Primula obconica fimbriata.—There is little doubt, I think, that this improved form will largely take the place of the original kind for pots and for general decoration. Having a somewhat bolder spike and larger individual

blossoms, there is no doubt about its superiority. That this species should so long have resisted all attempts at hybridising is remarkable, and which is but intensified when it is remembered that in colour and somewhat in form the plant varies when raised from seed. Even in the habit there are slight differences, some of the plants being decidedly more compact than others. In some flowers I have seen there is an indication of the star-shaped centre that alone attracts attention. What is of great importance in this kind is its comparative hardness, its free-seeding capabilities, and not least its perpetual flowering. Once a break is effected, the present barrier will be broken and some strange kinds may result.—E. J.

Rose Souvenir de la Malmaison.—A characteristic of this much-admired Rose is that it dislikes the great heat of summer, and good flowers under strong sun-heat are rare. When, however, cool nights replace the intensely hot and stuffy ones and refreshing dews put in an appearance, the flowers of this Rose improve. More recently formed buds grow apace, and sometimes handsome trusses adorn quite old plants of this kind. This has not been so general an experience this season, by reason of the absence of moisture either from the rainfall or from dews, though a few good blooms have appeared here and there. Only a few days since, notwithstanding the touch of frost on more than one occasion, some good blooms and quite a batch of prominent buds were noted in a large garden. This kind was, however, quite alone in this respect.

Saxifraga Cymbalaria.—In addition to *Alyssum maritimum*, which you mention as a late carpet plant on page 348, one may perhaps be allowed to suggest the yellow-flowered *Saxifraga Cymbalaria* for the same purpose. In my garden I have now in bloom what one may call the second crop of this bright little Rockfoil. The plants now in flower are the progeny of the seeds produced by plants which bloomed earlier in the year and which have not been long cleared away after their work was done. The plants now in bloom are less than an inch high. Those who do not know this little Saxifrage will do well to make its acquaintance by procuring a packet of seed in spring and sowing it where it is intended to bloom. Before long they will be rewarded by its little glossy Ivy-shaped leaves and its bright little yellow flowers. It sows itself so freely that one introduction is usually quite enough to ensure its establishment in a garden. It flowers quite well in the sun, but prefers, I think, at least partial shade with a fair amount of moisture.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Dracæna Sanderiana viridis.—Quite recently a plant bearing this name was noted at the Drill Hall, the plant being also presented to the floral committee for its consideration. The plant in question obviously claims parentage with the well-marked *D. Sanderiana* with variegated leaves, possessing the same prolific root-stock and the same identical habit. Indeed, the leaf coloration is the one point of difference. It is a difference, however, that should mete out a very considerable value to the plant, which to all appearance is capable of enduring much hardship. Only a single pot plant was shown, and from this some half dozen equal sized growths arose. So far as the exhibit alone is concerned, the subject is not an impressive one, but knowledge of the more familiar kind suggests a considerable value for the above plant. No tidings, we believe, were forthcoming as to whether the green form has been so imported, or whether it is but the variegated reverting to the more probable normal condition of the plant. Be this as it may, there was no indication of the slightest variegation in the plant referred to.

Linum flavum.—While we have almost a surfeit of yellow flowers in some of the autumn months, it cannot be truly said that we have too many of that colour when November comes in. At this time, indeed, flowers of any colour in the open garden are too few for us to be able to say

that any hue is too prevalent. One thus appreciates highly the golden yellow flowers of *Linum flavum* which have been spared to us, even though the want of sun or the weakness of its rays does not cause them to open as in the brighter months. Even the closed blooms look attractive high up on the rockery. One hears at times of this yellow Flax not being hardy. There are some gardens in which it does not stand the winter well, but if it has a sheltered position rather above the ground-level in a dry and light soil there is not much fear of it in ordinary winters. Some of the plants in this garden are several years of age. They come away from the base in spring if the frost has cut them down so far. It seeds freely here, and generally some of the seedlings produced have to be thrown away. Good-sized plants of *Linum flavum* are very pleasing in summer, and though less bright now, are yet appreciated.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Pyrethrum uliginosum.—While the Moon Daisy has the fault of being rather too tall for the time at which it flowers with us, it is a plant which can hardly be dispensed with by those who want outdoor flowers as late in the season as possible. Some plants of tall growth may be reduced in height without sacrificing the flowers by cutting them down when they have made a portion of their growth. *Pyrethrum uliginosum* does not, however, lend itself to this treatment as some other plants. This is due to its late-blooming habit, as cutting back delays it still further. Apart from other considerations, the height of the plant is a disadvantage, because of elevating the flowers to a position in which they are more exposed to the cold winds of the season, and thus more likely to be destroyed. A day or two ago I saw several long lines of this plant in gardens in one of our south of Scotland towns. The day was inclement and the appearance of the Moon Daisy was far from attractive under those conditions. Yet it could not be said that they were not worth growing, as it only needed a bright day or two to make many of the blooms quite fit for use as cut flowers. It is, of course, not everyone who cares for the blooms of *Pyrethrum uliginosum*, with their white rays and their greenish-yellow discs. They are, notwithstanding, flowers not to be despised.—S. A.

Victoria regia flowering in the open.—To answer to your correspondent "F. W. B." as to the flowering of the *Victoria regia* in the open air, I will look up my print of the plant in flower, published in the *Field* about twenty-five years ago. Meanwhile I may just say that the plant was flowered in an open tank at Behington, Cheshire, in the garden of Mr. Joseph Mayer, F.S.A., a relative of mine. I superintended the culture, and there was no glass or covering from the time when the small 4-inch plant was planted from the greenhouse. It flowered splendidly and the heat was never more than 75°, and not often so much. The year before I had grown the *Victoria regia* in my garden in the Lake district, where we have little sun and much rain. It budded, but owing to an accident, it was too late to flower before the September cold set in and checked it. I had no cover, and wind, not cold, was the worst enemy. The largest leaf was 5 feet 4 inches across, and ought to have been much larger. Coal and coke for the season with a large tank cost about four guineas. I had all the tropical Lilies with *Euryale ferox*, *Nelumbiums*, &c. I saw Messrs. Weeks' place in Chelsea. It was a tank in a courtyard, and I was told a cover was put on every night. I do not know whether it flowered, but there is no difficulty with fair conditions. Last year *N. stellata* flowered freely in my open pond in summer, no heat; put in in May, died in winter.—H. B.

Clorodendron trichotomum.—The notes on "Flowering Shrubs in South Devon" by your correspondent "S. W. F." are always of interest, and often afford one much valuable information in a pleasant way. One is at times a little envious of those who dwell in such a favoured region and who are thus able to grow plants denied to us in the north. Still, though we have to regret our inability to grow some things, we can none the

less enjoy the way in which your contributor talks of these shrubs in the sunny south. Among those spoken of on p. 342 is *Clorodendron trichotomum*, a fine shrub which is, so far as one knows, of no use as a flowering shrub in Scotland. There may be one or two places on the west coast where it will bloom; if so, I have not heard of them, but the climate is such that one or two favoured spots might be warm enough to bring it into flower in a warm season. I know several Scottish gardens in which it has been and still is grown, but in none of these has it ever bloomed. These gardens are in districts widely scattered, and it is a little disappointing to those who have this *Clorodendron* to have year after year the same unvarying record of "no flower." Even near Dublin, in the sister isle, one was disappointed to hear of non-success in places where one would have expected better results. I do not know any northern gardens in which the other species named by "S. W. F." (*C. Bungei*) has been tried. It may, perhaps, be happier in the north than its congener, but I doubt it.—S. ARNOTT.

Aster John Wood.—By a strange coincidence I was engaged in writing a note upon this *Aster* for your columns when the issue of *THE GARDEN* containing the news of the death of Mr. John Wood arrived. Although I never had the opportunity of meeting Mr. Wood in person, we had some correspondence, and, in common with many others, I have profited largely by his writings on hardy flowers. I may, therefore, be permitted to join in the expression of regret made by the correspondent who conveyed the news of the decease of Mr. Wood to us. An observer so keen and so well informed will be sadly missed in the ranks of admirers of hardy flowers. Many who grow the *Starwort* identified with his name will look upon it with fresh interest as a flower pretty in itself which will ever be associated with the memory of one known to us, if not in the flesh, by writings which have given true pleasure. Even had *Aster John Wood* not this association it would deserve a place in the garden on account of its own merits. It would be rash, in view of the progress in the *Asters*, to say that it will remain the best of the white *Starworts*. It will, however, be long grown as a flower of great beauty and usefulness in the garden and for cutting. Those who do not know it may be glad to have it brought under their notice and to have a brief description. It belongs to the *Novi-Belgii* section of the *Starworts* and grows about 4 feet high. The flowers are large and handsome, rather cupped in shape, and when at their best pure white, with a yellow disc. They pass off, like other whites, slightly pink. It is a valuable plant no one who likes the *Starworts* will regret growing.—S. ARNOTT.

Callistephus hortensis.—The note published in last week's *GARDEN*, p. 348, is both incorrect and misleading. Commenting on the plant introduced from China by Messrs. Vilmorin and Co., Paris, and described in their catalogue for this year as the "single large-flowered China *Aster*, new," and of which a coloured plate was published in *THE GARDEN* last year, the writer of the note states that "large business houses of repute will doubtless take some trouble to make it clear to their patrons" that this single *Aster* is the same as the weedy single-flowered reversions called "rogues," which too frequently come among the double-flowered forms. It is also stated that there are several colours of single forms to be had from seeds purchasable for a few pence, and that a good show of them has been made at Kew this year. Where are these seeds to be had? I have never seen among the "rogues" in *Aster* beds anything approaching even in form, stature, or colour the types as represented in *THE GARDEN* plate. I am certain that none of these coloured forms were to be seen in the border at Kew, the only single *Asters* grown there this year being Vilmorin's introduction, viz., typical *C. hortensis*. The note contains one statement only which is in accordance with facts, namely, that this single *Aster* made a "good show at Kew, the free-flowering of the plants being quite noteworthy."

It is too absurd to suggest that Messrs. Vilmorin, the greatest breeders of and dealers in *Asters*, as well as being a firm of "repute," would send out as new a plant which was simply a rogue, and that the *Botanical Magazine* as well as all the horticultural journals should publish pictures and special notices of it as being a worthy addition to garden flowers.—W. W.

PUBLIC GARDENS.

CHRYSANTHEMUMS AT VICTORIA PARK.

THE collection of *Chrysanthemums* at Victoria Park embraces all types of the flower, and consequently exercises a useful influence upon the minds of the many thousands of visitors which throng the large glass structure during the flowering season. Growers in more favoured localities have not the faintest idea of the difficulties which they at Victoria Park have to contend with. Impure atmospheric conditions, which must of necessity be associated with factories of all descriptions, and from whose chimneys soot and smoke are continuously emitted, cannot be conducive to the good health of plant life, and in the present instance of *Chrysanthemums* in particular. Incurved varieties have always been a special feature of the collection here, and probably the most pleasing sorts of those almost fully developed were Mrs. George Rundle, George Glenny, and Mrs. Dixon, all members of the same family. These plants were freely flowered. Other representative incurved sorts were Chas. H. Curtis, the large yellow, rather late in this instance; M. R. Bahuant, a large globular flower, carmine-rose, with deep bronzy reverse, and early; Lord Rosebery, a pretty silvery mauve, lined white, of good form; Baron Hirsch, on late buds deep chestnut-bronze; and numerous plants of D. B. Crane. This is a very neat rich bronzy buff bloom of good form and true incurved petal. The plant also is very dwarf. Those mentioned will suffice to show that both new and old varieties are appreciated. The Japanese sorts, of course, were largely in evidence, and the most interesting feature of this display was the varied character of the blooms representing this section. Flowers of bygone days, such as Margot, salmon-pink; Fair Maid of Guernsey, a popular white many years since; Stanstead Surprise, reddish purple, tall; William Holmes, brilliant crimson; Sunflower, rich yellow; Mlle. Lacroix, white; Gloire du Rocher, rich glowing crimson of neat form; President Borel, carmine-rose; Pallanza, rich yellow, and others were representative of the older varieties.

Those of more recent days were Mrs. E. G. Hill, having large blooms of pale flesh colour; Mrs. C. Blick, a very large pure white; Werther, a distinct claret-red; President Bevan, rose, shaded yellow, incurved Japanese; Mlle. Paul Lacroix, a beautiful soft yellow; William Seward, deepest crimson, very free and effective; Royal Standard, a deep blood-red colour, long florets, making a large spreading flower; Le Grand Dragon, deep yellow, tinted bronze; Mme. Couvat du Terrail, very large, creamy white; N.C.S. Jubilee, a pleasing silvery rose, incurved Japanese; Hairy Wonder, distinctly the best of the type; General Paquie, a rather flimsy bronze flower; Marie Calvat, and a grand batch of the pure white incurved Japanese Lady Byron. The blossoms of these plants were of a high order of merit. Another feature is that of growing a nice lot of decorative sorts, and under this heading were to be found pretty plants of Rycroft Glory, the October-flowering bronzy yellow. Others in splendid form were Lady Selborne, white, and James Salter, mauve-pink, still to be numbered among the freest and the best; the popular old gold flower, Source d'Or, and Margot, also grown freely. These were dotted about between the large-flowered plants and added considerably to the display. Singles were represented by such varieties as Mary Anderson, cream-white, still one of the best; Anemones, by the rich reddish crimson Descartes, which always looks very hand-

some for a week or two, besides other types of the flower in endless variety. The plants are arranged in two large undulating groups in a long glass structure with a raised pathway between them. This has the effect of hiding the pots and bringing the flowers well within the line of sight, thereby adding very materially to the pleasure of the visitors. To keep the display going for some time, a temporary structure outside shelters numerous plants for succession, and as the period of flowering is quite a fortnight later than usual, it will be quite another month before the display will be over.

SOUTHWARK PARK.

THE display of Chrysanthemums in Southwark Park is generally interesting, considering the adverse circumstances under which they are grown, the neighbourhood being a densely populated one and the smoky districts of Rotherhithe and Bermondsey so closely adjacent. In spite of these difficulties, Mr. Curle, the superintendent, always makes a good display, and one that is much appreciated by the residents and visitors. It will be at least a fortnight before the collection is at its best, but the plants are all coming on well and there are many fine buds of the most popular sorts rapidly opening, among which are Silver King, Duke of Wellington, Olive Ocleo, Australie, Mme. C. Audiguier, International, W. H. Lincoln, Eda Prass, Lady Byron, C. Orchard and others of equal merit in the Japanese section. At the time of our visit the large-flowering Anemones were not largely represented, the best being Descartes, a fine wine-coloured variety, very useful and judiciously employed in groups, such as the one now under notice. M. C. Lebocqz was also coming on in very good form. We missed, too, the interesting collection of hairy varieties which formed a peculiarly striking feature a few years ago, but which no doubt will be seen by later visitors. Incurved can only be seen at their best as the season advances, but R. Cannell, a fine large-sized flower of golden yellow-bronze; Baron Hirsch, very close, compact, deeply built, of a good colour; Duchess of Fife, pure white and very regular in build; Globe d'Or and D. B. Crane, of varying shades of yellow, are all well out and lead the way. M. R. Bahuant, very fine and globular, colour deep rosy carmine or maroon, is another of the early ones in this section.

Among Japanese that are conspicuous for their colour are Hamlet, a very old, but very beautiful flower of the Japanese section, and the colour a deep shade of soft rosy salmon, and H. Shoemsmith, yellow, with long drooping florets. Sun-flower, an old favourite, deep golden yellow, and Mrs. J. Shrimpton, deep orange-yellow, shaded crimson, are equally attractive. Oceana, the fine yellow colonial incurving Japanese, deserves special attention, as do also Lizzie Seward, bright rosy magenta, and Gambetta, a deep fiery terra-cotta, shaded crimson. Very useful and effective for its warmth of colour is Gloire de Mézin, a fine globular Japanese of a deep golden orange, shaded bronze. Then there is the old-time favourite, Elaine, whose snowy white always seems pure and chaste and generally commands admiration. Emily Silsbury is larger, but of the same colour, while Mlle. Marie Hoste is less beautiful, the colour not being so pure, but its size seems to commend it. There were also some very bright blooms of the pure pale yellow King of the Hirsutes, which, as its name implies, belongs to the hairy section, and amongst other old-established favourites at Southwark we again noticed some good samples of J. H. Runciman, rich golden yellow, shown in several examples. Mme. Ed. Rey, pale pink, but very large and tall, is useful for its earliness. L'Ami Etienne is another. A very pretty bright rosy pink is found in William Tricker, and for depth of colour in purples, Stanstead Surprise is at once useful and effective.

The plants are arranged in a T-shaped house in form of a central bed, with a bank running

round the sides, thus giving a path that enables the visitors to go right round the house without fear of confusion.

Closing of Coldfall Wood.—Great regret is felt at Muswell Hill and East Finchley at the decision of the Ecclesiastical Commissioners to close the Coldfall Wood, which is situated to the north of Fortis Green, and is a remnant of the old Middlesex forest. A road is now being made through the wood, and it is apparent that it is to be "developed." Though the wood was never open to the general public, a large number of residents were privileged to use it, and on their behalf Mr. Phillips, a local resident, recently forwarded a petition to the Ecclesiastical Commissioners asking them to reconsider their decision.

SOCIETIES AND EXHIBITIONS.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE floral committee of this society held a meeting at the Royal Aquarium, Westminster, on Wednesday, October 25. There were some very fine exhibits, among which may be mentioned Ada, a large Japanese of a golden bronze shade; Miss Lily Boutroy, also of good size; Mrs. Burgess, a pretty shade of salmon-purple with golden reverse; Mme. Gabriel Debie, a very large white Japanese; and Miss Elsie Fulton, also a large white Japanese. Several of these the committee desired to see again. Awards were not numerous, the standard now-a-days being a high one, even considering the great number of fine novelties that are appearing every year.

First-class certificates were awarded as under:—

CHRYSANTHEMUM MRS. A. H. HALL.—This is a very fine, massive built flower, large and globular, with grooved florets of medium width; colour deep orange-yellow, shaded golden bronze. Exhibited by Mr. R. Kenyon.

CHRYSANTHEMUM FLORENCE MOLYNEUX.—This is also very large, and is a close, compactly built flower of great substance. The florets are twisted, of good width and grooved. The flower belongs to the Japanese incurved section. The colour is white. From Mr. N. Molyneux.

CHRYSANTHEMUM EDITH PILKINGTON.—A Japanese with long drooping, medium-sized florets, which are twisted and curly. The colour is a pale shade of canary-yellow, deepening towards the centre. Staged by the same exhibitor as the preceding.

CHRYSANTHEMUM MISS GODSMARK.—An incurved of close and regular form, with a good breadth of floret, rather large in size, and the colour bright reddish chestnut-bronze. This came from Mr. R. Owen.

CHRYSANTHEMUM MISS ALICE BYRON.—A noble Japanese flower of great dimensions, very globular and deep in build, the broad florets closely and compactly arranged. Colour pure paper-white. From Mr. H. Weeks.

On Wednesday last, the 1st inst., a meeting of the floral committee of this society was held at the Royal Aquarium, Westminster, Mr. Harman-Payne occupying the chair. Several promising novelties were submitted: Miss Adelaide A. Cooper, a large Japanese of a pale rosy mauve; Mrs. Bagnall-Wild, like a Pink; Mrs. H. Weeks, and one or two others. Only one award was made, viz., first-class certificate to

LADY TEMPLE.—A very pretty Japanese Anemone with several rows of ray florets and a good disc; colour soft reddish terra-cotta. From Mr. R. Owen, Maidenhead.

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, November 7, in

the Drill Hall, James Street, Westminster, 1—4 p.m. A lecture on "Some of the Plants Exhibited" will be given by the Rev. Prof. G. Henslow, M.A., at 3 o'clock.

The Royal Gardeners' Orphan Fund.—At the usual monthly meeting of the committee, which took place at the Horticultural Club on the 27th ult., the following special donations were announced: Wimbledon Horticultural Society, sale of flowers, £6 10s.; Sandringham Estate and Cottage Garden Society, per Mr. Mackellar, £5 5s.; Betchworth, Brockham, and Buckland Horticultural Society, £4 6s.; the Rev. A. Lowe, The Vicarage, Rangemoor, Burton-on-Trent, harvest collection, £4 10s.; Mr. A. D. Christie, half of the amount collected through throwing open Ragley Gardens, Alcester, to the public, £2 9s.; one-third of the amount realised by the sale of fruit at the annual exhibition of art and technical work in connection with the Worcestershire County Council, £1 17s. 4d.; sale of flowers at Chislehurst show, per Mr. J. Lyne, £4 6s. The annual general meeting of subscribers was fixed for Friday, February 16, 1900.

A Quick hedge (A. C. N. C.).—Plant your Quicks as soon as possible. Dig the ground at least one good spade deep and plant either in a single or double line, as you please, but if single, plant about 4 inches apart, and if double, a little wider. Trim the tops of the Quicks back about half way before planting and see that the roots are well covered. Not much growth will be made next year, but in the autumn of the second year trim the Quicks in again, leaving from 6 inches to 9 inches of top, and in future years cut in moderately, according to vigour, with the hedge-bill till the hedge is of the height and density you wish it to be. On no account ever dig along the bottom of the hedge, but simply keep weeds and tall grasses down. Five feet is a good height for a railway hedge and 4½ feet will do, but a hedge will require more than five years to reach that height if cut annually so as to secure the proper density at the same time. Without cutting I have seen Quicks reach 5 feet in less than five years, but a good bottom is not got in that way. If your foreman cut 18 inches off your five-year-old hedge after you had already trimmed it he took too much, unless his object was to cut back to cause the bottom of the hedge to thicken up. If the hedge has been properly managed it should by this time be about 18 inches through at the bottom and dense to the top.—S.

ORCHARD AND FRUIT GARDEN.

ADVANTAGES OF ROOT-PRUNING.

WHERE the heads of fruit trees are confined to a limited space, it is obvious that by cutting the shoots back each season the growth made the following spring will be stronger than that of the preceding one unless something is done to counterbalance the root-action. Summer pruning to some degree has this effect, but not to that extent desirable where the head has a very limited space to extend itself in. Take cordon Pears as an example. We shall find that unless something more than summer pruning is practised the trees could not be induced to produce those fine crops that are so often to be seen in well-managed gardens. Many, however, fail to understand that by timely lifting of the trees they are thrown into fruitfulness at a much earlier stage than those which are allowed to look after themselves. It is by no means necessary that all varieties should be treated alike; neither is it advisable to be too hasty in shortening the roots unless there is time to attend to the wants of the trees afterwards. Many trees, both Apples and Pears, do not become fruitful until they have attained age unless specially treated in some way or other. If we take the Blenheim Orange Apple as an example we shall find that in most instances young trees that are left to themselves are fruitless; whereas, if timely attention be paid to their roots, these will commence to bear while young. Two years ago I had some trees that had been planted about eight years from which but very little fruit had been gathered, so that was an inducement for me to see what root-pruning would do. A trench was taken out all round the trees 2 feet wide, at a distance of 5 feet from the stems, and all roots found were severed to the depth of 18 inches or 2 feet. The soil on the ball of earth left for about 18 inches all round was then forked out from between the roots and the roots brought nearer to the surface, the trench being then filled in with a light, rich compost, in which the young roots

rambled freely. Last season the trees were thickly studded with fruit-buds, and if there had been a favourable season I should no doubt have had a good crop of fruit. Half a dozen trees of Bramley's Seedling which had not hitherto given me a bushel of fruit were treated in like manner, and this season these trees have given me far more Apples than they have done during the previous eight years they have been planted. On heavy soils some varieties are apt to make coarse roots and correspondingly strong wood. All the summer pruning that could be practised would not induce such to fruit, but if their roots were judiciously shortened this would prevent this rampant growth and throw them into bearing. We all have observed the short-jointed shoots of old trees that are so thickly studded with flower-buds as to present a picture when they are expanding in spring. Such trees instead of requiring root-pruning need assistance in another way, or they will fail to bring the crop to maturity. When grown in pots it is seldom that fruit trees fail to give a crop of blossom. Their roots being confined, the trees set flower-buds instead of making a strong growth, but when planted in a rich soil where the roots are allowed to ramble at will the growth is long-jointed and sappy, therefore incapable of making fruit-buds. Trees must be kept healthy, but at the same time not encouraged to make strong, ill-ripened wood, which is of no use. In small gardens where a variety is of more service than quantity it becomes necessary to plant several trees, all of which must be duly kept within bounds, otherwise they would soon become overgrown and spoil each other. If such have attention given to their roots for a few years till the crop of fruit prevents them from becoming over-luxuriant, there is little doubt but that they will pay their owners for the trouble thus bestowed on them.

H. C. PRINSEP.

Grape Buckland Sweetwater.—As a successful exhibitor of this fine Grape I agree with all

that "H. H." says in its favour in THE GARDEN of October 28. I consider it far superior to Foster's Seedling or any white Grape that ripens in the early summer months. As "H. H." remarks, one rarely sees good examples of this Grape, but probably this is owing to growers relying too much on young Vines for a crop. My experience of it is that on young Vines it is a shy bearer and the bunches come loose and badly formed, but on healthy Vines of several years' standing the bunches are large and handsome, the berries fine and of a rich amber colour.—H. F.

Apple Adams' Pearmain.—I recently saw this Apple in fine form on a wall cordon at Blickling Hall. It is more conical in shape than the majority of Pearmain, is a good keeper and fine for dessert. Whether this Apple is identical with any other of this section I am unable to say, but in one of the leading grower's fruit lists, I do not see it mentioned. Neither is that "useful for poor soils and exposed positions Apple," Brighton Pearmain, and this variety I know well, having found it a bearer when other sorts failed, a long keeper, and of a sweet, refreshing, though perhaps not the richest flavour. Most of the Pearmain are good keepers and deserving of any extra care which may be bestowed on their culture.—B. S. F.

Peaches on back walls.—Failure frequently occurs from planting Peach trees on the back wall of a vinery, as "A. D." points out on p. 272. I grow Peaches in such a position, and, given favourable treatment, the crop is invariably as good in one position as the other. Perhaps the most remarkable crop of Peaches from a back wall I have yet seen was at Bromham Fruit Farm, near Chippenham, this summer. The crop was a late one, and the house some 40 feet in length, 10 feet or 12 feet in width, and with such a low roof that one could scarcely stand upright under it. Here there were trees occupying a front trellis, trained very near the glass, and the amount of light allowed the back wall trees was so small, that most fruit growers would wonder how any fruit could be had. The crop as I saw it, however, was very heavy, much too heavy, in fact, as also was that of the front trees, the Peaches being under-sized and not very well coloured. There was no rounded trellis here to provide a maximum of light to the wall trees, and the great crops borne

remain a mystery. I can only assume that the low and somewhat flat roof, the suitability of the soil for Peaches, and plenty of water could account for it. I have often seen trees growing under much more favourable conditions bear much lighter crops.—W. S.

Apple Devonshire Quarrenden.—As an espalier, this useful, richly-coloured dessert Apple, has occasionally been commented upon in the pages of THE GARDEN, and in my opinion no orchard, however limited in size, is complete without at least one tree of it. Nowhere have I seen this Apple so frequently as in the eastern counties, though I believe it is very plentiful in Hampshire. A few days ago an amateur showed me a fine healthy espalier tree growing in a somewhat sandy soil. It annually produces good crops of finely coloured fruit, and is the true variety, as I have not the least doubt that there are two distinct sorts. I grew one in Nottinghamshire and the fruits were always larger than the type, more leathery, and, although on an espalier facing nearly due south, it never even in the most tropical summers took on that beautiful brilliancy characteristic of the true Devonshire Quarrenden. Intending planters should make a note of this. The flesh of the true Quarrenden is often quite coloured with a pink tint.—NORWICH.

Strawberries at Syon.—Both inside and out these are largely grown at Syon. I recently saw there a fine batch of 5000 in about three sorts. Royal Sovereign predominated and did not bear what "A." (p. 273) describes as a meagre look that so often happens at this season of the year. They, on the contrary, had a very healthy—indeed robust—leafage and stout promising crowns. I inquired of Mr. Wythes if Stevens' Wonder was represented among the batch, to which a very emphatic reply in the negative was given. Mr. Wythes does not believe in the practice of layering into fruiting pots direct for varied reasons. The extent of work entailed in layering and potting up of such numbers must, however, entail a considerable amount of work for a private garden having a limited labour staff. Outdoors they are grown entirely as annuals—that is to say, after fruiting once they are destroyed and new beds made for the next year's supply. The practice answers admirably at Syon judging from the condition of the beds as I saw them. For the forcing stock a large bed is planted, and in the spring all flower-trusses are removed as soon as they appear, so that the energy of the plants is concentrated on the production of runners. These plants allowed to stand bear a fine crop the next year, when they, too, are cut off and others take their place. Mr. Wythes has every reason to be satisfied with his prospects for next year.—W. S.

Late Peaches and Plums.—There are many late Peaches, but I confine myself to Walburton Admirable and Gladstone. Walburton Admirable I think, all points considered, the best late kind. I have a very fine variety that has been in these gardens for forty years. My tree is growing on a Plum stock and on a back wall. This gives me a fine crop, usually through September. It is large and of good flavour, but not so highly coloured as some kinds. Some find it shy to set, but this is not the case with me. Gladstone does magnificently here. I have two trees growing on a front trellis. Every other light can be thrown right open, and it is astonishing how this improves the colour. The fruit is very large, solid, and of the brightest crimson. I think it far in advance of some kinds as regards flavour. Sea Eagle is not to be compared with it, although growing side by side. I should not plant Sea Eagle again. Gladstone is a good grower and does not mildew so badly as some kinds. Although this is an early season, I had good fruit till about the middle of October. I am induced to try Golden Eagle, having seen it fine some years ago at Lyndford Hall, and it does well on open walls at Bovey House, near Linton. Have others grown this kind under glass for late work, and with what results? Good as late Peaches are for cold houses, I consider late Plums more desirable. I grow Reine Claude de Bavay on an up-

right front trellis close to the glass. Here it gives grand crops every year. This year my last dish was gathered on October 12. Golden Drop cannot be excelled; trees growing beside the above crop well and give a supply into November. Here the fruits can hang till they shrivel, and this is when they are at their best. I find these Gage Plums more profitable in these positions than Peaches.—DORSET.

ROSE GARDEN.

SOME GOOD POLYANTHA ROSES.

ONE of the loveliest Roses this autumn has been *Perle d'Or*, which still remains unsurpassed in its class. These Polyantha Roses should be grown more extensively than they are at present. An idea is prevalent that they are of very diminutive growth. That they may be kept very dwarf is not denied, for one may cut them down to the ground every spring, and they will flower just as freely; but still they will, if left almost unpruned, make really fine bushes. They are delightful subjects to plant upon walls in front of greenhouses, provided a good deep border is prepared for them. Like their relatives, the Teas, the plants, if not on their own roots, should be on the seedling Brier, and everyone who has grown Roses upon this stock knows how deeply its roots will strike down. This, I think, is a valuable feature of growing Roses upon the seedling Brier, for naturally, if the subsoil is good, the roots suffer less from drought and the growths are produced later in the season. One of the most profuse blooming of the Polyantha Roses is *Gloire des Polyantha*, yielding an abundance of deep pink trusses. Another valuable novelty is *Perle des Rouges*, certainly the richest and brightest colour at present obtained. *Anna Marie de Montravel* is one of the purest white Roses grown, every bloom upon the immense corymbs being perfect in form. *Cecile Brunner* should be grown in every garden if only to afford buds and sprays for button-holes. Every tiny bud is of such exquisite shape and the colouring of pale pink so clear and beautiful, that it is sure to find favour. Among pale yellow kinds which are not yet numerous *Etoile d'Or* is the prettiest, but *Madeleine de Chatellier* is by far the better grower. *Mosella*, sent out as a Polyantha, should be classed with the Teas. In form it is as perfect as a *Camellia*, white in colour, but with a lovely rich and clear yellow ground. *Mme. E. A. Molte* has delightful little buds of a chamois-yellow colour, changing as the flowers open to rosy white. Upon short stems these Polyantha Roses are lovely for the centres of very small beds, and they, together with the Monthly Roses, such as *Mme. Laurette Messimy*, *Mme. Eugène Resal*, *Queen Mab* and *Irene Watts*, should be more often planted in dwarf standard form. How pretty these Polyantha and China Roses are for conservatories in early spring! They strike readily from cuttings. If some plants are forced, their growths yield splendid cuttings inserted immediately after flowering. The more healthy and solid the cuttings, the better plants will result.

P.

Rose Hon. Edith Gifford.—Many of the Teas give a much larger number of flowers in autumn than this, but I think there are few that give them of such exquisite form and colour. The pink shading in the centre of the flower is intensified at this season of the year, and opening slowly as they do, the blossoms come of great substance. It was one of the first to bloom here this spring, and as there are now (October 30) fine flowers still open, it looks like being at least

one of the last of autumn. The plant has a fine strong habit of growth.—H. R.

Rose Prince Theodore Galitzine (Tea).—This is a gain in the right direction. There are none too many rich yellow Roses suitable to our climate, but a new-comer is welcomed if it possess a sturdy character. That this Rose is of this nature I have no doubt. In colour it resembles that lovely variety *Souvenir de Mme. A. Levet*, which has turned out to be exceptionally tender, and I should not attempt to cultivate it outdoors, but under glass planted out it would be a most attractive variety. The new kind appears to possess a far more vigorous nature, and has every appearance of being a hardier Rose. The colour is a rich deep orange-yellow, not so intense as in *W. A. Richardson*, but yet richer in tint than the majority of yellows.—P.

PRUNING ROSES IN AUTUMN.

THERE can be no doubt that Roses as a whole are much overpruned, more especially when they are required for garden decoration as distinct from exhibition flowers. I believe that far better results would follow autumn pruning of all such kinds as the Teas and most others that are not cut hard back in spring. Such kinds as *William Allen Richardson* or *Aimée Vibert* are often cut about in spring to their detriment, the shoots being cut either too hard back or left in a thick tangled mass. If such trees had a little of the small spray cut out from the centre now and the weak, unripened points taken from the shoots, they would not start any the earlier in spring, while the buds that remain would be stouter and harder, owing to the extra sap being diverted to them and the light and air playing freely about the whole of the tree. If this slight thinning of the shoots were done now, I see no reason for doing any pruning at all in spring to any true garden Roses. Those with the habit of *Crimson Rambler*, for instance, that keep sending up strong shoots from the base and flowering upon them the ensuing year may have some of the oldest and most straggling of the wood cut away. Frosts in winter would have more effect upon those left, making them harder, and the resulting young shoots would be less liable to succumb to cold winds than if left crowded and dark in winter. Again, when the autumn flowering of the Teas is over the points of the blooming shoots may be taken off. The upper eyes may be lost in spring, but this is no more than often occurs when spring pruning alone is practised. It is quite certain that the more open the trees are kept now, the hardier they will be in spring.

A GROWER.

Rose Empress.—What a charming autumnal Rose this is! Many Rose growers will remember a variety named *Mme. Bellenden Ker*, raised by Guillot some thirty years ago. *Empress* is not unlike this variety, but it grows much more luxuriantly, the plant developing into quite a large bush in a very short time. Its white, pink-tinted flowers make a delightful button-hole, being of perfect form, small, and very neat. As a standard this Rose is a great success, the fine head of growth and informal habit fitting it for this method of cultivation.—P.

La France as a wall Rose.—Has anyone tried this popular Rose upon a low wall? I do not mean the climbing kind, which is not at all constant, but the well-known dwarf type. Whoever plants a number of it near a low south or west wall or fence will be delighted with the behaviour of the variety. A good plan is not to nail the growths immediately on the wall, but to run some three or four wires, which should be painted, the whole length of and about a foot from the wall. Upon these wires spread out the branches. Planted in a good prepared border the growths produced in this way would astonish the cultivator, and would furnish him with an acceptable number of this best of all sweetly fragrant pink Roses. The pruning adopted would require to be of

a somewhat different character from the orthodox method. The three or four-year-old growths are almost entirely removed, which gives full opportunity to the one and two-year-old wood to produce the blossom. It is not advisable to prune the shoots retained too much. If good, plump, dormant eyes can be found about a foot or 18 inches from the ground, cut back to these rather than prune lower down. If the plants are growing in a really good Rose soil and they are all upon the Brier stock, they will not fail to send up vigorous young shoots. Many good Roses suitable for cutting could be cultivated in the manner described.—P.

ORCHIDS.

GONGORAS.

Few plants are more easily grown than Gongoras, and the flowers are very pretty and interesting, yet for some reason or other they are thought very little of by most growers. Of course, the flowers have not the same gorgeous colouring, nor do Gongoras make so fine garden plants as the Cattleyas and Lælias and a few other popular genera, but for all that they are in most cases well worth growing and in almost every case very free flowering. The flower-spikes are mostly pendulous, and for this reason the plants are best grown in baskets, otherwise they would thrive equally well in pots. The effect of the flowers is lost if the plants are grown on the stage, while if tied up they lose all grace and beauty. Owing to their very free-rooting nature Gongoras must have a fair amount of room in the baskets and a sound compost, equal parts of peat fibre, loam and chopped Sphagnum Moss suiting them well. The drainage must be exceptionally good and free, for few plants need more water while in active growth. *G. atro-purpurea* I have had continually in growth or flower for two years. As fast as one set of flower racemes was past another lot opened, and there are others equally free.

This being so, it is obvious that no decided resting or growing season can be laid down, but that the plants must be encouraged as long as they seem determined to grow. In the case mentioned above the roots not only filled the baskets, but pushed upwards and outwards into the air, and all who have had experience with plants of this kind know well how freely they imbibe moisture, never seeming to get enough of it. It would be quite different with sluggish roots or unhealthy plants, but such specimens as I mean can hardly be kept too moist in warm weather. Should they be inclined to rest in winter, by all means let them and allow less water and heat.

Regarding the growing temperature, this may be with the Cattleyas, and when at rest with the Mexican Lælias. Thrips are rather partial to the foliage, also red spider, and to keep these in check, frequent overhead washing with the syringe is necessary. The genus contains a score or more of species which it is not necessary to describe in detail. Several of these, including *G. odoratissima*, *G. atro-purpurea*, *G. truncata* and others, have often to do duty under the name of *G. maculata*, but they are all distinct. H. R.

Oncidium serratum.—The long scendent racemes of this Orchid are very bright and showy just now, and are useful for grouping. The flowers are at a considerable distance apart on the spikes which occur in the centre of the young growth. Under cultivation this plant does well in quite a cool and moist house, whether an Orchid house proper or fernery does not matter, and it likes fairly large pots filled with equal

parts of peat and Sphagnum Moss in a rough, open condition. The plant at first should be set fairly low, as the growth ascends each year and soon grows out of reach of the compost.

Catasetum callosum.—The peculiar tints of brown and green in this Orchid make it very attractive, and it has the same quaint appearance as others in the genus. I think it is not very generally grown or known, but it is certainly worth a place where this interesting section is cared for. Its culture is simple, a hot, moist house while making its growth, ample light to ripen the pseudo-bulbs, and a long dry rest in winter suiting it well. The most troublesome time is when young growths appear, as if moisture in excess settles in these, it is apt to cause them to decay.—H.

Dendrochilum Cobbianum.—Now that the flowers of this Orchid are past, no time should be lost in getting the plants put to rights at the roots, and any that require repotting should have this attention. The forming growths soon begin to root freely after being disturbed, and entering the fresh soil at once soon re-establish the plants. They should have the lightest and best position at command in the East India house, with ample moisture at the roots and in the atmosphere until the growth is complete. When the pseudo-bulbs are fully matured give less water and a cooler position.

Epidendrum evectum.—This belongs to the section of the genus having long, leafy stems and loose racemes of flowers at the extremity of these. In strong plants these are 4 feet and upwards in height. Like several others of its class, it delights in ample heat and moisture during the time the stems are growing, and the roots being vigorous, a rough open description of compost suits it best. Ample root moisture in summer and sufficient to keep the stems plump in winter should also be given. It is a native of New Grenada, and though long introduced, is seldom seen under cultivation.

Mormodes pardinum.—This species often flowers in late autumn, and I have noticed it in several collections of late. It is certainly one of the best of the genus, and its variety unicolor is quite a delicate and pretty kind without the spotting as seen on the type. It is often grown in baskets, and the racemes then take a semi-pendent direction, which is very pretty. The compost must be good peat and Moss in equal portions, a little loam being mixed with it for strong plants. During the growing season *M. pardinum* likes ample heat and moisture with a light position. When at rest much less heat suffices, and the roots should be kept on the dry side.—H.

Maxillaria grandiflora.—This charming old Orchid is worth growing for the sake of its delightful fragrance only, while it is also one of the prettiest of the genus. The plant delights in ample atmospheric moisture, with plenty of water at the roots when healthy, and unless these are given it is very apt to be over-run with insects, especially black thrips. Its culture is remarkably easy, and consists in keeping it in a cool house, the compost for strong plants being equal parts of peat, loam, and chopped Moss, with abundance of crocks and plenty of drainage added. Sponge the plants directly any kind of insect is seen about them, for these rob the leaves of their fine colour, which is one of the chief attractions of the plant.

Masdevallia tovarensis.—The flowers of this Orchid are perhaps the purest white of any, yet they have not that dead-looking appearance characteristic of many white-flowered Orchids. It is so free-flowering, that it is well worth growing for cutting alone, besides which the flowers have a very fine appearance on the plants, the white blooms and deep green leaves contrasting very prettily. The spikes continue to produce flowers for several seasons, but though it is not worth while on this account to leave all the old ones on, yet it is best not to cut them too close. *M. tovarensis* may be grown with other cool

Orchids provided the winter night temperature does not fall below 50°, but in a very cold house the leaves are apt to spot badly.

Dendrobium formosum giganteum.—It is pleasant to read of what is usually considered a difficult plant being so well cultivated as this Orchid evidently is by Mr. Hudson at Gunnersbury. I was much interested in the system so well described by "H. J. C.," and I feel convinced that so long as the Gunnersbury House plants can be kept to this annual routine of growing, flowering, and resting each in their proper season, so long will they be satisfactory. *Dendrobiums* as a whole, and this somewhat erratic kind in particular, are never so satisfactory as when they are kept to this annual cycle of growth and rest, and keeping them regular in this way is far more likely to prove a panacea to the ills that *D. formosum giganteum* is heir to than any details as to compost and temperatures often advanced.—H. R.

Winter treatment of *Cœlogynes*.—It is not everyone who is successful in retaining the bulbs of *Cœlogyne cristata* in a plump condition from autumn till spring. The chief reason doubtless is attempting to keep the plants in an almost root-dry condition, which invariably ends in shrivelling. I saw an extensive and very healthy collection in a gentleman's garden a few days ago, and on remarking to the gardener how plump every bulb seemed, he replied that the plumpness, which the plants always retain throughout the winter, was due to a frequent supply of water. He added it is a great mistake to attempt anything like dryness at the roots. Some who keep the roots dry give quite a cool house during winter, and of course in such quarters room-moisture would soon work mischief. The best and safest temperature in order to allow of the moisture recommended is one of about 60° at night.—B. S.

Dendrobium aureum.—This I have already received from one of my correspondents, but there is little use really in endeavouring to get it so early. It would be as useful in a month's time, and the plants after flowering would have a more suitable time in which to make their growth. It is a charming little species, more especially on account of the delicious fragrance of the blossoms, which is comparable to that of no other flower. Formerly *D. aureum* was grown a good deal on wood blocks, but this treatment is too poor for it, and far better results are obtained by growing in small pots or baskets in a compost of equal parts of peat and Moss. Its growing season begins directly the flowers are over, and for this reason the later it blooms the better. As the pseudo-bulbs or stems develop, the plants may be taken to the open air, and if kept out until the end of summer and kept on the dry side, the growth will be hard, well ripened and sure to flower freely. There are many varieties more or less distinct, and this is, perhaps, accounted for by the very wide range of country over which it is found.—H.

Sophronitis violacea.—The brilliant *S. grandiflora* is well known, and is a very useful autumn and winter-flowering Orchid, but the species named above is seldom seen in anything approaching good condition. One reason of this is that many gardeners, amateur and otherwise, will persist in treating all members of one genus alike. Now *S. grandiflora* delights in small pans or baskets filled with a little peat and Sphagnum over good drainage, but *S. violacea*, on the other hand, is of a rambling habit, and likes to run up a soft block of Tree Fern stem or a lightly dressed raft of teak rods. The rhizomes carry the little bulbs at a considerable distance apart, each one sending out a tier of roots on its own account, and to place such a plant in a small pot where it would not have the chance to extend itself without at the same time getting out of reach of the compost is quite wrong. As to temperature, anything a little below that of the Cattleya house will be best. In the coolest house the conditions during winter, when *S. violacea* is often more or

less active, are not suitable for it, but if placed in any great heat the growth is almost certain to be over-run with insects, especially thrips. As hinted above, the plant is usually more or less active, so drying off, as usually understood, must not be practised. Wherever the little roots are seen by their green tips to be on the search for moisture it should be provided. Should insects attack the plants, lose no time in clearing them out, for a species of such small stature will be very easily injured. The flowers vary a little in size and colouring, and are usually of a soft rosy purple.

Angræcum bilobum.—Though a dwarf species, this is an extremely pretty one, and the long racemes of pure white flowers have a fine effect against the deep green leaves. Its culture requires care, for the plants are small and easily checked by an ill-regulated system of ventilation in winter, a dry, harsh atmosphere or mistakes in watering; but, given regular and consistent treatment, the plant cannot be called difficult of cultivation. I like to give the plants just comfortable room in the pots and no more if they are to be so grown, but small teak baskets are also useful for them, as in such they may be brought well up to the light, a position they like. The East India house is the best for them, and during the whole of the growing season a strong, moist heat should be maintained. Only a very little compost of any kind is needed, a thin surfacing of clean freshly-gathered Sphagnum Moss being best. Large pieces of crocks should be laid over the bottom rods of the basket, the sides being lined very thinly with Moss. During winter not much water is needed, but enough to prevent the leaves shrivelling must always be allowed.—H.

NOTES AND QUESTIONS.—ORCHIDS.

Lycaste Barringtoniæ.—This species, a native of Jamaica, was first imported in the eighteenth century, and is still occasionally sent to this country, but it has never become at all popular, and is less so now than formerly. It has yellowish flowers and grows very strongly in a cool house, where to be satisfactory it should be kept moist all the year round, and potted in peat, loam and chopped Moss.

Restrepia Lansbergi.—The flowers of this Orchid are small, and some may call them insignificant, but they are really charming, and it is a pity such a lovely little thing has become so rare. The flowers have an orange-crimson tint, spotted with deep crimson. It is one of the prettiest in the genus, and may be grown in a fairly cool house with Masdevallias, the pots used being rather on the small side than otherwise.

"HARPER'S MAGAZINE" VERSUS ARTISTIC GARDENING.

In the September number of "Harper's Monthly Magazine" there appeared an article extolling builder's garden design. As is usual in productions of this kind, the writer appeared to think that his strongest position of attack and defence was in abuse and ridicule of artistic gardening. The usual arguments in favour of the pattern style were duly set forth, and there was nothing new of importance in the essay excepting the very ugly illustrations, which were its justification, or rather excuse.

The mistake made by these apostles of the T square and compasses is in supposing the two styles to be hostile; that the safe existence of either of them can only be assured by the death of the other. They are not hostile. Picturesque gardening has this advantage: its spirit is basic both in Nature and Art, and it must survive so long as there are trees, bushes, and flowers not cut into patterns in gardens made by man or in gardens made by God. The enemies of such gardening are enemies because they do not understand it; because they have eyes and see not; because it is all

around them and they do not know it. Yet even builder's gardening itself cannot well get on without natural form, and most extensive formal schemes and all the more interesting ones find in it much of their attraction. Some even of the finest of the Italian gardens depend much on informality for their best charm, on uncramped forms and irregular arrangement of vegetation.

It is always assumed by the opponents of informal gardening that it is an imitation of Nature, and thus out of place round a house where everything should suggest the restraining hand of man. It is not an imitation of Nature any more than a picture of Claude or Turner. The art could not have existed without Nature to suggest it, to provide motives and materials; but these motives she scatters around with a hand as reckless as generous, and the painter or gardener is compelled to choose from them, not to take them indiscriminately. He finds some of them better than others, and selects and alters, adds and subtracts to make a composition of unity; and the innate faculty of doing these things being exercised and developed, the artistic power of realising natural beauty, which is the justification of the artist, is produced. To do this, not with brush or pencil, but with the real and perfect materials of trees and plants and on the broad and varied surface of the earth, is surely as fascinating and idyllic an idea as art possesses. That it can be realised is proved—sometimes, and when it is proved it is often not recognised because of its very grace and fitness. These zealots of formal gardening are usually architects of a certain class who do such work when they can get it, and are struck by its profitableness. What a fine thing it would be (for them) if every house had a stone garden! Thus, being unable to understand an art that is not of lines and measures, whose proportions cannot be reduced to mathematics, they falsify its principles to suit their own purposes and draw conclusions as shallow as they are unfair. They all show a surprising ignorance of landscape gardening and its best examples and an equal familiarity with some of its worst. It would be as fair to take the crudest row of speculators' houses in London or New York as a type of contemporary architecture, or the saddest impertinences in terracotta and tortured Alternantheras of the architect-gardener as a type of formal gardening. It can hardly be supposed that these misrepresentations are made deliberately and of knowledge; they can only proceed from haste and ignorance. They show that their makers are quite impervious to a kind of beauty in which most of the civilised world delights, or at least by which it is soothed and pleased in one way or another.

To what, then, does all this tend? Does it mean that the endless phases of horticulture, from the village garden to the great parks of Europe and America, are things of no account? Has the cottage with its Vine-covered porch, its bushes and annuals and tiny plot of grass, as well as the calm and majestic vista of lawn and wood, at last been found futile and valueless? Does it mean that they are not beautiful, and so not art, or that they must all be swept away to make room for the barren pattern, the puissant triangle and the satisfying circle, for the pliant forms and many-twinkling smile of masonry and cast-iron, for the free and genial outlines of sheared plants and bushes? And are we to suppose that the myriads on both sides of the Atlantic who delight in the trees and flowers of the field and their unaffected array are imagining a vain thing? Is the vital and ever-renewing fascination, unreachable by any art dependent on geometry, that they find

in these living children of the soil a delusion and a snare? And are they to be educated into regarding them as mere materials for making colours and forms crudely based on rigid and unchanging architecture?

Naturalistic gardening at its worst is never so bad as the worst of builder's gardening, for it shows us the unutilised forms of plant and tree. Linoleum patterns! How many of them are as interesting as most of the absurdities perpetrated with coloured plants and the devices that often go with them! Naturalistic gardening at its worst may be trifling, but it owes it largely to the confusing wealth of its material. It is so difficult to know when to stop selecting things from the tempting catalogues of the nurseryman. These great resources bewilder the average designer of a garden, who is usually an amateur or local nurseryman, and he fills in too often with freckled monstrosities or the latest freak in variegation. Thus he gets "variety" of a poor sort and loses general effect, and the serene art of naturalistic gardening is supposed to be a thing of pettinesses and superfluities, and its enemies revile it for the things it has not done.

H. A. CAPARN.

PRIZES FOR WINDOW GARDENS.

Not long ago I spent several weeks in summer in the little English village of Ketton, and while there came to know of a pretty custom which it seems to me might be introduced into this country—that of giving prizes for the most pleasing windows filled with house plants. The houses in Ketton are built of stone, and many of them were in existence as long ago as when the Pilgrims were coming to this country, and have been lived in ever since. Almost without exception they stand close to the street, for English gardens are behind the houses, or behind high walls, and so the quaint lead-sashed windows are so near the sidewalks that the flowers which fill them show to the best advantage. A small fund had been set aside some years before by a lady, the income to be devoted to giving prizes each year to the owner of the finest window garden. The sum available for premiums was not large—as I remember it now £2 a year—and the only restrictions were that no one should compete who had a greenhouse—small glasshouses for forcing are much more common in England than they are here—that the competition should include only one window in a house, thus putting the occupant of the smallest house on a fair footing with her more prosperous neighbours, and that the general scheme of arrangement should be decided on at least one month before the day set for awarding the prizes, and not altered during the month. This last condition was to prevent anyone from procuring greenhouse or other plants at the last moment and making a temporary display. There were three judges. The year I was there the judges were the vicar's wife, another lady, and the village schoolmaster. There was a great deal of variety in the different windows, more than one would at first think possible, for the English are natural gardeners. The interest taken in each other's windows as the designs developed was intense, not only by the contestants, but by all the residents of the town. The window which took the first prize the year I was there was a study in green and yellow. A number of shelves were fastened across the window inside, and alternate shelves were filled with pots of Musk, with its delicate light green leaves and yellow flowers, and pots of Lobelia, with dark green foliage and dark blue blossoms. There were enough shelves so that the window was filled solidly full by the day the judges made their tour of inspection, and the effect of the mass of foliage and flowers in the soft grey setting of time-worn stone, of which the cottage was built, was very beautiful.—M. B. THRASHER, in *Vick's Magazine*.

TERRACE PLANTS.

WELL-GROWN plants in tubs or vases for the purpose indicated have an individuality quite their own. Given suitable positions for them, they are most attractive and add greatly to the charm of a garden, especially that part of it which is contiguous to the house. Our forefathers used to adopt this system of ornamentation during the 18th century to a large extent, as may be gathered from cuts and illustrations of the period. Their plants, however, were in my opinion too formal, being kept so by constant stopping and pruning. We see indications now

tinent and to the United States. As seen growing in the nurseries in and around Ghent and Bruges these Bays are wonderfully attractive, serving many good purposes. Oranges in tubs for the decoration of our terrace gardens are not now so often to be met with as they were a quarter of a century back, nor does it appear that any of the trade hold any specially good stock of them. This is to be regretted, for when well grown they are splendid features and decided acquisitions for the purpose in question.

There are other plants, however, which should

are only intended as such, finding a market chiefly in Germany, being in request most (so I am informed) at marriage festivities. My plants in tubs of both Myrtles and Aloysias (see illustrations) are now from nine to ten years old, all of them being my own propagation—the Myrtles from layers, so as to save time, the Aloysias from cuttings. The Myrtles were layered into 3-inch pots from an old bush during the summer of 1889, each layer when rooted making a compact, well-furnished example with five or six shoots. These have been grown on until now they are from 5 feet to 6 feet, and some 7 feet in height, with a diameter of 5 feet in most instances. By regulating the growth and by a small amount of tying they are now almost self-supporting. In the earlier stages I potted them annually, then every other year until tubs were adopted. They were placed in their present square tubs in 1898, from a pattern furnished by Mr. Leopold de Rothschild. These tubs, and all others of the same shape, are made of Pitch Pine as a framework with slate interiors, so that nothing but the slate comes into contact with the roots. By this means there should not be any risk of premature decay in the case of the wood, whilst the slate is better than wood, as it pertains to the roots.

The Aloysias are treated in a somewhat similar manner. These were struck from cuttings in 1890 (in the spring), being planted out in May, and kept to one shoot to each plant in order to obtain as long a stem as possible for the foundation of the future specimens during the first season. These have now developed into large plants, partaking more of the standard form, the tallest being from 7 feet to 8 feet high. This season in the spring I put two into the square tubs from round ones, and I find the increased rooting medium has greatly benefited them; so much so, that now I propose putting other specimens into the same kind of tub. The square tub has a better appearance, too, than the round one, being also safer against toppling over during strong gales. In the painting of these tubs dark green prevails. I find the best results follow when the Aloysias are started into growth in an absolutely cold house or in a sheltered spot out of doors, preferably the latter. The foliage is in consequence quite hardy and does not drop, which failing occurs when grown on early inside during a cold spell of weather in May. The Aloysias are pruned as in the case of a specimen Fuchsia and but little tying resorted to. The soil I use consists chiefly of turfy fibrous loam with some leaf-mould and a little lime rubble, all being rammed down firmly. The Myrtles have never been reduced at the roots, but the Aloysias have (again as with Fuchsias), and then placed into the same size of tub again.

The Pomegranates (both double scarlet and white) are grown as standards, these being imported plants. The difficulty with these has been to get them to flower. I found pruning, either severe or moderate, did not produce the desired results. Then I tried the let-alone plan, and this, the second season of trial has been very satisfactory in the case of the scarlet variety, the multiplicity of weakly shoots being more productive of flowers. The white variety has not responded so kindly; perhaps it may do so another year. These I treat like the Myrtles, not disturbing their roots. Next spring, however, I hope to put them into the larger square tubs using, in

The Box-leaved Myrtle in a tub at Gunnersbury House. From a photograph by G. Champion.

in many gardens that a revival is setting in in their favour, but I trust it will not develop into the strictly formal character followed by our forefathers. It need not be so in any, even the slightest degree; rather let us have a free, unconventional growth, with sufficient modification of the form to ensure well-balanced examples. We have quite sufficient proof that such plants are being sought after when we scan the advertisement columns of the weekly gardening papers. Sweet Bays, too formal oftentimes, are, we know, grown by tens of thousands in Belgium chiefly for exportation, but not so much to England as to other parts of the Con-

receive encouragement, such, for instance, as those now illustrated, viz., Pomegranates, Myrtles, and Aloysias (otherwise Lemon plants or scented Verbenas). These all serve distinctly good purposes and find plenty of admirers, as I can personally testify in the case of our own plants. When I have been questioned as to the sources of supply for Myrtles and Aloysias I have been compelled to answer in the negative. I do not know where they can be procured in any quantity of full specimen size. Small plants of the Myrtle, i.e., the Box-leaved form, are largely grown in Bruges and around, but these are quite pigmy plants and

addition to the soil already alluded to, some fibrous peat.

All of these plants have to be housed in this locality during the winter season for safety. So long as the frost to which they are subjected is not more than 5° or 6° they will not catch any harm. With more than this the tubs should be protected, but then even there is a risk which it is not safe to incur. So far I have housed them in an empty museum, but now, owing to their increased size, a larger place is being made ready for them, with more light in addition. The Myrtles have been used every season for the past four years in London; they stand well in Park Lane and never return any the worse for their change. Now these Myrtles are well established they flower most profusely every year, being at their best during September. The Aloysias have also been used for the same purpose. In each case a sunny position is preferable. Veronicas, as V. Andersoni, V. Hendersoni, and La Séduisante, are also being grown for the same purpose, but these are not yet at their best; to form such into standards takes time. The silver variegated form of *Euonymus elegantissimus* is also being brought on in the pyramidal shape. This, unfortunately, is not hardy; if it were so it would be a grand plant for more general planting. I treat these—Veronicas and *Euonymi*—as in the case of the Myrtles, &c., keeping them just free from frost.

J. HUDSON.

KITCHEN GARDEN.

QUALITY IN POTATOES.

THE first aim of a Potato grower should be to obtain quality, and in the selection of varieties this most important attribute should receive consideration. Speaking of varieties of Potatoes, one has to admit that their name is legion, and year after year new sorts, many of them, perhaps, only so-called, are placed on the market. Considering this, it is a wonder that the whole thing is not in a state of chaos and that varieties have not got mixed up in a perplexing medley. But such is not the case, and the reason is, I think, that out of the almost unlimited number of varieties in existence there is only a small proportion possessing good all-round qualities, and these have got a firm hold on public favour. The few leading varieties of both early and main-crop Potatoes are known and grown in every county and nearly all localities, which goes to prove that if a Potato possesses good quality it is certain to become popular. Nor is a tuber of this character long in gaining public favour, and if an illustration be wanted, take the well-known variety *Up-to-date*. This Potato is of recent introduction, and yet perhaps no maincrop sort enjoys a wider popularity. It would be interesting to know how many new varieties of Potatoes have been put on the market since *Up-to-date* was introduced, and how far the majority have succeeded in gaining public favour.

Admitted, then, that there are only a few really popular Potatoes, the advisability of introducing so many new sorts may be questioned. The argument is quite feasible, and it is an open question whether we are not getting too many named sorts of Potatoes, because numbers of them have so great a similarity that it would puzzle an expert to tell the difference. Considering the tendency there is to swell the already large Potato family with varieties that may or may not be distinct or new, it is quite time some means was adopted to put a check on the output. As the matter now stands,

there appears to be no reason why any individual should not raise a Potato, or get it from some other source, and send it out with a name without ever taking the trouble to ascertain whether it is the same as some other sort already in commerce. At the same time it appears to be equally necessary that new varieties should be introduced, for without these there would be a certainty of deterioration in the tuber and a possibility of its going out of cultivation altogether. In spite of arguments to the contrary, facts go to prove that the existence of any variety of Potato has a limit, according to its constitution. The best of Potatoes, however, perform a double office, for not only do they provide us with a staple food during their existence, but they are the parents of the standard sorts which follow them. If support is needed to the statement that even the best of Potatoes do not last indefinitely it can readily be found. Think of the grand old varieties which were popular say a quarter of a century ago. Referring to Potatoes that are on the wane, take *Magnum Bonum*, which still has many supporters. At one time this was the most popular main-crop Potato in cultivation, but the same cannot be said of it now, and the reason is that it has lost some of the high qualities it once possessed. In some districts where *Magnum Bonum* was the staple variety, it is hardly grown at all, and though I am quite prepared to be criticised for saying so, I am of the opinion that it is slowly following in the wake of other good sorts. Many of our best varieties, including *Up-to-date*, owe their origin to the well-tried *Magnum*.

I am not sure whether the ways adopted to encourage the culture of the best Potatoes are as good as they might be. Too much attention is given to appearance and not enough to quality and productiveness. The monster tuber is not encouraged in the best gardens, and rightly so; but at small shows a prominent class still is that for the heaviest tubers, and the gross, malformed specimens seen prove that this is not encouraging the best culture. We all know the value of an even tuber possessing no deep eyes, but this is not everything in a Potato, and tubers that are nice to look at invariably take first prize irrespective of their eating qualities and cropping. I know of one Potato now, a pretty kidney, which I have seen among the prize-winners at a score or more shows this year, and yet I have never heard anyone speak well of its flavour or productiveness. At present there is no other standard for adjudicating prizes for Potatoes except appearance, and this accounts for many sterling varieties never being seen on the show-board. We hear of this or that Potato being a good exhibition variety, and why? Simply because it presents an attractive appearance, and to the worship of this, profitableness and quality are sacrificed. I am not sure whether there is a direct way out of the difficulty, but growers can soon find out the sorts that are profitable; the worn-out, inferior, and synonymous varieties being weeded out and only the best quality varieties grown.

G. H. H.

Finishing off late Tomatoes.—It is a good plan to grow late autumn batches of Tomatoes in pots, as when planted out they must remain where they are, whether the house is furnished with hot-water pipes or not. When in pots they can be removed with comparatively little trouble from one structure to another. In order to prevent cracking and to bring the fruit up to the best possible condition for sale, a little fire-heat from the present time onwards is imperative, also regular and very careful ventilation. Wholesale defoliation must not for a moment be entertained,

but partial curtailment of the leaves may safely be practised, also the pinching of all laterals. This will allow of a free circulation of fresh air and ingress for light and sunshine. Great care must be taken in watering. The early part of the day must be chosen, and rather than fill the atmosphere with moisture on a wet or foggy day, allow the pots to get dry. Patience is needed to allow the fruit to attain to its full colour, as semi-ripened fruit is certain to realise unsatisfactory prices. A good late, but a free setting Tomato is really worth any amount of pains, as after the middle of October prices invariably rise, that is, for really good fruit. A rather more than usual restricted root-run, manure-free soil, and exposure to every ray of light and sunshine are imperative if a free set, normal size, and good finish are to be secured. It is not always our Septembers are as sunny and dry as those of the last two seasons have been, and it is when this month is wet and sunless that the evils of overfeeding and an unlimited root space are most apparent.—J. N. N.

CROPPING SMALL KITCHEN GARDENS.

MANY having large kitchen gardens have no idea of the trouble and anxiety inseparable from the task of supplying even an average establishment from perhaps an acre or an acre and a half of ground. There are far too many such instances, the case being worse still when such permanent fruits as Strawberries, Raspberries, and Gooseberries have also to be accommodated. Much may be done, however, by a little forethought. Of course, it is useless to talk of spare plots in such gardens being rested and turned up roughly for exposure to the weather. One crop must follow another as quickly as possible. In such gardens the dwarf kinds of Peas should always be grown, as they do not obstruct the light from other crops and various dwarf vegetables may be grown between the rows. For instance, between such varieties as *Chelsea Gem* and *William Hurst* occupying the earliest borders at from 3½ feet to 4 feet apart may be planted early dwarf Cauliflowers, protected in frames through the winter or raised in heat in spring. The best of Spinach may also be secured from the same position. Where more than one row of second early and successional varieties is grown side by side, the same course may be adopted. Perhaps, however, a row here and there at a considerable distance apart is the best, such sorts as *Stratagem*, *Fillbasket*, and *Wordsley Wonder* being adhered to. All that is then needed is just sufficient walking room between the rows of Peas and the other vegetables to allow of picking. The same remark applies to *Runner Beans*, which in such gardens should be supported by ordinary brashy Pea sticks, the haulm being pinched when the summit is reached.

The great point to be observed in growing one kind of vegetable between others is equality of growth, especially as regards height. The short to medium-haulmed Potatoes should be grown, there being many of such character very free-yielding and of good quality. If these are say 2½ feet apart in the rows, various green crops, such as autumn Cauliflowers and winter Broccoli, Kales and even Brussels Sprouts, may be planted between without fear of being smothered. I would not, however, advise the planting of many midwinter and spring Broccoli in these small gardens, as they so often succumb in severe weather, and the loss can be ill-afforded. A winter vegetable the importance of which I would strongly impress upon the owners and managers of small gardens is the hardy little *Rosette Colewort*. I regard it as indispensable, as, being compact in growth, the plants may be given as little as 15 inches

from each other. The thing is to sow the seed at the right date. So many, especially amateurs, make a mistake here. From July 7 to 21, according to locality, is a safe time for securing plants that will heart in in rotation throughout November and January. As for their quality, when grown on fairly good ground no winter vegetable surpasses them. They may follow Strawberries, second early Potatoes, Tripoli Onions, or indeed any crop which is cleared off the ground about the middle of August, at which date the young plants should be fit for transplanting. They do not require newly-dug ground, so that planting may take place between rows of spring-sown Onions approaching ripeness. Indeed, no better site can be chosen provided the Onions are sown in rows from 18 inches to 2 feet apart. The extra space is beneficial to the Onions, and more

stump-rooted forms of Carrots and small varieties of Beetroot. Another point of paramount importance is not to confine oneself to one variety of such uncertain things as Cabbage, but to have several strings to the bow—a row or two of each sort. B. S. N.

VEGETABLE REFUSE FOR PEAS.

It is amusing to read such notes as that by "J. C. B." on p. 337, where at one end he recommends the use of vegetable refuse and no manure, and at the other two lots of manure, one in November, the other in spring. No better friend to the gardener exists than good farmyard manure, and to think that by using the refuse of the crops one year we can grow a good crop the next is ridiculous. We have all met the gardener with some brilliant notion to revolutionise gardening and may have been impressed by his theories for

of it, and a dressing of vegetable refuse or even nothing would do it an immense amount of good, but to think that the fertility of the soil can be kept up out of the refuse of the crops that grow upon it is another matter altogether. Every bit of woody matter and all prunings from trees, stumps of Brassicas, and every other class of refuse that is useless to dig in I char, and keep another heap of vegetable matter, leaf-mould, odds and ends of compost and lawn sweepings. This I find of great value both in the kitchen garden and the flower garden, but I have never been able to keep up the fertility of the soil by its use as the gardener "J. C. B." speaks of has done. H. R.

NOTES ON TOMATOES.

— I consider for early work and general use Conference and Conqueror to be two of the very best; in fact, I have discarded many others for them. They are free setting and give fine fruit. I consider Ham Green Favourite the best for outdoor and late autumn work. Conqueror has been very good all this spring. Ladybird also is very good for this purpose, and so satisfied have I been with these that I have not tried any new ones this year. Green Gage is liked fresh for eating. I certainly consider the Tomato a vegetable, being used for cooking with seasoning, not sugar, and also classed with other vegetables in pickles, &c.—H. ELLIOTT, *The Wilderness, Sevenoaks, Kent.*

— The best Tomato is The Cropper. I have never seen anything to equal it for cropping, and the flavour is splendid. The above and Ham Green are, I consider, the best in commerce. The best outdoor kind is Cherry Ripe, and the best for winter and early spring crops is, I find, Frogmore Selected. I should say that a Tomato is a fruit, although it is admitted as a vegetable at horticultural shows. Still, I think it has more claim to be called a fruit, as it can be served up as dessert.—H. SANDWICH, JUN., *Calder Abbey, Calder Bridge.*

— The best Tomatoes are Ham Green Favourite and Chemin Rouge. Earliest of All is the best for outdoor culture and also for winter and early spring crops. I consider the Tomato a vegetable. I can appreciate a Tomato cooked in various ways or raw as a salad, but I am not of sufficiently educated taste to take it as a fruit, neither do I know anyone who, after a good dinner, would eat a Tomato by way of dessert.—J. CLEARE, *Toddington, Winchcombe, R.S.O., Gloucester.*

— There are far too many Tomatoes even to satisfy the largest cultivator. I always make a stand by older, well-tried kinds and give the newer sorts a trial by their side. If then they surpass in merit the older favourites in every point, then their position is assured. Some of the older kinds are difficult, however, to surpass. This much must be said of Tomatoes, that there is no uniform result attending the varied conditions under which they are grown. Were it so, then it would be an easy matter to say which are the best or the worst. I am no advocate for binding oneself to one or two sorts, even when grown in small numbers, simply for the reasons previously mentioned, and there is always interest to be found in variety. Frogmore Selected I have grown now for several seasons, and for general purposes there are not many others that can surpass it. I have had the heaviest crop of this, which furnished the roof of one small house, grown in pots, that I have yet seen. They were simply a rope of fruit from the base to their points and the individual fruits of uniform size throughout. Ham Green is a very similar variety and is one I grow largely. Its fruits are not of the exhibition type, but large enough for any other purpose. The Cropper and Champion are two of my newest additions; the former is the better of the two in weight of crop, but the latter has a particularly nice flavour. The former justifies its name, and has fruits of medium size and good in colour. For indoor culture Duke of York completes my list. Not being in favour as dessert

The Pomegranate (Punica Granatum) at Gunnersbury House. (See p. 373.)

profitable even in small gardens than crowding the rows, as much finer, heavier, better ripened bulbs are secured. Where it is the rule to destroy one Strawberry bed every year—and it pays to do so even in small gardens—no root-run is more favourable to the growth of Coleworts than the hard moisture-retaining Strawberry plot, and the ground has not to lie idle. One sometimes sees the throwing out of Celery trenches early in the summer advised, and in small gardens it is of the utmost importance, as the intervening ridges can then be used for a variety of subjects until the final earthing up is given. Cauliflower, Cabbage, and Lettuces all do well on the ridges, and no position suits dwarf Beans better, as the plants reap the full benefit of sun and air. Onions may also be so grown. Where the ground has to be cropped so continuously, it is wisest to grow the short or

a time, but there comes a time when his argument fails, and gardening as a whole is left in much the same position as he found it. Again, "J. C. B." in the first part of his article agrees with the gardener in question in placing the vegetable refuse in the bottom of the trench, while in the latter he sides with the farmer who keeps his manure near the surface so that the young plants feel the benefit of the manure from the start. Would it not be a better plan than either to dig the Pea quarters deeply in autumn in the old way and dig in whatever manure could be spared for this important crop as well as any vegetable or charred refuse to hand? I have just finished the preparation of the ground for midseason Peas—that for early varieties is occupied with Endive and July-sown Carrots—and have treated it as liberally as I can with regard to manure.

I can quite understand that gardens where manure has been dug in year after year get sick

here now, the yellow varieties are not given a place, but Sunbeam and Golden Jubilee have been proved to be first-rate. It is curious that they are not more in favour with lovers of the fruit in a raw state. The best kinds I have proved for walls are Early Ruby, Eckford's Prolific and Sutton's A. 1. Hathaway's Excelsior is an excellent one for the open border, as also is Sutton's Maincrop. Ham Green and Frogmore Selected are hard to beat for winter and early spring supplies. Of the latter I get full crops from pots in a moist forcing house in spring. The Tomato I consider strictly a fruit and not a vegetable, although it is eligible in vegetable classes. All the same, I cannot reconcile it classed as a vegetable pure and simple. It is a point that has long been contested, some claiming that Tomatoes are both a fruit and a vegetable, while others disagree with such a decision. Staged among choice fruits at a flower show they weaken the whole; associated with vegetables, quality and general appearance are distinctly enhanced. This comes from no fault of the fruit itself, but from the prevailing fashion and from an undecided point in their original cultivation as to whether their associates should be fruits or vegetables. The point could not apparently be decided then; it is rendered more difficult now.—W. STRUGNELL, *Rood Ashton Gardens, Troubridge.*

— I have not tried many of the varieties in commerce, but for several years have had a small collection, and have come to the conclusion that Ham Green, Earliest of All, Polegate, and Duke of York are the four best. All the above varieties I grow out of doors. Polegate and Duke of York produce larger clusters and finer fruit than the other two kinds. Ham Green and Earliest of All I use for early spring and winter use, as they set more freely than the others. Although when speaking of a Tomato we say fruit, yet I consider it a vegetable.—HERBERT NOBLE, *The Gardens, Ashton Court, Clifton, Bristol.*

— The Tomatoes I usually grow are Acme, Frogmore Selected, Ladybird, Hackwood Park Prolific, and the old Large Red. Outdoor Tomatoes are not grown here, as we are rather too far north for them to do well out of doors. For winter and early spring work I consider Ladybird and Frogmore Selected about the best. I never could see how the Tomato came to be classed as a vegetable. My opinion is that it would be better to give it a place among fruits. Of course, this question has two sides to it, and is very much a matter of opinion.—D. MELVILLE, *Dunrobin Castle Gardens.*

— A few years ago I used to grow a few varieties, including some of the newer ones, and found Challenger one of the best, so for the last year or two I have only grown it. I only grow Tomatoes under glass. It is of no use trying them out of doors in East Aberdeenshire; our winters are too cold and days too short to permit growing them even under glass.—J. FORREST, *Haddo House Gardens, Aberdeen, N. B.*

— I confine myself to two sorts, namely, Hackwood Park and Challenger. I have grown several other sorts under the same conditions, but found the two named to be the best setters and even-shaped fruit, the flavour also satisfactory. I think the manure they are fed with has a great deal to do with the flavour. When wanted for outdoors the plants must be well forwarded under glass. Ham Green will do well. Laxton's Open Air is a free setter, but comes too rough to be pleasing. I have seen Perfection do well outside. I prefer Hackwood Park for winter and spring crops. It is difficult to say which is the best, as so much depends on the culture at this time. I get fairly good results from this sort. In speaking of the Tomato we always speak of it as a fruit, and when shown it is generally as a vegetable. I think it should be called a fruit, as it can be eaten like an Apple or Peach, and its bright appearance seems to justify its being called a fruit.—CHARLES LACEY, *The Gardens, Burnhopside Hall, Lancheater, Durham.*

— I try most of the varieties, and I cannot find any to beat Frogmore Selected, Ham Green

Favourite, Perfection, and Challenger for all purposes. The two best for indoor work are Frogmore Selected and Perfection. I always consider the Tomato a vegetable.—S. J. RICHARDS, *Mount Edgcombe, Plymouth.*

— The varieties I prefer for inside culture are Polegate, one of the best Tomatoes yet raised; Duke of York, and a good type of Perfection. These are, in my opinion, three of the best, taking into consideration appearance, flavour, and freedom of setting. Golden Jubilee is a grand yellow, of exquisite flavour and of fine appearance. Carter's Outdoor is far and away the best I have tried for outside; it is most prolific, of good flavour, and extremely early. Earliest of All is a splendid winter and early spring Tomato. I consider the Tomato should be classed as a vegetable.—EDWIN BECKETT, *Aldenhurst House, Elstree.*

— The best flavoured Tomato I know is one I have grown here for some years. It was selected from Hathaway's Excelsior. For general purposes I grow my own selections of Challenger and Frogmore Prolific. When I choose one to propagate from, I generally use cuttings in the first place, then I get what I actually require, which is not always the case when saving seed from a selected fruit. On a low wall facing south I have had a fine crop of fruit. In addition to the two last named I have Hackwood Park and a variety named Laxton's Open-air. The latter is a capital outdoor kind. In my opinion, no one can expect to get Tomatoes fit to eat unless grown against a wall or up the roof, the same as Vines are grown. Fruit produced by plants grown together in great masses are only an apology for Tomatoes when compared with the real thing.—H. J. CLAYTON, *Grimston Park, Tadcaster.*

— I find Duke of York, Ham Green Favourite, and Frogmore Selected the best Tomatoes for indoor culture, the three being very free-setting, of good shape and flavour, and less liable to succumb to disease than many of the other varieties. In favourable seasons the above-mentioned do very well outside. The Tomato that I would recommend for outside is Up to-date, which sets freely. For winter and early spring work I would strongly recommend Earliest of All. My opinion is that the Tomato should be classed as a vegetable, as one very seldom sees it dished up as dessert.—C. ALLEN, *Worth Park Gardens, Crawley.*

— I consider Early Ruby, Hackwood Park, Prolific, and Hathaway's Excelsior the best, being heavy croppers and of excellent flavour. The best outdoor kind here is Early Ruby. The Tomato is a fruit used as a vegetable.—A. BLACK, *Carton Gardens, Maynooth, Kildare.*

— With the many varieties of Tomatoes now in cultivation, it is somewhat doubtful if any two persons would make the same selection of, say, one half-dozen. I have found the following as good as any: For early winter work, Early Ruby and Frogmore Selected, and for a general crop Chemin Rouge and a good selection of Ham Green Favourite. For outside, Early Ruby is, I find, the best. As to a Tomato being a fruit or a vegetable, it evidently holds the distinction of being both fruit and vegetable, but it will be some years before it is generally recognised as a dessert fruit. At the present time its proper place seems the salad bowl or the kitchen, although at times it may be seen staged amongst a collection of fruit. I was judging a few days back when I noticed a dish in a collection of eight kinds of fruit. But I do not think many gardeners would admit the Tomato in a collection if they had any of the usual kinds of fruit in a presentable condition.—J. LEE, *Gopsall Hall, Leicester.*

— I consider Challenger and Perfection still hold a foremost place as regards setting and flavour. Frogmore Selected and Swinton Park, new varieties of late years, are also good croppers, the flavour being all that can be desired. When true seed can be obtained of the old variety Comet, this, from a marketing point of view, is hard to beat. For outdoor culture, Comet, Large Red, and the Dwarf Orangefield give good results, either planted out or in pots against a south wall.

For winter and early spring supplies I have seen nothing to beat the Large Red. The Tomato, though classed as a vegetable and shown as such, should, by its habit of growth and handsome appearance, be entitled to what it is by right (botanically), a fruit.—J. HILSON, *Naworth Castle, Carlisle.*

— Varieties of Tomatoes cultivated here are a half-dozen, and the supply from May onwards is kept up from sowings made in January and about the middle of March. I have discontinued growing plants for fruiting in the winter. The varieties are Early Ruby, Conference, Perfection, Hackwood Park, Ham Green Favourite, and Frogmore Prolific. Early Ruby is included only for its earliness. It is not considered of such good flavour as any of the others, especially the two last named. Having room to grow sufficient Tomatoes indoors in a house devoted earlier in the year to Strawberries, I do not cultivate any great quantity outside, but Frogmore Prolific does well on walls confined to single stems, as also does Perfection. In another part of this county where Tomatoes are extensively grown tied to stakes in the open, Earliest of All crops heavily, and in parts of Worcestershire a variety called Evesham Early is much favoured. These have not yet been grown in this garden, but certainly appear to be good ones for outdoors. Although botanically a fruit, the Tomato is here used as a salad or cooked in some way as a vegetable.—J. GARRETT, *Batsford Park, Moreton-in-Marsh.*

— If I were limited to one variety I should certainly select Austin's Eclipse as being the most productive and equal in flavour to any other variety. For main crop I usually grow Eclipse, Frogmore Selected, Comet, Hackwood Park, Perfection and Dicksons' Monarch. For outdoor culture none do so well here as Laxton's Open-air, which crops splendidly, some ripening on the plants, the rest being cut at the end of October and hung up in a warm vinery, where they ripen well and keep us supplied with nice Tomatoes till Christmas. Though the variety is slightly corrugated in shape, it grows to a large size. I cut last year several of this variety outside quite ripe weighing from 12 ozs. to 14 ozs. each, and the crop was far heavier than anything I had inside. I grew Eclipse and Frogmore Selected for early use this year, having them ripe the end of May. Frogmore was earliest, but Eclipse had double the crop and keeps better, being firmer, and also resists disease better, being of vigorous constitution. I usually speak of a Tomato as a fruit, not in the literal sense, but meaning the fruit of the plant, as I consider it to be a vegetable. Could this question not be decided?—W. WRIGHT, *Taymouth Castle Gardens, Aberfeldy, N. B.*

— The best Tomatoes are, I consider, Early Ruby for a first crop, Perfection main and mid-season, and Trophy for late crop. Frogmore Selected, I find, is the best for winter and early spring. In the true sense of the word, I should consider the Tomato a vegetable.—J. RAINBOW, *Broughton Hall, Skipton-in-Craven, Yorks.*

— I find Polegate and Ham Green the best for general purposes, with Ladybird for winter and spring crops. Earliest of All is the best for outdoors. I consider the Tomato a fruit.—CHAS. DEANE, *Cassiobury Gardens, Watford, Herts.*

— My favourite Tomatoes are Conference, Challenger, and Ham Green. The last I consider one of the best both as regards cropping and flavour. For an outdoor crop nothing does so well as the Old Red. Conference does well for an early crop in pots. I consider the Tomato a fruit.—WM. ANDREWS, *Trigothuan, Cornwall.*

— The best Tomatoes I grow indoors are Duke of York, Challenger, and Ham Green, three good and free-setting varieties. The best outdoor Tomatoes I find are Early Ruby, the Old Red, and Dwarf Orangefield. I consider the Tomato a vegetable.—W. DRIVER, *Loujford House, Minchinhampton.*

— I have grown several varieties of these, but find Ham Green, Frogmore Prolific, Comet, and Hackwood Park reliable kinds to grow.

Earliest of All and Up-to-date are two good varieties for ripening out of doors, especially when strong plants raised either in frames or houses are planted out. Chemin Rouge is a free setter for winter and early crops. As to the Tomato being a fruit, I should not class it as such, but consider the seedsmen are right in cataloguing it in their list of vegetables and salads, for which it is used. I am pleased you are asking this question, as there is some doubt when it is exhibited in a collection of fruit whether it is admissible or not. I should never stage the Tomato in a collection of fruit or exhibit it as such.—A. CHAPMAN, *Westonbirt, Tethury.*

— The best Tomatoes I find are Frogmore Prolific and Viceroy. Viceroy, a type of the old Perfection, but a freer-setting and heavier-cropping kind, is the best for outdoors and also for winter and early spring culture. I consider the Tomato a vegetable. No doubt it is both fruit and vegetable. I would like to see this question settled. It should not be exhibited both in fruit and vegetable classes, and I think the Royal Horticultural Society should settle this question.

—JOHN LAMBERT, *Powis Castle Gardens, Welshpool.*

— I have grown a good many Tomatoes, and think the following the best: For early, Dunedin Favourite and Trophy; for summer and autumn, Invincible, Perfection, and Hackwood Park. I consider the Tomato a fruit.—J. SIMPSON, *Hurworth Grange, Darlington.*

— I find All the Year Round by far the best I have grown, taking into consideration freedom of setting and flavour. The best kind for winter and early crops is All the Year Round. I should consider the Tomato more a fruit than a vegetable.—T. SPENCER, *Goodrich Court, Hereford.*

— All things considered, there is no variety to surpass and but few to equal The Cropper, a variety raised by Mr. H. J. Jones and sent out by Messrs. Cutbush and Son. It is a moderately strong grower, very free setting, the fruit of medium size, Ham Green type, the colour good, and quality excellent. The Comet is also a good Tomato, but The Champion, the result of a cross between The Cropper and Perfection, is superior to it in point of weight of crop. In both instances the fruit is flat, round, very slightly corrugated, bright red in colour, firm, travelling well, and the quality good. Early Ruby is still the best open-air variety, that is for growing quite in the open. It is dwarf, the lower fruit nearly resting on the ground, free-setting, early ripening, not prone to cracking, and the quality is fairly good. Carter's Outdoor is a tremendous cropper, ripening early, not cracking, but the fruits are somewhat coarse. Against walls The Cropper, Comet, and Sutton's A I have done well. In point of cropping, form of fruit, and in particular flavour, no variety grown against walls surpasses Dedham Favourite, but the colour is against it. For winter and early spring crops I have found none to equal The Cropper. The Tomato is undoubtedly a fruit. It cannot rightly be termed anything else. It is largely eaten by the working classes, and by many is preferred to an Apple. Tomatoes, however, are not popular, nor apparently gaining in popularity as dessert fruit, and must still be associated with salad vegetables.—W. IGGULDEN, *Frome.*

— I consider the newer varieties of Tomatoes are a great improvement on the older sorts so far as flavour, size, and symmetry are concerned, but doubt whether any of the newer kinds can surpass the older ones for heavy cropping. Since the introduction of the smooth, round fruits of the Perfection type the corrugated sorts have gone out of fashion, and, compared with twenty years ago, are but little grown now. I was at one time a large grower of these wrinkled kinds, and although long since discarded, I still remember the great crops of fruit that such varieties as Large Red, Conqueror, and Orangefield used to yield. Having once given them up, it would have been useless to think of reintroducing them even if I had wished to do so, for the superior appearance, quality, and flavour of the newer and rounder kinds proved irresistible, and the wrinkled sorts would not have

again been countenanced. Among the newer kinds we have some very fine croppers, of which Frogmore Selected, Powley's Up-to-date, Hackwood Park, and Conference are a few notable examples, but I maintain that they do not surpass the corrugated and older sorts in this particular, while many others do not equal them. Taken individually, some of the newer sorts show a great advance in point of size, but I do not care for large, bloated-looking fruits, and much prefer medium-sized specimens for general purposes. Coming to symmetry, here again there is an immense improvement, and present-day varieties are in every way infinitely superior to the wrinkled sorts that were in cultivation twenty or more years ago. As regards flavour, there is a decided advance, and many people who would not at one time eat fruits of the more acid and older sorts, greatly relish the newer and sweeter kinds that now find favour with most growers. To sum up, then, my answer to the first query is that, with the reservation as regards cropping powers, the newer sorts are greatly superior to the old. I am not so large a grower of outdoor Tomatoes as many, as it is only any open spaces there may be on the fruit walls that are utilised for the purpose. All the same, I have found none to fruit with greater freedom and to be so satisfactory as Laxton's Open Air, and it is, in my opinion, the best Tomato for outdoor cultivation. I do not grow Tomatoes through the winter months. However, I make a start as early as possible in the new year, so that there shall be a good supply for the spring months. For this purpose I used to grow Orangefield, but having had my attention drawn to a variety named Early Prolific, I then abandoned Orangefield in its favour after trial. It is a good one to set, and although not large, the fruits are, for so early a variety, very freely produced. The fruits are smooth, roundish in shape, of a bright red colour, and exceedingly well flavoured. These are grown in rather shallow boxes, and fed well as soon as a good set has been secured. Although used more often than not as a vegetable, the Tomato is to all intents and purposes a fruit.—A. WARD, *Stoke Edith.*

— A good selection of Perfection Tomato, under whatever name known, still ranks as one of the best varieties in cultivation. The Polegate selection is a fine one; so, too, is Comet, and Duke of York, if not furnishing such large fruits, is a heavy cropper. Of the oval shaped fruits, Chemin Rouge, A I and Regina are excellent, both for cropping and for general usefulness. Flavour is in Tomatoes a nominal element. The best of this quality is found in the new Golden Peach, Golden Nugget and the pretty red Cherry-ripe. But there is great room for flavour development in the Tomato, and to that end raisers should specially direct their energies. A fine outdoor variety is Magnum Bonum. Probably it is the heaviest cropper and generally the most satisfactory, with the exception that the fruits are much corrugated. The smooth fruits are most liked. For winter and early spring cropping no variety I have seen is so good as is the new Winter Beauty. It is dwarf, compact habited, sets freely, and produces fine handsome fruits—a good feature in any winter variety. Tomatoes are fruits to some who consume them only in a raw or uncooked state, and these are by far the greater number of Tomato consumers. Small and medium-sized fruits are not only pleasing as dessert fruits, but they are soft eating, pleasant to the palate, refreshing and most wholesome. To exclude them from collections of fruit at exhibitions is absurd. Only by those who consume Tomatoes cooked or as salad-ing can they be classed as vegetables. Because used to make sauce no more makes them vegetables than does using Apples for a similar purpose make them vegetables. Such is the nature of the Tomato and so varied its uses that we must continue to class it both as a fruit and a vegetable.—A. DEAN.

