to be made, *i.e.*, that its buds are formed too late. But for this I would have had it long ago.—S. ARNOTT.

Rudbeckia Golden Glow (*syn.*, *R. laciniata* *flore-pleno*) was sent to me in flower four years ago by Mr. Gumbleton. Two years ago it had become rather common in English nursery catalogues, but I should say that it has certainly not been in cultivation in England for more than five years, though it rapidly became cheap, not for want of merit, because it is the best of the double large yellow composites. The flowers are so well formed, and live so well in water. Here a plant of it I have had for two years has grown to 10 feet high and is crowded with flowers. I may remark that the plant which was introduced from North America twenty years ago as *R. laevigata* (Pursh) has a single flower, and is also generally considered to be a variety of *R. laciniata*, but it comes into bloom a month later than the type *R. laciniata* and has less divided leaves. The flowers are smaller, but more sturdy and better formed than those of the type. With me it never ripens a seed, though the type produces fertile seed in abundance. I have never been able to ascertain its origin or to be sure of its true place in botany.—C. W. DOD, *Edge Hall*.

One hopes that the illustration of this double Coneflower in THE GARDEN of August 19 will be the means of introducing it more largely to British gardens. As a garden plant it is even more distinct than can be seen from the scale on which the plant is shown. Those who have seen this double form of *Rudbeckia laciniata* in growth can best realise its merits and its beauties. The flowers are, unless when too strongly grown, not at all lumpy, but are informal enough to make them both pretty in the garden and useful for cutting. The plant has also a good sturdy, upright habit, without being absolutely stiff. Those who wish strong plants of large dimensions which will produce massive blooms will do well to give *R. Golden Glow* strong soil and full supplies of water, but those who like blooms of moderate size will be pleased with those produced on plants grown in a drier position. One thinks this *Rudbeckia* likely to be a favourite plant in

the future, unless the rage for large blooms leads to its being grown into coarseness. It is at present in bloom with me.—S. ARNOTT, *Carse-thorn, by Dumfries, N.B.*

OBITUARY.

T. FRANCIS RIVERS.

WE sincerely regret to announce the death on the 17th of August at Sawbridgeworth of Mr. T. F. Rivers at the age of 68. His name will be a household word all over the world on account of the many varieties of Peaches, Nectarines and Plums that have been raised at Sawbridgeworth. Of Nectarines alone he placed two dozen varieties in commerce, among the first being Lord Napier, which is now grown in every garden where fruit is in demand. Early Rivers, too, quickly advanced in favour, while the latest, Cardinal, is now being largely grown. Of the Peaches that he raised, Early Louise, Early Rivers, Early Beatrice and Early Alfred will be found valuable where forcing is largely carried on. He also introduced many American varieties, including Alexander and Waterloo. Goshawk, Sea Eagle, and Gladstone, besides several other late varieties, were also raised by him. Among the Plums raised at Sawbridgeworth we may mention Grand Duke, Monarch, The Czar, Early Rivers, all of which have now become standard varieties. Among Pears, Fertility, a good market variety, Conference, Mag-nate and Princess may be mentioned, while of Apples we have Rivers' Codlin, St. Martin's, and Prince Edward. Cherry Early Rivers is now one of the most valuable early kinds we have. At Sawbridgeworth there is a fine collection of Grapes, including many Frontignan and Muscadine varieties very little grown, but which, though the berries are small, ought to be taken in hand owing to their fine flavour. Gros Colman, now so largely grown, and Gros Maroc Grapes he was instrumental in putting into commerce.

In T. Francis Rivers, the second Victoria medallist has passed away. He was chairman of the British Fruit Growers' Association, and took a great interest in the exhibition of British grown fruit held at the Guildhall in 1890.

The funeral, which took place last Monday afternoon, was attended by many sorrowing friends and employes.

M. Ferdinand Bergman.—We also regret to announce the death on August 10, at the age of 73, of M. F. Bergman, for many years in charge of Baron Rothschild's gardens at Ferrieres.

M. Henri Vilmorin.—It is with the deepest regret that just as we are going to press we are informed by telegram of the sudden death, on Wednesday morning, the 23rd inst., of M. Henri Vilmorin, head of the firm of MM. Vilmorin, Andrieux et Cie, seedsmen, Paris.

The weather in West Herts.—Another warm week, the seventh we have now had in succession. All the days were again warm, but during the nights preceding the 21st and 22nd the exposed thermometer fell to within 8° of the freezing point. The difference between the highest and lowest readings in the thermometer screen was on several days very considerable, amounting on the 22nd to 35°. At 2 feet deep the temperature of the ground has fallen slightly during the week, and is at the present time about 6° warmer than the average, but at the depth of 1 foot it is still as much as 8° warmer than is seasonable. With the exception of a very slight fall which took place early on the morning of the 19th, no

rain has fallen since the 15th, and no measurable quantity of rain water has now come through either of the percolation gauges for three weeks. The atmosphere remained mostly very calm and dry, while there was again a good record of bright sunshine.—E. M., *Berkhamsted*.

Ownership of fruit growing on overhanging tree.—In my garden is an Apple tree which overhangs my neighbour's garden by not more than a yard, and by standing upon steps in my garden and bending the boughs towards me, I can easily gather all the fruit that is on that part of the tree. My neighbour objects, and says that the fruit overhanging his garden belongs to him. Has he any claim to it?—FAIR PLAY.

* * * Your neighbour has no claim whatever to this fruit, and should he pull any Apples off the overhanging part of the tree you may bring an action for damages, and you will have no difficulty in that matter, or you may take criminal proceedings against him for theft. If he chooses, he may cut off the parts of the tree that overhang his garden, but he could not convert the severed parts to his own use. If Apples fall from the tree into your neighbour's garden, he has no right to convert them to his own use; and if he refuses you permission to enter to pick them up, you may enter without his permission, but you must first ask it, and you must not break his fence in entering.—K. C. T.

Melon award.—The misapprehension which exists with respect to the fruit committee at the recent meeting of that body giving an award to an unnamed Melon arose from the fact that the circumstances were unknown to the writer. The award of merit was granted subject to the sender forwarding a name, and also to giving further information as to the culture of the variety, which was said to have been grown quite in the open without protection since about the middle of June, thus making the variety to be a comparatively hardy or outdoor one. The Melon, though a small one, had a soft, succulent flesh of delicious flavour, quite equal to the very best ones from under glass, which all too rarely come to the committee table. It will thus be seen that no departure from established rule has been made.—A. D.

* * * We were quite cognisant of all the facts "A. D." refers to. There was no need to make the award at all until the facts as to the Melon had been obtained and submitted to the committee, as has always been done in bygone days. Many a time we have seen the committee take upon themselves to give a name to a fruit which had been submitted without a name and deemed worthy of an award, and why not in this case? This case only establishes a precedent, and anyone can send up any fruit, flower, or vegetable without a name, and, if deemed worthy, it will receive the hall-mark of merit, the name and particulars as to it being sent on afterwards.—ED.

Names of plants.—*Ida F. Smith.*—*Lilium superbum.*—*T. A. V.*—We believe the climbing Rose of which you send a shoot is *R. multiflora simplex*. It is a good variety for the wild garden, but unless you have plenty of space to spare, we should not recommend you to retain it in the garden. It could be transplanted and budded upon next summer, for it is much employed by nurserymen as a foster stock. Roses budded on this stock and allowed to remain without transplanting make enormous bushes, far larger than upon any other stock. We take the red Rose to be *Maréchal Vaillant*, and the white, *Olga Maria.*—*Anon.*—1, *Manettia bicolor*; 2, *Andromeda floribunda*.

Names of fruit.—*Admiral Koyanob.*—Peaches: 1, rotten; 2, *Salway*; 3, *Barrington*; 4, probably *Royal George*. Fresh leaves ought to have been sent at the same time as the fruit.

"The English Flower Garden."—*Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d. Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.*

ORCHARD AND FRUIT GARDEN.

FLAVOUR IN STRAWBERRIES.

MR. WM. ALLAN'S note (p. 99) on this subject suggests a consideration about the line hitherto taken, and that which may profitably be taken in future, by raisers of new Strawberries. One sees at the outset that the matter must be regarded from two quite different and almost opposite points of view by market gardeners and private growers. If the market man can be supplied by the raisers with kinds combining a heavy crop with size, colour, and firmness of berry, he will eagerly buy them without regard to flavour, for, unfortunately, the public seems to care little about this. The aim of the raiser and his productions have thus been greatly vitiated of late years. With all thanks to Messrs. Laxton, for instance, for the good work they have done among Strawberries, it must be confessed that very many of their new kinds have been of poor flavour. Even Royal Sovereign, which, taken all in all, is their greatest success up to the present date, cannot be said by any good judge to be of first-class flavour. The extent to which their Noble was grown is a proof how the public will swallow (literally) the very worst flavoured fruit.