— Ham Green Favourite Tomato maintains its position here as the best Tomato, producing a heavy crop of delicious flavour and handsome

appearance. It is relied upon for a general crop. Challenger, Duke of York, Frogmore Selected, and Ladybird have been grown here, and are all excellent kinds. This season is my first trial with Cestrian. It proves an excellent bearer, with large crimson fruit entirely without sutures, and of good flavour. Tomatoes are not grown here as an outdoor crop, Ham Green and Cestrian occupying a space towards the front of a late Peach house. All the Year Round and Ham Green are grown for winter and early spring. The former produces large clusters of fruit and remains a long time fit for use: it is also a hardy variety, a consideration where economy with fuel is required. The Tomato may be as much a fruit as a Melon is, and in many establishments it is partaken of as a fruit, but I should consider it a vegetable, and not admissible in a collection of fruit for exhibition.—GEORGE PHILLIPS, *The Gardens, Wyastone Leys, Monmouth.*

— My favourite Tomato is Conference, grown from seed which I have selected year after year since the introduction of this once popular variety. It hits the happy medium as to size, is of fine quality, of good colour and shape, crops freely, and has the quality, so valuable to those who cannot grow winter Tomatoes under glass, of keeping better after being stored than any other variety I know. Of course, it has not the sensational size of Duke of York and some others, and that may account for its not being more grown. I like it both for indoor (early and late) and outdoor culture. This year I am trying Up-to-date for the first time, and am pleased with the result both as a cropper and from a flavour point of view. Of the yellow-fruited varieties I have not found one to equal Golden Jubilee, a really grand variety of excellent constitution, handsome shape, and splendid quality. The Tomato ought certainly to be classed as a fruit without making any absurd restrictions as to size or on any other point. If not often served as a dessert fruit, it often occupies the position of a fruit when plucked from the plant, and a most refreshing fruit at that. In Government and in market returns it is classed as a vegetable, and perhaps it is as well that this is so, for railway rates are high, and might be still higher under another classification. J. C. TALLACK, *Shipley Hull, near Derby.*

— I believe the newer varieties are better in flavour, but certainly not freer setters. I should pronounce for the new ones, nevertheless. I do not grow many outside. I like Hackwood Park the best. Conference or Best of All I find the best for autumn and early spring. Tomatoes, I should say, are now equally used for the dessert and for cooking. I am not in favour of classing the Tomato as a fruit, and think it should remain a vegetable.—W. J. NOVELL, *Catton Hall, Burton-on-Trent.*

— The Tomato I mostly depend on for early and late forcing is Ham Green. I generally try any new sort of repute as sent out. I get Ham Green from a true source, and cannot see any to beat it for cropping and quality. I like Laxton's Open Air for outdoor culture on walls, and yet I mostly grow Ham Green for that purpose as well. Properly speaking, I think the Tomato ought to be classed as a fruit.—T. ANDERSON, *Laleham House, Staines.*

— For some time I have confined myself to Hathaway's Excelsior, finding it to be a most reliable kind both for indoors and out. This year I am trying Frogmore Selected, and as far as I can see on outside walls there is little difference. I consider a Tomato a fruit. At the same time, I do not think it could be allowed in a collection of fruit for dessert.—H. W. MATHESON, *Addington.*

— I consider Challenger and Chemin Rouge the two best varieties for heavy cropping, good shaped fruit and good setters. Frogmore Selected is of better flavour for eating in a raw state, but it is not such a good cropper as the other two. I have grown Golden Jubilee and have found it a good cropper. It sets well, has good solid fruit, less acid than most varieties, which has made it a favourite with many for eating in a raw state, while others consider the flavour insipid with-

out the small amount of acid. The three varieties above do very well here on south walls, and I always train them with four shoots from each plant and they give heavy crops. But for training up sticks in the open Earliest of All and Laxton's Open Air are the heaviest and earliest croppers. Ladybird and Earliest of All are the best for autumn and spring use. I consider the Tomato a fruit, used mostly as a vegetable. At present it cannot be classed with ordinary fruits eaten as dessert.—J. LANSDALE, *Barkby Hall, nr. Leicester.*

— I still continue to grow Perfection under glass in preference to all others. For outdoor, early spring and winter crops I consider Up-to-date the most useful; it is rather small, but of excellent quality.—T. LOCKIE, *Huntingdon.*

— The best, I think, for exhibition are Polegate and Perfection, but for freedom of cropping and general purposes for inside and out, both winter and summer, I have found nothing to equal Comet. I have tried nearly all the sorts. Up-to-date did well outside this year. I should certainly class a Tomato as a vegetable.—J. BOWERMAN, *Hackwood Park, Basingstoke.*

— I rely upon Ham Green and Frogmore Selected for general crop, and they are hard to beat for all purposes. Conference and Duke of York are also good. Hathaway's Excelsior is with me the best outdoor kind. Ham Green is the most reliable kind grown here for winter and early spring crops. I consider the Tomato a fruit, although always shown and used as a vegetable.—W. NASH, *Badminton, Chippenham.*

— I consider Austin's Eclipse the best all-round Tomato that I have ever grown, good alike both for early and late crops. It is an abundant cropper and of excellent flavour. Stirling Castle and Comet are also good. I consider the Tomato a fruit.—W. HUTCHINSON, *Eastwood Park, Renfrew.*

— I consider Perfection and Sutton's Dessert the best Tomatoes for flavour and setting. Earliest of All is the best for winter and spring, and also for outdoors. I think the Tomato ought to be classed as a fruit.—J. G. GOODMAN, *Abney House, Bourne End.*

— The Tomato I grow principally is Eclipse, both indoors and outside. It is remarkably free and prolific. Another variety is Frogmore Selected, rather more hardy, but it does not ripen so quickly. The Tomato is a vegetable.—E. TROLOPE, *Coombe Park, Whitechurch, Reading.*

— The best Tomatoes I have grown are Stirling Castle, Conference and Abundance. For cool unheated houses, I have found Ham Green suitable. I consider the Tomato a fruit.—EDWARD TATE, *Balcarres, Fife.*

— I consider Frogmore Selected the finest Tomato grown. It is a very free setter, of excellent flavour and equally good for winter and early spring crops; in fact I grow no other. I grow a few on a wall outside, but Tomatoes outdoors in these parts are not a success.—ARTHUR SMITH, *Edenhall, Langwithby, R.S.O., Cumberland.*

— Seeing that so many excellent varieties of Tomatoes are now on the market and seeing that so much depends on the locality (speaking of growing Tomatoes outside) it would be difficult if not impossible to name any one variety as being the best. Of the several varieties which I have grown here, both on walls and trellises, I find Challenger and Ham Green Favourite two of the most suitable kinds, both as regards free cropping and good flavour combined with a sturdy constitution. I do not, owing to want of room, grow many indoor varieties, but for early work I have a good opinion of Frogmore Selected. I think that the Tomato should be classed as a vegetable.—W. LUMSDEN, *Bloxholm Hall, Lincoln.*

Winter greens.—The present aspect of these is far better than was originally anticipated. I have been surprised to find how well Kales, Savoys, and Brussels Sprouts have come on in comparatively poor soils where water could not

be obtained, and plants once got in had to take their chance. No harm will have been done, and perhaps some good, if those who plant winter greens learn to get them out later rather than earlier, as whilst earliness may ensure stronger growth, it also promotes too early production. No one wants Kales and Savoys in before Christmas, and the present season is showing that those plants either got out late or greatly retarded in growth because of the drought will give of their heads or hearts after the new year comes in, and the later into the spring the better. Of course Brussels Sprouts may be earlier, as these, unlike other members of the Cabbage tribe, yield sprouts over several months. But plants that are very early, and as a rule very gross, produce gross sprouts for some time, until later, the stem becoming harder, the sprouts become also harder and smaller. Generally, stems that produce good hard and not large sprouts from the first of November onwards to the end of March are the most profitable and serviceable. Coleworts are much smaller than is usually the case, but these will be all the better for some two or three months' longer growth. With a continuance of open weather Autumn Giant Cauliflowers will continue to head in, and these just now are excellent; indeed, much sweeter and milder than were those cut in September. On the whole our winter green crop will not be a bad one.—A. D.

NOTES FROM SYON GARDENS.

No one would from choice select the end of September as a suitable period of the year to pay a surprise visit to Syon House Gardens, but even at that late date there remained much to interest those in quest of information, cultural or otherwise. To me the Peach trees on the open walls were a source of much interest, the extent both of variety and trees being considerable. Nowhere this season have I seen such clean and healthy trees, notwithstanding the tropical nature of the season and the lightness of the soil of which the garden is composed. Syringing and watering must have been closely followed up, and their general management was such that nothing short of the highest commendation seemed justified. The crop this season had not been so heavy as usual, but this is not to be wondered at when the garden is only about 17 feet above sea-level and in close proximity to lake, canal and river. The destructive frosts that were so universal at their flowering period must have been severe. One long stretch of south wall was filled with fine trees, as also was one with a west aspect. These latter replaced dessert Cherries that did not do well on this particular wall, though on cooler aspects they are a great success. Bush Peach trees planted on a south border some feet from the wall grow remarkably well, but Mr. Wythes contemplates removing them to a cooler site in order to make them later if possible in flower, and it is hoped safer from frost in spring. Some trees on a north aspect looked as happy as did others, and in not a single instance did any trace of blister appear, although there is no glass coping provided anywhere. The extent of the kitchen garden is 9 acres, and scattered over this large area are many hundreds of trees of all kinds. Apples and Pears are splendid examples of careful cultivation.

Besides these there are large quantities of Peaches and Figs in pots and permanently planted-out trees. Grapes have several large houses devoted to them, two or three of them being iron-roofed structures quite 30 feet in height, the borders being outside ones. As with other fruits, the demand for Grapes is heavy and continuous, 9 lbs. to 12 lbs. being required daily. Chrysanthemums fill several of the fruit houses and number some 1500, a large proportion of them being grown for specimen blooms. These looked remarkably well and I saw no sign of rust, which is a source of much complaint this year. A houseful of Cucumber plants (Syon House Prolific) was thickly hung with seed fruits almost ripe, and distinctly showed its prolific character. This is a

fine variety for winter fruiting. For every-day use in winter these are brought on in batches, mostly in pots, as also are Melons, for which Syon is also famous. At the end of September there were still many fruits in various stages of growth.

The large winter garden has recently undergone considerable internal modification, cumbersome stages having given place to a much more natural system of growing plants in beds, and the roof being draped with climbers. The central dome is filled with lofty Palms and a gigantic Bamboo some 40 feet in height. Three miles of hot-water pipes formerly served to heat this extensive winter garden, but a re-arrangement on more modern principles reduces this quantity by one-third, and, needless to say, with much more satisfactory results. To maintain a succession of decorative plants for these winter gardens needs considerable stock for periodical renewals. For the benefit of the young men in the bothy there is a good library, and in addition all the leading gardening papers are furnished weekly, so that every inducement is given for self-improvement. With 70 acres of grounds, 9 acres of kitchen garden, besides the glass, there is everywhere apparent the evidence of a master hand both in management and cultural skill. Walks, which have an extent measuring, I believe, five miles, are bright, free from weeds, and otherwise excellently kept. A combined steam lawn-mower and force pump makes the labour of mowing much more easy than hand work. In large gardens the steam mower should be a boon when thoroughly understood by the man in charge. In the height of summer when the demand is less for mowing it can be used most effectively for pumping water from the lake or other sources, and with hoses much good work can be done with a small expenditure of labour. From such a large area vegetables are forthcoming in proportionate quantity, but even at Syon the great and memorable drought had left its mark in the lateness of growth in many things planted. This is, of course, inevitable, particularly where the soil is light, as is the case here. Though September is not a month to choose to see Syon in its true aspect, many useful lessons may be learnt, and which in my case will not be soon forgotten. W. S.

GARDEN FLORA.

PLATE 1248.

NERINE MANSELLI.

(WITH A COLOURED PLATE.*)

PERHAPS it may interest some of your readers to know the origin of the Nerine figured to-day. In March, 1880, I purchased three seedling Nerine bulbs from Messrs. E. G. Henderson and Son, of St. John's Wood, under the names of *Nerine elegans*, *N. cinnabarina*, and *N. sanguinea*. *N. sanguinea* died; the other two did well and flowered. I was so charmed with the blooms of both these seedlings that I wrote to the person I understood was the raiser of these Nerines, viz., Mr. James O'Brien, when he was with Messrs. E. G. Henderson and Son. We had a long and interesting correspondence on the Nerine family, and I sent some of the blooms of Nerine Manselli to Mr. O'Brien, who afterwards sent them to Mr. G. Baker, of Kew, who thus wrote: "It is a fine plant, just about halfway between its parents, with a very broad fleshy leaf, and bright red, slightly irregular flowers. A decided acquisition to the series of garden forms." I sent some of the blooms of Nerine Manselli on December 18, 1887, to the Royal Horticultural Society, South Kensington, which were awarded a first-class certificate under the name of Nerine Manselli. As regards Nerine elegans, I have always cherished it. I con-

NERINE MANSELLII.

sider that it ranks next to *N. Manselli*. It blooms rather earlier, but it is neither so free-flowering nor so vigorous. J. L. M.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

PEACH HOUSES.—Just at present there will be but very little to do among the Peach trees, except to carry out the routine work of pruning, cleaning, and re-tying, as recommended in former notes, getting this work out of hand as quickly as is consistent with good workmanship. Before tying the trees, any painting that woodwork or

the necessity for utilising all available space for the storage of winter-flowering plants, it is imperative in the case of early Peach houses and vineries that these should be cleared out, so as to allow a week or two of full exposure to whatever weather may come before the houses are again put to work. If the nights are frosty, so much the better, as a touch of frost appears to pave the way for a kindly start when the time comes. Early houses are frequently badly treated in this way, and suffer accordingly. Being the first to be cleared of leaves, choice naturally falls on them for housing Chrysanthemums and such like plants, which require all the light they can get, but these plants should be moved on into later houses as soon as room can be found for them. This should not now be a difficult matter, as many of the

stronger than do those which have their roots and tops in the same temperature from the start, and this enhanced strength shows itself right through to the time when the Grapes are setting, the bunches being more sturdy and the individual flowers likely to set more freely. Before surrounding the pots with a good quantity of fresh Oak or Beech leaves each pot should be set firmly on a pedestal of some kind, so that there shall be no sinking out of position later on. Allow a fair space between the pots and the front wall of the house, so that the benefits of the hot-bed may be felt all round and not only on one side of the pot. If the bottom-heat has to be supplied by hot-water pipes, see that the pots are kept some inches above or away from these and the intervening space filled in with spent tan or some such material that will tone down the dry heat, for when the bottoms of the pots are brought too near the pipes there is considerable danger of the soil and roots becoming too dry near the bottom. The bottom-heat, however generated, should be carefully watched, and it will be quite sufficient for some time to keep it to from 55° to 60°. More than this will be harmful until the Vines show signs of growing, after which, of course, it may rise proportionately with the rise of the top temperature. I advised above the use of leaves alone, and prefer them for Vines, which have to be started so gently, as there is less fear of the bed becoming too hot than when manure also is used. A deeper bed into which the pots may be sunk to their full depth can safely be made with leaves alone. When the pots are in position the rods should be tied to the trellis, either coiled or bent into such a position that the middle length of the rod will be most elevated, as this will assist the Vines to break regularly, a great point in pot Vine culture. Tie them in the simplest possible way so that there will be as little danger as possible of breaking the new growths when they are again re-tied into their proper position for growing. A night temperature of 50° will be quite sufficient to start with, and a high day temperature may be kept down in sunny weather by the admission of a little air; otherwise the house or pit may be kept close up to the time when the buds are seen to be on the move. Syringe the rods occasionally with warm water on bright days and preserve a fairly humid atmosphere by damping down when necessary. This should not, however, be overdone. Pot Vines which were placed in position as I advised some time ago will probably require some water, and even those which have been outside and protected from rain may be on the dry side, but this is a matter that must be governed by individual circumstances; and one can only say that during the first part of their forcing career pot Vines require very little water indeed provided other conditions are right. More especially is this so with those that are plunged in damp leaves, as these will gain sufficient moisture by absorption up to the time they start. When growth commences, a steady circulation of air must be given.

PINES.—Careful attention to the bottom-heat will now be necessary in Pine houses and pits, and where there are no bottom-heat pipes or an insufficiency of them, the Pine grower's lot is not a happy one during the winter months. The turning over of hotbeds, mixing in fresh material, re-plunging, &c., are not very desirable work, and are also a source of anxiety, from the fact that new or re-made beds are apt to get too hot. A bottom-heat of from 80° to 85° must be maintained for growing stock; those resting will put up with a few degrees less. Watering will be reduced to a minimum, but must not be altogether neglected with plants swelling their fruits or with those that have nearly reached fruiting size, but which it is advisable to keep from showing fruit for the time being. Lift plants which are ripening their fruits out of the plunging material and give them the lightest possible position at the warmest end of the house, as this will greatly improve the flavour of the fruit. If the young stock is at all overcrowded, it should

The sweet-scented *Verbena* (*Aloysia citriodora*) at *Gunnorsbury House*.
(See p. 373.)

trellises may require should be done, and it is as well to remember that a coat of paint has another virtue besides that of preserving the woodwork, this being its destructive properties to insect life, and if only for this alone it would be true economy to paint oftener than is usual. Where there are many houses the work of re-tying has frequently to be left to inexperienced hands, and some instruction will be necessary, more especially in the matter of allowing plenty of room for the natural swelling of the wood, tight tying being one of the most common of errors. I like also to have a twist made in the matting after passing it round the wire and before bringing it round the shoot, this preventing the shoots coming into direct contact with the wire and tending to lessen gumming. Whatever may be

earliest flowered Chrysanthemums will be over, so that the plants may be cut down and stored in less space.

POT VINES.—Where these are grown as a relief to the planted-out Vines or for early work, it will be time to get them into position for a start, and they should be brought into the lightest pit available which has good heating accommodation. They may be started and well grown either with or without hot-bottom-heat, but, personally, I much prefer a plunging bed, and consider it especially valuable in the very earliest stages, as a gentle bottom-heat will then bring the roots into active work, while the tops are kept dormant for a week or two by admitting plenty of air and keeping down the temperature of the pit in the meanwhile. Vines treated in this way break

be overhauled and the most unpromising plants thrown away.

LATE GRAPES.—To keep ripe Grapes hanging on the Vines at this time of the year one must be prepared to go over them with the scissors frequently, removing every berry which shows any sign of decay. Fortunately, most of the Grapes grown for the winter season are thick-skinned and keep pretty well, but they give some trouble through the November fogs and must not be neglected. A little fire-heat, with ventilation, should be given during the day, confining the ventilation to the top ventilators in damp or foggy weather, but at night artificial heat will not be advisable except to exclude frost, it being far better to confine the drying-up process to the daytime.

CORNUBIAN.

KITCHEN GARDEN.

ASPARAGUS BEDS.—In light, warm soils Asparagus beds are assuming a yellow aspect sooner this season than usual, and there will be no gain in postponing mowing or cutting the grass after that stage has been reached. In small gardens possessing only a limited number of beds, cutting the stems off with a strong knife is the best, as the scythe is apt to tear the stalks out and injure the crowns. Some still favour autumn or winter mulching even when the beds occupy a low-lying position and consist of a heavy, retentive soil. On this account beds often suddenly go wrong, and even die off entirely. At the same time, although not approving of heavy manurial coverings at this date, I think that the crowns and roots, many of the best of which lie near the surface, are benefited by a slight covering of some short littery material. For many years I spread old hotbed material over mine, first giving a liberal sprinkling of some approved fertiliser. This affords protection should the winter turn out severe, and on porous, well-drained soils the roots never get too much moisture. Some still think good Asparagus cannot be grown without the use of a good deal of salt, but my experience is that that is more imaginary than real, as some of the most noted growers never use salt at all. All the same, salt is a good weed eradicator, and a sprinkling may well be given as soon as all weeds and rubbish have been cleared off the beds and previous to any mulch being applied. Care is needed in raking the surface of the beds, as after a genial autumn young growths frequently spring up, which are easily snapped off. Those who contemplate making new beds should avoid elevating them to any great extent and having deep trenches between, especially on light, well-drained soils, as thus formed much of the necessary moisture drains away from the roots, while in heavy, retentive gardens the water drains into the trenches, and there often stops, to work mischief. Where any old beds are being forced, avoid planting in the same position, or at any rate the old material. Choose if possible an entirely new site, using the old plots for other vegetables. Excellent Peas, Beans, and Cauliflowers may be grown on old Asparagus beds, bush fruit also doing well.

SOWING EARLY PEAS.—It is, perhaps, full early for this operation in the southern parts of the country, but further north from the present to the 20th of the month is a good date to get in the seed of dwarf hardy sorts. Some ignore autumn sowings, but where the border is light and warm and the situation sheltered, a week or ten days may be gained by open-air sowings. Peas transplanted in spring, which have been brought on even in cold frames and exposed to all the air possible, are apt to suffer from snowstorms and cutting winds should such prevail immediately after transplanting; whereas November-sown batches acquire a hardy constitution and readily respond to finer weather and longer days in February. I have found the plan of sowing fairly shallow and slightly ridging the soil over the rows to be of benefit. Thus treated, decay is less likely to occur should a wet period set in just after sowing. Provided the ground is fairly rich, no manure need be added, as it is easy to err in this

respect, especially if the manure used is of a strong, rank nature. The latter encourages a growth which is easily affected by frost, basal decay being likewise liable to occur. If any is necessary, use old Mushroom manure, and if need be add to it a small percentage of some safe artificial manure. Any of the dwarf hardy varieties answer well for open-air autumn sowings. Let the distance between the rows be about the same as the height of the haulm, this admitting plenty of light and air to the roots and haulm in spring. As soon as growth is well through the ground, place a few small Yew branches on each side of the rows to shield from cutting winds. Those who have no facility for forcing Peas in early spring, but who have a spare cold pit or two, will find it profitable to sow now such sorts as William Hurst, Chelsea Gem, or others of the same type. These will afford a few useful gatherings a fortnight or three weeks before the earliest spring-sown border lots come in. Use soot and lime freely over the surface in winter if slugs attack them, as they frequently do at this dull, damp period should it be mild. Watch also for sparrows, or a raid by them of a few days' continuance will blast the cultivator's hopes. It is a good plan when sowing to sprinkle a little leaf-mould in the drills before covering them in. It assists root action.

VEGETABLES AND THE SEASON.—Many gardens of a shallow, poor nature suffered much through the long absence of rain during the time winter vegetables were making their growth. On the other hand, where the soil was fairly rich and moisture-retaining, such crops as Brussels Sprouts, Broccoli and Kales made firm, good growth, and sprouts are now medium-sized and firm. Beet suffered much in some districts; several large market breadths which I saw were lying prostrate by reason of the drought. Large Beet is not wanted and is almost unsaleable, people preferring nice shaped smallish roots, these being, as a rule, much better flavoured and more suitable for slicing up. Dell's is still highly thought of, and it is undoubtedly a good all-round variety, but I prefer Veitch's Selected Red, a fine-shaped, richly coloured, good-flavoured Beet and just the thing for the dining-room. Green vegetables which have made a fair growth should be able to withstand a good amount of frost should such occur, which they will not do when growth is gross and soft.

J. C.

CHRYSANTHEMUMS.

THE DECLINE OF THE INCURVED CHRYSANTHEMUM.

THAT the prim and shapely Chinese type of Chrysanthemums so popular among older growers is on the wane one can see on all sides, and were it not for the substantial prizes offered for them at exhibitions the overshadowing merits of the Japanese forms would soon quite kill them. Much as one may admire their perfect ball-like shape, there is no getting away from the fact that they require a large amount of skill to produce them, and when they are produced, still more patience is needed in manipulating their florets to obtain that desirable shape. They are less showy on the plants than are the Japanese varieties, which now include every conceivable form, and are therefore less handsome for all kinds of decoration. The public takes but a languid interest in the class which has always been wanting in variety of colour. Take away the whites and the varying shades of yellow, and there is little left. Somehow, too, of late years really fine specimens have been rare. They will not respond to the high culture, as it is called, that is practised in the case of the Japanese kinds, and many growers for that reason are giving them up. It seems like ancient history to think of "Queens" so long regarded the ideals of the incurved type. Since they were seen so fine, varieties which are really bad forms of the Japanese are the leading ones. The flat and rounded floret has given way to those of any shape, so that the whole shall produce something

globular shaped. One by one the classes of Chrysanthemums go. At first the reflexed, then the Anemone-flowered, till by and by there will be but one family left. The neat little pompons will undoubtedly find favour for a long time to come for cutting; so, too, will the singles, but for exhibiting as specimen flowers there will be nothing left but the Japanese. We should deprecate any division of these whether shown in the usual way on boards or in more imposing vases. It is their variety of form added to their many colours that give them their beauty when placed together.

The loss of the incurved kinds, then, will not be felt, and I should not be disposed to offer prizes for them. That their exhibition is brought about by a certain amount of artificial means in the way of arranging the florets is pretty well known, and tends to deter would-be cultivators of Chrysanthemums from taking them up because of this dread of "curling." I do not care to foster the growth of all forms or classes of this particular flower because such have once been popular, but rather do everything to extend the culture of the best. Who, for instance, wants the lumpy show Dahlia now that we have the Cactus type, so much more elegant and in every way more useful? Why grow the somewhat delicate and few-petalled bizarre Carnation when fancy, coloured and self kinds may be obtained with little trouble out-of-doors in the open ground—full, fine, handsome blooms in rich profusion? Let the Chinese Chrysanthemum go like many another fashion in flowers. It will only live in the memory of those who, like myself, have spent no end of time in trying to make it presentable for exhibition.

GROWER.

Chrysanthemum Australian Gold.—I was much struck with the beauty of this variety when it was first introduced, but seldom since have I seen it so good as then. I met with it, however, in perfect form the other day among more kinds that had been cultivated with anything but pretensions to exhibit. It is an informal pyramid of light yellow, the florets being placed in charming lace-like arrangement. Probably the cause of failure with this kind is that it is generally overgrown.—S.

Chrysanthemum Cullingfordi.—One of the oldest of Chrysanthemums, this is also one of the best for growing in bush form, its bright and effective colour as well as its good habit being in its favour. In common with several others of the reflexed class, the flower-stems are weak and the blossoms do not always hold up their heads so well as one could wish. Besides being useful for growing in bush form, Cullingfordi is very suitable for striking late and growing on in small pots. The blossoms in this case are small, and therefore stand up better, but they are wonderfully bright, and come in well for late decoration in the conservatory.

Chrysanthemum rust.—This pest is making sad havoc again in this neighbourhood, and out of many collections visited I have not found one entirely free. In my own case there was no sign of rust until the plants were housed, though I had looked carefully for it, but as soon as they came under glass the little brown spots began to appear, and are now plentiful in spite of all I can do to stop them. I had hoped until the plants were housed that I had stamped it out by frequent applications of sulphide to the cuttings before they were removed from the old plants and also after they were rooted and potted up. I am now having every leaf that is affected sponged, but it is not to be checked in this way.—SUFFOLK.

Chrysanthemum Marie Calvat.—This Japanese variety, of continental origin has now been in cultivation long enough to determine its merits, and those growers who hurriedly discarded it because of its roughness from an early bud selection may now be interested to learn that blooms of exceptional size and high quality are finishing well. To arrive at this result the plants were stopped towards the end of April, and the

strongest succeeding individual shoots grown on strongly. In the course of time this shoot made a natural break, from which three shoots were taken up. These in turn ultimately produced crown buds (second crowns), from which really handsome blooms are now in the pink of condition. The colour is a soft rose and the petals are long and broad. The habit also is dwarf and the constitution robust.—D. B. C.

CHRYSANTHEMUMS AT SWANLEY.

THE annual display of Chrysanthemums provided by Messrs. Henry Cannell and Sons is always of exceptional merit, and this year's is no exception. The plants are housed in a large span-roofed glass structure admirably adapted to show them off to the best advantage. The collection, always up-to-date, comprises everything that is newest and best. Japanese are almost wholly now-a-days the feature at the trade displays, other varieties being mainly kept for stock and not contributing so much towards the general effect. This year Messrs. Cannell have varieties from home, colonial, continental, and American raisers, but these last are considerably in the minority. Most of the plants besides being well flowered are dwarf in growth, presenting a striking contrast to some of those we used to see years ago.

Dealing first with varieties of continental origin, M. Ernest Calvat claims first attention as being still the foremost cultivator in his country. Fairly well-known varieties from this raiser which appear again in good form this year are M. Fatzner, a grand incurving Japanese, very close and compact, and the colour tawny yellow; Marie Calvat, white, flushed purple, is big, but not attractive; Mme. Ferlat is fine in form and very pure in colour. Others, such as Mme. Couvart [de Terrail, Souvenir de Molines, Mme. Carnot, Werther, Le Grand Dragon (very large), Mme. G. Bruant (white, flushed purple), and N.C.S. Jubilee, need no description. Some of M. Calvat's newest flowers are President Lemaire, velvety crimson and gold, and Mme. Lucie Recoura, something after the build of Pride of Madford, and not unlike it in colour. Zephoris is a promising golden yellow Japanese, with flat, pointed florets, but Soleil de Decembre, of the same colour, seems to be too early to justify its name; M. H. Martinet is a big crimson and gold variety, and also of this year's set is Mme. Aristide Rey, a Japanese with broad florets, colour rosy amaranth, with reverse of silver. Eliane, golden yellow, and Lydia, a rosy amaranth, with a silvery pink reverse, are also quite new.

Some very promising novelties are on view from M. Nonin, whose name has only become familiar to English growers during the past three years, and several other continental raisers were also well represented. We noticed especially Amateur J. Lechapluis, a huge crimson and gold Japanese; M. Raymond Desforests, reddish velvety crimson, with deep golden yellow reverse; Soleil de Lyon, golden yellow; Mme. F. Daupias, pure white; Mme. Alphonse Rodière, President Dutrail, terra-cotta and gold; M. Gatellier, dull terra-cotta, and reverse of straw-yellow; Corcora, very fine pale blush-pink in the style of Lady Isabel; and Jules Bernard, a velvety, rich rosy amaranth with silvery pink reverse. Colonial varieties, which were so interesting last season, are keeping up their reputation again this year, and of these one of the most popular, viz., Nellie Pockett, is quite as good this year as last. Pride of Madford, Australie, Mr. T. Carrington, and Purple Emperor are well-known colonial varieties. Not quite so old, but seen in good form last season, are S. R. Upton, a fine yellow, and Miss Mary Underhay, a pretty shade of straw-yellow. Newer forms are to be found in Sydney Brunning, a large bloom of the Japanese type, colour deep reddish terra cotta with golden reverse; Marjory, bright rosy pink; Hector Brunning, dark crimson, with golden reverse; and Sir H. H. Kitchener, bright reddish crimson, reverse old gold. Mrs. Frank Gray Smith, deep

golden yellow, is another of these colonial newcomers, as is also Admiral, a white Japanese, not unlike the old variety Avalanche. Miss Poppy Brunning is very large and of a peculiar shade of colour, the inside being a dull buff-pink with a straw ground.

In whites Mutual Friend was large, Queen of Portugal being another. Pale yellows were well represented by an attractive batch of Mrs. W. Mease, and a very fine display was made by a number of plants bearing large blooms of the pale blush-pink Mrs. S. C. Probyn. Kathleen Rogers is also a large fine white. In the incurved section, which is not largely grown for the purpose of making a display, we might mention Globe d'Or, fine in colour, and Triomphe d'Eve. White Yvonne Desblancs also belongs to the same section.

OCTOBER CHRYSANTHEMUMS.

THERE is not an over supply of varieties that are at their best in October. Many by retaining early-formed flower-buds are made to produce blooms in that month, but they are usually of bad colour and ragged in shape. Some of the so-called outdoor sorts are really October ones, which if left outside run the risk of being cut off by frost ere they are in full bloom. These early autumn sorts are well worth growing in pots, as they provide a rich display of colour, although they will not, as a rule, respond to the disbud-ding so freely followed for the production of big blooms. At the present time we have Albert Chauson, orange, shaded red; Clinton Chalfont, bright yellow; Emily Silsbury, white; Gas-pard Boucharlat, bright bronzy red; Gladys Roult, white; Lady Selborne and its yellow form; Margot, salmon-pink; and O. J. Quintus, light pink. Queen of the Earlies and Yellow Queen of the Earlies are two really charming kinds at this season. Source d'Or has a bronzy shade quite its own, and Wm. Holmes is an old sort not beaten in its way. Soleil d'Octobre is a good yellow which blooms early, and one that may be thinned to get large flowers. General Paquet, too, produces large blooms in October. This is a good new kind, a bright bronzy yellow in colour. Mutual Friend is a fine white variety, generally at its best early in the autumn. Mlle. Lacroix, white, with its sport of a pink shade, and Annie Clibran form a useful pair to grow for early blooms. Elaine, a favourite white kind, is still noted for its purity of colour, although it has been cultivated so long. Lady Byron, white, and Lady Ridgway, salmon-buff, are now at their best, and will be past by November. Rycroft Scarlet is dwarf and free, and highly recommended for October flowers. Edith Tabor, clear yellow, is now in full bloom. This produces fine blooms, but the plant is of rather ungainly habit. Mme. G. Bruant, white, tinted rose, is a full, well-shaped flower thus early in the year. This season, however, it has not been so satisfactory as it was last. Klondike, deep rich yellow, is an ideal market grower's variety for October supply, the blooms being stiff and lasting when cut. A well-formed incurving bloom is Louise, and a dwarf grower too. This is early. The colour is blush white. The pretty little pompon Mlle. Elise Jordan blooms early, and its neat light pink flowers form a capital contrast to the large Japanese sorts. This is much admired. A variety I have under the name of Mme. Vaucher is a charming October kind. The shade of salmon-pink is rich and pleasing, and the plant is especially bushy and free. Rayonnante is a kind which blooms early. I do not admire its quilled florets, although it makes a good decorative variety.

H. S.

Yellow Chrysanthemums of recent origin.—These seem to be almost overwhelming this season, and some of the yellow novelties are really grand. Le Grand Dragon has shown some splendid blooms long before October was out. M. Louis Rémy is a pale yellow sport from one of the Mrs. C. Harman-Payne family. R. Hooper

Pearson is not only a noble bloom in size, but the colour is deep, rich, and attractive. Among the colonial seedlings, Wattle Blossom, Lord Salisbury, and Mrs. Frank Gray-Smith are of this colour. The continental novelties include Soleil de Decembre, which was well developed at several places long before October was over, and is of a golden-yellow shade. It is one of Calvat's, as is also Eliane, which has long strap-shaped florets loosely arranged. The same raiser sends us Zephoris, one of his best for 1899. This is large in size and pale golden. Soleil de Lyon is also a yellow novelty. Edith Pilkington, a certificated Japanese, has very long, drooping, medium-sized florets, which are twisted and curly. This is a beautiful shade of canary-yellow, deepening towards the centre. Mrs. A. Cross, J. E. Clayton, and several others of less attractive appearance must complete the list.—C. H. P.

Chrysanthemum Gloire du Rocher.—This is now left behind in the race for huge blooms, but for decoration it occupies a prominent position. On October 28 at the Chrysanthemum exhibition in Battersea Park it was one of the most noticeable of all the varieties there represented, the warm, light red tint of the handsome blossoms causing them to stand out from all their associates. Its comparatively dwarf, sturdy habit is greatly in its favour, while the distinct-looking foliage is well retained. It is quite an old variety as Japanese Chrysanthemums go, for it received a certificate from the National Chrysanthemum Society in the autumn of 1890, and was, I believe, distributed the following spring. The history of this variety is very interesting, as cuttings of several kinds were sent to Algiers, and the seed saved therefrom was returned to England. Among the varieties of which cuttings were sent was the then popular Val d'Andorre, the seed from which yielded Gloire du Rocher.—T.

NEW CHRYSANTHEMUMS AT HEYWOOD.

IN Lord Ludlow's gardens at Heywood, Wilts, Chrysanthemums have not only been well grown for some years past, but new kinds have received more than average attention, every season the best of the current novelties finding their way thither. By the first week in November a great many of the blooms were at their best, needing heavy shade to keep them for some later shows. Between 400 and 500 plants are cultivated for specimen blooms, and among this number only a rigid selection of the best of the older kinds is retained from year to year, many not justifying their retention after their first year's trial. New varieties of the present season would seem to be better in colour and bloom than usual.

That fine yellow, J. R. Upton, was the first to attract attention, and of its colour it is probably the finest to be seen. Its petals are very long and gracefully drooping, the colour bright and clear. Some blooms of Edith Dashwood, a good one that will be grown again, measure fully 7 inches in depth, of a silvery mauve shade of colour. Henry Weeks is a good addition to the incurved Japanese section, a rosy-crimson with bronze reverse. Hero of Omdurman produces a large crimson and gold bloom; Mrs. Barkley has fine broad petals of splendid substance, silvery rose in colour; President Nonin is a very solid incurved yellow Japanese, and President Bevan, another good addition to the same section, is of a bronzy-yellow shade. Miss Mary Underhay produces soft yellow-coloured blooms and has a particularly nice petal. Mrs. White Popham was enormous, as were also Mrs. Mease, N. C. S. Jubilee, G. J. Warren, and Mary Molyneux; these are not strictly new, but are indispensable sorts of recent date. M. Fatzner may be described as apricot with a deeper flush, and gives a neat flower. Miss Nellie Pockett, a fine incurved white, is good. Marie Calvat is a very striking flower both in character and colour, a delicate flushed rose. R. Hooper Pearson is an incurved Japanese of the deepest yellow; Mrs. Coombes, a rival to the old and well-tried Vivand Morel both in colour and size. Kathleen Rogers is a fine white, as also is Jane

Molyneux. Le Grand Dragon, a magnificent yellow, is both broad and deep. Lord Ludlow is a promising incurved Japanese of a bronzy-yellow hue, and Purple Emperor, one of the finest of its colour, was represented by some fine blooms. M. Louis Remy, the yellow sport from Mme. Louis Remy, too, is of pleasing appearance and large in size. Sir Herbert Kitchener and Mr. T. Carrington, the latter a silvery purple flower, complete a selection that to me seemed the best among the newer Japanese kinds open at the time of my visit.

Incurved are grown in less numbers than are the Japanese, but each year the collection is enhanced by the introduction of the best of the newer ones. Mrs. H. J. Jones is very massive, and in colour and appearance resembles a much enlarged Mrs. R. C. Kingston. Chrysanthemiste Bruant, a neat, pale bronze, is large and good. Dome d'Or has a descriptive title. Hanwell Glory is deep in build and of a pretty shade of bronze. Miss Annie Hills has a large pink flower. W. Neish in point of colour is perhaps the most striking of the new ones, bright gold, with a suffusion of reddish bronze. This is best on a late bud, the earlier ones being coarse or uneven in petal. These are only a few of those open, but they comprise those that will be retained for future growth, because of their desirable colour, smooth petals and perfection of character.

W. S.

NOTES AND QUESTIONS.

Chrysanthemumœur Dorothee Souille.—Looking round a lot of Chrysanthemums grown for cutting recently, I noticed a large number of this pretty kind. It is many years since it was sent out, and it belongs to a not very popular set—the Anemone-flowered—but the grower of these plants assured me it was a profitable kind.—J.

Chrysanthemum Peter the Great.—Naturally grown plants of any variety of Chrysanthemum are seldom seen, but there are some that are very beautiful when so grown. The old kind above named it struck early and allowed to take its own way makes a fine open pyramid quite naturally, and the point of every shoot is wreathed with the pale yellow blossoms. There may be others equally good, but I know of no other that makes such fine plants.—H.

Chrysanthemum Le Grand Dragon.—The present season has evidently suited this variety of last year's introduction, judging by the blooms recently submitted to the different floral committees and also by displays now being made by it in various private collections. Last season the impression prevailed that the bloom was thin and flimsy, although its rich deep yellow colour, sometimes tinted crimson-bronze, gave it a value which was not seen in other varieties. This season, however, the blooms are large, deep and rather full, while the petals are very long and the colour distinctly good. It is a plant of easy culture and of medium height.—D. B. C.

Naturally-grown Chrysanthemums.—Chrysanthemum societies should, I think, make a class for growing plants carrying from three to nine blooms, and exhibited so as to show the points of a perfectly grown plant. Groups are very pretty to look at, but do not afford one much opportunity of studying the individual plants which compose it. There must be many people who would much appreciate a chance of comparing their own plants at home with those grown in a first-class nursery, so that they might observe the stems and leaves and gain a useful object-lesson by seeing the condition in which a plant must be before it can give perfect blooms.—E. S. B.

Chrysanthemum Australie.—This variety will no doubt be seen in exceptionally fine condition at the leading shows this season, and from what I have seen the blooms will be set up true to character. The inside colouring of the petals, which are very long and broad, is rosy amaranth with a silvery white reverse, and these being of incurved Japanese form, it will be readily seen how massive is the bloom when finished. The National Chrysanthemum Society last season bracketed Mr. T. Carrington as "too much alike" to the above variety, but upon comparison the newer sort seems to be of a much prettier shade of colour, with shorter florets and smaller flowers. There certainly is some resemblance, but they are sufficiently distinct.—C. A. H.

STOVE AND GREENHOUSE.

CARDIOSPERMUM HALICACABUM.

THIS warm greenhouse climber is a native of Jamaica. The seed must be sown in a pot in heat in spring, the plant being an annual. It grows rapidly, and commences to bloom in the early stages of growth. The plant here illustrated was grown in a pot, the shoots being trained to the top of a young Larch tree inserted in the pot. The plant was about 4 feet high. The flowers, which are white and very small, are followed by big green pods, very similar to those of a Cape Gooseberry. In these pods are two round, black, hard seeds. As these seeds ripen, the bladder-like pods

Cardiospermum Halicacabum. From a photograph sent by Mr. J. Crook, Forde Abbey, Chard.

turn yellow and drop down. The leaves resemble those of a Hop.

The seed was sent me by a lady travelling in Egypt. It is not particular as to soil provided it is open in texture. The pods are produced freely, and, being uncommon, the plant is always admired.

Forde Abbey.

Acalypha hispida.—For a time this created quite a sensation, and when exhibited as a new and rare plant won many prizes. As ordinarily grown it has lost a deal of the novelty it first possessed, but anyone privileged to see the plants grown by Mr. Hudson at Gunnersbury House would not soon forget them. They had been grown on from cuttings into large single-stemmed specimens quite 6 feet in height. Their foliage was immense, and the floral racemes both exceedingly numerous and of great length. From

the leaf axils new racemes were issuing from the pot upwards, intensifying the already dazzling masses of colour. They were the finest plants I have seen anywhere, and there are many others who have expressed similar views. These stood on the floor of a span-roofed house, which was both warm and light.—W. S.

Momordica Charantia.—This when in fruit is a very ornamental climbing plant. In America it is known as the Balsam Pear. I grow a few plants every year on account of their highly ornamental fruit. It is an annual. My plan is to place three plants into a 4½-inch pot, and when well rooted these are transferred to 8-inch or 9-inch pots, using a Larch Fir top for the plants to trail over. They are grown on in a warm house till they have filled the pots with roots and set the fruit, when they are removed to a cold greenhouse for the summer. The fruit is long, like a Pear, prickly, and of a bright orange colour. When the fruit is ripe it bursts and shows the inside, which is of the deepest red. The fruit hangs on long thread-like shoots.—DORSET.

Salvia splendens and its varieties. — Always a welcome plant for the autumn because of its rich colour, its cultivation should be taken up more freely than it is. Where there are conservatories to be kept gay Salvias are invaluable, but to be really effective they should be grown in sufficient numbers to furnish well the structure intended for their reception at flowering time, and not arranged a plant here and there among others of a different shade. Grown and arranged in groups they at once arrest attention, but solitary plants, unless of exceptional size and merit, are ineffective. At Gunnersbury House at the end of September Mr. Hudson had a batch of 150 plants all in bloom, not of the old type, but the newer splendens grandiflora and compacta. S. s. grandiflora is a fine sort, having large spikes, the desirable feature of these being the retention for a long time of the calyx after the tube has fallen. This is a great gain over the old splendens. S. s. compacta, as its name implies, is of

dwarfer habit, quite as free-blooming, if not more so, and almost as fine in the flower. These, standing on the floor of the fruit houses devoted at the time to pot trees, presented quite a glow of colour. The plants were growing mostly in 8-inch pots.—W. S.

Drosera dichotoma.—This is perhaps the most generally grown of the Sundews, and a pretty and interesting plant. The leaves grow 6 inches or more in height and are cleft into two lobes, which with the long stems give the plant a very graceful appearance. Its culture is not difficult in a suitable house, a good position being the lightest part where cool Orchids thrive. The plants are best grown in well-drained pots or pans, these being placed on others inverted over pans of water or on a stage over very damp material. The compost most suitable for them is three parts of living Sphagnum Moss to one of peat fibre and a little coarse silver sand or crock dust. Anyone who knows the British species of

Sundew and has seen them growing in our native woods will at once see the kind of treatment the roots need. Usually they grow in native Mosses, often with their lower roots pushing under stones or sticks, and this is what they like under cultivation. Light syringings overhead are of great assistance to them, but one point must not be forgotten—fumigation is very dangerous. Occasionally one may fumigate a house in which they are grown without injury, but it is very seldom.

Bouvardia President Garfield.—It is now a good many years since this and the double white B. Alfred Neuner were sent out, but it is doubtful if we yet have any better. The pleasing flesh-pink double blossoms are very useful for cutting, and they last better than single forms, while on the plants they are very fine. I saw a nice batch of President Garfield recently at Culford, where it was growing in a cold pit with others and flowering freely. Bouvardias, like many other fine greenhouse plants, suffer badly from being coddled up in a great deal more heat than is good for them. It not only produces a weak, attenuated growth, but it brings insects in galore to feed on the already weakened growth. Such plants cannot be satisfactory in any way; they are not pretty to look at, they do not flower freely, and, moreover, the blossoms that are produced last but a short time only. Those who do not care to plant them out should at least, after repotting, give them a cool and airy position in a frame without the lights in summer, so that the growth is hard. The shoots during the summer should be kept pinched, the last pinching taking place in August.—H. R.

Early Roman Hyacinths.—One of the chief mistakes that are made in connection with the early forcing of this crop is that of putting the bulbs too early into strong heat and before the plants have rooted sufficiently. For those who must have these things in flower at the very earliest moment they are to be obtained, there must be no delay at any time. Nor must there be any mistakes in the work as it proceeds. There are those who are only now potting their supplies of these things, while the earliest batches of bloom are finding a ready sale in the leading markets. To get these thus early in flower, however, requires the greatest care and judgment, much more so, indeed, than at any subsequent period. These early supplies are obtained by potting the bulbs in August as soon as they are to hand, and after a good soaking of water covering the plants with about 4 inches of cocoa fibre refuse in the open. The time of introduction into heat should be proportionate to the time the roots have been potted. If from any cause the bulbs are not received or even potted as early as usual, allowance must be made for this by keeping them longer in the open, that the fullest possible amount of root fibre may be produced. Much of the success of the crop rests upon this, for with abundance of roots the plants will quickly respond to the warmer conditions of forcing. It is usually the weakly rooted or insufficiently rooted plants that produce feeble or stunted spikes, and such are of no value to the florist.

Varieties of Begonia Gloire de Lorraine.—The beautiful Begonia above-named a year ago, possibly less, was alone, and varieties of it appeared to come quite slowly. Now, however, in the space of a few weeks two distinct forms of it have put in an appearance, each possessing a value of its own. One of these is the pink-flowered sport that originated with Mr. Hudson at Gunnersbury House, and quite recently secured the award of merit from the Royal Horticultural Society under the name Mrs. Leopold de Rothschild. In this the blossoms are not only considerably larger, but of a decided pink tone. It was regarded as a charming addition to the original kind. Last week another variation appeared from Hawick, this time a pure white form, bearing the distinctive name Caledonia, or White Gloire de Lorraine. Such a kind has long been desired, and now that it really exists it is

obvious that it is a veritable pure white of the above plant. The floral committee, neither doubting its value commercially nor its merit from a horticultural point of view, desired to see it again, as the plants shown were but little removed in many instances from cuttings. Yet even the very smallest of these proved quite conclusively its chief value—its freedom of flowering. It is quite possible the plants have been hurried somewhat, or possibly over-cared for, hence the exceeding paleness of foliage, verging in some plants almost to yellow. Another season, however, will see the plants more fully developed and in their true character. It is one of the most important novelties of the year.

OLD AND NEW TREE CARNATIONS.

It is somewhat strange that while during the last twenty years great strides have been made in border Carnations, and almost innumerable really good varieties have been added to the list, comparatively few sterling additions have been added to the Tree or winter-flowering section. It is now some twenty years since I first commenced the culture of Tree Carnations, and were I to-day forming a collection, I would, having profit in view, confine myself, with one or two exceptions, to the sorts I grew then. I am aware many of the newer introductions are fine so far as the individual flower is concerned, but what both the grower for sale and the private gardener who has to fill the basket must have are good growers and free bloomers. Many of the market varieties would also please those who prefer good-sized blooms if good all-round culture is given and a little disbudding practised. Really good scarlet sorts are scarce, and whites even more so. Purity and Mme. Carle were considered the two best whites for years, but both had to give way to that, in my estimation, unsurpassed variety La Neige. True, the individual blooms are a trifle less in size than those of some of the shy-blooming whites, but the quantity a well-grown healthy bush will produce is something astonishing. The flowers also expand readily during the dull dark days of winter and are of the purest white and sweetly scented. The growth is particularly vigorous and branching, and the constitution so good that it is very seldom a plant dies. It is, moreover, one of the easiest to propagate. I have heard Uncle John well spoken of, but have not grown it myself. It may be a larger, but not a more prolific sort. Good reliable reds are also none too plentiful, my old favourite, Alegatière, not being, I think, yet surpassed. One can always depend on it, its extra large, noble, brilliant blooms being always admired and commanding a ready sale. The at one time much-applauded rival, Winter Cheer, has not proved a success—at least generally speaking. For every fully developed bloom I cut from it Alegatière gave me half-a-dozen at least, but the worst feature about Winter Cheer is its liability to partial withering and discoloration before the blooms are expanded. No doubt there are growers who succeed with it, but they are, I think, in the minority. Another good red Carnation I used to grow is John Baldwin, a lighter shade of colour than Alegatière and apt to show white veins, which at the present day would, I suppose, be considered a drawback from a market point of view, but which is immaterial in private gardens.

Pink varieties of sterling merit are few. In spite of the noise made about Mme. Thérèse Franco when first introduced, it has proved an indifferent variety, not a few having discarded it. Like other poor growers and shy bloomers, it may suit those who are satisfied if they secure a few large flowers, which are allowed to remain on the plants till they fade, but I should say that for every hundred plants of Thérèse Franco grown for market there are a thousand or more of Miss Joliffe and Reginald Godfrey—a pretty good proof of its marketable value. Miss Joliffe is a lovely Carnation, its rich shade of colour being so much appreciated in bouquets and button-holes, but, although of vigorous branching growth and

very free-flowering, it has, unfortunately, a tendency to die off suddenly. Some growers have no trouble with it, while others who once succeeded with it have had reluctantly to abandon its culture. Such no doubt bailed with much satisfaction the arrival of Reginald Godfrey, which, if not quite so vigorous and free, has a more reliable constitution. Yellow Tree Carnations are the scarcest of all; in fact, I do not know of a really yellow Tree Carnation worth growing from a cut-flower point of view. The best yellow, I believe, is Miss Audrey Campbell, which is really a border variety, but which, if struck in autumn or early in spring and grown on quickly in not too large pots, will give a nice lot of richly-coloured flowers during the winter and spring. J. CRAWFORD.

Freesias failing.—“Cornubian,” in his reply to a correspondent, says he has never met with a case of Freesia bulbs dying in the manner described, and it only shows that he has been very fortunate and successful in their culture. It is not at all unusual for them to die in the way described, especially when, as “Cornubian” says, they are dried off or removed from their pots too early before the growth is properly finished. I recollect purchasing a lot at a sale in Suffolk some four years ago, and on shaking the bulbs out I found every one “mummified,” as “Cornubian” so aptly describes it.—H. R.

Thunbergia fragrans.—Though the specific name of this Thunbergia is somewhat of a misnomer, for as far as my experience of it extends it is scentless or nearly so, yet for all this it is a very pretty climber for the stove or intermediate house. The pure white flowers, each about a couple of inches across, are borne throughout the summer and autumn months, and nestling among the very dark green leaves have a pretty effect. It is of a medium rate of growth, and may be used as a rafter plant if the structure is not too lofty. Unlike many climbers, this Thunbergia may be grown and flowered well when confined to a large pot, whereas the vigorous kinds, such as T. grandiflora and T. Harrisii or laurifolia, succeed much better when planted out in a prepared border.—T.

NOTES AND QUESTIONS.—STOVE.

Saxifraga Fortunei.—In the outdoor garden this autumn-flowering species is of but little value by reason of its tender nature. In the greenhouse, however, the plant is worth growing in pots, and with liberal treatment flowers with considerable freedom. It is only rarely, however, that sufficient interest is taken in these out-of-the-way kinds to do them justice. All the same, a well-grown plant is very pretty at the present time.

Manettia bicolor.—The bright yellow and orange tube-shaped flowers appear all the more effective as winter approaches. The plant can be grown and flowered in quite a small state. Single plants grown in 4½-inch pots, with the growths trained round four or five small sticks about 1 foot in height, bloom very freely, and when flowering subjects for furnishing have to be forthcoming at this time of year, such prove very serviceable.—A. W.

Tecsonia Van Volxemi fruiting.—Inquiry is made if this is edible by Mr. Renshaw (p. 294). Though not usually accepted as a dessert fruit, there are instances where the fruit is eaten and much liked. I have eaten it myself some years since. I have never known the fruit to be sent to table as dessert, but it has been gathered when quite ripe from conservatory plants by younger members of the families with whom I have lived. I have never heard of any harm accruing from eating the fruit.—W. S.

Celosias.—These are useful in many ways in the autumn and winter months, especially when used amongst Ferns, &c. Recently I saw a grand strain at South Villa, Regent's Park. All shades of red and the richest yellows were represented, the plants each from 1 foot to 1½ feet high and well branched. Mr. Kelf isolates his best plants every year for seed. A few days later I saw some nice dwarf plants in 4½-inch pots branched down to the pots and not more than a foot high at Didlington Hall, Norfolk.—DORSET.

Salvia splendens.—This showy plant is most useful for providing colour during the dull months.

At Bramley Park it is grown in quantity. The scarlet flowers are borne in great abundance and are found excellent for cutting. Cuttings are rooted in spring and the plants put into the open ground. They require but little care except topping the shoots once or twice during the summer to form bushy plants. They are lifted and put into pots early in autumn and come quickly into flower.—H.

Nerine japonica—Notwithstanding the immense numbers of this Nerine that are sent here every year from Japan, it is very rarely that one meets with it in bloom, and I have tried various modes of treatment with but little success. Whether the above name or that of *Lycoris radiata* is the correct one, it is certainly quite distinct from the generally grown kinds of Nerine, the rather narrow glaucous green leaves being one distinguishing feature, while another is the reddish crimson-tinted blossoms, with their unusually prominent stamens. I have not succeeded in flowering it regularly, and if any reader of THE GARDEN has done so, I shall be very pleased to learn the treatment given it.—H. P.

FLOWER GARDEN.

THE NIGHT-SCENTED TOBACCO.

(*NICOTIANA AFFINIS.*)

This well illustrates the fact that a really good plant will come quickly into favour provided no special difficulty exists in its culture. It was first mentioned in THE GARDEN of July 9, 1881, by Mr. W. H. Cullingford, of Kensington, who appears to have been the first to introduce it. He received seeds from Hyères, and showed a splendid plant at one of the evening fêtes of the Royal Botanic Society. No one has been deceived by the first appearance of this Nicotiana, as wherever one goes, either in town or country, he will be sure to find it grown, especially in suburban gardens, where few things as a rule do well. In the evening, when the flowers are open, the fragrance is the strongest, and the bold long-stalked flowers have a peculiar effect in the dim twilight. It does well in pots for the decoration of the conservatory and groups in the border look well. A bed on the grass filled with plants is very effective. A somewhat sheltered position is necessary, as rough winds give the plants a ragged appearance. It also requires a rich soil and plenty of moisture during dry weather. I have found that when the winter is not too severe the roots live and the plants start strongly in the spring, coming into flower much earlier than those which have been raised from seed and planted out. W. T.

Lobelias for stock.—I was very much interested in the note by "E. J." on p. 334 respecting keeping up a stock of Lobelia. Everyone who has had to keep up a large stock of this plant knows the liability of the plants, not only to damp, as "E. J." describes, but also to take mildew badly, a condition of things quite fatal to raising a large or healthy stock. As your correspondent says, such a method cannot be too widely known, and I for one am greatly obliged to him for the simple but useful hint. As I am situated I have not a great demand for this or any other bedding plant, but I have known the time when such a stock as he describes would have been invaluable.—H. R.

Fuchsia fulgens planted out.—Despite the innumerable varieties of Fuchsia that we have now in gardens, some of the original species still hold their own, being, at least in a few instances, particularly showy and quite distinct from the hybrid forms so generally grown. The tendency towards mixed beds in the flower garden during the summer months, which has made considerable headway of late years, has led to *F. fulgens* being grown more now than was at one time the case, as it is well suited for such treatment. Numerous examples of it have been very

satisfactory in many of the London parks during the past summer, and a bed of it at Kew near the Palm house was throughout the latter part of the season very attractive. The entire bed was filled with this Fuchsia alone, which grew freely, thus presenting a mass of its handsome rugose foliage set off by numbers of its showy blossoms.—T.

A pretty mixed bed.—A large round bed here, planted in the following manner, has been greatly admired during the past season. In the first place, *Lilium speciosum* and *Lilium Kratzeri* were planted three bulbs together about 5 feet apart, and not nearer the edge of the bed than 4 feet. Next came dwarf flowering Cannas, set out about the same distance apart, and which reached to within 18 inches of the margin of the bed. Lord Beaconsfield and Lady Heytesbury Fuchsias were planted round the Cannas, and then Betteridge's Quilled Asters were thinly disposed all over the bed, and the groundwork filled in with *Sedum Fabaria*, the same forming the outside ring or edging to the bed. About the middle of September, when the whole of these plants were in full bloom, this bed formed a

"H.'s" plan is an excellent one for those growers who are short of glass space, especially when there is an absence of the means of early seed-raising. Cuttings strike freely enough on a warm manure bed or in propagating pits, and a stock can soon be worked up in this way. From seed, however, it is quite as easy; in fact, more so, because careful sowing and watering ensure a sufficiency of plants from one sowing, and once pricked out no further anxiety remains.—S.

October climbers in South Devon.—The large purple stars of *Clematis Jackmani* have for the most part disappeared, though here and there a few belated blossoms may still be seen. Varieties of *C. lanuginosa* are still holding their wide-spread pale lavender and white blooms, while *C. songarica* creates a pretty effect now that it is covered with its feathery seed-vessels. *C. Vitalba*, the Traveller's Joy or Old Man's Beard, is also particularly decorative at the present time, especially when garlanding tall evergreens with its smoke-grey trails. Some lofty *Ilex* are now objects of great beauty, so thickly is their dark green foliage mantled by the growths of this

The Night-scented Tobacco (*Nicotiana affinis*). From a photograph sent by Mr. J. T. Newman, Berkhamsted.

charming picture. This *Sedum* might be used a great deal more often than it is, either alone or in conjunction with other subjects, its masses of pink flowers being always effective.—A. W.

Lobelias from seed.—On p. 254 "H." points out the uncertainty of Lobelias from seed, and advocates cuttings for next year's supply. Except for carpet bedding, where, of course, uniformity is most desirable, seedlings can be obtained quite true enough for edgings or carpeting; indeed, from a reliable source one gets seed so true to character, that very rarely are there any "rogues." No one can deny that seed-raising in spring is far less trouble than having to save one's store plants throughout the winter, especially when stock has to be potted up in summer and grown for several months. It is quite true, as "H." says, that Lobelias winter much better if established early in pots. Lifted in autumn, damp is a great enemy to late-potted Lobelias, though the precaution of topping them and getting a new growth just prior to lifting obviates this to a great extent.

Clematis, whose rope-like stems hang from the boughs in a fashion that recalls the lianas of the tropics. *Cobæa scandens* is still bearing its cupped blooms of deep purple, and *Ecchreocarpus scaber* shows an infrequent orange-yellow flower-spray. *Lapagerias*, both red and white, are yet in bloom on a shady north wall, and the blue Passion Flower is bright with its thickly strung oval fruits of clear orange hue. *Plumbago capensis* in a sheltered nook carried its pale blue blossoms through the greater portion of the month, and *Solanum jasminoides* at the commencement of October was at its loveliest, every swaying spray from the eaves downward being terminated by a many-flowered white bloom cluster, the whole forming a very cataract of blossom. *Tropæolum tuberosum* has retained its gorgeous appearance through the entire month, its orange and scarlet blossoms standing well out from the foliage, forming a bright flower fringe to the green background. *T. Lobbianum* has also created a brilliant effect with its scarlet flowers on a cottage

wall, and I noticed a vermillion trail of *T. speciosum* on the horizontal bough of a Yew in the early days of the month. The Virginian Creepers have been especially attractive, their glowing colours having doubtless been enhanced by the hot summer, *Vitis inconstans* in particular being remarkable for the richness of its colouring. Many of the Vines have been very decorative, *V. humulifolia* presenting a pretty picture early in the month with its bunches of turquoise berries.—S. W. F.

Crocus speciosus Aitchisoni.—To some of us at least the later flowering of this variety of the ever useful *Crocus speciosus* is a merit of no mean order. It is not everyone, of course, who cares for the *Crocus* in the late months of the year, and to such it seems unseasonable. Many of us, however, look upon these late blossoms as precious things, bringing us pleasure at a dull season. Those of like mind with me will not regret making the acquaintance of Dr. Aitchison's *Crocus*. In my garden it comes into bloom when the flowers of the type, in a practically similar position, are over. Nor is this later blooming its only recommendation. It is also noteworthy for its larger flowers, of equal beauty to those of the older form. To-day (October 23) it is only about a quarter of an inch above the soil, and cannot open for some time to come. *Crocus speciosus Aitchisoni* is an excellent grower in the light soil in which it is planted here, and gives little trouble beyond keeping deep-rooting weeds from trespassing upon it and giving it a slight annual top-dressing. Its flowers, like those of the type, are very pleasing with their purple lines and feathering on the blue ground of the main colouring of the segments. Although Dr. Aitchison's *Crocus* was rather high in price on its first introduction it is now much cheaper, and a few bulbs, or rather corms, are not beyond the reach of most admirers of hardy bulbous flowers.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Callistephus sinensis.—The caution regarding this single-flowered form of the China Aster, on p. 348 is particularly well-timed, for it has attracted a good deal of attention lately, and while personally I think it a delightful flower, yet many prefer the double blossoms, and would be disappointed to find it almost a counterpart of some that were destroyed directly they showed their true character, for the practice of eradicating the plants bearing single or semi-double blossoms has been rigorously followed for years. We shall, however, now probably see this *Callistephus* grown regularly in the future, and in addition to the form of which a coloured plate appeared in THE GARDEN of March 26 last year we may expect other colours now that attention has been directed to the beauty of the single-flowered kinds.—H. P.

—Is not this plant simply a single China Aster? Certainly I have seen it only at the Drill Hall, but I gather from Mr. John Weather's note that it is but an annual and needs the same treatment any ordinary annual Aster does. If this be so, would it not have been much better to have introduced it to commerce as a single-flowered annual Aster under the name of Mauve Beauty or some such name, as being then so much more likely to catch on with the flower-loving community than if offered under its botanical appellation? That it is a very charming garden flower there can be no doubt. Lovers of pleasing single flowers and of a soft and charming hue of colour will like it immensely. It simply needs treating as an ordinary Aster.—A. D.

NOTES AND QUESTIONS.—FLOWER.

Gerbera Jamesoni.—This is one of those striking plants that attract a good deal of attention, even in small quantities. This latter phase, however, for the present appears almost characteristic, for only by solitary flower-heads is one now and again reminded of its beauty, and not least its value in a cut state. It is one of those plants that not a few enthu-

siasm would like to see plentiful, or at least obtainable at a cheap rate.—E. J.

Helianthus H. G. Moon.—Those in want of one of the boldest of the Sunflower family should add this fine kind. It is one of the *H. multiflorus* group, and more closely approaches *H. multiflorus maximus* in stature than any other. Side by side with this it may not be widely removed in point of colour, yet I am inclined to regard the above—speaking entirely from memory—as having less pointed florets. In any case it is a fine subject where bold effect is desired.—E.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 7.

THERE was a great falling off in the number and extent of the exhibits on Tuesday last, owing no doubt in some degree to the *Chrysanthemum* shows, both suburban and local. It is well known that both this week and next the majority of these exhibitions are being held; hence it need not cause any surprise if the first meeting in this month is a smaller one than usual.

It was worth the journey, however, to see the charming exhibit of *Nerines* from Mr. Elwes, many of which are quite unique both in their character and colouring, being perfect gems in their way. Fine as the *Chrysanthemum* may be and appropriate to the season also, these *Nerines* are not one whit behind as regards beauty; no finer plants at this season could be desired for indoor decoration. A large group of *Begonias* (*Gloire de Lorraine* and Mrs. Leopold de Rothschild) came from Gunnersbury and made a pleasing display. Conifers of useful size and distinct character came from Bagshot. *Chrysanthemums* were shown in excellent condition from two or three sources. Orchids were not numerous, the best being *Cattleya labiata* in variety, than which there is not a finer autumnal flower in its class. Fruit exhibits were also limited, owing no doubt to the reasons already given. Fine collections of Apples and Pears were, however, sent from Belvoir and also from another source.

Orchid Committee.

First-class certificates were awarded to the following:—

CATTELEYA LABIATA.—Strange to say, no record exists of this well-known *Cattleya* having been certificated. Plants were shown by Mr. R. I. Measures, Mr. A. H. Smee and Mr. Leopold de Rothschild. Mr. Measures showed a plant with eleven flowers, Mr. Smee two cut flowers, and Mr. Rothschild a group of cut flowers, illustrating the varied forms. This species is too well known to need description here.

CATTELEYA LABIATA ALBA PRINCESS OF WALES.—This is a lovely form, the petals beautifully crisped on the margin, the lip white, with indistinct tracings of rose on the centre area of the front lobe and bright orange-yellow through the throat. It is one of the most distinct and beautiful forms of the white *C. labiata*. From Messrs. J. Veitch and Sons, Ltd., King's Road, Chelsea.

CATTELEYA LABIATA GILMOURIA.—A grand form, with pure white sepals and petals, the front lobe of the lip white around the margin, the whole of the centre area deep crimson-purple; the side lobes white, shading to yellow at the base and through the throat. It somewhat resembles *C. l. Cooksoniæ* (previously certificated), but the blotch in the centre of the lip is larger and of a deeper colour. The plant carried a two-flowered raceme. From Mrs. Briggs-Bury, Bank House, Darlington.

An award of merit was given to—
DENDROBIUM CELOGYNE.—This is an old and well-known species, the sepals and petals greenish yellow, suffused and barred with deep brown, the whole of the front lobe of the lip deep, almost blackish brown, the side lobes green, spotted brown, having some yellow at the base. The plant carried fifteen flowers and buds. From Messrs. H. Low and Co., Bush Hill, Enfield.

Messrs. H. Low and Co. were awarded a silver Banksian medal for a nice group consisting principally of *Cattleya labiata* in varied tints and forms, *Lælia trentonensis*, several varieties of *Oncidium Forbesi*, a plant of the lovely *Sobralia Lindenii*, the sepals and petals blush-white, the lip white, splashed with two shades of colour on the disc and through the throat, and a plant of the distinct *Catasetum callosum* with ten of its green and brown flowers. The distinct *Cypripedium insigne* *Laura Kimball* was also included. The top of the dorsal sepal of this is white, shading to greenish yellow, veined with deeper green at the base. The petals and lip have a greenish yellow ground colour, with a light suffusion of brown. Mr. E. Kromer, West Croydon, was awarded a bronze Banksian medal for a collection of about eighteen varieties of *Cattleya labiata*. The most distinct were *C. l. Kromeræ*, a distinct and pretty form, the sepals and petals having a blue tinge, the lip pale, almost white around the margin, with a distinct blotch of plum-purple in the centre. Another distinct form had rose-tinted flowers throughout. Several remarkable dark varieties were also included. A good variety of *C. granulosa* with a five-flowered raceme was also attractive. Mr. J. Douglas, Great Bookham, was awarded a bronze Banksian medal for fourteen distinct varieties of *Cattleya labiata* (cut flowers), also four spikes of *C. Harrisoniæ*, three spikes of *Aerides nobile*, three flowers of *Cypripedium Juno*, and *Cologyne Massangeana*.

Mr. R. B. White, Arddarroch, was awarded a silver Banksian medal for a group of cut spikes (about twenty-one distinct varieties) of *Odontoglossum crispum*. The most prominent were *O. c. Geraldine*, the sepals delicate rose, tinted with a darker shade, and a few brown spots in the centre, the petals lighter than the sepals, and beautifully fringed on the margin. The base and central portion are thickly covered with miniature brown spots, the lip white, with a large blotch of brown in the centre. Major Joicey sent flowers of *Cattleya labiata*. Sir F. Wigan showed a pale variety of *Cattleya labiata*, *C. Bowringiana* concolor, similar to that known as *C. B. lilacina*, and *Lælia pumila* (Low's variety), in which the sepals and petals are white, faintly tinted with rose, the lip deep violet, margined and mottled with white in front, the side lobes white, shading to deep yellow at the base. Mr. A. S. Hitchins, Clynton, St. Austell, Cornwall, sent *Cypripedium Hitchinsæ* (*insigne montanum* × *Charlesworthi*). The dorsal sepal is white, spotted with purple in the centre, shading to green, and spotted brown at the base, the petals greenish, suffused with brown, the pouch yellow, suffused with brown. Mr. M. Gillespie sent a yellow ground form of *Odontoglossum Andersonianum*. Mr. E. Ashworth showed *Cypripedium insigne* *George Ashworth*. Several hybrid *Cypripediums* were also included, consisting of the following crosses: *Harrisonianum superbum* × *Druryi*, the dorsal sepal white, purple at the base; and *lo grande* × *Charlesworthi*, in which the influence and intermediate characters of the parents could be plainly discerned. *C. Chamberlainianum* with varieties of *insigne* were also included. Mr. N. Cookson sent a hybrid resembling forms of *Lælia-Cattleya Dicaea* with two flowers. Mr. Leopold de Rothschild showed ten varieties (cut flowers) of *Cattleya labiata*.

Floral Committee.

The following were granted the award of merit:—

BEGONIA CALEDONIA.—This is a first-class addition to this family, and a plant likely to be much in request in the future. It is a pure white variety, a sport probably from the well-known *Gloire de Lorraine*. In all other respects save the colour it is the counterpart of the type. From Mr. J. Forbes, Hawick, N.B.

ANTHOLYZA ÆTHIOPICA VITTIGERA.—This is fortunately a re-introduction of a plant lost to cultivation. The plant possesses the growth of the strongest *Montbretia* or a small *Gladiolus*.

In the multiplicity of its growths from the corms it favours the former group, the leaf-blades being about 2 feet long, or nearly so. From this in *Montbretia* form the flower-spikes issue. These are quite 2½ feet long and carry numerous flowers which in colour are orange-scarlet, the tubular portion without being of a yellow tone. The blossoms are composed of six unequal segments, the uppermost nearly 2½ inches long, curving slightly, and extending completely over the stamens. The fiery colour renders the plant most attractive. It was received about eighteen months ago from Port Elizabeth in the shape of small *Crocus*-like corms, since which time it has attained quite vigorous proportions. It is fortunate so attractive a plant is so vigorous and free in growth. At present only two pots of this are known to be in this country. From Mr. J. T. Bennett-Poë, Cheshunt.

VIOLET MRS. J. J. ASTOR.—A welcome addition to the double-flowering Violets, the colour described as pink and heliotrope. We saw neither the one nor the other of these shades, and would prefer to call it dark reddish lilac. Indeed it is almost exactly the dark tone that is seen on the outside of the single pips of some of the darker coloured lilac blossoms. The flowers are large, fully double and fragrant. From Sir Trevor Lawrence, Bart., Burford Lodge, Dorking (gardener, Mr. Bain).

NERINE MISS WILLMOTT.—A remarkably striking shade of brilliant orange-scarlet, the orange being almost flame-like in intensity. From Mr. H. J. Elwes, Colesborne, Gloucestershire (gardener, Mr. Lane).

NERINE MRS. BERKELEY.—An entirely new shade and one of the most decided novelties of the year. The colour is of two shades of salmon, intense salmon prevailing, the margin of the petals being of a paler salmon hue. A very striking plant. From Mr. Elwes.

NERINE MRS. GODMAN.—This is also a decided novelty, yet one most difficult to describe. It is, however, one of those flowers wherein rose and magenta mingle to a large extent and to an almost equal degree. From Mr. H. J. Elwes.

Compared with many past exhibitions, this one was decidedly small, much vacant space being noticeable. This is of course directly due to attractions elsewhere. One of the largest exhibits before this committee, however, was that of *Begonias* from Mr. Leopold de Rothschild, Gunnersbury House, Acton (Mr. J. Hudson, gardener), which completely filled one side table, the two varieties being *Begonia Gloire de Lorraine* and its sport, *Mrs. Leopold de Rothschild*. The former is well known, the latter is the large pink sport that originated at Gunnersbury House. This is not only a decided change of colour, but the blossoms are also larger and of a pleasing pink. The newer kind is of firmer, denser habit of growth and a model of a good pot plant. All the plants were admirably grown and flowered, something like 120 excellent examples being staged. A silver-gilt Flora medal was awarded. A batch of some four dozen blooms of *Chrysanthemums*, all Japanese, came from Mr. Chas. E. Shea, Foots Cray (Mr. Miller, gardener). Some of the blooms were of high order, showing excellent culture. A few of the more noticeable were *Sunderbruck*, fine golden yellow; *Dorothy Shea*, bronze; *Lord Cromer*, crimson and gold, very fine; *Miss Elsie Teichmann*, pearly white; *Lady Ridgway*, salmon buff, shaded gold; *Oceana*, very fine yellow; *Mutual Friend* and *Gustave Henry*, grand whites; *Lady Hanham*, rosy cerise, with gold; *Edith Tabor*, *Pride of Madford*, *Lionel Humphreys*, reddish crimson, *Mons. Chenon de Leche*, &c. (*silver Flora*). From Messrs. J. Waterer and Sons, Bagshot, came an excellent group of conifers of medium size and well grown. These comprised such things as *Abies Nordmanniana*, *Retinospora filifera*, *R. pisifera*, *R. p. aurea*, *Thuja occidentalis*, *Abies Hookeri*, very distinct and compact; *Cryptomeria elegans*, *Sciadopitys verticillata*, a beautifully compact example, 3 feet high, of this rather scarce plant; *Cupressus Lawsoniana densa*, *Librocedrus decurrens variegata*, *Taxus hiber-*

nica Standishi, *T. grandis*, *Juniperus japonica aurea*, and others, all well furnished (*silver Flora medal*). Messrs. Veitch and Sons, Chelsea, staged a collection of the hybrid greenhouse *Rhododendrons*, which seem possessed of a perpetual flowering character, while Messrs. Hugh Low and Co. contributed a well-flowered batch of *Statice*s, probably *S. Butcheri*, the colour of which is very fine. A small collection of cut *Chrysanthemums* from Mr. W. Wells, Earlswood, Surrey, included the fine decorative kind *Etoile de Feu*, *Lord Salisbury*, a large flower of a pale primrose tint; *Miss Lucy Cheeseman*, rich gold; *Margaret Silhol*, pure white; *Francois Pilon*, a deep golden Japanese incurved; *Silver Queen*, delicate rosy lilac; *T. W. Barkis*, white; *Sir Herbert Kitchener*, &c. From Mr. H. J. Elwes, Colesborne Park, near Gloucester (Mr. Lane, gardener), came a beautiful assortment of *Nerines*, all seedlings, as yet unnamed. A few of the most promising have already been noted, but here also in a group of several dozen plants all in flower were many notable forms, and every conceivable shade of pink, rose, flesh, pale salmon, with nearly pure white or these with a scarlet rib, and others of intense colour, showing in no small degree the remarkable range of colour and not less so of form and beauty that is obtainable when discretion and judgment go hand in hand with the hybridist. Even the poorest of these things would be very beautiful in the cut state, and seeing the little room occupied in their culture, it is surprising that greater interest is not centred in these plants (*silver Banksian medal*). In a cut state the *Sweet Violets* from Mr. H. Rogers, Rendlesham Hall Gardens, Woodbridge, were very beautiful, the varieties *Marie Louise* and *De Parme* being those shown. The former is much the darker of these two double kinds, the flowers being very large in each case. A box of plants of the first named was also shown (*bronze Banksian medal*). A Tree or perpetual-flowering *Carnation* called *Oxford Yeoman* came from the Duke of Marlborough, *Blenheim Palace* (Mr. T. Whillans, gardener). It is a scarlet-flowered kind possessing but very few petals. Mr. W. Seward, The Firs, Hanwell, had the following *Chrysanthemums*: *Thos. Stephenson*, bronze, *May Neville* and *W. H. Whitehouse*, red-lilac. The Hon. W. H. Smith, Greenlands, Henley-on-Thames (Mr. Henry Perkins, gardener), had *Chrysanthemums* *H. Perkins, Jun.*, gold and bronze, and the Hon. W. H. Smith, a crimson velvet shade, good in colour. Mr. J. Corbett, Malgrave Castle, Whitby, also had one or two *Chrysanthemums*, the most telling being a rich yellow sort named *Jessie Corbett*. The flowers were, however, small, and not equal to those of present-day kinds.

Fruit Committee.

A first-class certificate was given to—

PEAR EMILE D'HEYST.—Very fine samples, flesh soft and rich in flavour. It has been long in commerce, but its merits had not been previously recognised. It is a good cropper and has a strong constitution. From Mr. G. Woodward, Barham Court, Maidstone.

Awards of merit were given to—

APPLE MISS PHILLIMORE.—Fruits of medium size, much in shape resembling those of *Cox's Pomona*, one of the parents. The flesh is of excellent flavour. From Messrs. G. Bunyard and Co., Maidstone.

CABBAGE ST. MARTINS.—One of several tried at Chiswick and sent up from the gardens; heads round, solid, white, turning in early. From a cross between *Christmas Defiance* and the *Rosette Colewort*. From Mr. G. Wythes, Syon Gardens, Brentford.

A collection of fifty dishes of Apples and thirty dishes of Pears was shown by Mr. Divers, gardener to the Duke of Rutland. The samples were good generally having regard to the district and climate, and were chiefly of Apples grown on bush trees on the *Paradise stock*, and of Pears on horizontal trained trees on walls. These latter were quite old, whilst the Apple trees

have been planted within a few years. Good samples of *Peasgood's Nonsuch*, *Warner's King*, *Dewdney's Seedling* (like *Stone's Pippin*), *Bismarck*, *Stirling Castle*, *Pine-apple* (like *Waltham Abbey Seedling*), *Newton Wonder*, *Alfriston*, *Bramley's Seedling*, *Tower of Glamis*, *Wellington*, *Prince Albert*, and *Lord Derby* were prominent. Of dessert varieties there were capital *Rosemary Russet*, *Ribston Pippin*, *Worcester Pearmain*, *Cox's Orange Pippin*, *Allington Pippin* (very handsome), *Bess Pool*, *Ross Nonpareil*, *Golden Winter Pearmain*, *Reinette du Caux*, *Cockle Pippin*, and others. Of Pears there were excellent samples of *Huyshe's Victoria*, *Easton Beurré*, *B. Clairgeau*, *Emile d'Heyst*, *Beurré d'Anjou*, *Beurré Jean van Geert*, very rich colour; *Gilgil*, very fine; *Beurré Diel*, *Beurré Rance*, and others. The entire collection was prettily dressed with coloured foliage, feathery blossoms of the wild *Clematis*, and highly coloured *Dartmouth Crabs* (*silver-gilt Knightian medal*). The other collection from Kent was that of a well-known market grower, Mr. A. J. Thomas, *Rodmersham*, *Sittingbourne*, who set up seventy-eight dishes of Apples and thirty-nine of Pears, nearly all very fine samples. Some exception was taken to the fact that several duplicate dishes were staged, a practice which the committee agreed must not be repeated. The Pears included *Beurré Samoyeau*, like a richly coloured *Beurré Clairgeau*, which also was shown; *Belle de Thomas*, large green obtuse fruits; *Princess*, *Bellissime d'Hiver*, *Marie Louise*, *Duchesse d'Angoulême*, *Belle Fouqueray*, *Columbia*, *Doyenné du Comice*, *Grosse Calebasse*, &c.; and of Apples the dessert included very fine *clean Cox's Orange Pippin*, *Court Pendu Plat*, *Claygate Pearmain*, *Worcester Pearmain*, *Carlisle Castle* (like *Gascogne's Scarlet*), *Baumann's Red*, *Egremont Russet*, *Gooseberry Pippin*, *Scarlet Nonpareil*, *Blenheim Pippin*, *Ribston Pippin*, &c. Of cooking kinds, very fine were *Prince Albert*, *The Queen*, *Lord Derby*, *Newton Wonder*, *Royal Jubilee*, *Gloria Mundi*, *Chelmsford Wonder*, *Bismarck*, *Lady Henniker*, *Mère de Ménage*, *Striped Beau-fin*, *Golden Noble*, *Yorkshire Beauty*, and *Withington Fillebasket* (*silver-gilt Knightian medal*). Mr. Vokes, Winchester, sent a small Apple, said to be the sweetest grown, but the sample hardly bore out that assertion. He also sent samples of a large *Cobnut*, said to be a chance seedling. It was agreed to ask for samples in the coats, also that *Gosford Cobs* be obtained for comparison. Mr. Allan, gardener to *Lord Suffield*, *Gunton Park*, *Suffolk*, showed huge *General Todtleben Pears*, some 2 lbs. each in weight, from a south wall. Mr. C. Ross, gardener to *Captain Carstairs*, *Welford Park*, *Newbury*, sent an Apple named *Tyro*, from *Welford Park Beauty* and *Pearson's Plate*, also *Pear McKinley*, raised from *Ne plus Meuris* × *Duchesse d'Angoulême*; fruit medium sized, having the form of *Ne plus Meuris*. It was very sweet, but had little flavour. Messrs. James Veitch and Sons had a large dish of a Crab named *Mr. L. de Rothschild*, raised by crossing *John Downie Crab* with *Cox's Orange Pippin*. It was pretty. Mr. R. Morrow, *Leominster*, had a pretty rich-coloured Apple, *Robt. Morrow*. Mr. G. Woodward, gardener to Mr. Roger Leigh, *Barham Court*, *Maidstone*, sent very large fruits of *Cox's Orange Pippin* and a smaller sample to show greater fitness for the dessert. Mr. R. Handley, gardener to *Miss Breton*, *Sandhurst*, *Berks*, had fine blanched *Cardoons*.

FRENCH CHRYSANTHEMUM SOCIETY.

At Lyons on November 3 to 12 the above society, which has only been established four years and which has now held its fourth annual show and congress, and numbers nearly 600 members, had a most attractive gathering, at which a number of well-known *Chrysanthemum* admirers and growers of various nationalities were present. The schedule made full provision for a representative exhibition, and there were numerous works of art, gold, silver-gilt, and silver medals offered as

prizes in the various classes. Among the exhibitors of new seedlings, Messrs. Vilmorin and Co., Ernest Calvat, Heraud, de Reydellet, Chantrier, Bonnefons, and W. Wells were the chief, and the floral committee of the society were engaged in a long and somewhat difficult task in making the awards, one of the exhibitors contributing no fewer than fifty-four novelties. Several first-class certificates were awarded to M. Calvat, whose blooms were bright, clean, and fresh, and of gigantic size, being by far the best in the show. Mme. Adèle Cordonnier Wibaux, a fine reddish crimson Japanese with gold reverse; M. O. de Meulenaere, a deep chestnut-crimson Japanese incurved; Mme. Alice Capitant, a pretty sulphur-white, tinted deeper in the centre; Mme. L. Druz, deep apricot-yellow, with golden centre; Salomé, a fine golden-yellow self; Mme. de Franqueville, rosy salmon, with golden reverse; Marquis Visconti-Venosta, deep rosy amaranth, with reverse of silvery pink; and Mme. Victor Delavier, very pale blush, very deservedly received first-class certificates.