The private grower, on the other hand, who would put flavour first finds himself very often hampered in this aim. British Queen has always been singled out as a Strawberry of peculiarly delicious flavour, and therefore as an obvious factor in cross-breeding to gain new high-flavoured varieties. But, unluckily, British Queen altogether refuses to grow in many districts, and this fastidiousness as to soil is transmitted to its offspring. Empress of India is on this account entirely valueless over a large part of the country. Here in N.W. Hampshire it fails, and only a few days ago I was staying with a friend who had been obliged to reject it from his large collection of Strawberries, although his garden is absolutely different from mine geologically. He is a gar-

dener of well-known ability and experience, and if cultivation could have established this variety it would not have been discarded. As Lady Suffield is the offspring of parents both of which contain British Queen blood, it is improbable that it will be amenable to general cultivation. Therefore Mr. Allan's high estimate of the fortunate consequences of crossing Countess and British Queen must be accepted with considerable limitations. What is required is a race of Strawberries of really high flavour which will grow vigorously and crop freely on any soil, good cultivation being, of course, always presupposed. It is, of course, not impossible that out of a great number of seedlings bred from British Queen on one side, one might be some day secured which retained the Queen flavour without the Queen constitution, but this is rather a forlorn hope. In my opinion by far the best all-round Strawberry for crop and flavour, conjoined with vigorous growth on all soils, is President, a fruit which has never quite received the due of its merits. It makes the best of preserve, and commends itself to most palates as a table fruit of fine, rich flavour. Much allowance must, of course, be made for different tastes. President suits my own, as containing a little more acid than such kinds as Veitch's Perfection, Empress of India, Countess, and others. These are very sweet and rich, but to my mind just a little flat and cloying when eaten in any quantity. Veitch's Perfection is, perhaps, the very richest of all, but this, again, is by no means everybody's plant, and unfavourable reports as to its behaviour have reached me from very diverse localities. The so-called perpetual Strawberries, St. Joseph, Oregon, &c., are very deficient in flavour, for fruits of such small size will never be much esteemed unless of quite unusually fine flavour. The desideratum is a fruit as rich and sweet as Veitch's Perfection, but just a trifle more brisk, on a plant which will flourish and crop abundantly on any British soil. It will come some day, for many minds and hands are at work on Strawberries.

At present the position is this: Several of the old varieties still hold their ground, a proof that there is no such superlative excellence in the new introductions as would appear from advertisements and shows. Shows are now held always and everywhere, and a box of fine new Strawberries can easily be seen, tasted, and plants freely sold on the strength of it. But when bought it commonly happens that they refuse to succeed like the older sorts in the garden to which they are sent. It is also an age of advertisements, and it is observable that every new Strawberry brought out is described as of excellent, high, rich, vinous, or similar adjective, flavour. In sober fact the advance made in Strawberries during the last ten years or so has been moderate and not at all startling, nor is it easy to indicate the line along which to work for greater results. If we knew for certain the parentage of such kinds as President and Vicomtesse, to take these as types of well-flavoured fruits with no special soil requirements, we should be helped. I quite agree with Mr. Allan that there must be loss rather than gain in such a step as re-crossing Empress of India with British Queen; the twice infused Queen blood must bring the resulting progeny too near to British Queen and limit it to a few soils. A point of excellence on which I should myself lay some stress is the absence of hard external seeds. Their great abundance on Royal Sovereign makes it unpleasant in the mouth and unwholesome to myself, and others tell me the same. It may serve as a useful stimulus that the ideal Strawberry has yet to be raised; the best qualities are still distributed over several good kinds, but united in none. I have myself been attempting a somewhat new departure in cross-breeding Strawberries, but am as yet not over sanguine as to the outcome, and certainly will not prophesy until it has been put to a rigorous proof.—G. H. ENGLEHEART.

— In his interesting note on the pedigrees of his Strawberries raised at Gunton Mr. Allan refers to Veitch's Prolific as a dark-coloured fruit.

Surely that is an error. So far as my knowledge of that excellent variety is concerned, I regard it as having more of the colour of British Queen than of Countess. One reason why I like Prolific so much, apart from its abundant cropping and high flavour, is its bright colour. I think that Royal Sovereign, just now the most popular Strawberry in cultivation, owes very much of its popularity to its bright scarlet hue, one that does not tarnish and become dull or objectionable in appearance when kept, as is the case with varieties of the Waterloo colour. But the oddest thing in Mr. Allan's remarks is to learn that Countess is chiefly responsible for giving Prolific its flavour, and not the highly flavoured British Queen and Empress of India. I have always thought that of all the Strawberries in cultivation British Queen was the highest flavoured. But whether it was wrong to use Empress of India in crossing British Queen or not—and to the mass of people it matters not one atom—the result seems entirely to justify the parentage, as Prolific so far has proved to be the best flavoured of all the newer Strawberries. One objection to some new ones is the profusion of seed-pips on the surface of the fruit, causing them to feel as rough in the mouth as alpine. From that defect Prolific is free. But whilst pedigrees have little interest for the Strawberry grower in general, they no doubt have much for the raiser. Still, I fear it will be generally conceded that all the blends of the finest flavoured varieties have so far given nothing more highly flavoured than are some of the parents.—A. D.

Plum Denniston's Superb.—Judging from the seldomness with which this Plum is mentioned in reports of fruit crops, I should imagine it is but little grown, but were I planting half a dozen dessert varieties, Denniston's would certainly be one of them. It matters not whether grown on a wall or in bush or standard form, it is a constant and prolific bearer, and, what is more, of first-class flavour. True, it is not large, but sufficiently so for dessert, and if once tasted at table it will be asked for again. To those who do not mind slightly shrivelled fruit I would say, leave a few on a wall tree until this stage is reached, and they will have delicious sweetmeats. It bears freely in quite a young state.—J. C.

Pear Beurre Giffard.—This early, handsome Pear is worthy of more general cultivation; indeed, I think it is to be preferred to some of the extra early ripening varieties, such as Citron des Carmes. It succeeds well on the Quince and is fairly prolific. The fruit is long, tapering, and extremely handsome, colouring up beautifully when exposed to the sun. The flavour is brisk, juicy, and refreshing if eaten in time. The fruit will keep in an eatable condition for a short time if gathered as soon as it parts from the tree, but it is never better than when eaten from the tree. I have grown Beurre Giffard as a horizontal cordon, in which form it does fairly well, but the growth is really too irregular for that style of training.—N. N.

Strawberries President and Keens' Seedling.—Being interested in Strawberries, I read with much interest the notes on the above by "H. R." and "D. T. F." and am of the same opinion as "H. R." I have found Keens' Seedling too small for the dessert. I admit there is no question as to quantity, but after the first fruits are gathered there are too many small ones. I am aware by the latter remark I lay myself open to criticism, but there is a demand for large fruits. It may be bad taste, but in these days growers have to respect that taste and grow kinds that are popular. For preserving, the small fruits are just the thing. Such fruits sent to market are classed as seconds or even lower, and do not pay the grower. By this it will be seen why large fruits are favoured by growers. The other remark of "D. T. F." is one that needs little comment. I thought the value of Royal Sovereign was too well known in the counties named for anyone to be surprised at its superseding Keens' and President. Most of my later years have been spent in the

counties named, and though President is retained by private growers it is much less grown than formerly, and Keens' less than the other.—S. M.

PEARS ADOPTED BY THE CONGRÈS POMOLOGIQUE OF FRANCE.

(Continued from p. 166.)

FAVORITE MOREL.—Originally obtained by M. François Morel, of Lyons, about 1870. The fruit is large or of fair size, a long Bon Chrétien in shape. The stalk is fairly slender, woody, curved, of medium length, set almost straight on the narrowly truncated fruit. The eye is open, regular, nearly flush with the rounded top of the fruit. The skin is rather rough, brilliant, changing from yellow to golden, slightly mottled with light tawny. The flesh is white, delicate, close, melting, and very juicy. It is a very good fruit, not liable to turn off, and ripening September and October. The tree is vigorous even on the Quince and very fertile. In cultivation this variety forms handsome pyramids, attaining large proportions.

FIGUE D'ALENÇON (*syns.*, *Bonissime de la Sarthe*, *Figue d'hiver*, *Silvange d'hiver*).—Originally obtained by M. Lecomte Mortefontaine about 1829 at Cussay, near Alençon. It is of middling size, long, pyriform, obliquely pointed and embossed near the stalk, which is short and thick, and is an oblique continuation almost of the fruit. The eye is small and open, placed sometimes flush with the fruit, sometimes in a slight depression. The skin is uniform without being smooth, yellow, spotted tender green, stained russet, shaded red-brown on the sunny side. The flesh is yellow, melting, very sweet, and highly aromatic. A very good fruit, ripening November—December. The tree is vigorous on the Quince and of great and sustained fertility. In cultivation this variety is easy to train and can be adapted to all forms, but likes a warm exposure and soil for the fruit to acquire its excellent quality.

FONDANTE DE CHARNEU (*syns.*, *Beurré des Charneuses*, *Désirée Van Mons*, *Duc de Brabant*, *Legipont*, *Miel de Waterloo*).—A chance seedling found near the village of Charneu, in the province of Liege, Belgium. The fruit is of fair size, in shape Bon Chrétien. The stalk is thickish, of medium length, set in an oblique depression, the eye medium-sized and open, set in a wrinkled cavity, the skin thin, light green, shaded pale yellow, largely stippled tawny, and sometimes red on the sunny side. The flesh is yellow, delicate, melting, very juicy and aromatic. A very good fruit, ripening September—October. The tree is of middling vigour on the Quince, of medium or satisfactory fertility. In cultivation it is easily trained, affecting naturally the pyramidal form. Double grafting and somewhat long pruning are favourable to its vigour and fertility.