In the cut bloom classes there were many exhibits, but the arrangement of them differs considerably from ours here in England, as does the general aspect of the show. In order to prevent any monotony in the arrangement the show is divided into groups of plants and blooms, which are arranged in beds on the level of the ground, and in some cases after the judging is over to improve the general effect, exhibitors' lots are mingled, which renders it difficult sometimes to particularise. Inasmuch, however, as the French exhibitors are not generally known to the main body of our growers and readers there will be no need to deal with the exhibits separately, and it must suffice to say that in the sections for cut blooms the best from an English point of view were such as President Nonin, Oceana, Mme. M. Ricoud (a beautiful shade of bright pinkish rose), Mme. Rozain, Mme. Deis, Secrétaire Rivoire, Mrs. C. Harman-Payne, M. Louis Rémy, G. J. Warren, Marie Calvat, N.C.S. Jubilee, &c.

Chrysanthemums in pots were largely represented, as is always the case at these continental shows. At Lyons a great feature is the large-flowered dwarf-growing varieties, and of these there was almost any number. M. Choulet, of the Municipal Gardens at the Park Tête d'Or, has practised this method with much success, and it seems to be generally adopted by his fellow townsmen. The city of Lyons contributed (not for competition) a large oval bed of these, and among them varieties such as Le Colosse Grenoble, Mrs. C. Harman-Payne, Van den Heede, Mme. E. Roger (the curious green variety), Mme. Deis, M. Louis Rémy, Iserotte, Surpasse Amiral, Australian Gold, Mme. Gustave Henry, Eliane (new), Souvenir de Molines, Mme. Carnot, Mme. Aristide Rey (new), and others figured very conspicuously. Messrs. Rivoire and Son, M. Rozain, M. Bouchard, Messrs. Biessy and Combet, and M. Charmet also were prominent exhibitors in the group classes. In the middle of the hall was a large circular group from Messrs. Vilmorin - Andrieux and Co., very bright in colour and well arranged. The principal varieties known to English exhibitors that it contained were N.C.S. Jubilee, Phœbus, Pride of Madford, Marie Calvat, Mme. Ed. Roger, W. Seward, Reine d'Angleterre, W. Tricker, C. Davis, Mrs. C. Harman Payne, General Paquier, and President Nonin.

Very charming were some of the floral decorations, and in this department Messrs. Biessy and Combet distinguished themselves by the light, delicate arrangement of some of their vases and baskets. Dinner-table decorations were also included. Miscellaneous groups of Palms, Ferns, fine-foliaged plants, &c., were not wanting. Some Dahlias, Cannas, Cacti, standard Roses, and other things of the kind were arranged round the sides and ends of the show room, and lent their variety to the general effect. Fruit was also shown, Grapes, Apples, and Pears being the chief, M. Henry Fatzler, of the Forceries de l'Aisne, making a fine display of his Cannon Hall

Muscat, Gros Colman, Black Alicante, and Muscat of Alexandria Grapes, about a dozen bunches in all, under a glass case, and for which a special award was made of a work of art in bronze. In the grounds there was a good display of Magnolias, Bamboos, conifers, ornamental shrubs, and gardening tools and implements.

The conference was an important part of the proceedings and extended over two days. M. Viger occupied the chair at the first sitting, and on the platform were representatives of the English, French and Italian National Chrysanthemum Societies. A welcome was given by M. Maxime de la Rocheterie to those present. Subjects of interest relating to the popular flower were discussed, M. Gérard leading off with a paper on cross-fertilisation, and showing the influence of the male and the female parents on the progeny. Following him came M. Chiffot, who discoursed on insect pests and maladies, and of which he said there were forty-one. The rust and remedies were explained and discussed, and this gentleman's paper was rendered the more interesting by a series of coloured drawings of the various insects and diseased leaves upon which he was treating. Other speakers followed. On the second day the conference was resumed, M. Maxime de la Rocheterie presiding. Further papers and discussions ensued, and these being brought to a close, the numerous company adjourned to the Park Tête d'Or, there to inspect the municipal greenhouses, the winter garden, the botanic garden and the alpine garden. A lunch to the jury—a grand banquet presided over by M. Viger—formed part of the entertainment, and as the weather was exceptionally favourable even for that district, the whole proceedings were specially enjoyable.

National Chrysanthemum Society.—Owing to pressure on our space we have been obliged to hold over the report of this show till our next issue.

NOTES OF THE WEEK.

Begonia Gloire de Louraine.—It is doubtful if any other variety can equal this lovely Begonia when grown in small pots (4-inch to 5-inch) for autumn decoration. It is a continuous bloomer over a prolonged period and is a good lighting-up colour, which is most essential.—GROWER.

Clerodendron trichotomum, referred to in last week's GARDEN as flowering in Devonshire, also flowered well at Penrhyn Castle, Carnarvonshire. Two small trees, each about 7 feet high, were covered with the pretty and very sweet-scented blossoms during September.—P., *Penrhyn Castle, N. Wales.*

Salvia Pitcheri.—If not remarkable for compactness of habit, this pretty Sage is certainly noteworthy for its spikes of distinctly-coloured flowers. Small though these undoubtedly are, they are singularly attractive, and, appearing here and there amid foliage of quite distinct character, the result is very pleasing.

A heavy rainfall.—Late in the afternoon of Friday, the 2nd inst., a batch of 8½-inch pots with watertight bottoms was placed in the open, being quite empty at the time. There were possibly a dozen or so of this size. Rain fell more or less steadily all Friday night, and the following morning nearly 4 inches of water were found in them. As it still rained and showed no sign of abatement, the pots remained, and on Sunday at 10.30 a.m. were full to the rim.—E. J., *Hampton Hill.*

Tibouchina macrantha.—The large saucer-like blooms borne by this are always admired. The plant is particularly fine in the waning months of the year, not merely for its attractiveness as a flowering plant, but for its distinct and striking aspect. Most frequently the plant is seen in small bush form, which is less striking than as grown at Kew. Here, trained near the roof-glass, the plant seems quite content, as evidenced by the large number and the fine colour of the flowers produced week by week. That planting out agrees with it is plain, and worthy of imitation.

Anomatheca cruenta.—This charming little South African bulb has seeded freely with me this year on a sunny rockery. I grew all my bulbs from

seed sent me by a Cornish friend in whose garden it grows like a weed. I find no difficulty in raising them, and, unlike most bulbs, they bloom freely the year after being sown. I sow out of doors where they are to bloom in April, and having more seeds than I can use I shall be pleased to forward some to any of your readers who care to have same as long as my supply lasts.—HERBERT E. MOLYNEUX, *Brantwood, Culverden Road, Batham, S.W.*

Primula floribunda.—This is certainly one of the most abundant bloomers of the whole genus, and, with the exception of *P. obconica*, will hold its own against all comers. As one of those easily managed plants that come so freely from seed it is a desirable subject in small pots where fringe plants are employed in the conservatory, or in groups and such like. A weak point, perhaps, in this species is the shortness of the main flowering stem, and greater boldness in this respect would be a gain. There is a pale primrose-coloured form of this plant, and, though somewhat larger in the blossoms individually, it is perhaps lacking the chief quality of the original kind, viz., its striking richness.

Anemone Pulsatilla.—I notice a note in your number of 4th inst. from J. Cornhill on the results of sowing home-grown seed of this beautiful Anemone. I had some very good seed from one of my plants this year and sowed them as soon as ripe. They came up even sooner than Mr. Cornhill mentions, and I have now a good stock of this valuable Anemone.—G. W., *Mount Usher, Ashford, Co. Wicklow.*

—Although I have raised this Anemone from seed, I have never had it germinate so soon after being sown as your correspondent Mr. J. Cornhill. I must admit, however, that my usual practice has been to sow in spring from want of the accommodation for a number of small seedlings in winter. Fresh seeds do not always remain for the twelve months mentioned by your correspondent. Frequently seeds obtained from seedsmen are, however, quite that time before germinating. As a general rule, few of the Anemones germinate so quickly as *A. coronaria*. Your contributor's experience is likely to be useful to some who may wish to grow the Pasque Flower from seed—a convenient way of raising a number of plants at a small cost. If I remember aright, the shortest time taken by *A. Pulsatilla* to germinate here was about two months.—S. ARNOTT.

Sternbergia lutea.—Here on a limestone soil *Sternbergia lutea* comes up year after year without any attention being paid to it. Last year the soil of the border had to be raised, and the bulbs were dug up and replanted, to the manifest improvement of the flowers this year. Two flowers among the lot turned up of a large size and decided Tulip shape. These I apprehend to be the true *S. macrantha*, a somewhat rare species. Is anything known of *S. colchiciflora* with a Jasmine-scented blossom? I have not been able to obtain it.—SHERBORNE, *Gloucester.*

—Unfortunately, *Sternbergia lutea* does not appear to be any the better of the plan of leaving it undisturbed here, although "W. R." has proved it to be efficacious with him. I have bulbs here which have not been moved for several years, but these have not bloomed since the year they were planted. The hope of inducing them to flower by adding lime to the soil will lead me to persevere. I desire, however, to thank your contributor for his note. The question of climate, which would occur to one, does not seem to apply in my case, as in a garden in the same county, with an almost identical climate, the *Sternbergia* flowers regularly and freely.—S. ARNOTT.

—When "W. R." on page 364 tells us that this bulb flowers every year in his garden, and that therefore it ought to do the same in Mr. Arnott's, he makes the error—too common with correspondents of gardening journals—of omitting to tell us where his garden is. It makes a great difference whether it is in Caithness or Cornwall, in Lancashire or county Cork. If, however, by the blue Bindweed "W. R." means the perennial *Convolvulus mauritanicus*, and not either *Convolvulus major* or *C. minor*, which are also blue Bindweeds, we may infer that the climate of his garden is mild, otherwise that Bindweed would not stand the winter. The fact is that the flowering of all *Sternbergias* in British gardens is subject to the soil and temperature of each garden. Nothing will make them flower regularly in my garden in Cheshire, where the mean summer temperature is low and the subsoil cold and wet.—C. WOLLEY-DOD, *Edge Hall, Malpas.*

* * The district referred to is Sussex; soil

rather heavy. We have seen it flowering very freely in Cambridgeshire, where the soil is quite sandy. A fault is not leaving it long enough in the same place.—ED.

Eranthemum pulchellum.—Formerly this well-known plant was justly prized for its free flowering and the colour of its blooms. Now, however, the plant is less frequently seen. The blue-flowered plants of late autumn and winter are not numerous, and this one at least, in consequence of its simple requirements, may be had in bloom for a long time. It is when associated with other things in the conservatory, where plants of a more or less enduring nature are necessary, that the above is found useful. Careful watering is necessary, water being given only to quite dry examples.

Notes from a Cornish garden.—The seeds of *Clematis graveolens* were only sown here in April, and this October it has flowered well out of doors. *Tacsonia Van Volxemi* was planted out of doors on a south wall two years ago, and has had no protection since. Three weeks ago two flowers came to perfection. *Senecio pulcher* is blooming for the second time, and *Ipomœa cœrulea* has at last ripened its seeds out of doors. In the cool house *Campanula Vidali* is also flowering for the second time. The first flower-spikes were none of them cut down until the seeds were ripe. *Cestrum aurantiacum* is particularly free-flowering this autumn.—C. R.

Chamærops Fortunei in fruit.—I send herewith a photograph of a plant of *Chamærops Fortunei*, one of two that have fruited here this season. This Palm usually blooms freely, but it was only this year I noticed that two of the specimens had female flowers. A fine, still day was chosen, and these bunches were fertilised with the abundant pollen from a male plant. The seeds, although plump and well filled, are not yet ripe, nor is it likely they will ripen now, the season being so far advanced, but it is interesting to see the Palms with these great masses of fruit. The photograph was taken by the Rev. Mr. Huband, of Killiskee, Ashford, Co. Wicklow.—GEORGE WALPOLE, *Mount Usher, Ashford, Co. Wicklow.*

November flowers in Devon.—I am forwarding you herewith a specimen of South Devon November flowers of the open air in the shape of a spray of *Lapageria rosea*, a large plant of which is blossoming on a north wall at Gnaton Hall, near Plymouth. Many finer flower-sprays than that sent are now hanging on the same plant, but at too great a height to be easily accessible. *Lapageria alba* is also in flower on the same wall. The single white Macartney Rose is blossoming freely on a wall hard by, while on southern walls *Ceanothus Gloire de Versailles* and *Abutilon vexillarium* are in bloom, and a large bush of the Mexican Orange Flower (*Choisya ternata*) in another part of the garden is freely studded with its white bloom-clusters.—S. W. FITZHERBERT.

* * Splendid in colour and in all ways.—ED.

Alyssum maritimum compactum.—There seems to be a diversity of opinion among your correspondents as to the origin of this plant; perhaps I can throw some light upon the matter. About eight or nine years ago I obtained from a friend, an amateur in the country, a few cuttings of this *Alyssum*, which I propagated and used for a small bed. Since then I have grown it extensively each season. Last spring I planted out over 3000 of it, and also distributed it in some other parks and gardens. It is very effective as an edging or as a groundwork for *Begonia* beds. I treat and propagate it precisely the same as *Lobelia*, the white variety of which I have quite discarded in favour of the *Alyssum*, which is a totally different thing from the old ragged annual; in fact, there is no comparison between the two.—W. B. GINGELL, *Ravenscourt Park, Hammer-smith.*

Exacum macranthum.—The stove flowering plants that can equal this in richness of colouring are few, and, although very easily grown, the plant is, perhaps, among those things rarely seen in flower save now and again in some botanic

collection. Why the amateur and the private gardener generally cultivate it so sparingly is not easy to say. By regulating the time of sowing the seeds it is possible to have quite a succession of flowering plants during the autumn months. Well-grown examples of this fine stove annual will attain to a foot or 18 inches high. Though a native of Ceylon, the plant was originally discovered at a considerable altitude and on this account will be found to do well in a warm intermediate house, rather than in the warmest part of the stove. A point to guard against is that of crowding the seedlings while yet small. Above all things it is necessary to keep the young plants moving. The corolla when fully expanded is about 2 inches long, divided into five broad segments. Its colour is of the most intense purple-violet, very rich and striking. The flowers, borne in a terminal corymb, are rendered all the more attractive by reason of the rich yellow of the prominent anthers.

A blizzard in Dublin.—A blizzard which passed over Dublin lately fell with especial violence upon Trinity College, whose grounds presented an appearance of extraordinary disorder and devastation. The portion of the park known as the "wilderness" was totally wrecked, nearly all of its fine old trees having been blown down. Some were uprooted, others—and these the largest—were snapped across, and in many cases trees were carried a distance of 15 yards or 20 yards. A great deal of injury was done in the college park and Fellows' garden. The force of the wind bent and twisted into almost every possible shape the wire railings along the engineering school. The damage done is very considerable, but the amount has not yet been estimated. Nothing, however, can replace the grand old trees which were such an ornament to the college grounds.—*Times.*

* * I am very sorry to say the above paragraph is too true. On Friday, November 3, at 11.30 a.m., a sudden blizzard, or cyclone, swept over the college park, uprooting and breaking off Elms, Willows, Hawthorns, Sycamores, Maples and Poplars. Some of the old Elms and Poplars were decayed and of no great ornamental value, but fine Thorns, Canadian Maples and a spreading Wych Elm beside the "broad walk" could ill be spared. Fortunately, bad as the results of the storm proved, its track was a limited one, 60 yards or 70 yards only, and so a far larger number of trees escaped than was injured; still in a park lying as it does in the centre of the city the loss was lamentable and in some cases well-nigh irreparable. The wind and rain, sleet, &c., lasted about an hour, but the actual damage to the trees took place in half a minute at the outside.—F. W. B.

Crocus longiflorus.—Some of the autumn Crocuses are not yet cheap enough to plant in sufficient quantity to delight us in fine autumns with a mass of their beautiful flowers. There are, however, some species not a whit less charming than those of high price, which are obtainable at a cost which would permit of their being planted in a free manner in many gardens. *Crocus longiflorus* is one of those. It is considerably more expensive than the spring-flowering Dutch Crocuses, but, when it can be procured from British firms of the highest class at a cost of 5s. 6d. per 1000, or less, it cannot be said to be a price beyond the reach of the average lover of flowers. It is, in point of beauty, worth far more. There are, as this is written (on November 6), several clumps in bloom here. Although the weather has been very stormy for some days, the scant sunshine of to-day shows them in a bright and pleasing aspect, calculated to yield us more than a passing pleasure. *Crocus longiflorus* is truly a charming species, charming alike in its rosy lilac flowers and in the fragrance they possess. It is of remarkably free-flowering habit, and only needs to fully appreciate its beauty that the flowers should spring through a carpet of some low-growing plant which is not leafless when the *Crocus* is in bloom. It is abundant in South Italy, Malta, and Dalmatia. It was classed by Mr. George Maw in the section named Reticulati,

on account of its corm tunics being composed of reticulated fibres. One can hardly refrain from expressing a hope that those who want to enjoy their gardens to the fullest extent will pay more attention to such flowers as this.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Crocus lævigatus.—Under this name I have had for a few years a little *Crocus* which is almost an ideal one for blooming in autumn. It came to me from a trade source which is usually a reliable one, but the colour does not tally with that given in the description of the species by Mr. J. G. Baker in his "Handbook of the Iridæe." That work states that the segments are "white, concolorous, or the outer with three to five distinct stripes of lilac down the back." In my specimens there is a much larger proportion of lilac on the flowers than one would gather from the description by Mr. Baker. They, however, nearly approach the colour given in the catalogue of the firm from whom my corms were purchased, and the vendors are usually so careful in verifying the names of the plants they sell, that I think this *Crocus* is correctly named. The general character answers in other respects than colour to the description in the handbook by Mr. Baker, and there is considerable variation in the colouring of the Croci in their native habitats, so that one is inclined to rest satisfied with the name given. One advantage this *Crocus* possesses to justify the remark with which this note opens, *i.e.*, that it is almost an ideal one for blooming in autumn. This consists in its exceedingly dwarf habit and the shortness of its tube. It is thus less exposed to the wild autumn winds and gales which, combined with the heavy rains which so often accompany them, are the potent enemies of the autumn-blooming Crocuses. Compared with some of the other species which come into bloom or are yet in flower beside it, the *Crocus* under notice is certainly small, but its less liability to premature destruction and its pretty appearance are merits of no slight degree. It also differs from most of the others in producing its narrow, grassy leaves along with the flowers. This is, I think, a pretty feature which adds to the beauty of the little flowers. *Crocus lævigatus* is said to come from the Greek mountains and the Cyclades, where, we are told, it grows from the sea level up to 2500 feet. It is quite hardy with me and never receives protection of any kind, although its flowers would probably be purer in colour if protected by a sheet of glass.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Hardiness of the Japanese Maple.—I am astonished that a correspondent on p. 312 of THE GARDEN considers the Japanese Maples tender. Since 1882 about twenty of these shrubs have been planted out here, and though they had several times to endure 6° Fahr. without a cover, they never suffered cold and are in robust health.—O. F., *Lehenhof.*

The weather in West Herts.—The past week was very warm, wet, and sunless. On two days the shade temperature rose to 60°, which is a very high reading for so late in the year. With one exception the nights were also very unseasonably warm. Both at 1 foot and 2 feet deep the ground is at the present time about 4° warmer than is seasonable. During the week rain fell on all but one day, to the aggregate depth of over 2½ inches, which is in excess of the average quantity for the whole month. For six minutes on the evening of the 3rd the rain was falling at the unusual rate of over an inch an hour. Since the month began eleven gallons of rain-water have come through the heavy soil gauge, and nearly as much through the light soil gauge. Both gauges are a yard square. In the last six days the sun has shone brightly for altogether only 3¾ hours.—E. M., *Berkhamsted.*

"The English Flower Garden."—Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d. Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.

FLOWER GARDEN.

HYBRID MONTBRETIAS.

SOME gardeners reject these as troublesome, and producing after a year or two nothing but a forest of green Sword-grass and spreading inordinately, but by attending to a few very simple rules they may be made a great addition to the ornaments of the garden. They like moisture and rich soil, and to have their head in the sun and their feet in the shade. In Cheshire they are not absolutely hardy, but only in ordinary winters. A long and severe frost kills them outright if not littered over.

To make them do well, the chief point is to keep them thin, and so they must be divided every year. This may be done at any time in autumn before the ground is frozen up. My practice at Edge after digging them up—suppose there are twelve stalks, that is, twelve bulbs in each clump, with three or four young points to each bulb—is to have fifty or one hundred pots ready and to put three bulbs into each pot, filling up with any waste soil, drainage being superfluous. The less they grow before March the better. They must not be cut down till spring. When all the pots are full they are placed together in some sheltered waste spot out of doors and well watered—for if kept dry they die—then they are covered with a foot or two, according to weather, of dry leaves or other litter, enough to ensure their safety from frost. By the end of March they are safe, and may then be planted out anywhere, letting the bulbs be at least 6 inches deep, either amongst herbaceous plants, which they like, or amongst low shrubs. I have some in beds of dwarf Roses, where they do and look very well. As they increase at least four-fold every year, the gardener must harden his heart and

not be tempted to let them grow more densely, but as he will find that most of his friends have as many as they want, throw the surplus on to the rubbish heap or the weed bonfire. I find one morning in each year enough to dig all up and fill a hundred pots, for the work may be done in the roughest and most hasty way without detriment to the welfare of the bulbs. Indeed, I have sometimes buried the clumps in a soil heap for winter, littering them over as described, and planting the bulbs out by threes in spring. The main objects are not to let them get frozen and not to let them get dry or grow during winter. I generally also replant three bulbs where I dig up each clump. If the winter is mild, these survive and the pots are not wanted; if they are killed, the pots take their place. They flower better if a spadeful of rich stuff is put in where each pot is planted.

If in full sun without shelter at the base the leaves become brown before flowering; if quite in shade, the leaves grow very fine and retain their green to the end of the season, but there are no flowers. M. Lemoine, of Nancy, the raiser, has sent out more than thirty kinds, most of which I have tried. I recommend especially

Etoile de Feu.—Scarlet, A 1 both in colour and habit.

Aurore.—Bright orange and very robust, growing more than a yard high.

Drap d'Or.—Bright yellow.

Solfatare.—Pale yellow.

Feu d'Artifice and Bouquet Parfait.—Mixed orange and yellow.

Pottsi grandiflora.—Scarlet outside, yellow inside, distinct and free-flowering, with ornamental seed-heads.

Besides the hybrids there are *Crocsmia imperialis* and *C. maculata*, with larger flowers than any of the hybrid Montbretias, but flowering later and rather less hardy.

Edge Hall, Malpas. C. WOLLEY-DOP.

TROPEOLUM TUBEROSUM.

MR. ARNOTT'S note (p. 249) on the non-flowering of this plant in his neighbourhood must have caused surprise to growers of it in various parts of the country, particularly those in Scotland, who experience no difficulty in getting it to grow and flower freely. It is well known that soils and climatic conditions prevailing in some districts are more favourable to the well-doing of certain plants than they are in others, and in this the *Tropeolums* are, perhaps, more fastidious than any other genus—*T. speciosum* especially so—but I was unaware that the variety under notice shared in this, as it succeeds well here in any position, and never fails to elicit admiration from the numerous visitors who pass through these gardens during the summer and autumn months. To the frequent inquiries as to the necessary treatment of the tubers and the methods of planting to ensure satisfactory results, I have always recommended it as the best and most easily grown of any of the summer-flowering creepers; but now that Mr. Arnott has enlightened us upon its behaviour around Carsethorn, I fear this laudation has been carried rather too far. It has been grown here for several years in very diverse situations as to shelter and aspect, and for covering bare walls, fences, or arbours for several months of the year very few are equal to it, and it requires but little attention. Flowering usually commences in July and continues until November, according to the situation of the plant and the amount of sun-heat available. Some of the fruit tree walls here are of an ancient style of construction, through which several wide doorways or arches giving access to the different departments are prominent features. Over these a wire or string following the curve of the arch is fixed, and the tubers being planted at the base, the shoots as soon as they appear and are of sufficient length are tied to these. Afterwards they have pretty much their own way, and ramble at will until the keystone is reached. Being planted on both sides of the arch, it is obvious that those on one side must receive more benefit from the sun than those on the other, but, with the exception of earliness, very little difference can be detected.

One of these growing on the east side and but a few feet distant from an intersecting wall in a southern direction is now (October 23) at its best, and on a 5-foot length of stem is bearing upwards of a hundred blooms, which for size, freshness, and colour are equal to any that I have ever witnessed. This plant, owing to the position it occupies, has probably never received the direct rays of the sun; certainly it has not done so for many weeks past. For twining around the pedestals of flower-vases, pillars, or sculpture work, this plant is most useful.

The culture followed here is to lift the tubers when the foliage is destroyed by frost and store them in company with Begonias, Dahlias, and similar roots until March or April, according to the weather. In planting out, a shovelful of good sandy soil is placed around the tubers, which are left about 3 inches deep when finished. Nothing else beyond tying the shoots is attempted or required. Such an expert hardy plant grower as Mr. Arnott should try this plant in his own garden, as, seeing that Carsethorne and this place are nearly in the same latitude and the climate very similar in both, a fair amount of success would probably attend his efforts.

JAMES DAY.

Galloway House, Wigtownshire.

Funkia subcordata grandiflora.—Because this plant when pot-bound continues to send up flowering material year after year, this enduring characteristic is too frequently interpreted the wrong way. It is a plant that quickly puts on a root-bound condition, yet at the same time it well repays very liberal treatment. For example, when the plants have finished their flowering in the autumn, a periodical shift to a larger pot and fresh soil will not be lost upon them. If this is done and the plants plunged in the open, covering the crowns deeply, greater vigour may be looked for the following season. This may be done every other year. Liberal supplies of manure water during growth will also assist this useful plant.

Michaelmas Daisies.—The importance of choosing a selection of these from flowering plants in the nursery is probably greater than in the case of any other plants, owing to the freedom with which they hybridise. Notwithstanding the labours of the conference, erroneous names are still too frequently found in trade catalogues. *A. densus*, for instance, is labelled *dumosus*; Robert Parker is sometimes called *Chapmani*, whereas the plant formerly known as *Chapmani* is now *lævis*, and so on. Had I to start again forming a collection I should select a few distinct species, and from the self-sown seedlings grow on and select the best. I have now several distinct forms obtained in this manner. One, a white form flowering in October, having flowers somewhat after the style of *acris*, but with more rays, branching somewhat like *horizontalis*, and forming a rounded, symmetrical bush about 2 feet high, is very effective. Another has the flowers of *horizontalis* with a tall (4 feet) branching habit rather like *polyphyllus*. A third has rosy purple clustered heads of flowers similar to *A. Novæ-Angliæ*, but with the habit of *Novi-Belgii* type, if there is one. Ordinary varieties, many equal to named sorts, are plentiful, but of course rigid selection is necessary. The sorts I should select as distinct are *vimineus*, one of the most graceful and attractive; *lævis*, a tall, spreading, sky-blue sort; *lævigatus*, rose, of dwarf, bushy habit; *Shorti* (or what I have under that name), one of the cordifolius section, dwarf and spreading, flowers of a lovely blue tint; *polyphyllus*, tall, white; *Amellus*, cordifolius, Coombefish-acre, and last, but not least, *A. spectabilis*, which seems to be less known than it ought to be. This is very distinct from most, forming a tuft of large leaves close to the ground and throwing up almost leafless branches with dark, glistening purple flowers. I also have a fine late-flowering

sort I got from Mr. John Wood, of Kirkstall, which I only know as Mr. Wolley-Dod's best blue. Just now it is in perfection. I do not much care for the white varieties of *Novi-Belgii* on account of the blackish centres so many develop in a few days. They quite spoil the appearance of the bush. I should like to know a variety in which the centres turn reddish brown only, as in *polyphyllus*.—T. J. W., *Woodside Park, N.*

PLANTS IN BLOOM IN THE ISLE OF WIGHT.

It may be interesting to some of your readers to study the effects of the unusually hot and dry summer of 1899 from such evidence as is afforded by the following list of plants actually in flower on November 1 in this garden. The ground, a few hundred yards from the sea on the undercliff, is on a steep slope facing south, and up to September, 1898, was waste ground, thickly overgrown with weeds and Brambles. Nearly all the plants mentioned were planted out between October and January, but some few, notably *Lasiandra*, *Sparmannia*, *Abutilon*, *Plumbago capensis*, *Heliotropes*, *Bouvardias* and standard *Geraniums*, have not yet endured a winter in the open ground. Very few annuals are grown here, and many perennials and bulbs being young and small when put in have not yet attained sufficient maturity to add to what in another year should be a much richer list.

Abutilons, two species, white and yellow	Gaillardias
<i>Amaryllis lutea</i>	<i>Helenium grandicephalum</i>
<i>Anagallis grandiflora</i>	* <i>Hypericum Moserianum</i> and <i>H. elatum</i>
<i>Arbutus coccinea</i>	<i>Heliotropes</i> (standards)
Asters (several)	<i>Ipomœa atro-purpurea</i>
<i>Bouvardia triphylla</i> and <i>B. Vreelandi</i>	<i>Lasiandra macrantha</i>
<i>Boussingaultia baselloides</i>	<i>Lithospermum prostratum</i>
<i>Cassia corymbosa</i>	<i>Lobelia laxiflora</i>
* <i>Cimicifuga japonica</i>	<i>Leonitis Leonurus</i> (buds just opening)
<i>Cistus formosus</i>	Pansies
* <i>Coronilla Emerus</i>	<i>Pentstemon</i> s
<i>Canna</i> s	<i>Phlox</i> (several)
<i>Coreopsis</i>	<i>Phygelia capensis</i>
<i>Cyclamen</i> s	<i>Polygonum baldschuanicum</i>
<i>Convolvulus mauritanicus</i>	<i>Physianthus albens</i>
<i>Colebinema</i>	<i>Plumbago Larpentæ</i> and <i>P. capensis</i>
<i>Desmodium penduliflorum</i>	<i>Portulacæ</i> s
<i>Diplacus glutinosus</i>	* <i>Santolina incana</i>
<i>Delphiniums</i>	<i>Statice profusa</i> and * <i>S. incana</i>
Dahlias	* <i>Spiræa Bumalda</i>
<i>Elmagnus macrophyllus</i>	<i>Sutherlandia frutescens</i>
<i>Erigeron splendens</i>	<i>Sagittaria montevidensis</i>
* <i>Erythrina crista-galli</i>	<i>Salvia angustifolia</i> and * <i>S. patens</i>
<i>Echinacea purpurea</i>	<i>Tritonia nobilis</i>
<i>Erysimum helveticum</i>	<i>Tuberoses</i> (still very fine)
<i>Fuchsias</i> (several)	<i>Veronica melensis</i> and <i>V. salicifolia</i>
<i>Gazania latiflora</i> and * <i>G. nivea Couronné</i>	Violets
<i>Geraniums</i> (Ivy-leaved)	<i>Zauschneria californica</i>
<i>Mme. Crousse</i> and <i>Souvenir de C. Turner</i>	
<i>Geraniums</i> (standards)	

* A few small late or abnormally early flowers only.

Freecias, which bloomed freely after being out last winter, are now showing leaves. *Hyla arborea*, the green tree frog, has bred here during the summer, and after an interval of disappearance, one young frog and two tadpoles were seen in the tank lately, the majority having already hibernated.

HENRY COOK.

Belvedere, St. Lawrence, I. of Wight.

Pyrethrum uliginosum.—That cutting back stems of this tall-flowering, tall-growing perennial may not be desirable in Scotland it is easy to understand. But in the south I have often found it to be capital practice, as here the shoots that have broken out from the shortened stem have flowered very little later, indeed almost simultaneously with the uncut stems. But if anyone will when the stems are 2 feet in height take off

the tops 6 inches long, set them singly into 3-inch pots as cuttings, and root them in a close frame, he will find that these, either grown in pots a couple of sizes larger and flowered in the greenhouse or planted outdoors, will bloom quite dwarf and make most useful plants. I prefer to have them, however, kept in pots, as under glass they bloom for a long season.—A. D.

MR. MOON'S HYBRID POPPY.

I AM glad to learn that Mr. Moon actually fertilised *Papaver rupifragum*, or rather *P. orientale bracteatum*, for as he distinctly says (p. 365), "my plant of *P. rupifragum* has never produced any seed itself." It may be, however, that it does so if fertilised with *P. bracteatum*. Will Mr. Moon still further oblige and enlighten us by saying which of the two parents is the seed-bearer and which the pollen parent in the case of the beautiful hybrid illustrated. According to Mr. Carrington Ley, however, it seems that spontaneous or accidental hybrids do occur, and also that some individuals of *P. rupifragum* after, as is presumed, a previous pollination continue to produce hybrid seedlings. This is a very perplexing statement, and may, as I said before, be due to the wind or a lucky fly carrying pollen unknown to him. Otherwise it seems inexplicable why one plant of *P. rupifragum* produces hybrid seedlings in his garden and elsewhere, while "several other plants" of that species in the same garden give seedling reproductions of itself pure and simple so freely as to become "almost a nuisance." In one case we have Mr. Moon's hybrid produced by actual hybridising or pollination, and in Mr. Ley's case we are asked to believe that a similar hybrid occurs without immediate pollination, but I think that wind or insects must have carried out that operation unknown to Mr. Ley. In any case I cannot believe in *pangensis* as a cause of his *P. rupifragum* continuing to produce hybrids. I shall be very glad of the seeds Mr. Ley is so kind as to promise me, and hope to experiment in other ways likely to throw additional light on this curious and complicated question. The flowers of nearly all the Poppies are so much frequented by pollen-eating flies and minute beetles, that the wonder is there are not more hybrids in this genus. Even *P. rupifragum* itself may possibly be a fertile natural hybrid, in which case one might the more readily understand the vagaries of Mr. Ley's plant. Nature is vast and often inscrutable, and it is an axiom of mine that "Nature does everything sometimes," by which I mean that a plant will naturally seed freely in one place and even produce hybrid progeny and fertile seeds, though as a general rule it may not do so in other places even when carefully fertilised. We cannot dogmatise on the mere groundwork of our own limited experience, as every observant gardener well knows.

F. W. B.

NOTES AND QUESTIONS.—FLOWER.

Planting small and choice bulbs.—Many choice bulbs, such as some Tulip species, are very small and liable to be disturbed or lost if planted in the open border. To obviate this, I find it answers well to pot them carefully in well-drained pots, which are then sunk a little below the ground level. I have so flowered the tiny-bulbed *Tulipa linifolia*, which had previously failed to bloom planted out in the ordinary way. I am now trying *Tulipa orphanidea* in this way, as this also is very small. It seems to be beneficial in another way—that is, ensuring better drainage and more warmth in the soil by which the bulb is surrounded.—T. J. W., *Woodside Park*.

Dark-flowered Crown Imperial.—Can anyone give me information about a dark reddish plum-coloured Crown Imperial? I saw one at Kew a few years ago, but as there was no label attached to it I could not ascertain its name. The darkest-flowered sort I have been able to get is the variegated-leaved variety. The flowers of this are much darker than in the ordinary red, and show up conspicuously in the border. The variegation of the foliage is also handsome, making the plant a most effective spring flower.

Since writing the above THE GARDEN has come to hand with the coloured plate of *F. l. longipetala*. This flower resembles that of the variegated variety. Is it in commerce?—P. J. W., *Woodside Park*.

STOVE AND GREENHOUSE.

EUCHARIS AMAZONICA.

I READ "H. R.'s" remarks on *Eucharis amazonica*, in the issue of September 30, with great interest. I have hitherto considered and treated it as a stove plant, but have often wondered if it really was or not. I should be glad if "H. R." would give us his mode of treating it.—C. R.

* * In the first place it is necessary that the house, though cool, be nicely tempered as regards atmospheric moisture. To attempt to grow it in an ordinary greenhouse where the air is dry and draughty is worse than keeping it in stove heat. A house to grow *Eucharis* properly should have a night temperature of about 55°. It should be provided with blinds to screen the plants from bright sun, and the ventilation must be carefully attended to so that a constant change of air is going on, but no draughts of cold air must reach the plants in winter. Any bulbs that need repotting must be shaken out of the compost at the end of March and be repotted in good fibrous loam, a little peat or leaf-mould, and a sixth part of well-decayed cow manure. Add to this some well-pounded charcoal or crock dust and sand, and an excellent rooting medium will be the result. In potting the bulbs use the 9-inch or 10 inch size, this taking about half a-dozen fair-sized bulbs. Drain well and cover the drainage with a little rough Moss or similar material. In potting keep the top of the bulb about an inch below the surface, if possible. But if the bulbs have been more deeply buried, it is not wise to bring them right up at once; do it a little at a time at each potting. Previous to repotting, the plants will have been, comparatively speaking, at rest, and a slight rise in temperature will just give the little impetus needed to start and re-establish the bulbs. Damp the foliage over frequently with tepid water, but keep the roots on the dry side. If the compost is in proper condition at potting time no water need be given for a fortnight, but after this, as the foliage begins to pick up and the plants to grow, gradually increase the supply.

Growth will be rapid all through the summer, and though all the plants will not probably flower at the same time, the great bulk of the blossoms will be produced from the end of July until September, after which a few chance spikes may push up. When growth is well away and until the flowers appear on the spikes, occasional waterings with well-diluted soot water are very helpful. The soot gives colour to the foliage and may be varied by occasional applications of nitrate of soda, say about three times during the season. After the flowers are past the plants make a little more growth, but not much, and it is more in the filling out of the leaves than in producing new ones. By November they should be practically at rest and must be kept well on the dry side, not, however, going to the length of allowing the least shrivelling. The night temperature may now be reduced to 50°, and only increased again as recommended above at the time of repotting. Once in three years is often enough to repot, and a sorting of the bulbs should take place then, bringing all those of flowering size together and growing the smaller ones by themselves. I need hardly add that a clean stock is necessary to success, and all mite-infested bulbs should be thrown away.—H. R.

Begonia carminata.—Of late years we have seen numerous additions to the shrubby section of *Begonias*, many of which are particularly valuable for winter flowering. The variety under notice may be regarded as almost perpetual

blooming, for it will often commence to flower quite early in the summer and continue till nearly the end of the year. This variety was raised from the white-flowered *B. Dregei* crossed with the pollen of the Brazilian *B. coccinea*, well known as a tall-growing species with large drooping clusters of bright red flowers. *B. carminata* is of a more bushy habit of growth, with flowers disposed much as in *B. coccinea*, but of a bright carmine pink colour. It is just now flowering freely and forms a pretty object in the intermediate house.—H. P.

Ixora macrothyrsa.—This *Ixora*, which is quite as well known by the specific name of Duffi as that of *macrothyrsa*, is a truly gorgeous species that differs widely in general appearance from the varieties usually grown. It is of a tall, rather straggling habit of growth. The flowers are borne in huge terminal heads, which in vigorous examples are over a foot across. Their colour is a kind of reddish scarlet that with age changes to more of a crimson tint. It is useless to attempt the culture of this *Ixora* in the shape of little neat bushes as in the other kinds, for its loose style of growth would necessitate continual stopping, and this would be done at the expense of flowers. The plants should be grown on freely, allowing two or three shoots to develop, and in the autumn these may reasonably be expected to each produce a huge head of brilliantly coloured blossoms. Plants that have done flowering should be cut back hard in the spring. This *Ixora* was introduced from the South Sea Islands, and was figured in THE GARDEN over twenty-one years ago.—H. P.

Gloriosa virescens.—The *Gloriosas* are usually treated as stove plants, but a specimen of this kind has been growing during the summer and flowering freely in No. 4 greenhouse at Kew. Though pretty and interesting, it is not nearly the equal of the old *G. superba*, whose wavy petals with their quaint markings combine to form a strange yet showy blossom. *G. virescens* differs therefrom in the segments of the flower being broader, while the petals are not crisped as in the other. The colour of the flower, too, is less bright. *G. Planti* is a form of this plant with reddish yellow blossoms. Considering the numbers of *G. superba* that are imported every year and the extremely gorgeous blossoms, it is a matter for surprise that we do not meet with it oftener. One reason, I think, is that many people attempt to grow it in pots, under which conditions it is seldom satisfactory, for the curiously shaped tubers extend in a horizontal manner.—H. P.

Begonia Dregei.—This pretty species once almost dropped out of cultivation, but of late, owing to the increased interest shown in this section of *Begonias*, it is grown much more than was at one time the case. It is a very useful plant, and of especial interest as being one of the parents of the now universally grown *Gloire de Lorraine*. *B. Dregei* forms a stout, fleshy root-stock (almost a tuber), from whence are pushed up succulent shoots that reach a height of 1 foot to 18 inches. The leaves are rather small, thin, and freckled irregularly with grey, while the small white flowers are very numerous. Whether it will be eclipsed by the new white-flowered form of *Gloire de Lorraine*, time will show. Another hybrid of *B. Dregei* is *B. weltoniensis*, which twenty-five years ago was much grown for market, in the shape of neat little bushes about 18 inches high. The bright green leaves with their reddish stalks were decidedly pretty, and, given much the treatment as a *Fuchsia*, the attractive pink blossoms were freely borne.—T.

Choice room plants.—It is particularly interesting to be reminded of some uncommon plants that do well in a cool room, and to those mentioned on page 324 I would add the distinct and charming *Dracena Godseffiana*, which in the London district has been in a cool room facing the east since last February. During that period it has twice pushed out a number of new shoots. As this *Dracena* is a native of Lagos, in Upper Guinea, the fact that it will succeed under such

treatment is all the more surprising. By artificial light it is particularly attractive, the cream-coloured blotches being very noticeable against the deep shining green of the rest of the leaf. The free, yet twiggy growth eminently fits it for growing into an effective specimen. Plants in dwelling-houses are liable to suffer from draughts, erratic watering (generally in excess), as well as from dust, but if carefully attended to it will be found that many subjects are not so difficult to keep in health as they are usually considered to be.—H. P.

Rondeletia speciosa.—This old West Indian shrub, which at one time was far more popular than it is now-a-days, forms a delightful feature in the greenhouse towards the end of the summer and in autumn, as when grown in the form of a neat bush and studded with its rounded clusters of brightly coloured blossoms it stands out quite distinct from its associates. The colour of the flowers is a kind of vermilion-scarlet with an orange-coloured eye. The variety major, which is better known than the typical kind, is of looser growth, while both the clusters and individual blooms are somewhat larger. The colour of the flowers too is rather paler. The blossoms stand well in a cut state, and in the variety major may be cut with long stalks, which greatly adds to their value in this respect. After flowering the plants should be kept fairly dry, even though many of the leaves may drop. In the spring it is better to prune them back hard, when in a stove temperature they will break at once and grow away freely. *R. speciosa* is also known as *R. odorata*.—H. P.

NOTES OF THE WEEK.

Chrysanthemum Etoile de Feu.—There is a striking individuality in the colour presented in this kind, which comes midway between that of *Val d'Andorre* and the still older *Tokio*, both bright colours among the so-called red shades. The kind here mentioned, however, is distinct from both, being of a red-crimson tone somewhat, and one that will prove particularly showy under artificial light.

Colchicum Sibthorpi.—Mr. A. Kingsmill sends us from his garden at Harrow Weald some fine flowers of this scarce Meadow Saffron. The flowers of this, which are among the largest in the family, are of a fine lilac shade, beautifully chequered. The blooms previous to opening stand boldly erect on stout stems 8 inches high and are very effective, and, owing to their great substance, last a long time.

Begonia Dregei.—This is a neat-flowered and pretty kind that may be grown in small pots for furnishing and for the greenhouse. The plant is of quite easy culture, and where the rose-coloured *Gloire de Lorraine* is grown freely, this should prove a useful companion. This pretty kind now, however, has a great rival in the white-flowered form of *Gloire de Lorraine* called *Caledonia*, that has recently put in an appearance.

November flowers in Berks.—I herewith send you samples of the variety of flowers which I gathered last evening in my garden. All are growing out of doors, the *Louicera* and the two *Veronicas* growing against the house. This will show the advantage of having a garden on a hill about 320 feet above "high-water mark," and sheltered from north and east, but, above all, the result of following the "English Flower Garden," my garden even now being gay and sweet.—B., *Forest End, Sandhurst, Berks, November 14*.

* * Many beautiful plants, too numerous to mention, in fine fresh condition.—ED.

Violet Mrs. J. J. Astor.—This is one of the most charming additions to the double-flowered *Violets* that has yet appeared. Hitherto the new doubles have had but very minor distinctions; so small, indeed, as not to be discernible in every instance. There is no fear of that in the kind named above, for in colour alone it is quite new, if not indeed unique. The colour may be described as reddish lilac, but is catalogued as pink and heliotrope. In any case the shade is quite novel and distinct from all that has gone before. Not only this, the flowers are very large—quite as

large as the largest double sort we remember, and, above all, deliciously sweet-scented.

Violet La France.—In the singles, this handsome as well as richly coloured form is a great gain. Large as that universal favourite Princess of Wales is, this kind is larger still, and while producing fine long stalks that render it of much value for bunching, it is said to be twice as free-flowering as the other kind named. Varieties that produce large flowers and plenty of them are not long in making way, and we have little hesitation in placing this handsome kind in the very front rank of single Violets.

Begonia Mrs. Leopold de Rothschild.—The fine batch of this brought to the Drill Hall last week by Mr. James Hudson, Gunnersbury House, shows to what an extent this and the parent kind, *Gloire de Lorraine*, are grown at the above place. The large batch of plants, every one of which was in fine flower, made a capital display, at a moment, too, when a large number of the usual exhibitors at the Drill Hall had gone elsewhere. The above-named kind, besides having much larger blossoms of a decided pink tone, possesses a much denser habit of growth, this alone rendering the plant pleasing and attractive.

Statiche Butcheri.—For its fine colour and freedom of flowering this Sea Lavender deserves to be extensively grown. To the properties already named should be added dwarfness and adaptability to small pot culture. This from the decorative point of view has a value of its own, and is increased when the plant is one that may be easily grown. Bushy plants little more than a foot high and with freely branching cymes to almost the same diameter may be grown in pots 4½ inches across, so small, indeed, compared with leafage and flower that the pot is hardly seen at all. Thus grown it is certainly one of the most desirable of autumn-flowering plants for the greenhouse.

Campanula balchinensis.—This pretty cross-bred *Campanula* is of twofold value, viz., as a flowering pot plant during summer, and, given greenhouse treatment, as a fine-foliaged plant during winter. To achieve the best results in the latter direction it is not prudent to allow the plants intended for winter work to flower to their fullest extent during summer. Rather should this be checked a little, and so allow a fuller leaf-growth. Even the flower-sprays long retain the pretty variegation which is so strong a feature of the plant, and the varying tints assumed when the plants occupy a light, sunny position in a warm greenhouse alone make it a worthy occupant of such in winter.

Nerine japonica.—Like "H. P." I am unable to flower this bulb satisfactorily. I have four dozen plants purchased two years ago, and up to the present have only succeeded in getting four lots to flower. I have grown them well this past season and given them a thorough rest. I only brought them to the front and watered them when I saw new growth starting. These few were in bloom about six weeks ago. The rest of the batch are growing freely in a midseason vinery on a shelf, but I cannot detect any more spikes of bloom showing. I thought of planting them outdoors close up to a wall and giving them the same position as I do *Amaryllis Belladonna*, which flowers abundantly every year. — J. MAYNE, *Bicton*.

Pulmonaria saccharata picta.—It is doubtful how far we are justified in applying specific names to some of the Lungworts, most of which are so close to the ordinary *P. officinalis* that there is no apparent difference between them except in the form or markings of the leaves. One of these is that known in gardens as *P. saccharata* or *P. s. picta*. Although, like most of the genus, rather a coarse plant, it has its uses. I am induced to write of it at present because of the appearance it yet makes on the top of a bit of rough rockwork, where its large, spotted leaves make it noticeable at a time when most plants of similar style have lost all beauty for the year. I am aware that some do not like plants with foliage marked like

this. One is quite prepared to admit that plants with spotted or variegated foliage may be, and often are, overdone in gardens where one often sees them far too largely used. The specimen to which I refer is, however, not near anything else with similar foliage, and is, all the time it is in leaf, of good appearance. It makes a pleasing combination of silvery grey and green, in some degree reminding one of the more aristocratic *Rex Begonias*. This is much improved when grown, as here, in a dry position. The flowers I do not much care for. — S. ARNOTT.

Nerine roseo-crispa.—The plate in THE GARDEN of November 11, and the references to the *Nerines* which have recently appeared in your columns, remind me that little is seen of this hybrid, which has, I think, been in cultivation for some time. It comes from *N. undulata* and *N. flexuosa* if Mr. Baker is correct in his mention of this plant in the "Hand-book of the *Amaryllideæ*," page 103. It cannot by any means be called a showy plant, but it has a quiet beauty which is often pleasing by way of a change from the more brilliant flowers under glass at the same time. It was sent me by Mr. J. N. Gerard a few years ago, and with simple treatment in a cool greenhouse has never yet failed to bloom. Its segments are narrow, but light and graceful in appearance and prettily crisped. The flowers are pale pink. The treatment it receives here is very simple and consists in allowing the plants to go gradually to rest in spring. They are repotted occasionally, but not annually, in August or September. At all seasons the pots are kept in a house from which frost is just excluded. *Nerine roseo-crispa* is yet in bloom with me in a greenhouse which has had no fire-heat since spring. — S. ARNOTT, *Carsehorn, by Dumfries, N.B.*

Crocus asturicus.—Despite the wild gales and drenching rains which have prevailed for some time, the autumnal *Crocuses* in sheltered positions in the rock garden have given us bright patches of welcome colour. They have not, of course, been seen at their best, yet one can appreciate their modest beauty even amid the gloomy weather which has prevented them from exhibiting their full charms. In addition to those previously mentioned in THE GARDEN the pretty little *Crocus asturicus* has been very pleasing, and, should we have better weather now, will be pretty for some time still. I regret that I have here only one colour in this *Crocus*. It is said to vary from purple to white, through every shade of lilac. Those I have here I should call a deep lilac. It much resembles in its general appearance *Crocus nudiflorus*, from which it differs by its leaves appearing at the time of flowering and by its bearded throat. The anthers are bright yellow or brown; the filaments are white and the stigmas deep orange. According to Mr. George Maw, *Crocus asturicus* abounds in the meadows of the Asturias at altitudes up to 4000 feet, and goes as far south as the Sierra de Guadarrama. Mr. J. G. Baker says it is intermediate between *C. serotinus* and *C. nudiflorus*. It is a neat *Crocus*, not so tall as some, and thus the better able to withstand the rude winds which are the arch enemies of the *Crocus*. — S. ARNOTT, *Carsehorn, by Dumfries, N.B.*

Sternbergia lutea.—In the notes sent recently on the above plant I have seen no reference to the form known as *S. l. angustifolia*, a form of *S. lutea* which flowers under ordinary conditions every year, and of which the flowers are quite as fine as those of the typical plant. Some twelve years ago I planted a group of bulbs in a narrow, well-drained border by the side of a house, and took some trouble in preparing the soil, mixing in a good quantity of porous material, broken bricks and mortar, and the staple soil was sandy. These bulbs turned out to be the broad and large-leaved form and they grew splendidly, but in spite of the border being a dry one, in which the *Belladonna Lily* did remarkably well, they only flowered well in four seasons out of twelve, and always after a really roasting summer. In a neighbouring garden less than half a

mile away some bulbs of the narrow-leaved form were planted in very deep and rich soil in a herbaceous border, and though no care was taken to prepare for them in any way, they flowered every year. These were not planted until the present cycle of dry seasons had set in, but it was sufficiently long to prove that the bulbs were far more free-flowering than those I had planted, and that they did not require the same amount of roasting. Perhaps some of your readers who have this plant under observation will compare notes on the foliage borne by their own and other plants which have differed in their flowering capabilities and report on the result. Will Mr. Lynch, of the Cambridge Botanic Garden, tell us something about the foliage of his plants, which, I believe, flower remarkably well? — J. C. TALLACK.

— This pretty autumn-flowering bulbous plant very frequently puzzles the cultivator. Now and again one may come across it a mass of bloom quite unexpectedly, and that without helping one to determine its special needs in the slightest degree. A few years ago I saw quite a plantation of it in a small nursery in the Thames valley. There must have been not less than 300 bulbs in the original planting, and these had increased largely, for there was not a gap anywhere. What surprised me was the fact that they were growing on a shady border. On inquiry I found they had occupied the ground some three years or so, and were planted in quite an ordinary way with no special knowledge at the command of the planter. So far as the soil was concerned, this was light and sandy, resting on a bed of gravel, the bulbs being planted about 5 inches below the surface. Years ago in the then famous nurseries of Messrs. Rollisson at Tooting a batch of bulbs on a narrow south border flowered quite freely. So far as position alone was concerned, these were in just the opposite of the former lot—indeed, were companions in a sunny spot with some clusters of *Belladonna Lilies*. In most instances of success, however, some time has usually elapsed before the plants have become established, and I incline to the opinion that a cold subsoil has more to do with failure than is usually imagined. In gardens where clay abounds it is rare indeed *Sternbergias* succeed. In a trench of lighter and well-drained soil, planted deeply and with plenty of old mortar rubbish, a better opportunity is afforded them. Usually the failures outnumber the successes. — E. J.

Seedling Nerines.—Those who were present at the Drill Hall last week had an excellent opportunity afforded them of inspecting quite a unique lot of cross-bred forms of these beautiful bulbous-flowering plants. As is pretty well known, Mr. H. J. Elwes has been engaged among these plants for some years past, the new and beautiful shades of colour, of which examples last week were brought to the Drill Hall, being some of the results of his labours. In mentioning new colours in the flowers of these plants one cannot omit that remarkable kind bearing the name of Mrs. Berkeley, the intense salmon hue of this being absolutely unique. Hitherto no such remarkable colour has appeared among the selections brought to Westminster, though it is said there are approaches to it somewhat less fine and distinct. Equally attractive is that named Miss Willmott, a bold and telling kind bearing a handsome head of flowers of the most brilliant orange-scarlet. Both kinds possess well-balanced heads of flowers that will be difficult to surpass. Again, too, among the several dozens of seedlings not bearing any distinctive names were many pleasing and attractive forms, not merely showing colour advancement, but a beauty of form or exceptional markings that distinguish them from the older kinds, as well as the earlier seedlings from the same source. Of course, the chief drawback to such things is the great length of time that must elapse before such plants can be put into commerce. The two kinds here mentioned, for example, will probably take many years before a sufficient stock can be secured for distribution, assuming, as is highly probable, that the plants at the Drill Hall were the only ones.

IN A CORNISH GARDEN.

I HAVE been to the south of Ireland and seen the Azaleas there, visited many a sea-shore garden, and naturally made up my mind that I knew something about what our island could do in shore gardens, but I had not the least idea of the beauty to be seen in Cornish gardens, and in none more than this nameless one about which I now have to say a few very inadequate words. The owner, dreading the advent of the tourist, prefers to remain fameless, and so I can have my say without let or hindrance. The

cool country and may be grown round our coast in many places.

It was even more surprising to see out of doors the Japanese Banana quite vigorous here and tall—in fact, as large as I had ever seen it in a conservatory—growing with most graceful effect in a sheltered corner. But perhaps the finest picture of all was that of Tree Ferns in an old quarry, with handsome healthy leaves and fine thick brown stems. The photographer has done his best to get the effect of these from the only available point of view, but the result

self—has a fine notion of wild gardening with such things as Azaleas and Hydrangeas, which the climate encourages him to plant on a large scale, and he would do the same with the Tree Rhododendron (*R. arboreum*) if seedling plants could be got in sufficient quantity. The effect of the Hydrangeas in the woods is very fine, they escaping the winter cold, which cuts them down so often in the midlands; here every shoot blooms. Such plants as the Gunnera and giant Sea Hollies are quite at home, as are also *Dracenas* and the rarer *Yuccas*. The beautiful Jasmine-

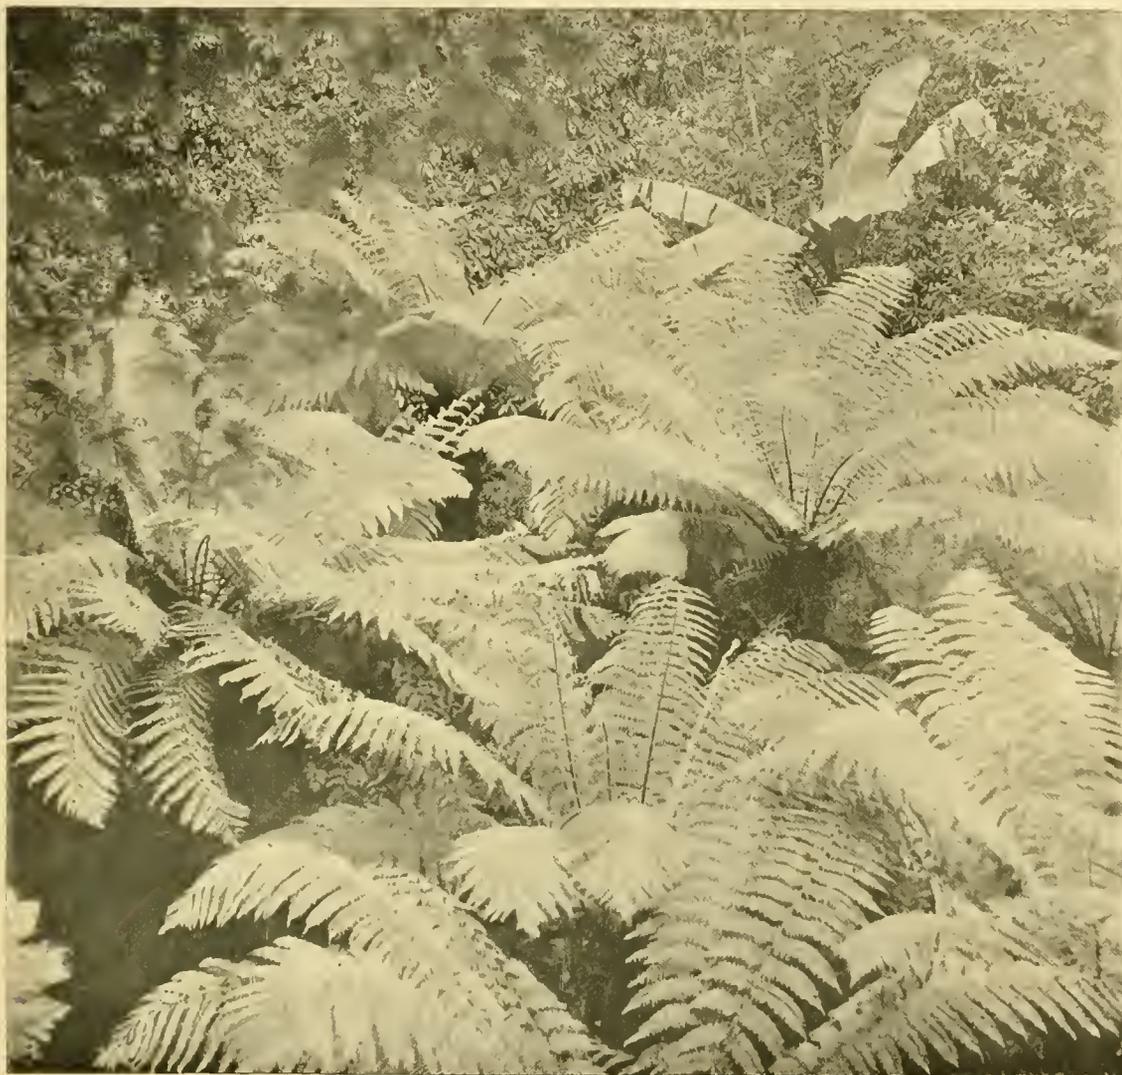

flowered *Solanum* is, as might be supposed, happy here, and displays a luxuriance of growth, bloom and fruit which are rarely seen further north, graceful as the plant is everywhere. The Bamboo also is quite at home in this beautiful and varied garden, which is also rich in the possession of many Water Lilies that float in a picturesque sheet of water below the house. Where there is so much of subtropical, and, as one might almost say, of tropical interest, one would less expect to see great attention paid to hardy plants, but they were as much thought of here as any others, and included a very fine collection of *Narcissi*, the raising of new varieties of which is diligently pursued and with very interesting results.

V.

A LABOUR-SAVING MACHINE.

In these days of economy in private gardens anything that will save labour ought to be welcomed on all sides. Nearly all the year round there is much sweeping to be done, and in the case of extensive lawns and long drives the labour expended in this direction falls rather heavily on those responsible for the management of the gardens generally. Any way it is a great relief to have men doing good work in the kitchen and fruit gardens who but for labour-saving arrangements would have been working to less advantage elsewhere.

Mowing machines effected a great saving in labour, also improving the appearance of lawns, and now we have sweeping machines to further economise labour in that direction. The one great drawback to these sweeping machines was the fact that they collected, but did not discharge, rubbish of all kinds, so that considerable time had to be wasted in emptying the receptacles. This difficulty Mr. T. Challis, of Wilton House Gardens, Salisbury, set himself to overcome with very gratifying results. By a very simple, yet clever arrangement, which I shall not attempt to describe, the man who steers the horse and guides the machine can, without changing his position, clear the collect-

Tree Ferns and Japan Musa in an old quarry (Cornwall). From a photograph by G. Champion.

garden is very near a cove by the sea, while the house faces sunwards, and on its cool side is a magnificent curtain of *Lapageria*, both red and white varieties, which were in fine bloom in the early spring days. It flowers early in winter and is a picture at Christmas-time. One can imagine what a delightful plant it is to have at such a season in perfect health, as it certainly was here, growing in peat borders in the shade of the house and with no enemy but the slugs, which have to be diligently watched. This plant is from a

does not in the least give the fine picture to be seen as one stands underneath the Ferns in the quarry. I need not say what a fine feature of the garden these Tree Ferns are, not merely put out in the summer as they have to be in other districts, but left out throughout the year, and in the finest state of health in which I have ever seen Tree Ferns. The New Zealand Flax is massed in bold groups, and the *Woodwardia*, another Fern of fine form, is quite free out of doors. The happy owner—a good gardener him-

ing box of rubbish, right or left, as the case may be, more easily than the larger mowing machines are cleared. Since perfecting this invention, Mr. Challis finds it possible to sweep eight acres of lawn in one day with a 4 feet wide machine drawn by a pony, while a 5-feet machine, such as I saw at work at Wilton, sweeps twelve to fifteen acres in one day, saving the work of twelve or more men. The apparatus is fitted to quite small as well as the large-sized sweeping machines, and from what came under my notice recently it does its work remarkably well. I did not see a machine at work on a coach drive or walk, but Mr. Challis assured me that it could be used for all such purposes. I ought, perhaps, to add that the invention is patented, and machines have already been sold and distributed in considerable numbers.

W. I.

ORCHARD AND FRUIT GARDEN.

STRAWBERRIES.

MR. ENGLEHEART contributes a most interesting note for Strawberry growers and raisers on p. 173. I could not help being struck with the pertinent and very truthful points which he raises in connection with flavour, constitution and variable aspects of culture. British Queen is no doubt a fine variety from a flavour point of view, but very few private or market growers seem able to make it a profitable one to plant. Those who possess the soil suited to its delicate constitution obtain a great deal of credit from consumers who are privileged to enjoy the fruit. British Queen and Countess I have planted repeatedly in small numbers with the hope of finding a spot suited to them, but the latter has been discarded, and the other raised but a languishing hope of success. Empress of India or Lady Suffield I have not tried. Gunton Park, which of the trio I supposed to be the strongest in constitution, has not yet given a satisfactory account of itself, and this experience makes one hesitate planting further doubtful ones.

The great influence soil has on Strawberries is very marked and disappointing when others meet with signal failures from no fault of cultivation, and the grower is often driven to adopt sorts suitable to his land entirely in deference to his own wish and desire. Latest of All, one of Messrs. Laxton's earlier introductions, has a good deal of British Queen blood in it, and for this reason it succeeds in but few places compared with such as President, Sir J. Paxton, or Royal Sovereign. In this garden there is no other variety that can compare with Latest of All for weight of crop or early bearing. Royal Sovereign, usually looked upon as a precocious fruiter, is very inferior. The plants grow strongly, but the flower-trusses are sparingly produced, and are very loose in habit. It is better as a two-year-old, but then not equal to others named. As a forcing variety there is no other to excel or even to equal it, all points considered. Leader comes near it, but as yet it has not been sufficiently proved, but an extended planting will decide its merits both as a yearling and older outdoor plants. The berries are firmer-fleshed and thus should travel well; its colour is brighter, though scarcely so dark, and the growth of the plant more moderate in strong ground than is Royal Sovereign. Its fruit is of large size, and the flavour, so far as I have been able to judge, is slightly above that of Royal Sovereign. The great faults of Latest of All are its pale colour, especially at the points, and the short time it keeps in hot weather when allowed to ripen well to the tip. It may be a better Strawberry for home use than market. In the former case the

fruit is more often gathered fresh for every meal; in the case of the market grower it is different. Mr. Engleheart is quite correct in saying that allowance must be made for different tastes. President from a flavour point of view is an excellent variety, but in bulk it is not so bright and taking to the purchaser as Sir Joseph Paxton or Royal Sovereign, and colour counts for much to fruit buyers. Certainly President is superior to many in flavour, but, like others, it is much influenced in its growth and size of berry by the nature of the soil in which it is grown. With me both President and Vicomtesse are under-sized and very similar in appearance; excellent they are as preserving sorts, but do not fill the basket like Leader, Sovereign, and Latest of All. Generally speaking, size takes precedence over quality if the latter is presented in small berries—at least this is my experience, gathered from remarks made by those with whom I have been brought into contact. I had almost resolved to plant some of the perpetual-fruiter varieties, but Mr. Engleheart's opinion of them settles what was to me an undecided point. I have never found small Strawberries much in request except for preserving, and presume that in the alpine sorts the fact of their fruiting outside the Strawberry season is their greatest recommendation. There must be disappointment or encouragement in the fact that the ideal Strawberry has yet to be raised. It is no doubt true that good qualities are distributed over several popular kinds, but the best not yet united in one. Growers would be glad if it were so; raisers probably are encouraged in knowing that it is not. It would seem almost difficult to learn in what direction to turn to find such an ideal, and there are no doubt some already weary of the effort to find it. There is one thing quite certain in Strawberry raising and growing, and that is the absence of any single variety that can be said to suit every garden or field in the matter of soil, situation, and climate. This is true both of their culture in the open and in pots. In the latter case it might be done by the importation of soil and suitable structures for forcing. Royal Sovereign comes nearer the ideal than any other Strawberry I know.

W. S.

Apple Armorer (Ross).—I planted a tree of this comparatively new variety two seasons ago, and it has borne a few fruits this year. These are small in size, flattish and regularly formed, and covered all over with brown russet. On tasting the ripest of the fruits I found it to be very short-eating, juicy, and with a very rich agreeable flavour. No doubt after being kept for a time the flavour would improve, as it is, I believe, a late-keeping dessert sort. It appears to me to be a desirable Apple to grow for private use, the prettily shaped fruits being just the right size for table use, and being a late kind, it should prove valuable for the dessert after Ribston and Cox's Orange Pippins have been used. The tree seems to be a rather slender grower, partaking a great deal of the character of some of the Nonpareils in this respect, but it may perhaps grow stronger another season.—A. W.

Apple Wormsley Grange Pippin.—At first sight many would pronounce this Apple to be identical with Wellington, there being a great similarity both in shape and colour. However, on closely examining a specimen the illusion is at once dispelled, for it can then be seen that the stalk basin and the eye of the fruit are distinct, while a very pleasant aroma is given off which is absent in Wellington. If necessary, a more conclusive test is obtained by cutting and tasting a ripe fruit, when it will be found to be particularly crisp and short-eating and possessing a sweet, brisk flavour. The fruits are straw-coloured with the exception of the part exposed to the

sun, which becomes suffused with a pink flush. It is a good cooking Apple, but many are very partial to it for eating. It is a seedling raised by Mr. Thomas Andrew Knight, and is not, I think, much grown, as I have but seldom met with it out of the county of Hereford.—S. E. P.

Apple Scholmaster.—There are some varieties of Apples which for some reason or other never seem to find favour with growers, and the one named may be included among the number. Why this should be I cannot understand, as it is neither tender nor a shy bearer. On the contrary, the tree is quite hardy, and as regards fertility, very young trees carry excellent crops of fruit. It is a first-rate cooking Apple for amateurs to grow, as when worked on the Paradise stock, bush trees can be kept in quite a small state without having recourse to lifting, the free-bearing qualities of the variety alone serving to keep them from making strong growth. It also makes a good standard on the free stock and is very suitable for orchard culture. The fruits are from medium-sized to large, conical and straw coloured, with a few grey dots widely dispersed over the surface of the skin. Where the fruits are fully exposed they become prettily coloured, standard trees generally furnishing the best examples in this respect. It has a white flesh, is juicy and acid, cooks well, and its season is from November to the end of the year. I have before now kept it in excellent condition some time after the time specified. This variety was introduced to public notice by the late Mr. Laxton, but is supposed to have been raised in Herefordshire early in the present century. It was certificated by the Royal Horticultural Society in 1880.—A. W.

DECORATING EXHIBITION GRAPES.

For some time past a growing desire has become apparent for a decided change in the method of staging Grapes at shows. The long, straight, formal rows of boxes or stands with the bunches arranged upon them symmetrically have at last, most fortunately, had their day, and now the era of a change has set in, as exemplified at the great show recently held in Shrewsbury. Several persons holding a high position in horticulture have strongly deprecated any change in the formal system so long in vogue by the votaries of order and primness. Visitors to the show in question had a magnificent opportunity of seeing what can be done in the way of decorating even show Grapes. As is well known, good prizes were offered for twelve bunches of Grapes in six varieties. Each bunch was to be staged on single boards of the orthodox pattern. Instead of all the bunches being arranged in one formal row, as is usually the way, they were arranged in two tiers, one above another; the extreme space to occupy was not to be more than 8 feet by 4 feet 6 inches. Non-flowering plants, in or out of pots, and loose foliage were allowed. A maximum number of six points was to be given for decorative staging, and as the Grapes themselves were to be judged by a system of points, effective decoration was of some importance. In both the first and second-prize stands five points were allowed for decoration. Probably the second-prize collection would have carried more if the exhibitor had not coated the Vine leaves over with some glutinous substance with the idea of preserving them longer in a fresh condition. In the first-prize exhibit from Mr. Lunt small Pitcher plants raised on neat pedestals were effectively employed. As a background small and graceful plants of *Cocos Weddelliana* were used along with small Ferns mounted on a base of green Moss. In the second-prize exhibit Palms and Crotons were pleasingly arranged among the Grape stands, the front portion being draped with trails of Smilax. The decoration of the six competing stands displayed much diversity of taste, as was to be expected, and afforded object-lessons of a valuable character.

The most effective plants to employ are well-grown narrow-leaved yellow Crotons of a drooping character, *Cocos Weddelliana* and small plants

of *Kentia Belmoreana*, with stocky plants of such Ferns as *Pteris serrulata* and its varieties. Trails of Vine laterals and *Smilax* on the top of the stands as well as on the cloth between the stands add materially to the effect. Red Crotons, dark-leaved *Dracenas*, and white *Caladiums* of the argyrites type are the least effective. The *Caladiums* contrast badly with the white paper on which the Grapes are placed, and the coloured plants alluded to with the black Grapes. In several instances trails of Ivy were employed. This addition had a somewhat stiff and heavy appearance, and so had the Crotons with broad and stiff leaves.

There is no reason whatever why this method of staging Grapes should not be generally

In this I quite agree with him, as the trees create a very beautiful effect when in bloom in the spring, and in autumn when laden with fruit they are equally effective. It is also a good cooking Apple, and some people like it to eat, the flesh being soft and sweet. Starlings are particularly fond of this Apple. Great numbers of trees of Emperor Alexander are grown in this neighbourhood, the local name for it being Stoke Tulip, in allusion, I presume, to the colour of the fruits somewhat resembling some of the bright-coloured border Tulips when in flower. It is an excellent cropper. The fruit, which grows to a very large size, colours grandly, and in the local market realises good prices, the fruit being too soft to

held over a rather large reserve of Red Currants, these Raspberries have come in most useful, as there has been sufficient of them both for cooking as well as for dessert. Red Currant and Raspberry tarts are always welcome in the summer, but when they can be had in the autumn they are doubly welcome, and are then looked upon in the light of a great luxury. It is surprising that these autumn-fruiting Raspberries are not grown more generally than they are, for their culture is very simple, the chief thing being to feed well and to thin out the canes early in summer. A wire trellis is, perhaps, the best to tie the canes to, and if the canes are kept from 9 inches to 1 foot apart, each one then has plenty of room for development. October Red is the sweetest flavoured, and therefore the best kind for dessert, while Belle de Fontenay, which bears fruits almost as large as those of the summer-fruiting Superlative, is more acid, and therefore more suited for cooking. Unless very severe frosts should come, the supply will last for another week or two.—S. P. H.

YOUNG AND OLD PEACH AND NECTARINE TREES.

AN interesting article on the above recently appeared. A correspondent advised intending planters of Peach trees to select them, if possible, while growing in the nursery and have their names attached. This is good advice, as so many disappointments occur through planting inferior trees. To plant gummy trees is to court failure, though sometimes with care they will grow out of that condition if planted in a not too deep and comparatively poor border. Very many trees at the present day after a few years' growth swell out unduly at the point of union with the stock, the natural flow of sap being thereby hindered and the tree finally collapses, often quite suddenly. This condition is, in my opinion, caused by the use of unsuitable stocks, which is not fair to purchasers. Those who have sufficient wall space do well to bring on a few young trees for removal under glass when blanks in Peach houses occur. As a rule, gardeners do not look for fruit the first season after planting—at least, when the trees are bought in—the rough-and-ready treatment they receive at lifting-time, and the subsequent journey by rail being anything but favourable to the retention of the bloom-buds—if such there be—in a plump condition, and the same may be said of the fibrous roots. Moreover, thickly-grown nursery trees are not always sufficiently ripened, and so shrivelling of the wood often occurs. If healthy young trees well furnished with bloom-buds are growing in the home garden, and care is taken to prepare the right sort of border beforehand, and to lift systematically, there is not the slightest reason why fruit in quantity should not be forthcoming the next summer. I have even known such trees planted in early autumn in an early forced house to bear a few very nice fruit. I think many err in making too much border to start with; indeed, the more I look at the subject the stronger is my conviction that grand crops of the very finest Peaches may be grown in borders of very limited size. Well-drained borders, say 2½ feet deep, consisting of good holding yellow loam and old plaster or mortar rubble, without any further addition, will grow the finest Peaches. The compost, well mixed previously, should be thrown together piecemeal and made as firm as possible. This firmness is indispensable for the formation of fibrous roots, as in loose borders, especially when of a rich nature, the roots formed are of a shoelace character, and do not permeate it before the soil becomes sour. Much depends upon moving Peach trees at the right moment. When the foliage is taking on a yellow tinge is the time to lift, and the soil about the roots should be in a thoroughly moist condition. Some attach little or no importance to securing a ball, but I certainly would do so where practicable, as favouring a more speedy and satisfactory root action. Plant shallow, from 4 inches to 6 inches from the surface, water

Jasmine-flowered Solanum. (See p. 393.)

adopted even in the two and single bunch classes. Anything that will serve to break up the long formal rows so long adopted by societies in all parts of the country will be a step in the right direction, and will not detract from the appearance of the Grapes themselves, but will tend to render them all the more interesting to the general public.

E. MOLYNEUX.

Apple Emperor Alexander.—A note on this Apple appeared in a recent issue of THE GARDEN, in which the writer speaks of it as being a good variety to plant for effect in the pleasure grounds.

send any great distance. It is best grown as a standard; bushes, unless they can be allowed a great deal of latitude in the way of growth, seldom bear more than half a crop, and sometimes not that.—S. E. P.

Autumn-fruiting Raspberries.—A great many people when looking round these gardens lately have been surprised to see the autumn-fruiting Raspberries carrying such heavy crops of fruit. I cannot call to mind a season in which they fruited more freely than they have done this, the tips of the canes having been literally loaded with large and well-coloured berries. Having

home, and apply a mulch of old Mushroom manure or similar material. If the weather is close and sunny, syringe the trees once a day till the foliage falls and keep the house fully aired and moist. If the roots of such trees are examined in a month's time a colony of young fibrous rootlets will be found and the wood and buds will remain as plump as if the tree had not been moved. We sometimes see it asserted that young trees are necessary for the production of fine crops of large Peaches, but my experience is that old trees, that is to say, those from ten to fifteen years old, produce the finest fruit, all other conditions being equal. The finest fruits of Royal George I ever saw were on a tree which I suppose would be quite twenty years old. If due preparation is made, large trees, if in good health, will stand removal with impunity and fruit freely the following season. I have often heard gardeners say, and I have proved it myself, that when old Peach and Nectarine borders of great width and depth are cleared out, comparatively few roots of a fibrous character are found, the soil in most instances being sour and unenticing. H.

Apple Washington.—The hot weather of the summer now past has just suited this American Apple. I grow it as a bush in a warm position, and it invariably yields a good crop of fruit. This season has proved no exception to the rule as regards crop, but the tree has surpassed itself by producing large highly-coloured fruit of splendid quality. It is a soft-fleshed Apple, and therefore much appreciated by those who cannot eat those of firmer texture. It is also juicy, very richly flavoured, and at its best during November. If kept long after that period its flavour then deteriorates.—HEREFORD.

Two good late Peaches.—Both Prince and Princess of Wales Peaches have been a great success this season, the latter being more highly flavoured than usual. Prince of Wales is always the better flavoured of the two. The fruits of Princess of Wales were, however, much the larger and were very handsome when fully ripe with their yellow skins striped with red. Prince of Wales was quite as dark in colour as Bellegarde and very juicy and richly flavoured. Where the Peach will succeed as an outdoor fruit a place should always be found for these two kinds. I have Prince of Wales on a wall facing north-west, and Princess of Wales in a position exactly due west.—A. W.

Apple Golden Reinette.—Two specimens of this Apple were handed to me for identification the other day. These were exceedingly well grown, and possessed all the characteristics as regards shape, colour, and flavour of this fine old variety. I was informed that these had been gathered from a standard tree, the yield being a heavy one. This Apple used to be grown extensively in our orchards in years gone by. Grown as a standard, the yield from a single tree often runs into several hundredweight, and this is the best way of cultivating it for market. It also succeeds well either in the form of a bush or espalier. The fruits keep well in a cool store and may be had in good condition until March with the flavour unimpaired.—HEREFORD.

Apple Mabbott's Pearmain.—For many years a standard tree of the above has been growing in a grass paddock here. How long it has been in its present position, and where the tenant who then rented the paddock and planted the tree procured it from I am unable to say. I have known it for the past thirty years, and previous to learning its name I looked upon it as being a local seedling. Some seventeen years ago the late Dr. Bull applied to me for a specimen fruit of this variety, together with any information I could afford as to its history, &c. I replied that I had not got it and that it was quite unknown to me, little dreaming that I had a full grown tree of it well laden with fruit in my charge. I was unable to get it named until a few years after this occurred, but have always set great store on it as a dessert Apple for mid-winter

use. In some seasons it comes almost as large as the old Pearmain, and keeps quite as long. I saw one or two good dishes of typical fruit at the recent Crystal Palace show, the grey freckles on the skin—which are so characteristic of the variety—being very prominent. It is a handsome and highly flavoured sort; the tree is hardy and well adapted for orchard culture.—A. W.

Late Strawberries on north borders.—In the issue of THE GARDEN for September 30 there appeared an excellent article from "Norwich," the perusal of which afforded me much interest. I quite agree with all that "Norwich" has to say with regard to cultural details, and the remark he makes with regard to the variety named Loxford Hall having to be well grown he might, I think, have extended to nearly all the late varieties. According to my experience, late Strawberries require a rich soil, and I therefore always have plenty of manure dug in prior to planting, the quantity being considerably in excess of that afforded for the early and midseason sorts. I generally grow them on borders under walls which are covered with Morello Cherry trees, and having two such borders, the one being of great length and quite three times as long as the other, I arrange the cropping so that a portion at any rate has a whole season's rest from Strawberry growing. Here they succeed remarkably well and bear crops of very fine fruit, the supply lasting over a long period. With regard to varieties, I have tried several of those named by "Norwich," but have given up all in favour of Oxonian, which is quite at home in this locality. This I treat as a biennial, as the berries being required simply for dessert, the fruit the third season, though plentiful enough, lacks size, and is not considered sufficiently large enough for our requirements here. Treated in this way fine fruit can be secured both the first as well as in the second season if the precaution be taken to layer the early runners. To secure plenty of these latter, a few plants should be grown in the open expressly for the purpose, as runners taken from plants on north borders are, as a rule, too late to be of any service the first season, *i.e.*, from a cropping point of view.—S. E. P.

TREATMENT OF AMERICAN BLIGHT.

M. LOCHOT, formerly head gardener to the municipality of Dijon, and at the present time filling the same office to the Prince of Bulgaria, has described in a recent number of *Pomologie Française* his method of treatment, which he considers to be more effective than any that has been tried hitherto. He says:—

I resolved to carry out the treatment after the fall of the leaves—that is to say, during the month of November. At this season there is nothing to fear from further laying and the insects will have reached their maximum of increase; they await the first of the cold weather before hiding themselves under the old bark, or more generally the roots nearest to the tree-stem. During the winter and spring the treatment is less effectual, as one is unable to get at all the insects that are on the roots. Take a fire-proof vessel of 4 to 5 gallons capacity, put in it 1 lb. of black soap and 1½ quarts water and place it on the fire until the soap is entirely dissolved in the water, when remove and allow the liquid to cool, keeping it carefully under observation meanwhile. Have at hand a quart of raw petroleum and a wooden spoon. When the solution of soap and water has sufficiently cooled and become semi-liquid, stir it quickly with the spoon in one hand and with the other gently pour in the petroleum. If this is properly performed the mixture will be absolutely homogenous, and will have the appearance of a brown creamy liquid. At this stage pour in 2 quarts of water, stirring constantly the while, and then leave it to become quite cold. All that is necessary now is to add the quantity of water needed, say eight quarts, to obtain twelve quarts of liquid, and in addition about half a pint of colour-

less tobacco juice strong in nicotine. The mixture will keep indefinitely; it is semi-liquid and milky in colour. The essential thing is to add the petroleum to the dissolved soap at the right moment. If the soap and water are too hot, the petroleum remains on the surface and there is no proper mixture. If too cool, the soap will be lumpy and the result no better. The right moment can be ascertained with a little practice. I have always found it best to add the nicotine last of all. The use of ordinary tobacco juice is not to be recommended for this purpose. When the trees are attacked, no attempt should be made to carry out the treatment during growth. The leaves are an obstacle to the operator, retarding his work and compelling him to miss many of the insects, and so the whole thing has to be done again in the autumn. It is much better to apply the treatment in November in the following way: Remove any leaves that remain on the tree, and then cut away all the parts that are past recovery. Young trees of the year one is often obliged to cut down entirely, the eyes at the base being altogether lost. The leaves and wood that are cut away should be collected and burned. Then for the space of 20 inches all round the stem remove the soil as far as the collar of the first roots. Take a paint-brush of medium size, half used, so that the bristles shall be stiff and well able to penetrate the small cracks in the wood, especially the wounds made by the insects. All that remains now is to paint the tree all over, not forgetting the stem and the root collar. Replace with a little new earth the soil that was removed and the operation is complete. It is quicker to set two men to work, one to prune and clean the tree, the other to apply the insecticide. Avoid changing the man who wields the brush, as in a little time he will have become very dextrous at it and the work will be done much better.

On the above remarks of M. Lochot, M. Daubeny in the *Revue Horticole* makes the following observation: "I have been able to prove the excellence of these recommendations, having been guided by my own experience to proceed exactly in the same fashion. But if the method laid down by my colleague is not altogether a novel one, it has at least the indisputable merit of being practical."

Nectarine Spenser.—Never has this late Nectarine been so good as it has during the past season. The fruits not only grew to a large size, but they put on a splendid colour almost as dark as mahogany, and the flavour was delicious. I have but one tree, which covers a good area of wall, and this carried a crop equal to one fruit for every square foot of space covered by the tree. The latter is very hardy, vigorous, and fruitful, and I consider that next to Humboldt it is the best late Nectarine we have. A gentleman interested in Peach and Nectarine growing, when looking round just as the fruits were beginning to ripen, was impressed with the handsome appearance of this variety, and intends adding it to his collection this autumn. My advice to those who do not grow it is to do so, for wherever the Peach will succeed outdoors this Nectarine will also flourish and bear abundantly.—A. W.

Cutting back Raspberries.—Many hesitate to cut back their Raspberry canes when newly planted, especially when they are purchased from the nursery, more particularly when they happen to be strong. Nurserymen foster this failing by sending strong rods carefully preserved their full length. Inexperienced growers are those of course more likely to fall into such error. So planted it commonly happens that the energies of the plant are used up in its effort to fruit, leaving the sucker growth, which is the all-important part, to chance, with the result that the cane often dies at the end of the fruiting season. Severe shortening is almost as great an evil as the other extreme. I saw canes quite recently that had been cut back to less than a foot from the soil, and the results were very plainly to be seen in the broken lines of summer shoots. This comes from pruning too soon or at the time of planting. Had they been

slightly shortened then, and when growth was active in spring still further pruned, the sucker growth would have been more surely established. This would seem to have been uppermost in "A. D.'s" mind when penning his note on p. 272. The weather at the present time is most favourable for transplanting the canes from home-grown beds, though full early for getting them from distant nurseries, at any rate in a season when growth is so late as the present one. Rain, however, is badly needed for moistening the soil for all newly-planted trees.—W. S.

Exhibiting Grapes.—There is little to find fault with in the present method of exhibiting ordinary fruits at shows, whether in collections or otherwise, with the exception of Grapes, and these do badly need improving in appearance, as long rows of bunches on boards are far from pleasing. But when the Shrewsbury Executive do make an effort—and a remarkably successful one, too—in the direction of making one Grape class there attractive and pleasing, it is a little disheartening to hear of such an objection as is made by "H."—that the dress accessories practically caused the Grapes to play second fiddle. I am absolutely certain that whilst every on-looker was pleased with the accessories of plants, flowers, and foliage, not one but regarded the Grapes as the exhibit. It would be as wise to say that a dressed dinner-table is the dinner, and not the substantial foods placed upon it.—A. D.

PLANTING APPLE TREES.

THOSE who have a light, easily worked soil have a great advantage as planting time comes round compared with those growers whose soil is heavy and stubborn. No matter how far one looks forward and prepares, there are sure to be some places that have to be made ready almost at the last minute, and the trees suffer accordingly. This season I have had all holes ready for planting on the grass and all beds and borders made up the last two months, and the soil that was thrown out of the holes was mixed with as much good compost as could be spared. The lumps were broken down and the rains have softened the whole of it, so that the trees when they arrive can be planted as fast as a man can unpack them. I usually have a water-cart filled ready and thoroughly soak the roots after removing the outer packing material, then as they are unpacked all ragged ends of roots are cut clean and the trees planted. It is important that enough fine soil be at hand to cover all the roots, and the upper tiers of these are left about 2 inches beneath the surface. Quite recently I was asked what stock was the best to have Apples worked on so that they could be planted sufficiently deep that vegetables of different kinds might be planted over them. It has again and again been pointed out in THE GARDEN that unless fruit tree roots are kept up and allowed to take advantage of air and surface warmth, the produce of such trees is not at all likely to be worth anything.

When planting thus early in the season it is well to give the roots a thorough soaking of water as soon as they are just covered and before placing the top soil on. All ramming and treading should be done before watering and the dry soil placed as loosely as possible. Nothing is more troublesome in heavy soils than the cracking in hot weather that follows ramming or treading of the upper layer, and this is easily prevented, as described above, either mulching or lightly hoeing the surface in spring. Where rabbits and hares are troublesome the stems must be protected the same day as they are planted, for these are both very much more partial to newly-planted trees than to those that are well established. Standard trees are easily protected by tying on straw bottle-cases with wire. If done with string the animals soon nibble them off, but they never seem to begin on the straw, and if they do, a little tar and water smeared over it will stop them. They are far better than hay-bands. Bush and pyramid trees must be surrounded by wire netting, which must be turned

outwards at right angles an inch under ground. This will be found a much better way than letting it into a trench, as the rabbits always begin to burrow close by the wire and will go under it, but when they come on the netting they give up the attempt. Staking should also have immediate attention, or a sudden storm of wind and rain will ruin a lot of trees. Here hay-bands are useful, and well twisted and tied to firmly inserted stakes are the best means of keeping the trees steady. Tall and very erect-growing kinds like King of Pippins should not be planted in the most exposed places, but any kinds such as Beauty of Bath that are more spreading in habit and have the fruit removed early may be, as these are gathered before the autumn gales. H.

WINTER GRAPES.

MOST people like to get as much variety as possible into their fruit whether outside or in, and though the aim is a good one in many respects, it is not without its drawbacks by any means. Respecting Grapes, for instance, a good deal of misconception as to the best varieties exists, and in speaking now more particularly of winter varieties it is a little remarkable that so much valuable space is given up to such second-rate kinds as Black Alicante and others. This Grape is an excellent keeper without a doubt, but this fact does not account for its culture in houses where good Lady Downe's, Gros Colman or even in some cases Black Hamburg and Madresfield Court might be kept. A rod or two of Alicante for the latest supplies should be ample, and in place of it more of the two first-named ought to be grown. Take Gros Colman, for instance; much of the disfavour in which this is held may be traced either to over-cropping or insufficient time. Time it must have to bring out its proper flavour, and if not over-cropped there should be no difficulty in getting the colour laid on. In common with one or two others, Gros Colman is very liable to be attacked by red spider, and naturally this has a bad effect. No Vine, unless thoroughly healthy, can be expected to finish its fruit properly, and red spider is very prejudicial to health. The attack often follows sun-scorching, or, indeed, anything that lessens the vitality of the foliage, so one precaution will be careful ventilation on bright mornings so long as the foliage is tender. Lady Downe's finishes much quicker than Gros Colman, and yet has the merit of hanging well on the Vine or keeping in the Grape room. Its handsome appearance, too, is all in its favour, and it is one of the best and most attractive kinds in cultivation. The skin, though fairly thick, is not tough and leathery like that of Alicante, and its freedom of setting gives it a very decided advantage over the capricious Alnwick Seedling. Gros Maroc is a handsome kind that keeps fairly well, but, taking into consideration the room it needs and the lack of flavour after it has been hanging a little while, it is not nearly so good as the two former. Mrs. Pince is an excellent kind where it does well, but in some places this often fails to colour properly, and though of the richest flavour when well finished, is no better than the last named. The new Grape Diamond Jubilee exhibited at the Palace and elsewhere this season looks a promising kind, but whether it will bear out the encomiums passed upon it this season when brought to the test of culture of course remains to be seen. H. R.

Pear Flemish Beauty.—This seldom-seen Pear was referred to a few years ago by a writer to THE GARDEN, and I think it was Mr. Temple, of Carron House, Falkirk, who replied to the note, speaking in favourable terms of it. It is

not, perhaps, what one would term a buttery fruit, but when well ripened on wall or espalier it is very pleasant eating and extremely handsome. It belongs to the rounder-shaped section and makes a very handsome dish. It needs somewhat careful culture, as the tree is apt to grow grossly in strong, rich soils—at least, when on the Pear. I have never grown it on the Quince, but judicious root-pruning will eventually remedy unfruitfulness. It quite deserves to be included in every collection.—NORFOLK.

Strawberry Latest of All.—I have written of Latest of All just as I know it; that is enough for me. I have written of it also as I have seen it in the south on strong soil. If it has behaved differently in the neighbourhood of Sheffield that may be due to both climate and surroundings. So far as I have seen Laxton's varieties, if Royal Sovereign be the best, certainly I regard Latest of All as the next best from that raiser. I know Elton Pine also, and knew it well half a century since. It was in its day a good late variety, but certainly it is far from being satisfactory everywhere. Like Latest of All, it seems to do best on stiff soil. I grew it for many years at Bedford, where it always gave good crops, but whilst the first fruits ran of good size, the later ones were only useful for preserving. Latest of All has fine fruits throughout, crops more heavily, and has better flavour. Certainly in the south, where the fruits become well finished, they are of excellent flavour. I have said nothing as to the parentage of Latest of All, and it is a matter of absolute indifference as to what that parentage may be. We need only concern ourselves as to the merits of the variety.—A. D.

FIGS CASTING THEIR FRUIT.

I HAVE some young Fig trees which show fruits towards the end of summer. These fruits fall off in spring. Do Fig trees show fruit one year and ripen them the next, or should they show fruit in spring and ripen them the same year? Mine have fruit on now about the size of Filberts. The trees are on a north wall, and were raised from cuttings taken from a good bearing tree.—A READER, Ireland.

* * * It is quite natural for Fig trees planted outdoors to cast the fruits which attain the size in the previous autumn of those that "A Reader" inquires about. Those which should stand and ripen will now be so small as to be not readily discerned, and, given the proper position and treatment, there should be enough of these to provide a nice crop; indeed, it is only these formed on the previous year's wood that are of any value for outdoor fruiting. The second crop, *i.e.*, Figs which form on the wood made during the current season, are too late to be of any use except, perhaps, in the longest of summers and the best possible situations. "A Reader" has chosen the worst of situations for his trees, *viz.*, a north wall, and he must never expect a crop of Figs from trees so placed, for the Fig tree requires all the sunlight that can be given it in order to ripen up its wood. Warmth at the roots, too, is necessary during summer—that is to say, the soil must feel the influence of the sun, a thing impossible in such a position. If "A Reader" wishes to succeed, he will lift his trees and plant them against a south wall in a border composed of soil that is not over-rich and with which have been incorporated broken bricks and mortar rubbish in liberal quantities, forming at least one-third of the bulk with the latter ingredients. This border can hardly be made too solid, as a hard root-run tends to prevent gross wood and causes the wood which is made to ripen up early. Favourite and good positions for Fig trees are elevated situations in cobble-paved yards or a narrow raised border by the side of a hard gravel walk. The above will indicate the lines to be worked on to command success. "A Reader" does not say in which part of Ireland these trees are growing. If in the south or south-west there will be no need for protecting the wood in winter, but in colder districts it

would be necessary to tie the branches in bunches, bringing them low down towards the ground and covering them with dry Bracken or some other such material, which may be lightly bound round the bunches of branches or held in position with mats. This should be left on till late in spring, as the embryo fruits are very susceptible to frost, and the wood also gets killed back in severe winters if unprotected.—J. C. T.

LATE DESSERT APPLES.

In this district (Sussex) the late dessert varieties of Apples are more plentiful than the early kinds. May be this is owing to the trees not flowering so soon or the bad weather which we experienced in May.

Golden Nonpareil was one of these, and though not one of the best of our dessert Apples it is still useful as a variety, as if left till late on the tree it keeps well into the spring. The fruit though small is well shaped and makes a pretty dish.

Golden Harvey.—How seldom is this pretty little highly flavoured dessert Apple seen on the exhibition table. Can it be because it is not

being a clear yellow when fully ripe. There is so much difference between the fruit grown on a north wall and that which is fully exposed, that unless one was well acquainted with them he would not take them for the same variety. When allowed to hang long on the tree the fruit will keep sound until March. This is one of the most useful varieties we have for stewing whole, and is a great favourite with cooks for that purpose.

Duke of Devonshire.—This is another of those late varieties that finds little favour with exhibitors, though it is as handsome in shape when well grown as Golden Noble. The tree is hardy and an excellent bearer. This season, though with me the Apple crop is anything but a good one, there has been a fair sprinkling. When fully ripe the fruit is of a beautiful lemon colour strewn over with russet, and often on the side next the sun in exposed places it has a dull red cheek. The flesh, which is crisp and sweet, is of a yellowish colour. If allowed to hang till November on the tree the fruit will keep plump till March or April.

Sturmer Pippin.—In this we have one of our most valuable dessert Apples for spring use, and, unlike any of those previously named, it is a

wall under my charge. It was healthy and did not form gross wood, yet it would not fruit. I waited for six or seven years, as a gentleman who visited my employer stated that in his district—the west of England, I think—it fruited and was of delicious flavour. In all the reports of the fruit crops which have appeared in THE GARDEN I do not remember having once seen Aston Town named. I should be interested to learn if any reader of THE GARDEN has a tree which bears fruit, and if so, what his opinion of it is. I have only seen it named in one or two fruit catalogues.—B. S. N.

GARDEN FLORA.

PLATE 1249.

ROSA HISPIDA (R. LUTESCENS).

(WITH A COLOURED PLATE.*)

THE Roses that constitute the spinosissima (or pimpinellifolia) group are not only very charming in the beauty of their flowers, but they are also particularly welcome because they herald in the great Rose season. The plant now figured is one of this group, and it is one of the

Hydrangeas in a wood in Cornwall. (See p. 393.)

sufficiently known, or is it on account of judges giving a preference to something with colour in it? It certainly cannot be from lack of flavour, as there are few, if any, more highly flavoured Apples to be found growing in our orchards. The tree is hardy on most soils, though with me it is apt to canker. It is a most prolific bearer, and keeps in fine condition for a long time if allowed to hang on the tree till November and when gathered placed in a cool place.

Golden Russet.—With me this tree has rather a loose habit, but otherwise it is well suited to the soil and the fruit grows to a fair size. It is a good cropper, being hardy and less liable to canker than some others. Like all others of its class, the fruit should be allowed to hang as long as possible, then be stored in a cool place. When ripe this makes a very pretty dish, especially when grown in an exposed place, for then the fruit on the sunny side has a tinge of red covered with russet spots.

Court of Wick.—With me this variety seldom fails to produce a crop. An old tree growing against a north wall is usually loaded with fruit, and though the Apples are not so large as those grown on bushes in exposed places on the Paradise stock, the fruit is of a better colour,

showy variety. I have it growing on a north wall, where the fruit is of a green colour, changing as it ripens to a yellowish green, but in the open where fully exposed to the sun the fruit is of a bright red on the sunny side, and this season it is brighter than usual. Seldom a season passes but what there is a crop on the wall, though sometimes trees in the open suffer from the late spring frosts and wet weather. The fruit ought never to be gathered until the leaves begin to fall, when if stored in a cool place it will keep sound till the following May.

There is quite as much art in preserving Apples in a sound condition as there is in growing them, but unless suitable places are provided it will be impossible to do this, no matter what care is taken. We too often see them stored in dry, airy lofts where fire-heat is provided instead of in cool, damp places, from which frost can be excluded without the aid of artificial heat.

H. C. P.

Pear Aston Town.—How seldom do we see this Pear mentioned—the reason, I expect, being that it is only in a few soils and localities that it succeeds. I once had a trained tree on a west

earliest to flower. I have seen it in bloom in the open air during the last week of May. It is a Rose about whose origin there has always been a good deal of doubt. It is known to have been cultivated in a garden at Islington as far back as the year 1781, but no record exists of when or from whence it was introduced. Loudon and others alluded to it as the “Yellow American Rose,” and Pursh—a German botanist who published a “Flora of North America”—described it as *R. lutescens* and included it in that work. The later American writers, however, unanimously discard it. It was then generally looked upon as a native of Siberia, but as no authenticated wild specimens are contained in the public herbaria, this remains nothing more than a surmise—at the same time probably a correct one, judging from the fact that its nearest allies are found in that country. The theory that it was a hybrid of garden origin was disposed of when plants were raised from seed, for these have invariably come

* Drawn for THE GARDEN by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by J. L. Goffart.

ROSE - ALBA

quite true. Mr. J. G. Baker, our leading authority on wild Roses, now regards it as nothing more than a variety (probably Siberian) of the Scotch Rose, so that its proper name will be *R. spinosissima* var. *hispida*. Certainly it does not differ in any essential respect from the common Scotch Rose more than the variety of *R. spinosissima* known as *altaica* (or *R. grandiflora*) does.

The plants from whose flowers Mr. Moon made the accompanying plate are 5 feet to 6 feet high. Thus they are giants compared with the ordinary Scotch Rose. The stems are sturdy and quite erect, and thickly set with slender bristles. The leaf consists of seven to eleven leaflets, which are of a rich green and considerably larger than those of the Scotch Rose. Of the flowers, which are single and about 2½ inches across, Mr. Moon's drawing will give

interest that is being taken in the wild types of *Rosa*, this plate of *R. hispida* will be welcome. It is a plant which ought not to be overlooked.

Kew.

W. J. BEAN.

THE WEEK'S WORK.

OUTDOOR FRUITS.

PLANTING.—The weather up to the time of writing has been wonderfully open and mild; just what is required by those who have a considerable amount of planting to do, and all that is required in that way with home-grown stock is, or should be, now completed, but with bought-in stock the case is different, as one has to wait until the nurseryman is ready to send; and as the summer has been dry and there have been no frosts sufficiently severe to influence the fall of

together, syringing the branches freely, and then enveloping them for a day or two in thick Russian mats, which should be kept saturated while in use. It ought to be remembered that the roots of such trees, or, indeed, any others, should have very little exposure when the time comes for planting, and the good grower will have all the holes prepared, filled up to as nearly as possible the requisite height to receive the lowest roots, and also have in readiness any helpful ingredient that one may have at hand for encouraging the roots to commence making fibres straight away. With this part of planting I have already dealt, but I may add to my former remarks that I have found in orchard planting that a few shovelfuls of garden soil are useful when one has nothing better in the shape of mellow, crumbly loam to give the trees. Look over each tree before planting, and remove everything in the shape of fractured portions of roots to a point behind the fracture, even if this entails a considerable sacri-

Bamboos in a seashore Cornish garden. (See p. 393.)

a better idea than any words can. The colour is certainly, I consider, one of the most charming to be seen among these wild Roses; at first a delightful soft shade of yellow, it becomes paler and more creamy with age. As has already been intimated, this Rose can be increased by means of seed. Of this its black fruits enclose an abundance. Plants can be obtained more quickly, but in less quantity, by layering.

A group of some half a dozen plants in the sunk Rose garden at Kew always makes a lovely picture in the early days of June. To see it at its best, not less than that number of plants should be grouped together. Of course, it only blooms once a year, but, after all, that is a characteristic common to most shrubs, and there is certainly no lack of flowers when it is in bloom. To those who share in the reviving

the leaf, the chances are that orders given will not have been dealt with so early as usual, and the most one can do is to be as nearly as possible prepared to deal with the trees when they come in. Nurserymen's ways are not those of the private garden, for they are obliged to anticipate orders and to lift large numbers within a short time. This is unavoidable, and the best is probably done under the circumstances, but the fact remains that trees often come to hand with their roots and branches somewhat shrivelled or in a drier state than they ought to be, and if they are planted right away the bark is a long time in plumping up again. The best thing to do with all those that are not too big for such treatment is to bury them for a day or two, root and branch, in damp soil; this acts like magic in the way of plumping them up, and they are then in a better state for planting. Trees too big to bury may, however, be helped by heeling them in thickly

fice of some of them. It is best to cut back to the point of junction with another root if possible.

PRUNING.—After having finished the trees on north walls go on to those on other aspects. The occupants of these are generally more mixed, and as the wood of the Pear tree is much more brittle after the turn of the year than it is before, I like to deal with these early enough to avoid this extra brittleness. There cannot be the least doubt that most of the old Pear trees throughout the country are carrying far too many fruiting spurs, and this will account for most of the poor, scabby fruits that one sees about. There is no sense in leaving so many, as, provided there are sufficient to carry a crop, the rest are superfluous for the time being, and the timely removal of a few spurs bodily here and there all over the trees not only gives those left plenty of room, but it forces new spurs to form round the point of severance that take the place of the older ones which

are removed in their turn in future years. Consequently the trees eventually have plenty of vigorous fruiting spurs close at home and none of the rugged, Moss-covered and unsightly ones, which can only produce mediocre fruits. In addition to the wholesale removal of spurs, some of those left on may be judiciously shortened with advantage. On wall trees the wood growths must be cut back to within a bud or two of their base unless they are required for extension. Young trees which have not yet filled their allotted space must be pruned with an eye to form. For those trained horizontally the leader must be left just the length to provide a pair of branches next year at the proper distance from those immediately below, and with one bud above to carry on the upward progress. No matter how carefully one may prune, some of the side branches will grow stronger than others, and those who attempt to cut these strong leads back close only encourage the evil, for they break again with extra vigour, and it is really the weakest that should be hardest pruned to encourage stronger breaks. The strong ones may be toned down by depressing the ends of such branches when training, and the weak encouraged by elevating them. The only time when shortening back tends to weaken shoots is while they are growing; we may then check them by pinching out their points soon after midsummer and supplementing this by vigorously stopping further breaks at the first leaf, ultimately at the winter pruning cutting back to the next bud behind that which broke into growth after the shoot was pinched. Fan-trained Pear trees are more easy to form, and though they are not often seen, they are equal in every way to those of the more orthodox form. It is necessary with these to keep the centres in check until the lower branches have become well extended, and it must not be forgotten with these or any other trees that the promptings of Nature are towards vertical growth; consequently the upright portions of a tree are always the strongest unless counteracted by the art of the cultivator.

PLUMS.—In pruning Plum trees one has to allow more license to spur-growth than is advised above for Pears, as their nature is to be more straggling, so that it is impossible to keep them close to the wall and get good crops at the same time, but it is often possible to shorten a few spurs slightly, and this should be done whenever there appears to be a good show of flower-buds. Old Plum trees are rather subject to branch-dying, and where any branches show signs of this it is advisable to lay in new shoots to replace the old whenever the collapse comes. This, of course, has to be provided for during the growing season by allowing a few of the best placed shoots to run on without stopping them when summer pruning. I allude to these now to caution young growers against over-shortening such shoots, as hard pruning will never assist in building up fruitful wood. If laid in to full length, or only slightly shortened, a year or two is sufficient to bring them into a condition in which they will be bristling with fruiting spurs in place of the gross and fruitless shoots produced by hard pruning. The only excuse for shortening such shoots is to remove unripened wood, if any, and well-ripened shoots may be laid in intact. Breast-wood must of course be cut hard back to the spurs, and other useless shoots that may have developed must be cut clean away.

FIGS.—To make certain of a crop of outdoor Figs, protection of the wood is necessary, and to this end the branches should now be unfastened from the wall, tied loosely into bunches and brought down as low as possible into a position where they can be conveniently covered with some dry protective material, such as Bracken, over which some Russian mats may be lightly bound. The branches should then be fastened securely either to the wall or to stakes, but the nearer they can be brought to the wall the more shelter they will get from rain, and the protecting material should always be kept as dry as possible. The old-fashioned way of protecting Fig trees, *i.e.*, bringing the branches quite down to the ground

and burying them in soil, is a really good method to apply to those trees whose branches are still supple enough to bear it.

CORNUBIAN.

KITCHEN GARDEN.

NOVEMBER CABBAGES.—Presuming a sowing of Cocoa-nut, Wheeler's Imperial or St. John's Day Cabbage was made in June, nice-sized white heads should now be plentiful. These are preferable to ordinary side sprouts produced by summer plants having been cut hard back and allowed to break again. Slight frost improves the flavour of these Cabbages, but in such an advanced state they will not stand much hard weather, especially should such occur immediately after soaking rains. They should be used freely while in a sound state. The more hardy Colewort may be reserved, as the plants which have not yet arrived at maturity will continue to grow and heart in, even in December, provided only ordinary frost occurs. Many gardeners do not now sow the main batch of spring Cabbage so early as formerly, as if September is warm and the ground sufficiently moist, the plants get too advanced in growth, especially in warm, sheltered gardens. Even in the midlands I did not sow till the end of July, and then the plants were too large and sappy in November to please me. I have known growth to be checked at this season of the year by thrusting the spade in on each side of the plants and severing the lower roots, but I do not care for the practice. Where this is done, the soil must be made very firm again by treading round each plant.

PROTECTING GLOBE ARTICHOKEs.—It is, perhaps, rather soon to advise packing material round this somewhat tender vegetable, but as bad weather may come at any moment, it is as well to be provided with an ample quantity of the right kind of material, so that covering may be done expeditiously. A few gardeners do not favour covering the stools at all, but I am convinced that even on retentive soils it pays—that is, if the material used is of the right kind. To pile a quantity of semi-decayed manure round the roots as some do is simply to court disaster, as if this becomes saturated and afterwards frozen it only adds fuel to the fire, as it is converted into a soddened mass, which is sure to cripple, if not entirely ruin, the crowns and roots. What I prefer is a covering in November or early in December, if the weather remains open, of Bracken, or, failing this, light straw litter, working this well in amongst the few remaining leaves and around the crowns, renewing the covering in January. Many postpone covering until frost has actually wrought mischief, which is, I believe, done sooner on strong soils than some people imagine. The practice of severing a number of stout surplus side offsets, say, in autumn, potting these up, and giving frame protection during winter is commendable, more particularly where the garden lies low and the soil is strong and retentive. Planted out in March with good balls of roots intact, nice useful heads are secured the first season. Let the frame in which they stand on a hard ash bottom be drip-proof, as if once wet gets into the centres, decay may ruin many of them. Jerusalem Artichokes may now have the old growths removed, if only for appearance sake, cutting them off about 6 inches from the ground. When lifting, preserve only the best and most even-shaped tubers for seed. This is the only way to keep a good stock true.

EARLIEST SEAKALE.—The time has now arrived when all who wish for early dishes of Seakale should get a batch of crowns into warmth. No advantage is gained by attempting to force badly ripened crowns, as these are generally slow in coming away and the growth is always inferior in size and quality. Where the advice given in spring was acted on and a sunny border planted with thongs for early work, these will now be valuable. The temperature of a Mushroom house, or, say, 55° at night, is suitable, as in such growth is sturdy and of good flavour. Some of the best Seakale forced indoors I have seen was produced

by embedding the crowns in leaf-mould in a brick partition between two Mushroom beds. The slight heat from each bed induced root-action, the top being covered with boards to husband all the heat possible. The partition was sufficiently large to admit of several batches in different stages being placed in. When extra early dishes are needed and well-ripened crowns are at hand, it may be accomplished by putting some half-dozen into a 12-inch pot, covering these with another inverted pot, and standing them on a board over pipes in a Pine stove or other similarly heated structure. I would advise lifting a good number of crowns from the most forward bed before the month is out, laying them behind a north wall in leaf-mould or ashes. This entire rest secures a readier response when placed in heat. The Lily-white is certainly a very fine, delicate-looking Kale, but I have an idea that it does not respond quite so quickly when placed in forcing quarters early in the season as the old variety. It has a very delicate appearance when dished up. After plunging the roots in leaf-mould I always soak the compost with warm water, and moisten overhead as required with the syringe, the slight steam engendered being beneficial to growth.

ENDIVE.—It will not be safe to leave Endive out on wet, exposed borders and quarters after this date, especially in the case of the curled varieties. With repeated rains and frost, the centres soon get crippled and practically spoiled. Any surplus plants of the latter section still out of doors may be blanched where they stand by simply covering them with flower-pots, or by placing broad slates flat on them when in a perfectly dry condition. In lifting the ordinary broad-leaved plants, see that they are quite dry; then tie up each with a piece of matting in order to prevent any soil finding its way into the centres. Where room is scarce the plants are sometimes of necessity crowded together, but, unless compulsory, avoid it, a free circulation of air between and around the plants being necessary to preserve them in the best possible condition, especially with plants that are to be kept till spring. Do not coddle, but, while admitting plenty of air, prevent, if possible, the ingress of snow or heavy rains. For latest supplies in spring I have found no variety surpass Fraser's Broad-leaved. It has a very hardy constitution and does not run to seed so soon as some sorts.

J. C.

TREES AND SHRUBS.

SOME ORNAMENTAL CRABS.

ALTHOUGH an orchard in bloom is one of the most beautiful sights that could be seen, the Apple tree for various reasons, including the ephemeral nature of its bloom-time, is not the tree that all desire for the adornment of parks and pleasure grounds. Yet we need not be altogether deprived of the glory of Apple blossom in such places, seeing that the numerous Crabs which we have not only excel in beauty of foliage and grace of form the homelier orchard tree, but also in the profusion and splendour of their blooms, and their fruit, if small, is often quite as effective. Among those introduced into our country, mostly from the Far East, there is a large number of hybrids and varieties, and the full knowledge and systematic grouping of the *Malus* race are very difficult to arrive at. One of the best known kinds is

Malus baccata, a tree with a pyramidal or dome-shaped crown which will grow to the height of 33 feet. The flowers of this type are pure white and fairly large, the leaves are long, oval shape, smooth and hard in texture. The fruit the size of a Pea or rather larger, is yellow or red in colour and borne on a long stalk. The fruit calyx falls soon after the blossom. The species has been freely hybridised, particularly with *Malus*

prunifolia, which in growth, foliage, and bloom resembles *M. baccata*, but has larger fruit, the calyxes of which sometimes fall off and sometimes remain. These hybrid forms Wenzeg included in one, viz., *M. cerasifera*; often, however, they have been considered to be varieties either of *M. baccata* or *M. prunifolia*, as they happened to resemble one or the other.

M. prunifolia is in habit of growth and foliage very similar to *M. baccata*. The fruit is about the size of a Cherry, and a bright purple-red in colour. The fruit calyx, however, is not set in a hollow of the summit, but directly on the summit. The blossoms of the type are white, and the leaves are almost smooth. There are numerous hybrids of *M. prunifolia* the blossoms of which are tinged with rose and the under sides of the leaf more or less covered with hair. In particular the hybrids with *M. paradisiaca* are much to be recommended for the fair size and brilliant colouring of the fruit.

M. coronaria is a tree with broad and rounded crown and horizontal branches. It is a native of North America and will grow some 33 feet high, though oftener much smaller and sometimes quite shrubby. It is the latest in blossom of all Apples. The blossoms are rose-coloured or white with rosy flush or fleckings, and exhale a pleasant perfume of Violets. The leaves are broad elliptic or broad oval shape, the under sides being hairy at first and afterwards smooth and slightly lobed. The fruit, which is of fair size, long, and borne on slender stalks, is of a yellowish green colour and perfumed, and at both ends hollowed as in the cultivated Apple. A variety with rather narrower, more lobed, and more hairy leaf, is the variety *ivensis*, to which belongs the handsome variety known as Beechel's Crab, which is distinguished for its scented rose-red blossoms. Closely related to the preceding is

M. angustifolia, but the leaves are smaller and narrower, generally unlobed, leathery in texture, and almost evergreen. It is a native of the Southern States, is nearly always of lower stature, and is even more to be recommended than the preceding. Very different in habit of growth is

M. spectabilis, which is tall in the crown with upright branches, and grows about 26 feet in height. It is native of China and quite hardy. The blossoms are white, flecked with red, and generally double; the leaves are long, slightly indented, on the upper sides glossy and on the under sides hairy. The fruit is globular, medium sized; the fruit-stalk also is not set in a hollow, and is stout and fleshy in texture. The hybrids of this variety are numerous, the best known being *M. Riversi*, a cross with *M. paradisiaca*, and *M. Kaido*, a cross with *M. Ringo*.

M. Ringo resembles *spectabilis* in habit of growth, but is smaller and shrubby. The blossoms are likewise flecked with rose. The leaves are thinly haired on the under side. The fruit is oval-shaped, generally yellow with red cheeks, hollowed out at the base. A handsome full-blooming pyramidal-shaped variety is *M. Ringo fastigiata bifera*, which often blooms twice in the autumn. A very handsome, distinct Apple is

M. Halleana (syn., *M. Parkmani*), which is a small tree 10 feet to 13 feet high, with a broad, open crown. The leaves are smooth and leathery in texture; the leaf-stalk is russet-coloured like the twigs, the blossoms rosy, double more or less, and gracefully borne on long, slender, red-brown stalks. The fruit is small, scarcely the size of a pea, and covered with russet. It ripens very late in the autumn, and the seed is remarkable for its large size. This Apple is one of the most ornamental and distinct in blossom, and is, like *M. floribunda*, particularly handsome in its branches. *M. Halleana* is a comparatively little-known species, and if not so abundant in bloom as some others, yet deserves a prominent place in the garden for the sake of its graceful shape and delicate colouring.

M. floribunda is one of the most deserving of a place in decorative planting as well as one of the best known kinds. It is always a shrubby tree, never much more than 10 feet or 14 feet

high; the branches spread more or less horizontally and its breadth is great in comparison with its height. The leaves are small and lance-shaped, indented, somewhat leathery of texture, and in the young leaf hairy. The blossoms are borne upon long stems, the buds are a dark purple-red, but the open blossoms are bright red or white and rosy flecked. The fruit is about the size of a Pea, yellow, and the calyx falls off. *M. floribunda* var. *atrosanguinea* is a very distinct variety, which has much to recommend it. Here the flowers change from deep purple-red to a bright rose colour. *M. floribunda* is a particularly delightful variety by reason of this changing colour of its blossoms; these in a single branch may display all gradations of tone from deep purple to tender red and white. A very handsome cross between it and *M. prunifolia* is

M. Scheidekeri, with its double, rose-flecked, abundant blossoms and its vigorous upright growth.

M. Toringo resembles *M. floribunda*, but is more straggling and looser in habit and the twigs often droop to the ground. The leaves, which are more or less lobate, are a dead light green. The blossoms are less striking than in *floribunda* and rose colour on the outsides only. The fruit is very small and is formed of three or four compartments, whereas in *M. floribunda* it is formed of five. *M. Toringo*, if less handsome than *M. floribunda*, is to be recommended on account of its low growth for planting in front of taller shrubs. A striking variety, which is known to me only as a small specimen, is

M. Niedzwetzkyana. The branches of this are a deep brown colour; the leaves are at first a deep red-brown, changing later on to deep green, and the fruit and flowers are red. It is a native of the Caucasus and closely related to *M. paradisiaca*, the parent stock of our cultivated Apple.

M. cratægifolia and *M. rivularis*, both with small fruit and white, not very showy blossoms, are of little importance for decorative planting, and are found only in botanic gardens now and again.

In spite of their close relationship, there is a great difference between the varieties as regards habit of growth, which allows of a wide choice in their use for the park and garden. Thus for grouping among the higher trees, *M. baccata*, *M. prunifolia*, and *M. cerasifera* are well suited, and for something lower, *M. spectabilis*, *M. coronaria*, and *M. Halleana*. In planting in the forefront of the higher trees, *M. floribunda*, *M. Toringo*, and *M. Halleana* are to be recommended. To the handsome Crabs, as regards blossoms, belong the tree-like *M. baccata* and *M. spectabilis*, and the lower-statured *M. floribunda* and *M. Halleana*. On account of its late bloom time and its large, agreeably-scented blossoms, *M. coronaria* is particularly deserving. The most decorative as regards their fruit are *M. prunifolia* and *M. cerasifera*, also *M. baccata*, with its numerous varieties and forms. For profusion of blossom and beauty of fruit, combined with their indifference to soil and situation and perfect hardiness, the Crabs are well deserving of a foremost place among flowering and ornamental fruit trees and shrubs.—*Deutsche Garten Zeitung*.

Hibiscus (Althæa) celestis.—Most readers will, I think, agree with J. C. Tallack (p. 326) as to this variety being one of the most beautiful of all the garden forms of this species of *Hibiscus*. It can scarcely, however, be regarded as new, for it is at least fifteen or sixteen years ago since I first became acquainted with it. The variety *celestis* is, I believe, of continental origin. Other good single varieties that have come under my notice are *totus albus*, pure white; *Painted Lady*, blush-white, with a crimson blotch at the base of the petals, which received an award of merit from the Royal Horticultural Society two years ago; *roseus striatus*, pink, striped with a

deeper tint; and one met with in some nurseries as *albus*, a pure white flower with a conspicuous crimson blotch at the base of the petals, thus forming a crimson centre to the blossom. This I take to be the typical *Hibiscus syriacus*, or *Althæa frutex*, and if so, it is certainly equal to any and superior to most of the garden varieties.—T.

Catalpa fruiting.—Reference has been made to the fruiting of two varieties of *Catalpa* recently in THE GARDEN—*syringæfolia* and *bignonioides*—which, though perhaps not of rare occurrence, is not common. No doubt the great heat and drought of the present and past years' summers account largely for this. I have seen several trees more or less freely fruited this year—at Heywood, Wilts, Rood Ashton and Gunnersbury House. The last-named is the one referred to in THE GARDEN of September 23, and is much the freest-fruited specimen I have ever seen. It is not so large as either of the other trees mentioned, but there are more seed-pods on it than on both the others put together. It would seem that this fruiting is somewhat general, as in Mr. Webster's note he speaks of the abundant flowering of the *Catalpa* all over Southern England. The two first-named trees I have seen in flower for several seasons, but until last summer no pods were noted, and then only a few. The Gunnersbury tree was a perfect picture. Its position did not seem to me to be the most favourable for giving such a wealth of fruit, as it stood in a break of other trees. The only inference that could be drawn seems to be its protection from frost and cold winds and the husbanded sun-heat gathered from the nature of the surroundings. The *Catalpa* is such a distinct and ornamental tree, either as a lawn specimen or planted in a clump, that the wonder is more planters do not favour it. It is so late in coming into leaf, that the older native labourers here regard it here as a sign of safety for putting out the more tender bedding plants when the *Catalpa* buds burst into leaf, which is not until the month of May is more or less advanced. It would be interesting to learn from other readers whether the fruiting of the *Catalpa* is general in the warmer counties.—S.

BIGNONIA RADICANS.

I HAVE seen one or two notices about the beauty of *Bignonia radicans* lately in THE GARDEN. I have one I planted some ten or twelve years ago in a S.E. corner which has a stem nearly 6 inches in diameter. It is the major variety. When I first had it I wanted it to grow so as to form a coping to a wall, which it will do if the soil suits it, because the shoots cling and run along like Ivy, but the border I planted it in was a rich one, and though it lived it did not increase in thickness of stem, nor did it send out any fresh shoots. Seeing one day in THE GARDEN that it grows on hills and naturally roots like a Vine amongst rocks, &c., I moved it to its present position beside an old lean-to potting-shed with an ugly roof, which it now completely hides and is a sight to behold every season. In making alterations I had to raise the ground some 3 feet on my garden side to the level of the field behind, which I had bought in order to make a cart road into the field. This I did by heaping up some 3 feet of broken tiles I had handy and surfacing with gravel. I had forgotten this when I ordered my gardener to plant it where it now grows so well, and well do I remember his look of disgust when I came home in the afternoon and found him with a crowbar still working out a hole to plant it in and not finding any soil. As he had got down some 3 feet I told him to stop and to fill up the hole with some soil and plant it.

The next season it started into vigorous growth, and in about twelve years has reached its present proportions. I kept layering the terminal shoots every year till it had covered the space I wanted, from which every year from every joint it throws up shoots some 3 feet long, each terminated by a magnificent bunch of its orange-red flowers. These annual shoots at about the end of March I prune back to one or two base buds, and the

display is reproduced every season. To show how it likes and has taken possession of its well-drained mass of old tiles, I may remark that suckers from the roots are constantly springing up in the roadway and as far as 10 feet from the base. It is rather difficult to strike, but if at the spring pruning some of the shoots are laid in at the foot of a wall, as one does scions of Apple trees to keep them plump, longways and buried about 6 inches, they will root from the joints and throw up shoots the following year; these can be lifted, and make nice plants without any trouble.

Colchester.

H. D. PALMER.

YEW TREE POISONING.

LAST week a fine four-year-old cart-horse, in the best of health, was turned into a paddock adjoining my garden in Wiltshire. On the next morning he was observed to be grazing, about 9 a.m., without a symptom of illness. About 9.30 a man who was near saw him floundering against a gate. He then recovered himself to some extent, blundered on for some 15 yards, supporting himself to some extent by an iron fence, and then tumbled over, taking the fence with him, and, after a few kicks in the air, was found to be dead. That morning he was opened by the local veterinary surgeon. All the organs were healthy—no trace of any poison was to be found—but in the stomach there were from twelve to twenty shoots of Yew, about 3 inches long apiece, unchewed, lying on the surface of the stomach. No one connected with the place was aware that there was any Yew tree accessible from the field, but after minute research there was found to be one stunted specimen of an Irish Yew under a Beech tree, almost merged in other little shrubs, and from this it was evident some shoots had been recently torn off. The nearest could not have been less than from 2 feet to 3 feet distant on the inside of the fence, and the horse could only reach them by straining his neck over the iron fence, which had a barbed wire running along the top bar, and tearing them off, for they bore signs of being torn rather than bitten off, and were so undamaged in the stomach that some of them were afterwards fitted to the branch from which they were taken. The horse seems to have died within ten or fifteen minutes of the first shoot having been eaten. It seems extraordinary that the virus of the undigested shoot should have been so powerful as to destroy vitality so completely and in so short a time.

I may add that calves and horses and a donkey have been in the field throughout the summer with absolute impunity.—GRANVILLE R. RYDER, in *Times*, October 12.

Choisya ternata.—Considering what a beautiful plant this is when it does well, it is surprising that it is not much more grown—at least in the southern and western counties. It is hardy when well established on a suitable soil, and that is a deep holding loam, not very wet or cold. Here growth will be very free in summer, and the beautiful white flowers will be freely produced in spring. Like the *Andromedas*, it is apt to start away rather early in spring, and should cold winds occur, the young foliage is often cut about, but the plants get over this, and by midsummer are a mass of the bright glossy leaves. Sometimes in a fine summer a second lot of flowers is produced, but these are seldom so good as the first. The flowers and foliage have both a rather pleasant scent, and both are nice for cutting. The best place for *C. ternata* to flower is on a sheltered wall, but here the plant is not so pretty as when grown into a large, rather spreading bush in the open. It is one of the plants that so easily strikes root, that nurserymen can easily supply it not grafted, and if it is required to be propagated at home, take cuttings of the half-ripened shoots now and place singly in pots in a greenhouse or frame.—H.

Viburnum plicatum.—On p. 325 attention is directed to the value of the sterile form of our

native *Viburnum* and also of the Chinese *V. macrocephalum* for forcing into bloom early in the year, but no mention is made of the Japanese *V. plicatum*, than which there is not a more beautiful kind either as a shrub in the open ground or for flowering under glass. It has of late years been largely grown for this latter purpose; indeed, though by no means a novelty, it is only within recent times that its merits have been generally recognised. At one time it was considered tender, and this idea limited its planting till our American cousins repeatedly called attention to its great beauty, the result being a far more general recognition of the value of this beautiful shrub. Now considerable numbers are grown for forcing alone, not only in this country, but also by the Dutch cultivators. Like the other *Viburnums*, this must not be forced at all hard, but brought on gently, otherwise the display of bloom will be but meagre; whereas when assisted with a little heat it flowers so freely that the entire bush will be quite a mass of blossoms. The partially expanded plaited leaves are of a

Escallonia macrantha, while *E. montevidensis* still retained a few of its white flower-heads at the commencement of the month. The *Habrothamnus* in a sheltered corner showed a cluster or two of tubular crimson flowers, and the double Jew's Mallow (*Kerria japonica* fl. pl.) against a cottage wall was bearing a goodly number of orange blossoms, while the *Laurustinus* is rapidly changing the maroon of its flat flower-heads to white as the blooms expand, but the tasselled bracts of *Leycesteria formosa* are now flowerless. *Koeleria paniculata* has been particularly gorgeous in its autumnal colouring, and the Snow-berry (*Symphoricarpos*), absolutely loaded with its white balls, has created a surprisingly striking effect where planted in breadths at the edge of the shrubbery. The large standard *Magnolia grandiflora* continued to expand its fragrant ivory-white chalice to the end of the third week in the month after twenty weeks' profuse blossoming. Many of the shrubby *Veronicas* are in flower, and in a sequestered garden the massive flower-spike of a *Yucca* stands out prominently, while the

Woodwardia out-of-doors (Cornwall). (See p. 393.)

pleasing bright green tint. As an outdoor shrub it is unsurpassed for its wealth of blossoms, and its distinct, somewhat spreading habit imparts to it quite a distinct appearance.—T.

Ornamental shrubs of October.—*Abutilon vexillarium* has continued to produce its crimson and yellow blooms on slender arching shoots, and *Abelias* have borne a few flowers, while the ivory-white inflorescence of *Aralia spinosa* was noted in the early days of the month, after which the large deeply-cut leaves became highly decorative as they changed colour. The autumnal tints of the *Amelanchier* have also been extremely beautiful. The *Strawberry Tree* (*Benthamia fragifera*) is thickly set with its crimson fruit, and the *Barberries* have been ornamental both in their fruit and foliage. *Caryopteris mastacanthus* bore its pale blue flower-heads well into the month of October, and the Mexican Orange Flower (*Choisya ternata*) and the yellow-flowered *Cytisus racemosus* were both to be seen bearing autumnal bloom here and there, as was the pink-blossomed

feathery plumes of *Pampas Grass* and *Eulalia* have attained perfection.—S. W. F.

Sedum amplexicaule.—Those who admire alpine flowers can appreciate and take an interest in plants which may be of value to the botanist, but which those who only care for flowers of brilliant effect do not trouble about. The former may think *Sedum amplexicaule* worthy of a remark or two, but the latter will assuredly think it beneath their notice. Yet it is a plant which, when seen in autumn, is an object of much curiosity on the part of visitors to the garden to whom it may be pointed out. The curiosity is tempered, it may be, on the part of some unversed in the ways of plants by a little incredulity when informed that the apparently dead fragments of a plant will before long spring afresh into life. One can well forgive this touch of incredulity because one knows that it arises from want of knowledge, and a feeling that one may be too

sanguine in expecting that that singular-looking object can ever become the source of plant life. *Sedum amplexicaule* is in late summer and early autumn reduced to greyish, swollen, spiny-looking stems, which look more like some dead creature of the sea or air than a plant. Later, from these stems rise the green leaves. These are verdant throughout the winter, and in early summer the greenish yellow flowers are produced. There are several forms of this plant, or, it may be, two or more species of similar habit. There are here three forms differing but little from each other. One came as an Italian form. Another was called S. "retroridum." It was sent with a query added to the name, and one has little hope of ever ascertaining with confidence whether or not the query is justified. At the present time these Stonecrops are pretty in the rock garden, with their neat green carpets of foliage.—S. ARNOTT.

THE USEFULNESS OF BIRDS IN GARDENS.

In each order of the animal kingdom there are species both useful and hurtful, the latter seeming to increase in number as the scale descends. Insects, for instance, are generally to be feared; whereas the presence of birds is in very many cases of inestimable benefit. They are the best friends of plant life. They seem to have been created specially to keep in check the multitudes of insects which swarm upon foliage and even attack the bark of trees. A rapid view of our native birds will be enough to show us how much good the garden derives from their presence.

Buzzard.—This is a very inactive bird; ordinarily perched on a post, a mound of earth, or a stone, it spends a good part of its existence in a state of inertia. The food of the buzzard is composed of mice, moles, young or disabled birds, frogs, lizards, serpents, the larger insects, and worms. Mice, however, are its favourite food. It watches the holes of these rodents, and when the little furred tenant makes his appearance snaps it up in a twinkling. It costs the lives of twelve to fifteen mice a day to keep the buzzard in food; nay, as many as twenty have been found in the crop of a single bird. It is computed that one buzzard will on an average destroy 5000 to 6000 mice in a year, not counting those which go to furnish food for the young buzzards. The buzzard seldom attacks game, being but poorly provided with arms for such encounters unless it be some sick or disabled bird, or perhaps a young hare. For casual poaching of this sort, however, it ought not to be condemned, as its usefulness far surpasses the harm it occasionally does in this way.

The kestrel.—This also lives chiefly upon mice and insects. Its favourite haunt is the church roof and among old ruins, where it keeps a ceaseless look-out for its prey.

Owls are equally beneficial to agriculture by reason of the quantity of mice they devour, which is a strong argument for their protection. Charles Waterton, the naturalist, protected the owl and established him in the neighbourhood of his own dwelling. "If these birds," he said, "only came out in the daytime, one could then perceive what numberless quantities of mice they destroyed, because, when rearing their young, they take a mouse to the nest every twelve or fifteen minutes." He speaks of having collected a peck of balls of fur, the excretions of owls during a period of sixteen months, and which he found among the ruins. Generally speaking, all owls, large and small, are of great utility in the country, excepting the great horned owl, which does great harm by destroying game. The smaller kinds of owl are so necessary to agriculture, that their propagation might well be assisted and a hollow tree left here and there for their habitation. Wherever there are several of these birds one can surely count upon the extermination of mice, and the

good which they effect in this way is far above the profit one might get by cultivating the ground occupied by such trees. The Belgian farmer, however, is so much bent on utilising every little corner of his land that every hollow tree must go, so it happens that owls which live only in the hollows of trees have almost totally disappeared from Belgium.

The Fern owls are productive of great good by the nature of their food and their voracity, as they consume innumerable quantities of butterflies the caterpillars of which are so destructive. After sunset they capture swarms of gnats, which disport themselves among the marshes, and exterminate thousands in a very short space of time.

Swallows also live entirely upon insects, which they seize on the wing. They are always hungry, and the chase after food continues far into the night. The good that swallows do is well known; they destroy legions of noxious insects, and for this reason their propagation ought to be encouraged. Cleanliness, however, requires that when the breeding time is over the nests should be demolished, as they always swarm with vermin.

The flycatcher also is extremely useful, and might be called the martin of the wood. It destroys a host of insects noxious to man and beast. The shrikes also are of the number of benefactors, but these are accustomed to prey on insects much larger than grasshoppers and butterflies.

Crows and rooks often follow the labourer to the field to pick up and feed upon the insects which the plough has uncovered, including the grubs of cockchafer, and later on, when the season is more advanced, the cockchafers themselves fall victims to their appetite. The method of the rook is to alight upon some tree where these cockchafers are to be found and shake the branches by the movements of its body and wings, so that the cockchafers are thrown to the ground, whence they are easily picked up and devoured. The presence of these birds is beneficial in agricultural places, as the birds and eggs which they occasionally destroy are not to be compared with the multitudes of hurtful insects which they devour. There are localities where, owing to a false prejudice, the crows have been completely destroyed, and too late the good they might have done has been recognised.

Nightingales, redbreasts, linnets, finches, tits and wrens feed principally upon insects, some also on worms and caterpillars, but for the most part they live upon berries in the late season. What evil they do is of little importance, whilst their usefulness is great in exterminating a host of noxious grubs. By many the usefulness of

The tomtit is unrecognised. Yet this bird searches out in the Moss which covers the stems of trees the eggs of butterflies, *Gastropacha neustria*, *Liparis dispar*, *Gosmetra hirtaria brumaria*, &c., and in addition a multitude of caterpillars. Besides being actively useful, there is nothing to be said against this bird in any way. In winter it lives upon the seeds which it stored away in the autumn. The tomtit builds in the holes of trees, where it makes a nest of very simple construction, in which it deposits ten to fifteen eggs. As the presence of these birds is of immense benefit in orchards, it is the practice, in the absence of hollows in trees, to supply a substitute for these in the shape of boxes made like those used for tame starlings, but rather smaller, say 6 inches long and 4 inches wide, inside measurement, with a round hole in the upper part at the side large enough to admit the bird and small enough to keep sparrows out. The roof should be slightly slanting, so as to let the rain water run off, the whole being covered with bark and Lichen in order to look like a part of the tree itself, and fastened to the stem of a fruit tree. One such box sheltering several tomtits will suffice, especially if the birds are young, when they are very voracious in the destruction of all the insects in a garden, a result which would be impossible without these birds, whatever other precautions might be taken.

The tree creepers inhabit woods and orchards where the bark of the trees is thick and rugged, never ceasing to climb and flit about in quest of the insects and grubs on which they feed. They do not appear to be so fond of seeds and grains, which they swallow without taking the trouble to open. They are beloved of the farmer and gardener, as they keep the fruit trees clear of caterpillars.

The nuthatch runs along the branches, and hops from twig to twig in a continuous hunt after the insects and worms which form his food. He is a remarkable climber, and even clings upside down to the undersides of branches. The nuthatch is very fond of caterpillars and the eggs of butterflies, which he eagerly searches after in the hollows and fissures of trees. He also eats seeds and all kinds of grain, even the hardest. His way of opening nuts, of which he is very fond, is to place them in a narrow fissure, and, gripping hold of them at the same time, uses his beak with such violence that in the end the shell is broken. For the winter the nuthatch lays in a store of nuts and berries, which he hides in the hollows of trees, where also he builds his nest. When the nest is quite made he walls up the opening with clay, leaving an aperture hardly large enough to admit of his own going and coming.

The wryneck, which is allied to the woodpecker, is known for its remarkable way of turning its neck in circles like a snake. It is never found in treeless places, but neither is its home in the denser forests. It clings obliquely to the stems of trees, and remains so poised for some minutes. It is not made for climbing, and its tail, owing to its extreme flexibility, affords it no leverage. It, however, flits from branch to branch with ease and can run along the ground very swiftly. It is fond of its bath also. The food of the wryneck consists principally of insects, grubs, and the eggs of butterflies and ants, which it takes by thrusting its long viscous tongue into the cracks and hollows of trees or by darting out its tongue. It has the reputation of being a very useful bird and one that does no harm. The female wryneck lays her eggs in the holes of trees in the dust of decayed wood without any preliminary preparation. These same holes are used by these birds as night shelters.

The woodpecker is a very active bird, constantly on the move examining the bark of trees for insects, grubs, caterpillars and butterflies' eggs, which it seizes with its long and adhesive tongue, or when this is not long enough it splits the bark with repeated blows of its beak and so gets at its food. The woodpecker builds in decaying trees, which also serve as shelter in the night-time. Its instinct is unerring in selecting the tree for its purpose. Its dwelling it hollows out with its beak with infinite pains and skill. It is careless in the construction of its nest, and a few chips form the only bed of the young brood. As this bird never selects a sound tree for this purpose it is not destructive. It is rightly regarded as a useful bird by reason of its ridding the trees of great numbers of insects and caterpillars.

The cuckoo feeds chiefly upon insects and caterpillars, even those of the hairy kind, such as *Bombyx dispar* and *B. pini*. It is quite common to find the hairs of these caterpillars in the stomach of a dead cuckoo, and sometimes completely lining it. As they are very greedy birds they consume a prodigious quantity of caterpillars. They have a right, therefore, to be considered as very useful birds for the plantation and forest. One may get an exact idea of their utility when one considers that the *Bombyx pini* lays 600 to 800 eggs and lays twice in a year. The multiplication of these insects would be frightful but for the great voracity of the cuckoo. The cuckoo devours eggs, grubs and caterpillars with an eagerness which knows no interruption except during the period of sleep, as it eats continuously. It is easy to estimate the number of these insects devoured by the cuckoo. Suppose one cuckoo to devour a single caterpillar every five minutes in the long summer days of fourteen hours, we may estimate the number disposed of

in one day at 168. According to this computation, 100 cuckoos consume 16,800 caterpillars per day. Assume the number of female butterflies among these to be 8400, and that each female lays 500 eggs, the result is that in a single day 100 cuckoos will have destroyed 4,200,000 caterpillars. How precious the existence of the cuckoo is to plantations and forests can therefore be seen at a glance. We know how the Pine forests especially suffer from the over-multiplication of caterpillars, and instances are frequent within our own knowledge of plantations which were infested by these noxious insects having been cleared of them in a very short time by bands of cuckoos *en route* for warmer climes chancing to pass that way, the consequence being that in the following year there was no cause to regret the presence of these insect pests.—*Semaine Horticolé*.

ORCHIDS.

ONCIDIUM VARICOSUM.

For winter blooming there is probably no other in the genus to surpass this fine *Oncidium*, and although it may not be so easy to cultivate as some, there is no question that it is very badly treated in many collections, and this accounts for a large number of the plants that reach this country soon dying. It will be a long time probably before this and similar kinds are all gathered from their native habitats, but this is no reason why such lovely plants should be so badly treated. There is a natural anxiety on the part of those who purchase newly-imported plants to see them flower, and to tell such to remove the spikes when they show is useless. But at least the plants may be relieved by taking off most of the flowers, allowing a few to form to see what the variety is like, and removing these early. What is the use of flowering a fine variety if its flowering is going to cause its death? Far better get some vigour into it first and then let it flower properly. With regard to compost and repotting, the best way to keep the roots alive over a number of years is to have them healthy at first, and as soon as the peat and Moss begin to show signs of decay, let these be removed and replaced by new. If the plants will not stand the disturbance of removal one year, they certainly will not after another season of growth in sour or decayed material. The longer they are left, in fact, the less likely are they ever to be of any further value as flowering plants.

Another mistake frequently made in its culture is treating it like a stove plant. Although *O. varicosum* likes a moderate amount of heat,

it does not require to be always in a hot and very moist state, as though this enervating condition may at first produce apparently good results, fresh green leaves and large pseudobulbs, the hardening influence of sun and air is needed to give this growth proper stamina. One may grow a Vine at a tremendous rate, and an inexperienced person may think the treatment satisfactory, but those who know the results of this forcing condition are quite aware of how unsatisfactory the Vine would be from a fruiting point of view. And so it is with these South American *Oncidiums*; they require something more than to be merely excited. The best plants I know of *O. varicosum* are grown in a fairly large house devoted to various *Cattleyas* and *Laelias* besides some of the warmest section of *Odontoglossums* and evergreen *Dendrobes*. Rather a curious mixture, some may say, but by careful arrangement all or nearly all are satisfactory. It is kept at an intermediate temperature, rather below than above that of the usual

ately, is not plentiful, though hundreds of plants so labelled are included in some collections. The feature of the flower is the beautiful chrome-yellow lip, which is broad and roundish; the sepals and petals are dull yellow with brown workings. Strong plants produce spikes a yard and a half long, much-branched and many-flowered. H. R.

***Dendrobium infundibulum*.**—In a small receptacle close to the glass in the coolest part of the *Cattleya* house this pretty *Dendrobe* thrives, but I have never been able to do very much with it in more heat or in a really cool house. The effect of the one is that the plants grow weakly and often out of season; in the other it is not free enough, and winter comes before the growths are finished. Equal parts of peat-fibre and *Sphagnum* Moss over good drainage suit it well, and during the time the plants are growing frequent damping overhead is advisable to keep thrips in check.—H.

***Odontoglossum odoratum*.**—This may be grown by anyone having a cool *Orchid* house, and

In a Cornish garden. (See p. 393.)

Cattleya house, and the baskets and pans in which this *Oncidium* are growing are suspended in the coolest part near a ventilator. Here the growth is not particularly rapid, but it is free enough; there is the whole summer to do it in and it is useless hastening the plants unduly. Just now the spikes on these are unfolding their first flowers, and in a week or two they will make a fine display. *O. varicosum* likes ample supplies of moisture all through the growing season and while in flower, a much reduced supply sufficing when at rest.

The flowers in the typical form are not so large as in the true *O. v. Rogersi*, but this, unfortun-

although some of the varieties are rather poor, there are some good ones among them, and these are well worth growing. I have had it with spikes nearly a yard in length covered almost from end to end with the pretty sweet-scented flowers. The usual colour is a pale straw-yellow, with spots of crimson and brown, but there are darker forms and some nearly white. *O. odoratum* is also known as *O. gloriosum*, good forms of it having received this name.—H.

***Odontoglossum blandum*.**—This pretty species I have received for a name. It is usual for this to flower in early spring, but possibly the flowers sent are from a newly-imported plant which has not yet settled down to its season. O.

blandum is an uncommon little plant, worth growing in the best of collections, and the charming white flowers, with their distinct purple spots, are sure to be admired. The place to grow it is quite up to the glass and close to a ventilator in the cool house. It is a native of high alpine latitudes, so anything approaching a stuffy or close atmosphere should be avoided. During the season of growth the syringe should be freely plied about the bulbs and leaves, applying the water in the form of a very fine spray. The plants do best in very small receptacles, like the hanging pans now so much in use. The roots cling closely to these and stand more moisture than they would do in large pots. Thus they can be kept nearly always moist, a condition in which they are found growing naturally. It is a very difficult Orchid to import, and this has made it scarce under cultivation.

Cypripedium insigne giganteum.—On the last meeting of the year held on December 15, 1896, the late Major Mason and Mr. E. Ashworth each showed plants of *C. insigne* which were so nearly identical, that the Orchid committee could not distinguish sufficient differences to recognise the two names under which the plants were placed before them. Mr. Ashworth's plant was again shown in a great deal better condition, and was awarded a first-class certificate on December 13, 1898, as *C. i. Harefield Hall var.* It was undoubtedly one of the finest varieties of *C. insigne* that has ever been seen. There is no record of the late Major Mason ever again exhibiting his plant. It was not until the recent sale of the collection at The Firs that the plant first shown as *C. i. giganteum* again became prominent. Two small plants of two growths each were included in one lot, which when offered realised 140 guineas, the plant, I believe, passing into Mr. Ashworth's collection. We may thus look forward for another opportunity of being able to determine the distinctive features of the two varieties when grown side by side under similar conditions.—H. J. C.

SOCIETIES AND EXHIBITIONS.

NATIONAL CHRYSANTHEMUM SOCIETY

NOVEMBER 7, 8, 9.

THE chief exhibition of this society, held on the above dates at the Royal Aquarium, was of a very high order of merit. Chief interest centred around the competition for twelve vases Japanese blooms, each vase containing five blooms of one variety. The exhibits were staged in St. Stephen's Hall, and the blooms kept wonderfully fresh for the whole of the three days of the show. Great change was noticeable in many instances when compared with what was the rule some year or two back, the plan of arranging large exhibition blooms in vases instead of on flat boards, creating a pretty effect and showing the value of the large handsome flowers for decoration. Fine quality was represented in the majority of the Japanese blooms, and the incurved flowers, too, were much better than many expected. Anemone blooms made a charming display, ably supplemented by other types of the Chrysanthemum. Three displays made by a similar number of trade specialists were also remarkable features. Vegetables were also represented in splendid condition. Both dessert and cooking Apples were staged in large numbers, the competition being keen and the quality of an exceptionally high order of merit.

OPEN CLASSES—CUT BLOOMS.

One of the chief classes was that open to Chrysanthemum and horticultural societies. In this case there were five competitors. The leading position was occupied by the Portsmouth and District Horticultural Society, the blooms being contributed by Messrs. J. Agate and C. Penford, members of that society. The Japanese blossoms were good and the incurved sorts distinctly meritorious. The Japanese were represented best by Mrs. J. Lewis, a pure white, in grand form this year; Mons. Pankoucke, still a good yellow;

Percy Penford, a new bronzy yellow seedling; Florence Molyneux, the best new white Japanese incurved, and the finest novelty of the season so far; Mrs. Mease, Mrs. White-Popham, Mons. Hoste, Mme. Carnot, and the new yellow flower Miss Edith Pilkington. The most noteworthy of the incurved flowers were Lady Isabel, Globe d'Or, Chas. H. Curtis, Violet Tomlin, shown well this season, Mme. Darrier, Ernest Cannell, a pretty deep fawn colour; Jeanne d'Arc, and a charming bloom of the refined Princess of Wales. This exhibit was very closely followed by the Sevenoaks and West Kent Gardeners' and Amateurs' Society, Mr. W. Tebay, gardener to Mrs. Rycroft, Everlands, Sevenoaks, contributing the whole of the flowers. Both types of the flower were in fine form, the Japanese being represented best by a grand bloom of Mme. Gustave Henri (white), Mrs. Lewis, Mutual Friend, Mrs. Mease and G. J. Warren. Incurved were seen best in Ernest Cannell, a grand flower; Miss Dorothy Foster, a lovely silvery mauve colour; Chrysantheme Bruant, a new continental sort of splendid size, of a beautiful rosy buff colour; George Haigh, W. Tunnington, Duchess of Fife and Jeanne d'Arc. The Bromley and District Chrysanthemum Society was a good third, no less than eleven men of Kent contributing flowers. The Japanese were very strong, the exhibit losing points in the incurved display. This was one of the best competitions for the challenge trophy since its institution. The leading class for incurved blooms was one for thirty-six distinct varieties, and the four competitors made an excellent display. Mr. W. Higgs, gardener to Mr. J. B. Hankey, Fetcham Park, Leatherhead, was first with large, neatly incurved, globular blossoms, and fairly even throughout. Exceptionally good were Duchess of Fife, still the largest white; Mrs. H. J. Jones, another handsome white, with broader petals than the last named; Chas. H. Curtis, Hanwell Glory, a large, bright bronze flower of splendid globular shape; Yvonne Desblanc, pearly white; Countess of Warwick, a large, handsome flower; D. B. Crane, Mme. Ferlat, George Haigh, Lady Isabel, Ialene, a pleasing rosy violet; Ma Perfection, Chrysantheme Bruant, Bonnie Dundee, and the members of the Princess of Wales family. Mr. G. J. Hunt, gardener to Mr. Pantia Ralli, Ashstead Park, Epsom, Surrey, was second with a less even lot of flowers. For forty-eight Japanese blooms, distinct, there were six exhibitors, and not a bad lot was staged. The leading stands left very little to choose between them, and ultimately Mr. E. Vallis, Bronkham Fruit Farm, Bronkham, Chippenham, led. His blooms were very large in the back and middle rows, the front row in many instances showing a decided falling off. The colour, too, in most cases might have been improved upon. The flowers of special merit were G. J. Warren, one of the best in the show; Nellie Pockett, white; Edwin Molyneux, Mutual Friend, Mrs. Barkley, an enormous flower, soft rosy mauve, broad strap-like petals; Mons. Hoste, Mrs. Coombes, a soft silvery pink; Mme. J. Bruant, Mrs. J. Lewis, Pride of Madford, Wm. Bardney, a new incurved Japanese, velvety crimson inside petal, silvery reverse; Emily Towers, Mr. A. Barrett, Mme. M. Ricoud, Simplicity, Phœbus, M. Chenon de Leche, Souvenir de Mme. F. Rosette, Australie, Swanley Giant, Oceana, Edith Tabor, Lady Ridgway, a salmon-buff, incurved Japanese; Mme. Carnot, Lady Hanham, and Vivian Morel, the latter two still good. Second prize was awarded to Mr. J. W. McHattie, gardener to the Duke of Wellington, Strathfieldsaye, Mortimer, Hants, who was close to the leading stand. His blooms of Le Grand Dragon, Chas. Davis, Mrs. H. Weeks, Préfet Robert, Mons. Hoste, Mrs. White-Popham, Soleil d'Octobre, Mutual Friend, G. C. Schwabe, and Edwin Molyneux were excellent. The five competitors for twenty-four Japanese blooms, distinct, made a capital display, Mr. McHattie easily leading with a large, fresh, and even lot of blooms of good colour and form. The best were Australie, Edith Tabor, Mons. Hoste,

Australian Gold, Milano (a splendid flower, colour cherry-carmine), Mrs. Mease, Mrs. H. Weeks, and Lady Hanham. Second honours were well merited by Mr. W. Meredith, gardener to Mr. Geo. Wilder, Stanstead Park, Emsworth, Surrey, who showed Australie, Master H. Tucker, Mons. Pankoucke, Mme. Carnot, and Mons. Hoste well. For twenty-four incurved blooms, distinct, there were only two competitors, Mr. W. Higgs leading with a nice lot of flowers, novelties such as Hanwell Glory, Chrysantheme Bruant, Ialene, Mme. Ferlat, D. B. Crane, Mme. Ed. Roger, Countess of Warwick, and Lady Isabel standing out most prominently. Second prize was awarded to Mr. G. J. Hunt, whose blooms were uneven in size, novelties in this instance again standing out conspicuously. For twelve incurved blooms, distinct, Mr. Silas Cole, gardener to the Rt. Hon. Earl Spencer, K.G., Althorp Park, Northampton, led with very deep globular flowers of good quality, Mrs. R. C. Kingston, a pretty lilac-pink, striped white, of good form; Charles Curtis, Countess of Warwick, Topaze Orientale, very large, pale straw colour; Ma Perfection, a beautiful flower, pure white; Princess of Wales, and Violet Tomlin, being the best. Second prize was won by Mr. F. G. Foster, Brockhampton Nurseries, Havant, who staged large but irregular flowers, novelties in this case making an excellent show. The good qualities of Chrysantheme Bruant and Countess of Warwick were again apparent. The class for six incurved blooms, one variety only, is always interesting, and the five stands contained a pleasing variety. Duchess of Fife was represented in magnificent condition by Mr. W. Higgs, large, even, globular flowers securing first prize, second prize going to Mr. Hunt for the same variety, but for flowers distinctly smaller and also very shallow. Six blooms white Japanese, one variety only, were this year shown in vases, and a pleasing break away from the orthodox this proved to be. Mr. J. W. McHattie led with a grand vase of Mrs. J. Lewis, snow-white, and in magnificent condition, Mr. W. Higgs following with a lovely vase of the popular and graceful flower Mme. Carnot. In the class for a vase containing six blooms Japanese, yellow, one variety only, there were six exhibitors, Mr. W. Higgs leading with superb examples of Mrs. Mease, Mr. Wm. Allan, gardener to Lord Suffield, Gunton Park, Norwich, following closely with grand examples of the bright yellow variety Phœbus. Six Japanese blooms, any colour except yellow and white, these also exhibited in a vase, were well staged by eight competitors. In this case Mr. McHattie was again first with very handsome blooms of Australie, Mr. H. Perkins, gardener to the Rt. Hon. W. F. D. Smith, M.P., Henley-on-Thames, second, with smaller examples of the same variety. Mr. McHattie again led for six Japanese blooms incurved, distinct, showing a capital even lot of heavy, massive, and solid-looking blooms—Duke of Wellington, colour deep salmon-buff; Mme. Desblanc, very fine; President Bevan, Swanley Giant, N.C.S. Jubilee, and Préfet Robert. Of the remaining six exhibitors, Mr. H. Perkins was placed second with Australie and a white seedling in good form. There were but two entries for six Japanese blooms, hairy-petalled, not less than three varieties. A pretty lot received first prize, this being sent by Mr. John Justice, gardener to the Rt. Hon. Sir R. Temple, Bart., The Nash, Kempsey, Worcester, with a nice variety of well-grown blooms, Lecocadie Gentils, White Swan, Hairy Wonder, and Louis Boehmer being those exhibited. Mr. H. Love, Sandown, Isle of Wight, was second with a much less even display. The next class was undoubtedly the chief feature of the meeting. This was for very valuable prizes with gold and other medals accompanying them. This competition was for twelve vases of specimen blooms of Japanese Chrysanthemums, distinct, each vase to contain five blooms of one variety. The vases were specially made by Messrs. James Green and Nephew, of Queen Victoria Street, E.C., who kindly lent them for the occasion. There were

some fifteen entries, reduced to nine actual competitors on the morning of the show. The vases were arranged equi-distant on long tables in St. Stephen's Hall, and formed quite a show in themselves. Ample space—about 2½ feet square—was allotted each vase, and arranged thus the display was a delightful change from the older method of showing handsome blooms on boards. Mr. McHattie led with grand blooms in almost every instance. Several were remarkable for their great size, and others for refinement and purity of colour, and they may be safely said to have represented the different types of Japanese blooms very well. The varieties worthy of notice were Mrs. White-Popham, Chas. Davis, Simplicity, Mrs. Mease, M. Chenon de Leche, Milano, Mrs. J. Lewis, Australie, and Mrs. Coombes. A very narrow margin divided the second prize lot, which was staged by Mr. W. H. Lees. In only one case could there be traced the least weakness, this being in the case of James Bidencope. These flowers were splendid examples of the variety, but the colour (purple-amaranth) is rather fleeting. Specially good in this exhibit were Mrs. Coombes, Oceana, Mrs. G. W. Palmer, G. J. Warren, Pride of Madford, Mutual Friend, Lady Ridgway, Mrs. Mease, Phœbus, and M. Chenon de Leche. A splendid lot of flowers secured third prize for Mr. J. Spink, Summit Road Nursery, Walthamstow, E., who had Marie Calvat, Mrs. White-Popham, Chas. Davis, and Mme. C. Desblanc in exceptionally good form. No less than eighteen exhibits were staged in the class for twelve Japanese blooms, distinct, and the margin dividing the different prize-winning exhibits was very narrow. Mr. Geo. Neville, gardener to Lord Chesham, Latimer, Chesham, Bucks, was placed first with a stand of good quality, even form, good colour, and beautiful finish. A grand lot of flowers also came from Mr. J. W. Roberts, gardener to Mr. G. J. Skilbeck, Clonard, Harrow Weald, who was placed second, this exhibitor having M. Chenon de Leche and M. Ed. André in magnificent condition. For Mr. Norman Davis's prizes given for blooms of Japanese varieties in different colours, comprising six classes, the competition was not so keen as was anticipated. For the best specimen white Japanese bloom, out of seven entries, Mr. G. Hagon, gardener to Mr. E. Arthur Lees, Fowley Park, Liphook, Hants, was first with a medium-sized bloom of Mme. Carnot. For the best yellow, Mr. James Brooks, gardener to Mr. W. J. Newman, Totteridge Park, Totteridge Common, Herts, was first with a splendid example of Phœbus. Mr. G. Hagon was again first for a pink or mauve bloom, showing a well-coloured Vivand Morel. In the crimson self, a medium bloom of E. Molyneux secured the first prize for Mr. J. Sandford, gardener to Mr. Wright Ingle, North Finchley, N. For a purple self, Mr. J. Brooks was first with a good bloom of Pride of Madford, and out of six competitors for a bronze-coloured Japanese, Mr. J. Sandford was again first with Mrs. G. W. Palmer. A pleasing change from the large, full flowers was that provided by a class for twelve vases single Chrysanthemums, each vase to contain six blooms. A silver cup offered by the Cannon's Restaurant, Ltd., was given as first prize in this class. There were only two competitors, and the leading exhibit came from Mr. G. W. Forbes, gardener to Mme. Nichols, Regent House, Surbiton. These blooms were very handsome, the best varieties being Admiral Sir Thos. Symonds, Annie Tweed, Earlswood Glory, Crown Jewel, Alphonso, Little Pet, Miss Annie Holden, Miss Mary Anderson, and Mrs. Walton. Mr. W. Aldridge, gardener to Mr. G. Lacey, Springfield House, Palmer's Green, N., was second with a weaker lot of flowers. For six blooms of Nellie Pockett, Hon. W. F. D. Smith, M. Louis Remy, Lord Ludlow, and two other Japanese sorts, for which a special prize was offered, Mr. H. Perkins was first with a nice bright lot. The premier Japanese bloom in the show was a charming example of the primrose-coloured Mrs. Mease, this coming from Mr. W. G. Prudden Clark, a Hitchin amateur.

ANEMONES, REFLEXED AND POMPONS, &C.

Of three competitors for twelve large-flowered reflexed blooms, Mr. T. Caryer, gardener to Mr. A. G. Meissner, Alderholme, Weybridge, was first, showing Dorothy Gibson, Cullingfordi, Cloth of Gold, Miss Florence Lunn, Phidias, King of Crimson and Golden Christine; second prize was awarded to Mr. J. Barrance, gardener to Mr. G. Taylor, Hadley Bourne, Barnet. The five exhibits in the class for twelve large-flowered Anemone blooms made a charming display, Mr. William King, gardener to Mr. James Warren, Waltham Cross, winning first prize with a nice even lot. Beautiful flowers of Gladys Spalding, Mrs. Judge Benedict, Mme. Robt. Owen, Descartes, Empress, M. Chas. Lebocqz, Mlle. Nat. Brun, Lady Margaret and Junoo were neatly disposed. Second prize was awarded to Mr. A. Ives, gardener to Mr. E. C. Jukes, Hadley Lodge, Barnet, with pretty flowers, some, however, not fully developed. There were also five entries for twenty-four large-flowered Anemone blooms in which Japanese Anemones were included, Mr. W. King winning first prize with flowers of good quality. The most noteworthy were John Bunyan, Fabian de Mediana, W. W. Astor, Owen's Perfection, Mrs. Caterer, Sir Walter Raleigh, M. Dupanloup, Empress, Surprise and Mrs. Levin. Mr. A. Ives was second with much smaller blooms. Twelve Japanese Anemone blooms, distinct, made a pretty class, Mr. King again leading. Mr. Ives again secured second prize with a pretty lot of flowers, though distinctly smaller. There were four competitors for the prizes offered for twelve bunches of Anemone pompons, distinct, Mr. C. Brown, gardener to Mr. R. Henty, Langley House, Abbots Langley, securing premier honours with a charming lot of these delightful flowers. The best were Emily Rowbottom, Fred. Boyce, Antonius, Mme. Challenge, Bessie Flight, Miss Nightingale, Mr. Astie, Magenta King, Madame Sentir and Regulus. Mr. T. Parkins, gardener to Mr. Ward, Highgate, was second with a less even display. A class for twelve bunches pompons, distinct, three blooms in each bunch, is always pleasing. Mr. T. Caryer was first with an even lot of blooms of high quality and good colour, Pygmalion, Mrs. Holmes, William Westlake, Mlle. Elise Dordan, Prince of Orange, Perle des Beautés, La Vogue, Rubrum Perfectum and President being his best bunches. Mr. T. Parkins was second with an even lot of flowers, but duller in colour. Mr. G. W. Forbes was again to the fore with six varieties of singles in bunches or sprays of six blooms each, shown in jasper vases. This was a grand lot of even form, bright clear colour and large size. Mr. W. Aldridge was second with smaller blooms.

CUT BLOOMS—AMATEURS—DIVISION A.

For eighteen blooms Japanese, distinct, Mr. A. Page, gardener to Mr. A. L. Reynolds, Ravenscroft, North Finchley, was placed first with a nice fresh, even lot of blooms of good colour and medium size, Secretaire Fierens and Mons. Demay Taillandier being noteworthy. Second prize was secured by Mr. Joseph Acock, gardener to Mrs. Baco, Sutton, Surrey, with a very even lot of flowers, Mrs. G. W. Palmer being remarkable for colour. Eleven entries for twelve Japanese, distinct, found Mr. David Alger, Milton Bode, Down House, Bath Road, Reading, first with a nice fresh lot of blooms, Simplicity, Chas. Davis, Vivand Morel, and Mrs. White-Popham standing out distinctly. Mr. A. Page was placed second with a fine lot of flowers, Master H. Tucker and Mrs. G. W. Palmer being staged in rich colour. For six Japanese, distinct, out of ten competitors Mr. E. Ryman, gardener to Mr. O. Sapper, South Park, Reigate, led with flowers of good quality, President Nonin being his best. Mr. J. Denyer, gardener to Mr. Edwin Smith, Ingleside, Chatham, was second. The last-named was first for six Japanese, one variety, showing six very pretty and not over-large examples of Mrs. Mease. Mr. A. Page was second with medium blossoms of Australie. Mr.

Chas. E. Wilkins, Swanley, was first for twelve incurved, distinct, showing Lady Isabel, Chrysantheme Bruant, and Chas. H. Curtis well. Mr. A. Hooney took second place, having rough flowers. Mr. Wilkins was first out of seven entrants for six incurved, distinct, Lady Isabel and Chas. H. Curtis being his best flowers. Second prize was won by Mr. C. H. Martens, gardener to Mrs. Langton, Raymead, Hendon, with smaller, neatly arranged and prettily finished blooms. For six incurved, one variety, Mr. A. Hooney was placed first with irregular blooms of Chas. H. Curtis, while Mr. Wilkins, with charming blooms of Globe d'Or of good form and broad petals, secured only second prize out of five exhibitors. The class for six bunches of pompons, distinct, was a pleasing variation, Mr. W. Aldridge leading with a very neat lot. Mr. A. Page was second, having a grand spray of Anemone pompon Fred Boyce.

DIVISION B.

For eighteen Japanese, distinct, Mr. Martin Silsbury, Providence, Isle of Wight, was a good first, with heavy blooms; Mrs. J. Bryant was his best flower. Of twelve entrants for twelve Japanese, distinct, Mr. A. R. Knight, Ashford, was first with a capital lot of large and even flowers, Mrs. Mease, M. Chenon de Leche, and Secretaire Fierens standing out distinctly. A nice stand secured second prize for Mr. W. E. Reeve, Maybury Road, Woking. Eight competitors in the class for six Japanese, distinct, made a brave display. The first prize went to Mr. E. Brown, jun., Southampton, with nice even flowers, but distinctly behind the second prize stand in point of quality. The latter came from Mr. Reeve. Six Japanese, one variety, was a pleasing display, Mr. Henry Love beating four others with good flowers of Mrs. White-Popham. Twelve incurved blooms, distinct, were poorly represented, Mr. Jas. Falconer, Maldon, being first with neat and pretty blooms of D. B. Crane and Chas. H. Curtis. Mr. W. G. P. Clark staged rather rough flowers in a class for six incurved, distinct, and was awarded first prize. For six bunches of pompons, distinct, Mr. Clark was again first. Four classes were reserved for maiden growers, and in each case the competition was keen and the blooms generally of a high order of merit.

OPEN CLASSES—PLANTS.

Circular groups evidently have come to stay. On this occasion the groups were arranged on the ground floor, and made a pretty effect when viewed from the galleries. A conical method of arrangement is the practice adopted, and certainly might be improved upon. A break away from the present stiff method might with advantage be followed. First prize in the present instance went to Mr. J. Spink, Walthamstow, with a neatly arranged group, comprising blooms of high quality and good colour, all well developed. The plants were not too crowded, and a pleasing effect was got by the association of Crotons, Eulalias, Cocos Weddelliana, Ferns, &c., the group being surmounted by a noble Kentia. A good second was found in Mr. W. Howe, gardener to Sir Henry Tait, Bart., Park Hill, Streatham Common, S.W., who had a very handsome and highly-coloured group of Chrysanthemums and fine-foliaged plants, each well disposed. For six trained specimen plants there were three entries, Mr. J. Brooks, sen., gardener to Mr. Walter J. Reynolds, J.P., The Grove, Highgate, N., was a good first with neatly tied and freely-flowered examples of Miss Watson, Col. W. B. Smith, John Shrimpton, Phœbus, Maiden's Blush, and Mrs. Mease. Second honours were secured by Mr. F. E. Wright, gardener to Mr. J. Troup, Essex Lodge, Upper Clapton, a capital plant of Vivand Morel being his best. For four standard-trained specimens, the trio of exhibits made a grand array of colour. Mr. G. Whitbourne, gardener to Mr. S. Nichols, Walthamstow, was first with a pretty even lot of plants, well flowered. Cleopatra, Eva Knowles, W. Tricker and Sunflower represented a nice assort-

ment of colour. Mr. E. Easey, gardener to Mr. F. Bishop, 23, Highbury New Park, N., was second. In the class for four trained specimens, Mr. G. Whitbourne again led with very large, well flowered and neatly tied specimens of President Nonin, J. Shrimpton, Col. W. B. Smith and Vivand Morel. Second prize was awarded to Mr. Tom Stone, gardener to Mr. R. A. Cockburn, St. Neots, with freely-flowered plants. The only exhibitor of six standard-trained specimens was Mr. F. E. Wright, who showed fairly good plants of recognised specimen sorts. Six specimen-trained pompons were represented by two exhibits, that coming from Mr. T. Stone being a long way ahead of his rivals. They were large plants, freely flowered, neatly tied, and embraced a nice assortment of colours. Each of the *Cedo Nulli* family, white, lilac and golden, was represented. Fred Boyce, a pompon of *Anemone* form, but far too large; *Sour Melanie* and *Mme. Marthe* were the plants set up. Second prize was awarded to Mr. F. Gilks, gardener to Mr. A. Morris, Streatham, who had smaller, but irregular specimens. For a single specimen plant, Mr. J. Brooks, Sen., was first with a fine plant of *Chas. H. Curtis*, and Mr. Easey second with a rather poor plant of *Mme. Desblanc*.

BOUQUETS, EPERGNES, &c.

There was only one competitor in the class for a table of wreaths, bouquets, &c., illustrating the decorative value of the *Chrysanthemum*. First prize was awarded to Mr. L. H. Calcut, Fern Bank Nursery, Stoke Newington, for an exhibit showing considerable artistic skill and pleasingly disposed. Miss C. B. Cole, The Vineyard, Feltham, was first of five exhibitors for three epergnes of *Chrysanthemums*, &c., with appropriate foliage, in this case showing white and pink single-flowered blossoms. This was a pretty arrangement, though not effective under artificial light. Second prize was awarded to Mr. A. Merridew, who had the two outer epergnes lightly arranged with orange and bronze flowers, and the centre stand with pink and white singles. In the class for two vases of pompon and *Anemone* pompon *Chrysanthemums* arranged with any foliage, Mr. Mark Webster, gardener to Mr. E. J. Prestoo, Kelsey Park, Beckenham, was first. Second honours rested with Mr. W. C. Pagram, gardener to Mr. J. Courtenay, Weybridge, with a very pretty set of dwarf vases. For a vase of six blooms of one variety of Japanese, Mr. W. Howe led with a charming vase of the white *Lady Byron* and autumn foliage, followed by Mr. J. Denyer with a pleasing vase of *Mrs. H. Weeks*. For two hand bouquets or posies of *Chrysanthemums*, Mr. Webster was credited with leading honours, staging two beautiful examples, using singles in one case freely. A very poor pair gained second prize for Mr. E. Cowell, Lower Tooting, S.W. A hand-basket of *Chrysanthemums* for drawing-room table brought out a spirited competition, this class being open to ladies only. The judges placed *Mrs. Strugnell*, 213, Brixton Hill, S.W., first with a pretty combination of large yellow and white flowers, &c., with *Croton* and other foliage. A huge basket of large blossoms, pink and white, with a few small pompons and suitable foliage to relieve any heaviness, came from Miss Easterbrook, The Briars, Fawkham, Kent, who was an excellent second. No less than twelve exhibitors in the amateur division arranged a vase with six blooms of one variety only of Japanese flowers. The place of honour was taken by Mr. E. Jones, 51, Bower Street, Bedford, with handsome blossoms of *Mme. Carnot* and appropriate foliage. Mr. E. H. Chitty, Highgate, was second with pretty blooms of *Lady Hanham*. An exceedingly pretty class is that for a hand-basket of natural autumn foliage and berries, Miss Easterbrook securing leading honours with a superb basket, embracing a wonderful variety of berried plants and foliage.

FRUIT.

For three bunches white Grapes, Mr. W. R. Allen, gardener to Rt. Hon. Lord Hillingdon, Hillingdon Court, Uxbridge, was first, showing

Muscat of Alexandria in good form, Mr. W. Taylor following with rather smaller bunches. Eight exhibits of three bunches black Grapes made a fine display, Mr. W. Taylor leading with Black Alicante, bunches large and splendidly coloured. Mr. W. H. Lees was second with large, handsome bunches of *Mrs. Pince*. For three bunches *Gros Colman* Grapes, Mr. Chuck, gardener to Mr. Herbert Thelluson, Brodsworth Hall, Doncaster, was first with shapely bunches and large berries of good colour, Mr. W. Taylor following with smaller and less oven bunches. The ten collections of six dishes dessert Apples fit for table were remarkably fine. The first prize went to Mr. R. Chamberlain, gardener to Mr. F. M. Loneragan, Cressingham Park, Reading, this exhibitor staging *Cox's Orange*, *Ribston Pippin*, *King of Pippins*, *Blenheim Orange*, *Gascoigne's Scarlet*, and *Fearn's Pippin*. Second prize was won by Mr. Walter King, gardener to Mr. Jeremiah Colman, Gatton Park, Reigate, with a very handsome lot. For six dishes cooking Apples, a magnificent collection, with fruits of large size, good colour, firm, and of high quality, secured the first prize for Mr. W. T. Stowers, gardener to Mr. G. H. Dean, 70, Harold Road, Sittingbourne, Peasgood's Non-such, *Mère de Ménage*, *Emperor Alexander*, *Lane's Prince Albert*, *Bramley's Seedling*, and *Glory of England* (very fine) being his varieties. A good second was found in Mr. Wm. Camm, gardener to the Duchess of Cleveland, Battle Abbey, Sussex. Pears, too, were well shown, eight entries for six dishes dessert Pears fit for table being set up. Mr. Wm. Allen was first with excellent examples of *Doyenné du Comice*, *Emile d'Heyst*, *Marie Louise*, *General Todtleben*, *Marie Louise d'Uccle*, and *Beurré Diel*, Mr. T. Stowers being placed second for a very heavy lot of fruits.

VEGETABLES.

For a collection of vegetables, nine distinct kinds, for prizes offered by Messrs. Webb and Sons, there were six collections. Mr. E. Beckett, gardener to Lord Aldenham, Aldenham House, Elstree, Herts, was first with a beautifully arranged lot of vegetables of the highest quality. Mr. A. Basile, gardener to Rev. O. L. Powell, Woburn Park, Weybridge, was second for a nice lot of vegetables of good quality. For six dishes Potatoes, Mr. E. S. Wiles, gardener to Hon. Evelyn Hubbard, M.P., The Rookery, Down, Kent, was placed first with an even lot of tubers beautifully finished. There were other classes of a similar character, of which space will not permit details being given. Special notice must be given of the thirteen classes, embracing all the most popular vegetables, for prizes offered by Mr. Robt. Sydenham, Birmingham. In each class no less than five prizes were offered, and in each class the competitors averaged ten to eleven. The large character of the display can therefore be gauged to some extent. In addition to the money prizes a handsome challenge cup, value fifteen guineas, is held by the winner of the greatest number of points in the thirteen classes. Mr. Beckett was an easy first with forty-nine points, Mr. Empson, second, with thirty-three points, and Mr. Brown, third, with twenty-two points.

MISCELLANEOUS EXHIBITS.