FONDANTE DES ROIS (*syns.*, *Belle de Flandres*, *Beurré Duyv*, *Beurré Spence*, *Bosc peer Excellen-tissime*, *Guyule à Heuze*, *Impératrice de France*).—Originally found in a wood near Alost, Flanders. The fruit is large, sometimes very large, Bon Chrétien shape, regular in contour, the stalk shortish, not stout, set straight in a narrow, deepish, and regular cavity. The eye is medium-sized, half open, in a shallow, regular, and wide cavity. The skin is thin, yellow, stippled grey and green, washed red-brown and carmine on the sunny side. The flesh is white, juicy, with a pleasant aroma. A good fruit, ripening September—October. The tree is of normal vigour on the Quince, of great and sustained fertility. In cultivation this variety is hardy and easy to train, lending itself to all forms. It does equally well as a standard, when its fruits attain a handsome size.

FONDANTE DE PANISEL (*syns.*, *Délices d'Angers*, *Délices d'Hardenpont d'Angers*).—Originally obtained about 1762 by the Abbé d'Hardenpont at Mont Panisel, near Mous, Belgium. The fruit is medium-sized, spherical or conical-oval, wider or as wide as high, with a bumpy surface. The stalk is short, thick and fleshy, continuing a pro-

tuberance at the end of the fruit. The eye is medium, open, in a deep and wide cavity. The skin is rough, thick, golden yellow, stained tawny and red-tawny on the sunny side. The flesh is yellow, melting, very juicy, and pleasantly aromatic. A very good fruit, ripening October. The tree is somewhat deficient in vigour on the Quince, and is of great and sustained fertility. In cultivation it is easy to train, affecting naturally the pyramidal form. It requires to be grafted on the Pear in order to attain to large dimensions.

FONDANTE THIRRIOT.—Originally obtained in 1858 by MM. Thirriot frères at Moulin à Vent, Charleville (Ardennes). It first fruited in 1862. The fruit is of fair size, pyriform and narrowly hollowed about the stalk, regular in contour. The stalk is stout, long, rather thick, set straight, or nearly so, in a fold. The eye is small, open, in a normal and regular cavity. The skin is rough, bright yellow, much stippled grey-brown, washed rose and mottled red on the sunny side. The flesh is white, very juicy, and pleasantly aromatic. A very good fruit, ripening at the end of October to December. The tree is fairly vigorous on the Quince, very vigorous on the Pear, and of great fertility. In cultivation this variety does well on all stocks, but it is best to graft it on the Pear to obtain handsome trees.

FONDANTE BOISSELOT.—Obtained originally by M. Boisselot, of Nantes. It first fruited in 1861. The fruit is of fair or medium size, more wide than high, regular in contour. The stalk is stout, long, curving, set rather obliquely in a wide and fairly deep cavity. The eye is medium sized, closed or half closed, in a rather deep, wide cavity. The skin is thick, greenish yellow, partly washed with dull reddish grey. The flesh is white and delicate in flavour. It is a good fruit and ripens January—February. The tree is vigorous on the Quince and on the Pear, blossoms much, but is only fairly fertile. In cultivation this variety thrives on all species of stocks and quickly forms pyramids.

GRASLIN.—A chance seedling found on the Malintourne estate belonging to the (Graslin family at Flée (Sarthe). The variety was propagated by Dr. Bretonneau in 1841. The fruit is of fair size, bulging on one side, irregular in form. The stalk is long, stout, fleshy near the fruit, set on the blunted point of the fruit. The eye is medium sized, open, in a shallow, wide and regular cavity. The skin is thick, light yellow, stippled and stained tawny, sometimes rosy on the sunny side. The flesh is white, luscious and agreeably aromatic. A good fruit, ripening October—November. The tree is of normal vigour on the Quince and fertile. In cultivation this hardy variety may be grafted on all stocks and cultivated in all forms.

HELENE GREGOIRE.—Obtained in 1840 by M. Gregoire Nelis, of Jodoigne (Belgium). It first fruited in 1852. The fruit is medium or large in size, Doyenné in form, more or less embossed about the stalk, which is stout, short, swollen at both ends, and set in a narrow cavity surrounded by unequal bumps. The eye is open, in a shallow, wide, irregular cavity. The skin is thin, delicate, golden, mottled and streaked yellow, very slightly tinged orange-red on the sunny side. The flesh is very delicate, juicy and deliciously aromatic. A very good fruit, ripening September—October. The tree is of normal vigour on the Quince and fertile. In cultivation this easily trained variety naturally affects the pyramidal form; it, however, succeeds in all forms and on all stocks, but it requires a warm soil.

JALOUSIE DE FONTENAY (*syn.*, *Belle d'Esquermes*).—Found originally on the Bonchereau estate near Fontenay (Vendée) and propagated by M. Levcque about 1828. The fruit is of medium size, pyriform. The stalk is stoutish, fairly long, sometimes straight on the point of the fruit, sometimes turned aside by a small gibbosity. The eye is medium-sized, oftenest closed, in a shallow cavity, the skin fine, unctuous, straw colour, abundantly stained russet green, tinged chamois on the sunny side. The flesh is white, delicate, and deliciously aromatic. A very good

fruit, ripening September—October. The tree is of medium vigour on the Quince, of great and constant fertility. In cultivation this easily trained variety is specially adapted for the pyramidal form.

JOSEPHINE DE MALINES.—Obtained originally in 1830 by Major Esperen, of Malines. The fruit is medium-sized or nearly so, embossed near the stalk, which is of medium length, stout, fleshy, set in a slight bumpy depression; the eye small, open, in a small wide depression; the skin thickish, citron-yellow, marbled tawny-brown, relieved with orange-yellow, with rusty stipplings on the sunny side. The flesh is rosy white, very delicate, juicy, sugared, with a pronounced aroma of rose. A very good fruit, ripening throughout the winter until March. The tree is vigorous on the Quince, of normal fertility. In cultivation this variety lends itself fairly well to regular forms. It requires long pruning, leaving the spurs to be fertile. It adapts itself well to espalier form, which improves the size and quality of the fruit.

JULES D'AIROLES.—Originally obtained in 1836 by M. Leon Leclerc, of Laval. It first fruited in 1852. The fruit is large, Bon Chrétien shape, rounded at top, and hollowed towards the stalk. The stalk is stout and thickish, of medium length, set in a cavity. The eye is medium, open, with erect sepals in a shallow and wide cavity; the skin uniform bronzed yellow, slightly tinged carmine on the sunny side. The flesh is white, very delicate, oily, and rather musky. A good fruit, ripening November—December. The tree is of normal vigour on the Quince, of great fertility. In cultivation this variety forms satisfactory pyramids. It may be grafted on the Quince or on the Pear.

(To be continued.)

Dessert Raspberries.—I am pleased to note a revival of Raspberries for dessert, and I note there is a liking for those kinds with a brisk flavour. The handsome Superlative is one of the best in this respect. In the report on the fruit crops, Mr. Thomas says the Raspberry is much appreciated at Windsor as a dessert fruit. There can be no question as to the value of the Raspberry for dessert, and I wonder it has been neglected so long. The yellow-fruited kinds are most valuable for that purpose, they being even superior to the red sorts. Before glass became so common the Raspberry was always recognised as a dessert fruit. We have excellent red varieties in Hornet and Baumforth's Seedling, these with the later Superlative being the leading red varieties. New Guinea is also a splendid new white. To this may be added the older Yellow Antwerp, a large pale yellow fruit, sweet, and of good flavour, and if still later kinds are desired there are the October Yellow and Orange d'Automne.—S. M.

Peaches in Russia.—If I remember aright, "R. K." a year or two ago inquired as to the best early Peaches, and some readers of THE GARDEN replied. I think the two varieties he condemns were recommended. A season's failure with any one kind does not prove that the variety is bad; indeed, I am sure many of our home growers who grow Peaches in quantity will not agree with "R. K.'s" remarks. Of course, many of us do not know of the difficulties of forcing in Russia and it is unfair to criticise, but when "R. K." says Amsden June is poor and flavourless I certainly do not agree with him. The remark that it is bitter points to the culture being at fault. I grow it largely, and there can be no fault found with it. I admit it has faults, but all Peaches, American kinds or otherwise, if left after being ripe on the trees lose flavour badly. Far better gather a day too soon than too late, as, like some kinds of Pears, these Peaches are best gathered and placed in a cool room. I am surprised at "R. K.'s" condemnation of Hale's Early, as this is, I consider, one of the very best of the early varieties. There is certainly something wrong with the treatment when Hale's Early gives such few fruits, and the few

fruits have split stones. The losing of the leaves points to some defect. It is difficult to advise when such an excellent variety as Hale's behaves so badly and is only fit for the rubbish heap.—G. W. S.

SOME RESULTS FROM BUDDING AND GRAFTING.