At the north-western end of the building, Mr. Norman Davis, Framfield, Sussex, and Mr. H. J. Jones, Rycroft Nursery, Lewisham, S.E., each occupied a platform 20 feet by 10 feet, arranging in oriental vases, trumpet vases, and numerous other receptacles flowers of a representative character. In the case of the former, huge yet handsome blossoms of *Mme. Carnot* and its sports, *Western King*, and other leading sorts were artistically displayed, the blooms in Mr. Davis' exhibit being of exceptionally high quality. Mr. Jones' exhibit towered somewhat above its neighbour, and artistic skill in the disposition of the blooms, associated with autumnal and other foliage, made these two exhibits, which were to all appearance one, the leading feature of the show. New varieties were pleasingly

interspersed among the Ferns and other plants. A large gold medal was awarded to each exhibitor. A similar award was made to Messrs. H. Cannell and Sons, Swanley, for a very long table, on one side of which were rows of large, handsome *Chrysanthemum* blooms of new sorts, the other side containing gorgeous bunches, some seventy-two in all, of the newest and best of the popular zonal *Pelargoniums*. At either end of the table were arranged groups of richly coloured and striking flowers of the most noteworthy *Cannas*. Mr. John Green, Norfolk Nurseries, Dereham, also had a large table of cut *Chrysanthemums* arranged in triangular spaces (silver medal). Small gold medals were awarded to Messrs. B. S. Williams and Son, Victoria Nursery, Upper Holloway, and Messrs. William Cutbush and Son, Highgate, and Barnet Nurseries. The former had a grand table of *Gloire de Lorraine* *Begonias*, *Orchids* in variety and *Heaths*. The Highgate firm had an immense table of *Chrysanthemum* blooms, *Ericas* in variety, *Roman Hyacinths*, *Bouvardias*, *Carnations*, backed by graceful *Bamboos*. Messrs. John Laing and Son, Forest Hill, decorated the north-western fountain, using *Chrysanthemums* and a variety of fine-foliaged plants and hardy shrubs for the purpose. The *Ichthemic Guano* Company, Ipswich, received a silver medal for their stand decorated with pretty plants of freely-flowered *Chrysanthemums* and a splendid array of black and white Grapes. Mr. T. S. Ware, Ltd., Tottenham, and Mr. Robert Owen, Maidenhead, both exhibited cut blooms of *Chrysanthemums* in variety, and in the case of the latter several promising seedlings were noted. Messrs. Peed and Son arranged a pretty conical group of *Chrysanthemums*. Messrs. Isaac House and Son, Westbury-on-Trym, had a small table of several of the best sweet-scented *Violets*. Mr. J. Agate, Havant, had a dozen handsome flowers of *Florence Molyneux*; and Mr. Forbes, Hawick, N.B., his new white *Begonia*, *Caledonia*.

A meeting of the floral committee was held at the Royal Aquarium, Westminster, on Monday last, 13th inst., Mr. Thomas Bevan occupying the chair. Several novelties were staged, but in one instance only was a first class certificate awarded. Commendations, however, were made in several cases. A first-class certificate was awarded to

CHRYSANTHEMUM RALPH HATTON.—A large silvery mauve incurved flower, inside of florets of a rosy-mauve colour. From Mr. H. Weeks, The Gardens, Thrumpton Hall, Derby.

The following kinds were highly commended:—

GENERAL SYMONDS, shown by Mr. Weeks, is a large incurved flower of a pale golden-buff colour, inside of petals suffused crimson.

VICAR OF LEATHERHEAD, from Mr. H. Jones, is a Japanese flower of a lovely golden-yellow colour, deepening in the centre, the florets long and of medium width, slightly curled. This is said to be a cross between *Lady E. Saunders* and *Edith Tabor*.

GEORGE TOWERS is a Japanese flower of a bright rosy-purple, with silvery reverse, and commended by the committee for its colour. This was sent by Mr. Weeks.

MRS. F. B. GARRARD is also a Japanese flower of medium size, with rather broad florets which lack substance. The colour is a pleasing primrose, deepening to yellow in the centre. This came from Mr. T. Priest, Cherry Tree Lane, Iver Moor, Bucks.

MRS. GROGAN is an incurved variety of a rose-pink colour, with broad petals. Also from Mr. Priest.

LITTLE PET is a small-flowered single of the truest type, colour a pleasing rose-pink. A freely-flowered plant was exhibited, and this appeared to be about 3 feet 6 inches in height. This came from Mr. G. W. Forbes, The Gardens, Regent House, Surbiton. The committee wished to see again *Capt. A. d'Albert*, a pretty flesh-tinted incurved, with rather narrow pointed florets; *Flying Fox*, a rich golden-yellow incurved, a cross between *Oceana* and *Phœbus*; and *Arthur King*,

a large, though somewhat rough, incurved white, tinted flesh.

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, November 21, in the Drill Hall, James Street, Westminster, 1—4 p.m. A lecture on "Fruit Growing in South Wales" will be given by Mr. J. Basham, F.R.H.S., at 3 o'clock.

— Examination in Horticulture, 1900.—The day suggested for the examination, April 17, 1900, being Easter Tuesday and highly inconvenient to many, has been altered to Wednesday, April 25.—W. WILKS, Sec.

PUBLIC GARDENS.

CHRYSANTHEMUMS IN BATTERSEA PARK.

This collection of Chrysanthemums is well worth a visit by those who are interested in the metropolitan displays. The plants are nicely arranged and the flowers are all fully out, and in addition to the usual large sloping bank of bloom there are many freely flowered plants of Japanese and pompons, such as Margot, Source d'Or, l'île des Plaisirs, Sœur Melanie, Rosinante, Aigle d'Or, La Vogue, and others which are used to brighten up the sides and lower end of the roof.

Japanese are here in great force. Souvenir de Petite Amie and Mme. Gustave Henry are useful whites. N.C.S. Jubilee is a fine deep bloom of a pretty shade of silvery pink. M. Chenon de Leche is a well-known favourite everywhere, while Australian Gold, in the pale yellows, is of good size and of a soft, clear shade. The curious green Mme. Ed. Roger seems to maintain its peculiarity of colour wherever seen, and always arouses interest. President Nonin is big and solid, and for a pretty thing we think Mme. A. Rousseau, rosy pink, will require some beating. Rose Wynne, Good Gracious (very fine), John Shrimpton, William Seward, and La Triomphante form a happy blending of colour. Mme. de Sevin, purple, and Mrs. S. C. Probyn, pale silvery pink, are both good. Mrs. E. S. Trafford, Australie, large, but always dull; Hamlet, a bright salmon-red; Eda Prass, W. Tricker, pretty pink; and the strikingly effective Gloire du Rocher need no further mention. Purples are represented by Alberic Lunden and the old Edouard Andiguier. Good standard whites comprise Lady Byron, Mrs. H. Weeks, Florence Davis, Florence Piercy, Lady Selborne, Niveum, and the like, while yellows in all their variety of tint are met with in J. H. Runciman, a good deep golden, globular flower, Gloriosum, Modesto, Sunflower, Edith Tabor, &c.

The incurved are grown and do fairly well, considering they are not quite so likely to please the average visitor. Queens, Empresses, and Princesses are, of course, among the best, although Lord Wolseley, C. H. Curtis, Jeanne d'Arc, Mrs. W. Shipman, Globe d'Or, Prince of Wales, Baron Hirsch, the Beverleys, and a few others similar run them rather close. A few Anemones, of which we might mention Descartes, rich deep wine colour and large in size; John Bunyan, M. C. Lebocqz, and Delaware, complete the list, except just a mention of that pretty little gem, Elise Dordan, a pompon that most usefully helps to lighten a big group of the type seen at these public shows in the parks. We understand there are about 2200 plants in the collection, and varieties to the number of something like 250.

Oasis in Chancery Lane.—The narrow piece of ground by the side of the new Record Office in Chancery Lane, on part of which the old Rolls Chapel formerly stood, has just been turfed and planted with shrubs and flowers.

Open spaces.—At the monthly meeting of the Metropolitan Public Gardens Association, 83,

Lancaster Gate, W., the Earl of Meath, chairman, presiding, it was stated that the association had commenced the laying-out of the churchyard of St. Mary's, Plaistow, and that the faculty having been granted for Christ Church, Blackfriars, this ground would shortly be taken in hand. A letter was read from the New River Company declining to allow the association to deal with the enclosure in Percy Circus as a public garden, but stating that steps were being taken to rescue the ground from its neglected condition. It was agreed to support schemes for the acquisition of Albert Square, E., as a public garden, for the extension of Brockwell Park, and for the conversion of the Latchmere Allotments, Battersea, into a public recreation ground. It was announced that the Acton District Council had accepted the association's offer of seats for a site near the parish church, and it was decided to offer to plant trees in various thoroughfares in Paddington and elsewhere, and in St. John's Churchyard, Westminster.

TEACHING GARDENING TO WOMEN.

THERE is a very long article in the *Nineteenth Century*, with much pretence of learning, upon horticulture as a profession for ladies. It is, however, but an advertisement in praise of horticultural colleges to which so much public attention has been drawn of late years. These colleges appear to be something like the agricultural colleges to which a farmer, who finds it hard to make £100 a year clear profit, has a chance of sending his son at a cost to him of £200 a year! These things are, we fear, got up in the interests of the staff rather than of the students. Towards the end of the article we find contra dictory matter culminating as follows:—

The practical result of all this is that out of 100 women who begin to train as women gardeners, thirty-eight only have held situations, and some of these have since abandoned the work. Out of the thirty-eight who have accepted employment, twenty-four only had completed their studies, and eighteen only—two of whom have since given up gardening as a profession—have taken the college diploma. Therefore, so far as the women's branch of the horticultural college at Swanley is concerned, only sixteen qualified gardeners are at work out of the hundred women who have attempted the training.

The weak point of such institutions is that they offer teaching at too high a price, while the poorest boy willing to work can get better teaching for nothing in any good nursery or large garden. In such his chances of gaining knowledge are greater than at one of these colleges. The consequence is that while the youth in the nursery or good garden is, at no expense, learning his work, the student at the college is paying heavy fees for what is little more than theoretical instruction, and when at the end of a given period the one has a knowledge of his trade at his fingers' ends, the other can only produce a diploma.

The writer gives the most eloquent testimonial when she couples the term "educated gardeners" with Swanley Horticultural College, of which she was lately the secretary, and says that it "has not, I believe, added half-a-dozen to their numbers since its first establishment, some ten years ago."

Landscape architects.—The good old name of landscape gardener, which is the best possible term, is not good enough for our foreign friends, who wriggle out of it in various ways at some cost. The French invented the term "landscape architect," which the Americans have taken from them, and air very much in spite of the absolute incompatibility of the two things. Once in talking with Edouard André about this subject he said that it arose from the dislike in France of

any professional man to be called a gardener in any shape. The most amusing thing, however, in the way of such compound titles that has lately come to us is a letter from an American—a very interesting letter, too—which is headed as set out below. So that the same paradoxical idea is spreading into other fields, and those who so dub themselves are not even afraid of the ridiculous.

Up-to-date Poultry Culture.

OBITUARY.

MR. J. SHRIMPTON.

THE Chrysanthemum community is deploring the recent death of Mr. John Shrimpton, for fifteen years past the confidential acting foreman and raiser of seedling Chrysanthemums under Mr. William Seward, The Firs, Hanwell. He died from cancer, after a prolonged and painful illness, at the age of fifty-nine years. Born at Norwood, Middlesex, in 1840, he early in life served under Mr. Lamb, then gardener to Miss Thackwaite, of Norwood Green, at that time a leading and successful cultivator of Pelargoniums, Cine-rarias, &c. On the death of Mr. Lamb he went to Osterley Park Gardens under Mr. Welch, head gardener to the Dowager Countess of Jersey, and on Mr. Welch leaving he succeeded to his position and served under the Countess, and also under the Duchess of Cleveland, in all a period of twenty-one years. He had been with Mr. Seward for fifteen years, and during that time raised from seed some very fine Chrysanthemums of the Japanese type, such as William Seward and John Shrimpton, which were the earliest to be put into commerce. Other fine varieties were John Seward, Dorothy Seward, Mrs. J. Shrimpton, John Neville, Joseph Brooks, Mrs. Hermann Kloss, &c., and in addition an incurved variety named Hanwell Glory. Most of the foregoing were awarded certificates of merit.

The weather in West Herts.—Since the month began all the days have been warm, and there have been but three cold nights. On the coldest night the exposed thermometer only showed 4° of frost. At one foot deep the ground is now at about a seasonable temperature, but at 2 feet deep is still 2° warmer than the average. No rain has fallen since the 10th, but during the previous eleven days 3½ inches of rain were deposited—or three quarters of an inch more than the average quantity for the whole month.—E. M., *Berkhamsted*.

Antholyza æthiopica vittigera.—Allow me to correct the statement with regard to the *Antholyza æthiopica vittigera* which I found at Port Alfred (not Port Elizabeth), and brought back to Mr. Bennett-Poë.—E. L. RILEY.

Planting a garden (J. H. S.).—Judging a garden one has never seen from a piece of paper is very difficult, as the best result can only be got by someone who has seen or knows the place, soil, conditions of country, and the climate. What is best to be done must be bound up with your own tastes and wishes. Generally the best results with hardy plants are got in two ways—by selecting only the best plants and good varieties of them, and grouping them in free and picturesque ways.

"The English Flower Garden."—Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d. Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.

THE GARDEN.

ORCHARD AND FRUIT GARDEN.

FLAT *VERSUS* SLOPING BORDERS.

IN most gardens fruit tree borders at the foot of walls are generally of such a width, that, independent of the growing of fruit trees, a good portion of the same is available for the cultivation of vegetables and the growing of Strawberries, &c. These borders, in order that they may benefit to the full from the warmth of the sun's rays, are invariably made so that they slope from the foot of the wall to the edge of the footpath, which latter generally forms the boundary line. Sometimes they have a very gentle fall, but often slope somewhat sharply, for the sharper the angle, the greater the amount of heat absorbed. This, of course, has its advantages, but it must be remembered that the sharper the slope, the drier does the soil get, and though in an ordinary season this is not a matter of any great moment, in a dry time it is a very serious matter, and occasions a great deal of extra labour in making good the loss. A border having a nearly level surface, or one which slopes very gently, does not benefit to the same extent, perhaps, in the absorption of sun-heat, but as a set-off against this the soil does not dry so quickly, consequently the roots of the fruit trees do not suffer to anything like the same degree in a dry season. During the past three seasons those having sloping borders know to their cost what an amount of labour has been consumed in supplying the roots of fruit trees growing in them with the requisite amount of water to keep them in a healthy growing condition. Where a supply of water is at hand and hydrants are placed at convenient spots about the garden, matters under such circumstances are much simplified, but when the water has either to be hauled or carried long distances it is quite a different matter, and where labour is none too plentiful the trees are then often left to their fate. These sloping borders are, of course, useful for the raising and growing of early crops of vegetables, but for fruit trees they are, unless in cold or low-lying, damp localities, very undesirable. Having had a few of such borders to deal with, I know full well what a

dry season means, and although more advantageously situated as regards water supply than many, it runs away with a great deal of extra labour to keep the soil about the roots of the trees in a moist condition. I have been altering some borders of late years by making the portion occupied by the roots of the fruit trees quite so, or nearly flat, so that water, whether applied artificially or otherwise, at once sinks in and affords benefit where it is most needed. The worst case of all I am dealing with this season. This was raised to such a height that there was a difference of 18 inches between the level at the foot of the wall and that at the edge of the walk. The supplying of the trees (Pears) growing against this wall with water during the past three seasons has given rise to such a great amount of extra labour, that I at last decided to lift the trees and plant them at a lower level. The surface of the border was lowered, and it is now nearly flat, and although the alteration has occasioned a great deal of labour, I am sure there will be a great gain from a labour point of view in the future, while the trees themselves will greatly benefit by the alteration. A. W.

Pear Seckle.—Those who have a demand for small Pears with excellent flavour ought to grow this sort, for it is one of the surest croppers and of most lovely flavour. I find it succeeds best as a bush or low standard, and if the fruit, that usually sets in bunches of from three to five, is thinned out to one, it will attain a fair size. With me it is usually at its best about the end of October. The tree is of excellent habit. The wood should be thinned out freely, as the terminal buds are mostly fruit-buds.—J. G., Gosport.

Pear Emile d'Heyst.—This Pear has done well this season, but unfortunately the fruits lasted but a short time in sound condition. This is a defect from which several other sorts suffer, and more particularly this year than in others, owing no doubt to the great heat of the past summer having hastened maturity. Emile d'Heyst is a good cropper on the Quince, and the fruits are large and very nicely coloured. I have seen it stated that it equals Marie Louise in quality, but such is not my experience. All the same it is a good Pear, and where Marie Louise is not a success, no doubt it would form a good substi-

tute. Marie Louise still occupies the foremost position here for quality and flavour, two others nearly approaching it being Doyenné du Comice and Thompson's.—A. W.

Pear Alexandre Lambre.—Although not by any means a new Pear, it having been raised and subsequently fruited by Van Mons in 1844, it is one well worthy of cultivation. My one tree of it, which is on the Quince, has never quite failed since it came into bearing, and it invariably bears well. It is a very hardy variety, and the fruits, if not large, are sufficiently so for all ordinary purposes; in fact, many persons prefer Pears of this size to larger ones, such as Pitmaston Duchess and Doyenné du Comice. With me the flavour is excellent and the fruits remain in good condition longer than many of the November Pears do, and I find it extremely useful at this time of the year. It is a free grower and forms either an open pyramid or bush, the habit of growth perhaps lending itself more readily to the former method of training than to the latter.—A. W.

Strawberry beds.—The present outlook for next year's Strawberry crop is by no means rosy in this locality, for with very mild weather and continuous downpours of rain the plants are now making growth freely. If it is really necessary that they should make their flowering crowns and then go to rest after the way that we have always treated our pot plants, then I think that if they turn out well after the present experience we have taken a good deal of unnecessary trouble with our pot plants, for from midsummer to Michaelmas the old Strawberry plants in this locality looked far more dead than alive, the old foliage lying flat on the soil. It was not until October was well advanced that enough rain fell to revive them, but now in November they are making growth that ought to have been made three months ago. I shall watch the result with much interest. The crop was as near as possible a failure this year, and the conditions that led to it are even worse this season—at least, I find it so.—J. G., Gosport.

Peaches in Sussex.—Some few weeks ago I was visiting in Sussex, and although I had not the privilege of seeing the early and midseason crops of Peaches outdoors there, I saw the late ones, and can therefore accept all that your correspondent has to say as to the Peach season having been such a very successful one in the county of Sussex. I was assured by one grower that the crop in his particular case had been a

heavy one from the beginning to the end of the season, which statement agrees with all the writer of the note in question has to say on the subject. In spite of the severe visitation of frost during the time the trees were in bloom they escaped serious damage in many places as well as in Sussex, and a friend of mine who at the time feared he had lost the whole of the crop was agreeably surprised to find afterwards that he not only had quite sufficient fruits, but a good few to spare when they came to swell off. I saw in a Sussex garden one of the finest crops of Salway Peach I have seen anywhere. The tree was carrying a full crop, and the fruits were very large for the variety. I had not an opportunity of putting flavour to the test, but was told that it was generally good. The chalky soil of the border seemed to suit Peaches, judging by the growth the trees had made and their general appearance. This variety is the most unsatisfactory one I have to deal with, and I cannot get it to crop with any degree of regularity. I have but one tree which, when it fails to set a crop, makes far too strong growth. This season I am having the roots lifted and shortened, which will, I hope, induce greater fruitfulness in the future.—S. E. P.

VARIATION IN COLOUR OF BEURRE SUPERFIN PEAR.

As this Pear succeeds remarkably well here and being a great favourite withal, I grow a good many trees of it both in the form of cordons and bushes. Both forms of tree bear well, and the fruits with one exception are of superior quality, but it is respecting the wide diversity there is in the colour of the fruits that I am prompted to write this note. This variation is so pronounced in some cases that only those thoroughly acquainted with this variety would recognise them as being one and the same Pear. The exception mentioned above has been brought about by double grafting. The fruits produced by some of the cordon trees are clear skinned, or at the most having but a few flakes of light brown-russet on the surface, and they invariably grow to a very large size. Some cordons, on the other hand, carry fruits whose skins are entirely covered with a rich dark brown russet, and these never attain such large size as the preceding, though equal in point of flavour. The bushes, too, produce fruit of this character, but hardly so large. The shape of the fruit in all instances is identical, the trees are all on the Quince, and yet there is this wide difference in the colour of the skins. The same thing occurs every year. The composition of the borders in which the trees are growing is the same; they all receive the same kind of manure, and are therefore cultivated under the same conditions. It is very puzzling, and I must admit that I am quite at a loss to account for this variation in colour. Happily, it makes not the slightest difference as regards the flavour and quality of the fruit, but it is a difficult matter to convince some people that they are not two distinct sorts. Regarding the double-grafted tree mentioned above, *Beurre Superfin* was in this case worked on *Knight's Monarch*, the original stock being the *Quince*. When this began to bear it was noticed that the fruits neither turned yellow nor brown, but assumed the greenish yellow tint of *Knight's Monarch*. The shape is that of *B. Superfin* in every particular, but the flesh is of a deeper yellow and the flavour midway, or partaking of both varieties. This is, of course, a very different case to the above, where nothing can be adduced to account for the difference in the colour. If all the cordon trees produced clear skinned fruits and the bushes the reverse one could have accounted for it by supposing that the shelter afforded by the wall and the extra amount of warmth experienced by the fruit would cause the skins to be of a finer texture. Under the circumstances I am, as previously mentioned, unable to give an explanation, and it would be interesting to know whether any other grower has noticed

such a wide distinction in the colour of the fruits of this fine Pear.

It may be interesting to some to know that the finest fruits of *Beurre Superfin* I ever had were from a tree worked on the *White Thorn* as a stock. The fruits were of a beautiful clear yellow in colour when ripe, with just a slight suffusion of red on the side facing the sun, and the flavour was delicious. Unfortunately, the stock grew so slowly that the scion began at last to lack nourishment and refused to grow.

Stoke Edith, Hereford.

A. WARD.

THE SAND PLUM.

This interesting wild Plum of the south-western sand plains has been described and illustrated in these columns, and some endeavour made to gauge its economic status. Mr. W. L. Hall, who has recently been studying the species in Kansas on the ground where it is most abundant, speaks very hopefully of it. He distinguishes and describes three types as follows:—

1. A common type growing in almost pure sand, 4 feet to 10 feet above the water level. Bushes in scattered thickets, 2 feet to 4 feet high, branching and bearing fruit from the ground up. Leaves small, 1 inch to 2 inches long, never open to a plane surface, thick, shining, finely serrate. Fruit three-fourths to one and one-eighth inches in diameter, globose. Colour bright red clouded over lemon yellow ground. Flesh yellowish, tender, juicy, sweet, somewhat fibrous, and adhering firmly to stone. Ripe in Southern Kansas the first week in July.

2. A small group of bushes growing in a very large thicket on the Arkansas River. Bushes extremely dwarf, but tree-like, 3 feet to 4 feet high. Branches unusually stout, growing laterally more than upright. Leaves larger than on common types, dark, shining green. Fruit large, one inch to one and one-fourth inches in diameter, rounded or flattened. Colour dull red, but somewhat hidden by the heavy bloom. Flavour excellent. Ripe in latter part of July. A variety surpassing many cultivated sorts.

3. A small clump of bushes found near the variety last described. Bushes small, 2 feet to 3 feet high. Foliage scant, leaves small. Fruit fine in appearance, one inch to one and one-fourth inches in diameter, roundish, bluish pink colour, with delicate bloom. Skin thin. Flesh juicy, melting, rich. Flavour sweet and good. The most delicious sand Plum that has yet come under my observation, and worthy of place in any orchard.

Just what relation these types bear to the species type, or what botanical or horticultural importance they may have, does not seem to be determined, but it is some satisfaction to note that an active interest is being taken in another native fruit. There are great possibilities yet unrealised in our native fruits.—*Country Gentleman*.

Apples at Ottawa.—There are 653 varieties of Apples under test at the Canadian Experimental Farms at Ottawa. Of these about 160 are Russian. The following standard varieties are said to be thriving best: *Baxter*, *Ben Davis*, *Canada Baldwin*, *Delaware Red Winter*, *Duchess*, *Duke of Connaught*, *Gano*, *Gideon*, *Haas*, *Lawyer*, *Longfield*, *Malinda*, *McIntosh Red*, *McMahan White*, *Missouri Pippin*, *North Star*, *Patten's Duchess*, *Patten's Greening*, *Pewaukee*, *Plumb's Cider*, *Red Astrachan*, *St. Lawrence*, *Salome*, *Scott's Winter*, *Stark*, *Swayzie Pomme Grise*, *Tetofsky*, *Wealthy*, *Winter Bough*, *Winter St. Lawrence*, *Wolf River*, *Yellow Transparent*. This is a good long list. It offers chance enough for anyone to choose. It may be noticed that not more than seven of these are Russian varieties, or less than the proportion of Russian varieties in the whole orchard. This would indicate that there is some chance of salvation for Apple growing in cold climates, aside from the Russian varieties. The list, considered at its face value, is a distinct encouragement to northern Apple growers.

Thinning Apple trees.—Writers on fruit culture are continually advising that orchard trees and others should be well thinned, yet specimens where the pruning knife has done its

work properly are not often met with. At *Bramley Park, Surrey*, I noted recently an Apple plantation which has been well cared for in this respect, and it formed a splendid object-lesson in its results. Fine well-shapen, clean specimens were hanging like the proverbial ropes of Onions; not one sort, but all alike. The *Ribston Pippin* appeared equally free to fruit, as did *Lord Suffield* and *Blenheim Orange*. The trees are mostly standards, the oldest being about twelve years, and all were planted by the present gardener, *Mr. H. Paddon*. A not over-deep natural soil has been improved by having a hole some 2 yards square duly prepared for each tree. This is occasionally replenished by additions in the way of top-dressing, and grass or weeds are kept from these patches, which are mulched with manure in summer. In a very dry season like the last copious supplies of water have been applied to the roots to help in finishing such an unusual crop. These items, however, important as they undoubtedly are, have not done so much, to my thinking, as intelligent thinning of the branches of the trees. Looked at casually, many of the branches seemed a yard apart. They were several yards long on the older trees, and studded with fruiting spurs from base to apex. Nearly all the growth indeed goes to making fresh spurs instead of lengthy leaf-shoots, the trees being so well in hand that little summer pruning is required. Superfluous growth has been prevented in the younger stages of the trees by timely root pruning, and now the crops of fruit that are gathered each season also assist in this direction. All the well-known Apples of merit are represented, and they provide a constant supply from July to well on in the following spring.—H. S.

APPLE EXHIBITIONS.

SINCE the holding of the great Apple congress at *Chiswick* we have had fine displays of Apples as public exhibits, not only at the *Crystal Palace* and the *Drill Hall*, but also all over the country, but with none of these has there been any effort made to render them instructive, as was done at the congress. Since that event, whilst we have materially increased Apple varieties, we seem also to have so far advanced in culture, that for the past few years the fruits have been publicly presented in form and in quantity that seem to have excelled all previous displays. But whilst the superb collections seen from time to time evidence the existence of these grand fruits, they tell nothing as to how produced. If a great display of from 100 to 150 dishes of varieties be shown by a nurseryman, the common assumption is that all have been produced on the usual two or three-year-old trees, just ordinary nursery trees. That may be a correct deduction, or it may not, but certainly the age as well as form of tree should be clearly indicated, because to all intending fruit growers it is matter of the highest importance they should know what description of tree may seem most suited for their purposes. This matter becomes of far greater importance when fruits from any private garden are exhibited, because these are the products of established or garden trees, and not of those of the nursery grown only for sale. Apples in gardens are grown under so many diverse conditions; some are grown in pots and partially under glass; some are grown on walls, some on espaliers or cordons, some on bush trees, some on standards, and in the case of the latter, not a few on grass in orchards. Then there is the question of stock, whether *Crab* or *Paradise*. But when a large collection from any private source is exhibited, not a word is said to indicate how these fruits were produced. Would it be too much to suggest to the council of the *Royal Horticultural Society* that henceforth no medal shall be

awarded to any collection of either Apples or Pears unless the fruits are grouped according to the nature or form of the trees that produced them? How much better would it be to place a large card against each section indicating whether grown on bush, standard, espalier, cordon, wall or other trees, and what the stock, because this would be information which the public would greedily seize upon and utilise. Even some information as to the nature of the soil in the nursery or garden generally, and situation, whether high or low, exposed or sheltered, would be valuable. It is a matter of common notice and comment that our fruit nurserymen invariably illustrate their catalogues with portraits of young or nursery trees. Now these have no interest for the private grower, because they do not represent established trees. Were these illustrations photographic portraits of trees several years planted, such as had become established and had been under ordinary garden culture for some time, how much more of value would they have. Were the collections of fruit to which reference has been made ornamented by good pictures of some of the trees from which the fruits have been gathered, how interesting would these be also. Perhaps it may be possible to offer good prizes for collections from private gardens of from forty to fifty dishes, distinct varieties, exhibited in this sectional and very educational way. I have seen ordinary collections of both Apples and Pearsshown time after time, one being but the replica of the other. They are fine, even beautiful, but still show such monotonous repetition. Real originality in arrangement, especially with an eye to either novelty of presentment or of educational value, seems beyond the ken of the ordinary exhibitor. If there is one question more than any other in relation to Apple culture that is important, it is what description of stock and tree is best suited for ordinary culture to enable fine clean Apples to be produced most profitably and in the greatest abundance. That is a something worth taking a little trouble to elucidate. It is a problem that is of the first importance to solve. A. D.

The good effects of root-pruning.—Practical fruit growers will, I think, agree with all that Mr. Prinsep has written (p. 369) as to the value of root-pruning fruit trees which fail to bear through making a too luxuriant growth. I am a great advocate of the system, and never fail to practise it directly I find a tree—whether young or otherwise—begins to make strong growth and fails to set fruit-buds. Root pruning is not by any means new, but it is not resorted to so generally as it should be as a means of inducing fertility. My first experience in root-pruning was gained about thirty years ago, and the gardener under whom I then served, and who was at that time a noted fruit grower, used always, when necessary, to practise it with most excellent results. The same benefits invariably accrue from its adoption here; in fact, on a fertile soil such as I have to deal with it is imperative to root-prune young trees planted round the vegetable quarters to keep them within bounds and to prevent them unduly shading the ground. Once the strong growth is checked and the trees become fruitful it is not often they give further trouble, and the fact of their bearing fruit of course then supplies the needful check afterwards. There is hardly a season passes in which I do not see this simple expedient neglected in different parts of the country, and yet when the advice is given that root-pruning could rectify matters, it is not acted upon as often as it might be. At the present time I am root-pruning some young cordon Plums planted three seasons ago. This has become necessary on account of their making far too strong growth, and the severing

of the strong roots and the laying out of the fibrous ones afresh will, I have not the slightest doubt, bring about the desired result. The soil is now in splendid condition for carrying out this kind of work, and the sooner it is done the better, as the wounded portions of the roots then have the chance to heal over.—A. W., *Stoke Edith.*

KITCHEN GARDEN.

DEEP STIRRING OF HEAVY SOILS.

OLD customs die hard and old ideas are very difficult to get rid of. The idea that it is harmful to dig heavy soils deeply is one of the latter, and owing to this mistaken notion, there are scores of gardens that might be greatly improved simply by deeper culture. It is a fact that a great deal of money has been spent both by farmers and gardeners in draining such soils that is practically wasted owing to the shallow system of cultivating. Nearly all heavy soils are very productive when they are brought into a condition that the roots, whatever crop is on them, can obtain a proper grip, but the condition of such soils in too many instances is a few inches of loose earth directly over a hard pan of clay, that prevents moisture going down and keeps it on the surface, rendering this sour in wet weather, while in dry seasons the moisture does not rise freely from below as it should do, and cracking and other evils result. In this garden when I took charge of it the men were in the habit of digging without opening a trench of any kind, simply turning the upper few inches of soil over with spades held at a very slanting angle. In consequence, it was the custom to wait for frosts before commencing the preparation of the principal quarters in autumn and working for a few hours until the sun came through and made the surface sticky when the digging was left until the next morning. With an open trench it is quite easy to dig such quarters at any and all times of the day, excepting, of course, just after heavy rain.

The system I follow is to clean round the paths first, throwing whatever loose soil and rubbish there may be pared off on to the bed. Then a trench two spits wide and one deep is taken out and removed to the furthest end, or if the position and shape of the ground will allow it, a start is made at the lowest corner and the trenches are made diagonally. The bottom of the trench is then broken up as deeply as possible with five-tined forks, but none of the bottom soil is brought to the surface. This bad soil below is the bugbear of those who will insist that heavy soils ought not to be deeply dug. If the quarters are to be manured the manure is then put in and the upper inch of the surface, which is often weedy, is pared off and put into the trench. The next two spits are then turned over on this. By this means the men have a clean and dry piece of ground to stand upon instead of the loose surface, every inch of the soil is moved—an impossibility under the other system—and no bad soil is brought to the surface. Very little consideration is sufficient to show that every season the tilth must be deepened, the mechanical condition of the soil is improved so that frost, air and light penetrate more deeply and, above all, surface water gets away more rapidly. Soils so treated improve in a remarkable manner in short, and very quickly; it is easy to get on them early in the season and owing to the deeper root-run the crops thrive much better.

It should, of course, go hand in hand with efforts to improve the staple itself, but this unfortunately is not so easy. Heavy soils that

are deficient in lime are much improved by placing small heaps of unslaked lime, say a pailful in a heap at intervals of about 4 yards or 5 yards apart all over, gathering most of the surface soil and placing over these heaps which, as the lime slakes, breaks down finely and may again be spread about. I have frequently seen this practised on quite large fields in several of the South Wales counties, and not only does it improve the surface tilth, but it is very destructive to various insect pests. Burning the top spit again is of the greatest utility, but this is expensive over large areas, though very applicable to gardens. Such additions to the soil as burnt earth and garden refuse, road sand and ashes are, of course, well known to be serviceable, but this is a very slow and tedious way of lightening and improving these stubborn clays and loams. H. R.

Carrot Early Gem.—The roots from the early autumn sowings still in the ground ought to have a little protection now that most of the leaves are down, as a few sharp frosts have occurred, and these young roots are more tender than fully grown ones. Where there is plenty of convenience in the shape of brick pits, early forcing may commence on hotbeds of leaves, and this kind is an excellent one to sow at the same time as one of the early forcing kinds to form a succession to the latter.

Turnip Green Ring.—This Turnip is also known as Greentop White, and possibly by other names, as is usual when a good variety is in the hands of several seedsmen. I always grow as much of it as possible, as I consider it the hardiest of the white kinds, and only a little, if any, behind the yellow ones, while it is of superior quality to the latter in most cases. After those of the Snowball type are past it is very useful to fall back on, as at this time of year there is a great demand for all kinds of roots for flavouring. Late sowings that do not turn in may be left in the ground, and will yield a useful crop of greens in spring.

Heeling in Broccoli.—It is perhaps somewhat premature to speak of this work yet, but it is very easy to be caught napping, and we sometimes get frost and snow ere November is ended. Some gardeners entirely ignore the practice, but there can be no doubt that many a useful lot of plants has been saved by banking up the stems. Much depends on the district, position of garden, and the variety grown, also whether plenty of room was allowed at planting time and a moderately rich root-run only given. The dwarf-growing varieties such as Model and Backhouse's Winter White seem to escape more often when unprotected than those having a greater length of stem exposed. I have known hay-bands entwined carefully round the stem and amongst the leaves immediately under the crown with very good results.—J.

French Tomatoes.—Having read in last week's GARDEN the interesting notes on Tomatoes, I think you will be pleased, perhaps, to add the result of my experience to the answers of your correspondents. I consider Reine des Hâtes the best Tomato for winter and early spring. It is undoubtedly the earliest of all French varieties. I cannot compare it with English ones, as I have not tried them. It requires but little heat and is not liable to mildew. It begins to bear clusters very near the soil, and yields medium-sized, smooth fruits, which are perfect both in colour and flavour. Its freedom of setting is, perhaps, not quite satisfactory, but to decide this I will grow it another year. Ponderosa is a capital Tomato for amateurs. I do not know of another that grows so vigorously and bears so heavy a crop of large fruits. Varieties of Tomatoes being so numerous, it is impossible to say which is the best, the season and conditions under which they are grown having to be taken into account. Though a fruit, the Tomato must take its place in the market or at

exhibitions amongst vegetables, since it is unprovided with the sweet flavour which is, I think, the best criterion of a dessert fruit. In France it is generally served up with meat, and consequently is always looked upon as a vegetable.—FELIX CH. NAUDIN, *Antibes (A.M.), France.*

Pickling Cabbage.—These are indispensable in all gardens, but they sometimes cause disappointment in several ways, chiefly perhaps by suddenly bursting open if heavy rains occur previous to cutting. Gardeners are apt to make matters worse by allowing red Cabbages to stand uncut too late in the season. Some cooks prefer them after they have received a few sharp frosts on them, but wholesale bursting then often occurs. If not required at once, it is wise to pull them up and suspend them from the roof of a cool shed or outhouse; splitting is then avoided, although they are really crisper when pickled straight from the garden. Large ungainly heads seem to split more readily than the medium ones, and having proved this, I have sowed seed in February in a Carrot frame or boxes and secured good useful heads, which have remained plump and sound till frost came. If any have been unsuccessful with their autumn seedlings, they may with every confidence sow as advised.—J. C.

NOTES ON TOMATOES.

— I consider the best Tomato to be Perfection either for summer or winter use; at least, I have found it so. I tried Tomatoes here outside in 1893, which was a good season, but they did not pay for the labour, so I have never grown them again. I consider the Tomato a vegetable.—J. JEFFREY, *Harewood House Gardens, Leeds.*

— I consider Early Ruby the best early Tomato that I have grown; next comes Scarlet Queen. For autumn crop I grow Royal Chester. Laxton's Open Air did very well out of doors on the kitchen garden wall. I consider a Tomato a vegetable.—JOSEPH MADDOCKS, *Cowley Manor, Cheltenham.*

— The best Tomatoes are Frogmore Selected, Ham Green Favourite, Chemin Rouge, and a selection of my own, which for cropping and other qualities is superior to the above. It is difficult to decide. Last season Early July and Early Prolific were the best among several others. In this locality Flying Dutchman is claimed to be as good as any outdoors. Frogmore Selected, Chemin Rouge, and Sutton's A 1 I have found good for autumn and early spring. Those who eat the Tomato uncooked would probably call it a fruit, while those who prefer it cooked may look on it as a vegetable. I should say it is a fruit.—T. H. SLADE, *Poltimore Gardens, Exeter.*

— The best Tomatoes are I find Stirling Castle, Conference Improved, and Eclipse. Setting and flavour are largely a matter of management so far as the small-fruited varieties are concerned. Early Ruby is a reliable sort for outdoors and early work. The Tomato is a vegetable, as such it is cooked; employed raw in salads and when eaten without preparation it is not as a dessert fruit, but nearly always along with something else.—R. P. BROTHERSTON, *Tynningham, N.B.*

— The Tomatoes I grow after giving a number of varieties a fair trial are Perfection and Ham Green Favourite. These when well grown are, I consider, difficult to beat. For a yellow I grow Golden Queen, and for winter the same varieties. In early spring Early Ruby is good. I consider the Tomato a vegetable.—J. SOUZA, *Walhampton Park, Lymington.*

— So far as my experience goes I have found Ham Green, Dedham Favourite, and Conference excellent Tomatoes. As a finely-flavoured and free-setting Tomato of excellent shape and size I would choose Regina. I do not think anything of the much-lauded Best of All, which opinion is also held here by others. I find it woody and tasteless. For early crops and for outdoors I have yet to see a better than Earliest of All. I have tried a small Plum Tomato (red) here, but find it leathery. Of the yellows I only know Sun-

beam, which is good, though not a heavy cropper. Its appearance with its flushed cheek is very taking. I have one other very fine round Tomato which I do not know the name of, and locally called Bracknell Giant. For actual weight of crop here I suppose Maincrop would beat all. The lower trusses had from eight to fourteen good fruits. I should call the Tomato a vegetable.—H. GALLIFORD, *Furley Copse, Burfield, Berks.*

— I find Hero of Chester does better than any other I have tried, and it is of excellent flavour. Scarlet Queen I find a very free setting variety in winter and spring. I think the newer sorts of Tomatoes are the best, as they are smoother, of better shape, and of better colour. I consider a Tomato more of a vegetable than a fruit.—C. STEWART, *Haynes Park, Bedford.*

— I consider Perkins' No. 1, Frogmore Selected, and Cannell's King the best. Perkins' No. 1 was by far the best outdoors with me last year. It was tested by the side of ten other varieties. I do not grow Tomatoes for winter use. For early spring work I like Perkins' No. 1 and Frogmore Selected. I consider the Tomato a vegetable.—W. HAYLOCK, *Elington Park.*

— I consider Trophy the very best in cultivation, taking into consideration size, colour, flavour and cropping. In the yellow varieties Greengage is still the favourite. Early Ruby I find the best for autumn and spring work. I consider the Tomato a fruit.—BAILEY WADDS, *Birdsall Gardens, Yorkshire.*

— The best Tomatoes I should say, taken all round, are Up-to-date and Duke of York. Early Prolific and Early Ruby I find are the best for outdoors, and for autumn and spring I prefer Early Ruby. I consider the Tomato a vegetable.—T. H. WINSKILL, *Staunton Park, Staunton-on-Avon, Hereford.*

— The best Tomatoes I find are Challenger, Conference, Frogmore Selected, Ham Green Favourite and Perfection. The best outdoor kinds are Earliest of All and Laxton's Open Air. The best kinds for winter I find are Ham Green or Conference, and for early spring Early Ruby. I consider the Tomato a vegetable.—G. WADESON, *Doveridge Hall Gardens, Derby.*

— I find Early Ruby one of the very best as it sets well, carries heavy crops of bright red round fruit and also does very well outdoors. I also find it extremely useful for sowing about the middle of June for giving a supply through the autumn up to Christmas. Frogmore Selected is also another grand Tomato very prolific and the fruit of good size, even and round in shape, bright red and of good flavour. Hackwood Park is a fine Tomato and of good flavour, but it does not set so well with me. Perfection is a good exhibition sort carrying heavy crops of large round bright red fruit. I think the Tomato should be classed as a vegetable, as it can be served up in so many ways.—C. PENFORD, *Leigh Park Gardens, Harant.*

— Perfection and Conference have always done well with me. For setting and for flavour I am disposed to give the place of honour to Up-to-date, which I consider an excellent Tomato. I should consider a Tomato, properly speaking, a fruit.—J. SHORT, *Hunnersknott, Darlington.*

— Amongst red Tomatoes, the one that stands out above all others is a variety named The Cropper. I favour it here on account of its excellent appearance, freedom of setting and delicious flavour. This variety, if the strain is kept pure, will rank amongst the very best Tomatoes in cultivation, all points considered. I find here that it is a good plan to grow Tomatoes from cuttings; they set with greater freedom and I think a heavier crop is obtainable if this method is adopted in preference to raising plants from seed. Earliest of All is the best outdoor Tomato I have grown, and I am also well satisfied with it as a winter and spring cropper. Amongst the yellow varieties, Golden Jubilee is perhaps the best yellow kind for a general summer crop. Judging it from every point of view, it must be well spoken of by those who use Tomatoes either as a fruit or a vegetable. The Tomato, properly

speaking, must, I think, be catalogued as a fruit, but, like some other fruits, it can be with advantage used as a vegetable either by itself or mixed with other vegetables, as the cook may think proper. To call the Tomato a fruit is the proper definition in my opinion.—JOHN MACKINNON, *Terregles, Dumfries, N.B.*

— I can recommend Frogmore Selected and Best of All for winter fruiting. Sutton's Early is a good one for outdoor culture. I consider the Tomato is either a fruit or a vegetable according to taste. Some people prefer to eat it as a fruit, while others prefer to have it cooked. It was always looked upon as a vegetable until about twenty years ago.—JOHN GLOVER, *Belle Vale Farm, Gateacre.*

— Earliest of All is the best for growing under glass and is also the best flavoured. Perfection is the best outdoor kind. I always considered the Tomato a vegetable.—JAMES TEGG, *Bearwood.*

— The Tomatoes I consider to be the best are Polegate, Ham Green Favourite, Earliest of All, Frogmore Selected, Duke of York, Chemin, and Perfection. The best outdoor Tomato is Maincrop, and the best kind for winter and early spring Chemin. The Tomato I consider a fruit.—D. COOPER, *The Gardens, Hanger Hill House, Ealing, W.*

— I have tested a number of Tomatoes, including the newest varieties, but find nothing so good as Conference. It is quite big enough, a capital grower and cropper, solid, and of good flavour. Tomatoes do not succeed out of doors here. I grow Ham Green, Hathaway's, and Conference. If restricted to one I would choose the last. I consider the Tomato a fruit. The best flavoured Tomato I consider to be Golden Queen. I had a strong prejudice against yellow-skinned fruit, but am compelled to acknowledge that in delicacy of flavour and firmness of flesh this beat all. Jubilee seems equally good, but I should like to test it further before expressing a decided opinion.—W. B. UPJOHN, *Worsley, Manchester.*

— I have tried many so-called new sorts, but have found none to beat Ham Green. Frogmore Selected holds second place; this is slightly corrugated, but is a most excellent free-setting and good quality variety. For outdoors I have found none better than Earliest of All, Sensation, and Carter's Outdoor. The only drawback to the last-named is its corrugated form, but this may be overlooked, being a heavy cropper, of excellent quality, and one of the first to colour. Those who have to depend on outdoor Tomatoes I would strongly recommend to give it a trial. For years I have grown Earliest of All, Frogmore Selected, and Conference for winter and early spring use, and could wish for nothing better. I consider the Tomato a vegetable.—F. CLARK, *Orchardleigh Park, Frome.*

— In my opinion Maincrop is the best Tomato for private gardens. It has a fine strong constitution, is free-setting, bears freely, is of good flavour, and resists disease. I have tried all the leading varieties, but I cannot find one to come up to Maincrop. The best outside varieties here are Trophy, Hathaway's Excelsior, and Frogmore Selected. Chemin I consider one of the best winter sorts. I consider a Tomato a vegetable.—A. MCGLASHAN, *Wedmore Court, Bromley, Kent.*

— My favourite varieties are Ham Green, Regina, Royal Jubilee and Perfection. The best outdoor variety is Ham Green. I should think as the Potato-Apple is a fruit it would be rather inconsistent to class the Tomato strictly as a vegetable.—T. CHALLIS, *Wilton House, Salisbury.*

— I have not tried many kinds, but have stuck to a selection of Hackwood Park for a general crop. It sets freely and is a good sized fruit, and smooth. I grow it in quantity against walls, and have found nothing better. For early fruiting Earliest of All is the best I have grown. I have no experience of winter crops. I always look upon a Tomato as a vegetable, and should never think of exhibiting it in a collection of fruit.—R. LLOYD, *Brookwood Asylum Gardens.*

PENJERRICK.

THIS is the fairest garden I have ever seen in Britain, absolutely distinct and almost wonderful in the vigour and grace of its trees and rare shrubs. The gardens fill a little

forgot all about a garden as we know it. It is curious how often in our wind-swept isle we see this graceful sub-tropical effect—at Mount Usher, at Fota, at Carhays, Menabilly, on the colder east coast now and then, and

effects resulting from the right use of the many fine things that may be so grown.

Penjerrick is a few miles from Falmouth, and for very many years was occupied by the late Miss Fox, who was devoted to her garden, and throughout these lovely grounds there prevails that charming simplicity which so surely indicates a love for the beautiful in Nature. The ground is traversed by a public road on a lower level, and the rustic bridge over the road which connects the distant parts of the pleasure grounds with those near the house is so planted out that no line of division can be observed. The grounds contain, among other beautiful plants, fine Magnolias, groups of rare Himalayan Rhododendrons, including the variety *R. Roylei*, which is but seldom met with. Here also is what is probably the finest specimen in England of *Arundinaria nobilis*, whose graceful fronds measure over 24 feet in length. In a shady glen close by is a Tree Fern (*Dicksonia antarctica*) with an unusually large head of perfect fronds, and which has been grown out of doors for years. Among other Ferns in this glen *Lomaria magellanica* grows profusely, and has handsome evergreen fronds. A most picturesque effect is produced by the pendent branches of a Weeping Beech fully 80 feet high. Among the many conifers is *Fitzroya patagonica*, 25 feet to 30 feet high; *Dacrydium Franklini*, about 10 feet by 12 feet; *Cephalotaxus Fortunei*, 14 feet high by 12 feet through, and *Podocarpus andina*, fully 40 feet high. Very beautiful when in bloom are an *Embothrium coccineum*, about 40 feet high, and *Acacia melanoxylon*, nearly as large. V.

Dacrydium Franklini at Penjerrick, Falmouth. From a photograph by G. Champion.

valley sloping seawards and 200 feet above it, and looking from the house down the garden vale it seemed in some lovely Pacific glen, not a trace of any of the conventional lines we see in gardens visible; in fact, one

even in Northern Ireland, as in Lord Annesley's grounds at Castlewellan, and these and many other sea-warmed gardens have many charms, but Penjerrick more than any garden I have seen has the most picturesque

Symphyandra Hofmanni.—While the mild season is responsible for the continuance of this plant in bloom, it is yet worthy of a note, though its wonted time of flowering is over. Although it is with me only of biennial habit, it reproduces itself so freely by means of self-sown seedlings, that it is to all intents and purposes as good as any hardy perennial, with the exception that it cannot be depended upon to come up in exactly the place desired. It has now been here for several years and has never failed to give me more than enough of young plants to serve my purpose. I have at command very little information regarding it in its native habitats. It, however, comes from Bosnia. It cannot have been long in cultivation in this country, and one seldom meets with it in gardens. Some two or three years ago I came across some plants of what looked like the same thing under the name of *S. Kaufmanni*. I ventured to say at the time that they would probably prove to be simply *S. Hofmanni*, and that the name of Kaufmanni had arisen from a blunder not difficult to understand.

On comparing the plants at their flowering time it was found that they were identical. I mention this as it is likely that others have received the plant under the name of *S. Kaufmanni*, and, so far as I can discover, there is no such plant. Like the other *Symphandras*, this species is very like some of the *Campanulas*, but possesses the connate anthers which pertain to the genus. Here it forms a neat conical or pyramidal bush a foot or more in height, producing a number of bell-shaped white flowers. As the wider or open part of the bell is turned to the ground the flowers are not so effective as if upturned, but they have the merit of lasting much longer than if the flower were erect. It grows well in the light soil here, and, though not showy, is frequently noticed by those who know something about plants. Seeds are procurable from some seedsmen in spring.—S. A.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS AT FRAMFIELD.

A visit to the charming old village of Framfield, Sussex, is at all times an event looked forward to, but at this season of the year when the Chrysanthemums are at their best, an inspection of the collection of Mr. Norman Davis is interesting. The vineries face south-west, and here the Chrysanthemums appear to revel. In the lofty and lengthy houses the 14,000 plants, which are grown for market and exhibition, are arranged. Contrary to the usual rule in nurseries, the plants are not crowded in the houses; instead, there is plenty of room for each plant to be handled and examined, and as a result the floral display is probably unequalled. One of the sights at this establishment is the exceptionally grand lot of Mme. Carnot and its sports, Mrs. Mease (sulphur) and G. J. Warren, the lovely canary-yellow flower. These plants are flowered on second-crown buds, and consequently are somewhat tall, though not so tall this year as usual. A row of plants on either side of a long house contained these three sorts, and without exception they were all fit for exhibition. The pots were not by any means large, those 9 inches in diameter being the popular size. A splendid hatch of Mr. H. Weeks' seedling, named Mrs. Barkley, showed how valuable it is for exhibition. The florets are very broad and strap-like in their formation, the colour rosy pink, with a silvery pink reverse. Another seedling from the same raiser named Victory is a very promising flesh-pink Japanese; flower of large size and great depth, petals broad and numerous, building up a massive bloom, the plant of good habit. Henry Weeks, rosy crimson, flushed carmine, Japanese, was in evidence everywhere. The plant is one of easy culture, and no doubt next season, when it has recovered from persistent and continuous propagation, the blooms will be frequently staged. R. Hooper Pearson, the richest yellow Japanese, was flowering freely. Propagated late, little time had been left for the plants to make much progress; all the same, they were developing useful blossoms in this case, coming like a vastly improved Oceana. Lord Cromer appears to be one of the best of the new crimson Japanese flowers, although in this case the blooms were rather flat. When grown strongly and given a long season of growth, the blooms should be deeper and the colour rich. The petals are of medium width, the reverse of a pale gold colour. Blooms of Madeline Davis, although not over large, were refined and pleasing. The colour may be described as pearly white, tinted rosy violet. The petals are of medium width, though rather short, but they are numerous and make a chaste and full bloom. The habit is dwarf. J. R. Upton, a plant from the Antipodes, comes up to expectations. The blossoms seen here this season were of immense size, and should be useful on the exhibition table. The florets are very long and broad, developing into a deep rich yellow flower. Great value is set

upon the blooms of Western King, regarded here as representing all that is chaste and beautiful. The blossoms belong to the incurved Japanese type, and they are of the purest white. Each plant will develop a goodly number of large flowers on a most desirable habit of growth. Another more recent novelty is Annie Prevost, very similar in form and colour to the last named, but the flowers are larger. When finished the blooms have quite a globular form, and the plant possessing a dwarf, sturdy habit, it may be considered one of the best varieties for grouping in cultivation. Samuel C. Probin is a good companion plant to the last named, being a dwarf, sturdy kind. The blooms are large and massive in build, with broad petals curling and incurving at the ends. The colour may be described as cherry-crimson with a pale silvery reverse, and the plant is of easy culture. A welcome addition to the Japanese is Miss Maud Douglas, this being a pale rose-pink flower with a silvery reverse. It is a large, somewhat loosely incurved Japanese bloom, late flowers throwing back their rather broad petals pleasingly and making an exhibition sort of high merit. The tint of pink is distinct from all others. The plant has a good constitution and also a good habit. Another sort belonging to the incurved Japanese is Mrs. W. Cursham. This plant was certificated by the National Chrysanthemum Society last season, when its unique petals and form were greatly admired. The petals are broad and of splendid substance, prettily curling at the ends and tightly incurving. The colour may be described as flesh-pink, with a pearl-coloured reverse. A few plants of John Bridgman, a lovely rosy pink flower of the easiest culture, being a kind of refined Etoile de Lyon in its build, prove how many really good things are unknown. The flower is a large, full one and the constitution is good.

The manner in which the large Japanese blooms of Mrs. Coombes have been exhibited proves conclusively how valuable this sort is. This may be regarded as one of the best introductions of last spring. An exquisite flower is Emily Towers, of a rich rose-pink colour, tinted silver. The blossoms are large, having broad pointed florets, making an ideal exhibition variety. An old sort, or at least comparatively so, is Daül de Jules Ferry. This is in grand condition this season, developing blossoms of rich, pure amaranth with a silvery reverse, and proving the wisdom of retaining some of the older sorts. H. J. Jones was coming of a deep rich crimson, and not nearly so brilliant as seen the previous season; it may, however, finish a much brighter colour. Over-propagation has much to answer for. Another rich colour was seen in Helen Shrimpton, a beautiful cherry-crimson, and a flower of large size. Late buds of Richard Dean, usually a very coarse flower, were giving blooms of a very deep rich crimson colour, proving conclusively the correct method of culture has been attained here. The reddish bronze sport from Edith Tabor, Mrs. Barks, was well represented. This can hardly be considered a pleasing colour. Another excellent sort, especially for grouping, is Mrs. James Beisant. This is white, tinted rose, developing a large number of full blooms on a nice habit of growth. A continental introduction, Mme. A. Rosseau, contrary to catalogue descriptions, was giving handsome blooms of a rosy carmine colour with a silvery reverse. The petals are very long and tubular and form a very large spreading flower. Numerous superb examples of other Japanese sorts were largely in evidence, the most noticeable being richly coloured Edwin Molyneux, Lady Byron, still one of the best whites, though a trifle early; Mrs. J. Lewis, one of the best whites this season; Lady Ridgway, rosy buff; Mme. Rozain, Master H. Tucker, a grand chestnut-red; Congres de Bourges, deep puce; Mrs. T. A. Compton, white, shaded lilac; N.C.S. Jubilee, silvery pale pink; Mrs. White-Popham, Australian Gold, Little Nell, like a white Mrs. C. Harman-Payne, and others too numerous to mention.

A pretty collection of incurved sorts included the Queens, Princesses, and Tecks. The newer incurved sorts included grand examples of Chrysanthemum Bruant, rosy buff; Mrs. N. Molyneux, ivory white; Topaze Orientale, straw-yellow; Ma Perfection, pure white; Mlle. Lucie Faure, pure white, of immense size; Miss Annie Hills, blush, of true incurved form; Hanwell Glory, bright bronze, and several others. Anemones were seen in beautiful form, Descartes, reddish crimson, and Owen's Perfection, very chaste, with long tasselled guard florets, standing out conspicuously. Decorative sorts are very largely grown, huge breadths of Klondike, a very rich yellow Japanese, dwarf and free; Clinton Chalfont, a lovely bright rich yellow; Gladys Roul, a unique and pretty pure white flower; Eynsford White, l'Île des Plaisirs, chestnut-crimson, and others of undoubted merit. The thread-petalled and other curious sorts were represented by Mrs. James Carter, pale sulphur; Mignonette, white, tinted salmon; King of Plumes, rich yellow; Golden Shower, and numerous singles and charming little pompons.

M. Nonin's seedling Chrysanthemums.

—During the past two or three seasons there seems to be some probability of this French raiser coming to the front. Several of his novelties have done well, and although not favoured with a climate like some of his fellow-countrymen, he has nevertheless achieved a marked success. Comtesse de Boulaincourt, Mlle. Louise Brossillon, Emile Nonin, Mme. Frederic Daupias, Mme. Gabriel Debrie, Amateur J. Lechaplais, and several others are now fairly well known and are regarded with favour. M. Nonin's nursery lies some little distance to the south of Paris, in the open country. At one time he was the president of the Paris Chrysanthemum committee, and his fine group at the Palais de l'Industrie in 1896 will not be soon forgotten by those who saw it.—C. H. P.

New French seedlings.—Whatever may be thought to the contrary, there is little likelihood of a cessation of French novelties which some of my friends seem to be prophesying this autumn. M. Ernest Calvat staged at the recent Lyons Chrysanthemum show the finest lot of blooms I ever saw, and in addition to his lot, M. Bonnefons sent upwards of fifty, many of which were certainly promising, although presented under less favourable conditions. MM. de Reydellet, Heraud, and Chantrier were well represented at the same show, and from Messrs. Vilmorin-Aodrieux and Co. there came a very substantial batch of novelties. Other raisers, such as M. Nonin, M. Morières, M. Lacroix, M. Rozain, &c., are also actively engaged in the work, to say nothing of the Italians, whose novelties are as yet but little known in this country.—C. H. P.

Chrysanthemums at the Aquarium.—Never before perhaps has so much effort been expended on the utilisation of the big-bloom Chrysanthemum as was to be seen at the Aquarium last week, when the Messrs. Davis and Jones in a way renewed their old-time partnership, and virtually joined hands in showing what could be done with these things when a little discretion and good judgment are brought to bear on the work. A finer display of cut blooms artistically arranged has in all probability never before been seen. Arranged side by side almost without division on a specially erected stand beneath the organ gallery, these splendid groups formed a most imposing feature. Regarded individually there was indeed but little between the two, and the little there was had rather to do with the different styles of arranging. Big vases some 3 feet high of oriental pattern were occupied with the finest flowers that could be got. Equally tall, though of course less bulky, were the glass vases, that, too, had their complement of handsome blooms. Disposed here and there these taller vessels constituted the principals, and it was here naturally that a difference occurred in the arranging as also in the furnishing material. On the one hand, the

blooms, arranged in the form of a drooping oval pattern, were fortified with prettily tinted foliage that had a very pleasing effect, and on the other, trails of Smilax and other things were prettily interspersed with the flowers. Standing aloft, as these vases did, afforded ample room for a pleasing array beneath for a groundwork and for subordinate groups and vases generally. This was carried out in excellent taste and with but few plants.—E. J.

Chrysanthemum Hairy Wonder.—The fashion for the curious class of which this is the best was very short-lived—if, indeed, it ever existed outside of dealers' lists—and we now rarely see this variety. It is a flower worth growing because of its curious formation, the

rative or border class, growing barely 3 feet high. A year ago the few plants I then had were in their prime on November 18; this season they are about a week in advance of this. Both last year and again this season no protection of any kind has been given, and a line of it some 50 feet long; every plant of the lot bearing about three fine sprays similar to those sent, was a splendid sight. Although fine, the examples submitted hardly do justice to the fine rich colour, for they have been cut and in water since Thursday, the 9th inst. In the earlier stages the base of the florets displays a rich red-orange tone, thus adding a warmth of colouring invariably admired. What I value most, however, is the exceeding hardness of the variety; indeed, in this respect it is the

tended cultivation, seeing it comes so good and so late in the open air, more especially after the tropical summer we have had.—Ed.

NOTES ON VARIETIES.

In selecting sorts to grow, one must of course look to these exhibited at shows to be somewhat of a guide, but after having seen some thousands within the past few weeks, I have come to the conclusion that there are a considerable number, even of popular exhibition kinds, which are anything but beautiful. It is size, and size only, which makes almost every competitor for prizes include such in his collection. Of course, individual taste has a lot to do with the choice of varieties, but apart from its dimensions we cannot imagine anyone thinking the dull-coloured sort Mrs. C. H. Payne a beautiful type. Unfortunately, from this several others differing in colour only have been obtained by sporting, so that it is rarely one meets with a stand of blooms which does not contain the type, Mrs. G. W. Palmer or Mme. L. Remy. The one is a dull bronze, the other a dirty white. Yet another is forthcoming called M. Louis Remy. This is a yellow, and certainly the best, but there are so many really good varieties of all shades of that colour that I hope this will not become popular with exhibitors too. A careful look at the first-prize collection in the large class for four dozen distinct Japanese blooms at the Aquarium will illustrate my meaning, that although they are big, many of the sorts would not please a grower who may select them because they were included in the winning stand. Pride of Exmouth is a full deep bloom, but short in the petal, with little grace in formation, and not a pure white. Mr. A. Barrett is another sport from the variety just noted and has the same defects, being a large mop-like, ugly flower. Mrs. J. W. Barks is a very dull bronzy sport from a charming yellow variety, Edith Tabor. M. Hoste is big, but wanting in grace and substance, and Mme. Gustave Henry a bad white of flat, dumpy form. Mme. A. Brun does not appeal to me at all, and Susie has washed-out shades of white and rose. This stand contained many that were indeed charming, and a very good selection might be made from it. G. J. Warren, E. Molyneux, Mme. Carnot, Mrs. Mease, Phœbus, Nelly Pockett, Lady Hanham, Miss Elsie Teichmann, Mrs. Barkley, Surpasse Amiral, Vivian Morel, Emily Towers, Le Grand Dragon, Lady Ridgway, Eva Knowles, and Oceana are lovely types. So, too, is Lord Ludlow, a bright bronzy yellow of much refinement.

A very beautiful flower of President Bevan was to me one of the surprises of the year, and when its culture is better understood it will be highly esteemed. Its rosy buff tint is a charming shade, and its loose, incurving form perfect in its way. A magnificent white is Florence Molyneux, but like another grand white, Mrs. H. Weeks, it is, I believe, somewhat shy in producing such huge, well-formed blossoms, and one must grow but a single flower to a plant. A few choice varieties are: Henry Weeks, crimson; Hero of Omdurman, crimson, with buff tint; Mrs. Coombes, pink; Edith Dashwood, mauve tint; and W. Cursham, buff. These are among the best of Chrysanthemums, and all novelties of this year raised in this country by Mr. H. Weeks. J. R. Upton is a splendid yellow; it appears to me even finer than G. J. Warren. The colour is richer and its form is most graceful. The Wonderful has a name which is too high-sounding, at least until we see more of it. Roslyn is an advance in colour, the shade deep lake, quite a violet tint. The flower, too, is of capital form. Lionel Humphrey is a big reddish bloom, but there is a want of finish in its recurving shape. Mme. Desblanc, a clear pink of deep incurving form, will be esteemed by many who like this type of the Japanese.

From a point other than size and a useful yellow for cutting appears to be a variety named Klondike. The blooms are kept erect by a very

In the garden at Penjerrick. (See p. 413.)

downy nature of its florets being such a novelty. The sort is somewhat tender in winter and difficult to keep; hence its propagation will always be slow. Once established as a small plant, it succeeds well with ordinary treatment and blooms of large size are obtained. The colour is a decided tint of buff and varies in depth, the later buds giving the better colour. If other kinds of different colours equal to this were raised, there is no doubt they would find plenty of admirers and also add to the interest the Japanese varieties give.—H.

Chrysanthemum Golden Sheaf.—I am sending you a couple of sprays of one of my seedling Chrysanthemums which I have named as above. It is, as you will observe, of the deco-

rest I know. For this reason I hope to raise others from it. Though quite a fine display has been made by the plants, many of the central buds bore evidence of enforced blindness from the prolonged heat of summer, and I am surprised any blossoms so good as those sent ever appeared at all. Golden Sheaf is the result of crossing an improved and well-coloured form of Mrs. G. Wermig with pollen from Admiral Symons. The seedling has inherited the colour and strap-shaped florets of the pollen parent and partaken in the habit of growth somewhat of the seed parent—that is so far as height and freedom are concerned.—E. H. JENKINS, *Hampton Hill.*

* * * Very beautiful richly-coloured flowers. This variety is well named, and it is well worth ex-

stout stem. Golden Shower is of quite a different type and will be liked by those who care for the curious. It is reddish-bronze in colour, and the hair-like florets hang so lightly that it should prove a valuable kind for cutting. Etoile de Feu is another valuable kind, the red and gold being so bright and effective. There is just a suspicion of its not being a good one to last when cut, but it is so distinct that one must try it.

Nelly Pockett is charming from every point of view, she blooms the perfection of form, of pearly whiteness and with a stout stem. In bush form grown in small pots it makes a pretty plant. So, again, does John Pockett. The colour of this is distinct; Indian red with buff reverse would describe it. Master H. Tucker is a crimson-coloured sort and grand for general cultivation, but it is usually spoiled by the severe dis-budding adopted to make it come big. It may be grown large, it is true, but, as we mostly see it, the colour is not striking. Apart from their value as show blooms, that fine trio, Vivian Morel, George Davis and Lady Hanham, are excellent for all purposes to which Chrysanthemum flowers may be put, and William Seward in its rich crimson shade has few equals. H. S.

CHRYSANTHEMUMS AT LEWISHAM.

THE Ryecroft Nursery, now well known for its Begonias, Pelargoniums, and other subjects, is just now very gay, several large glass structures being full of Chrysanthemums. Considering there are about 7000 plants on view, the effect can be, perhaps, better imagined than described.

Although the Ryecroft collection contains the cream of all the foreign raisers' productions, there is a goodly number of varieties which are purely of Mr. Jones's own raising. It follows that many of these are not yet widely known, but there can be little doubt that in the future many of them will make a name for themselves amongst the most fervent admirers of the autumn queen.

Among Australian kinds of recent date, Mr. T. Carrington, Oceana, Wallaroo, The Wonderful, Nellie Pockett, and Fair Maid, a large Japanese of a delicate shade of pink, but rather tall in growth, are noteworthy. From other sources in good and effective shades of yellow, J. E. Clayton, a very pure, fine yellow sport from Eva Knowles; R. Hooper Pearsons, deep and rich; Mr. Gerald Williams, Sir H. Kitchener, Mrs. A. Cross, Solar Queen, and Hugh Crawford are worthy of special mention. Mr. A. Barrett, rosy buff; Edith Da-hwood, of nice form and of a pretty pink shade, are also good, but very much brighter and finer than the last named is Mary Molyneux. Lionel Humphrey is a fine crimson and gold of large size, and much more vivid in colour is H. J. Jones. Other sorts of varied form and colour are to be found in Mrs. W. Seward, H. Weeks, Lady Hanham, Mrs. Coombs, Emily Towers, Mrs. White-Popham, Mrs. Barclay, fine silvery pink, and Mr. W. Mease, a fine warm terra-cotta sport from the old favourite Etoile de Lyon. Of sports there were several interesting forms from well-known varieties besides those just mentioned, for we noticed a sulphur Mutual Friend, a yellow M. Chenon de Leche, and a most striking deep crimson sport from President Borel, which will certainly rank among the good things for the October displays.

Continental varieties, both new and old, include M. Fatzler, always good; Mme. C. Terrier, N.C.S. Jubilee, M. L. Remy, Mme. Gabriel Debrie, pale pink, one of M. Nonin's best; the curious green Mme. Ed. Roger, President Bevan, Rayonnante, M. Chenon de Leche, Mrs. J. Lewis, Le Grand Dragon, &c.

Although the collection contains a fine display of the highly coloured purples and crimsons, some of the paler and daintier colours are by no means less attractive, including G. J. Warren, and Mrs. S. C. Probyn, delicate pink. Good whites are represented by Simplicity, Mutual Friend, the newer Princesse Bessaraba de Brancovan, Jane Molyneux and the like. In hairy varieties there

were some excellent examples of Hairy Wonder, which still maintains its well-deserved reputation, the pure white variety known as White Swan, and a pale pink novelty called Prof. Jacquinet.

The incurred section, of which the Ryecroft collection contains a very choice selection chiefly for stock, is not largely represented in the annual display, but Mrs. H. J. Jones, a fine flower very deep and regular in build, is of a beautiful shade of pure white faintly tinted with pink. In another house there is a pretty display of freely flowered bush plants, which show very plainly that the Chrysanthemum can be grown and utilised for other purposes than merely figuring on the show-board. These comprise the very effective Ryecroft Scarlet, Mabel Williams (white), Ethel M. King, Pride of Mychett, Sunbeam (golden-yellow), the white Clinton Chalfont, White Quintus, Nellie Brown and several excellent medium-sized decorative Japanese which are of great service for this form of floral adornment or for cutting in quantity.

The collection, notwithstanding the inroads made upon it at this season of the year for the numerous exhibitions, contains many more sorts than we can conveniently find room to notice.

Hairy Chrysanthemums.—When the first of this class of Chrysanthemums (Mrs. Alphous Hardy) made its appearance in this country it was heralded by such a flourish of trumpets that one was inclined to look upon it as indispensable to any garden, and the varieties that succeeded it were just as highly praised. Now, however, many gardens and exhibitions of Chrysanthemums may be visited without finding a single representative of this class, except Hairy Wonder, which is far the best of the hairy section of Chrysanthemums. In a stand of cut blooms its distinct appearance singles it out at once for notice. This variety when first exhibited in the autumn of 1894 received an award of merit from the Royal Horticultural and a first-class certificate from the Chrysanthemum Society, but it was not half so much talked about as the earlier kinds which have not stood the test of time.—T.

Chrysanthemums—discarding old varieties.—Like "H." (p. 350), I think it has not been an unmixd gain by any means the loss of some of the older varieties, and undoubtedly some of those he names are as good as the best in cultivation to-day. The constant running after new kinds that are little, if any, improvement on the older ones has sickened many of the cult. It is a well-known fact that judges of Chrysanthemums give points to new kinds, and though a grower may stage equally good varieties and as well grown, a stand with new kinds in it takes the prize. I can bear out all "H." says in regard to Belle Paule. This lovely variety was very much admired when sent out some eleven or twelve years ago, and there is no more graceful or beautiful kind to-day that I know of, though having been out of the exhibition arena this last ten years, I am, perhaps, not so well qualified to speak as "H." Jeanne Délaux, or F. A. Davis, as it was at one time labelled, is also a lovely kind, but it was always a weak grower, and one of the kinds that cultivators some years back used to graft on a strong-growing kind like Comte de Germany. This variety, again, as far as I am aware, has never been beaten in its distinct colour, and is as well worth keeping as the somewhat uncertain E. Molyneux.—SUFFOLK.

Single Chrysanthemums.—These are again proving their value for conservatory and house decoration, nice little plants with heads about a foot across being easily grown in $\frac{1}{2}$ -inch pots. Such plants now covered with the charming Marguerite-like blossoms cannot fail to please, and as they are so easily reared, one never feels any compunction about their use in rooms where rare or valuable plants would be likely to be injured. They are of course just as useful for growing on into larger plants, but it is small shapely bits for room decoration, filling small vases and forming a change in groups of larger

kinds that are so much wanted now. Struck at various times from March onwards until June, they will be of various useful sizes. During their growing season they should be given a good light position outside, but not quite in the sun, as this is apt to make the lower leaves fall, and naturally with such plants as these it is important that these are kept on. It is not wise to overfeed these small plants, as the object is not so much large individual flowers as a pretty general effect. At the same time starvation treatment will not do, this also causing the loss of foliage noticed above. Liquid manure or top-dressings, the former once a week, the latter once in three, from the time the pots are well filled with roots will be ample.

—Whilst the present mode of exhibiting these exists they will never become popular. The flowers neither lend themselves to severe dis-budding nor to be staged on flat boards. To see them at their best the plants must be cultivated in a natural style and every bud allowed to open. I saw at one exhibition this autumn plants grown in the manner stated above used most effectively in a group by forming a groundwork. Plants bearing large blossoms were dotted in among them at irregular intervals, and the whole produced something choice in floral arrangement. Show singles are to my taste too large, and many of them are indeed manipulated to make them single, *i.e.*, florets are taken away which if left would make the variety what it really is, a semi double one. This habit brings disappointment to those who select kinds from exhibitions. My idea of a single variety is one that has but one row of florets and a good centre disc. Snow Wreath, white, and Miss Mary Anderson, tinted white, are capital forms. Another, Miss Rose, is quite alone in its habit of growth. This does not produce long, raceme-like branches as most of the sorts do, but forms a dwarf, bushy plant that gives a level-looking mass of pretty light rose colour. From those at present in bloom the following are selected as excellent in every way: Annie Tweed, crimson, of a dark shade; Earlswood Beauty, white; Emily Wells, rose colour; Eucharis, white; Framfield Beauty, crimson; Golden Star, yellow; King of Siam, crimson; Miss A. Holden, light yellow; Mrs. D. B. Crane, cerise-pink; Mr. A. Double, terra-cotta; Purity, white; Rev. W. E. Renfrey, purple-red; Scarlet Gem, bright terra-cotta; and Snow Wreath, white.—H. S.

CHRYSANTHEMUMS AT CHELSEA.

MESSERS. VEITCH AND SONS have a collection of Chrysanthemums that shows great discrimination has been exercised in deciding what varieties shall be admitted into it, and also that considerable care is bestowed upon it in growing the plants for exhibition at this time of the year. The number of varieties may possibly be fewer than at some of the trade displays, but at any rate they are of the best in their various sections, and, considering the disadvantages that the town growers of the popular flower labour under, it is surprising to see what can be done under adverse circumstances. Chelsea is not the best place in London in which to grow the Chrysanthemum, yet we have never failed to be surprised at the finely-developed blooms we always see there, and occasionally, as this year, when our call is early enough in the season, to find the colours so clearly and nicely defined, for it is chiefly perhaps in this respect that the country-grown blooms show the difference to an ordinary observer. In the large span roofed house devoted to the major part of the collection we noticed first of all H. Weeks, a large Japanese, with florets slightly curly at the lips, colour dull crimson, with reverse of gold. Emily Towers is another large Japanese, with broad florets, colour white, tinted purple.

Some good varieties of Calvat's are there, and notably N.C.S. Jubilee, a beautiful silvery pink variety now well known. Then M. Fatzler is good everywhere, and we can say this with certainty, having seen blooms in London, Paris, and Lyons.

Le Grand Dragon, M. Chenon de Leche, Mme. Carnot, and Soleil d'Octobre have all been described many times, and are at once standard sorts and eminently suitable for all purposes. The curious green Mme. Ed. Roger is in good form, and among other varieties from this source Mrs. J. Lewis, a white introduced a few years ago; Marie Calvat, white, shaded purple; and Louise, a beautiful pearly pink Japanese incurved, do remarkably well. In various tones of yellow from pale sulphur to the richest golden we see such grand things as Mrs. W. Mease, Lord Ludlow, Phœbus, Modesto, Princess Charles of Denmark, Sir II. Kitchener, and R. Hooper Pearson, while whites are well represented by Mrs. Weeks, Elsie Teichmann, Nellie Pockett, Kathleen Rogers, big and solid, Lady Byron, and Mrs. C. Blick. W. Seward is fine in its velvety deep crimson. Rayonnante is a curious deep pink porcupine variety, and in purples Mr. T. Carrington, Australie, and Mrs. White-Popham all help to brighten up the group. Chatsworth, a colonial variety seen last year, is very good again, and other brightly coloured sorts are still used at Chelsea in such as J. Shrimpton, Hairy Wonder, Pride of Stokeil, J. Bidecove, &c.

In another house a lot of very useful bush plants is flowering freely, and only shows to what uses the Chrysanthemum can be put besides being grown for exhibition. Very attractive are some of the popular show sorts in this form, and Messrs. Veitch have some nice plants of W. Tricker, Souvenir de Petite Amie, J. Shrimpton, October Yellow, Charles Davis, W. Seward, Source d'Or, Dr. Sharpe, Lady Selborne, Mme. Carnot, and it would be difficult to say how many more.

NOTES AND QUESTIONS.

Chrysanthemum Firefly.—This Anemone pompon is not nearly so well known as it deserves. It is a reddish coloured blossom with a bronzy-yellow disc, and is one of the most effective small flowers. For associating in a limited degree with yellow and orange-coloured Chrysanthemums it is unequalled. Under artificial light growers will find this sort a splendid acquisition.

Chrysanthemum Chrysanthe Bruant.—This is a distinct acquisition to the incurved section, and during the past fortnight has been exhibited in several leading stands. The blooms are large with beautifully incurved florets of good breadth, early flowers opening a rosy buff, later buds developing large globular flowers of a chestnut-bronze colour. The plant is of medium height, and is also of easy culture.

Chrysanthemum H. J. Jones.—On account of its colour this was thought highly of last autumn, and it certainly is an advance in that direction. A bright crimson-scarlet is a tint really wanted. The size and form of the blooms are excellent. Probably there is a shortness in the florets that will not please exhibitors, as sorts not having long ones cannot build up a flower of huge dimensions, but in every other respect it may be recommended.—S.

Chrysanthemum Hanwell Glory.—Though only seen for the first time at the end of last season and not distributed until the spring of the present year, growers of the incurved type of the Chrysanthemum have already recognised the merits of the flower for exhibition. Beautiful examples have been freely exhibited, large, deep, globular flowers of a bright bronze colour, each bloom neatly incurved. Like the newer Japanese sorts, the incurved blossoms are getting larger.

Chrysanthemum Clinton Chalfont.—This lovely Japanese Chrysanthemum has always been regarded as an October-flowering variety, but, owing to a late season, blossoms of a bright rich yellow are now and have during the last week been at their best. The colour deepens slightly in the centre of the blossoms. The plants should be disbudded, as in this way the blooms develop into a useful size and the growth makes a stout, erect flower-stalk. For cutting it is invaluable.—D. B. C.

Chrysanthemum Sœur Melanie.—This fine old hybrid pompon has been very fine during the past fortnight in the open border, and within the same period several instances of its beauty have been seen in the cottage gardens a little way removed from the

London smoke. The plant possesses a robust constitution, is also fairly dwarf, and without being disbudded produces charming blossoms for cutting, comparing favourably with many of the newer kinds. Catalogues describe the flower as pure white, but grown in the open the blossoms are slightly tinted brown.

Pompon Chrysanthemum.—The rage for large blooms of Chrysanthemums still continues, and as a result of it the pretty little pompon varieties are often disbudded to such an extent that much of their true character is lost. This feature was very noticeable at the recent Aquarium show both in the case of cut flowers and of specimen plants. One of these latter—Sœur Melanie—was so severely treated, that the blooms regularly disposed over a formal specimen were far too large to be regarded as pompons, and in beauty they did not compare with those of the same variety grown in a more natural manner.—F.

Chrysanthemum Mrs. Mease.—Of the three members of the Mme. Carnot family, the variety under notice has done exceedingly well this season, and from a practical point of view probably more flowers of typical form have been seen of this variety than of either of the other two sorts. Reports have been current of the large number of buds which have failed of both Mme. Carnot and G. J. Warren, but of the lovely pale primrose blossoms of Mrs. Mease little news of failure has been heard. It is the most refined flower of the trio, and for the second time has been selected as the best Japanese bloom in the great show of the National Chrysanthemum Society.

STOVE AND GREENHOUSE.

THE NIGHT-FLOWERING JASMINE, OR DESERTED SWEETHEART.

(ARABIC, EL MAHBUBEH EL MATRUKEH.)

AMONG the many interesting tropical trees and shrubs introduced into Egypt during the time of H. H. Ismail Pacha there is one which seemed to have almost, if not quite, disappeared from cultivation when it was re-imported from India a few years ago by Mr. G. B. Alderson, of Ramleh, in whose garden it flowers annually at this season. The botanical name is *Nyctanthes Arbor-tristis* (L.), and it is nearly related to the Jessamine, especially the *Jasminum Sambac* of our gardens. It is much cultivated in the East Indies and Burmah for its honey-scented flowers, which are also used in dyeing.

In describing this small tree or shrub in his "Flora Indica," 1832, Dr. W. Roxburgh says:—

Of what country this is a native I know not, for I have never found it but in a cultivated state, and it is always raised from seed, which may be the reason we have no varieties of this most delightfully fragrant plant. In our Indian gardens it is found in the state of a large shrub or small tree. It flowers on the coast nearly all the year round, but in Bengal only during the rains. The seeds ripen in the cold season.

Dr. Wallich says he found it in an apparently wild state near the banks of the Irrawaddy on the hills near Prome. It delighted the celebrated Dutch traveller, John Hugh Linschoten, who published an account of it with a quaint plate exactly 300 years ago in his book of travels into Portuguese India, annotated by the well-known botanist of that day, Bernard Paludani. Linschoten's description is in Latin, of which the following is a translation:—

The sad tree.—A tree which is called "sad" because it only flowers by night throughout the year may be reckoned among the marvels of Indian vegetation. Even at sunset no flowers appear, but soon after the expiration of half an hour it is conspicuous for the beauty of its numerous blossoms, which fill the nostrils with their sweet odour. With the rising sun these flowers fall off and the ground is quickly covered with them, as it were in grief at the demise of the tree; the latter, reviving again in the evening, proceeds to flower and lose its flowers alternately by night

and day through the year. It is of the size of Plum tree, and much in request in the vicinity of houses for its fragrance; it is of great vitality, as even if cut down to the ground, after six months the shoots will be covered with flowers, and if a branch is pulled off and inserted in the ground it will forthwith proceed to flower and shed its blossoms. The flowers are like those of the Citron, but their tubes (eyes) are reddish yellow; they are used in the same way as saffron both for dyeing and cooking; not that they are of equal value or flavour, but they take the place of saffron when the latter cannot be procured.

Dr. Paludani adds to the above that—

Many persons consider that the distilled juice of the flowers is good for affections of the eyes if folds of linen are dipped in it and then applied to them. "This tree, continues Linschoten, "is only found in Goa, Malacca, and other places where the Portuguese have planted it about their residences. It was, without doubt, first brought to India from Malacca. It is not found in the interior."

In the Malay language it is called Singady, and by the inhabitants of the Deccan, Parisitico or Pul, by the Arabs Guart, and by the Persians and Turks Gul. They explain the origin of the name by the following Indian legend:—

There was a certain nobleman named Parisitico whose exceedingly beautiful daughter was wooed by the sun, and when, dazzled by his charms, she had surrendered to the importunity of so glorious a lover, she was basely deserted by him for another damsel of whose beauty he had become enamoured. Hence the grief of the deserted one, who in a fit of sad despair put an end to her own life. The corpse was placed on a funeral pile and consumed by the flames. They positively assert that this tree sprang from the ashes of the betrayed beauty, and that, in token of her grief and indignation, it sheds its flowers with the rising sun and closes its petals, preferring to exhibit its testimony of ceaseless weep during the gloomy hours of night.

The inconstancy of the moon is a favourite theme with western poets; but here we have a favourite plant of a "Peuple de l'Orient" as their emblem of the fickleness of the sun. The Portuguese made many attempts to cultivate the "sad" tree from seed in Europe, but never succeeded, and Dr. Paludani says that he had no better luck with the seed brought to him by Linschoten. Dr. l'Ecluse (Clusius), who was at that time director of the Botanic Garden at Vienna, and the most distinguished botanist of the day, thought that the falling off of the flowers at sunrise might be caused by the poverty of the juices of the flower which the rays of the sun dried up, as he noticed that these flowers which were least affected by the sun lasted longer than the others.

The climate of Alexandria is probably the northern open air limit for the growth of this tropical tree; here it flowers only once a year, and during the month of October. There is another tree, introduced into Egypt by Ismail Pacha from the Straits of Malacca, but since disappeared, which has the same habit of flowering by night and shedding its blossoms in the morning—*Barringtonia speciosa* (L.)—known to our Singapore colonists as the Painter's Brush, from the appearance of the flowers before they expand; these consist of four white petals and a great number of stamens about 4 inches long, the inner half of which is coloured white, the outer half rose-coloured and the anthers bright gold. The stamens are closely packed together before the flower expands, but after sunset they radiate outwards in a circle, having somewhat the appearance of a huge Passion Flower, but more beautiful. After sunrise the ground is strewn with these splendid flowers which have

a delicate scent. The tree is handsome, with evergreen leaves as large as those of a Cabbage. *Alexandria.* R. M. B.

Ruellia macrantha.—This is to a great extent a neglected plant, for it is one of the prettiest of warm greenhouse or stove species, yet not by any means popular. The propagation is easily effected by cuttings, which require a little bottom-heat to root freely, and as soon as struck may be potted singly and grown on in plenty of air and light in the stove. Frequent pinching in a young state is advisable to cause a branching habit, and the flowers will occur freely towards autumn in bunches at the leaf axils. The colour is a pretty bright red with white stripes.

Curculigos.—The value of these plants is often overlooked, and Palms being so cheap and plentiful they are in danger of dropping out of cultivation altogether. This would be a pity, as there are several very handsome species, notably *C. recurvata*, which, though not so well able to stand drought and ill-treatment as some of the hardier species of Palms, is very useful for house decoration. Curculigos are easily propagated by division and removal of the young growing points with a few roots attached, potting these up singly and placing over a little warmth. The compost should be substantial and a liberal water supply afforded while growing.

Hedychium coronarium.—White and fragrant flowers are always in demand, especially when, as in the case of this pretty Ginger-wort, they are produced in a dull season. Its culture is not difficult provided sufficient warmth can be maintained, but nothing like a dry atmosphere is likely to be productive of good results. If the temperature and abundance of atmospheric moisture are well kept up, then progress is rapid from the time the plants commence to grow. The plant should be rested a little in winter and started in spring. The compost may consist of equal parts of loam and peat, with a liberal admixture of half-decayed cow manure and a sprinkling of sand.

Rivina humilis.—Many people grow this pretty berried plant in far too much heat and heavy shade, the consequence of this being that the berries fall off with the least disturbance and the leaves fall early, leaving a half bare-looking plant. I saw a nice batch recently that had been brought on slowly in a cool greenhouse with barely any shade, and these were very pretty and useful, the berries of good colour and so firm, that a vigorous shake was necessary to make them fall. This untidy habit is the only fault of the plant, which is one of the most graceful and pretty in cultivation, and if it can be partially overcome in this manner it is worth doing.—C.

Imported Liliium auratum.—The first importation of *Liliium auratum* this season was disposed of in the London auction rooms on November 8, and though limited in numbers, they were in a very satisfactory condition, better, I think, than the first importations have been for some seasons past. They appeared to have been better ripened previous to packing than the earliest ones sometimes are, as many of them are often unsatisfactory; indeed, two years ago a great many of the first consignment perished completely. As comparatively few were offered on November 8 and the bulbs were plump and sound, they realised of course good prices; still, for all that, I much prefer the later importations, which are generally sounder and heavier than these early ones.—H. P.

Carnation Miss Audrey Campbell.—As recently stated, yellow Carnations that will bloom during winter and spring under pot culture are the scarcest of all. Those, however, who like the colour and wish for a supply in winter should grow Miss Audrey Campbell either in pots from

infancy or lift plants from the open border in, say, September and pot up. A lady living in North Wales wrote me last week, stating that she had lifted this variety from the open garden, and the plants are now laden with partly expanded and smaller buds. Perhaps the best thing to do in the case of border plants would be to keep the majority of blooms picked off during the ordinary flowering season, or say up to August. One of the best features in the character of Miss A. Campbell is its continuous habit of flowering. I remember Mr. James Douglas telling me, several years ago, that he had had it in bloom all the winter. Its form, size and colour are excellent.—N. N.

Berried plants at Chrysanthemum shows.—Some Chrysanthemum societies have a much more varied schedule than others. By this I mean the inclusion of subjects other than Chrysanthemums. Some now have a class for Violets, which is generally well filled, the fragrant exhibits affording much pleasure to visitors. Poinsettias, Primulas, and Orchids are likewise included. There is, however, another class of plants worthy of representation at such meetings,

with plants of the Begonia. The flowers remain fresh a long time, while the golden tuft will continue effective long after the petals have dropped.—H. P.

GARDEN FLORA.

PLATE 1250.

SEEDLING VERBENAS.

(WITH A COLOURED PLATE OF V. ELLEN WILLMOTT.*)

If the Verbena is to regain its lost popularity it will probably be through the medium of good strains of seedlings. Several new named kinds have recently appeared, and some have been certificated, this fact being considered an augury of returning popularity, but the same diseases and the same causes that carried away the good Verbenas of days gone by will again appear and have a like effect. The difficulty

Dicksonia antarctica in the open air at Penjerrick. (See p. 413.)

namely, the berried section. A class for Solanums would be sure to be well represented, and what more showy when well grown and fruited? Then the pretty brilliant berried *Rivina humilis* would not lack admirers, having a grace and beauty all its own. Well-berried bushes of *Skimmia japonica* and other varieties would also prove very effective.—J. C.

Begonia Aigrette.—This distinct form of *Begonia semperiflora* was recently illustrated in the French journal *Le Jardin*. It was exhibited at a meeting of the Horticultural Society of France and attracted a good deal of attention. This particular variety originated from seed of *B. semperiflora atropurpurea*, of which in foliage and habit it is an exact counterpart. The distinguishing feature is the male blossoms, the centre of which is filled with a dense globular mass of staminoïd segments of a brilliant yellow tint, thus forming a striking contrast to the red petals and deeply tinted foliage. This variety is said to have been proved for two years in the open ground during the summer, when in a mass the yellow portion of the flowers presented the appearance of *Calceolaria* blossoms intermixed

lies not so much in summer culture as in winter preservation, when fungoid and other insect pests infest them and debilitate the stock, which thus becomes useless either for propagation or subsequent planting out. All this evil can be avoided by relying upon a fresh stock of plants raised each year from seed. If those who are trying to popularise and improve the Verbena would work with a view to securing good strains in distinct self colours of kinds that could be raised from seed, and be relied upon to come fairly true, their labour would be better rewarded. In many gardens we have seen excellent batches of Verbenas, as healthy and free blooming as the most fastidious could desire. The plants were raised from seed, which is sold

* Drawn for THE GARDEN by Mrs. Hensley in the gardens at Warley Place. Lithographed and printed by J. L. Goffart.

VERBENA ALIEN WINDT.

in separate colours, and these from the seed in question proved very true in colour and habit of growth. At all times healthy seedling plants have an immense advantage over those propagated by cuttings from a stock which has been coddled, and is perhaps debilitated and diseased. There is no reason why the Verbena, like Asters, Stocks, and other things, might not be improved in this way and rigidly selected until we have distinct strains rich in all the variety of hues characteristic of the flower producing seed, which saved with care and in separate colours might be thoroughly relied upon. There is no need whatever for naming different kinds,

garden, where Verbenas grow particularly well. One year I noticed among them an unusually large flower of a beautiful shade of pink, and seeing that the plant itself was very vigorous and that the duration of its flowering season was beyond the average, and that it was even more free-flowering than other Verbenas, I propagated exclusively from it. Now the stock is practically unlimited, and I give away many thousands of plants every spring.

THE WEEK'S WORK.

KITCHEN GARDEN.

SALADING.—At this time of year, and indeed till spring, salading in its varied forms is in great

Arundinaria nobilis at Penjerrick. (See p. 413.)

which, so far as the Verbena is concerned, only tends to limit its culture; moreover, in the newer and finer forms of Phlox Drummondii we obtain distinct strains in separate colours, which in their way are equally as good as Verbenas, yet we do not trouble to name them. The giving of separate names is too frequently adopted, and could easily be dispensed with in many families of popular garden flowers.

Miss Willmott, of Warley Place, who raised the fine variety we figure to-day, says:—

I used to raise several thousand Verbenas from mixed seed to plant a long bank in my Tresserve

demand, and it behoves gardeners to preserve intact any surplus batches of Lettuce and Endive which were left on the borders when the pits and frames were filled, as it seldom happens that there is any too much left in those structures in March and April, particularly after a severe winter. Those possessing a Peach case or orchard house may well utilise them for accommodating both Lettuce and Endive. With a free and constant circulation of fresh air damp will cause very little trouble. In this position it is an easy matter to blanch them piecemeal by darkening the plants with flower-pots when not laid in too closely, or by laying one or more garden mats, or even sheets of brown paper, over them. Of course, any plants so housed must be used first, as at the approach of spring, tree cleaning and surfacing will necessitate a complete clearance of everything from the house. When lifting, secure as good a

ball as possible, as this makes all the difference. In regard to watering, it is best to soak the balls to settle the new soil round them after a few dozen have been laid in, as then the foliage can be laid on one side and the water prevented from going into the centres. Many blanch Endive in the Mushroom house, a very convenient way, but in my opinion the leaves are never so crisp and enjoyable as when treated to a comparatively cool place. Where Chicory is esteemed, a batch of roots may be introduced into the Mushroom house at the end of the month, Dandelion being served in the same way. If these various subjects are used say alternately, they make a very pleasing change in the salad bowl. All younger batches of Chicory that are left in the open border must not be neglected, or severe frost following soaking rains may work irreparable mischief. Nursery beds of Lettuce, such as All the Year Round and Hardy Hammersmith, which according to previous advice have been surrounded with boards furnished with cross-bars, must be covered with mats or canvas every evening if the weather looks in the least threatening. There is nothing better than dry leaves for protecting rows of Brown or Hick's Hardy Cos Lettuce at the foot of south or west walls, this being proved after severe weather by the frequent green, fresh-looking condition of plants which have been accidentally covered with them, others unprotected by their side being very often damaged or destroyed. The chief thing to be observed in the management of all kinds of salads in the frame-yard at this particular date is careful ventilation. It is always best to keep the lights continually tilted over the Endive frames in order to preserve the leaves in a dry condition, as if laid in soil close to the glass, 10° or 12° of frost will often work mischief when the centres are wet. Lettuce planted in October, likewise Cabbages in frames, will now be all the better if the soil is stirred with a small rake, giving afterwards a sprinkling of soot or soot and wood-ashes, as in wet or damp weather slugs are always troublesome. Remove dead and yellow leaves at short intervals and avoid coddling, or indeed covering of any kind, unless the weather is unusually severe.

HOTBED MATERIAL.—In gardens where early Potatoes, Peas and Carrots are expected early in the new year it will be advisable to commence to get together such material as good Oak or Beech leaves, stable litter of a somewhat long character, and, indeed, any loose littery garbage from the general rubbish heap, as it is astonishing what a quantity is needed for building up a good-sized hotbed capable of accommodating several two- or three-light frames. The beds will not be made up at the earliest before the middle of December, but as a general rule leaves and litter are only forthcoming piecemeal, and ample time is necessary for accumulation. Where shed room is at command it is likewise expedient to remove under cover a liberal quantity of suitable material for planting and sowing these early forced vegetables in, as it is most uncertain what the weather may be like when the time for the work arrives, and nothing is so hindering or detrimental generally as cold, sticky compost.

PEAS IN POTS.—December will very soon be upon us, and where early dwarf Peas are grown in pots preparation must soon be made. William Hurst, Chelsea Gem, American and English Wonder are all good for the purpose. Use 10-inch pots and a rich, open, loamy compost. Road scrapings are excellent as a corrective in pot Pea culture, also a sixth part well-decomposed manure. It is not wise to exceed this quantity, or a sappy, unsatisfactory growth will follow, and it is always an easy matter to apply artificial manure later on. Allow a good margin for water and earthing up when the haul is some 3 inches high. Give good drainage and a light, airy position near the roof-glass, and if possible not far from the ventilators. Do not exceed a night temperature of 45° for the present, nor give much water till growth appears well above ground, or the seed will be liable to decay.

J. C.

FRUITS UNDER GLASS.

POT STRAWBERRIES.—Probably by the time these notes appear a reminder that winter is at hand will have come to us in the shape of moderately sharp frosts, warning us that those things which require winter protection of some sort must soon be attended to. I am no advocate for wintering pot Strawberries under glass, as I find that the crowns are best suited by exposure, but the roots require something more than the pots to preserve them from injury in very frosty weather. Having tried almost all the various ways recommended for wintering the forcing Strawberries, I have come to the conclusion that plunging the pots in ashes quite up to the rims is the best way, and gives them as nearly as possible the conditions they would be under if planted outdoors. Ashes protect the pots, and it requires more than the frost of an ordinary winter to do either them or the pots any harm provided they are sunk quite to the level of the bed. Stacking the pots is a worse method in more ways than one, for the pots do not protect each other nearly so well as do the ashes, and, for another thing, the soil in some of the stacked pots is very liable to become drier than the roots like it to be. For the latter reason I also object to bringing the plants under glass to winter, as the drier conditions of even cold houses or frames prevent the uniform moisture which, as I think, the plants enjoy, provided the pots have been well drained, and these conditions are not to be attained through the use of the water-pot, no matter how carefully it may be used. Again, it is well known to those who have to force almost any kind of crop early that frost provides the one thing needful for a kindly start, and unless they get it they are difficult to move, and this applies quite as much to Strawberries as it does to our Seakale, Rhubarb and other things. Bringing them under glass at this early date, or, indeed, before it is really necessary to do so, though it may be the easiest way of dealing with them, deprives them of the undoubted advantages they gain by being subjected to frost. All that is necessary is to bring them under cover soon enough, before starting them into growth, to allow the surface to get dry enough to bear the ramming which may be necessary, and this must not be done when the soil is wet. Of course, those batches which are to be started almost immediately need not be plunged, and will be all the better for full exposure to the weather right up to the time when they must be brought in, as we rarely get frosts of any great severity much before Christmas.

FIGS.—Pot Figs which were brought into their forcing quarters as suggested a week or two ago will now show signs of being on the move, and should be plunged in some of the fermenting material—leaves and manure, or leaves alone—which has been in the course of preparation during the past few weeks. Take care that this material is not too hot and that the temperature does not rise rapidly after the pots are plunged. Leaves alone rarely do this, but I like to have a little stable litter mixed in for the sake of the ammonia given off, and which always appears to impart a healthy growing atmosphere to the house. The amount of care necessary to attain success with hotbeds is really very little, as it is very easy to reduce the temperature when it rises too high by making a few holes in the bed. These need not be large, but should be deep enough to get well below the centre of the bed, as it is this middle portion which becomes hottest. After the holes have been open for a day or two, the material pulled out may be again returned. For testing the temperature, a few test pegs—strong pointed stakes—should be pushed well down into the bed here and there, and if these are drawn out and felt at intervals of a few days, it is easy enough to detect and regulate any immoderate fluctuations of temperature. Remember that in forcing at this time of the year, slow and steady should be the order of progress. Use the syringe in moderation, and in its use be governed by the state of the weather outside and by the chances afforded for ventilation, as excessive humidity of

the atmosphere is really harmful to the Fig during the winter season, and tends to the production of flabby leaves that cannot resist the attacks of rust. Take care that the roof-glass is clean and bring the plants as near to it as possible. Rather low span-roofed houses, with a good big centre bed for the trees, are the best and most convenient style of house for pot Figs. Whenever the weather is at all fit and sharp draughts can be excluded, a little air should be given daily, but beware of having both top and bottom ventilation on at the same time unless the outside air is unusually mild and still. Generally speaking, top ventilation is the safest, and this should be given on the leeward side of the house. The minimum night temperature may now be raised to 60°, with the usual rises by day and with sun-heat.

ORCHARD HOUSE.—The Chrysanthemum season will soon be on the wane, and where the orchard house has been devoted to these plants for the past month or two, the earliest opportunity should be taken of clearing them out so that the house may be washed down and put in order to receive the trees. Of course it will not be necessary as yet to bring in the trees unless they are wanted for forcing. Still, it is more convenient to have them at hand in order to carry out any repotting or regulation of the drainage if these operations were not carried out as recommended soon after the fruit was picked and before they were taken into the open. Other advantages of having them under cover are that they may be kept drier at the roots and that they are safe from the attacks of birds on the buds, as a pair of bullfinches would very soon strip all the flower-buds from a set of pot dessert Plums, of which they are particularly fond, and they are capable of doing much mischief without being observed. While writing of these mischievous birds it may be as well to point out that, contrary to the generally received opinion, they do even more damage in mild weather than they do when it is frosty, so there should be no false idea of security up to the time when winter sets in. Where any of the older pot trees are getting unwieldy or unhealthy, they should be replaced with some new stock. The present is a good time to secure such from the nurseries, and in choosing them make sure that they are on clean stems at the point of union between stock and scion, also that they are well set with fruiting-spurs and healthy, though not gross, in growth. Nursery trees frequently want potting when they are bought in, and in any case it is advisable to examine their roots, potting those which need it and regulating the drainage of those which seem capable of going through another season in their present pots. Do not give large shifts, and see that the potting mixture contains plenty of porous material in the way of mortar rubbish; also remember that firm potting and planting lay the foundation for good fruiting wood. Keep the house for the present fully ventilated, even to the extent of admitting a few degrees of frost, as this will do good to the trees, but do not forget to empty the hot-water pipes, if any, or if this is inconvenient, sufficient heat must be kept in them to keep up circulation of the water to prevent them from bursting if the weather turns severe.

VINES.—The greater portion of the pruning should take place before Christmas, even though the Vines are not to be started for some months, for there is no need for further delay when the crop is off and the leaves fallen. Early pruning relieves all anxiety as to bleeding, and there is then no need for using styptic. Most Vines may be pruned as recommended for Black Hamburg a week or two back, but Gros Maroc, Gros Guillaume, and one or two other coarse-growing varieties do best when pruned on the long-spur principle. In shortening back any young rods which may have been run up, do not be led away by the wonderful reports of Vines which have filled their allotted space at express speed and given heavy crops. I do not doubt the facts, but such Vines do not last long and are not suited for private places, where the clearing out of a viney

means a sad gap in the supply. Of course, where houses are plentiful this gap would not be much felt, but if we require Vines that will live and bear good crops over a long period they must be built up gradually, and young canes must be cut back at each pruning beyond the point where the pith is large and the wood on the soft side. Progress may be slower in this way, but there will be less trouble in the end. Continue thoroughly cleaning both Vines and houses, especially the houses, as fast as opportunity arises.

CORNUBIAN.

OCTOBER IN SOUTH DEVON.

THE autumnal tints of the past month have been particularly varied and bright, and have entirely eclipsed the October display of the three years immediately preceding. Last year, indeed, the leaves had scarcely commenced to change colour by the end of the month, and it was not until December that the Elms in the valley showed their brightest yellow in the scanty remnants of foliage that had not fallen. This year, however, many of the Elms are already almost bare of leaves, and the woodland glows with its pageant of daily shifting tints. The Beeches' ruddy copper flames afar; the Spanish Chestnuts gleam in robes of amber, orange, and russet; the Scarlet Oaks flaunt their brilliant hued foliage; on cliff face and house wall the Virginian Creepers spread their crimson mantle; the Vines show wondrous tints of purple, bronze, and maroon in their symmetrical leaves, some of which glow with a rich scarlet when the rays of the setting sun fall athwart them. In the garden many of the shrubs and trees, such as the Sumachs, *Koeleruteria paniculata*, and *Amelanchier*, are particularly decorative at this season of the year. A spreading specimen of the *Amelanchier* standing on a lawn backed by a magnificent Cedar of Lebanon created a lovely picture in mid-October. In the hedgerows there is a marvellous profusion of berries this autumn. The wild Guelder Rose is bright with its clusters of crimson fruits that look like large semi-transparent glass beads. Now that the high Hawthorn hedges are for the most part denuded of their leaves, the long lines are flushed deeply red with the innumerable haws that stud so thickly the thorny twigs. Here and there is a spot of brighter colour where the scarlet haws of Dog Rose or Sweet Brier gleam a vivid scarlet, or the berried Bryony hangs its tangled skein from the straggling hedge. The Holly is bearing a multitude of berries such as has not been seen for many a year, and in consequence predictions of a severe winter are to be heard on all sides. Very pretty are the effects produced by the large Holly bushes standing up from the hedgerows with their countless clusters of vivid tinted berries thrown into high relief by the sombre foliage, while now and again a charming picture of natural artistic grace is provided where some tall bush is festooned with the wreathing, smoke-grey trails of the Traveller's Joy (*Clematis Vitalba*), between whose feathery seed-vessels the scarlet berries gleam and the dark green polished leafage shows. Early in the month along the verges of copse and spinney the coral-pink Spindle-wood berries displayed their soft colouring, but these trees, curiously enough, contrary to the case of almost every other berry-bearing subject, in most instances fruited more sparingly than in former seasons in this immediate neighbourhood.

In the shrubberies the Barberries have been very attractive with their slender arching branches thickly strung with clusters of small bright red tubular fruit, and the Ivy garlanding old tree trunks and ancient masonry has been daily murmurous with the host of insect life that has haunted its blossoms. Early in the month a few slight frosts played havoc with the Dahlias and Heliotropes in some gardens, but in others no damage was done, and these at the present time contain Dahlia plants no leaf on which shows a suspicion of frost-bite. This year the title applied to the week in which St. Luke's Day occurs of

St. Luke's summer has been no misnomer, for from one day before to seven days after that date the weather has been warm, still, and rainless, and the fair sprinkling of martins and swallows that still remained with us seemed justified in their tardy departure, though the rain and wind that set in after this spell of halcyon weather must have rendered them dubious as to the wisdom of their late stay.

Sheltered gardens that have not been touched by the frost have exhibited a fair amount of brightness throughout the month, in the early days of which the giant spires of the *Acanthus* were still decorative. *Achillea ptarmica* fl. pl. The Pearl has not ceased producing its small double white flowers, and the Sweet Alyssum yet clothes a high bank with its honey-scented blossoms. *Anemone japonica alba* Honorine Jobert has bloomed throughout the month, and the flesh-pink variety has been especially noticeable in many cottage gardens. Though inferior to the white form both for indoor and outdoor decoration, it is of a pleasing shade of colour and entirely lacks the crude tint of the type. At the commencement of October many of the *Belladonna* Lilies were still in bloom, but the flower *par excellence* of the month was the

Starwort, or perennial Aster. Exquisite colour-schemes are afforded by a collection of these subjects on a bright and still October day, the soft hues that melt suavely into one another and the varied heights of the plants completing a picture in which the beauty of distinct form is enhanced by harmonious tints. Staking is a necessity in the case of the taller Starworts, or their branches will be levelled to the earth, especially if their leaves be wet, by the first storm, but this operation requires to be carefully undertaken, or the effect produced will be the reverse of artistic. In many cases the process of staking is not taken in hand until the plants are in flower, when a large stake is driven into the centre of the clump and the flowering growths tied tightly to it. Such a method of procedure, which may well be termed "torture at the stake," effectually destroys the natural grace of the plants, which with their bunched-up flower-heads, some turned inward and some outward, present the appearance of a sheaf of corn instead of exhibiting the characteristic elegance that is the feature of their slender branching flower-sprays. The central support should be inserted into the clump before the plants have quite completed their growth, and several green-painted Bamboo canes of a suitable length firmly fixed, with a slight outward inclination, around the circumference of the clump an inch or so within the outermost shoots. These canes can be loosely looped together with tarred twine, and connected here and there by the same material to the central stake. Treated in this manner the plants retain their natural grace of contour, while the staking is practically invisible, and are enabled to withstand all but exceptionally severe gales without any impairment of their ornamental qualities. Of the tall Starworts, the most effective has been *Aster Novi-Belgii* Robert Parker, the tall branching flower-sprays, often 6 feet and more in height, set with pale mauve, golden-centred stars that are not so crowded as to detract from its graceful appearance. *A. puniceus pulcherrimus* is another handsome plant, attaining under favourable conditions a height but little inferior to that of the last-named variety. Its flower-shoots are, however, of far robusiter growth and their side sprays shorter, while the blooms, that are of palest mauve, turning to white, hide the shoots in their profusion. *A. N.-B. Harpur-Crewe*, an early-flowering white variety, had lost its beauty at the commencement of October, but the later blooming whites, *niveus* and *polyphyllus*, were decorative for a longer period, while the dark, purple-blue *A. N.-B. Archer-Hind*, with *A. N.-B. Pluto* and *A. N.-B. Flora*, both dark-flowered varieties, retained their blossoms well through the month. *A. Amellus bessarubicus*, the first Starwort to expand its flowers, continued to bear its large purple-blue,

golden-centred blooms, and the white *A. cordifolius* and its lilac-blue variety, *A. c. elegans*, bore their spreading branches thickly studded with diminutive flowers, while the little *A. ericoides* produced its tiny white Daisy-like blooms, and the old cottage favourite, *A. diffusus horizontalis*, its small maroon and white flowers. Of the *Novæ-Angliæ* section, the purple *A. N.-A. Melpomene* and the rosy *A. N.-A. ruber* have been effective, while *A. grandiflorus*, the latest of all the perennial *Asters*, was in fine bloom in mid-October. Its large deep purple flowers, with their bright yellow centres, render it a most decorative object when in full flower, but its lateness makes it unfitted for planting in situations not conducive to early maturation, since the advent of frost before its blossoms are fully expanded prematurely terminates its display. In the colder districts it should be valuable as a pot plant for the conservatory or cool greenhouse. *Aster* (*Chrysocoma*) *Linosyris*, colloquially known as Goldlocks, was still in flower at the commencement of the month. The

Tuberous Begonias, although creating a less gorgeous display than in the preceding month, were still bright during the opening days of October, and the large-flowered *Cannas* had not entirely ceased to display their brilliant blossoms, while *Canna Ehmanni iridiflora* yet held here and there a ehming flower-scape of cherry-pink. *Campanula carpatica* and other of the dwarf Bellflowers produced a few blossoms, and the *Marguerite Carnations* bore many a flower amid the blue-green leafage. The *Valerian* (*Centranthus ruber*) has borne in diminished numbers its heads of bloom, pink, white and red, and the early *Chrysanthemums* were still in evidence at the beginning of the month, while towards its close the later varieties commenced to expand their blossoms in the open garden. The

Autumn Crocuses (*Colchicum*) have been blooming well, being especially decorative when their leafless blossoms were afforded the setting of mossy bank or verdant lawn. *Coreopsis grandiflora* continued the display of its single golden blossoms through the greater part of the month, and *Cosmos bipinnatus* produced its white and pale flesh-coloured flowers. There is also a darker tinted variety of this flower, its magenta-like hue, however, rendering it particularly undesirable for use either in the garden or for indoor decoration. These subjects should not be planted in soil that is rich and deep, or they will make growth at the expense of flower-production until the autumn is well advanced, and in this case early maturation is desirable. *Crinums* have continued to flower throughout the month, *C. capense*, *C. Meorei*, *C. M. album*, *C. Powellii* and *C. P. album* being all represented in different gardens. The *Cactus Dahlias* have also prolonged their display where they have not been cut by the frost, and now and again the *Delphiniums* manifested their presence by a tall light blue flower-spire, and the annual *Larkspurs* have not entirely lost their brightness, while *Doronicum plantagineum excelsum* Harpur-Crewe has borne a sufficiency of widespread golden stars to fill an occasional flower vase, though not materially contributing to the brightness of the garden. The *Mexican Daisy* (*Erigeron mucronatus*) is still in flower, and *E. speciosus* exhibits a few mauve golden-eyed blossoms, relics of a prolonged blooming period, while at the commencement of the month the *Coral Tree* (*Erythrina crista-galli*) in a late garden was displaying its crimson flower-spikes. The great *Fuchsia* bushes are in many cases still bright with blossom. *Gentiana acanthis* shows a fair sprinkling of deep blue blooms, here and there *Geum coccineum* gives a spot of bright colour, and the *Water Aven* (*G. rivale*) in a corner of the wild garden is bearing its buff flowers. *Gaillardias* are bright with their crimson and gold, and in warm borders the orange of the *Gazania* shines with little diminished splendour. On southern rockeries the *Sun Roses* (*Helianthemum*) have expanded a few bright blossoms, and the perennial *Sunflowers* have sustained their display of gold throughout the

greater part of the month, *Helianthus latiflorus*, *H. rigidus* Miss Mellish and *H. giganteus* being the most decorative, while the *Jerusalem Artichoke* (*H. tuberosus*) in kitchen gardens has been flowering freely. Now and again *Helichrysums* were to be seen in flower, and towards the close of October the giant *Christmas Rose* (*Helleborus altifolius*) produced the first of its white chalice.

Hunnemannia fumariæfolia has been bright with its yellow blossoms, and early in the month the *Hydrangea* bushes were still ornamental with their massive blossoms ranging in colour from Forget-me-not blue to bright pink, while *Hypericum Moserianum* was bearing a few of its yellow flowers. Before the conclusion of the month the lovely *Algerian Iris* (*I. stylosa*) had commenced its lengthened period of bloom, in open winters its fragrant blossoms being produced continuously until the end of April. In porous soil in the south-west, especially if planted in a sloping bed, this *Iris* increases at a particularly rapid rate, two or three tubers forming an immense clump in a few years' time. The *Torch Lilies* (*Kniphofia*), though failing to maintain the extent of their earlier display, have in many cases borne their vivid flower-heads through the month. *Lobelia fulgens* had not lost the vermilion of its flower-spires in the early days of the month, and *L. rosea* still displayed the velvet-pink of its blossoms. The *Lily* of the Valley plants have produced an abundance of scarlet seed-berries, an event of rare occurrence in any but exceptionally dry seasons. Until the close of the month the *Corn Marigolds* were golden in certain fields, while the *French* and *African Marigolds* have contributed much to the brightness of the October garden. Late-sown seedlings of *Nicotiana affinis* are yet in bloom, as is *Oxalis floribunda resea*, while the

Tufted Pansies are far from flowerless. *Paris Daisies*, both yellow and white, were bearing a sparse scattering of flowers at the commencement of the month, at which period the *Ivy-leaved Pelargoniums* were here and there producing a few bloom-trusses, and the *Welsh Poppies* (*Meconopsis cambrica*) and *Iceland Poppies* (*Papaver nudicaule*) were displaying infrequent blossoms, while *Pentstemons* and herbaceous *Phloxes* were also continuing to flower. The *Winter Cherries* (*Physalis Alkekengi*) and the newer introduction *P. Franchetti* have borne their bright orange calyces, some of those of the latter variety being of large size, while the integument is of greater consistency than is the case in the elder form.

Phygelius capensis remained in flower in a few instances until the second week of the month, and *Plumbago Larpentæ* made a charming picture with the maroon-bronze of its foliage almost smothered in the soft blue of its flower-heads. Not many months since this plant was referred to in these columns as a useless introduction, but, whatever may be its demerits in more northern districts, in the south-west and along the coast-line of Dorsetshire and Hampshire it is without doubt one of the most valuable autumnal bloomers. It spreads rapidly, in fact almost too rapidly, soon covering a large extent of rockwork if not rigorously kept within bounds and appears indifferent to soil, succeeding equally well in a heavy or light staple, while it may be seen flowering with equal freedom in a moist situation as in one that is dry and sunny. At the commencement of the month *Pyrethrum uliginosum* was still decorative with its lofty flower-stems of narrow-rayed, white stars, and *Ludbeckia purpurea* bore its ruddy blossoms, while *R. Newmanii* held its orange, black-centred blossoms through the entire month, as did the tall growing *R. nitida* its larger flowers of bright gold. Of

Roses there was no week when a bowlful could not be culled from the open garden for indoor decoration, even *Hybrid Perpetuals* yielding not a few brightly coloured buds and half-expanded blossoms that added variety to the collection, though *Chinas* and *Teas* contributed nine-tenths of the available flowers. The single white *Macartney Rose* has continued to produce its chaste golden-centred blossoms, which it has now

borne without intermission for over four months. This Rose is an excellent climber and soon covers a considerable expanse of wall, while its foliage is practically evergreen except when seared by severe frosts, while in the south-west it is useful for growing on pergolas and arches. *Salvia patens* had not ceased its display of rich blue in the opening days of October, when *S. fulgens*, *S. coccinea*, and *S. rutilans* were also in flower in the garden. *Scabiosa caucasica* is bearing its porcelain-blue flowers in the case of plants raised from seed during the present year, the Winter Flag (*Schizostylis coccinea*) displays its crimson bloom-spikes, and the glaucous foliage of *Sedum Sieboldi* is crowned with flat, mauve-pink flower-clusters. The so-called Winter Daffodil (*Sternbergia lutea*) has produced its golden, Crocus-like blooms in profusion. Very bright are these in the garden, while they are equally acceptable for indoor decoration. *S. macrantha*, a particularly fine species with far larger blossoms, was also in bloom at the commencement of the month.

Stokesia cyanea, a flower not unlike a single Aster in contour and colour, except that it lacks the yellow eye, was in full bloom early in the month, and in a sheltered spot in the open *Sparmannia africana* was bearing its white flower-trusses. In some gardens the Thrifts (*Armeria*) are displaying autumnal blooms, and the purple and white varieties of *Tradescantia virginica* are not as yet entirely flowerless. Violets in the open are in fine bloom, and those transferred to the pits at the end of September are fully established and promise an excellent winter supply of blossom. I have not as yet seen any individual single Violet flower to excel a well-grown specimen of Princess of Wales in size. *Zauschneria californica* has borne its scarlet tubular blossoms well into October, but has scarcely flowered so freely as might have been expected after such a sunny summer. Annuals, such as Stocks, Antirrhinums, *Salpiglossis*, *Eschscholtzias*, Zinnias, Cornflowers, and others, have materially contributed to the floral calendar of the month.

S. W. F.

ORCHIDS.

ARUNDINA BAMBUSÆFOLIA.

This is a little out of the ordinary run of Orchids and not at all a popular plant, yet it has many claims to attention. The pretty light green of the stems and foliage is always attractive, while the blossoms are very bright, and are produced, moreover, over a long season. These occur from the ends of the tall Bamboo-like stems, and vary a good deal in size. The sepals and petals are pale rose, with a deeper suffusion, while the lip has a fine deep purple front lobe, with lines of orange-yellow leading to a white throat. This *Arundina* is the only one at all likely to be seen in most collections, and, being a native of hot countries, it likes a position in a warm, moist house. As a rule it is relegated to a shady corner, but this is hardly fair to it, as though not liking bright sunshine, it requires a certain amount of light, especially during autumn and early winter, to properly consolidate the stems. Plants so treated are far more likely to flower freely than are those treated as above. The atmospheric moisture should be especially well maintained in order that thrips and red spider may be kept at bay. This will also cause the free emission of young shoots from near the top of the stems, such shoots being very useful for propagating. Like those of *Dendrobiums*, these small and vigorous shoots when placed half a dozen together in a pot make far more rapid progress than do pieces of the older plants divided up. Badly furnished specimens, too, may be improved by having these young shoots pegged down around the compost and allowed to thicken and grow up, removing a few of the older and worn-out

shoots annually. The roots of *Arundina bambusæfolia* are very freely produced and vigorous, liking an open and free but substantial compost, a good mixture consisting of equal parts of peat-fibre, loam, and chopped Sphagnum Moss with abundance of large lumps of charcoal or burnt clay to keep all open. Many growers use sand, but I could never see any advantage in using this material for terrestrial Orchids. It has a tendency to reach the drainage and clog this, and, except when of the best and coarsest quality, has not much value in opening the compost. Crock dust or pounded

old worn-out compost is removed, and any dead roots present should be cut away. Set the plants a little below the rim of the pots in order that water may be easily supplied and surface the compost with rough Moss. During the growing season keep the syringe going among the foliage and stems, but this must not be done in dull or wet weather. In winter a fairly moist house and a temperature of about 60° at night suffice.

Odontoglossum Schlieperianum citrinum.—A correspondent sends a nice bloom under

Phyllostachys nigra in the grounds at Penjerrick. (See p. 413.)

charcoal is a far better material according to my experience, being lighter and not so easily silted downwards by the continual watering as silver sand. In any case, and whatever is used, the drainage must be very carefully laid and there must be plenty of it, for the plants do not require very frequent disturbance at the roots and the latter need a good deal of water even in winter, the plant having no pseudo-bulbs to sustain it over a long period of dry rest.

When repotting, see that the whole of the

the above name, but I cannot see that it differs from the form that I have known for years under the name of *O. S. flavidum*. The brown spotting has entirely disappeared, and its place is taken by a few similarly sized blotches of a deeper tint of yellow than in the type. It is evidently from a well-grown plant, and very useful such varieties are at this time of year.—H.

Odontoglossum cristatellum.—In this pretty species, which unfortunately is not at all plentiful, the flowers are not unlike those of a small *O. triumphans* in colour. It has been said that it is a natural hybrid, though from what

species it would be difficult to say. It is of dwarf habit, and the flowers are produced on scapes about a foot high. The plant is a native of high Andean ranges, and, consequently, likes a cool and pleasantly moist temperature, rather small pots, and a position where ample ventilation is assured. It does not require a drying-off season.

Masdevallia calura.—This is a Costa Rican species, and a very beautiful little plant. The leaves are only a few inches in length, the flower-spikes bearing a single blossom only. The centre portion of the flower where the sepals are united varies a little in colour, beautiful shades of chocolate-red and purple, becoming paler at the margins and finishing in deep orange-yellow tails, being the usual tints. It is most like *M. Reichenbachiana*, with which species it is said to grow in its native haunts. It does best in medium-sized baskets of peat and Moss.

Brassavola glauca.—The pure white lip and greenish sepals of this Orchid contrast prettily, and altogether it is one of the best, if not the best, in the genus. It is of a Cattleya-like habit as distinct from the reed-like stems and foliage of many other species. A native of Mexico, it likes a moderate heat only and to be grown in baskets or on rafts, with a rather thin layer of compost. A little excitement in spring and ample light all the year round are necessary, as when grown in a shady house the plants often refuse to flower. The blossoms are produced singly from the top of the newly-formed bulb.

Lælia amanda.—This is usually supposed to be a natural hybrid, but whatever its origin it is a very beautiful Orchid, its large and showy blossoms having a refined and delicate appearance. These are each upwards of 4 inches across, the lip a little deeper rose than the rest of the flower, and having still deeper radiating lines upon it. It grows about 9 inches high, and each pseudo-bulb has a pair of leaves, from between which the flower-spikes issue. The best compost is a rough and open one, consisting of peat and Moss over good drainage, and the plants should be slightly elevated.

Paphinia grandis.—Although one of the finest in the genus, this is not a good plant to have a lot of in flower, for the scent of the blossoms is by no means pleasant. These are often 5 inches across, white, barred with brown and purple, and they proceed from the last formed pseudo-bulbs. A native of Brazil, an intermediate or Cattleya house temperature suits it best, and the plant should be suspended near the glass if possible. The leaves cannot stand strong sunlight, but the plants do not flower freely in a dark house. Ample moisture should be given while growth is active, and it is very important that the compost be kept sweet.

Cypripedium Spicerianum nigrescens.—Although this cannot by any means compare with the type for beauty, it is an interesting plant and a remarkable variation. The lip has a pinched and puckered appearance and the dorsal sepal is not so fine, the former being of a dusky purple or black tinge. It does not grow so strongly as the type, which is now one of the brightest and most beautiful in the genus. It likes a good substantial compost with ample supplies of moisture while growing, a light position and plenty of warmth. Strong plants flower very freely and the blossoms last long in good condition.

Rodriguezia planifolia.—None of the Rodriguezias or Burlingtonias like a lot of compost, and one of the finest lots of plants I have seen was grown on blocks of teak wood with their ends in water, sufficient moisture ascending the blocks for the needs of the roots. But this method is rather too poor to be recommended in a general way, and a better plan is to nearly fill a basket with drainage and simply surface this with Sphagnum and a very little peat. Grown in this way, I recently noted this pretty species, which has rosy crimson flowers produced on short, but graceful spikes. The rather thick and hard leaves betoken a liking for a fair amount of

sunlight and air. They are very apt to be attacked by a soft white scale, and this must be carefully kept at bay if good results are looked for.—H.

Catasetum Christyanum.—The contrast between the bright emerald-green of the lip and the dull tints of chocolate and purple in the other parts of the flower is very marked in this curious species, and good spikes of it are very attractive. It is an easily grown kind with stout fleshy pseudo-bulbs and long pale green leaves, which for the most part fall away in autumn. Its culture may briefly be described as similar to that of the deciduous Dendrobiums, both liking a very strong, moist heat while growing with a good deal of sunlight; just as much of the latter, in fact, as can be managed without damaging the foliage. During this time the roots must be kept very moist, but when the flowers are past and the pseudo-bulbs complete, very little water is needed. During the winter months a temperature of about 55° at night is ample, and the plants must stand in full sun.

Odontoglossum Rossi.—If this pretty Orchid were worth a guinea or two a lead instead of being one of the cheapest in existence, it would be thought a great deal more of. As it is, it is certainly one of the prettiest of cool house species and also one of the most easily grown, a fact that should recommend it to beginners in their culture. It is a very variable species, and those who know one form would hardly recognise others as belonging to it, but all are strikingly pretty and very free flowering. Not being a large growing plant, the receptacles used for its culture should only be large enough to take the plants easily, allowing, say, 1 inch for compost all round. Equal parts of good peat fibre and Sphagnum Moss used over good drainage is the best compost, and the lighter the position the better for the plants. While not agreeing with cutting up this Orchid into very small bits, I am sure it is also a mistake to have too large plants of it, as these get bare in the centre after a few years. Plants large enough to fill 5 inch pots are big enough for all purposes.—H.

COOL ORCHIDS.

AMPLE light and a sweet, pure atmosphere are necessary for cool Orchids now, and a great deal of care is required in watering. The majority of the section of *Odontoglossum* to which *O. crispum* and its allies belong will be growing freely, and the roots should be by now working nicely in the new material supplied some time ago. The cool Orchid house at the back of a north wall is not, I think, so frequently built as formerly, and it is in the winter-time that the advantage of a more open and light position is most manifest. But in any case it is imperative that the glass be kept quite clean outside by frequently washing it down and inside by syringing. The plants, too, in a number of instances are arranged too far from the glass, and may, by elevating on inverted pots, be brought much nearer to it. The plan of arranging these with the smallest in front near the path in span-roofed houses is a very bad one, and just the opposite conditions are right, though a little more trouble in watering is inevitable. Such things as large plants of *Maxillarias*, *Lycastes* and *Anguloas*, although they like light as well as any, do not suffer in the same ratio as small bits of *Odontoglossum* and *Oncidium* if kept further from the glass, so this ought to be kept in mind when staging.

Respecting the watering referred to above, I like to see the small plants occasionally dry, for a plant always kept wet, or even moist, never seems to root with so much vigour as one that is allowed to look for moisture a little. But to go to the other extreme and let the young growth suffer from want of it is just as injurious. When the Sphagnum begins to look a little white it is usually time to water the roots, and it is not wise in every case to wait for this. The cool house is often used for resting quarters for Dendrobiums of the deciduous section, but whatever is done in

this way must be secondary to the needs of the bona-fide inhabitants of it, and to crowd the glass with baskets, keeping the light from these, is a great mistake. Again, it is necessary to see that the Dendrobiums are clean before bringing them in, red spider or thrips being often introduced in this way, and these are difficult to eradicate. A little sulphur dusted about the new growths of the *Odontoglossums* will act as a deterrent, and is a necessary precaution where fire-heat has to be applied. Fire-heat should be used with caution, and the night temperature kept at or about 50°. Anything above this is likely to lead to trouble from insects, and it is not wise to go much below, or the growth will not be so free as desirable.

H. R.

Cypripedium Arthurianum.—The growth of this *Cypripedium* is not so strong as that of most hybrids, yet it is a thrifty plant when well taken care of, and though even now too rare to be seen in every collection, there are many fine specimens of it where it has been carefully grown for years. The parentage is easily discerned, the influence of *C. Fairrieanum* being plain in the drooping petals, while that of *C. insigne* is quite obvious also, so much so that it may almost be taken for a variety of it.

Angraecum Eichlerianum.—This species is very seldom seen under cultivation, yet the blossoms are very pretty and interesting. It grows tall and rather slender, and has medium-sized flowers, with a large lip shaped like a helmet as its principal feature. These have pale green sepals and petals; the lip is white. It may be grown in the warmest house, and owing to its tall habit it is best to give it a pole or trellised block in order that any roots produced on the stem may have something within reach to take to. A native of the west coast of Africa, it requires ample heat and atmospheric moisture, and the raft should be lightly dressed with Moss. If grown in pots, the compost may consist of Sphagnum and charcoal only.

Phalænopsis Esmeralda.—Although a rather dwarf species, this *Phalænopsis* is a fairly good grower and flowers freely, though perhaps somewhat irregularly. The flowers occur on erect spikes from the upper part of the plant and vary a good deal in colour, some being a pale rose or nearly white, others a bright amethyst-purple with many intermediate shades. The plants do well in the intermediate house with other Moth Orchids, and require to be well ripened by standing in a good light towards autumn. This is more necessary with this species than some, as in its native place it is almost, if not quite, deciduous. The roots are stout and vigorous for a *Phalænopsis*, and it may be grown in medium-sized baskets or pots in a rough mixture of crocks and Sphagnum Moss.

Sobralia Lindenii.—It frequently occurs that distinct and attractive species of Orchids become established in cultivation before any description has appeared in the gardening press. The above *Sobralia* is one of these. It is one of the finest forms that has yet appeared, and is worthy of every consideration. The first plant that flowered in this country appears to have been the one exhibited at the Drill Hall meeting of the Royal Horticultural Society on October 15, 1895, when it received an award of merit. It came from the collection of Mr. C. J. Lucas, Warham Court, Horsham. The history of the plant then given by Mr. Lucas was that under the name of *Sobralia Lindenii* a few imported tufts were sold by Messrs. Linden, of Brussels, at Messrs. Protheroe and Morris's rooms in Cheapside on September 12, 1893. No particulars were then or have since transpired as to its native habitat. The flowers are as large as those of *S. macrantha*, fine in form and substance. The variation, as far as I have seen, has not been great. In the first place the sepals and petals were bluish-white, the petals much broader than the sepals. The lip also was bluish-white on the basal lobes, but the front portion was of a rich crimson-purple, shading off to a lilac tint towards the margin. The deep-coloured area is traversed by well-defined

white lines, which give it a distinct and charming appearance. The plant has since flowered in other collections. Quite recently two plants have been sold the sepals and petals of which have been pure white, the lip white, flushed with rose towards the base in front of the deeper colouring on the disc; the side lobes white, with alternate deeper purple and white lines running through the base of the throat. The growth resembles that of *S. xantholeuca*. It appears to have a robust and free constitution.—H. J. C.

FERNS.

SUNLIGHT FOR FERNS.

It is in the winter that one realises how greatly the value of well-grown Ferns is above that of others that have been kept heavily shaded all the summer. No greater mistake can be made than to think heavy shading necessary; it is injurious in every way. Badly-grown fronds damp off now, while those that have been hardily grown keep far better. Our market growers especially have found out the advantage of ample light, and the amount of sun allowed their plants would surprise most private growers. In the spring of the present year I saw a house in one of the large market-growing establishments north of London filled with *Adiantums* of the tenerum and Farleyense section. The sun was high and very powerful, but not an inch of shading was on the whole of this expanse of glass, and the only protection I saw was a few sheets of newspaper on a newly-potted batch. The Ferns looked the picture of health, the charming tints on the young fronds giving the plants a lively and gay appearance. In contrast to this, one may enter scores of private gardens and find the fernery heavily shaded quite early in spring and in late autumn. There are some Ferns that have an especially charming appearance when grown in the fullest light. *Adiantum macrophyllum* is one of these, and the bright red tints on the young fronds are exquisite. Several of the *Nephrolepises* again show very pretty tints, and there is also a beautiful colour in well-grown plants of the new *Anemia rotundifolia*. In the *Gymnogrammas*, again, there is no comparison between plants that have been grown in a good light and others that have been weakened by being kept in the dark.

One of the chief things in Fern culture is the surprising amount of variety in tints of green as well as form of the fronds, but to grow all in a shady house is to destroy a lot of this. That fine Fern, *Microlepia hirta cristata*, as an instance may be brought to a very deep green by growing it in a cool shady house, but this is not advisable, as the pale tint natural to it is very distinct and pretty, besides which the tassels form more freely in a good light. I could not grow *Adiantum Capillus-veneris* fissum well until I brought it up to the light, but since then I have had no trouble with the centre damping, as it used to when growing away from the light. Many more instances could be given if necessary, but those cited will be sufficient to call attention to this phase of their culture. C. H.

Fern spores.—It was not at all a question of my own knowledge or ignorance that I raised, and to which Mr. Hemsley has replied; it was rather because I wished to ascertain what was in Mr. Hemsley's mind in making the suggestion as to precautionary measures in relation to isolating Ferns for the production of seed-spores. I thank him very much for what he has written. In eliciting this information, whilst not a Fern

grower, I wished to learn what were his reasons, and as they are identical with my own, no harm has been done. But I have no doubt there are many readers both amateur and professional who, being Fern growers and perhaps raisers, will benefit very much from what Mr. Hemsley has told them.—A. D.

Hardy Ferns.—Winter treatment.—One of the greatest drawbacks in the culture of our beautiful British Ferns and their varieties is that,

destroyed, are crippled for the season. All hardy Ferns grown in pots should be stored during the winter in a pit with a northern aspect where they get little or no sun, and during severe frosts should have some protection. If lights are used they should be removed in mild weather. Although it is as well to have them under cover at this season, they must be kept as cool as possible. A good covering of dry Bracken is the best protection for the deciduous sorts. It is in the early

Cordylines at Penjerrick. (See p. 413.)

being considered hardy, sufficient care is not given during the winter. Even in their native habitats, where they get a good deal of natural protection, they often suffer, especially from the frost late in spring. Those grown in pots usually ripen off earlier in the autumn, and in mild weather start into new growth again long before their natural period, and on the return of cold winds and frost the young fronds, if not quite

spring that the most care is necessary, especially with the varieties of the Lady Fern (*Asplenium Filix-femina*), as they are inclined to start early, and a slight frost or even a cold wind will damage the young fronds. The spring wind frosts also damage the evergreen sorts more than at any other time. It is advisable to leave all the old fronds on the deciduous sorts until the new ones have well started into growth.—H.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 21.

THE exhibition of Tuesday last was a marvellous one in every respect. The hall was filled from end to end with varied exhibits which were of high-class quality. No one would have dreamed a quarter of a century back that such shows as we now see under the auspices of the Royal Horticultural Society so repeatedly could ever be maintained. The mere fact of making such shows a question of pounds, shillings, and pence is now eliminated. The motives of the majority of exhibitors now-a-days is to further the interests of horticulture, and not one of mere sordid gain.

By far the greater display of Tuesday last came under the investigation of the floral committee, and when it is mentioned that two gold medals were awarded by this body, some idea of the quality may be arrived at. Without entering into details it may be stated that no finer exhibit of cut Chrysanthemums set up in an artistic manner has ever been seen in the Drill Hall than that on Tuesday last, which reflects great credit upon Mr. Lees, the gardener at Trent Park. Turning from these to the magnificent group of winter-flowering tuberous Begonias, an exhibit in itself absolutely unique in character, one scarcely knew which to admire the more—culture and taste displayed in arrangement on the one hand, or the scientific and patient labours of the hybridist on the other. These winter-flowering tuberous Begonias are invaluable for this season of the year; in fact, they are the finest addition made to our plants for the dull season that has ever been produced. Other exhibits of Chrysanthemums were to be seen—groups in the old-fashioned orthodox style and cut blooms upon boards, as in ages past. A notable innovation was, however, to be noted in an exhibit of pompon Chrysanthemums in earthenware vases, Smilax trailing upon the white paper ground—a pretty and suggestive arrangement. Of other groups special note should be made of one of the early forms of Poinsettia pulcherrima, which is quite distinct from the type and a better grower. A grand display of winter-flowering Geraniums of the zonal section was also on view. These were almost equal as an exhibit to the Chrysanthemums and Begonias first noted, and of these it is quite safe to say they were the finest lot ever sent to these meetings at this season of the year. Taking into consideration also the fact that they came from Westonbirt, in Gloucestershire, it was wonderful how fresh they looked. A large group of well-grown Ferns from the north of London should also be noted for good culture and effective arrangement. Orchids were displayed in a profuse fashion, too, for November, Cattleyas and Cypripediums predominating. Of the latter, note should be made of the charming little exhibit of Cypripedium insigne Sandera, which is quite a gem in its distinctive features. Some other choice forms of the same genus were also on view. Cattleya labiata in varied forms made a charming display.

Of fruits, the chief features of interest were the collections of Apples, upon which the colouring was most brilliant, such as can only be obtained in the most favoured of the country districts. A few vegetables only were shown, these being select stocks of the most approved kinds.

Orchid Committee.

Awards of merit were adjudged to the following:—

CYPRIPEDIUM MILO (Westonbirt variety).—In this the dorsal is about $2\frac{1}{2}$ inches across the top, white, becoming suffused with rose, and spotted with rose-purple in the centre, the basal half green, heavily spotted and suffused with dark brown. The large petals are deep brown, mottled with greenish yellow; the lip rich brown, highly polished, and margined with yellow. From Captain Holford, Westonbirt, Ledbury, Gloucestershire.

CATTELEYA MRS. J. W. WHITELEY (C. Bowringiana × C. Massaiana).—Though the intermediate characteristics of the parents are manifest in this it is scarcely distinct from pale forms of C. Mantini. The sepals and petals are deep rosy lilac, the lip similar in colour around the outer lobes, the centre rich crimson-purple in front of the deep orange disc. The plant carried a two-flowered raceme. In growth it resembles Cattleya Bowringiana. From Sir J. Miller, Bart., Manderson, Duns, N.B.

CATTELEYA VESTALIS (C. maxima × C. Dowiana aurea).—The sepals and petals have a very pale tint of rose, and the lip shows the influence of C. maxima by the lines of purple over the surface. The margin is white, suffused and veined with deep rosy purple, the side lobes having a distinct tint of salmon, shading to yellow, lined and suffused with purple through the throat. From Messrs. J. Veitch and Sons, Ltd.

ODONTOGLOSSUM LOOCHRISTYENSE LADYBIRD.—This is a garden hybrid between O. crispum and O. triumphans. It is a beautiful variety, the sepals rich yellow with some purple spots on the basal half. The petals are clear yellow, lighter on the base and centre, slightly crisped on the margin. The broad, flat lip, in the way of O. triumphans, is white, shading to yellow on the disc, with a large brown spot in front and some smaller ones on the sides. The plant carried a ten-flowered raceme. From Mr. W. Thomson, Stone, Stafford.

Messrs. J. Veitch and Sons, Ltd., showed a grand group, one of the finest features being the exhibit of eight plants of the lovely Cypripedium insigne Sandera. Other Cypripediums were C. Prospero, in which the intermediate characteristics of the parents could be plainly observed; C. Actæus, which had large brown and purple spots on the dorsal sepal; C. Creon and C. enanthum superbum. Good forms of C. Arthurianum, some fine C. Niobe, C. Hero and a good form of C. Enid, in which the dorsal sepal is white beautifully suffused with rose, the petals heavily suffused with rosy-purple, were also shown. The most prominent among hybrid Lælio-Cattleyas was a grand form of L.-C. Dominiana (purpurata × Dominiana) with two flowers. The open portion of the lip was $2\frac{1}{2}$ inches across and 3 inches long, rich crimson, veined with a darker shade of crimson, with a small light blotch in the centre at the front. The basal portions have the yellow lines of the C. Dowiana parent. The sepals and petals, also unusually large, were of a bright rosy-lilac. L.-C. Decia was included in varied forms. L.-C. Lady Rothschild has fine deep rose sepals and petals, the front lobe of the lip rich crimson. L.-C. Semiramis is very similar to the last variety, having a broader lip with a larger white central area. L.-C. Statteriana was also included. Cattleya Pearl (C. fausta × C. Harrisonia) has deep rose sepals and petals, the lip also rose suffused with crimson, shading to yellow in the throat. C. Atalanta with its richer crimson and purple flowers was very attractive. C. Portia shows the influence of the first-named parent. In Cattleya Ariel (C. Bowringiana × C. Gaskelliana), shown for the first time, the sepals and petals are deep rose, the broad front lobe of the lip crimson-purple, the side lobes rose, shading to yellow at the base. Epidendrum Wallisii-ciliare was also included. A silver-gilt Flora medal was awarded. Messrs. H. Low and Co., Bush Hill, Enfield, sent a small group, consisting of Oncidium varicosum, Lælio-Cattleya Nysa, L.-C. exoniensis, L.-C. Decia, some good Cattleya Dowiana aurea, Cypripedium insigne Laura Kimball, a good form of C. Milo, C. Henry Graves, and a good plant of Cynoches chlorochilon with three female flowers. Messrs. Paul and Son, Cheshunt, sent round baskets filled with C. insigne and its varieties, C. Leeanum, C. Spicerianum, and C. Ashburtonæ, and two baskets of the pure white Masdevallia tovarensis. Mr. E. Kromer, Bandon Hill, Beddington, Croydon, sent fifteen vases of cut Cattleya labiata flowers and a variety with splashes through the centre of the sepals and petals, to which the name of C. I.

Kaiser Wilhelm II. was given. Captain Holford was awarded a silver Flora medal for a choice group of Cypripediums. The most prominent among them were C. insigne (Harefield Hall var.), with its immense dorsal sepal finely spotted; C. i. Sandera, with two flowers, and C. i. Youngianum, shown as C. i. Ernesti. C. i. Dorothy, another yellow form, C. vexillarium, C. Arthurianum, and C. Niobe were well represented. Numerous forms of C. Leeanum, C. Morganae, C. Pitcherianum, good varieties of C. Charlesworthi, and C. Spicerianum were also included. Mr. J. Bradshaw, Southgate, was awarded a silver Bankian medal for a choice group. Among the fine Cattleya labiata was a white form, C. I. J. Bradshaw, the sepals and petals pure white, the lip white, suffused faintly with rose, with some orange-yellow in the throat. Some good forms of Cattleya Mantini, a good C. maxima, Lælio-Cattleya Mrs. Astor, the petals pale yellow, the sepals darker, the front lobe of the lip rosy-purple, shading to yellow in the throat, and a dark form of Cymbidium Traceyanum with a thirteen-flowered raceme were also shown. Lælia autumnalis alba was also included. Mr. W. A. Bilney sent eighteen vases of cut Cattleya labiata flowers, a good form of Vanda cœrulea, and a nice spike of V. Sandariana. Frau Ida Brandt, Zurich, sent Pescatorea Gareana and P. Dayana. Mr. W. Thomson showed Odontoglossum crispum Meteor, a beautiful form both in shape and substance, the deep rose suffusion from the back showing through the sepals and petals, the almost white surface thickly covered with small brown spots. The plant carried a three-flowered spike. Mr. H. Little, The Barons, Twickenham, sent a three-flowered raceme of the long-bulbed section of Cattleya maxima, the type that was more frequently met with some years ago than it is at the present time. Mr. R. Ashworth, Oaklands, New Church, Manchester, sent a plant of a white Cattleya labiata named C. I. White Empress. The sepals and petals, of fine form and substance, are pure white, the lip white, with an oval-elongated crimson blotch in the centre and some yellow in the throat. The plant resembled to a great extent the one exhibited at the last meeting by Mrs. Briggs-Bury, with the exception of the blotch, which was broader and less elongated in the plant previously certificated than in Mr. Ashworth's variety. It would be interesting to compare these last two varieties with C. I. Cooksonæ and C. I. Sandera, both having previously been certificated.

Floral Committee.

The following received an award of merit—

BEGONIA SYLVIA.—This, an addition to the B. socotrana crosses with the tuberous-rooted Begonia, is of quite a new shade of colour. The older flowers are salmon-rose in tone, while the younger blossoms are more heavily flushed rose. The habit, too, is more erect and the flowering very free, even quite small plants being full of blossom. From Messrs. Jas. Veitch and Sons, Ltd., Chelsea.

DRACENA THE QUEEN.—A pretty and graceful kind for table work, the leaves, which are distinctly narrow and rather long, being striped with scarlet on a coppery red ground. From Messrs. Jas. Veitch and Sons, Ltd.

PELARGONIUM LILIAN.—This is one of the zonal section, the truss large and compact, the flowers well formed, of fair size, and of a pretty shade of delicate pink. From Capt. Holford, Westonbirt, Gloucester (gardener, Mr. A. Chapman).

CHRYSANTHEMUM MRS. ALFRED TATE.—This is best described in its true light, viz., a clear chestnut-bronze sport from the well-known Etoile de Lyon. The sport is evidently as meritorious as the original, and is a decided and attractive novelty. From Mr. F. A. Bevan, Trent Park, New Barnet (gardener, Mr. W. H. Lees).

Messrs. James Veitch and Sons, Ltd., King's Road, Chelsea, showed a beautiful group of new winter-flowering Begonias. In the past quite small scraps of blossom have been all that has

been seen of the Begonia in winter, even where some care has been bestowed upon its culture. In towns and low-lying or smoke-laden districts even this supply has been reduced to a minimum. For the future, thanks to the Messrs. Veitch, the conservatory and the greenhouse in midwinter may be made as bright and cheerful as in midsummer by the free use of these beautiful and attractive kinds. Already have several new and very showy kinds put in an appearance, and now no season passes without an addition being made to the list of novelties. Nor is it merely a new plant or a new colour; there is a decided improvement in habit, vigour, and freedom. All this was clearly shown at the Drill Hall this week when the earliest of the race as also the most recent additions were placed side by side. As is probably now well known, these new winter Begonias have been raised by crossing *B. socotrana* and varieties of the tuberous-rooted section, thus showing the value of well directed effort. Among the earliest was Myra, with a rather loose spreading habit. Another is Ensign, a richly coloured kind, erect in growth, fine in foliage, handsome, and free. Winter Cheer is another whose colour may be anticipated by its name. Bright, free, and cheerful, erect in carriage, this is one of the best. It may be described as cerise-scarlet. Mrs. Heal is another, flowers large, almost scarlet, and very free. Sylvia, described elsewhere, is the most recent of novelties in this line. A very pretty form more bush-like in habit is John Heal, free and graceful in habit, with rosy scarlet blossoms in plenty. One long table was not quite capable of holding all the plants, and a wonderful array of colour was the result (gold medal). Mr. F. A. Bevan, Trent Park, New Barnet, had a magnificent arrangement of Chrysanthemums. The group generally had much in common with some others previously noted, with the exception that the flowers were more liberally employed and that all were of the finest description, to say nothing of the perfect taste in arranging. It is not possible to name all in such a fine exhibit as this, but the arrangement was in this wise: A central figure was a tall and graceful Palm—*Phoenix rupicola* probably—and on either side of this, fronting each way, were tall masses of *Phœbus* and *Oceana*. There were a dozen blooms of each of these grand yellows, every one of the highest standard of excellence. From this centre of gold, extended right and left vases or receptacles of the handsomest kinds in commerce, such as *Mme. Carnot*, *G. J. Warren*, *Mutual Friend*, *Madeline Davis*, *Chas. Davis*, fine bronze; *Joseph Chamberlain*, gold and crimson; *H. J. Jones*, a remarkable shade of velvet crimson and huge, spreading flowers; *Mrs. J. Bryant*, rose-pink, with mauve; *Beauty of Castlewood*, *Mons. Chenon de Leche*, *Chatsworth*, a picture of rare beauty; *Surpasse Amiral*, a mass of gold; *Ma Perfection*, *Empress of India*, very fine; *R. Hooper Pearson*, a dozen or so in glorious colour, and many more. Then around and here and there small and large baskets were grouped with pretty and pleasing single kinds that greatly enhanced the value of the exhibit as a whole. Foliage in variety was employed pretty freely, and of this we noted *Beech*, *Bracken*, *Oak*, the silky heads of the *Clematis*, and even fronds of the *Osmunda* were employed for the tone of colour. These and a few *Croton* leaves were the chief, all interstices being hidden by a bed of fresh green Moss. This was one of the finest groups ever seen at the Drill Hall (gold medal). Another very striking feature was that of *Pelargoniums* from *Capt. Holford*, *Westonbirt*, *Gloucester* (gardener, *Mr. Chapman*). Usually such things are merely set up in trusses of bloom, from which no lesson is forthcoming. In this instance it was a pleasure to see the plants, and, remembering that these came from a distance, the entire lot was highly creditable. From the clear and lofty tableland whereon *Westonbirt* is situated we may expect to see these bright and vivid colours to perfection. The largest examples were in 8 inch pots, and not a few of the plants carried from a dozen to eighteen handsome

heads of bloom. The feature of the group was the great variety, showing how well these plants succeed in pure air. Among the finest was *Ian Maclaren*, a salmon-scarlet, with salmon margin; *Dr. Nansen*, snow-white; *H. de Percival*, pink and white; *Norah*, soft pink; *Athlete*, fine dark crimson; *Zenobia*, cerise-scarlet, very telling; *Chaucer*, rose; *Paul Campbell*, crimson, immense truss; *Mrs. Simpson*, centre salmon with white margin; *Lady Newton*, pale salmon with scarlet Picotee-like edge, and *Agnes*, pure white. *Lady Chesterfield* was also fine. From the same source came that striking stove climber, *Ipomœa Horsfallia*, a fine plant too rarely grown to perfection. A silver-gilt Flora medal was awarded. A capital exhibit of *Chrysanthemums* came from *Mr. F. H. Flight*, *Cornstille*, *Twyford*, *Winchester* (gardener, *Mr. W. Neville*), in about equal proportions of Japanese and incurved varieties. For freshness and good finish, and in the latter particularly, nothing better has been seen this year, the varieties including *Mme. Ferlat*, *Lady Isabelle*, *Major Bonafon*, *R. C. Kingston*, *Le Marcedon*, *Bonnie Dundee*, *Ma Perfection* (very fine), *Miss Haggas*, &c., the Japanese sorts being represented by *Master H. Tucker*, *G. F. Warren*, *The Wonderful* (a golden-bronze), *The Convention*, *President Nonin*, *Mme. Gustave Henry*, *G. C. Schwabe*, *Graphic*, *Viviani Morel*, and others, for which a silver-gilt Banksian medal was awarded. From *Nunhead Cemetery* *Mr. J. W. Witty* sent a group of that most curious of all *Chrysanthemums* called "What Ho." It is an illustration of the never-ending freaks of the *Chrysanthemum*, the single row of florets emanating from the disc falling into a confused, meaningless tangle all around, in which neither beauty, grace nor merit was, to our thinking, discernible. It is far from free-flowering, and many plants did not carry a single good head of florets. An exhibit of pompon and Anemone-flowered *Chrysanthemums* came from *Lord Aldenham*, *Aldenham House*, *Elstree*, *Herts* (gardener, *Mr. E. Beckett*). Of the pompons, *Primrose League*, *Elinore*, *Orange Beauty*, *Golden Mme. Marthe*, *Chas. Dickens*, golden bronze; *Rosinante*, reddish pink; *Wm. Westlake*, *Snowdrop*, perhaps the smallest and fairest of all the tribe; and *Helen*, a claret-coloured sort, were the best (silver Flora medal). *Mr. J. T. Bennett-Poë*, *Holmwood*, *Cheshunt*, sent a large group of *Pinguicula caudata*, with many bright blossoms. It is a pretty moisture-loving species, and revels in the shade and cool of the greenhouse. A hybrid pink *Hippeastrum*, *Mrs. Garfield*, came from the same source, the trumpet-shaped flowers being heavily veined with white. Bunches of double Violets came from *Mr. W. Evans*, *Forde Abbey*, *Chard* (gardener, *Mr. Crook*), the varieties being the white *Comte de Brazza*, *De Parme*, and *Marie Louise*. *Chrysanthemum Golden Mme. Ferlat*, from *Mr. A. J. Willmott*, *Exmouth*, *Devon*, was hardly equal to many kinds, but, representing as it apparently does a sport from *Mme. Ferlat*, would suggest good material to work upon. A rather telling incurved *Chrysanthemum* named *Mrs. W. Howe* was staged by *Mr. W. Howe*, gardener to *Sir H. Tate*, *Streatcham Common*, the colour being golden bronze and the blooms fairly large and well formed. A pure white Japanese kind called *Snowdrift* was sent by *Mr. H. Weeks*, *Thrumpton Hall*, *Darby*.

Ferns from Messrs *J. Hill* and *Sons*, *Lower Edmonton*, included some good things, and in a few instances large examples also. Of the more prominent was *Brainea insignis*, with something of the *Blechnum* in its general aspect. *Adiantums* were good generally, and included *A. Faulkneri*, *A. scutum*, *A. decorum magnificum* (a fine piece, 4 feet across), *A. Williamsi*, &c. The graceful *Onychium auratum* was very pleasing. A pan of the miniature *Davallia parvula* bore evidence of good culture. Not least among the miniature gems of this lot was the pretty *Actinopteris radiata australis*, whose fronds of an inch or so across constitute a perfect miniature of the well-known *Latania borbonica* in the general outline rather than in formation. The leaf-stalk is

only 2 inches or so long, and the appended leaf-blade is divided into four sections, each section again divided into four linear lance-shaped segments, the whole forming a complete frond of great beauty. *Hymenophyllum hirsutum*, a pan of which was also shown, had the brownish tint of autumn, a characteristic more or less permanently retained. Other plants included large examples of *Davallia Tyermanni*, *Lomaria gibba*, *Polypodium sporadocarpum*, &c. (silver Flora medal). Messrs. *Cripps and Sons*, *Tunbridge Wells*, brought up a very fine group of *Poinsettias*. The plants in 5 inch pots were about 3 feet high and carried foliage to the soil (silver Flora medal). Messrs. *J. Peed and Son*, *Roupeil Park*, *West Norwood*, had a group of *Chrysanthemums* in pots. Here many of the leading sorts were noted, *Phœbus*, *Modesto*, *Mme. Ferlat*, *R. Hooper Pearson* and others. Unfortunately, the group was not in a good light, and much of the effect was lost thereby (silver Banksian medal). Cut blooms of *Chrysanthemums* from *Mr. Godfrey*, *Exmouth*, were in many instances showy and good, *Surpasse Amiral*, *Wattle Blossom*, *Capt. Bellamy* (rich yellow), *Autumn Glory*, *Mme. C. Ray* (pink), *Joseph Chamberlain* (crimson and gold), and *Wilfred Godfrey* (gold) being the best. *Miss Mercer* is a pretty single white, which, if dwarf in habit, would prove quite an attractive kind (silver Banksian medal). A batch of *Cyclamens* from Messrs. *Hugh Low and Co.*, *Enfield*, included *Bush Hill Pioneer* in both red and white forms. There were also what was termed the double kinds, which, if possessing additional petals, do not seemingly have the grace and beauty of the original kinds (silver Banksian medal). Messrs. *George Bunyard and Co.*, *Maidstone*, sent cut plumes of a good *Pampas Grass*, *Glycerium argenteum Louis Carrière*, in which a reddish tint prevailed. Messrs. *Sander and Co.*, *St. Albans*, set up a few plants of *Dracena Sanderiana*, *D. Godsefiana*, and *Linospadix Petrickiana*. *Kentia Sanderiana* is a neat and pretty Palm that sends forth basal breaks as in *Areca lutescens*, &c. *Arbutus Unedo Croomei*, tinted red on the more exposed side of the bloom-clusters, was contributed by the Messrs. *Veitch and Sons*. This in a favourable position should prove a useful kind. We believe the variety is also called *A. U. rubra*.

Fruit Committee.

Awards of merit were given to

APPLE BARSALEG PIPPIN.—The fruit of this is conical, skin yellow, much striped with red, flesh soft and juicy and exceedingly pleasant. It is said to be a good cropper. From *Mr. Basham*, *Barsaleg*, *Monmouth*.

PEAR DOUBLE DE GUERRE.—A very handsome and well coloured baking variety, the fruits of good size and not unlike those of *Durondeau*. From *Mr. F. Lloyd*, *Croydon*.

Mr. Basham staged very fine collections of Apples, one grown in his own nursery, the other representing varieties grown in the county of *Monmouth*. Each comprised 100 dishes, and included many very fine samples, whilst colour was striking. The nursery-grown group included very good *Bramley's*, *Murfit's Seedling*, *Emperor Alexander*, *Prince Albert*, *Peasgood's Nonsuch*, *Mère de Ménage*, *Tyler's Kernel*, *Bismarck*, *Annie Elisabeth*, *Catshead* and others. Rich in colour were *Hoary Morning*, *Crimson Queening*, *Baumann's Red Reinette*, *American Mother*, *Ten Commandments*, &c., whilst of dessert varieties, *Allington Pippin*, *Wheeler's Russet*, *Braddick's Nonpareil*, *Mabbott's Pearmain*, and *Adams' Pearmain* were good. In the county collection the dishes, some of which came from old orchard trees, were very fine, *Blenheim Pippin*, *Newton Wonder*, *Prince Albert*, *Beauty of Kent*, *Peasgood's Nonsuch*, *Bess Pool*, *Cox's Orange*, *Ribston*, *Claygate Pearmain*, and *Court pendu Plat* being the best. A silver-gilt Knightian medal was awarded. Messrs. *J. Laing and Sons*, *Forest Hill*, set up a collection of some eighty dishes of Apples, *Golden Noble*, *Tyler's Kernel*, *Mère de Ménage*,

Mabbott's Pearmain, Adams' Pearmain, Sandringham, and Ribston being the best. Beautiful colour was found in Tom Putt, Cox's Pomona, Flanders Pippin, Fearn's Pippin, and Gascoigne's Scarlet (silver Knightian medal). Messrs. Harrison and Sons, Leicester, had a good collection of vegetables, including Up-to-date, Banbury Cross, Rousham Park, and Leicester Globa Onions, Up-to-date, Motor, Windsor Castle, and other Potatoes, Lyon, Exhibition, and Leicester Hero Leeks, Intermediate and Blunt-rooted Carrots, good Beet, Parsnips, &c. (silver Banksian medal). Mr. Basham sent Apple Cissy, somewhat resembling a large Nanny. It is a conical, handsome fruit, rich in colour, flesh firm, but wanting in flavour. Messrs. Wallace and Co., Colchester, sent fine fruits of Allington Pippin. Mr. H. Spencer, Goodrich Court, Ross, had a seedling Apple not unlike Tyler's Kernel or large Hall Door, but it had no merit. Some Cobnuts from Mr. Vokes, Winchester, saved from the previous meeting for comparison with others, were found to be the same as Cosford Cob. Mr. J. Crook sent very fine and richly flavoured Winter Nelis Pears from Forde Abbey, and also Apples to show colour, Wellington especially. Lord Ducie sent fine fruits of the Japanese Medlar (*Diospyros Kaki*) grown on a wall outdoors at Tortworth Court. These were large and of clear yellow colour, but quite hard. A Cucumber named Wilton's Prolific was found to be Rochford's Market. Mr. G. Wythes sent from Syon House Gardens Barkham's Dwarf Beet, which was thought to be like Dewar's Short-top. Mr. Notcutt, of Woodbridge, sent Winter Orange stewing Pear.

NOTES OF THE WEEK.

Chrysanthemum Miss Rose.—Among the single-flowered varieties this possesses a charm all its own, the habit being dwarf, while the flowers are produced very freely. Even when grown in pots with liberal treatment this freedom is seen, and with greater liberty in the open beds the plant is a marvel of free-flowering. A group of this kind at Kew near the Orchid houses is very effective now, the third week of November.

Violet Princess of Wales.—I am sending you a few blooms of Violet Princess of Wales. I consider it the best of all single Violets either for frame or border culture. I commenced gathering flowers from the open borders in September, and at the present time the plants are blooming very freely—much more so than The Czar. These I send were gathered from frames.—G. J. SQUIBBS, *Llangedwyn, Oswestry.*

* * * Fine in size and lovely in colour.—Ed.

Pear Bonne de Malines.—Mr. Crook sends us from Forde Abbey Gardens, Chard, some very fine fruits of this Pear, better known as Winter Nelis. They are from a tree growing against a wall some 12 feet high, the tree covering a space of 12 square feet. It is grafted on the Pear, the soil being a free loam, and in dry weather is given liberal supplies of water. This Pear, in our estimation, is the best flavoured of any, equalling the favourite Doyeuné du Comice.

The Sea Buckthorn (*Hippophae rhamnoides*).—I have had a plant of this for ten years which has never produced berries. It has gradually thrown up a number of suckers this year. It has six berries. Is it possible that some of the suckers can be male plants? There is no other Sea Buckthorn within 400 yards, and though I have planted two male plants beside a female one, the former are so young that the latter has not as yet borne any berries. I should be very glad to have some explanation of this.—HIBERNIA.

Dahlias and Marigolds in the open.—The 20th of November is certainly a late date for either of the above to be seen in presentable flower, more particularly in the neighbourhood of the Thames at Hampton. Of the Dahlias there was a number of really good serviceable flowers, all of the Cactus type seemingly, but little the worse for their rather late appearance. A beautiful lot of Marigold flowers of a pretty strain covered the dwarf bushes as freely as in August. Near by *Jasminum nudiflorum* had already burst into a yellow mass of bloom, telling of winter's near approach. How the Dahlias had

escaped frost is not easy to tell, as they were quite exposed in the garden and not 100 yards from the river.

Apple Peasgood's Nonsuch.—Some grand specimens of this fruit have been exhibited in Devon this autumn, notably Exeter, Exmouth and Sidmouth, but perhaps not quite so highly coloured as last season. I have an espalier, also a tree with four shoots trained round an upright iron trellis, both cropping regularly every season and finishing up very fine fruits. I send two for you to see. Each tree carried over five dozen fruit this year, the majority nearly as fine as those sent.—J. MAYNE, *Bicton, Devon.*

* * * Superb specimens, one being 13 inches in circumference. It would be hard to find better ones.—Ed.

Eschscholtzia crocea.—I have cut many fine flowers of this during the week just past, and I should say this is about a record for lateness, though the plants are now full of buds, which would all open if the weather kept as mild as it is now. The plants are self-sown seedlings from those that flowered in summer, and are very pretty with their fresh green leaves and showy blossoms. Dahlias here are holding out in a remarkable manner, and I could cut a bushel of flowers as fresh and beautiful as in August.—SUFFOLK.

A fine Epiphyllum truncatum.—A specimen of this Epiphyllum such as one rarely meets with nowadays is in full flower in the succulent house at Kew. It is grown in the form of a standard, being grafted on to a *Pereskia* stock about 4 feet high. The Epiphyllum has formed a large branching head a yard or more through, which is profusely laden with its brightly coloured blossoms. The conditions under which this plant is grown in the succulent house are highly favourable to the production of blossoms, as the occupants of that structure are not shaded at all during any period of the year.—T.

Aster grandiflorus.—The great heat of the present year cannot be said to have exercised any good influence in respect of this, probably the finest of all the perennial Asters. The prolonged heat, holding many things so firmly in its grip that growth meanwhile was an impossibility, likewise delayed the growth of this, and its flower-heads in open gardens, notwithstanding rain and many favourable days, are no more plentiful than in many a past year. As a pot plant, however, it is still worth every care, and if plunged in the open garden where copious waterings can be afforded it will repay all in due course both by its dainty habit of growth and its attractive and numerous blossoms.

Celosia pyramidalis.—When the greenhouse or conservatory is given over to the Chrysanthemums other things are apt to be overlooked, yet the above in well-grown plants is effective in the greenhouse, and at least gives diversity, both of character and certainly of colouring, to the usual occupants. Too showy it may be for some who do not care for such gaudy colours, yet among many things in the greenhouse, especially plants of heavy and sombre leafage, a few of the above would materially assist. Such easily produced plants should be of much assistance when good plumes are obtainable in pots 6 inches across. Not least of their value is the time such things remain in presentable condition.

Cornish Gilliflower Apple.—I am sending some samples of this year's crop of Cornish Gilliflower Apple. I was taken to task last year for putting this about on a par with Ribston and Cox's, but still hold to the opinion that, given samples like this, it is very little behind those varieties. The trees bear very fairly with me, the chief drawback being the attacks of birds, which display a strong partiality for the fruit and go for it while yet in a green state. I am compelled to net the trees.—E. BURRELL.

* * * Beautiful fruit. It is a pity this fine fragrant and handsome Apple is not more and better grown. Our friends in Cornwall ought to send to the market large quantities of it. We believe it does not fruit very often in consequence of the cutting away of the fertile parts of the shoot in

had pruning. No American Apple is better in flavour or handsomer.—Ed.

Chrysanthemum Val d'Andorre.—This, though an old kind, is just as well worth growing as ever. This much is fully borne out at the present moment both in the Royal Gardens, Kew, and in the big vinery at Chiswick. In each instance several plants display well the showy chestnut-red or mahogany-red flowers that are produced on stout stems, the entire plant being about 3 feet above the pot. At Kew the plants are grouped in the front of the centre bed in No. 4 greenhouse, and immediately behind it is that other highly-coloured sort, Tokio. Those who prefer such showy and decided colours should grow these, for in the dismal surroundings of a foggy day both kinds are seen to advantage, while not a few of the more mixed-up shades are either washy or indistinct.

Colchicum Sibthorpi.—This fine Meadow Saffron, which deserves the praise you give it on p. 391, is later with Mr. Kingsmill than it is with me. It has been past here for some time. I am much interested in the genus, although one finds that some do not care for the flowers, and would be glad to know if the corms at Harrow Weald are established or if they were planted late in the season. It is possible that there is more than one variety of *C. Sibthorpi*, and that, if more, these flower at different times. One would gladly, if possible, have the fine flowers a little longer. Nearly all the Meadow Saffrons are out of bloom here, but a few doubles still remain, with *C. holophum*—or what I have for it—a free-blooming little Meadow Saffron. The Crocuses now in flower are more fascinating, but there is more than room for all at this season.—S. ARNOTT.

Caryopteris mastacanthus.—The frequent references to this pretty shrub in the gardening press have probably led to its introduction into many gardens. It will be a favour if some of the readers of THE GARDEN who are living in some of the colder districts will inform me if it has flowered with them in the open this year. It is offered in some catalogues as a hardy shrub. My experience of it in the open is as yet limited here to the current year and to its conduct during the past winter. The March frosts destroyed the young shoots, which were considerably advanced, and fresh growth had to be made. Flower-buds were formed in autumn, but these have not opened. I think it is possible that the plant, which is in a warm position, might have opened its flowers had it not been for the check in spring. Could we rely upon the *Caryopteris*, it would be a valuable shrub for the rock garden.—S. ARNOTT.

Callistephus sinensis.—With reference to the remarks made by "H. P." and "A. D." on p. 385 relative to this plant no parallel can be drawn between it and the single forms of the ordinary annual Asters. The single annual Asters in commerce, which are reversions from the double forms, are coarse and straggling in growth and bloom very early, before the doubles. *Callistephus* (*Aster*) *sinensis*, on the other hand, blooms very late, when all other Asters (double and single) are past, and has a fine symmetrical growth, with flowers of a highly refined character and distinct in colour. Moreover, it reproduces itself true from seed and has every indication of being a distinct species.—P. R. BARR.

— I did not at first think much of this when the plants flowered, but I changed my mind after. They bloomed later than any of the other Asters, and certainly were very beautiful and much admired. I cut some blooms four days ago. This *Aster* is well worth growing, as the colour is so soft and uncommon. I have been able to save a lot of seed.—G. S. JELLCOE, *Wimborne, Nov. 11.*

Antholyza æthiopica.—The other day we directed attention to the beautiful and rare, if not indeed remarkable, variety of the above species called *A. æ. vittigera* that Mr. Bennett-Poë brought to the Drill Hall. At the present time the form minor is yielding a few flowers at Kew in the No. 7 range. From this example one is not greatly impressed with its showy character or its

freedom. Apart, however, from its smaller stature, the flowers are almost self-coloured, devoid of the yellow exterior to the tube of the corolla as seen in the variety *vittigera*. We incline to the opinion, however, that a much more liberal treatment is needed to fully develop flowering-spikes in so free-growing and vigorous a plant. The increase of the rootstock as much as the general character of the growth all tend to strengthen the suggestion that with greater freedom for the roots a much freer flowering would ensue. Montbretias as pot plants flower with little trouble in the first year, but this freedom of flowering is not maintained without special care, as repotting, &c. The above forms of *Antholyza* are more vigorous than the majority of Montbretias, and coming into bloom in the early autumn would form an attractive and picturesque group if accompanied by a greater freedom of flowering each succeeding year.

The blue Primroses.—It is often said that the flowering of Primroses and Polyanthus at this time is unseasonable. This is hardly correct, for it is the usual thing for many to throw up blossoms at this season if the weather is at all open. A good many are now showing a few flowers, and among them are Mr. G. F. Wilson's blue Primroses. In spring we shall possibly be told that these flowers are not so good as the others. This saying misses one of the points which distinguish them from our ordinary Primroses. This is their early blooming habit. They are at their best before the others are in full beauty. The blooms at present being produced are on shorter stalks than in spring, but they are in no other respect inferior to those given in the spring-time. They are of that deep rich blue which was the aim of the raiser, and which is wanting in the flowers produced when our charming wild Primroses are in the heyday of their modest beauty. I have at present a couple of clumps of seedlings now some three years old which are blooming freely in rather heavy soil and in a cold exposure. The flowers are very beautiful indeed and only require to be seen to draw forth admiration. The colouring is vastly superior to the slaty-blue shown by some plants in April and May.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

***Sternbergia lutea*.**—In answer to Mr. Tallack, the following, I have no doubt, will include the information he desires. *Sternbergia lutea* is not a free-flowering plant, neither is it a free-growing plant. It dies out, while the variety *angustifolia* grows and flowers in the most satisfactory manner. I suspect that this plant is always referred to whenever any good account is given of the species. This variety with me produced leaves 12 inches to 14 inches or more long and three-eighths of an inch wide, forming a fine mass of foliage. The type has shorter leaves and at least half an inch broad. It does not appear to be worth growing from a garden point of view, while the variety *angustifolia* is one of the finest of autumn-flowering bulbs and quite indispensable. In the light soil of the Cambridge Botanic Gardens it does remarkably well, and probably its success may largely be due to summer dryness. There are forms with still narrower leaves than this, and Mr. Baker mentions the var. *græca* which has leaves only one-twelfth of an inch to one-eighth of an inch broad, and flowers with oblanceolate perianth segments. There are a similar form in Crete with a longer peduncle and also the var. *sicula*, the precise dimensions of which are not given.—R. IRWIN LYNCH, *Botanic Gardens, Cambridge.*

—What has appeared in THE GARDEN regarding this "Lily of the Field" shows us that the desire to help others which exists among those devoted to their gardens is in no way abated. Not only from your pages, but also from private letters received one has again found this in connection with difficulties experienced. Judging from specimens sent and from the information supplied, I think that in most instances the *Sternbergia* which blooms so regularly and well is

the variety of *S. lutea* known as *angustifolia*, which is referred to by Mr. Tallack in THE GARDEN of November 18. From various quarters I have had specimens sent me with a courtesy I desire to acknowledge. It may be that most of the references we have seen in past years may be to this narrow-leaved variety. It is recognised by some of the older works of reference, but does not find a place in Mr. Baker's handbook of the natural order to which the genus belongs, unless it is the form *S. sicula*. While, as "E. J." suggests, a cold subsoil may have a good deal to do with the failure of *S. lutea*, that is not the cause of its non-flowering here in the past. The addition of lime, as formerly advocated, is little trouble and is well worth a trial.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

***Convolvulus Cneorum*.**—When we in the north have to bewail that our gardens are deprived of much of their charm by the weather conditions, the delightful articles by your South Devon correspondent give even greater pleasure than when our flowers are plentiful. The pleasure is, perhaps, mingled with sadness at the thought that we cannot refresh our eyes with looking upon the flowers themselves. One is led into this train of thought by a couple of branches of *Convolvulus Cneorum* in bloom included in a box kindly sent me with some bulbs by Mr. T. Archer-Hind. Not only can we not have it in flower here at this season, but I hardly think that we can grow it permanently in our northern gardens. I do not know that it is growing without protection in any Scottish garden, unless it may be in one somewhere on the west coast, such as that of Mr. Osgood Mackenzie, where the influence of the Gulf Stream gives a mildness to the air we have not even in the south-west. This *Convolvulus* recalls the recollection of it in the delightful garden at Mount Usher, in Co. Wicklow, where it seems to thrive to perfection. It is, indeed, a lovely plant with its silky stems and leaves and its exquisite white flowers flushed with pink on the exterior. Like most plants covered with silky hairs, it seems to dislike much rain in winter, and in wet districts needs to be covered with glass. A little protection of this kind is not too much trouble for the pleasure given by this lovely flower.—S. A.