HAVING an old tree of the true Early Grosse Mignonne Peach, and fearing its early collapse, which the occasional or yearly decaying branches indicate with some certainty, I inserted a few buds on to another large and healthy tree of Alexandra Noblesse growing in the adjoining or second early house, the old tree for many years furnishing a good crop in the early one. Alexandra Noblesse, as is well known, matures its crop a good deal later than the Grosse Mignonne; yet, strange to say, these conditions are quite reversed by the union of the early on the later variety. Some of the fruit from the Alexandra Noblesse were soft and ready for use, while the others were quite hard, and all were cleared before the Grosse Mignonne had ripened its crop. It is not a little curious that the union of an early variety on a late one should change its character so completely. There is, too, a distinct loss of colour brought about by the same cause, the early one taking on a good deal of the paleness of Noblesse. In flowering it was most profuse, and in setting it was equally free. Another instance showing the variable influence of grafting is furnished in an outdoor Pear. The stock—a French variety whose name I am unable now to give—was headed down because of its worthless character and grafted with Marie Louise d'Uccle, a young tree of which has fruited freely for the past six years. By grafting it on the French variety, this free-bearing trait has so far been entirely lost. Grafted in 1894, the tree has become quite equal in size to its original state, but no crop has been borne yet, and the spring of this year furnished but two or three flower-trusses. The tree, a vigorous one, was root-pruned to bring it into a normal state of growth two years after grafting, but this did not bring about the change usually obtained. Unless there are some prospects soon of fruit, re-grafting with another variety will be tried. No doubt the vigorous nature of the stock is too much for the precocious tendencies of the scions. It is not the soil that makes the difference, for the two trees are within 20 feet of each other. In the same border was a tree of Beurré Clairgeau that remained stationary in its growth for several years and had quite a stunted appearance. Instead of cutting it out I put on some grafts of Williams' Bon Chrétien to ascertain whether by re-grafting a new lease could not be given it. Results proved this to be so, and both growth and fruit now proceed quite satisfactorily. The fruit of the original B. Clairgeau was so small that it was useless for any purpose.

Another change brought about by grafting I once saw in the garden of a friend. In it was one particular tree that was not vigorous, but which ripened its foliage and crop very early in the autumn. It occurred to the gardener in charge that Doyenné Boussoch, a favourite variety with him, might be enhanced in its colour by uniting it to this slow-growing tree, and so it did. The fruit does not become so large as usual, but the bright flush extending over the whole surface of this Pear made it a most remarkable and striking dish for exhibition. I do not remember the variety on which it was grafted, but it was one that itself produced brightly - coloured Pears, and the two were

allowed to grow together on the same stock. The broad foliage of the Doyenné Boussoch was distinctly conspicuous in its association with the narrower leafage of the foster-parent.

Other instances can be cited in which results do not always bear out one's expectations, but they afford interest all the same. Nurserymen in dealing with the many hundreds of varieties find that double-grafting is a great gain to increase in one or suppress in another growth which is not satisfactory treated in the ordinary manner. I have seen buds inserted in the main branches of young Apples trees remain dormant for more than eighteen months, simply because the branches were not shortened back to the buds after they became united. On this being done the bud immediately showed signs of activity, and eventually developed an unusually strong shoot. W. S.

Wills.

LOOSE VERSUS SOLID VINE BORDERS.

THAT is an interesting article by "H. R." (page 2) on Vine borders. There is much truth in his remarks on what the constituent parts of a Vine border ought to be. "H. R.," however, does not say anything about firmness, which I consider so essential in all well-made Vine borders. If sufficient opening material such as that described by "H. R." is used, the compost may be rendered solid and yet perfect drainage exist. Formerly gardeners seemed to favour loose Vine borders, and I have known newly-made borders to be turned over with five-tined forks so that they should lie loosely, but of late years very firm borders have found favour with some of the most successful growers, and I must say I think the idea is correct. A market-growing friend of mine in Derbyshire, who grew grand Grapes, planted two houses with Vines. The border of one was left in a loose condition, that of the other being made as firm as possible. A moderate layer of compost was laid on at a time, this being rolled with the garden roller. The soil was wheeled in in a semi-dry condition, and by the time the border was completed it was as hard as a road. My friend, of course, took the precaution to incorporate a good percentage of old mortar rubble, charred wood, and similar material. The Vines were planted in the same way and had exactly similar treatment in both houses, but there was no comparison between the weight and quality of the crops. The wood on the Vines in the firm border was much the harder and ripened sooner and better, and the bunches larger and finer in every way. When the last layer of soil was rolled, the surface was slightly pricked over with a five-tined fork to allow of a free and even entrance of water. Where the garden roller cannot be used, an equal solidity could be secured by other means. In planting Vines in these hard borders there is no necessity for disentangling the roots, as the water cannot pass down by the side of the balls without entering it, as in the case of loose borders. C. N.

Summer pruning of Peach trees.—I attach much importance to the late summer pruning of these. Of course, with early and late kinds the dates will differ as regards the time to do the work, but there can be no doubt as to its utility with trees in a vigorous state, especially those that have filled their allotted space and cannot be given extension. The result of summer pruning is seen at a glance, as by the removal of old, useless wood there is room to lay in fruiting wood for another season. This wood gets well matured, an important point, and one that should not be overlooked. To old, worn-out trees my remarks are not applicable, as often the wood on such trees is poor and none too thick. I have referred to extension, and I am much in its favour, but at times it happens that young trees have filled their allotted wall space. Much may be done by cutting out at this season and laying

in a stock of good wood. By doing this work now the trees benefit greatly and there is little to do in the winter.—G. W. S.

Summer pruning of Raspberries in dry seasons.—In hot, dry summers pruning now is beneficial, as with so little rain it is important that the new canes get as much moisture and light as possible to perfect their growth, as upon these depends next season's crop. I am aware some growers object to prune at this season, the reason being the old canes have not done their work, but my contention is that there is a great drain on the plants after having given a crop, and then to furnish the new canes for another year any assistance is beneficial. The old canes draw moisture away from the new ones and also obstruct growth by crowding them. I fail to see of what use they are, and in gardens where high culture is given to get fine fruit and in quantities, my advice is to remove the old canes as soon as the fruit is cleared. If this work is done early a much better growth will be secured. At the same time it is well not to allow all the shoots that show to remain. I prefer to leave three to a stool. Some leave more, but a great deal depends upon the soil and the culture given—variety also, as some kinds are much stronger than others.—G. W.

THE SAND CHERRY AS A STOCK.

HAVE any experiments been made in England with *Prunus pumila* and *P. Besseyi* as a stock for the Plum, Peach and Apricot? In experiments at the Iowa and South Dakota Agricultural Colleges this Sand Cherry, as it is popularly called, makes a good budding and grafting dwarf stock for our native Plum (*Prunus americana*) and for Japanese Plums and to a less degree for the European Plums. Peaches also do well on it. Cherries unite with difficulty. The Sand Cherry, a dwarf bush 4 feet to 5 feet in height, is a native of South Dakota and the North-west. It endured 40° below zero F. last winter on the college grounds at Brookings and is bearing a heavy crop of fruit this year. Native Plums blossom freely on this stock at two years, and some when one year of age. Flowering Almonds do well on Sand Cherry, I am informed by a Minnesota nurseryman. Japanese Plums make a strong growth and blossom very early. The experiments so far show that early fruiting is caused by this stock, but the tree is dwarfed. The stock will not sucker, although roots when much cut by the cultivator will sucker occasionally. The need of a hardy stock for the North-west may be inferred from the fact that Myrobalan, St. Julien, Marianna, and Chickasaw Plum roots, also those of Apricot and Peach, are all killed in our winters, leaving the hardy native Plum top, such as De Soto, Forest Garden, Rollingstone and Hawkeye, to die. The past winter has caused widespread havoc in North-western prairie nurseries in this line. The only stocks that are sufficiently hardy appear to be the native *Prunus americana* and the Sand Cherry. For the culture of stone fruits this stock certainly deserves a trial. It grows very readily from seed and from layers.

At Brookings we are now selecting the best for fruit from nearly five thousand plants, and hope to develop something of promise from the seedlings. The plants bear at two years of age and endure the severest drought. This is to be expected, as these plants come from the dry, sandy prairies of North-western Nebraska and South Dakota. The plant varies according to its habitat in hardness and drought-resisting capacity. The fruit varies much in size, being often nearly as large as the Early Richmond Cherry, mostly black, sometimes brownish red or yellow, and generally bitter. Occasion-

ally plants are found bearing fruit with scarcely a trace of bitterness. At Brookings we already have several thousand plants growing from seed of these selected plants, and are prepared to fruit 100,000 in the next few years if necessary to get the ideal plant we want.

Professor Saunders, director of the Canadian Experiment Stations, has been working in this line for several years, and has already several varieties named and under propagation. The field is one of much promise.

South Dakota, U.S.A.*

OPEN-AIR FIGS.

I WAS pleased to note in Mr. Parker's remarks on the fruit crops that open-air Figs even in standard form were carrying good crops of fine fruit. I think I remember him telling me that the fine, but in the majority of instances shy-bearing Castle Kennedy grew and cropped well as a standard at Goodwood. No doubt the soil and general surroundings favour Fig culture in that garden, but I feel confident that, were a little more care and labour bestowed on the trees, Fig culture in the open, at least on walls, might be made tolerably easy and fair crops certain. Many, I believe, of the fine old trees planted by our forefathers in the more favoured counties never rallied from the terrible crippling they received from the frost in January, 1895. Had sufficient protection been afforded all would have been well, but many were left entirely to the mercy of the weather and others merely encased with ordinary garden mats, whereas dry Bracken should be freely distributed over the branches previous to the mats or bags being fastened on. Probably more exposed standards are harder than trees on walls, but it would be interesting to learn from Mr. Parker if the fine old trees at Goodwood received any covering. Many present-day gardeners appear to think outdoor Figs not worth troubling about when they can so easily be produced under glass, but even from an ornamental point of view they surely merit attention, while I maintain, and I know many more will do the same, that well-grown open-air Brown Turkey or Brunswick Figs have no equal in point of size, appearance, and flavour. Well do I remember the fine specimens of these two varieties my father used to grow in Essex, the making of muslin bags and enveloping the Figs being quite an undertaking. But, even where good trees exist, they are sometimes allowed to grow from year to year unthinned till the wood forms a perfect thicket, defying entrance to sunlight and air, laying in the young growths also being ignored. There is no wonder that they come to be deemed unprofitable. Only a few days ago I saw two fine healthy trees growing against a sheltered wall of a villa residence near Norwich, and there can be no doubt that perfect shelter is indispensable in the culture of outdoor Figs. In planting, two very important points to be observed are perfect drainage and a confined root-run. If this be neglected, gross shoots, barrenness, and disappointment are sure to follow. A rich larder to start with is likewise fatal, this being the rock on which many planters founder—a medium loam and ordinary garden soil in equal proportions, with a free admixture of old mortar rubble as a corrective, suiting best. If planting on a wall, choose either a south or south-west corner, and keep the roots within bounds for a few years at any rate by slabs or brickwork, making sure that provision is made for the escape of superfluous water. Raising the bed intended for the roots a foot above the ordinary level is likewise a good plan, and this is easily done. This encourages the formation of a colony of fibrous roots. Figs more than many fruits are prone to make a far greater percentage of shoots than can be properly exposed to the influence of sunlight and air; therefore early disbudding should be practised—midsummer and autumn laying in of the wood also being impera-

tive. Nothing responds more readily to a surface mulch of old Mushroom manure than the roots of Figs, colonies of fresh fibres soon running into it, these being further benefited by an annual top-dressing of loam and lime rubbish. I am confident that were the above details regularly attended to, remunerative crops of fruit might be secured. At the beginning of December provision must be made for protecting the trees from frost. Various means will suggest themselves to the cultivator, but nothing, I think, surpasses common Bracken in a dry state, kept in position by ordinary garden mats. The wood of well-cared-for trees should have been well matured last autumn, and except on uncovered trees which were injured by the frost late in March, fruit ought to be plentiful this season. NORFOLK.

Ripening young pot Vines.—"Cornubian," in his practical calendar notes on pot Vines, refers to the fact that some growers now-a-days leave the Vines in the pit or house where growth has been made "to mature." Although I do not see that there is any advantage beyond saving labour in average seasons, it is decidedly a gain when the autumn turns out wet, as, even though rain-water be prevented from entering the pots by slate coverings, as suggested by "Cornubian," yet the atmosphere cannot be controlled, and over-moistness retards ripening and encourages late lateral growth. In fine autumns the foot of a south wall is about as good a position as the Vines can occupy. No doubt, as "Cornubian" says, it is a bad plan to withhold root moisture too suddenly and early, such treatment having an injurious effect on the eyes which are to produce bunches next year. A gradual diminution is what is wanted, no further supplies of manure water being given after the above stage is reached.—B. S. N.

Bees and wasps.—Although perhaps rather early to write definitely on the subject, wasps are so far very scarce, and it is to be hoped they will continue so. Up to the present I have heard of but two nests having been found in this district, and the insects in both cases were weak and have since dwindled away. They should be scarce, as I have directed a rather merciless crusade against them the past three seasons, during which time a grand total of 302 nests has been destroyed. With regard to bees, these are inflicting more damage than ever, especially among Apricots, while Raspberries have also been badly attacked by them. I am trapping great numbers by means of bottles filled with cider and sugar and the old-fashioned device of placing handlights one on top of the other. Large quantities of bees, however remunerative they may be to their owners, are certainly a great nuisance to the fruit grower, as flies, wasps, and birds are quite sufficient to contend against without bees being added to the list. Some people will not believe that bees do any harm, but anyone calling here while Apricots remain ripe on the trees can see for himself that they, when present in large numbers, are far more destructive than wasps.—A. W.

Plum Early Violet.—In all the reports of the fruit crops which have from time to time appeared in THE GARDEN I do not remember to have once seen the above Plum mentioned. Several years ago I had occasion to write about it, and mentioned that the midland counties were the only ones in which I knew it to abound. I think it was Mr. D. T. Fish who replied, stating that the variety in question was propagated somewhat largely in Huntingdon nurseries. Mr. Fish also corroborated my statement as regards the usefulness of Early Violet. I have lately been reminded of it by seeing fine samples of it in the Norwich fruiterers' shops. Upon inquiring I find it has been pretty freely planted in some districts in East Anglia, and that, as in the midlands, it grows and crops freely. In size and even appearance it resembles Early Rivers, but is not, like that variety, considered a dessert Plum. All the same, it is in great request for cooking and makes a fine preserve.—NORWICH.

TREES AND SHRUBS.

CARAGANAS.

COMPARED with some, or indeed most, of the hardy leguminiferous shrubs, the Caraganas cannot be put in the first rank as regards showiness, and this is, perhaps, the reason why so little is said or written about them. As in most other genera, the species are not all of equal merit, but the best of them are decidedly worth a place in the garden either for the beauty and abundance of their flowers, or because of their quaint and graceful habit. Others, like *C. jubata*, if not exactly beautiful in the common acceptation of the word, may at least claim notice as interesting plants; they represent a type of shrubby vegetation characteristic of desert regions which in the nature of things cannot be very

odd or terminal leaflet is wanting. In most instances the leaf-stalk ends instead in a sharp point. The stipules, too, are spine-tipped, and they (as well as the leaf-stalks in some species) remain on the branches after the green blades of the leaflets have fallen and become hardened into ordinary woody spines. This is a curious and somewhat unusual adaptation of these organs to serve the purpose of arming and protecting the plants. The flowers are always solitary on the stalks, papilionaceous, and nearly always yellow. Most of the species ripen seed in this country, by which means they can be increased, as also by cuttings and layers. They are usually, however, grafted on *C. arborescens*.

Some of the Caraganas, as, for instance, the one now figured, make a striking feature planted singly on a lawn. Others, like *C. pygmaea* and *C. aurantiaca*, are better in groups. To those

it was introduced in 1752. In a wild state it is found in localities of varying fertility, and in the more favourable ones is often tree-like, and attains a stature of 15 feet to 20 feet. It reaches the same size in cultivated ground. The leaves are composed of six to eight pairs of leaflets, the stalk ending in a small spine and having also two others at the base, the latter being really stipules. The flowers appear in May and are bright yellow. They are borne singly on slender stalks about 1 inch long, several of which come from each joint of the previous year's wood.

C. A. VAR. NANA is a dwarf shrub compared with the type, its branches being stunted and gnarled. It grows slowly in height, and can thus be grown in places too restricted for the larger-growing varieties. In its flowers and leaves it does not differ from the type.

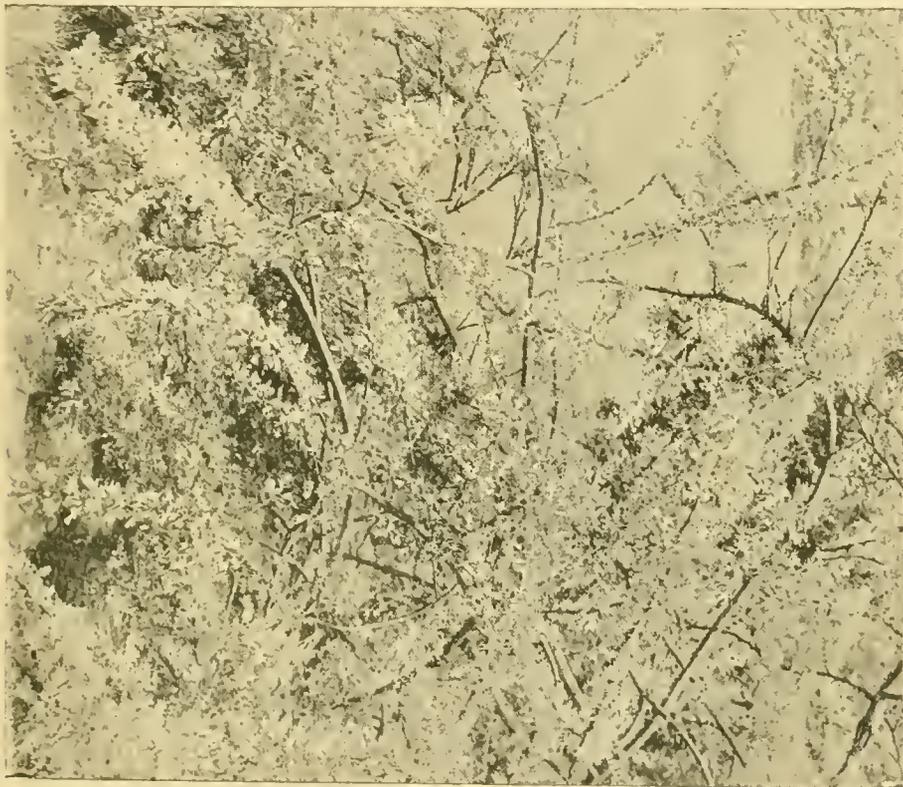

C. A. VAR. PENDULA is a weeping sort, and perhaps the most pleasing of the varieties of this species. It should be grafted on high standards of the ordinary *C. arborescens*, as its branches grow almost vertically downwards. It flowers, perhaps, even more freely than the type. Some nurseries grow it as *C. japonica pendula*.