***Tropæolum tuberosum*.**—It is gratifying to see from Mr. James Day's courteous and valuable communication on p. 389 that the beautiful *Tropæolum tuberosum* is more amenable to cultivation with some than I had supposed. While my remarks upon it were principally directed to show its want of value as a hardy perennial, at the same time I had known of so many disappointments with it as a half-hardy plant, that I was hardly prepared to hear of it flourishing and flowering so well in the adjoining county to that from which I write. Wigtownshire is, of course, as one has found from correspondence, rather warmer than this, but I imagine that the difference lies in a slightly higher winter temperature rather than in more warmth in summer. It is not improbable, therefore, as Mr. Day suggests, that this *Tropæolum* might succeed with me as a half-hardy plant, seeing that it does so well at Galloway House as to merit the praise given it by one so careful and observant as Mr. Day. The cases in the south of Scotland in which it has come under my observation have been a little further inland than this, and in gardens which, to my knowledge, have more warmth in summer than mine, which gets a good deal of wind and which is cooler on this account. The experience of your correspondent shows us another example of a truth we all need to keep in mind in our gardening, *i.e.*, that gardens in the same districts vary much, and that we cannot say without reservation that any given plant will or will not succeed in any specified garden. By the way, a research for records of experience with this *Tropæolum* has reminded me of what I had forgotten, that the tubers are edible. I do not know if any of your correspondents have cared to submit them to the test of the palate. The description of their flavour is not particularly tempting.

They are said to have a perceptible flavour of Watercress, with some of its acrid character. Although not hardy with us it may be in, say, Devonshire.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

PUBLIC GARDENS.

A recreation ground at Worsley.—We learn that Lord Ellesmere and the Bridgewater Trustees have given to the district council an extensive tract of land known as Roe Green for a public recreation ground.

Park de la Tete d'Or, Lyons.—This park lies just outside the city of Lyons and is of great extent. It contains the municipal greenhouses, a fine winter garden, an alpine and botanic garden, the whole under the care of M. R. Gérard. At the time of my visit the beauty of the open-air gardening was over, but in one of the greenhouses there was a large collection of *Chrysanthemums* grown in what is termed the "culturo lyonnaise," which consists in striking the cuttings as late as May and growing only four or five blooms on a plant. These are consequently very dwarf, but they are useful for grouping, and under the care of M. Choulet, the originator of this method, they certainly presented a very nice appearance. Specially noteworthy were Mme. Gustave Henry, President Nonin, Mlle. M. A. de Galbert, William Seward, Souvenir de Petite Amie, and Mrs. C. Harman-Payne, all too well known to need description. *Fée du Champaur*, white; *Le Drac*, a large yellow; *Mme. Leblanc*, a fine large pure white incurved; and *Jules Chrétien*, a rosy pink Japanese, with velvety pink reverse, were others equally well done. Others in good form comprised H. Jacotot file, *Surpasse Amiral*, Mlle. Philomène Claret (a large pale bluish Japanese), Lord Brooke, Marie Louise, Mme. Carnot, Mme. Ed. Roger, and Mme. Zurick. In the winter garden, a large glass structure about 80 feet high, were several fine groups of *Chrysanthemums* in full flower. Outdoors some fine groups of Dahlias were untouched by the frost. In the botanic garden many of the annuals, bedding plants, and herbaceous plants were still in bloom.—C. HARMAN-PAYNE.

The weather in West Herts.—During the past week the days were of about seasonable warmth, while nearly all the nights proved cold. On each night the exposed thermometer fell below the freezing-point, and on the coldest of these registered 10° of frost. The latter is the lowest reading as yet recorded here during the present autumn. At both 1 foot and 2 feet deep the ground temperatures are slightly below their respective averages for these depths. No rain has now fallen for nearly a fortnight. Throughout the week the air remained very calm, the mean velocity at 30 feet above the ground on two days being less than a mile an hour. The record of bright sunshine was very poor, four days being altogether sunless. My Dahlias, which had lingered on in a crippled condition since September 29, were killed to the ground by the above-mentioned frost, that of the night preceding the 18th, which is a fortnight later than the average date of their destruction in the previous fourteen years, but five days earlier than last year.—E. M., *Berkhamsted.*

Names of plants.—E. J. Randell.—1, *Adiantum gracillimum*; 2, *Pteris scaberula*; 3, *Tydæa* sp.; 4, *Enonymus japonicus aureo-marginatus*.

"The English Flower Garden."—Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d. Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.

CHRYSANTHEMUMS.

A PLEA FOR A HARDIER CHRYSANTHEMUM.

WHAT Mr. E. H. Jenkins says about his Golden Sheaf in THE GARDEN of November 25 induces me to offer a few remarks upon a phase of Chrysanthemum growing which has for some time appeared to me to be deserving of more notice than has hitherto been paid to it. This is the desirability of raising and growing hardier Chrysanthemums than have of late been introduced.

It must be apparent to most that there are great numbers of admirers who, from choice or necessity, are unable to indulge their liking for the Chrysanthemum from lack of the necessary glass structures. It is likewise apparent that there are thousands of gardens which stand in need of some brightening when November comes. There are some flowers to be had then in ordinary seasons, but their number is very limited and they might be added to with advantage. So far as I know, we have little but the Chrysanthemum to look to for a revolution in hardy flower gardening in November. I have done my best to show the usefulness of other flowers, such as the autumn Crocus, but one must admit that there is room for many other plants, and, above all, room for those which will give us flowers for cutting.

It is, of course, incontestable that in a few seasons there is no difficulty in having Chrysanthemums in bloom outside. I can recollect seeing, one mild winter years ago, a considerable number in bloom in the open in the suburbs of Edinburgh well into December. Our northern capital is not noted for its warmth in winter, so that the fact of these plants being in bloom is encouraging to those who would desire to make use of them in the open. That was, however, a mild season, and cannot be taken as representing the average winter in the Edinburgh district. It is also possible for many in favoured regions to grow many of these flowers to a surprising excellence in their districts. Before me as I write are good blooms grown in the open air by a Cardiff

amateur. These are finer than we could expect to secure here from the same varieties.

All this is, however, only introductory to my main point, which is that raisers should try to obtain flowers capable of standing better than those we now have the weather of our winters. Is it impossible to produce such? I think not. We have some Chrysanthemums much hardier than others. I see some in gardens which are for all purposes equal to hardy perennials. Cannot someone with time and space take these up and evolve from them what would practically be a new race? I am at present inclined to think that our newer Chrysanthemums are not so hardy as those of older date, but there are others better qualified than I am to give an opinion on this point. From my own observation I also think that a hardier race of these flowers would require to be smaller and less irregular in their outlines than our modern Japanese Chrysanthemums. The latter are too large and allow the rain too much entrance to be suitable for standing the stress of our wintry weather. One finds that some of the old reflexed flowers stand better than most. White Christine is, for example, the best I have tried, with the exception perhaps of an old purple one, which I take to be Webb's Queen, which was in this garden when I came to it more than fifteen years ago, and which without protection flowers annually, though late. The reflexed petals seem to throw off the rain and thus guard the blooms from one of the dangers which befall flowers in the open in our winters. The singles and the pompons are also good and useful for outdoor bloom, and one cannot but believe that important results would follow persevering work upon the lines I have ventured to suggest. From the note by Mr. Jenkins already referred to, I think what I have said will meet with his concurrence. He deserves our thanks for engaging in experimental work of a kind which may have a powerful influence upon the gardens of the future. There is ample room for workers in the same field.

S. ARNOTT.

Chrysanthemum Jeanne Delaux.—Is there a richer dark purple Chrysanthemum than the

above? If so, I am unacquainted with it. Those who grow graceful sorts for cutting know its value, a vase tastefully filled with its shaggy blooms having a charming appearance. One may now inspect a great many collections without seeing a plant of Jeanne Delaux. It is not one of the most robust growers, which perhaps accounts for its partial disappearance. If the plants are pinched in March and potted in good loamy compost they will grow into nice serviceable bushes, a dozen or so plants, if little or no disbudding is done, furnishing a most useful lot of flowers. I was pleased to see it mentioned by a correspondent a week or two ago. I do not know if it would be considered sufficiently large for exhibition at the present day, but a good bloom used to tell years ago.—J.

Single Chrysanthemums.—The value of single Chrysanthemums for the decorator has been but tardily recognised, but there are signs that this neglect is to be a thing of the past, for they are beginning to play an important part in trade exhibits. At Manchester Messrs. Clibran had a fine display, showing sprays of many good and distinct new varieties, but as these were almost all shown under numbers, the exhibit was not so useful as it might have been to one taking notes. Among named varieties three crimsons were very good, viz. Felix, Amy Huntley, and Winifred Hull, each differing in shade and form. Mr. Wells had an exhibit of Etoile de Feu, a very bright-looking crimson-bronze, that carries good sprays, but it had almost too many petals to be called a single. While writing of this section of Chrysanthemums it may be useful to add a short list of the older ones which I have found most useful. Mary Anderson, white, changing to blush, is probably the best known of all, and its tawny yellow sport, Miss A. Holden, is also good. Miss Christie, bright terra-cotta, is quite brilliant while the flowers are young. Marguerite is very free, pure white, medium size, the flowers somewhat rough in form, but very useful. Buttercup bears many flowered erect sprays of rather small, round flowers, buttercup-yellow in colour. Emily Wells is one of the very best, bright rose, medium-sized flowers that stand erect on long sprays. Prolific is rather large. The flowers, which open blush-coloured, mottled with white, soon change to a paler hue, and are then very much like those of Mary Anderson in form and colour, but larger. This is a very free variety. With Snow Wreath I am disappointed; it looks like a bad seedling of Avalanche, and should not be classed as a

single, as it has several rows of petals. Snow-drift is a useful white variety. For those who like very dark crimson Annie Tweed will prove a charming variety, very much like Mary Anderson in habit, form, and size. Useful late varieties are Admiral Sir T. Symonds and Kate Williams, both large-flowered yellows. Mrs. A. E. Stubbs, creamy white, of good form, with fairly long, narrow-pointed petals, and Best of All, a small-flowered lilac variety, which is the latest of any I have grown, are also good.—J. C. TALLACK.

—Some of the single-flowered Chrysanthemums are used at Kew for planting in the open border or in beds, particularly those old varieties Mary Anderson, Miss Rose, and Mrs. A. le Mout. The first two are different shades of blush or pale pink, while Mrs. A. le Mout is a bright amaranth-crimson. It was sent here from the United States in 1885, while the other two were sent out by Mr. Cannell at much the same date. All are of good sturdy growth, with small or medium-sized flowers borne on firm stalks, so that they are but little affected by wet or wind.—T.

BORDER CHRYSANTHEMUMS AT CHISWICK.

HAVING watched the development and ultimate flowering of a goodly collection of so-called summer-flowering Chrysanthemums during the present season in the Royal Horticultural Gardens at Chiswick, it has occurred to me that such information as these afford may interest those of your readers who cannot frequently visit the society's gardens. This year the collection has been grown on the south side of the great vinery in the long border adjacent thereto, but separated from the vinery border by a broad gravel path. The plants are set out usually two of each kind and at about 3 feet apart, a space that permits of very full development in each case. At the outset it may be said it is no year to judge this flower in the open, but as a set off against such a remark is the fact that the collection referred to is under one and the same treatment. Remembering also that we have now experienced two summers in succession both of extreme heat and drought long continued, it behoves cultivators of this section of the Chrysanthemum to look about for those varieties that are proving useful and more or less reliable as dry weather kinds. It may be taken for granted that those that do fairly under trying circumstances may reasonably be expected to do even better with more favourable conditions. Thus it is at Chiswick. Some few kinds have done extremely well, equally so in several positions; others less so, yet good for the season, and still a few others unmistakably prove of little value for the border or the garden. In some private gardens where such details as watering could be more freely or frequently indulged in, some of the kinds mentioned as of little worth may prove a success, e.g., Ambrose Thomas, which at Chiswick is quite a failure, has proved quite a success in my own case, flowering well, and with only two good soakings of water all the season. The plants of this kind at Chiswick are at the end of the border, and may have suffered from the larger tree roots near. I have no knowledge as to how the Chiswick border was prepared and how it was manured and so on, but the ample space afforded each plant should at least have gone a very long way to making them a success.

Of those I noted, the following are good in each and every instance: Vicomtesse d'Avane, reddish lilac, 2 feet, early, very free; M. E. Lefort, orange and gold, 2 feet, early, free, sturdy; Jacinthe, 1½ feet, white, lilac tinted with age; Mignon, 1 foot, gold; American Star, 2 feet, white and lilac, a great bloomer; Salter's Early Blush, very early and free; Fred Pele, crimson pompon, 2 feet; Illustration, 1½ feet, white, early. The varieties of the Mme. Desgrange section are all good, though not up to their usual form. Other good kinds are M. Dupuis, a pretty bronze, 2½ feet high, habit rather thin; Crimson Queen, 2 feet, fine bush, quite a late October

kind; Henri Yvon, reddish lilac, free, 2 feet; Nellie Brown, the sport from Rycroft Glory and in habit a counterpart of this. Jean Vuillemet is a very attractive crimson, 2½ feet high; Ivy Stark, a fine bush, but is best with liberal treatment; Mme. Eulalie Morel, a most fascinating flower, cerise and gold, very free and excellent in habit. Ambrose Thomas is still one of the most showy, though not a success in this particular instance. Harvest Home is a fairly well known kind, and Bronze Prince is of the right colour.

The above are the best in this collection. It is necessary, however, in view of the increasing number of so-called decorative or border kinds, to call attention to what appears an error by the indiscriminate way in which all sorts are bundled into this group that are not up to standard requirements of other sections. It is obvious that the Japanese section is being largely employed by the raisers of these things as much in height and habit as in colour. Not a few of these after a feeble attempt at flowering disappear completely, leaving no trace of a cutting behind, which is perhaps the most honest declaration of their unsuitability. What is needed, and what, moreover, should be the chief aim of the raiser, should be to endeavour to obtain perfectly hardy kinds, such indeed as may be grown on the border from year to year, and by this prove themselves of special value to the border. One of the most sturdy and hardy that I know is Mons. E. Lefort, though the flowers may not suit all. At the same time, for its hardiness, sturdy and strong habit, with freedom of flowering, it should make an excellent seed parent for future work. Nor does its dwarf habit require any support. Many kinds now being introduced are too tall—4 feet, and some even more. All such are too tall for the purpose and quickly become victims to the rough winds of late autumn. E. J.

NOTES AND QUESTIONS.

Chrysanthemums grown in Moss.—Mr. Truffant, son of the well-known Versailles nurseryman, has invented a liquid manure which enables one to grow Chrysanthemums from the cutting to the flowering stage without the use of soil of any sort. The plants, which are grown in Moss, are fed with the manure, which, it appears, contains all the nourishment necessary, throughout the whole season. A pretty little exhibit of dwarf plants in Moss, in pots, which had received this treatment, was set up at the Lyons show by M. Delvert, the blooms all of good size and well coloured.—C. H. P.

Chrysanthemum Mrs. White-Popham.—I saw some fine blooms of this grown on plants with single stems in small pots, and it would appear that this mode suits it better than any other. The blooms each measured 9 inches by 7 inches—large enough for anything. The colour is not over bright, yet pleasing, the tints of rose and white being distinct. In form the variety differs. The blooms from early buds are recurving, with just a curl at the tip of each floret, but from late buds they have an incurved Japanese form of noble build. This latter form pleased me most, although the plants that produced them were considerably taller.—S.

Chrysanthemum Mrs. Filkins.—As a decorative variety either in pots or for cutting this is an extremely useful kind. For small vases the flowers seem better fitted than large ones. They resemble a Sweet Sultan more than anything I know, and as such they ought to find more cultivators. It would seem, however, that these thread-like Chrysanthemums have a greater future before them, for raisers are giving them some attention, and colours are being added in varied shades. Mrs. Filkins has been grown for some time in a few gardens. Those unacquainted with it ought to make an effort to obtain cuttings at once.—W. S.

Chrysanthemum M. Louis Remy.—I have seen this variety growing and exhibited on two or three occasions this autumn, and in the latter case, was able to compare it with the well-known Phœbus, and I could not help being struck with its similarity. Phœbus differs much in character in different soils and from varying buds, as do many other varieties of Chrysanthemum. As a variety M. Louis Remy is quite distinct and, as is well known, comes as a sport from Mme. L. Remy. Phœbus, for an old variety, retains its popularity among some exhibitors by reason

of its sterling qualities, but whether it will be ousted by the more recent M. Remy remains to be seen. I should not be much surprised to find them bracketed together for exhibition.—W.

Chrysanthemum General Symons.—We are sending you this morning a specimen bloom of a sport which occurred on Western King, and should feel much obliged if you could give a report on same in your next issue. The sport is of the same habit and constitution as the parent plant and goes by the name of General Symons.—F. ROBIN & Co., Balmoral Vineries, Guernsey.

* * A very pale yellow bloom, the florets closely incurving as in the parent.—ED.

ORCHIDS.

PILUMNA FRAGRANS.

THE true form of this lovely Orchid cannot even be guessed by looking at the half-starved, insect-infested plants one often sees, or by large specimens that have all the centre bare and the few good bulbs mostly hanging over the sides of the pans. When really well grown it is a very beautiful plant, its chaste white blossoms, with dense yellow eye, showing up remarkably well against the deep green of the foliage and bulbs. Healthy newly-imported or semi-established plants may easily be kept going and increased in size annually, but those which have been ill-treated for years in Orchid or other plant houses have lost all the vigour they ever possessed, and only on rare occasions do they revive and make good plants. The reason in most cases is that they have lost their power to produce roots, or at least in sufficient quantity to re-establish them properly. Healthy specimens, on the other hand, produce roots freely, and in consequence get a capital hold on the compost and flourish accordingly. Given a strong plant fresh from an importation, this should be thoroughly cleaned and most of the loose scaly sheaths removed. Avoid injury to the rhizomes and the old bulb bases, as these often produce breaks that make a well-furnished plant, and it is difficult at times to say with certainty whether a bulb is really dead or only badly shrivelled. By the time they are well plumped up and fit for potting one may generally tell with more certainty which is good or otherwise.

Give them room in the pots, but avoid a great depth of compost, and allow a quantity of large rough lumps of rocks and charcoal to encourage free root action. A surfacing of Sphagnum Moss kept just moist prevents the necessity for very frequent watering, and is advisable, as the latter tends to fine down the compost, before the roots have obtained a good hold of it. Respecting the supply of water to established plants, there are few Orchids that like more than this, always provided the compost is in good order as described above. At no time should the compost be really dry for any considerable time, but especially when growth and roots are both active. The bulbs once shrivelled, the roots soon follow suit, and the plants are then in a bad way. P. fragrans likes a little more warmth than is afforded in the Odontoglossum house, and if no intermediate house exists it is better with the Cattleyas than here. The gentle warmth keeps the roots on the move in winter and prevents that stagnation of the plants noted above. It is a mistake to leave them too long without repotting. Pilumna fragrans is also known as Trichopilia fragrans, and there is a variety called nobilis with larger flowers than the type needing exactly the same treatment.

Calanthe vestita luteo oculata.—This is generally preferred by florists and Orchid growers

to the variety with crimson eye, and it is a very chaste and beautiful Orchid, as are most kinds in which yellow and white are combined. But few are so generally useful as this. The health of the plants is often endangered by standing them about in cold, draughty houses or corridors when in flower. It is a heat-loving plant and cannot endure such treatment, especially when to this is added careless watering. These items of mismanagement often lay the foundation for an attack of the black spot in the bulbs.

Repotting Thunias.—Although there is no hurry as yet, the Thunias should be carefully watched after they show any sign of starting at the base and, when convenient, repotted. They need not, of course, be watered, but it is very bad policy to wait until the roots are starting before repotting and then to bruise and damage these in the operation. They cannot, in short, be potted too early, and as the present is a dull time for this kind of work, they may be attended to and time saved later on. The plants like a substantial medium to root into, good loam with a little chopped Moss and peat-fibre answering well.

Dendrobium squem.—This would not be thought much of in the middle of the Dendrobium season when the handsome deciduous kinds are at their best, but just now it makes a variety, and it is really not without merit. It is of semi-pendulous habit, this suiting it for basket culture, and the stems are about a foot and a half in length, the upper parts of which are covered with the flowers, produced in pairs. The sepals and petals are creamy white, the lip having a yellow blotch. Like most of its section, it delights in ample light, heat, and moisture while growing, with a distinct resting season.

Back-breaks in Orchids.—The practice of cutting partly through the rhizomes of pseudo-bulbous Orchids to cause them to throw back-breaks is well known as a means of propagating rarities and improving existing specimens, but it is often done at the wrong time, *i.e.*, just as the plants are commencing to grow. It is far better to do it in late autumn; then the basal eyes have the winter in which to swell up, and the breaks are early and in season. Late breaks are weak and often do not ripen up properly with the older bulbs, but are still growing when other parts of the plant are at rest. There need be little fear on the score of the parent plant, for if this is of sufficient strength to bear the operation at all, it will do so now just as well as at any time.

Sophrontis grandiflora.—In dull, cold weather, when outside all is dull and gloomy, the glowing blossoms of this pretty Orchid have an added charm. They are very large for the size of the growth, and as the pseudo bulbs at the time of flowering are often only partly made up, it is important that the plants are well treated and not allowed to stand about in draughty or dry living rooms or conservatories. Well-flowered plants have a very beautiful effect among white-flowered species, or, indeed, among almost any other Orchids, a group of which they brighten up in a wonderful manner. Any moist and well-ventilated house a little warmer than that where the coolest section thrives will suit it, but the roots need very careful treatment and must not be kept too long without fresh compost.

Coleogyne cristata in winter.—I quite agree with "B. S." (p. 371) that it is a great mistake to withhold water from this useful Orchid in winter, but it will not always prevent shrivelling to keep the roots moist. There is one form of *C. cristata* with round pseudo-bulbs that is a good deal easier to keep in a plump state than the later flowering form with oblong ones. Why this is so it would be difficult to say with certainty, but I think that the fact of the pseudo-bulbs occurring at much greater distances on the rhizome, and being therefore farther from the compost, may have a little to do with it. Any way, the fact remains that you may have the two plants standing next to each other and treated identically, and the one will shrivel while the other keeps plump. Again and again I have

warned cultivators against drying their plants, but one is constantly coming across specimens so treated.—H. R.

Odontoglossum Edwardi.—The plants of this fine species are now pushing up flower-spikes, and it is well to see that the temperature in the house wherein it is grown is kept steady, and not allowed to fall below 50° at any time. Again, the spikes are apt to be bent by coming into contact with the leaves when in a very young state, and if by a little manipulation they can be given a straight course it is all the better for them, as when once lost they can never regain their characteristic shape. The tips of the spikes, too, are apt to come into contact with the glass and be disfigured. Keep the roots fairly moist, and if green fly attacks the spikes remove it at once with a damp sponge, or the flowers will be ruined. The peculiar violet-purple tint of the flowers of this species makes it quite distinct from all others.

Angræcum sesquipedale.—The beautiful pure white blossoms of this species are now open, and where sufficient specimens are grown the display will go on for several months. Although the plants grow rapidly and show a marvellous greenness of leaf when in a hot, moist, and shady house, there is no question that flowers are more freely produced when the plants are given a slightly drier condition of the atmosphere and ample sunlight. This paucity of flowering in plants heavily shaded has often been noted by those who have seen the plants growing naturally, and it is just the same with cultivated specimens. Root moisture in abundance it likes without a doubt, and the more the roots are encouraged to ramble about over the stages or elsewhere the better it is for the plants, though, of course, it will be awkward to remove such specimens. Good Sphagnum Moss and large lumps of charcoal and burnt clay are the best compost.

Sobralias.—These are fine now in many collections, and the large *Cattleya*-like blossoms are very beautiful against the handsome foliage and stems. The typical *S. macrantha* is still one of the best, and many of the white and yellow forms are chaste and lovely Orchids, the blossoms following one another in quick succession. Though many are of tall habit, there are several with stems only a couple of feet or so in height, and these are beautiful plants where the houses are not large enough to admit of the tall growers being admitted. The culture is so easy that the merest tyro in Orchid growing may take them up with every prospect of success. They like plenty of root room and a compost consisting of good fibrous loam, leaf-mould, peat, and chopped Moss in about equal proportions, adding some rough lumps of charcoal and crocks. Drain the pots well, and allow the surface of the compost to come well below the rims, as the roots need abundance of water during the growing season. The cool end of the *Cattleya* house will be found a suitable position, taking care that ample light, but not direct sun, reaches the plants.

NOTES AND QUESTIONS.—ORCHIDS.

Lælia pumila.—I recently saw this charming little species in fine condition at Fir Grange, Weybridge. In this *Lælia* the rich colour of the lip is particularly noticeable, and a plant bearing a dozen good blooms is very effective. This species, being of such lowly growth, is evidently best suited when hung up near the roof. At Fir Grange it is treated in this way, so that the young growths are fully exposed to light and a free circulation of air.—J. C. B.

Cattleya labiata at Fir Grange.—This very useful *Cattleya* has been making a brave show for some time past in Mr. Bilney's garden at Weybridge, the flowers being high in colour and freely produced, one spike carrying nearly a dozen well-developed blooms. For brightening the Orchid house at this time of the year this *Cattleya* is invaluable, and one may truly say that it is indispensable wherever Orchids are cultivated. It evidently enjoys the treatment it gets at Fir Grange, the growth being very stout and the leaves having

that healthy hue which characterises this family when in the enjoyment of congenial conditions.—J. C. B.

Vandas at Weybridge.—*Vanda cœrulea* is grown well at Fir Grange, Weybridge. The flowers have that exquisite clear blue shade that distinguishes this Orchid in its best form. The plants get the benefit of abundant light, the house in which they are grown facing south with good ventilation. In a close, stuffy atmosphere and where the plants are grown far from the glass, the flowers are sure to be deficient in that fine blue tint that renders this *Vanda* so attractive. Associated with it is the imposing *V. Sanderiana* to which in 'colour it forms' a remarkable contrast.—J. C. B.

STOVE AND GREENHOUSE.

POTTING PLANTS IN WINTER.

MANY plants may be repotted during the winter, and by so doing it will relieve the work in spring when so many things need attention. In potting during the winter there are several important items to which particular attention should be given. It is, perhaps, owing to the omission of these details that plants suffer when disturbed in cold weather.

The first thing is to see that the soil is in good condition. It should be prepared some time before use, and for plants taken from warm houses it should be warmed by some means. There is nothing more destructive to the young and tender roots than putting them into cold soil. The result is that the points which should penetrate the new soil are destroyed, and consequently the plants receive a check, besides which the new soil may get sour before the roots can make a fresh start. I have, on examining sickly plants, found that the roots (which were perfectly healthy at the time of potting) had every appearance of having suffered as suggested above.

With regard to condition of soil, it should be rather dry than otherwise, but if as near as that of the plants to be potted all the better. Sufficient attention is not paid to the condition of plants with regard to moisture. If the ball is too dry it is difficult to wet it through properly afterwards, and if too wet it is liable to get pressed up and prevent the roots getting away freely. Another important point is to avoid exposing the plants to a cold draught or to leave them about in the potting shed longer than is absolutely necessary. This and taking them from one place to another are a great source of danger. With regard to watering, I like to settle the surface by using a fine-rosed can, giving later sufficient water to pass through. This may be done a day or two later, according to circumstances. If the pots are new and they are quite dry, they should be moistened before they are used.

Attention to these small details will conduce towards success at all times and with all plants, and though a little more liberty may be taken in warm weather, it is absolutely necessary to use the greatest care when dealing with tender plants in winter. A. HEMSLEY.

Cyclamens.—A splendid exhibit of the best forms of Cyclamens by Messrs. Sutton at Manchester only helped to accentuate the poorness of the so-called *C. Papilio* shown by the same firm and others; not that the plants were worse grown or flowered, but the ragged edges and curious form of the flowers gave one the impression of indistinctness, and the general effect of the groups was ragged and poor. I noticed that Messrs. Sutton had judiciously left a wide gap between their plants of this and those of their best selected types of such well-known and beautiful varieties as Vulcan, Salmon Queen and the giant white, crimson and pink forms, all of which threw their well-formed flowers well above the foliage. All

the Cyclamens exhibited by Messrs. Sutton were young plants flowering for the first time, and were models of good culture under the express system now in vogue by most growers, for they looked almost too big for the 5-inch pots which they occupied.—J. C. TALLACK.

Begonia Dregei.—Though an old inhabitant of gardens and useful for flowering during the last months of the year, this is not often seen. A group exhibited by Messrs. Sutton at the Manchester Chrysanthemum show recalled it to my mind. The plants in this group were very healthy and covered with their small white blossoms, while the leafage was also ornamental, the leaves reminding one of those of *B. weltoniensis*, though they are smaller and rather more angular than those of this variety. It is an ideal plant for the front row of a group, as it is a dwarf grower and the habit is sufficiently bushy to enable the plants to quite hide the pots. Though generally propagated from cuttings, this *Begonia* is far better when raised from seed, as the seedlings come true and do not assume the stunted habit that cutting-raised plants sometimes do. *B. Dregei* is specially interesting just now as being one of the parents of the popular *B. Gloire de Lorraine*.—J. C. T.

Begonia Gloire de Lorraine.—This has now quite taken its place as one of the most popular of winter-flowering plants and is a very beautiful one. At the Bury St. Edmunds Chrysanthemum show recently some very good plants were shown by several exhibitors, a fine lot coming from Mr. R. Burrell, of Westley Hall. The plants were very well grown indeed and, as usual, profusely flowered. It is usual to propagate this by stem cuttings, but Mr. Ingram, the grower of these plants, informed me that he got much better results from rooting the leaves in the same way that *Gloxinias* and similar plants are propagated. The plants, he says, break more freely and are not so likely to damp when rooted—a source of trouble to many growers. At least if it has no other benefit, this method will prove a very rapid mode of increase, and I should say that the young plants would not run so quickly to flower, which would be a decided advantage. At any rate it should be worth trying, and I should like to hear what other growers of this fine plant have to say upon the subject. As a rule, I think the difficulty has been not so much in rooting plants as in getting nice healthy cuttings without flower-buds. The small leaves would probably not produce more plants than could be left in one pot, and shifted on they should make nice bushy stuff.

Begonia Caledonia.—Under the above name Mr. Forbes had at Manchester several plants of the new white *Gloire de Lorraine*, and the plants must have been in much better condition than were those recently exhibited at the Drill Hall, for though the leaves were paler than those of the type, they looked healthy enough, and the paleness was only what one might expect from a white-flowered variety, while they had nothing of the drawn appearance noted in the reports of the plants first exhibited. I see no reason why it should not be well grown under the same conditions as suit the parent form, but it is questionable if it will ever be so useful, as, though the younger flowers were perfectly white, those which were older were slightly dingy on the outside of the petals, so that large plants carrying many flowers would not show the absolute whiteness desirable unless they were staked up and stood well below the eye on the one hand, or hung well overhead and allowed to droop naturally on the other. They should not be staged or hung in the direct line of vision. Of course, one must allow for the injurious effects of travelling a long distance and for changes of temperature, and I have no doubt that the plant will become popular, for I do not see that it can be much improved on as a white variety, and the slight defect alluded to above is only what one would expect in a flower so delicate in texture. Undoubtedly the bright colour of the parent form has as much to do with its popularity as its freedom of flowering, coming

as it does in the dullest months of the year.—J. C. TALLACK.

Tibouchina macrantha.—Comparatively few readers would recognise that old favourite, *Lasiandra macrantha*, which is on p. 387 referred to under the name of *Tibouchina*. These changes in nomenclature which are continually taking place are often a source of endless trouble and confusion. With an extensive library at one's command these changes are not of so much account, but where limited means exist they cause a great amount of worry. Whether known by the generic name of *Lasiandra*, *Pleroma*, or *Tibouchina*, there can be no doubt as to the great merits of the plant in question, which each recurring autumn forms a most attractive feature trained to the roof of No. 4 greenhouse at Kew. The coloured plate of this plant which was given in *THE GARDEN*, August 5, 1893, was drawn there. It was formerly regarded as essentially a stove plant, but Kew has shown us that a warm greenhouse exactly meets its requirements. A near relative is the charming *Pleroma elegans*, a compact, upright-growing shrub from the Organ Mountains of Brazil, which was introduced more than fifty years ago by William Lobb. The flowers of this are of an intensely rich bluish purple tint and a little over a couple of inches across. Unfortunately, it is a difficult plant to cultivate.—H. P.

EUCCHARIS AMAZONICA.

I TAKE it that "H. R." has some special object in his treatment of the above so that "the great bulk of the blossoms will be produced from the end of July until September." It should, however, be at least remembered that for general value as much as utility not many will be desirous of getting the great bulk of blossoms at such a time. During the stated months the variety of choice flowers is great, and with such Lilies as *L. longiflorum* vars., *L. speciosum* vars., Tuberoses grown cool, and a host of hardy flowers, there is certainly less need for *Eucharises* during the summer months. It is a curious fact, but the time stated above is that at which market growers try not to have the *Eucharis* in bloom. This is for a two-fold reason: Trumpet Lilies (*L. longiflorum*) abound, with *Gardenias* in plenty also, and *Eucharis* flowers in hot weather so quickly become transparent. Assuming the idea is that of less heat for these things, it certainly does not follow that the greatest value is secured by giving the *Eucharis* the cooler treatment "H. R." speaks of. Where batches of *Eucharis* are grown for maintaining as near as possible a constant supply of bloom, a July flowering is favoured for but one reason, viz., that with proper care this very batch is regarded as reliable for flowering in January and early February ensuing. For the sake of the latter the former crop is often sold at a sacrifice, the two together, however, making a fair average. So far as potting the *Eucharis* is concerned, particularly in regard to its efficacy, it is usually overdone. I have now in mind a large houseful of bulbs placed in 10-inch pots two or three years back. With warm treatment the bulbs quickly filled the pots, and now for nearly two years have become so vigorous, that the pots are no longer capable of the strain, and a whole pot is hardly to be found in some hundreds. The result is the bulbs protrude, and many nearly rest on the stage. The soil also is virtually used up and the foliage much paler than many would care to see. But the crops of flowers and the great vigorous spikes all come as of yore, except for the increase due to increasing bulbs; indeed, it is a mystery that the plants flower so well. I am not suggesting that this mode of growing *Eucharis* should be copied; at the same time it proves how greatly such things are benefited and, indeed, sustained by proper atmospheric conditions and when the bulbs are up to flowering size. The greatest enemy to the *Eucharis* is not the mite, but the man and the water-pot. Given warmth and atmospheric moisture, and according to season a judicious use of the syringe, it is surprising how really little

root water is needed. But there must be no lack of moisture in the air. Nothing is more essential than this, and nothing is more fatal to good results than continuously wet soil or imperfect drainage. With the pots exposed to the warm inside conditions the plants much longer remain healthy than when given bottom-heat. Where thousands are grown, this latter is quite impossible. E. J.

Lilium longiflorum from Japan.—From Japan we now receive immense numbers of Lily bulbs, and whilst many species are represented amongst them, by far the larger number consists of *L. auratum* and its forms, *L. speciosum* and *L. longiflorum*. The importations of this last have now attained such proportions that they must materially affect the Bermuda-grown *Lilium Harrisii*. True, these last reach here towards the end of July and in August, so that for early work the Japanese bulbs do not affect them in the least, but later on the case is very different. The greater number of these bulbs from Japan consists of a very good form of *L. longiflorum*, which, when less plentiful than it now is, used to be called *Wilsoni*. That grand variety *giganteum* is also largely imported, while *Takesima*, in which the stems and unopened buds are tinged with chocolate, is grown to a certain extent. For outdoor planting these Japanese bulbs are particularly valuable, as they usually reach here in a firm, solid state, and may be planted at once, or, if preferred, may be kept sound in slightly moistened soil for some time. Valuable as they are for planting out of doors, a great many of the huge importations disposed of in the London auction rooms are bought up by some of the large growers for Covent Garden Market and potted up in order to form a succession to the Bermuda *L. Harrisii*. Their season of blooming when grown in pots will depend altogether upon the treatment given them, as they are very amenable to gentle forcing and may be had in bloom in early spring; or grown cooler, they can be kept back till summer is well advanced. Of late years bulbs from South Africa, though limited in number, are valuable for prolonging the flowering season, as they usually reach here in a dormant state in April or May.—H. P.

NOTES AND QUESTIONS.—STOVE.

Justicia calycotricha.—This is an old-time popular plant, but now not often met with. Like many other *Acanthads*, it branches but sparingly, and the flowers are borne in terminal heads. In this the blossoms are of a canary yellow colour, while the segments of the calyx are long and hair-like, thus giving to a head of blossom an uncommon, fluffy appearance. It remains some time in bloom, and is valuable from the fact that it flowers in midwinter. This *Justicia* is a native of Brazil, and was introduced in 1824. It is also known as *Schaueria calycotricha*.—T.

Rhododendrons in flower.—After a week of almost incessant fog, the various members of the Javanese section of *Rhododendrons* are flowering with great freedom, being, in fact, quite unaffected by the atmospheric conditions experienced of late. Few, if any, classes of plants are so valuable for autumn and winter-flowering within the London area, as sulphur-laden fogs—the bane of the plant grower—do not injure the expanded blossoms or the unopened buds. True, some of the bright-coloured flowers are at this season rather paler in tint than when they expand under more favourable conditions, but this is of little importance. The lighter hues are as clean and fresh as ever.—H. P.

Jacobinia chrysostephana.—Among the more uncommon winter-blooming plants this merits extended cultivation, as its flowers are particularly valuable during this dull season of the year. The flowers, which are borne in a terminal head, are of a curved tubular shape. The exterior of the tube is a bright orange, while the expanded mouth is of a rather lighter tint. It is a native of Mexico, was introduced in 1870, and is often met with under the generic name of *Cyrtanthera*. Given ordinary stove or intermediate house treatment, it does well. The plants must not be stopped too much, as the object is to obtain good vigorous shoots which can be depended upon to each bear a crown of golden blossoms. It is now in bloom in the T range at Kew.—H. P.

TREES AND SHRUBS.

THE BAMBOOS.

THERE are some fifty species and varieties of these graceful plants which have proved to be hardy in all but the most exposed and coldest parts of our island. Of hardy Himalayan Bamboos we have only *Arundinaria* (*Thamnocalamus*) *spathiflora*, *A. aristata*, and *A. racemosa*, for *Thamnocalamus* (or *Arundinaria*) *Falconeri* and *Arundinaria falcata* are invariably cut down by severe frost. *A. macrosperma* is the one species which comes to us from the United States of America, and although the Andes and the Himalayas have in all probability many Bamboos which will, when they are introduced, prove perfectly hardy, we have at present in the main to depend upon the *Arundinarias* and *Phyllostachys* of China and Japan for the beauty which is to be obtained from these giant grasses. Nor can we complain. Grace and

our biting easterly and north-easterly winds. They are more deadly than frost. The softer and moister westerly winds, blow they never so hard, will do less damage to plants which come from such storm-vexed regions as the coasts of China and the islands of Japan. It is very important that every autumn the plants should be well mulched with cow manure, and this again should be covered with dead leaves. To prevent the latter from blowing away it is expedient to surround the plant or group with wire netting. This has the additional advantage of keeping out rabbits and hares. The mulching protects the roots from frost in the winter and prevents evaporation in summer. When the plants are thoroughly established these precautions become unnecessary, and they may be left to shift for themselves.

But above all things I would warn my readers against planting out imported Bamboos in their permanent places before they have recovered from the effects of the journey. I

When you take the plants out of the pots be careful not to disturb the roots in any way. You must not attempt to comb them out as you would the roots of trees, for they are as brittle as glass; place them in the earth as they are, and they will soon find their way about. If possible the newly-planted Bamboos should be well watered during growth. It must be remembered that Bamboos will not show their true characteristics for several years. But by taking the above precautions much time will be saved and many disappointments avoided. For transplanting Bamboos (from one part of the same garden to another, not for sending them on a journey), May and June are perhaps the best months, though I have moved them without any ill effects during the whole summer up to the end of September. The worst time is from November to March, for the plants need to have made some roots in their new homes before they can resist our cold winters and biting spring winds.

As regards propagation, very little need be said here, for I doubt whether the propagation of hardy Bamboos, except by division, is likely to become a successful industry in this country.

PROPAGATION BY DIVISION.

The best moment for this operation is, in our climate, the latter end of April or May. The process is very simple. The plants should be divided into clumps of two or three culms with their rhizome, in order to ensure a new growth from the buds on the internodes of the root-stock. If the tufts can be lifted with a ball of earth, so much the better. They should be planted in beds at distances of 2 feet, carefully watered, and protected by a top-dressing of well-rotted cow manure and dead leaves. With the same care they may be planted at once in their permanent homes.

In this account of the hardy Bamboos, so far as they are at present known, I have marked

with an asterisk those species which, from their beauty and hardiness, are best worth cultivating in this country.

NATIVES OF THE HIMALAYAS.

ARUNDINARIA FALCATA. — A beautiful plant which dies down every year in this country as it does under the snows of the Himalayas. In the temperate house it does not lose its leaves or stems, but remains perfectly green. New culms come up from the base in the following summer. Often confounded with *Thamnocalamus Falconeri*, from which it differs mainly in having a far longer ligule to the sheath. The stems are yellowish green, very slender and graceful, round, and with short internodes, the nodes being but slightly raised and of a purplish colour. The ramification is close and thick. The leaves are of a fine green colour, paler on the lower surface, and about 5 inches in length and striated. Not to be recommended for general planting.

ARUNDINARIA (THAMNOCALAMUS) FALCONEI, even more tender than *A. falcata*, is cut down by

Bamboos in England (*Phyllostachys nigra* at Gunnersbury House). From a photograph by G. Champion.

elegance are the characteristics of the Bamboo, and in no genus are these more conspicuous than in the lovely group of *Phyllostachys*, while some of the *Arundinarias* will, if planted in suitable places, grow into dense thickets of almost tropical aspect. There are few gardens in which some sheltered nook, backed by evergreens, might not be beautified by a feathering group of *Phyllostachys Henonis* or *nigra*; while in the wilderness glorious effects may be produced by the grand foliage of *Arundinaria Métaké* or the stately plumes of *Arundinaria Simoni*. Background is the great secret of getting the best effect out of plants in which beauty of form is the dominant feature. By the side of a stream, on the banks of a lake, among the rocks cropping out of the hill-side, the Bamboo is thoroughly at home. If such a place can be found with rich soil and under the influence of the sea-air, so much the better. Above all let the Bamboos be sheltered from

have myself lost many fine specimens in this way. Now that a sad experience has taught me how to treat them I rarely lose one. The plants should only travel during the period when they are at rest. They will be received, therefore, during the late autumn or winter. If they have come from abroad, the balls of earth round the roots should be thoroughly soaked; they should then be potted and placed in a cool house for the winter; the leaves should be copiously syringed with rain-water twice a day, but the roots should not be kept too wet. In this way many species will keep their leaves as green and fresh as if they had never been disturbed; but even those that lose their leaves will early in February begin to show little fat buds that will soon develop into branchlets. Early in May begin to harden off the plants, as you would *Geraniums* for bedding out, and at the end of May place them in their permanent homes.

frost every year in most places. The habit is less vigorous, the leaves smaller, and the stem more slender and of a brighter green. Leaf-sheaths and blades glabrous. Leaves striated. The confusion between these two species has been very general. The majority of the plants hitherto cultivated in this country as *A. falcata* have proved to be *Thamnocalamus Falconeri*. Mr. Osborne, gardener to Mr. Smith Barry, at Fota Island, County Cork, informs me that the late General Munro identified the specimens grown there under the former name as true *Thamnocalamus Falconeri*. The so-called *A. falcata* flowered in the gardens of the Luxembourg, in the south of France, and in Algiers in 1876. Mr. Smith Barry's plants flowered and seeded at the same time; it is, therefore, possible that the mistake in nomenclature was universal, and that all these plants were indeed *Thamnocalamus Falconeri*. As regards the hardness of the species, Mr. Osborne writes as follows: "The above-named Bamboo (*Thamnocalamus Falconeri*) throws up numerous canes here from 20 feet to 25 feet. I have often wondered at the reports in gardening papers in England of its sending up canes from 6 feet to 8 feet high, but, unfortunately, I have learned the reason this season. We had an unprecedented sharp frost in January last (1894) which killed the tops of all the *Thamnocalamus*, with the result that, instead of throwing up a few monster canes to the height mentioned, they have thrown up numerous small canes about 6 feet or 8 feet high around the old stools. It must take several years of very mild winters before they reach their usual strength. Many other Bamboos were not in the least injured, so far as I could judge. The frost registered at Fota was 26° Fahrenheit below freezing point." From this it is evident that the species is not thoroughly to be depended upon even in the usually warm climate of the west of Ireland. How it fared in Devonshire and Cornwall, where there are, or were, many fine specimens, I have not heard. Messrs. Watson and Bean consider the *Bambusa gracilis* of the French cultivators to be identical with *Thamnocalamus Falconeri*. I can detect no difference between the two.

A. RACEMOSA.—A low-growing *Arundinaria*, growing as high as 15 feet in its own country. Stem smooth and round. Internodes about 2 inches apart, leaves 2 inches to 4 inches in length and narrow, cross veins well defined. After the trying winter of 1895, quite green and fresh at Kew Gardens. Found at an elevation of 12,000 feet in the N.E. Himalayas.

A. ARISTATA.—A pretty *Arundinaria* of moderate size, with purplish stems and tessellated leaves. This latter quality, taken in conjunction with the great altitude at which it is found in the North-Eastern Himalayas—as high as 11,000 feet above the sea-level—indicates it as a hardy Bamboo.

A. (THAMNOCALAMUS) SPATHIFLORA.—Another hardy Bamboo with tessellated leaves from the Himalayas, where it is found at an altitude of 9000 feet. Most of the specimens which I have seen grown under this name in English gardens are not the true *A. spathiflora*.

NATIVE OF NORTH AMERICA.

A. MACROSPERMA.—The solitary species of the United States of North America. This Bamboo appears to vary in height according to its habitat—in the Southern States from 10 feet to 35 feet high, while in the north it does not exceed 10 feet. It is the *Arundinaria* described by Michaux. The stems are round (sometimes slightly flattened on one side at the point of branching), slender, and much-branched. The sheaths are purplish in colour, very persistent, and fringed at the top with a few rather coarse hairs, the leaves about 7 inches long by 1½ inches broad, the upper surface smooth, the lower downy, having the edges slightly serrated—very partially on one side. Interesting rather from the fact of its being the one representative of the family in the vast area of the United States of North America than from its beauty. Some botanists divide the taller and

shorter varieties into two species, but Munro treats them as identical. *M. Marliac* sends out a Bamboo under the name of *Bambusa Neumannii* (it is called *Hermannii* in the botanic gardens at Brest) which appears to be the same plant as *A. macrosperma*; indeed, both *M. Marliac* and *M. Blanchard*, the director of the Brest gardens, so regard it, although they do not know from what country their Bamboo was originally received. The shrubby form, *A. macrosperma suffruticosa* or *tecta*, is the variety grown at Kew and here. It is a very active runner, and demands plenty of space.

NATIVES OF CHINA AND JAPAN.

**A. FORTUNEI*.—Three plants of no relationship to one another are at present the bearers of this name, respectively green, silver variegated, and golden variegated. As there is absolutely no similarity between them, I have re-named two of them *humilis* and *auricoma*, leaving the name *Fortunei* to the silver-striped species which has the prior claim to the title.

**A. HUMILIS*.—A green species, about 2 feet to 3 feet high, looks as if it might in time grow a few inches higher. The stem is round and green, the nodes not much raised, the internodes 3 inches to 3½ inches in length. Ramification in threes, and long in proportion to the stem and internodes. Habit erect. Bright evergreen leaves, smooth on both sides, 4½ inches long, three-quarters of an inch broad, and tapering to a point. Petiole inconspicuous; sheaths reddish, hairy at the end and sides, and terminating in a true leaf; very rampant root-stock. A very pretty plant to form a carpet. Syn., *Bambusa gracilis*. Messrs. Veitch, of Chelsea. A native of Japan.

**A. FORTUNEI FOL. VAR.*—A silver variegated dwarf Bamboo about 3 feet high. Stem round, green, and erect, but rather more zigzagged than the green variety. Nodes not very prominent, sometimes hardly perceptible; internodes about 2 inches, long ramification, mostly in pairs. Leaves about 5 inches long, by half or at most three-quarters of an inch wide; a bright colour beautifully striated with white in a young state, but the variegation is apt to fade in the older leaves, which become rather spotty. Very short petiole; sheaths hairy, terminating in a leaf; loses its leaves in winter, but is, nevertheless, a beautiful plant in summer, and should be cultivated; a strong runner at the roots.

**A. AURICOMA*.—A golden variegated dwarf Bamboo, taller than the two preceding sorts, rather over than under 3 feet high; stem round and erect, with a purplish green colour; nodes inconspicuous; internodes about 2 inches. Leaves striped with bright yellow, from 5 inches to 7 inches long by 1 inch to 1½ inches broad, very pubescent, like velvet on the under side, slightly pubescent on the upper surface. Short petiole; purplish green sheaths, very hairy at the sides, ending in a leaf. Not such a strong runner as the two preceding kinds, but a beautiful and conspicuous evergreen plant.

**A. MAXIMOWICZI* (*Marliac*).—A golden variegated dwarf Bamboo, probably a synonym of the last species. I can detect no difference between them. The name is sometimes given wrongly to *A. Simoni striata*.

**A. CHRYSANTHA*.—A dwarf variegated Bamboo, probably a variegated form of *A. humilis*. Differs materially from *A. auricoma*, inasmuch as the lower surface of the leaf is markedly ribbed and lacks the velvety down of the latter species; on the other hand, the down on the leaf-sheaths is very conspicuous. For beauty it is not to be compared with *A. auricoma*; it is far less brilliant, and the variegation is somewhat muddy and uncertain, a great portion of the plant being quite green. It is a very free runner, but has little else to recommend it, unless it be for a collection.

**BAMBUSA PUMILA* (? *Arundinaria*).—A very pretty dwarf Bamboo. At first sight this would strike the observer as *A. humilis* under another name. It is, however, I think, certainly a distinct species. It is smaller in habit, the leaves are less

broad, shorter, and do not taper so gradually to a point. The teeth of the serrated edges are less conspicuous. The lower sheaths are hardly so hairy, and the nodes are less well defined and far less downy. The stem is more slender.

**A. HINDSI*.—A distinct and beautiful species sent out by French nursery gardeners under the name of *Bambusa erecta*. With me it has grown to a height of about 9 feet, but will evidently attain a greater stature. It was described by Munro from a fragment of the top of a culm, only 18 inches long. His description is therefore incomplete. The stem is round and very straight; the internodes are about 6 inches long, but much shorter towards the top (Munro, therefore, having only seen the top, makes them 2 inches to 3 inches). The young dark green stems have a lovely white wax on them like the bloom on a Grape. The branches are quasi-verticillate and erect. The sheaths, which are very persistent, are slightly hairy on the top. The leaves are 6 inches long by about five-eighths of an inch across, slightly serrate and hairy, especially on one edge; they are thicker than in most Bamboos. The colour is a beautiful dark green, fairer underneath; the veins are more conspicuously and beautifully tessellated than in any Bamboo that I have observed. The Japanese name is *Kanzan-chiku*.

**A. HINDSI VAR. GRAMINEA* (the *Taimin-chiku* of Japanese gardens).—A smaller plant than the above, with leaves 9 inches long by five-eighths of an inch broad, and yellow stems; considered by the authorities at Kew to be another form of the same species. The tessellation of the veins of the leaves is not quite so strongly marked as in the type. Sent out by French gardeners as *Bambusa graminea*. When once established, a very strong runner.

**A. JAPONICA*.—A fine and valuable plant, generally grown in gardens under the name of *Bambusa Métaké*. The word *Métaké*, or, more correctly, *Médaké*, is Japanese for "female Bamboo," but there is no scientific reason for using the word "female" in connection with this plant any more than there is for our calling the *Dendrocalamus strictus* of India the "male" Bamboo. Grows to a height of about 11 feet or 12 feet. The stems are thick, round, and green, very straight until the branches of the second year appear. The hairy sheaths, which completely envelop the stem, are very persistent, but quickly wither, and their dead colour rather detracts from the beauty of the plant. Ramification only takes place when the stem has reached its full height, the upper nodes being the first to show signs of it. The sheaths on being forced away from the parent stem do not fall, but roll themselves round the stems of the branches. The leaves are from 8 inches to 1 foot in length by about 1½ inches, sometimes more, broad. The upper surface is smooth and shining, the lower side paler, rather glaucous and wrinkled; the edges are finely serrated. The creeping root-stock in well-established plants is very active, so that care must be taken to give the plant plenty of room. The most effective specimen which I have seen in this country is in Mr. Buxton's garden on the borders of Epping Forest, where, upon a promontory jutting out into a piece of ornamental water, it has quite a tropical appearance. It has been the fashion rather to undervalue the *Arundinaria japonica*, and certainly in a young state it is somewhat disappointing; in time, however, it makes a fine bold feature. *Arundinaria japonica* (*Bambusa Métaké*) was first introduced into Europe by Siebold in 1850. It flowered and fruited in the Bois de Boulogne in Paris and simultaneously all over France and in Algiers in the year 1867 or 1868. Under the name of *Bambusa Ya-daké*, the Japanese send out an *Arundinaria* which they claim to be *Phyllostachys bambusoides*, which it evidently is not. The name *Ya-daké* (Arrow Bamboo) is due to the straight, round culms being used for making arrows. It appears to be no more than a form of *Arundinaria japonica*; indeed, in its present young state there is no difference to be detected. Evi-

dently, however, the Japanese gardeners consider the two to be distinct plants.

**A. SIMONI*.—This, the tallest of our Arundinarias, was introduced into France by M. Simon, French Consul in China, and named after him by Carrière, who described the plant. At Kew old-established plants have reached a height of 18 feet. The culms are round and straight—slender in proportion to their height—during growth entirely encased in the sheaths, which are smooth and striated, with the upper part of the edges finely haired. The sheaths are at first green, shaded off to dark violet, but they soon wither, and as they are persistent they rather spoil the effect of the plant (as is the case in *A. japonica*). Here, again, ramification does not take place until the stem has reached its full height. The branches in the second year almost surround the stem which presents the appearance of a round plume. The leaves are from 10 inches to 1 foot long, slightly hairy, lanceolate, longitudinally ribbed, ending in a long narrow point. On the lower face of the

Maximowicz. Flowered, but did not seed, in Mr. Smith Barry's garden in Fota Island, County Cork, in the year 1893. The Japanese name, Narihira-daké (*Bambusa Narihira*, Marliac), is a synonym of *A. Simoni*. It was so named after Narihira, the hero of a romance of the eleventh century called the "Isé Monogatari," one of the classics of Japan, written in prose, with poetry interspersed. The author is not known. *Bambusa Narihira* is sent out by certain nursery gardeners as a distinct species, but this distinction is imaginary.

**BAMBUSA PALMATA* (? *Arundinaria*).—A strikingly beautiful species, conspicuous from the size of its leaves, which are often used by Japanese peasants to wrap up the bit of salt fish or other condiment which they eat with their rice. With me it is about 11 feet high, or rather more. The stems are round, but slightly flattened towards the top. The colour is bright green, but the stems are somewhat shrouded by the persistent dead sheaths. Each node, whether on the stem

humbler scale, the plant being only about 2 feet high and the leaves smaller and more rounded at the point. It has the same round stem, flattened at the top, and the same single-branched nodes. The leaf-sheaths, however, are somewhat capriciously fringed with coarse hairs. The leaves are about 7 inches long by about 2½ inches broad, green above, glaucous below, glabrous and much ribbed. The edges wither in winter, giving the plant a variegated but, ultimately, shabby appearance; but the thick new foliage of spring is very beautiful, and the plant runs fiercely, soon making a thick carpet and ousting all weeds. Sometimes sent out as *A. tessellata*, which is wrong, and often called by the Japanese *Kumazasa*, on account of its withering edges. (See the remarks on *Phyllostachys kumazasa* or *viminalis*.)

BAMBUSA SENANENSIS.—A plant was received in 1894 from Japan under this name. I cannot detect any difference between it and *Arundinaria Veitchi*. The Japanese name for it is *Yakibazasa* (the Sword-edged Dwarf Bamboo). There is another Bamboo, a tall species used for making furniture, &c., which also goes by the name of *senanensis*, and which the Japanese call *Sudzudaké* (the Reed Bamboo).

ARUNDINARIA METALLICA.—A species closely resembling *A. Veitchi*, but lacking the ugly withering of the leaf edges in winter. A native of the north of Japan and the island of Yezo. Perfectly hardy.

**BAMBUSA TESSELLATA*.—Described by Munro as *Bambusa tessellata*, but evidently, if it be correct to class the preceding species as *Arundinaria*, this should follow suit. Moreover, Munro says, "I have only seen the dried leaves of this species when sewn together and in the state so largely used by the Chinese in packing their tea." Probably had he had better opportunities he would have referred all these plants to the same genus; as it is, he gives the genus as doubtful. A very beautiful species, noteworthy as having the largest leaves of any of the hardy Bamboos. The stem is about 2½ feet high, round, slightly flattened at the top, the colour a purplish green, much hidden by persistent withered sheaths, one branch from each node (in one case only I found two springing from the same node). The edges of the sheaths are hairy at their base; leaves 18 inches and more long by rather over 4 inches wide, tapering beautifully to a point, bright green above, glaucous beneath; midrib well defined. Munro notes a tomentose line on the side of the midrib, but this is not visible to the naked eye, and a very strong lens reveals very minute hairs upon the lower surface of the living leaf, which he describes from his dried specimen as glabrous. Both edges are serrated.

Short petiole. The tessellation which gives its name to the species may be seen by holding up a leaf to the light, but as it is to be found in so many Bamboos, the name is not well chosen for purposes of identification. A feature of the plant is the pretty way in which the slender new culms spring from the carpet of arching foliage. Also known as *Bambusa* (or *Arundinaria*) *Ragamowski*.

**ARUNDINARIA NIPIIDA*.—A very lovely species from North-Western Szechuan. The culms are purple-black, very slender and round. The leaves are small, lancet-shaped, and tessellated. Quite the hardest of all our Bamboos, for in the bitter weather of February, 1895, it stood as green as in midsummer. Originally sent out in error as *Arundinaria khasiana*, which is a non-hardy Indian species with striated leaves.

**A. ANGUSTIFOLIA*.—A lovely little Bamboo, about 2 feet to 2½ feet in height. The stems are round, very slender, and when young of a purplish colour. It is much branched; the leaves are about

Bambusa palmata at Castlewellan, Co. Down, Ireland.

leaf there is a distinct difference in colour on the two sides of the midrib, to which Mr. Bean has called attention; the one half is green, the other half slightly glaucous—a very curious feature. So far as experience at present goes, this is the greatest runner of all the taller hardy Bamboos. Its young and straggling shoots will appear at a great distance from the parent plant. It should be planted in a perfectly isolated position in the wild garden, where it may wander at pleasure without injury to any neighbour. So powerful an invader might easily become a nuisance instead of a beauty.

A. SIMONI VAR. *STRIATA*.—Careful observation and closer acquaintance lead me to think that any distinction between this and the type cannot be maintained. Both have a certain amount of silver-striped variegation in the leaves of young shoots, and in both it disappears with age. Is sometimes sent out by nursery gardeners under the names of *Bambusa calipta* and *Bambusa*

or on the branches, only carries one branch. The branches of the second year often overtop the parent stem. I can detect no hairs on the sheaths. The leaves are the chief beauty of the plant. They are each from 1 foot to 13 inches long and 3 inches to 3½ inches broad, tapering rather suddenly to a very fine point: the petiole is rather inconspicuous. They are much ribbed, the midrib being very prominent and glabrous. The colour is an intensely vivid green on the upper surface, glaucous on the lower. Both edges are serrated. The rhizomes are exceedingly active and travel far. A hold group of this Bamboo, with a background of Hollies and associated with Lady Ferns and such sympathetic compatriots as *Ophiopogon japonicus*, *Funkia Sieboldi*, and *Anemone japonica*, which always seems to grow best under shade, is a most effective and striking object.

**ARUNDINARIA VEITCHI* much resembles *Bambusa palmata* in its habit, though on a far

$4\frac{1}{2}$ inches in length by three-eighths of an inch in width; they are serrated on both sides, and somewhat capriciously striped with silver variegation. The leaf-sheaths are slightly hairy. This is the *Bambusa Vilmorini* of French gardeners. I have named it *angustifolia* on account of its narrow leaves.

A. NAGASHIMA (Marliac).—A dwarf Bamboo about 3 feet high. The stems are round and purplish green in colour; the leaves, which are from 6 inches to 7 inches long and three-quarters of an inch in width, are sharply serrated on both edges; the leaf-sheaths are hairy. So far this Bamboo has not developed any characteristics of especial merit, and is, perhaps, hardly worth growing, except in a collection.

***A. MARMOREA** (Japanese Kan-chiku).—I have chosen the name "marmorea" on account of the very peculiar appearance of the young stems, which are folded in purple sheaths, delicately marbled with a pinkish silver-grey, through which, near the knots, peep glimmers of the bright emerald-green or dark purple of the stem itself. The stems, which in colour are purple, shading off to a brilliant green, are very slender and round, rising at present with me to a height of 4 feet or 5 feet, but promising to grow taller. The branches cluster thickly round the stems in threes, and are much longer than the internodes, which are very short, not more than from 1 inch to at most 2 inches, so that the dense foliage has all the appearance of being verticillate, and the fully developed culm assumes the shape of a fox's brush. The leaf-sheaths are very distinct: their colouring is unlike that of any other Bamboo that I have seen; they are downy at the top, and have besides round the base a conspicuous little fringe of hairs, which seems at first sight to spring from the node; the ligule is very tiny. The leaves, which are bright green, are about $4\frac{1}{2}$ inches long by three-eighths to five-eighths of an inch broad; they are serrated on both edges, and have a marked constriction at about half an inch from the very sharp end; indeed, the leaves are so pinched in at their point that they seem to terminate, as it were, in a tongue. The rhizome is very active, new shoots appearing at some distance from the parent plant. This is altogether a unique dwarf Bamboo, as pretty as it is strange.

***A. PYGMEA**.—The best and the smallest of the dwarf Bamboos, invaluable for making a carpet of soft brilliant green. Grows with extraordinary rapidity, the root-stock travelling great distances and at a considerable depth. Stem about 6 inches to 16 inches, round, much branched; internodes very short; leaves about 4 inches long by half an inch to three-quarters of an inch broad, edges serrated, both surfaces downy, the lower surface glaucous, leaf-sheaths hairy at top. This wonderful little plant grows so thick and close, that no weed has a chance against it, but its rampant habit makes it advisable to give it plenty of room. For this reason I should not recommend its adoption for edgings, as has been sometimes advised. Being a confirmed vagrant, it is impossible to keep it within bounds.

A. LAYDEKERI.—Apparently a semi-dwarf Bamboo, not, so far as my experience of it goes, particularly attractive, though it should have a place in a collection. The stems in the third summer are about 3 feet high, but will probably grow higher; round, much branched; apparently, therefore, it is an *Arundinaria*. The leaves are about 6 inches long, dark green, but rather shabbily mottled on both surfaces, serrated on one edge and slightly so on the other; leaf-sheaths hairy at top. The branches, which are long in proportion to the length of the stems, from which they stand out rather markedly, give the plant a conspicuous habit.

BAMBUSA QUADRANGULARIS.—A curious and rare Bamboo, which owes its name to its square culms, like the stems of one of the *Labiatae*, a feature which is conspicuous only when the plant has attained some size. This it has not yet done, so far as I am aware, in outdoor cultivation in this country. Though it is apparently weather-proof,

the growth is by no means rapid, and we shall probably have to wait some time before its value as a hardy plant is established. There is a good specimen in the temperate house at Kew. The stem is much branched and the branches almost verticillate. The leaves, which are of a deep green colour, are about 8 inches by 1 inch wide, serrated on both edges; leaf-sheaths hairy at top, internodes short, the nodes very markedly prominent. A very beautiful and peculiar member of the family, which it is much to be hoped will thrive with us. Runs freely at the roots. It was supposed at one time that the square shape of the culms was due to some artificial treatment, but the young stems, even in their present development, have sufficient character to disprove this. Groves of this Bamboo upwards of 30 feet high are to be seen near Osaka, the Venice of Japan.

***PHYLLOSTACHYS HETEROCYCLA**.—This very strange freak of Nature is called by the Japanese Kiko-chiku, or the "tortoise-shell Bamboo," from the curious arrangement of the alternately and partially suppressed internodes at the base of the stem, which sheathe it in plate armour like the scales on the tortoise's back. At about 2 feet or 3 feet from the ground the nodes are regularly defined, as in other Bamboos. It was thought at one time that this abnormal feature of the stem was due to artifice on the part of the Japanese gardeners, past masters of the art of torturing plants into all sorts of quaint shapes and conceits. But an examination of a section of *Phyllostachys heterocycla*, with its very curiously alternated septa corresponding with the outer scales, shows that the grotesque markings are the handiwork of Nature when in a playful mood. The other characteristics of this Bamboo do not differ from those of the *Phyllostachys* of the *mitis* and *aurea* group. The leaves are from 3 inches to 4 inches long and about half an inch wide, very minutely serrated on one edge and almost imperceptibly so on the other, bright green on the upper surface, bluer underneath. I believe that the first living plants of this species introduced into England were those received from Japan in 1893, though it was exhibited at the Paris exhibition of 1878, and named *heterocycla* by Carrière. The imported stems are about 5 inches round, and the plant has the appearance of growing into a large and important Bamboo.

P. MARLIACEA.—A very handsome species—evidently a *Phyllostachys*—at first sight bearing a strong likeness to *Phyllostachys Quiloi*. My plants are about 15 feet high, but promise to become much taller. The stem when freed from the sheaths is very handsome—a dark green shining like enamel; the internodes at the base are very close together, not more than $1\frac{1}{2}$ inches to 2 inches. The branches are long and graceful, leaves a very intense green on the upper surface, glaucous below, about $4\frac{1}{2}$ inches long by 1 inch wide, more conspicuously serrated on one edge. The young leaf-sheaths are purple and deeply blotched and furnished with rather long and coarse purple hairs. The habit of this Bamboo is very graceful, the culms forming the most elegant arches, beautiful both in form and colour. The catalogue of the Yokohama Gardeners' Association gives the native name as *Shibo-chiku*, the "wrinkled Bamboo." This alludes to the furrowed wrinkling of the stem, which is largely used for canes and umbrella sticks.

P. FASTUOSA.—However difficult it may be to distinguish between some of the species of hardy Bamboos, this very stately and beautiful plant stands out quite conspicuously among its fellows, having marked characteristics which are all its own. The bright green stems, heavily splashed with purple-brown blotches, are straight, very hollow, the wood being a mere shell and extremely brittle. The internodes, which are grooved, are short, only from 5 inches to 6 inches long in a stem 15 feet high; the lower end of the culm for 2 feet or 3 feet is bare of branches. The branches being four or five times as long as the internodes, erect, and much divided into branchlets, the top of the culm wears a false air of verticillation, giving the plant the appearance of an *Arundin-*

aria, which, however, the groove in the internodes and the non-persistent character of the leaf sheaths seem to contradict. The leaves are from 5 inches to 7 inches long by three-quarters of an inch to 1 inch in width, tapering to a sharp point, and markedly constricted at about an inch from the end, which has the appearance of a little tongue. Their colour is bright green on the upper surface and very glaucous underneath. Both surfaces are smooth, the lower one distinctly ribbed; both edges are serrated, but, as is frequently the case in Bamboos, the one is more so than the other; the veins are very closely tessellated. The petiole is long and well defined. The leaf-sheaths are rather thick and hairy, being a shining purple in colour on the inside face, which is highly glazed. The rhizome, which appears to be very active, is more fistulous than that of any Bamboo which I have observed. A section which I measured showed an oval hollow in the internode of the root-stock a quarter of an inch long by one-eighth of an inch broad. The stems with me are from 16 feet to 17 feet high, and rather more than 3 inches in circumference. There is every reason to believe that this Bamboo will prove to be one of the most valuable of the group. Tall, spreading, gracefully plumed with foliage, which for richness and beauty of colour is without a rival, it cannot fail to make a striking feature in the wild garden. It was first imported from Japan by M. Latour-Marliac, of Temple-sur-Lot, in 1892.

P. BAMBUSOIDES.—A name invented by Siebold and given by nurserymen, both in Europe and Japan, to many species, all of which have been described under some other title. Collectors will act wisely if they reject any Bamboos offered under this name, as they are sure to find it identical with some other species already in their possession—in nine cases out of ten some cheap *Arundinaria*.

***P. AUREA**.—The distinctive name *aurea* is not very happily chosen, for there is nothing golden about the plant unless it be the yellow stems, and these are not peculiar to the variety named. The stems are very straight and erect in this country, growing close round the base of the plant, which gives it the appearance of having caespitose roots; whereas it has a true rhizome, which in its native climate runs freely. It is seen at its best when planted in bold masses, as the individual plant by itself has too much of the shape of the birchen rod of an old-fashioned dame's school in the kingdom of Brobdingnag. A distinguishing feature of this species is the shortness of the internodes at the base of the stem. The leaves vary much in size, some being about 4 inches long by half an inch wide, others from 6 inches to 7 inches long by 1 inch or even more broad. The petiole is well defined, the insertion of the young leaves very hairy. One edge of the leaf is conspicuously serrated, the other very slightly, the teeth on this edge being placed irregularly and at great distances apart. Both surfaces are glabrous. At Shrubland, in Lord de Saumarez's garden, *Phyllostachys aurea* is 14 feet 6 inches high, the canes being $2\frac{3}{4}$ inches round. In the year 1893 a Bamboo was received here and Kew from Japan under the name of *Bambusa sterilis*, which the Japanese Gardeners' Association describe as closely allied to *Phyllostachys heterocycla*. This appeared to me to be undistinguishable from *Bambusa aurea*, and Messrs. Watson and Bean now share my opinion. Curiously enough, the plants were covered with an undeveloped inflorescence, which proved to be infested with a hitherto undescribed ergot.

I may here note the great confusion which has prevailed in the descriptions of several of the *Phyllostachys* tribe. *Aurea*, *mitis*, *Quiloi*, *Henonis*, *viridi-glaucescens*, *flexuosa* have all been jumbled up in the most hopeless tangle. This has been due partly to the fact of plants being sent out by dealers under any and every name, partly to the eagerness of collectors to describe plants before time had enabled them to develop their characteristics. *Phyllostachys aurea* may always be recognised by the peculiar

swelling under each node, a feature which no other Bamboo in our collections possesses.

**P. MITIS*.—This is the tallest, and in that respect the noblest, of all the Bamboos capable of being cultivated in this country. Unfortunately, it suffers terribly in hard winters, and is only to be recommended for exceptionally favoured situations. At Shrubland the culms of plants imported seven years ago are 19 feet 5 inches high and 4½ inches in circumference. In China and Japan it grows to 60 feet high. The stems, some of which spring out of the ground like spears, are, when fully developed, beautifully arched, and have for that reason a grace which is not to be found in *P. aurea*. The young shoots when they first appear above ground seem to hang fire for a while before taking their upward growth. When once they start they are very rapid, growing in this country as much as 6 inches in the twenty-four hours. The utmost growth that I have noticed is 4½ inches in the twenty-four hours, but mine are young plants. Messrs. Rivière have made most interesting experiments on the growth of Bamboos, of which they give tables. The maximum growth of an adult plant of *Phyllostachys mitis* during twenty-four hours in Algiers was 20 inches. They note that *P. mitis* grows most during the night, whereas the other plants of similar growth, such as *viridi-glaucescens*, *aurea*, *nigra*, &c., make their chief growth during the day. *Bambusa Tulda*, in Bengal, is said to grow as much as three centimetres (upwards of 1½ inches) in an hour. As in *P. aurea*, the leaves, which vary much in size, are serrated on one edge, the teeth being almost if not quite absent on the other. The petiole is shorter than in *aurea*, and the hairy growth at its insertion less conspicuous. The sheaths differ much in colour, but are generally brownish and spotted with purple. As the branches are developed the withered sheaths drop off, leaving a shining deep green stem, which gradually ripens into a bright yellow. The branching begins at the base, and as soon as it is thoroughly active the growth of the culm ceases. The underground procession of the rhizome is much more marked than in *P. aurea*, the stems appearing alternately along its course. Although its running powers are in this climate not great, still in *P. mitis* the rhizomatous character is well maintained. The young shoots of this Bamboo are eaten in China and Japan. Some gastronomers profess to detect in them the taste of Asparagus; this, I confess, demands some faith. The consistency is crisp and pleasant, like Celery, but the flavour depends upon the sauce—at least that is my experience. As pickles and sweetmeats they are but poor eating. To its culinary merits, such as they are, the plant owes the synonym *edulis*, which is at any rate less foolish than *mitis*.

**P. SULPHUREA*.—A handsome golden-stemmed Bamboo, which in appearance has great affinity with *P. mitis*, though Messrs. Rivière see a connection between it and *P. flexuosa*. It is far stiffer and not so free a runner as *flexuosa*, while the only difference which I can detect between it and *mitis* is that it is not so tall and has a more brilliantly coloured stem. The other characteristics are the same; indeed, it would puzzle an expert to tell them apart. Messrs. Watson and Bean lean to this opinion. It is perfectly hardy and well worth cultivating, but difficult to obtain. At Shrubland it is growing to a height of 13 feet, with a circumference of 2½ inches round the stem.

**P. QUILIOI*.—A very distinct Bamboo, introduced from the north of Japan by the French Admiral Du Quilio in 1866. This species has a loose habit of growth. The branches are long in proportion to the culm, the leaves are large, serrated on both edges, and often marked with purple spots on a deeper green ground than is found in the foliage of any of the other *Phyllostachys*, except *Marliacea* and *Castillonis*; the hairs at the insertion of the leaves are deep purple. The sheaths are most peculiar; they are of a pinkish brown colour, deeply mottled with purple spots, and, as they fall, reveal a brilliantly

polished dark green stem. The culms are more upright than those of *P. viridi-glaucescens*, less compact and more arching than those of *P. mitis* and *P. aurea*; the root-stock is far more active than in either of the two latter species (in this country), while it does not seem to run so much as that of *P. viridi-glaucescens*. I cannot help suspecting that those who have described the plant hitherto have not had the true species before them. I know that this is the case in one instance, where *P. Quilioi* was actually described from a plant of *P. mitis*. Altogether a notable Bamboo, growing at Shrubland to a height of 18 feet 6 inches, the canes having a circumference of 3¾ inches. Syn., *Phyllostachys Mazeli*.

**P. VIRIDI-GLAUCESCENS*.—A most elegant and graceful Bamboo, to which many cultivators give the palm of loveliness. It grows to a great height—nearly 18 feet at Shrubland, 14 feet at Kew—while the slender, tapering culms are not more than 2 inches round. The root-stock is very active, the plant being a great runner, while many of the culms come almost horizontally out of the ground, giving the plant a very widespread. The leaves are generally about 3 inches or 4 inches long and about three-quarters of an inch across; one edge is serrated, the other only partially so towards the point of the leaf. The petiole is well defined, and short brown hairs encircle the insertion of the leaf. The leaves are of a bright green, in pretty contrast with violet stems, which turn to a yellowish green. The stem is much zig-zagged. Once established, this is a perfectly hardy Bamboo, but it is not safe to plant out specimens which have travelled. I have lost a large percentage in this way. It is better to pot newly-arrived plants and let them remain in a cool house until they have recovered from the effects of their journey.

**P. FLEXUOSA*.—Sometimes considered to be identical with *P. viridi-glaucescens*. On the other hand, Messrs. Rivière, who recognise the similarity, say, "We have not remarked in the spathiform sheaths of this Bamboo the toothed membranous expansions which we have met with in many other species of the same group, notably in *P. viridi-glaucescens*." There is, moreover, the fact that *P. flexuosa* flowered and fruited all over France and in Algiers in 1876, while *P. viridi-glaucescens* did not, and this would seem to indicate a different plant. It is certainly not easy to detect any outward and visible sign of difference between the two. *P. flexuosa*, which must not be confounded with the prickly species described under that name by Munro, was introduced into France from the north of China in 1864.

**P. VIOLESCENS*.—This is sometimes said to be a variety of *P. viridi-glaucescens*, but quite different both in appearance and behaviour. It is somewhat more tender, the leaves being apt to be cut by frost, which gives the plant an ugly appearance in winter, but with the spring the culms are clothed with new foliage, and after all it is only those shoots which come into existence in the late autumn which suffer. The foliage is rather darker and larger than in *P. viridi-glaucescens* and the plant more straggling, the rhizomes running rampantly. But the most distinctive feature is the deep purple colour of the young stems during their first year. This is lost in the two-year-old stems, which change to a greenish yellow or brown. The plants at Shrubland are 15 feet high, and the culms 2¾ inches in circumference.

**P. HENONIS*.—To my taste this is one of the loveliest of all our Bamboos; indeed, it would need the inspiration of a poet to do justice to its beauty. Nor is that its only merit, for it is perfectly hardy, and bears up bravely against our rudest and coldest weather. Of all the plants that I imported not one has gone amiss, though they were subjected to hardships to which, now that I know better how to manage, I should not dream of exposing them, and which proved fatal to a good many of their travelling companions. The Shrubland plants are now 14 feet high, the stems 1¾ inches in circumference. The tapering leaves are about 4 inches long and about half an inch across. They are very smooth on the upper

surface and ribbed on the lower, serrated on one edge and very slightly on the other. The colour is a pale green, and less glaucous on the lower surface than most of the leaves of the *Phyllostachys*, the midrib prominent, the petiole well defined. The slender tall stems are green at first, growing yellow with age, slightly zig-zagged. The root-stock runs rather freely. But it is to its habit that this Bamboo owes its surpassing loveliness. The two-year-old culms, borne down by the weight of their own foliage, bend almost to the earth in graceful curves, forming a groundwork of the most elegant beauty, from which the stems of the year spring up, arching and waving their feathery fronds, the delicate green leaves seeming to float in the air. I regard *P. Henonis* as the embodiment of every grace to which plant life is heir. The Japanese synonym is *Ha-chiku*, the Chinese characters with which it is written signifying the "light or volatile Bamboo."

**P. NIGRA*.—This is perhaps the best known, and from its black stems the most easily recognised of the hardy Bamboos. On the Riviera and in Algiers it grows to a height of about 30 feet, the stems being nearly 6 inches round. At Shrubland and at Kew it is 10 feet high and the stems are 2 inches round. At Leonardslie it is 20 feet high. With me the plant has been a little capricious and difficult to establish, but once it has taken hold of the ground no Bamboo seems hardier. The stems are of an olive-green colour during their first year of growth, changing to shining black the following year. They are slightly zig-zagged. The leaves, which are from 3 inches to 4½ inches long by three-quarters of an inch broad, are green on the upper surface and glaucous underneath. The rhizome runs with some freedom. Messrs. Rivière call attention to some peculiarities in the structure of this Bamboo upon which, as they are more interesting to the botanist than to the gardener, it is unnecessary to dwell here. It is enough to say that in *Phyllostachys nigra* we have a plant of striking beauty and undoubted hardness. It is the rhizome of *P. nigra* which furnishes the Wanghai cane of commerce.

**P. NIGRO-PUNCTATA*.—It is doubtful whether this species can be separated from *P. nigra*. The only difference is in the colour of the stems, which are speckled instead of being pure black.

**P. BORYANA*.—One of the handsomest and most vigorous of the hardy Bamboos, very graceful in its habit, as indeed are both *P. nigra* and *P. nigro-punctata*, of which some authorities consider it to be a variety. As in their case, the stems are green during their first year, but change colour the second year to a dull brown splashed with large deep purple or black blotches.

P. FULVA.—A newly-imported Bamboo from Japan. Perfectly hardy and promising to be a valuable decorative plant.

**P. CASTILLONIS*.—A most lovely plant—indeed, one of the best of the many good gifts which we owe to Japanese gardens. The foliage is larger than it is in most of the Bamboos, some of the leaves being as much as between 8 inches and 9 inches long by nearly 2 inches broad. When they first appear they are striped with bright orange-yellow, which in time fades to a creamy white. Both edges are serrated. The petiole is short, the leaf-sheath dressed with a frill of long brownish purple hairs. The stem, which is much zig-zagged, is bright yellow and green, the latter colour remaining in the deep channels left by the pressure of the branches, so that the two colours are alternate all the way up the culm, the hues being intensified with age. As the sheaths of the branchlets are of a very pretty pink, the plant has a tricoloured effect which is most pleasing; the branches come in twos and threes. I understand that at Castlewellan this species has attained a height of 20 feet, with a proportionate circumference of the stem. Twenty-four degrees of frost in January, 1894, did them no harm, but M. Marliac tells me that the foliage is apt to suffer from snow. This, however, can at the worst be only a temporary evil. One of my plants is

extremely curious as a variation from the type. Not only is the variegation absent from the leaves, which are bright green, but in the stems its position is exactly reversed, the channels being yellow and the rest of the culms green. The Japanese name is Kimmei-chiku (the Golden Brilliant Bamboo).

**P. RUSCIFOLIA* (*P. kumasasa*—*P. viminalis*, Marliac).—A pretty little Bamboo, described by Munro as *P. kumasaca*, though the Japanese name is *bungozasa*. The stems are about 18 inches high, purplish green in colour, with brown sheaths, much zigzagged and very slender, distinctly channelled from the pressure of the branches, which spring in twos and threes, sometimes in fours, from the nodes. The leaves are from 2 inches to 4 inches in length, and an inch, more or less, in width; ovate; soft hairs very conspicuous on the lower surface, but none on the upper surface or on the insertion of the leaves, which are serrated on both edges.

BAMBOOS OF DOUBTFUL ORIGIN.

BAMBUSA DISTICHA (*B. nana*, Hort.).—A pretty little dwarf Bamboo, sent out as *Bambusa nana* by gardeners. The name *nana* belonging already to a Bamboo described by Roxburgh, its repetition was confusing. Stem about 2 feet high, round, very slightly zigzagged; branches and leaves distichous; leaves hairy, especially at the base, and serrated at the edges, about 1½ inches long by three-quarters of an inch broad, tapering to a point; leaf-sheaths hairy; rhizome inclined to run, but far less so than in *Bambusa pygmaea*. A very distinct little plant, most useful for a choice corner in a rock garden. The origin of this Bamboo is doubtful. Mr. Watson says, "It is more like *Chusquea tessellata* (Munro, New Grenada) of any of the specimens in the herbarium."

ARUNDINARIA ANCEPS.—A very beautiful Bamboo discovered by Mr. Jordan, superintendent of Regent's Park, in the stock of a dead nursery gardener, whose books being destroyed or lost, it was impossible to trace its origin. It is probably a Chinese species. In general habit very like *A. nitida*, but absolutely distinct; the culms are brown when ripe instead of purple-black; the leaf-sheaths are hairy instead of being absolutely without hairs, and the petiole of the leaf is yellow, whereas in *A. nitida* it is purple.

A. NOBILIS.—A grand *Arundinaria*, probably of Chinese origin, growing to a height of 24 feet at Menabilly, in Cornwall. Loses its leaves in winter, and in very severe seasons the culms die down, reappearing the following summer. In Cornwall it is quite hardy, only losing its leaves in early summer when the new ones are ready to appear. The tall stems are yellowish in colour with very dark purplish nodes, of which the lower rim is broadly marked with grey; much branched. The lanceolate leaves are thin and bright green, with a purple petiole, the colour of which is continued along the edges, fading away to the point. There are no cross veinlets, the leaves being striate.

A. B. FREEMAN-MITFORD.

MOSS LITTER.

TO THE EDITOR OF THE GARDEN.

SIR,—I am not fond of splitting straws, or disentangling Moss litter for the matter of that, but I cannot help noticing in a recent issue of THE GARDEN that your correspondent "H. H." writes: "Mr. Shaw says that the value of the peat-moss for the ground before it has been used as a manure (*sic*) is as great as that of straw." If "H. H." will kindly re-peruse my letter he will find that I make no assertion of the sort, but that I simply ask a question: "What would be the manurial properties of unsoiled straw?" I am no chemist and quite ignorant on the subject; therefore I ask for information, having no desire to try the experiment myself. I do not admit, neither have I ever admitted, that the peat-moss remains as

an absorbent. Such an admission would be in direct opposition to my experience. If properly made it disappears and becomes an integral part of the soil, but I did write that occasionally a large lump may be found, and I added that there ought to be no large lumps. However, all the contentions anent the possible damage which might result from these undigested lumps are wiped clean off the slate by the excellent letter from your correspondent "Cor," describing the cultivation and products of the peat-moss bogs near Preston, and it is useless to discuss them further. I can only regret the contrast between "H. H.'s" short letter and my long one. I have no doubt we both write in accordance with our experience and our lights, but I must say that adding lime to good manure surcharged with ammonia seems to me very like throwing away a good ham and drinking the water it has been boiled in. Judging by the farm waggons and carts which pass my gates loaded with moss-litter manure, I fancy that the farmers in the neighbourhood not only use it, but pay for it, and I do not

celerates the process like the addition of putrescent animal matter, which acts as a ferment and greatly hastens the decomposition. The soils for which peat forms the best manure are the chalky and clayey. Sand has too little tenacity; it lets the gases produced by the decomposition escape instead of attracting them, as clay and chalk do, and thus preventing their escape.

GARDEN FLORA.

PLATE 1251.

TULIPA SPRENGERI.

(WITH A COLOURED PLATE.*)

IN the earlier stages of its growth no other Tulip is so distinct in its general appearance as the one figured in the coloured plate to-day. It will, from its absolutely distinct habit, puzzle the keenest Tulip connoisseur, who will refer the plant when not in flower to any genus but to the one to which it really belongs.

Bamboos at Kew (*Phyllostachys viridi-glaucescens*).

know what they could do with it except plough it into the land or spread it on their pastures. The following extract from an article on "Peat" in the "National Encyclopædia" may possibly interest your readers:—

Peat contains all the elements of the richest manure, and may by an easy process be converted into humus; for this purpose the agency of alkalis is the most effectual. If the tannin be decomposed, decomposition of the vegetable fibre will go on and soluble humus will be formed. When newly dug up, if caustic lime be added to it before it is dry the moisture of the peat slakes the lime, which acts on the gallic acid in the peat and neutralises it. If the mixture be then excited to fermentation by the addition of animal matter, such as urine or manure, oxygen is absorbed and carbonic acid evolved, and the residue converted into an excellent manure containing much soluble humus. The same may be effected more slowly by mixing peat with clay or marl and allowing the mixture to remain exposed to the atmosphere for a considerable time, frequently turning it. But nothing ac-

Its introduction into Europe dates from about 1894, when Mr. Baker named it and described it. The Messrs. Van Tubergen, of Haarlem, Holland, have for many years received it from their Armenian collector, who first sent it to them from the hills in the neighbourhood of Merzifun. The crimson and black Tulipa armena and a fine new golden Tulip with green basal blotches, *T. galatica*, usually come with it; in fact, it always seems to grow in company of these, as collected bulbs of either of the latter named species invariably contain a larger or smaller percentage of *T. Sprengeri*. Botanically it comes nearest to the European *T. Haageri*, but as a garden plant it is totally distinct. The bulb of this Tulip is not large, egg-shaped, and surrounded by a very hard, brown-black skin, in this respect somewhat resembling *T. Clusiana*. The leaves are narrow,

* Drawn for THE GARDEN by H. G. Moon from flowers sent by Messrs. Van Tubergen, Haarlem. Lithographed and printed by J. L. Goffart.