C. A. VAR. REDOWSKI, of which an illustration is now given, is a plant of remarkable habit. Its branches are long and serpentine, dividing but little. A shoot will grow for several years without branching. This gives the shrub a curious and interesting, but still graceful aspect. Of this and of its free-flowering nature the accompanying picture of a specimen at Kew will be sufficient evidence. This plant is about 10 feet high and 18 feet across, but in habit, of course, quite thin and open. The flower is identical with that of the typical *C. arborescens*, and so is the leaf. I do not know whether it will come true from seed, but it is easily grafted on *C. arborescens*, or, still better, layered.

C. AURANTIACA.—Nearly allied to *C. pygmaea* and at one time considered a variety of it, this is now regarded as a distinct species by the German authority Koehne. It is the last addition made to the genus, and was put into commerce by Dr. Dieck. It grows some 3 feet or 4 feet high, and although erect when young, the branches become straggling and pendulous (even prostrate) with age. The leaves consist of four small, linear, pointed leaflets, and appear in the axils of a triple spine, which is really a modified leaf-stalk and its pair of stipules. The flowers are pendent and hang in profusion in a long row from the previous season's growth. Like those of *C. pygmaea* in size and shape, they differ in their deeper, more orange-yellow colour. They also come a week or two earlier. The botanical distinctions between the two species consist chiefly in the calyx of *C. aurantiaca* being larger and more conspicuously lobed and in the leaflets being more pointed. It is a native of Central Asia.

C. CHAMLAGU.—In foliage this is one of the best furnished and handsomest of the Caraganas. The leaves consist of two pairs of leaflets, which are obovate, smooth, and from half an inch to 1½ inches long. In all the other cultivated Caraganas the foliage is of a dull or even greyish green, but in this it is dark and glossy. The terminal pair of leaflets is the larger. The plant grows probably about 3 feet to 4 feet high in a natural state, but I have not seen it on its own roots. It appears to be always grafted on *C. arborescens*, and on standards about 5 feet high it certainly makes a handsome specimen, the branches being drooping and the habit more bushy and luxuriant than is common to this genus. The flowers are solitary on each stalk, of large size (for this genus), and yellow, acquiring a reddish tinge with age. It was introduced from China in 1773, and is a native also of Japan.

C. FRUTESCENS.—If not so well known as *C. arborescens*, this has at least been grown in gardens for an equal length of time. Both species were introduced to Britain in 1752. It is quite distinct from *C. arborescens* by reason of its leaves invariably consisting of but four (two pairs of) leaflets. These are (in the type) obovate, from half an inch to 1½ inches long, smooth, and dull

Caragana arborescens var. *Redowski* in the Royal Gardens, Kew. From a photograph by G. Champion.

abundantly represented out-of-doors in this country. The Caraganas have, however, other virtues to recommend them. They are perfectly hardy and (with the exception of *C. jubata*) easy to accommodate; they are, moreover, well adapted for poor soils, thriving where many other things would starve. The name Caragana is derived from Caragan, the native name for *C. arborescens* among the inhabitants of Mongolia. Although the species are comparatively few—about fifteen—the Caragana region fills the centre of the great terrestrial mass of the Old World. Stretching from the Black Sea and the Caucasus in the west, it reaches to China and Japan in the far east, and from the Himalaya and Afghanistan in the south, it extends northwards to the middle latitudes of Siberia. All the Caraganas are deciduous and the leaves (in the cultivated species) are equally pinnate—that is, the usual

who have not the space or desire to grow the whole of the species and varieties here mentioned, those marked * in the following list may be recommended as a selection of the best.

I.—SPECIES WITH FOUR LEAFLETS.

- **Aurantiaca* Chamlagu (syn., chinensis)
- **Frutescens* **Pygmaea*

II.—SPECIES WITH MORE THAN FOUR LEAFLETS.

- Arborescens* *Jubata*
- var. *nana* *Microphylla* (syn., Alt-
agana)
- *var. *pendula* *Spinosa*
- *var. *Redowski*

C. ARBORESCENS.—This species, with its varieties, is the chief representative of the genus in gardens. It is the tallest and most robust of all the Caraganas and is well worth growing, especially in its pendulous forms. A native of Siberia,

dark green. The flowers are bright yellow, and are often borne in great abundance during April and May. The shrub itself is some 7 feet or 8 feet high and of moderately erect habit (the other Caraganas with four-parted leaves are all distinct from this in their pendulous, low habit). A native of Central Asia, and reaching from South Russia to Japan and China.

C. F. VAR. ANGUSTIFOLIA is very distinct in its leaves, the four leaflets of which are narrow and wedge-shaped at the base, whilst the apex (which in the type is broad and rounded) here tapers to a point. Originally found near Odessa, in South Russia.

C. JUBATA.—Being the most singular-looking of all the species, this is worth growing as a curiosity. The branches appear to the eye a confused mass of leaflets, spines and woolly hairs. The bark also is woolly and the stipules bristly. The leaf-stalks have spiny tips, and persisting after the leaflets have fallen, they become transformed into slender spines, which remain on the plant for some years. It does not make any show in flower, the blossoms being few and white, tinged with red. They appear in April and May. First introduced in 1796 from the region of Lake Baikal, in Siberia, it has since been found much further south in Mongolia, and even Afghanistan. It is a dwarf shrub, 1 foot to 2 feet high, and inhabits desert regions. Like some other shrubs that grow wild under similar conditions, it is not easy to rear from seed and grow on its own roots in the open ground. It thrives, however, at the base of a dry, warm wall. Plants intended to be grown without this protection may be grafted on *C. arborescens*.

C. MICROPHYLLA.—In this species the leaves are composed of some six or eight pairs of leaflets, and these leaflets furnish a distinguishing character in being, as the name suggests, smaller than those of any other species. They average about a quarter of an inch in length, are of elliptical outline, and a grey-green colour. The shrub itself grows 6 feet or so high, is wider than it is high, but still of graceful habit, the growths being long, slender, and but little branched. The yellow flowers appear in May, but so far as I have seen make but a meagre display. A native of the Central Asiatic region from Altai and Dauria eastwards to China, &c. Introduced in 1752.

C. PYGMEA.—Although scarcely a pigmy, for under cultivation at least it is 3 feet high, this is still one of the dwarfest of Caraganas. It is really a pretty shrub when well in flower, especially after such hot summers as those we have lately had in this country. It has a straggling, rather thin habit, the branches being long, slender, and half-pendulous. The leaves appear to be arranged at each joint in fascicles of four or eight, but there are really only one or two leaves, each consisting of four small, narrow leaflets half an inch or so long, and the stalks so short as to be scarcely discernible. The flowers are pendent and hang in long horizontal rows from the branches; they are a clear yellow, and appear in May and June. Nearly related and very similar to *C. aurantiaca* when out of flower, this can be distinguished by characters pointed out under that species. It is a native of Central Asia, and reaches from the Caucasus to the Himalaya and the Altai Mountains. Introduced in 1751.

C. SPINOSA.—Next to *C. jubata* this is the best armed of the Caraganas in cultivation. The leaves consist of two or three (occasionally four) pairs of narrow, wedge-shaped leaflets each half an inch to three-quarters of an inch long, and not averaging more than one-eighth of an inch in width. The most noteworthy character of the leaf is the stalk. This is stiff, and stands out beyond the terminal pair of leaflets in the form of a sharp spine. After the leaflets have fallen, this woody, spine-tipped leaf-stalk still remains to arm the plant. The shrub is 4 feet to 6 feet high, and has long, thin, crooked branches. The flowers are bright yellow. A native of Siberia. Pallas, the Russian botanist, observes that this Caragana is plentiful about Pekin, and that its branches are stuck in clay on the tops of walls to keep off would-be trespassers

—just as broken glass is used here. It does not, however, appear to be a native of China—at least Mr. Hemsley does not include it in his "Index Floræ Sinensis."

Arboretum, Kew.

W. J. BEAN.

THE WEEPING ASH.

(*FRAXINUS EXCELSIOR VAR. PENDULA*.)

THE common Ash is one of the most distinct and graceful, as also one of the most useful of all our native trees after the Oak, which, of course, has long held the first place in our national history. The Weeping Ash is merely a weeping form of the type, occurring naturally or by chance here and there both in England and Ireland, and probably elsewhere. The weeping variety appears to have become popular as a grafted plant in gardens towards the end of the last century, and one of the oldest, or at any rate largest and finest, specimens I ever saw is, or was, at Elvaston Castle, near Derby. There are also some very tall and remarkable grafted specimens at Castlewellan, Co Down, and elsewhere in Ireland. In reading the other day a rather rare old book entitled "A Narrative of a Residence in Ireland," by Mrs. Anne Plumtree, a quarto, published in London in 1817, I found on pp. 92, 93, and part of 94 the following account of the original tree in England, as also of others she saw in Ireland about the date mentioned, an account so interesting to all who are fond of ornamental native trees that no apology is needed for introducing it here, especially as but few people now-a-days have a chance of seeing the book from which the extract is made. It would be interesting to know if the original tree at Gamlingay, near Wimpole, Cambridgeshire, still exists, and its present state of health and dimensions.

Between Lurgan Green and Dundalk my attention was arrested by seeing in a hedgerow, among a number of Ash trees with which it was interspersed, two of the kind now well known in England as the Weeping Ash. One of these was of a great height, and was evidently a tree of many years' growth. It must have been much, much more ancient than the date when these trees came into general notice in this country. It had, however, been stripped of its long branches, and only a few young shoots were now growing from the top. The other was of a considerable size, larger than any I ever saw in England, the parent stock excepted. It is remarkable that this tree, now to be seen in almost all plantations, was scarcely known till within somewhat more than the last thirty years. At that time the existence of the parent tree, though then of a great age, was known to very few. Chance led to my becoming acquainted with it. It stands in the village of Gamlingay, near Wimpole, in the county of Cambridge, where a woman, who had been servant in my father's family, went to live with her husband. Seeing this woman occasionally, she talked to us very much of a great curiosity in their village, a Weeping Ash tree, and one day when some of the family were at the village, she took us to see it. It was then in a field close by a farmhouse, a large forest tree, the trunk growing to a great height, quite straight, without a shoot, and from the head the long branches hung sweeping to the ground, forming a perfect arbour within; it did indeed appear to us a great curiosity. She said that her husband had taken some grafts from it, which he had grafted upon common Ash stocks, and if the experiment should succeed she would request my father's acceptance of one. In due time one was brought and presented to him at his living of Wimpole, in Cambridge, and the man having been servant in Lord Hardwicke's family, another was presented to his lordship's steward to be planted in the grounds. These I have good reason to think were the first two known out of Gamlingay.

Since that time the breed has spread very much; but I believe it may with truth be affirmed that all are descendants in a direct or remote line from the same parent. The dispersion of the family has brought the parent into more notice, and occasioned investigations to ascertain if possible its origin and age; but the oldest people in the place, one man eighty-eight years of age, could only say that he remembered the tree ever since he was a boy and always a large and well-grown one. The last time I saw it was about three years ago. A very neat, small house had been built close by it, where lived the curate of the parish, and the tree was enclosed in his garden; he had rescued it from the axe, to which it had been sacrilegiously doomed. It was not in so great beauty as when I first knew it; one side had suffered exceedingly in a hard winter, and so much had died, that on that side the arbour was quite laid open; on the other side the branches hung with as fine and majestic a sweep as ever. A remarkable thing is that if the seeds of this tree are sown they come up common Ash trees; the only way of propagating the species is by grafts. The same casualty that first produced this tree must probably have operated to produce those in the hedgerow on the Dundalk road, but no such chance as that I have mentioned ever drew these into the same notice; they seem to stand here wholly unheeded.

F. W. B.

ORCHIDS.

PESCATOREA CERINA.

WHEN well grown and flowered this is one of the most charming Orchids in the section to which it belongs, and though considerable care is undoubtedly required in its cultivation, there is no reason why it should not be included in every amateur's collection. From a tufted mass of leaves the flower-scapes are thrown up and each bears a single blossom about 3 inches across, pale yellow, with a circular crest to the lip, which is marked with brown and purple lines. When commencing their culture a little thought should be given to the habit of the plants. They are quite bulbous, and an examination of newly-imported specimens will show that they do not grow naturally where there is any great accumulation of *débris*, but rather on the bare portion of a tree branch or on the face of Lichen-covered rocks. These circumstances point to a thin compost being needed, and the absence of pseudo-bulbs shows that they do not require any long season of dry rest. This has proved to be the case under cultivation, but still the roots require a good deal of sustenance, and anything like bare block treatment will not do. The compost most likely to suit them is one that allows of frequent moistening without any danger of souring, and that holds moisture enough for the needs of the plants, but not to excess. Fibrous peat and fresh Sphagnum, with large lumps of charcoal and ballast, do this, and only about an inch of this is necessary for small plants, larger ones requiring a little more thickness. An important point, and one that in potting Orchids is too frequently lost sight of, is firming the plants so that they cannot sink. I have seen many plants of this and similar kinds looking very unhappy for this very reason. Spreading laterally as they do, the centre of the plant easily gets lower in the compost than it ought, and I have seen good results by fixing the plants to rough blocks of wood and placing these in pots, simply filling around them with the compost. As to temperature, the *Cattleya* or the East India house may be chosen, the latter if the *Cattleya* house is very large or light, as *Pescatoreas* like a snug, moist corner where actual sunlight never reaches them without, as it were, being filtered by the interposition of

other plants. A little consolidation is needed in autumn and just then a little more light than usual, a slightly drier atmosphere and more air may be given. Water in plenty is an absolute necessity to them while growing, and it is for this reason that the light make up of compost is safest, though I have seen loam used for them successfully. In winter when evaporation is slower less moisture is needed, but even then the roots must not be much dried. H.

Chysis lævis.—This pretty plant I noticed in good condition recently, and it is one of the finest in the genus. The stems are pendent, and the young growths proceeding from them produce fine, handsome racemes with eight or nine flowers on each. The sepals and petals are orange-yellow, the lip yellow, with spots of crimson and a fine showy crest. *C. lævis* is a native of Mexico, and during the growing season delights in ample moisture and heat with cooler treatment during the resting season.—H.

Disa grandiflora Borrelli.—This variety differs from the typical *D. grandiflora* in having the sepals of a much brighter more scarlet tint, with a lighter tinted lip. It was introduced by Mr. W. Bull, of Chelsea, some years ago. The plant thrives under exactly the same conditions of culture as the type, and, like it, must be kept clean and free from thrips. Air and moisture, combined with a low temperature and shade whenever the sun is bright enough to harm the foliage, should be allowed; a rather loose, open compost of growing Sphagnum and peat fibre with ample moisture at the roots being also necessary.

Angræcum Scottianum.—This *Angræcum* is very distinct and worth a place in all collections. The stem and leaves are terete and the flower panicles bear but few blooms, these being yellowish-white in the sepals and petals, the lip pure white in front, the spur having a reddish tinge. *A. Scottianum* thrives in the hottest house in baskets or pans kept in a light position, and during the growing season the house should be reeking with moisture and the roots kept well supplied. It is a native of the Comoro Islands, and though very rare for some time after its introduction in 1878, it is now more generally grown.

Cypripedium Exul.—The flowers of this pretty species do not vary so much as those of *C. insigne*, which it much resembles both in habit and flower, but there is a certain amount of variation. At Ickworth there is now a very beautiful clear lemon-yellow form with few spots on the dorsal sepal, and these of a deep purple. It seems to bear the same resemblance to the type as the montanum varieties do to *C. insigne*. The great fault of *C. Exul* is its somewhat shy-flowering habit, and it is not at all unusual to see large well-grown plants with only one or two blooms. Anyone who has it flowering really well would be doing a favour by recording particulars of treatment followed.

Schomburgkia tibicinis.—Although in many cases this plant is not particularly free-flowering, it may usually be induced to throw up spikes by thoroughly ripening and hardening the growth and keeping the plants on the cool and dry side in winter. The plant in habit, manner of flowering, and the shape of the blossoms is a good deal like *Lælia superbiens*, to which it is doubtless nearly related. The roots are freely produced when the plants are healthy, and like a rough, open description of compost in rather large pots. The spikes rise in summer, and are apt to be covered with a gummy exudation, possibly a natural protection to the flowers from crawling insects that may affect their fertilisation.

Dendrobium nobile Cooksonianum.—Although this variety is very striking and effective it cannot in my opinion compare with many others for beauty. The dark blotches on the petals give the flower a rather heavy appearance that is

noticed more on a well-flowered stem than in individual blooms. The plant is fairly plentiful and easily obtained, and its culture does not differ in any material particular from that of the typical *D. nobile*. It originated as a sport in a north of England collection, and though fairly fixed will occasionally throw flowers out of character. Such a case I noted in a neighbouring collection recently, a fine stem carrying a score or more of true *Cooksonianum* flowers with a few smaller ones below, not exactly of the ordinary type, but quite distinct from the others, the segments having the normal position and being much lighter in colour.

Cymbidium eburneum.—There are a chasteness and purity of colour about this Orchid not seen in any other *Cymbidium*, and it deserves all its popularity. At first the habit is almost like that of a *Vanda* or *Aerides*, but eventually the stem

Stanhopea oculata.

thickens at the base into a stoutish pseudo-bulb. The lilac-scented blossoms occur upon erect spikes at the axils of the leaves and are ivory white with the exception of a few spots and a yellow stain on the lip. *C. eburneum* is one of the easiest of Orchids to grow, and though often found thriving in a cool house will not fall out with warmer treatment, provided it is accompanied by proper ventilation and ample atmospheric moisture. The practice of damping with soot or manure water instead of clear is especially helpful to these Orchids with large green leaves. The compost ought to be of a substantial quality, a good percentage of sound fibrous loam being mixed with the peat and moss. During the summer, healthy well-rooted specimens require a large amount of moisture, but in winter when comparatively speaking at rest much less suffices, though even then the roots must be kept moist.

STANHOPEA OCULATA.

THIS is certainly one of the finest of *Stanhopeas* and a very beautiful Orchid. It may be easily grown by anyone having plenty of heat at command and a moist atmosphere, this latter being particularly necessary on account of the plant being so liable to attacks of red spider. It does best suspended close up to the roof and lightly shaded, in which position the plants get hard and flower freely. If insects do attack them, they will not do so much harm as to plants growing in heavily shaded positions whose foliage is softer and more easily punctured. The wire basket has long been the favourite receptacle for *Stanhopeas*, and nothing that I know of is likely to supplant it. Well made, of good stout copper wire, with fairly large spaces between the wires, it is rigid and lasting, conducive to cleanliness and in all ways suitable. For compost use a little loam fibre and good clean Sphagnum Moss, placing large pieces of charcoal or crocks in the bottom and sides to facilitate the passage of the spikes. Water freely all the year round, sprinkling the foliage frequently with tepid water while growth is active. Though *S. oculata* is even now only occasionally met with, it has been in cultivation nearly three-quarters of a century, having been introduced in 1829. H.

Masdevallia Carderi.—This species is very pretty when well grown, and quite distinct from any other known kind. The flowers are produced on semi-pendent spikes, and in colour are a pretty combination of yellow, white, and purple, the lip and petals being, as usual, inconspicuous. The plant does best in a basket suspended in the coolest house during the summer months where ample moisture is kept up in the atmosphere, and if in winter the temperature is kept up to 50° and ample light afforded, it may remain the whole year round.

Oncidium dasystyle.—This pretty little species I have noticed blooming freely this week, and the wonder is that it is not more grown by lovers of curious and pretty Orchids, for the flowers are both showy and interesting in structure. The peculiar likeness to the Bee Orchid is more apparent in some plants than others, the purple tint in the lip callus varying greatly. The spikes appear at the base of the last-formed bulb and bear several small yellow flowers with the purple marking described. It likes a position not far from the roof-glass, and the rooting medium should be free and open without being very extensive. Some growers do it well on blocks of Tree Fern. The intermediate house is best for it.

Stanhopea graveolens.—This is one of the prettiest of the *Stanhopeas*, and less common than most. I noticed a nice plant flowering recently, the scent from the flowers filling a large stove in which it was grown. The species is of vigorous growth, clean-looking, and with lighter pseudo-bulbs than usual, the colour of the blossoms a pretty light yellow on the sepals and petals, merging into a bright apricot-yellow on the lip. The blossoms occur on two or three-flowered scapes in the downward direction usual in the genus. A brisk moist heat, with ample light and not too frequent disturbance of the root, suits it best. *S. graveolens* is supposed to be of Guatemalan origin, the earliest record of its flowering being in 1840.—H.

Arpophyllum giganteum.—A well-flowered plant of this species is very ornamental, though quite different from the majority of Orchids. The flowers are borne on loose spikes and are rosy purple. So very free-flowering are the plants that large specimens bloom from every shoot, and a very handsome plant is thereby produced. Its culture is extremely easy, yet in many places the plants are almost killed by neglect. It grows naturally on trees in localities where collectors

state that the wind is extremely rough at times, yet the *Arpophyllums* thrive in the most exposed places. This shows that the roots are very strong, and it will be found under cultivation that growth is stronger when the latter are given a semi-terrestrial make-up of compost rather than a mixture such as suits epiphytal plants generally. The best place to grow the plants is on a light stage not far from the roof-glass in the *Cattleya* house. It does well when the top of the plant is within a foot or so of the roof, and needs very little shading. The *Cattleya* house is the best, but it is not a fastidious plant, and will often thrive in a vinery at work or in an ordinary stove. No drying off is necessary. A little pruning of the older stems improves the plant's appearance and allows the light to reach the young growths. Large pots are required for specimens, and these should have the drainage very carefully placed.

AUTUMN-FLOWERING ODONTOGLOSSUMS.

ALTHOUGH there are other kinds in this favourite genus that flower in the autumn, the section containing *O. grande*, *O. Insleyi* and similar kinds are those which are usually looked upon as autumn flowering. A strong family likeness runs through all these species, though each has its distinctive marks and its likes and dislikes. Taken all round, they are much the easiest of *Odontoglossums* to grow, and of *O. grande* I may say that the finest specimen I ever saw was grown in quite a mixed collection of greenhouse plants where no special attention was given to Orchids. For a cool fernery there is nothing among Orchids more suitable than these *Odontoglossums* and *Cymbidiums* of the *giganteum* and *Lowianum* types. Where even a fairly moist temperature is kept up in a greenhouse during winter, these plants may be turned out into a frame in the hottest summer months and successfully grown. It is no uncommon thing to see such kinds as *O. crispum* and the like advertised as plants for an amateur's greenhouse, easily grown in the greenhouse, &c., when everyone who knows them is perfectly well aware that without a house that is properly suited to their requirements the percentage of successes will be very low, and that an amateur's greenhouse as usually understood is about the last place where one would try to grow them.

The autumn-flowering kinds, on the other hand, are not so easily incommode by slight deviations from the ideal treatment, and are far more likely to succeed under adverse conditions than those with which I have compared them. They have a beauty distinctly their own; the flowers are, of course, less chaste-looking than those of *O. crispum* and *O. Pescatorei*, but they are remarkably handsome and distinct from everything else in the floral world. They last even longer than those of the *crispum* set without injury to the plants, for though, as a matter of fact, the latter hang on the longest, it is at the expense of their own substance and the health of the plants. The former may be left on as long as they will last without any fear provided the plants are healthy and the roots kept moist. The best known kinds in this section are *O. grande*, *O. Insleyi*, and *O. Schleiperianum*, and if a good number of plants of these three and their varieties are grown, they will flower from August until quite late in spring. As mentioned above, they are not fastidious as to temperature or structure, but the conditions they like best are mentioned below, and these should be followed as nearly as possible. From the end of May until the beginning of September it is impossible in an ordinary summer to keep them too

cool and shady. The atmosphere should be heavy with moisture, and the plants screened from the sun from 8 o'clock in the morning until 6 at night. Night and day the air should be freely admitted—through the lower ventilators as much as possible—so that the leaves of the plants are often blown about by the air currents. This will ensure a good and clean start, and by the time the sun begins to lose power in autumn, the young growths on *O. grande* will be getting well away and probably beginning to show flower-spikes. Just where these show there are loose sheaths and the top of the growth may be open, so that water is apt to collect there. For this reason it will be safest to stop syringing overhead, though at almost any other time this is useful when the weather is bright. The pots used may be of fairly large size, as the roots are apt to push further from the centre of growth than are those of many other *Odontoglossums*, and the compost, too, should be very rough and open. Root moisture is necessary all the year round, the most being required just when the bulbs are finishing and the flowers forming. Good peat fibre, with half its bulk of *Sphagnum Moss*, is the best for these Orchids, and the drainage must in all cases be carefully attended to. As hinted above, there are many varieties of each of these species, *O. grande* having several that bear much larger blossoms than these of the type and of brighter colour. *O. Insleyi*, again, is variable, some of the forms being very cheap and easily obtained, while others are far from plentiful. *O. Schleiperianum* has many colour varieties, so there is no fear of sameness, and all are beautiful Orchids.

Warscewiczella Wendlandi.—In this we have one of the most attractive in the genus to which it belongs. The growth is fairly strong, and the flowers are each upwards of 3½ inches across, of a chalky white tint except the lip, which is prettily marked with a bluish purple. In positions where it succeeds nothing is prettier at this time of the year, but, having no pseudo-bulbs to sustain it during a period of rest, it naturally requires very judicious watering, more especially in winter. Again, with regard to the roots. I know of a collection where a large quantity of loam is used in the potting compost, and the way the white, fleshy roots luxuriate in it proves that it is just to their taste; but, again, unless a really vigorous root action takes place the loam would be simply poison to the roots. A strong plant enwraps the loam and the roots get the mastery of it, as it were, but a weak one would simply die from want of moisture or else be overcome by its closeness and the want of air. A little loam added to the usual peat and Moss will, as a rule, be safest and best for inexperienced growers to use, and the best position for the plants is one not far from the roof-glass in a shady, moist house with an intermediate temperature.

Dendrobium d'Albertisi.—None of the *Dendrobiums* with the habit of this species are easy to grow, and this is no exception to the rule, though one occasionally comes across good specimens of it. The plants like ample light, in this coming near the species of another section, like *D. Phalenopsis* or *D. bigibbum*. It is not so tall-growing as *D. stratiotes*, and this fits it better for basket culture, though when the plants are in flower they must come down. Over-watering at the roots during early summer is, I am convinced, a frequent cause of failure with this and many others of the section that do not, as a rule, make much root or top growth at that season, and if only growers would study their plants and take note of their peculiarities, instead of treating all alike, they would not be nearly so apt to fall into these mistakes. *D. d'Albertisi* is not particularly strong-rooting, and it is best when establishing

plants, to do so in as small baskets as possible. It is easy enough to shift this entire into one of a larger size, but when given too large a size at first, the plants often fail to establish themselves, as they cannot reach the sides. The flowers of this species have long, twisted, emerald-green petals, sepals pure white, and a white lip with magenta-purple markings.—H.

DENDROBIUM FORMOSUM.