TULIPA RIPOSI GORI

of a very pale green, and arranged as in a tuft. They are produced very late in the season, which is a decided advantage in a cold climate. The flower-stems are each about 1½ feet in height, supporting a very elegantly formed pointed flower of a uniform glowing vermilion-scarlet, without any other shade of colour. Only the three outer segments of the flowers are tinted at the outside with a sort of dove-grey; this, however, is not perceptible when the flower is fully open. The conspicuous anthers are bright sulphur-yellow. Its time of flowering—the middle to the end of June—is also quite exceptional, all other Tulips being

many to whom this flower is dear. Like many other Eastern Tulip species, its propagation from offsets is extremely slow, but as it flowers at a propitious time it can set and ripen its seeds to perfection. JOHN HOOG.

Haarlem, Holland.

THE WEEK'S WORK.

FRUITS OUTDOOR.

PRUNING.—Having finished those trees on walls which should be pruned before winter, we go on next to trees in the open, such as cordons, espal-

frequently happens that as the side spurs grow the trees become too thick; consequently the question arises as to whether we should permit this and put up with a good deal of inferior fruit, or cut away sufficient of these leading growths to admit sufficient light and air to those remaining. I prefer the latter course, and never let a season pass without having a good look over all the trees, thinning all those that need it. No doubt fairly thick trees, if well balanced, look better during the winter and after they are pruned than do others which have been kept much thinner; but it is not to this that one has to look if good fruits are desired, for the thinly trained trees are the ones which give the best results as far as quality, which should be the main object in growing garden fruits, is concerned. Old trained Pear trees in the open, like those on the walls, are very much given to producing long and ugly spurs on which the fruiting or flowering buds become altogether too numerous and congested, and these may well be dealt with as recommended earlier for those on wall trees; indeed, the keeping of such spurs well in hand is one of the most important factors in Pear culture after the trees have reached a free fruiting age. To young trees of Apples, Pears, Plums, &c., which have not yet arrived at full size a different system from that in vogue generally should be applied. It is nothing short of ridiculous to cut away from these year after year all but a few inches of the new growth made, yet how often do we see this done without any discrimination. Of course, it is necessary in building up an espalier, for instance, to shorten the lead down to a point from which it is intended the next pair of branches shall spring, leaving one bud above this point for the next year's lead. This is obvious; and again sometimes it is necessary to shorten a branch here and there rather closely for the sake of balance, but when it comes to the leading branches already formed or the leading shoots of cordons there is no sense in cutting away ripened growth, for we only retard the formation of the tree and also its fruiting. The only excuse for hard pruning is to give strength, but well-planted and well-treated trees generally grow quite strongly enough, and for a weak shoot here and there some support can be provided until the natural strength comes. For summer pruning the secateur is a very handy tool, and no permanent harm is done by the squashing which this instrument gives to the shoot, but in winter the case is different, and I would not have such a tool in use, for the bruised surface left never heals over properly. For big branches the saw is the best implement, trimming the surfaces, and especially the bark, with a sharp knife later on. In the hands of a handy man a good chisel is useful, too, for removing growths too big for the knife, but for anything smaller there is nothing to be compared to a good sharp knife in the hands of a person competent to use it. I say this advisedly, for there is much so-called pruning done by incompetent persons. One of the chief faults of these is that they take no notice where they make their cuts or in what direction they run; consequently, trees under such pruning soon bristle with dead snags that in very many instances are the forerunners of dying branches. The only proper way to shorten a young growth is to cut it back quite close to a bud, and the cut should slope in the same direction that the bud is pointing, as such cut surfaces will soon callus over and disappear; whereas, any wood left beyond a bud will certainly die back to the bud. Again, in shortening a big branch it should be cut back to the junction with another branch or else cut out entirely, and in either case the cut should be made neatly close at home. Another thing to remember is that one should not shorten shoots indiscriminately to so many inches long, but each must be dealt with individually, so that each bud selected as the terminal one should point in the direction in which the branch should grow. This will be generally outwards, and trees so pruned will not only be done properly, but they will look much better,

Arundinaria japonica (Bambusa Metake) at Castlewellan.

long past when this one comes into bloom; in fact, in Messrs. Van Tubergen's nursery it usually flowers when most of the ordinary single and double Tulips have been lifted. A group of it in flower is one glowing solid block of colour and very beautiful. Although, happily, we have quite enough other flowers in the month of June that we need not particularly care for a display of Tulips at that season of the year, still the very fact that a Tulip has been introduced into cultivation which prolongs the Tulip season for over a month will secure it a place in the gardens of

liers, pyramids, and all so-called trained trees. These are generally planted near the principal walks where tidiness is an object, so the sooner the work is pushed forward the better it will be. All those trees which have filled their allotted space must be pruned on the same principle, that is, the growth must be restricted; in fact, almost every bit of wood growth which has been made during the past year must be cut away. Now and then main branches of pyramids are allowed to divide themselves into two or more leads while they are young and before they are clothed with fruiting spurs. This is all right when these new leads have plenty of room for development, but it

as most of the cuts will be concealed. One more item—not, perhaps, of so much importance, but which reveals the good workman—consists in making the cuts short, *i.e.*, as nearly straight across the shoot or branch as is consistent with the free working of the knife.

BUSH FRUITS.—The actual time when these are pruned does not make much material difference, provided the weather is mild when it is being done, and one likes to do them in good time, so that the prunings may be gathered up out of the way of the mulching material, which will be wheeled among the bushes during frosty weather. So long as the main branches are thin enough it matters little what form the bushes take, but the usual basin shape is as good as any for Red and White Currants, while Gooseberries appear to be best suited grown as open bushes. Black Currants may have some of the older branches removed bodily, and the young growths should be left intact; sucker-like growths springing from the base should be encouraged, and not cut away. Red and White Currants are best spurred in closely all along the main branches, leaving no young wood, except for extension. For Gooseberries I prefer a combination of old spurs and new wood, as we get fine fruits from the lengths of young wood left in, and I am inclined to think that the extra vigour the bushes get by encouraging young wood tends to lessen the danger from red spider. A word of caution may be necessary with respect to pruning Gooseberries before spring in places where bullfinches are plentiful, as the opening out of the bushes renders access easier to the birds, and early-pruned bushes must be protected in some way from their ravages. On weeping varieties like that best of all late dessert Gooseberries, Red Warrington, the shoots should be rather more severely shortened than those of stronger and upright growth. Where the Gooseberry caterpillar has been very troublesome it is wise to skin off the top 2 inches or 3 inches of soil from under the bushes after pruning is finished, taking this right away to where it may be burnt and replacing it with some fresh material. If this is inconvenient, the best remedy is to spread an 2 inches or 3 inches thick over the plot, for the sawflies do not seem able to get through this material when hatched from the chrysalis stage, in which they winter buried in the soil under the bushes.

CORNUBIAN.

KITCHEN GARDEN.

FRENCH BEANS.—Special pains will now be imperative where anything like success is to be achieved with this vegetable. Those who took the hint I gave some time ago to lay in in dry quarters a nice quantity of light loamy compost for placing in the pots will now realise the advantage, as the seed sown in semi-dry soil stands two chances to one against seed sown in wet, sticky compost. Water in the majority of cases will not be needed until the seed germinates, when a thorough moistening must be given. Dribbles administered often are not only deceiving, but also harmful. From the present time till the middle of January, Beans forced in pots or boxes must be given as light a position as possible near the roof-glass. It is useless attempting growing them in dark or dirty structures. A steady regular heat is also especially important, as a few days suffice to draw the growth up when subjected to, say, more than from 60° to 65° by night. I do not care to use the syringe overhead during the winter months, though moisture of an atmospheric nature according to the weather is necessary both for aiding in keeping red spider and white fly at bay and for assisting growth. Care must be taken in the matter of feeding, as roots being few and of a less vigorous texture than those formed by spring-sown batches, they cannot assimilate strong doses of liquid manure. All the same, plants in fair vigour growing in open compost will be benefited by applications of farmyard liquid the colour of pale ale at every alternate watering. On no account crowd the plants, about four

plants in a 6-inch pot being as many as can be properly exposed to the action of sun and light. It is useless waiting for the late-formed pods to swell off, as they seldom do so in any quantity, so that as soon as a couple of gatherings have been made the plants had better be thrown away. Where Beans must be had, the best and, indeed, only way of making sure of a fairly constant supply of tender, normal-sized pods is by having as many batches following each other as possible, allowing only some ten days or so to elapse between the sowing. Then some sorts are certainly better suited for winter culture than others. Had I a good light house I would not scruple to sow the good old *Sion House* in addition to *Newington Wonder* and *Mohawk*. Even at this period and until the new year a chink of air should be given whenever the weather will allow of it. Do not wait for sunshine, but open the ventilators somewhat when the air is calm and mild. It is astonishing how favourably this tells. Of course, Bean forcing in midwinter is uphill work.

MINT AND TARRAGON.—The sooner roots of both these herbs are potted or boxed up the better, as then if subjected to a cool temperature they get a good foothold previous to being moved into slightly warmer quarters. Often insufficient root-room is allowed, the roots being lifted in a hurry and placed at once in too much heat, the result being not only weak, spindly produce, but a general weakening of the clamps from which they do not soon recover. Some good soil to which say a fifth part of rotten manure has been added should be provided, and later on, when growth is active, manure water given. A Peach house at rest is a good position for the pots or boxes for several weeks, Tarragon being rather excitable, and often in mild winters becoming fit for use by the new year if potted now. Relying upon Mint roots from crowded, weakly beds is most unsatisfactory. Both it and Tarragon are often treated in a slipshod sort of way, but in many establishments it is of such importance that pains taken with forced batches are well repaid.

MUSHROOM HOUSE.—Up to the present very little artificial heat has been required in the Mushroom house. So much the better, as the produce under cool conditions is always of a sturdier, better coloured and flavoured character than when the pipes have to be heated in order to maintain the orthodox night figure of 50° to 55°. When the supply is being well maintained, the lower of these is the better, as much artificial heat invariably produces a dry, harsh atmosphere, which materially affects the quality of the Mushrooms, and if continued long dries many of the tiny buttons up. Even now-a-days one sometimes finds a much too sloppy, steamy condition in Mushroom houses, this being responsible for the great proportion of what are termed black heads. Some who have sufficient heating power are not in favour of covering the beds at all, but I prefer to surface newly-spawned beds with a little dry oat straw, keeping the same from pressing on the soil by first laying a few bushy pea stick tops on the bed. Continue to prepare more fresh, sweet material for the formation of new beds, droppings from corn fed horses kept dry from the first being indispensable for the production of the finest produce. Standing a barrow in the stable-yard uncovered for the reception of the droppings is a common, but a bad practice, as they often become saturated by heavy rains, and even if afterwards dried are never so good. Avoiding fierce heating and exercising patience until a sufficient quantity has been got into a safe condition for firm ramming have more to do with the production of fine Mushrooms and plenty of them than purchasing the spawn from any particular firm. A cool place quite free from wet is the best store for the spawn, but a too warm, drying temperature should be avoided.

J. C.

Ornamental pots.—There are now great numbers of ornamental pots, jardinières, &c., intended for the reception of plants in situations

where the ordinary earthenware pot would be out of keeping with its surroundings. In most cases the pot in which the plant is growing is supposed to drop inside the more ornamental one, but the great mistake is frequently made of so contracting the mouth of this last, that only a small pot can be inserted, and the plant therefore is out of all proportion to the large globular-shaped jardinière. This need not be, as various shapes might be suggested to which this objection would not apply. A rather widely expanded, yet deep Tulip flower seems a good ornamental design for those that object to a plain shape as being too simple. At all events, the swollen body and contracted mouth which one meets with everywhere are the worst of all, and often cause the plant to be sacrificed by turning it out of the pot in which it has grown in order to drop it into its place.—H. P.

DESTROYERS.

THE CANKER FUNGUS.

(*NECTRIA DITISSIMA*.)

THE following very interesting remarks on this destructive fungus appear in a leaflet just issued by the Board of Agriculture:—

It is customary with fruit growers to style the various disorders which affect and kill branches and boughs of Apple trees canker. Injuries from frost, hail, improper and excessive pruning, and from insects, such as the woolly aphid and species of *Lachnus*, all come under this common appellation. It is the same in Germany, where these diseases are termed *Krebs*, and in France, where the name is *Chancre*; and much confusion exists generally as to the real nature of the maladies. There is no doubt that frost, hail, wrong and untimely pruning, and insects have injurious effects upon Apple trees, but they are quite distinct from those caused by the canker fungus. Injuries of this nature are also frequently described somewhat vaguely as being due to hypertrophy, or excessive sap formation, whereas hypertrophy may be said to be the effect rather than the active cause of these troubles. A not infrequent notion regarding canker is that it is due to unsuitable soil, to want of drainage, or to excess or lack of manure, or of certain manurial constituents. But cankered trees are found on all soils, drained as well as undrained, and where manure has been freely or sparingly applied. It is natural to find this, seeing that the cause of the true canker is the very dangerous fungus known as *Nectria ditissima*, which is far more destructive than frost, hail, bad pruning, unsuitable soil, or too much or too little manure. Like most other injurious fungi, it is difficult of detection, except by careful or trained observers. Upon examination of a bough or branch infected by *Nectria ditissima*, it will be seen that some of the twigs or shoots formed are dead or dying, and that there are series of wide cracks or fissures in the bark for some distance round them, and sometimes also running upwards and downwards on the boughs, which are abnormally swollen near the twigs. Places will be noticed in some cases upon infected trees where the bark is rolled back in raised and distorted forms round the affected branches, leaving the black and decaying wood exposed in the middle of the circular or oval spaces denuded of bark. Above these the branches are dead, or partly dead, or dying. Further investigation will demonstrate that there is but little living wood, and that the formation of wood has been for some long period disorganised, as shown by the irregularity of the "annual rings." The fungus on one stem, or bough, may be still living and destroying; on another stem, or bough, it may have died, but the bough, or stem, has been rendered practically useless for fruit bearing. Very large boughs are often found ruined in this way, and occasionally young trees have large canker centres in their main stems which must materially affect their powers of fruit

production and their full development. Young boughs of Apple trees often have the whole of their bark ringed by the fungus, especially near the tips, so that they die, and in this case it is generally held that frost has caused their death. It will be found that the fungus, as a rule, is located near and round the shoots or twigs, because the cuticle there is tender and to some degree extravasated and liable to receive injuries from frost or hail, making it a convenient home for the spores of the fungus, which commences life as a saprophyte—*i.e.*, a feeder on decayed substances. The canker fungus attacks some varieties of Apple trees more than others. Those which yield the best eating Apples are most liable to it. Cox's Orange Pippin is a variety subject to this disorder, as is also the Ribston Pippin, while the Golden Pippin and several of the Renets, or Reinettes, notably Reinette des Carmes, are somewhat liable to canker. Trees with the thinnest and smoothest bark are most liable. In France, trees bearing cider fruit are not usually cankered as much as those producing fruit for the table. Varieties of the Reinette type are specially attacked as well as some of the Calville tribe; and in Germany, according to Goethe, Reinettes, especially the Reinette de Canada, are most frequently infected. Goethe states that the canker fungus is very common in Alsace and in the Rhine districts of Prussia, where thousands of trees succumb every year to its attack. He adds that there are certain regions where the Apple trees most liable to infection cannot be cultivated.

Pear trees are affected by *Nectria ditissima* in the same way as Apple trees. Fortunately in this country the attack on Pear trees is not so frequent as on Apple trees, though in France it appears to affect both pretty equally. The effect of the fungus and its methods of attack are precisely the same as upon Apple trees. Plum trees are also infested by this fungus. This fungus is also destructive to Oak, Beech, Ash, Hazel, Alder, Maple and Lime trees.

DESCRIPTION AND LIFE HISTORY.

The perithecia, or spore bearing cases, of the fungus appear first as minute red dots. From the spores emanating from these a mycelium is produced, which penetrates the rind and wood, whose juicy tissues are dried up and destroyed. The action of the mycelium in course of time, though it moves slowly, causes distortions and malformations of the surrounding parts, and death to all the branch above the centre of its action. Perithecia, or spore-bearing cases, are formed on the surface of the rind after a time. They are crimson, and are found in small groups; they are clearly visible to the naked eye, and are slightly flask-shaped. Within these are cylindrically-formed asci containing eight spores, each having two colourless cells. They germinate in water quickly, and placed upon trees infect them with canker. Hartig and Goethe have infected forest trees by placing spores of *Nectria ditissima* upon their living parts. They have also infected trees by placing *Nectria* spores upon parts injured by hail, or with decayed matter on them, and show that *Nectria ditissima* is both saprophytic and parasitic. This has also been proved by De Bary. In addition to the perithecia emanating from the mycelium of *Nectria ditissima* there is, at all events when it is actively parasitic, a formation of conidia evolved from a stroma of cushion shape. This takes place before the development of the perithecia, which contain the spore-bearing asci. These conidia have also been made by Hartig and Goethe to infect forest trees, and to germinate freely upon decayed and living tissues.

METHODS OF PREVENTION AND REMEDIES.

One obvious way of preventing the spread of canker is to be careful not to make use of grafts from infected trees, or grafts showing any trace of the fungus. Young trees should be examined closely for any signs of canker. Any wounds caused by hail, pruning, or other causes upon them should be viewed with a strong pocket lens to discover the red

perithecia of the fungus. Infected parts should be cut out with a sharp knife and tar applied, and, where possible, infected branches should be cut away, and, together with all the pieces cut out, burnt to prevent the spread of the fungus. It would be desirable to note the trees that canker most readily, and to avoid planting these varieties. If a tree is badly cankered in an orchard or near other trees it would be expedient to cut it down and burn it. A strong solution made with 20 lbs. of sulphate of copper to 100 gallons of water applied in the late autumn or winter would undoubtedly check the fungus and destroy it in its conidia and spore stages. This could be applied with a knapsack machine where the trees are small, and upon large trees with the help of a ladder where the disease has affected only a few branches. The spray should be directed for some time on the infected spots, and it would be necessary to spray them two or three times during the winter. When trees are badly infected they must be sprayed all over by means of a garden engine with strong pumps and long hose, like the engine used for hop washing. Sulphate of iron, dissolved in warm water, would be of value if applied in the autumn and winter at the rate of 1 lb. to every gallon of water. It would at the same time remove lichenous and mossy growths which harbour fungi and insects, and injuriously affect the trees. Apple trees should be kept free from the common Apple aphid and the woolly aphid, as these convey fungus spores from tree to tree. In woods and plantations the diseased branches should be removed from infected trees and burnt. Foresters should examine trees that show signs of decay with a pocket lens to ascertain if the *Nectria ditissima* is the cause of the evil.

DISEASES MISTAKEN FOR CANKER.

There is more than one disorder of Apple trees wrongly designated as "canker," and injuries from hail, frost, and other climatic causes are often generalised under this term. The action of true canker is, as common observation indicates, comparatively slow. Hartig states in his "Baumkrankheiten" that it does not usually extend more than half an inch in a year; while in other attacks attributed to canker the disorder usually spreads with far greater rapidity and trees are quickly destroyed. One form of affection of this nature is undoubtedly due to bacterial agency and to the bacillus defined by Professor Burrell in the "American Naturalist" as *Micrococcus* (*Bacillus*) *amylovorus*. This microbe is most disastrous in its effects upon Apple and Pear trees in the United States, and spreads with great rapidity. Pear trees, perhaps, are more liable to this infection than Apple trees in the United States, but the liability of the two kinds of trees varies in different States. It attacks chiefly the inner bark and cambium of the body of the tree, as well as its most important branches. Unlike the fungus *Nectria ditissima*, producing the ordinary canker, which establishes itself only in already existing wounds, scars, and cracks upon the bark of trees made by pruning, hail, insects, or by other fungi, the *Bacillus amylovorus* descends with the sap in the living bark, through the twigs and branches, to the body of the tree. Trees infected by this microbe are found to be perfectly healthy at their roots and up to the part where the blight has reached, showing that infection comes from the upper part of the tree. It sometimes commences its attack in the blossom or on the tips of the shoots at the ends of the branches. In the spring it is said to be always first noticed on the blossoms, which turn black as if injured by frost. The microbes stand cold well, and it has been found that the bark of infected trees contains living colonies for a longer period in the winter than in the summer. In spring-time, when the trees are full of sap, the microbes invade new bark and spread rapidly. At this period of the year, too, a viscous, sweetish, brownish yellow substance exuded from parts of the stem and branches attracts bees and other insects, which convey the microbes to the blossoms, and thus disseminate the infection extensively. In this country Apple and Pear trees are often seen with the blossoms blackened as if by frost, with the tips of their branches withered or dying, with deep wounds in the bark, and with their skin peeling and cracking in all directions. Frequently no trace of *Nectria ditissima* can be found in these cases, and the appearances correspond generally with those occasioned by the *Bacillus amylovorus* in America. The treatment which has been found successful in arresting this disease in transatlantic orchards may prove equally successful in this country. It is simple, consisting merely in cutting out and burning every particle of infected wood before the sap begins to rise. The infected centres may, however, be cut away at all times of the year. American experts advise that a careful inspection should be made of all Apple and Pear trees two or three times during the summer. It takes two or three years for the disease to become a serious epidemic; but the early removal of the first cases will prevent this development, and will, at the same time, save much labour later as well as many valuable trees.

FLOWER GROWING IN THE SCILLY ISLES.*

As the Scilly Isles are the main source of the flower supplies in our markets at the beginning of the year, they may appropriately be noticed first among the flower-producing districts of the country. The soil is nearly all of granitic origin, and, for the most part, the cultivated top soil is a sandy loam, mixed with clay in some places and with peat in others, but nowhere heavy. There are large tracts of almost pure sand, but nearly all that is cultivated is admirably suited to the growth of bulbous flowers and market-garden vegetables. Encircled as the islands are by the Gulf Stream, their climate is remarkably mild and equable, protection to tender crops even in winter being needed only against the frequent gales of wind to which they are subject. Frost rarely occurs, while snow seldom falls, and hardly ever lies on the ground more than twenty-four hours when it comes. The rainfall is moderate. Seeing that the prosperity of the islands is mainly dependent upon climate, as will be shown hereafter, a tabular extract from "The Climate of the Isles of Scilly," by Dr. Macklin, of St. Mary's, Scilly, will not be out of place. The averages of rainfall for the several months are those of twenty-five years, and the averages of temperature cover twenty years, all being based upon Dr. Macklin's observations. The islanders would be glad of more rain than they get in the spring and summer. The mean daily range of temperature in twenty years is given by Dr. Macklin at 6.8°. October has the lowest range, or 5.9°; April the highest, or 8°. The mean maximum range was 11.5°, November being lowest with 2°, and April highest with 15°. The mean range for the whole year during the twenty years was 15.1°—*i.e.*, the difference between the mean temperatures of the warmest and the coldest month. Taking the six winter months alone, the mean range was only 3.7°. For the six summer months the mean temperature was 57°, and for the six winter months 47°, showing a difference of only 10°. These figures indicate not only a mild, but also a remarkably equable climate. Dr. Macklin further states that the mean temperature of the Scilly Isles is one degree warmer than that of either the west of Cornwall or the Channel Islands. When the late Mr. Augustus Smith, in 1834, became, mainly from humanitarian motives,

* Extract from a paper on "Flower and Fruit Farming in England." By Mr. William E. Bear, in the Journal of the Agricultural Society of England.

Lord Proprietor of the islands (a title given to the lessees holding under the Duchy of Cornwall), they were over-populated, and the people, who partly lived by smuggling, were in a distressed condition. The sub-division of holdings had been carried on to a disastrous extent, and very many of them consisted of scattered plots of land. Mr. Augustus Smith set himself to the reform of the abuses which he found prevalent. He stopped smuggling, made education compulsory, enlarged and consolidated the small holdings, and allowed only one child in a family to succeed to his father's farm, practically forcing the rest of the youths to migrate to the mainland, to emigrate to the colonies, or to go to sea. Never was a benevolent despotism better justified by results, though it was some years before the islanders became generally prosperous. Steadily, however, Mr. Smith, who spent all the rental of the islands for many years in improvements, educated the people in habits of industry and ultimately of enterprise, until, from being among the poorest small farmers in the United Kingdom, they became the most generally prosperous. The extent to which the sub-division of holdings had been carried before Mr. Augustus Smith's time may be imagined when it is mentioned that, long after the con-

Mr. Smith's rule began, and at any rate he made it successful for some years. The ordinary farming of the period, chiefly consisting in the growth of small areas of corn and a few Potatoes, and the keeping of stock on the grass land, was not very profitable; and the first extensively advantageous change which the Lord Proprietor induced the farmers to make was gradually to convert their farms into market gardens, for the production of early Potatoes, Asparagus, Seakale, and other crops. The earliness of these products rendered them exceptionally profitable, and for many years the Scillonians were prosperous market gardeners of the old kind, as producers of culinary vegetables. A still more advantageous change, however, was yet to come. In 1870, or a year earlier or later (strangely enough the date of the important event has not been precisely recorded), the father of Mr. Allen, the present steward, packed for the late Mr. Augustus Smith, then Lord Proprietor, a box of Narcissi, and sent it to Covent Garden, receiving £1 in return. When this became known, a few of the farmers began quietly to collect bulbs wherever they could find them growing in the fields or hedgerows, and to cultivate them so as to increase stocks, getting a few flowers for

production was small. In 1883 Mr. Dorrien-Smith went to Belgium, Holland, and the Channel Islands to obtain information as to the cultivation of the Narcissus. In the Channel Islands he found the people devoted chiefly to the production of Grapes, Potatoes, and other vegetables, and growing very few flowers; while in Belgium and Holland Narcissi were a month later in flowering than in Scilly. Hence he concluded that it would be safe to extend the cultivation of these flowers, and he bought bulbs extensively for himself and his tenants. From that time the cultivation of the Narcissus rapidly extended and many new varieties were introduced, very high prices being paid for some of them. In 1885 the Bulb and Flower Association was founded by Mr. Dorrien-Smith, to promote the growth of the flowers by holding annual shows and otherwise. By that time the exports of flowers from the Scilly Isles had become considerable, amounting to 65 tons in the year, and the quantity increased to 85 tons in 1886, to 100 tons in 1887, to 188 tons in 1888, and to 198 tons in 1889. Exports steadily increased up to 1893, when they reached 448 tons, after which there was a falling-off, due to variation in the crops; but the

Bamboos (Dorset coast).

solidation had been in progress—namely, in 1870—the sizes of farms in St. Mary's were reported by Messrs. Scott and Rivington to range from five to fifteen acres, with the exception of one of thirty acres, which included a large proportion of untilled land. On the other islands, the same writers stated, the farms were still smaller, many covering only three acres, while the largest farm on St. Agnes was twelve acres in extent. At the present time the smallest farm in St. Mary's is ten acres, and the largest is eighty acres, exclusive of some rough grazing land; while the extreme areas are about five to twenty acres in St. Martin's, five to twelve acres in Bryher, and four to fifteen acres in St. Agnes, not counting the downs, which the tenants on these last three islands have in common. Bearing in mind the greatly increased returns of the land since 1870, the enlargement of the holdings is significant. Before Mr. Smith's time kelp-making had been one of the most remunerative industries of the islands, and when it ceased to pay, a fishery company was formed, but soon became moribund, though the industry has since been restored to some extent. Shipbuilding was started, either shortly before or shortly after

market in the meantime. The varieties growing in the islands at the time, as stated by Mr. T. A. Dorrien-Smith, the present Lord Proprietor, in a paper read before the Royal Horticultural Society in 1890, were the old double Daffodil (*Telamonius plenus*), Campernelli, Scilly White, Grand Soleil d'Or, two varieties of Grand Monarque, Biflorus, Poeticus recurvus, and Poeticus flore-pleno. How the bulbs were introduced is not certainly known, except that Campernelli was raised from two bulbs presented to Mrs. Gluyas, the wife of a Scilly resident, nearly sixty years ago by the captain of a French vessel. Mr. Dorrien-Smith is of opinion that the rest were introduced by the governors, as the greatest numbers were found around their former country seat in St. Mary's, or they may have been brought to Tresco first by the monks who once resided there. In 1875, when Mr. Dorrien-Smith took up his residence in Tresco, the demand for flowers was still small, and prices were not tempting enough to induce the Scillonians to grow them upon a large scale. It was not until 1880, about ten years after the few pioneers commenced operations, that the industry became thoroughly remunerative, and even then the

climax was reached in 1896, when 514 tons were exported. It is worth while to pause for a moment to consider what 514 tons of flowers represent. The steamship owners roughly allow eight boxes to the cwt., or 160 to the ton, the weight of the boxes being included. According to this calculation, 82,240 boxes of flowers, which in the case of Narcissi contained 21 to 51 bunches (of twelve flowers) per box, and in that of Anemones 72 bunches, were sent out of the Scilly Isles in 1896. One grower, who appears to have larger boxes than those referred to above, says that he packs 36 to 100 bunches in a box; but the precise accounts kept at Tresco have enabled Mr. T. G. Brown, farm manager to Mr. Dorrien-Smith, to favour me with the statement that the number of bunches of flowers of all kinds averages about 7000 to the ton of flowers and boxes, and 514 tons would therefore be equivalent to about 3,598,000 bunches. The flower crop in 1897, although a good one, was not so heavy as that of 1896, and the exports fell off to 476 tons. For the present year (1898) they will be smaller in quantity, the crop having proved the worst ever grown, taking yield of flowers per acre. Various reasons for this comparative failure

families for two or three hundred years. Although the agreements are yearly, and in most cases, I believe, verbal, evictions are almost unknown. Security for improvements rests mainly upon confidence in the permanence of the hereditary custom, though Mr. Dorrien-Smith invites his tenants to make known their desires as to improvements, with a view to arrangements as to compensation. Apparently the tenants are well contented with the friendly arrangements made between themselves and their landlord. As a farm almost invariably descends to a relative of a deceased or retired tenant, there is no competition as to rents, which range from 2s. 6d. per acre for rough grazing land to £3 for land suitable for flowers and in favourable positions. Although, instead of falling, as in most parts of the country, rents have risen in the Scilly Isles, they appear to be moderate under all the circumstances, including heavy and continuous expenditure on the part of the landlord for the advantage of the people. Rates are moderate, and there are no licences in Scilly. In this connection it may be mentioned that the general prosperity of the people is indicated by almost entire absence of pauperism. Each island supports its own poor, and there are now only five paupers in St. Mary's, one in Tresco, one in St. Martin's, and none in St. Agnes or Bryher. The

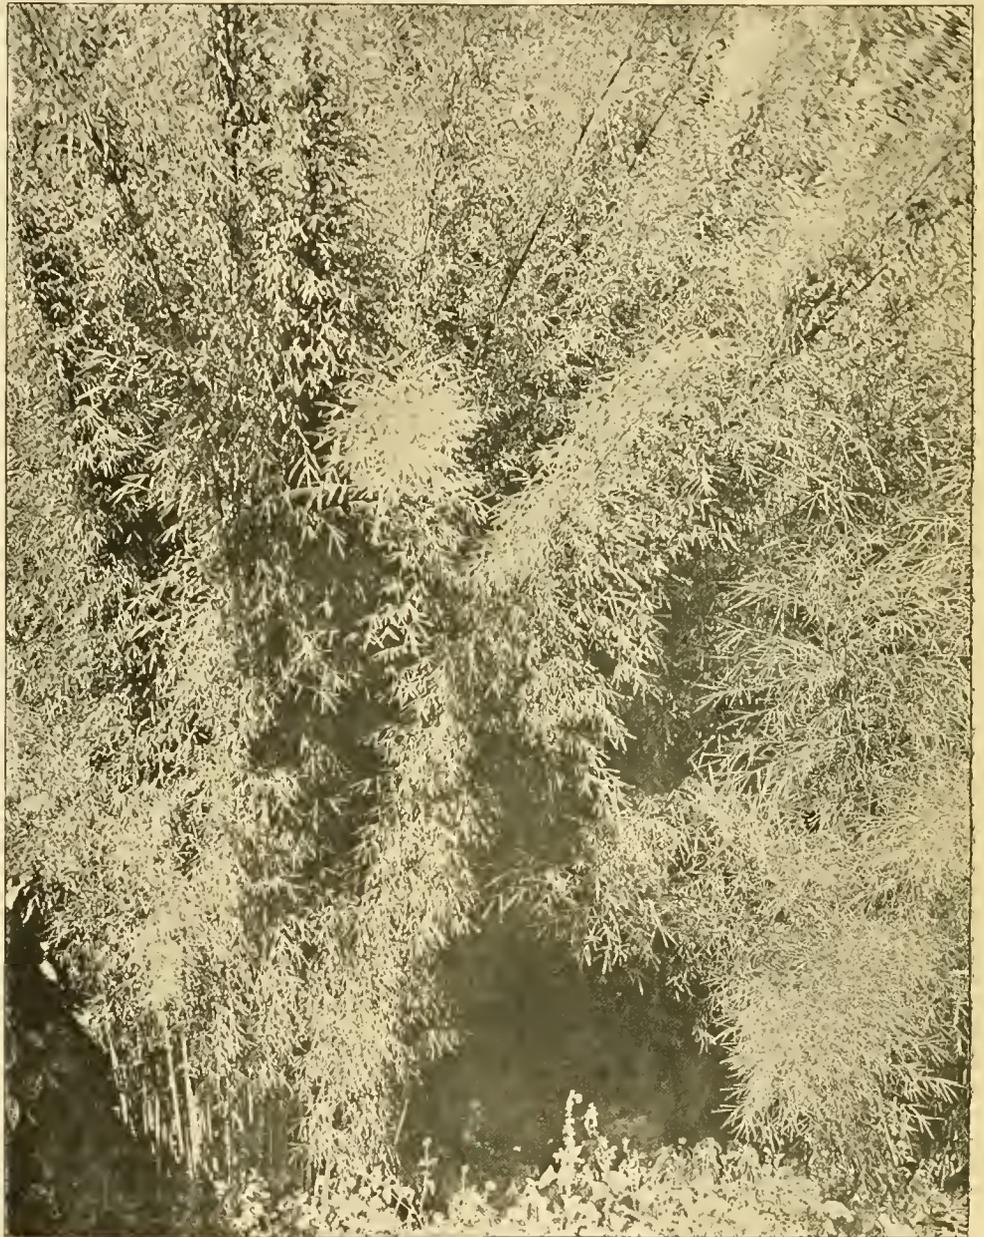

CULTIVATION

of the Narcissus is comparatively simple when once it has been ascertained whether any specified variety will flourish in a particular soil or climate. In Scilly the bulbs are usually planted in October, the small sorts about 4 inches by 2½ inches or 3 inches apart, and large bulbs about 6 inches by 4 inches to 6 inches. In some cases the land is carefully weeded up to the time of flowering, while in others it is left untouched during the growing season, so that it becomes covered with weeds. The manure most extensively used is a compost of seaweed, farmyard manure, earth, and road-scrappings, nitrate of soda or guano and bones being also used by some growers. Mr. Dorrien-Smith and other careful growers manure heavily for the preceding crop—usually Potatoes—and then, as they do not allow their bulbs to stand more than two or three years, no direct manuring of the flowers is necessary as a rule, though artificial manure is applied if they seem to need it. This plan is considered preferable to the direct manuring of the flower crop. But the majority of the growers allow at least some varieties of their bulbs to stand six or seven years, or even longer, and in such cases the crops may require supplementary manuring, though they do not always get it. The Scilly growers have been censured for allowing their bulbs to stand so long, and there is no doubt that the crops become overcrowded under such circumstances, with deterioration in the sizes of bulbs and flowers alike as the result. But the saving of the expense of digging up and replanting is a great consideration, and the Polyanthus varieties, which are usually left standing longest, are said to deteriorate less on that account than the Daffodils or some other varieties of the Narcissus. Still, the best growers maintain that no variety should be allowed to stand longer than three years, because, apart from the deterioration caused by the overcrowding of the increasing bulbs, a

frequent change of soil is needed for the Narcissus as much as for other crops. The different varieties of flowers are picked, as already stated, from the beginning of January, or occasionally a little earlier or later, until June, expanded in glasshouses, tied in bunches of twelve, packed in boxes, and shipped to the great markets of England and Scotland. The leaves, when they have died off, are removed, and sometimes used as food for cattle. If the crop is to stand, the soil over the bulbs is cultivated during the summer in order to kill the

half of the year, with an hour for dinner, and from 6 a.m. to 6 p.m. in the summer half, with time for breakfast as well as for dinner.

THE EXPENSE of growing Narcissi is one of the questions as to which growers are naturally reticent, and inquiries upon that point could not fairly be pressed, though growers are occasionally invited to disclose even more delicate particulars of their private affairs—as, for example, in the case of a leading Scillonian who recently received a letter from a lady, unknown to him, asking him how much his in-

Arundinaria nobilis at Menabilly.

weeds. For transplanting or marketing the bulbs are taken up in June.

PICKING is mostly done by men, and bunching by women and girls, assisted by men in their overtime when work is in full swing. Men's wages are 15s. a week; but they earn a great deal extra by bunching and packing by the piece in their overtime. Their regular hours are from 8 a.m. to 5 p.m. in the winter

come was. The expense of cultivation varies greatly with the time during which crops stand and with the cost of bulbs, some of which are purchased at very high prices, while others are simply the increase of crops grown in the islands, and worth very little to sell, if they can be sold at all. If a statement made by a grower on the mainland may be accepted as accurate, to the effect that 240,000 of small

varieties of bulbs are required to plant an acre, or about half as many of the largest, it may be readily imagined that the cost of planting even home-grown bulbs is by no means small, and that it is very heavy when varieties by no means the newest are purchased at £3 to £10 per 1000. With respect to new hybrids there is, of course, no question of planting by the acre, as they frequently command £5 to £10 per bulb, and I have seen one for which fifty guineas was refused. In the past very high prices were paid by enterprising Scilly growers for varieties now comparatively common, such as Emperor, Empress, and Sir Watkin. One grower informed me that he had paid £50 to £80 per 1000 for such varieties a few years ago, while another said that he had bought Sir Watkin at £30 earlier than the neighbour who said he had paid £80. This discrepancy I am not able to clear up; but when Scilly growers bought bulbs at even £30 per 1000, it is to be presumed that they planted only a few rods of land with them, and extended the area as the bulbs increased. The expenses of manuring, cultivation when properly done, picking, raising and collecting bulbs, packing, freight, and marketing bring the cost of growing Narcissi up to a large sum per acre. With respect to the returns, they vary enormously with crops and prices. A high authority informed me that a good crop of a particularly free-flowering variety at 1s. 6d. per dozen bunches would give a gross return of £100 per acre, and probably choicer and less productive kinds, sold at higher prices, make quite as good returns. But prices fell alarmingly in 1897, and although they were much better in the early portion of the present season, they have been extremely low at times since the end of March. Some details as to the fall in prices will be given presently in the evidence obtained from growers.

My visit to the Scilly Isles was made in the middle of March, and the earliness of production is indicated by the statement that by that time most of the varieties of the Narcissus extensively grown had been marketed. Mainland growers will understand this earliness when it stated that more than half the crop of Grand Monarque and about half that of Empress had been disposed of before March 14, while ornatus was just beginning to come into bloom in places. In consequence of the mildness of the winter the early varieties were ready a little sooner than usual, while the late sorts were checked by the cold weather of March. In the preceding remarks I have given to a great extent the information obtained during my stay in the islands, but it remains to give a brief account of my visits to typical farms.

Mr. Martin John Sutton kindly supplied me with introductions to Mr. Dorrien-Smith and two other large growers of flowers, one of whom, Mr. E. W. Banfield, met me shortly after my arrival, and drove me to his farm at Holy Vale, St. Mary's. This farm, of 30 acres, about 12 acres of which are occupied by flowers, has been in the hands of Mr. Banfield's family for 300 years. After walking through the flower fields, protected by excellent fences of Veronica or Escallonia, and noticing the flourishing appearance of the Narcissus plants, I was shown a beautiful display of cut blossoms of several varieties expanded in a glasshouse and ready for packing. In one day Mr. Banfield has sent away 3500 bunches of a single variety. Where the bulbs are allowed to stand for six to eight years, Twitch often gains a strong foothold in the soil. Referring to the mildness of the Scilly climate, Mr. Banfield said that the Narcissus crops had never been

killed by frost. They have been frosted, but have always recovered. The land has hardly ever been too much frozen for the plough to work. Four men are employed regularly upon the farm, with extra hands in the flower-picking season.

Mr. W. M. Gluyas, J.P., of Field House, St. Mary's, who is Dutch Consul for Scilly, as well as a flower grower, has thirty-six acres of cultivated land, including about ten acres of flowers, with 100 acres of rough grazing land. Among the first things noticed on this farm were Berberis Darwini in full blossom (on March 14), and the Arum Lily (*Calla aethiopica*) flourishing rampantly in the open ground, and just coming into blossom two months before its usual time. The flower (*Narcissus*) season started this year, Mr. Gluyas stated, at Christmas, though the beginning of January is a more common time for the first open-air supply, and in late seasons picking does not begin until February. He started this season with Soleil d'Or, and Scilly Whites were ready at the beginning of February, a few weeks earlier than usual. The old double Daffodil began to bloom at the end of January, and Wallflowers in February. Mr. Gluyas also grows *Anemone fulgens* and double white Stocks, ready in March; and Spanish Irises and scarlet and white Gladioli, which begin to bloom in May in early seasons, though the latter are more frequently June flowers. Although he is a fancier of Roses and grows them in his own garden, Mr. Gluyas said that they did not flourish in the Scilly Isles, as the soil did not suit them. Five men and one boy are employed regularly on this farm, and a few extra in the flower-picking season, with some women and girls to bunch and help pack.

Mr. Mumford, of Old Town, St. Mary's, has about fifteen acres of open-air flowers and some fine hothouses in which he forces Narcissi in the winter. His first supplies of forced flowers were ready this season a little before Christmas. The plants are kept out of doors, after being potted in the summer, until November, when they are taken into the hothouses. They will not bear forcing from the first. As an example of the fall in the prices of varieties once rare, but now grown very extensively, Mr. Mumford said that seven or eight years ago ornatus sold at 12s. a dozen bunches; whereas it now frequently realises only 1s.

The most extensive grower of flowers in St. Mary's is Mr. Francis Watts, of Old Town, who holds eighty acres of land, besides some rough grazings, thirty acres being occupied by bulbs. Ten men are regularly employed on this farm, extra men and women being required in the flower-selling season to do the bunching. Mr. Watts says that bulbs should not be allowed to stand more than three years, as they get overcrowded when they are left for six to eight years, and the blossoms are in consequence smaller than they should be. The crop should be changed to Potatoes, heavily manured, after which bulbs may be planted again. Mr. Watts has hothouses in which he forces Narcissi. He grows in the open, besides the Narcissus, the *Anemone*, *Iris*, *Marguerite*, *Gladiolus*, and a few other flowers.

Mr. Barnes, of Normandy, St. Mary's, farms 44 acres of land, 16 acres of which are under flowers. He informed me that he was one of the few growers, including Mr. Richard Mumford and Mr. Trevellick, who began to collect the bulbs growing wild in St. Mary's in or about the year 1870, though it was two or three years before he sold any flowers in the market. Mr. Barnes's flowers are grown in small enclosures sheltered by very high and luxu-

riantly growing fences, and his beds are kept admirably free from weeds. Some of the bulbs are grown between and under fruit trees, and they have a flourishing appearance. Guano and dissolved bones are used as manure. The newer varieties of Narcissi are allowed to stand only three or four years, but Scilly White and other old kinds six or seven years. Mr. Barnes is of opinion that the common sorts (chiefly the Polyanthus varieties) will stand "almost as long as you like," while Sir Watkin, Emperor, and others of the Daffodil division will not do well after standing three years. Alluding to the fall in the prices of new varieties, he said that six years ago the flowers of Sir Watkin sold at 14s. to 15s. per dozen bunches, and now are worth only 3s. to 4s., but, of course, a great fall from the extreme prices obtained for flowers when they were rare was to be expected, and it is to be borne in mind that the bulbs were also extremely dear when growers first purchased a few of them.

Mr. Methuselah Watts, another grower of the Narcissus in St. Mary's, occupies 18 acres of land, 12 acres of which are under flowers. He has a hothouse consisting of four spans 18 feet wide each, connected, and a movable glasshouse, which he places over portions of his Narcissus crop growing in the open ground when he desires to force the flowers. The same bulbs can be forced two years in succession when they are thus left in their original beds, whereas, when they are potted and moved to a fixed hothouse, they can be forced only once. Mr. Watts had some choice and beautiful varieties ready for packing at the time of my visit. The last grower of bulbs in St. Mary's visited was Mr. Trevellick, of Rocky Hill, already mentioned as one of the pioneers of the flower industry of the islands. Like other early growers, he named only four varieties as being at all common in Scilly when the flower trade was started—Scilly White, Soleil d'Or, Grande Monarque, and the common double Daffodil (*Telamonius*). At the outset, when there were only two or three sellers of flowers in Scilly, and the market was not well prepared for Narcissi, the price was about 5s. per dozen bunches; but later on, as the demand increased, the rate rose occasionally as high as 24s. per dozen bunches. Last year prices were so low that they were barely remunerative, but in the early part of the present season they were better. Many new varieties have been introduced into the islands at great expense; but Mr. Trevellick doubts whether it would not have paid best to stick to the old kinds. He grows 7 acres of flowers, and had many beautiful varieties in course of being packed on the occasion of my visit.

Small plants for decoration.—In the early months of the year all propagating cases and lights are usually full, but just now it is a slack time, and where a large demand exists for small creeping plants it is good policy to push their propagation a little now. The plants once they are struck need not be hurried along, but kept near the light and grown stocky, so that with the increasing light in the spring they will make fresh growth and be nice and bright for use. Small pots full of Club Moss and *Isolepis*, for instance, may be prepared, also small bits of Ferns, such as the *Pterises* and *Gymnogrammas*. It is seldom that one gets over-stocked with such, and they often prove useful for associating with small pots of forced bulbs. *Pilea muscosa* again is very useful, the pretty fresh green of the fronds making a capital setting for bright-coloured flowers. The green and purple *Tradescantias* strike readily without any bottom-heat or without a propagating case, but *Fittonias*, *Panicums*, and the more brightly tinted of the *Tradescantias* need a little

encouragement. The less they are watered overhead during the time they are in the frame the better, as this is apt to lead to their making leaves of poor substance, that are sure to fall off at the first slight check. The harder they are grown from the first, the better they stand.

BIRDS AND FRUIT GROWING.

In the *Field* of Sept. 9, page 470, is a note from Mr. F. Boyes, of Beverley, describing the great damage done to the fruit crops this season by blackbirds and thrushes. He states that in his district no fruit crop has escaped them; they have even attacked his Apples and quite destroyed his crop of Victoria Plums. I can fully confirm this statement as regards the fruit grown within ten miles of London. In my own garden I have not picked a single Strawberry this year. The bush fruit of all kinds has suffered greatly. Cherries cannot be grown without netting, as the trees are stripped by the starlings as soon as the fruit is ripe. My own suburban garden is chiefly devoted to Apples and the choicer kinds of dessert Pears. Both of these have been seriously attacked. The early cooking Apples, such as Lord Suffield, Rieger, were not attacked, as the softer bush fruit was more attractive, and the Apples were gathered before the small fruit had all been picked; but the later crops have suffered greatly and have had to be gathered. In my own case the Pears have all had to be protected, or I should not have a single one left, every one being attacked as it became ripe. When good eatable Pears cannot be bought even off the barrows in the retail markets in London under from 2d. to 3d. each, they are well worth some trouble to protect. My garden has recently presented the spectacle of trees bearing some hundreds of muslin bags, each containing a Doyenné du Comice, Beurré Superfin, or other good variety, but the process of protection is troublesome and expensive, although the bags do for successive years. Pears suffer mainly from the attacks of the tits, which hold on to the stalk of the hanging fruit by one foot and peck a hole near the upper part. This is at once utilised by wasps; rain enters, and the Pear is not only rendered unsaleable, but is spoiled for domestic use.

With regard to the adverse influence of many birds on the increasing pursuit of fruit farming, I may quote a communication I have received from Sir Walter Gilbey, who, some ten years ago, commenced with a fruit farm on 4 acres of rather heavy land at Elsenham, Essex. The crops were most successful, and the fruit culture was rapidly extended, so as to include Victoria Plums, Apples, bush fruit, Gooseberries, Strawberries and Raspberries, and now 50 acres are under cultivation; but each year the number of birds steadily increases, and the damage done by them can hardly be over-estimated. Thrushes of the various species and blackbirds abound, and are shot by dozens. Sparrows are kept in check to some considerable extent by the local sparrow club, but Sir Walter estimates that many tons of the Strawberries and Raspberries are destroyed by the birds, which have greatly increased, owing to the recent county council enactments. In his desire to benefit the agricultural population Sir Walter has let out a large field in allotments for Strawberry growing, he having tilled the ground and stocked it with Strawberries adapted for preserving. The fruit is picked by the allotment holders, delivered at the jam factory, and purchased at the rate of 2½d. per pound. During the last season upwards of 2 tons were gathered, returning the allotment holders nearly £50; but although these Strawberry allotments were immediately in front of the cottages, the holders found it necessary, during the time the fruit was ripening, to pay an old man past laborious work to scare away the blackbirds and thrushes; otherwise, being so numerous, they would have destroyed the crop. This he accomplished with a rather comic arrangement of sitting from sunrise to sunset in the middle of the allotment in an extemporised shelter, and having near each corner

of the allotment ground an old tin kettle containing stones freely suspended, and from these kettles strings led to his central station, pulling which enabled him to make a terrific din which frightened away any birds that approached or settled.

The craze now existing for the preservation of birds of all kinds, injurious or otherwise, will undoubtedly lead to a reaction. At the present time the utmost nonsense prevails regarding them. We have in the *Times* of this week the killing of a couple of farmyard Muscovy ducks and their young recorded as a violation of the Wild Birds Protection Act, and as a wanton destruction of rare birds. The evil of ill-considered and useless legislation is already making itself felt in other countries beyond our own. In a recent work on the "House Sparrow" I recorded the fact that whilst other birds are allowed to be shot, this injurious species was ignorantly protected by the French legislature. On my visit to the vineyards during the present autumn I found the sparrows had largely increased, and in the trees surrounding the château in which I was staying I for the first time noticed the nightly accumulation of the sparrows at roosting time, such as may always be heard in the autumn in the trees in England in places where these birds abound, and in the vineyards they are now loudly complained of as attacking the ripe Grapes.—W. B. TEGETMEIER, in *Field*.

—I read with interest "S. E. P.'s" remarks on the above subject. In one garden to which birds of all sorts had free access, no gun being used from one year to another, I was annually much annoyed by blackbirds and thrushes spoiling most of my best Apples. Most of the trees were in espalier form, and although fish nets were used and even placed over double, they thrust their beaks through the meshes, working much mischief in a single day, or, I might say, morning, as it is before the workmen are about that they make their chief raids. As "S. E. P." remarks, these pests usually select the finest, best-coloured specimens, and a few minutes suffice for completely scooping out a large fruit. No doubt firing a gun a few times has a terrifying effect, though in time they seem to get accustomed to anything. In regard to tom-tits pecking Pears I may say that in the same garden I always had to net my wall trees in September with small mesh netting, or all the best fruit of some varieties would have been spoiled. One favourite tree of Marie Louise in close proximity to a wood was in dry autumns annually attacked by blackbirds and had to be netted.—J. C.

ROSE GARDEN.

CLIMBING ROSES.

SINCE the advent of Crimson Rambler much attention has been directed to this useful class. Although many of the kinds now largely grown are of modern introduction, some of the best are also some of the oldest. For instance, just now that fine Rose Aimée Vibert is brightening our walls with its snowy blossoms, which harmonise so beautifully with the rich shiny green foliage. This Rose is doubly valuable, for it not only flowers freely in the summer when Crimson Rambler is blooming, but it also gives a welcome late autumnal display. If we could but infuse this late-flowering quality into the true climbing Roses, a good work would be achieved. Where climbing Roses are mingled with late-flowering Clematises the absence of blossom upon the Roses is not so marked, but arches covered with summer-flowering Roses alone appear in the autumn rather dismal. A fine late-flowering variety as well as an early one is Longworth Rambler. It is really not so rambling as the Multiflora and Polyantha sections, but it is so good that no one who has a fair-sized garden can afford to overlook it, and, moreover, it retains its shiny foliage well over Christmas. As a good companion to Crimson Rambler, the bright yellow Aglaia must become very popular. It appears to be quite as

hardy as the former, and I can vouch for its rampant growth. The only fault with it so far is its shy blooming. All who have this Rose should not prune it in any way; simply allow it to grow at will, and the raiser says by the third year it will be smothered with large pyramidal trusses of bright yellow blossoms, which are individually about the size of those of Gloire des Polyantha. Those who desire a bold effect from these rambler Roses must be prepared to exercise considerable patience, and eventually they will be rewarded. Aglaia takes some of its beautiful yellow colour from one of its reputed parents, Rêve d'Or, although its growth is distinctly that of the seed parent, Rosa Polyantha. The raiser, Herr Lambert, has met with much success in his efforts at crossing these rambling Roses. A promising kind, a seedling of Crimson Rambler, is one named Helene, having large trusses of delicate violet blossoms. Among his novelties for this year he has a variety named Leonie Lamesch, which should prove a valuable acquisition. Herr Lambert in his cross-fertilisation experiments has adopted a method likely to lead to good results—that is, he crosses some of his seedlings with each other that are themselves the result of crosses. Thus a strange mixture of varieties takes place that must certainly produce good and unlooked for novelties. Psyche will certainly make a very pretty Rambler. The rosy pink, charmingly shaped buds, produced as they are in large trusses, will be a welcome addition to this tribe. The old variety Félicité-Perpétue is a capital white companion to Crimson Rambler. Its beautiful rosettes of white blossoms are well known. If one were quite sure as to its hardiness, Claire Jacquier would be the Rose to plant where a vigorous climber is desired. It will make quite an arbour in itself with just a slight amount of support, and its pretty bunches of nankeen-yellow blossoms, individually as tiny as those of Perle d'Or, would be a charming feature in a garden. Although it is reputed to be tender, I am inclined to think this to be more imaginary than real. A few years ago all Teas were looked upon as only fit for greenhouses, and to day probably no tribe is more extensively grown outdoors than this and its kindred class, the Hybrid Teas. One of our largest growers has his Teas upon the top of a hill, and he never protects them. Of course, it is well known that Roses and fruits suffer less from frost upon hills than they do in the valleys, but yet even here some years ago we should have been afraid to leave our Teas unprotected. Doubtless most gardeners are aware of and utilise the Crimson Rambler as a decorative plant for the early spring months. Plants procured with 8-feet to 10-foot shoots, these twined around three or four sticks, will bloom most profusely and are a valuable addition to the usual decorative plants, especially where required to stand in recesses, fireplaces, &c. Plants procured now in 8-inch pots would require no preparation beyond an examination of the crooks and a top-dressing of good compost. When the flowering period is over, repot and afford them plenty of heat and moisture; they will then make some good growths for the next season's crop.

PHILOMEL.

The Indian Rose at Delgany.—I was very glad to see the beautiful and characteristic photograph of Rosa moschata as growing and flowering on the post office and other cottages in the village of Delgany, Co. Wicklow. As is well shown by the photograph, this fine old rambling Rose extends along the eaves of the little cottages, being trained and spurred back Vine fashion every year. Indeed, were this not done it would long ago have covered the roofs of the cottages, as it has done the old kiln at Mount Usher, where Messrs. Walpole, observing its beauty at Delgany, introduced it some years ago. Where there is ample space on pergola, arch, wall, or tree this is one of the best of all the single-flowered cluster Roses, and well deserves to be more extensively planted, especially as this variety seems superior to the ordinary type. Delgany lies a mile or so inland

from Greystones and the sea, and it is a very pleasant walk from the railway station at Greystones, across the golf links to Killencarrig, past the Cherry orchards, and then up the road till Delgany is reached. Not only did the La Touche family bring this beautiful climbing Rose into cultivation here, but their influence and patronage on the gardens and gardening of the district were far-reaching and most encouraging. One of their gardeners, the late Mr. Pennick, took a plot of ground—30 acres or so—on their estate, on part of which he established a thriving nursery, growing what at that time were rare and valuable shrubs and trees. This nursery is still in existence at Upper Kendalstown, and contains fine specimens of *Pinus insignis*, *P. Pinea*, and other conifers, and until recently it was rich in Himalayan *Rhododendrons*, &c. *Erica arborea* grows 10 feet to 15 feet high there, and *Drimys Winteri* is nearly 20 feet and flowers freely. There are also fine male and female *Araucarias*, healthy to the ground, and a quaint old *Arbutus procera* near the old greenhouses, but the place is not so rich in rare shrubs as it was when first I saw it twenty years ago. *Photinia serrulata* grows wonderfully well here, its young foliage being intense crimson in colour, and in the village of Delgany there is a very fine specimen fully 20 feet high, and the most perfect in health and symmetry I have seen. *Hypericum triflorum* was distributed from Pennick's nursery twenty-five years ago, but it is not there now, I believe. Soil and climate are well-nigh perfect, and there are extensive views towards the sea.—F. W. B.

NOTES OF THE WEEK.

Rose Laurette Messimy.—We have this Rose in fine showy bloom, many flowers and buds, on the last days of November in an open position within thirty miles of London. This is six months' duty this beautiful Rose has done for us this year.

A curious form of *Anemone japonica*.—I have sent you leaves of a remarkable form of *Anemone japonica cristata*. They have been, unfortunately, frozen; consequently have passed their best. It is sufficient, however, to show you how very distinct it is from anything else in that way.—AMOS PERRY.

***Saintpaulia ionantha*.**—The pretty violet-blue flowers of this plant are a considerable attraction when the plant is flowering freely and also grown in considerable quantity. It is so to be seen just now at Syon House, where the plant is largely grown by Mr. Wythes for use on the margins of the stages. In such instances the plants crop up here and there among grasses and other equally interesting material, the rich violet blossoms having a most distinct appearance.

***Pelargonium Ian Maclaren*.**—This is perhaps one of the finest of the more richly-coloured salmon shades in these showy flowers, the colour being almost salmon-scarlet, with salmon margin. Apart, however, from its colour it is a free bloomer, medium-sized plants in 7-inch or 8-inch pots carrying something like a score of fine heads. This variety was among the most attractive in that unique lot that Captain Holford sent last week to the Drill Hall.

***Campanula pyramidalis alba*.**—It is surprising how this charming Bellflower continues to expand each and every blossom on the stem. Commencing its flowering quite early in July, the plants have maintained an unbroken chain till now, though the actual flowering, so far as effect may be said to be produced therefrom, has ended some few weeks since. All the same, from a height of about 6 feet to within an inch or so of the earth blossom upon blossom has emerged from the stem, and though these later ones have greatly diminished in size, they are still quite pure and good in form at the very end of November.

***Masdevallia tovarensis*.**—A very beautiful effect was secured by some plants of this pretty Orchid at the Drill Hall a week ago. The plants were sent by Messrs. Paul and Son, Cheshunt, who grow the plants with but little heat at any season. In this way at flowering time the flowers, if on dwarfier stems, are at least sturdier and calculated to endure longer when cut. In any case the group referred to in some degree shows what the amateur with but little heat may accomplish, as not only these, but *Cypripediums* and

some *Odontoglossums*, especially *O. crispum* var., succeed admirably in cool structures, and with a little care quite a goodly assortment may be catered for.

***Sternbergia lutea*.**—Referring to the various notes about this plant, I beg to state that I had all the species and sub-species under cultivation here, but none has been so satisfactory as the Platten, see variety of *S. lutea*. This is sure to flower, either a little sooner or a little later, from the end of September to the end of November. A clump has still (Nov. 27) a few flower-buds. *S. macrantha* and *S. Fischeriana* bloom but once on big imported bulbs, but the colder climate of the middle parts of Europe does not ripen flower-buds for the next season, and the bulbs gradually dwindle away.—MAX LEICHTLIN, *Baden-Baden*.

***Caryopteris mastacanthus*.**—In reply to Mr. Arnott, I can say that *Caryopteris mastacanthus* has flowered well with me for the past two seasons, but I think it is a bush that does not improve with age—I mean in the quality and size of flowers. Some young cuttings struck last year have made splendid growth and flowered well—better than the parent. *Clerodendron trichotomum* has done remarkably well this season, being covered with its large and beautifully-scented blossoms. It was visited by many of the humming-bird moths. My garden is about 250 feet above sea level.—H. MITCHELL, *Rush Green, Hertford*.

—With regard to the hardness of *Caryopteris mastacanthus*, my own experience in South Derbyshire is as follows: Some four years ago I received a rooted cutting of this among the plants distributed by the Royal Horticultural Society, and it was planted at the foot of a wall facing east, where it has since remained without any protection whatever being given to it in winter. It is not trained to the wall in any way and now forms a bush about 4 feet high, which was covered with bloom about a month ago. It has flowered profusely every year.—H. S.

***Pinguicula caudata*.**—A beautifully-flowered group of this pretty plant was recently noted at the Drill Hall. The prostrate leaf tufts from which the brilliant carmine blossoms issue render it always an attractive plant, particularly so in groups, as in this case. The plant really presents no difficulty to the cultivator, provided always it has its fill of moisture and is given a cool position uniformly so at all times. Flowering, too, as it most frequently does, quite late in the autumn when the surroundings are as gloomy as can be imagined, the plant is particularly welcome by reason of its brilliant flowers. The species is also well grown at Syon House, where we have lately seen it flowering. In Syon Gardens it is the companion of not a few choice cool Orchids.

***Arbutus Unedo Croomei*.**—The exhibit of this that Messrs. Veitch brought to the last meeting of the Royal Horticultural Society when seen in good established plants or in groups would certainly make a pleasing addition to this class of hardy shrubs. The colouring on the exposed surfaces of the bell-like clusters of blossoms is very pretty and distinct, and in the mass is very attractive. In certain districts these *Arbutuses* are very free both in growth and flowering, one such being the district around Bath on the Weston side, where numerous large examples may be seen in excellent condition. These, however, are principally of the old type, to which the above would make a capital companion. It is evidently as free as the original kind, and merely requires age to bring it into greater prominence.

***Chrysanthemum Admiral Symonds*.**—A few years since quite a stir was made about this pleasing semi-double variety, and not a few growers for market made a very considerable hit by growing this kind while the rage for it lasted. This of course was all too brief, and now the same kind is not cared for and few trouble to grow it. But the variety still maintains its old-time beauty, and those who appreciate flowers of its class, with available stems of perhaps 20 in. long, will not be disappointed with it from a decorative standpoint. It may be planted out and lifted

with good results where some attention can be paid to summer watering; but for this class of work it is not well to indulge in too late stopping. The colour varies from pale to deep canary-yellow. As a late November bloomer it is by no means to be despised where light, graceful flowers are preferred to huge lumpy ones.

***Stokesia cyanea*.**—Stokes's Aster is one of the plants which can be flowered by the Devonshire readers of THE GARDEN, but is seldom of use with us in the north. It comes into bud too late and seldom opens. I am aware that it sometimes appears in stands of hardy flowers in the west of Scotland, but I believe it is then the result of greenhouse cultivation for at least part of the year. Several years ago, in going through the garden of a keen exhibitor, I saw several pots of *Stokesia cyanea* in a greenhouse. Upon making inquiry I was informed that they were intended for a stand of cut herbaceous flowers. If the letter of the show schedule was not broken, one would think that the spirit of it was being disregarded. Now that we have so many Asters we have little reason, perhaps, to regret our inability to flower the *Stokesia*. It is, however, so fine in its way that one is not willing to admit failure in blooming it.—S. ARNOTT.

Double *Cyclamen*.—The so-called doubling of some flowers, while regarded by the hotanist as monstrosities, is not objectionable to a large number of people. Of this number very few, I expect, would be in favour of a double flowered strain of *Cyclamen*. There is a pleasing uniformity in the simple reflex of the corolla in these plants which any considerable addition thereto would seem to diminish, if not destroy. The feather on the petals is quite another matter, and this does not interfere in any appreciable degree with the calyx cup, as would be the case by the introduction of an indefinite number of petals. Usually when an addition to the number of petals occurs, the addition is forced out of place and the grace and beauty the flower once possessed are lost. Certainly such forms are not so attractive, and, above all things, no group appears less suited to this so-called doubling than the *Cyclamen*. Seekers after novelty may see something in the change and may hope to evolve great things out of the same, but from the point of added beauty and utility they are a step in the wrong direction.—E. J.

***Aralia Sieboldi variegata* in flower.**—In the glass-covered entrance to the Chiswick gardens of the Royal Horticultural Society a finely-developed plant of the above has produced a couple of large branching inflorescences. These have become a very considerable attraction by reason of the fine development of the heads of bloom. The blossoms are creamy white, arranged in quite globular heads. The inflorescence is pyramidal, the laterals radiating almost horizontally from the main portion, terminating with one of the globular heads referred to. A closer view reveals a singularly beautiful arrangement of the blossoms, which individually are somewhat Hoya-shaped, while closely arranged in a perfectly rotund head. These heads are of many sizes, and the whole surmounting the rich glossy foliage, well marked with its creamy variegation, is seen to advantage. The value of this practically hardy plant with the protection here afforded is materially enhanced, not merely from the much finer leafage, but by enabling it to throw up its fine heads of flowers that in the open garden appear too late to admit of their development.

***Crocus ochroleucus*.**—Through the kindness of Mr. E. A. Bowles, of Waltham Cross, I have just received a pretty form of *Crocus ochroleucus*, a pleasing autumn-flowering species whose only fault here is that it is not so hardy as one would like. The form received from Mr. Bowles appears to be rather smaller and more shapely than what I have up till now grown. All those I have had have been pretty with their creamy white segments marked with yellow at the base and their yellow tube. It is a *Crocus* one would like to have in a large clump instead of in the shape of the few plants one has to be thankful to possess.

Some day, it may be, these charming autumn and winter Crocuses will be so much sought after that they will be as largely grown as some of the popular Dutch varieties. In the meantime those who care for them must, as the late Colonel Trevor-Clarke once told me in an interesting letter about the flowers, "uphold the banner of the Crocus" and bring them before the notice of other admirers of floral beauty. The one under notice deserves a place among the others despite its comparative tenderness in my garden. It comes from Northern Palestine and the borders of Syria.—S. ARNOTT.

A note from Carsethorn, N.B.—Dahlias here are over for the year, but a few Sweet Peas remain to day (November 27). *Tropeolum Lobbianum*, which was injured by the frost in October, is growing again and is giving a few blooms. Monthly Roses and Longworth Rambler are still in flower, and a fine bloom of Mme. Isaac Pereire was cut on the 24th. It is finer in autumn than in summer. There are yet some Starworts, and *Erigeron speciosus* has some blooms upon it quite equal to those it gives us earlier in the year. *Linum flavum* does not open, but it yet shows abundance of its bright yellow pointed buds. *Oxalis Bowieana* is in like state. It gives little colour now with its rolled up flower-buds, but it is invaluable for months at a time. Mr. Buxton's variety of *Anthemis tinctoria* retains its almost perpetual blooming properties. Marigolds are gay yet, and give some colour. A few Chrysanthemums are in bloom, among them being some of the newer early varieties which were belated because of the dry weather which set in after they were planted. Chrysanthemum coronarium is also in bloom. So is *Saponaria calabrica*, whose bright little flowers carpet the spot where Poppy Anemones and Snowdrops will afterwards appear. *Mecconopsis cambrica* and *Papaver nudicaule* are both in bloom, and the annual Scabiouses have not yet departed for the year. *Galanthus Rachelæ* gave a couple of its pendent eardrops, but the slugs soon discovered that they were toothsome. Others are on the way. Crocuses and Colchicums yet give us flowers, but they also need guarding from the depredations of the slimy pests. *Campylopus portenschlagiana*, *C. persicifolia*, and some one or two others of the genus have not left us, and the pretty Primrose in two or three colours is welcome now. By the doorway a low plant of *Jasminum nudiflorum* clambers up the evergreen Rose and looks gay with its yellow flowers. Still higher up is a hardy Fuchsia, whose flowers, though a little bleached by the weather, are acceptable still. Mr. Harpur-Crewe's double Wallflower has anticipated its single companions, and a copper coloured *Verbascum phoeniceum* has thrown up a dwarf spike. *Papaver rupifragum* is also in bloom. Hydrangeas have not yet left us, and one might give a wonderfully long list of other plants which yet give some brightness to dull, but mild days.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, December 5, in the Drill Hall, James Street, Westminster, 1-4 p.m. A lecture on "Some of the Plants Exhibited" will be given by the Rev. Prof. G. Henslow, M.A., at 3 o'clock.

National Chrysanthemum Society.—The executive committee of the above society held a meeting at Carr's Restaurant, Strand, on Monday evening last, when Mr. Percy Waterer presided. The minutes, &c., having been duly dealt with, Mr. Harman-Payne made a brief statement concerning the visit of the National Chrysanthemum Society's deputation to the recent Lyons show of the French Chrysanthemum Society, and expressed satisfaction on the part of his colleagues and himself at the very warm reception accorded to them—a formal report being promised for the next meeting. It was also moved that the newly-formed Danish Chrysanthemum Society be admitted in affiliation. The awards made at the

society's show last month were then considered, and duly confirmed the amount of prize money amounting to £366 13s., while various medals for miscellaneous exhibits were given in addition. It was arranged that the annual dinner be given to the members of the floral committee at the conclusion of the season's work. Fourteen new members were elected, and the treasurer gave a brief report on the financial position, which was regarded as satisfactory.

PUBLIC GARDENS.

CHRYSANTHEMUMS AT WATERLOW PARK.

CONSIDERABLE improvement in the housing accommodation has been made at this park, the glass structures formerly used having been renewed or lessened in their height, thereby giving the display a more pleasing and neat appearance. As compared with other seasons, the display is distinctly ahead of other years, many of the plants developing blooms of the highest quality, and most of them of remarkably good and bright colour. From an educational point of view there is much for the ordinary visitor to learn. Most public displays, including the shows of local societies and such exhibitions as are held by the National Chrysanthemum Society, are more or less monopolised by the huge Japanese blooms, until many a casual observer has come to regard the Japanese type of the Chrysanthemum as the only one grown, or at least worth growing. Mr. Pallett, the superintendent here, however, has a mind not by any means narrow, and, seeing that his object is to interest and educate the public, has been wise enough to provide variety both in types and forms. Because of this fact Japanese, which of course predominate, are ably supplemented by blooms of the incurved, Anemones, pompons, and singles, and as these different forms are pleasingly intermixed, their various characteristics are beautifully brought out, the smaller blossoms contrasting well with the larger and bolder flowers. One large and lofty square house has a pathway running between two huge banks of plants, and running out from this is a long range of vineries, with charming groups arranged along each side a path of good width. Standing out conspicuously from other Japanese sorts were Graphic, which had handsome blooms of good colour, evidently from a late bud selection, and Lady Hanham, the lovely cerise tinted chamois sport from Vivand Morel. These plants were grown quite freely, and were giving blooms of good colour. The parent variety, Vivand Morel, was also represented in good form, late buds giving lovely silvery mauve blossoms. Chaz. Davis was developing blooms of a rich reddish bronze colour, and these were of large proportions. Joseph Chamberlain was seen in splendid condition, the blooms being exceptionally large and full, the glowing crimson colour of the inside of the florets contrasting favourably with a golden bronze reverse. President Bevan is thought much of, its pretty yellow colour, tinted rose, making a refined incurved Japanese bloom. A variety rarely met with is a creamy white named Queen of Portugal, this passing to a pure white with age. The lovely white blossoms of Mrs. C. Blick were frequently met with. Lady Byron was just past its best, its large chaste blossoms of pure white serving a useful purpose in the early part of the season. The blooms of John Shrimpton, although not by any means large, gave a welcome bit of rich crimson colour here and there; so, too, did G. W. Childs, the flowers of which also are only of medium size, but the colour is the brightest shade of crimson, invaluable for conservatory displays. A few exceedingly fine blooms of Eva Knowles were in the pink of condition, and rarely, if ever, have better flowers of this variety been seen. A somewhat new incurved Japanese sort is Samuel C. Probyn, colour cherry crimson, with a silvery reverse to the petals, making a large, massive flower on a dwarf habit of

growth. The delicate whitish primrose blossoms of Miss Elsie Teichmann were very noticeable, contrasting well with the richer self-coloured flowers. Other Japanese sorts worthy of mention as being in good condition were the popular bright yellow Phœbus, freely grown; Louise, pearly blush, dwarf and fresh so late in the season; and Mlle. Marie Hoste, a creamy white, almost a forgotten sort now. Numerous highly coloured blooms of Val d'Andorre were frequently in evidence. President Borel, a rosy purple, is still regarded with favour; W. H. Lincoln with its rich yellow though rather stiff, erect petals, was seen in good form, and the lovely silvery pink Comte F. Lurani carried several blossoms of a useful size.

Incurved varieties were pleasingly interspersed, Mrs. Geo. Rundle and its sports, George Glenny and Mrs. Dixon, carrying numerous blossoms of a dainty kind, and D. B. Craze, the golden-buff sort, was in good condition. The richly coloured blooms of Descartes, La Marguerite, M. C. Lehocqz were the best representatives of the Anemones, while of the pompons there were numerous plants, freely flowered in most cases. The best were Mme. Marthe, white, and Golden Mme. Marthe; Rubrum Perfectum, deep rich crimson, rather late; Perle des Beantes, bright rich crimson; President, rosy purple; Mrs. Mardlin, a pale rose sport from the last-named, and numerous plants of the bright crimson Howard H. Crane. Marie Stuart was the best of the Anemone pompons. The rosy purple J. B. Duvoir was used largely for the front rows.

The proposed extension of Brockwell Park.—At a recent meeting of the Lambeth Vestry a report was received from the special committee appointed to consider the expediency of acquiring, as an addition to Brockwell Park, Herne Hill, an area of about 42½ acres adjoining the park. The existing park contains about 84½ acres. The committee came to the conclusion that it was imperatively necessary, in the interests of the growing population of Lambeth, to prevent the erection of buildings on the open space adjacent to Brockwell Park and to preserve this fine piece of country for town dwellers. They therefore recommended that the vestry subscribe the sum of £15,000 towards the purchase of the additional land, the sum to be raised by a loan for fifty years. The motion was carried unanimously.

Trade commissions.—By the honesty of a servant the following has come into my hands: "Dear Sir,—I trust the enclosed present will reach you safely. Your kind acknowledgment will oblige." These words are lithographed, and bear the address of one of the first firms of nurserymen. The "present" amounted to a very large percentage on a small account, and of course came out of my pocket. This is the third case of similar dishonesty, each case affecting a different firm, which has come to my knowledge within the past year.—W. G. RUTHERFORD, *Dean's Yard, Westminster, in Times.*

The weather in West Herts.—A very warm week for the end of the autumn. The nights have been lately very warm, while the day temperatures have remained nearly as unseasonably high. The temperatures below ground have been getting gradually higher during the past week, so that the readings both at 1 foot and 2 feet deep are at present about 3° warmer than their respective averages for the time of year. No rain has now fallen for nearly three weeks, and no measurable quantity of rain-water has come through either percolation gauge for the last five days. On the 25th the atmosphere was remarkably calm, the mean rate of movement of the air at 30 feet above the ground being less than a mile an hour. On only three of the last thirteen days has any sunshine at all been recorded.—E. M., *Berkhamsted.*

Name of fruit.—*Jas. McKenzie.*—Grape Black Hamburg.

FERNS.

SUNLIGHT FOR FERNS.

I QUITE agree with the remarks of "C. H." (THE GARDEN, p. 424) with regard to the advantages of exposing Ferns to all the sunlight possible. I have often advocated the necessity of more light and less shading for Ferns. There are some which delight in a more shady position than others. I find most of the Aspleniums do not do so well when fully exposed to the direct rays of the sun, but even for these light is essential. The Davallias do well if fully exposed during the winter, but when the sun gets more powerful some shading is advantageous. It may be taken generally that those which show no coloured tints in the young fronds like more shade than those which have the bright rosy tints, though this is not absolute. The Nephrolepises, for instance, never develop the rosy tints, but when well exposed they have a lighter and more pleasing shade of green, and may be grown in the most exposed positions, and, provided the watering is carefully attended to, will make more satisfactory growth than when subject to heavy shading. The Adiantums are the most remarkable. Considering the fragile nature of the fronds, they withstand full exposure to the sun where others with fronds of greater substance suffer. I would, however, call attention to the fact that those who have been growing Ferns under heavy shading must not expose them until they have been gradually inured to the new treatment. Taking A. Farleyense as an instance, I have seen plants which have been grown in a high temperature, with thick shading and plenty of moisture, which have made fine deep green fronds. To expose such would mean that either a dry atmosphere or a very little sunshine would shrivel the fronds up, but start young plants and grow them on under drier and more exposed conditions, and there will be little risk of them suffering from sunshine if watering is not neglected. All Ferns when

exposed require more attention, but over-watering should always be avoided. The same mistake is often made with regard to watering as with shading—that is, it is overdone. Where the pots are well filled with roots and the plants have good healthy fronds they will take up a considerable quantity of water, but with those that have not much top or have been reotted great care should be taken not to get them too wet, for if the soil gets soddened and sour they will never make satisfactory growth. When reotting, if the balls are fairly moist and the soil in good condition, only a slight surface watering should be given. Except when placed in a very dry position this will be sufficient for several days. It will be better to err on the side of keeping them a little too dry than otherwise, provided the fronds do not get withered beyond revival. A. HEMSLEY.

BASKET FERNS.

It is hardly the proper time to disturb any plants at the roots, but where a little extra warmth can be given there is no better time for filling baskets which are to be suspended from the roof, as they will get the full benefit of the light and there is no danger of the sun being too powerful, while there will be sufficient time for the plants to get well established and hardened before the sun gets too strong. The Nephrolepises, Davallias, &c., are the most suitable for baskets, but there are many others which may be recommended. In filling the baskets, young, free growing plants should be selected and only a thin layer of Moss should be used, for if too much space is taken up with it it will decay and leave a space, and the soil will get loose. For covering the under surface of the baskets there is no better material than Ficus repens. If a few young plants of this are put round the edge and pegged down they will soon form a good covering, and will help to keep the soil together without taking much nourishment from the Ferns. Some of the Davallias will in time cover the baskets, but most Ferns are slow to cover the under surface, and the Ficus cao always be thinned out or removed altogether after the Ferns get well established.

In some cases two or three varieties may be grown in the same basket, but for the fernery I like to keep each sort separate, using baskets in sizes to suit the growth of the Ferns. Large baskets are generally objectionable on account of being too heavy, but such Ferns as Stenochlæna scandens, Nephrolepis ensifolia, N. davallioides, Davallia ornata, &c., can only be seen to advantage when grown in large baskets. The most popular basket Fern is Nephrolepis exaltata. This is now recognised as one of the best market Ferns, and is used extensively both in pots and baskets. This Fern also finds much favour in America, where it is generally known as the Boston Fern. A. H.

SELAGINELLAS FOR MARKET.

FEW of the Selaginellas prove of much value for market. S. Kraussiana (more generally known as denticulata) is grown extensively. The demand is, perhaps, a little uncertain, but sometimes it is wanted in very large quantities. Well-grown stuff will generally pay fairly well. There are various methods of treatment. I like to get short, fresh material to start with. Where stock is plentiful, about four or five good patches may be put into a 4½-inch pot, and if done well it gives little trouble, and may be well exposed to the light from the start. Almost any soil may be used, but a fairly rich, open compost will be found to suit it best. To do Selaginella well it must be exposed to the light. It is a mistake to suppose it can be grown under the shade of other plants. With sufficient moisture it may be grown fully exposed to the sun, and will make short, compact growth and keep its colour well. S. Martensi, the erect-growing variety, finds some favour, but could not be sold in quantity like the above, though when well grown it is very serviceable for decoration. S. Emiliania makes a very pretty and useful plant either in a small state or grown on in a 4½-inch pot. It should be propagated from small cuttings and grown on singly. The cuttings are slow in making a start, but after the crown of the plant is formed they soon get away, making symmetrical, compact little plants. S. amena may be recommended as one of the most useful. Like the last named, it is rather slow in making a start, the cuttings

taking some time to form roots, but when once it gets a start it grows freely. The deep green, feather-like fronds or growths are of a peculiar wiry substance, and it is one of the best to stand exposure. These last two may be propagated by putting small cuttings into pans or boxes and potting singly after they are established. A loose, open compost should be used. If grown on in a stove temperature they will make more rapid progress, but before taking them out for use they should be hardened off, and although they luxuriate in a moist atmosphere, they stand well in a drier air if not subjected to a sudden change.

The Selaginellas are most serviceable for edging groups and filling up under coloured foliage. Some are also used extensively for cut-flower work. A. H.

NOTES ON HARDY FERNS.

In gardens otherwise well managed we often see corners adjacent to buildings and with cold aspects filled up with rubbish and generally the most untidy part of the place. This need not be, for in addition to the flowering plants that delight in shady, cool positions, we have in the hardy Ferns the means of making such corners charming all the year round. Enthusiasts in hardy Fern culture often say that no flowering plants should be associated with them, but this I hardly agree with—at any rate, when deciduous as well as evergreen species are included in the collection. Such pretty effects may be produced by the use of such things as the hardy Vincas and Squills, Anemones and Primroses, that to leave them out of such arrangements is to rob them of half their brightness and beauty, and being mostly of dwarf habit, they do not in the least detract from the soft green tints of the young fronds of the Polystichum and similar deciduous Ferns. Dealers in hardy Ferns now catalogue an immense number of forms of the commoner species, such as Polypodium vulgare, and there are few more beautiful among exotic kinds than some of these. The Welsh Polypody, for instance, that used at one time to grow in large numbers, notably about Wentwood, in Monmouthshire, is one of the prettiest, and even the common type is very beautiful, especially in early spring and in late autumn, when the fronds are ripe and the older ones taking on the old gold tint characteristic of them. This is very fine in some of the red sandstone districts in Gloucestershire. Then the Hard Fern (*Blechnum Spicant*) in some forms is exceedingly beautiful, and I have gathered wild forms of it in South Wales as finely cut and long in the frond as a *Nephrolepis*. The hardy and ubiquitous *Asplenium Adiantum-nigrum*, again, has many forms, so have the *Athyriums*, to say nothing of the large number of beautiful species that have come to us from North America and Japan.

There is no lack of material, then, for beautifying the places mentioned, and the form and manner of planting will depend somewhat upon individual taste. Where abundance of large stones of a rough and jagged kind, or any with a natural appearance can be had, something in the nature of rockwork is usually attempted. On the one hand, this does not need to be made flat and regular; on the other, there is no need of making it bristle with rough stone. A stone in a hilly country often shows a round surface, sometimes quite a level one, while in slaty districts or where pennant and sandstone are found there are flat beds one over the other. Such fearful and wonderful arrangements as the common or garden rockery with sharp points sticking up at every foot or so are seldom, I should say, seen in a state of nature. In planting it is

a mistake to be dotting the plants about all over it at stated heights and intervals. If a good large clump of the Royal Fern can be had, let this be placed in a bold and prominent position; also large clumps of such as the Soft Shield Fern, and let the dwarfier kinds have to be looked for, as it were. If an old log with Polypodium already established upon it can be obtained, this may be used as a place whereon to establish others such as like a clinging position more than to be planted in soil. I have seen the wild *Hymenophyllum* thrive well in this way as well as the Black Spleenwort that is so much at home in old masonry everywhere. But wood, as a rule, is not a good material for the purpose indicated. It soon decays and looks untidy, and there is never the same thrift in delicate species of Ferns as there is when their roots can lay hold of stones. But in localities where stone cannot be had one must perforce be satisfied with wood for the purpose.

GROWER.

FERNS FOR DECORATING ROOMS.

MANY of these most beautiful in themselves are of but little value for house decoration. To have them suitable for this purpose the fronds must be green, yet so hardy as not to be affected by the cold draughts from open windows. We too often see during the winter the frosty air blowing in on plants as they stand on tables near the windows, and if such are at all tender their foliage is soon cut down. Amongst Ferns there are but few more useful for this work than the *Pteris* family. Their fronds are hardy, and at the same time many of the species are most pleasing. If we take *P. tremula* we shall find that more of this variety finds its way to the market than any other. It is alike useful in a young and small state as well as when grown to a goodly size. This species stands well in a room, particularly if not too much pot-bound to need frequent watering, as plants in such places are apt to get dry, particularly during the summer months. In small pots this plant is most useful, for when well grown it can be employed for a variety of purposes, and being of such free habit it makes, in a 5-inch or 6-inch pot, a nice specimen well furnished with its noble fronds. Seedlings are so easily raised, that a good stock may be worked up in a short time. It is not at all particular as to soil, but a light, rich sandy loam seems to suit it best. Thousands of plants of *Pteris serulata* are sold daily in our markets, thus testifying to its popularity for decoration. Its hardy constitution, easy cultivation and graceful habit at once place it in the front of our decorative Ferns. Either in small pots or when grown to a larger size it is alike useful, as its light graceful fronds lend themselves to almost any place, and being of such a lasting nature do not soon suffer when exposed to cold winds or allowed to get dry. The freedom with which this variety is produced from spores and the rapidity of its growth enable it to be used more often than could otherwise be done were it more tender. It enjoys a liberal amount of water and should not be exposed to the scorching rays of the sun during summer, otherwise the fronds are not of that freshness so desirable. There are several varieties of this all more or less beautiful. *P. s. gracilis*, *P. s. cristata*, *P. s. Lysi* and *P. s. tenuifolia* are amongst the most graceful, and may be used according to the tastes of the decorator. *Pteris cretica* is deservedly one of the most popular greenhouse species for decoration, particularly the variety known as *albolineata*, the bright line down the centre making it very attractive, particularly when the fertile fronds are removed. *P. c. Mayi* is also a beautiful form of the above, being of dwarf habit. This comes quite true from spores and grows very readily. *Lomaria gibba* in a young state is very attractive, and thousands are used every year for table and other decorations. Grown in small pots they are most useful, and may be employed for a

variety of purposes; their light, Palm like fronds which grow so close to the pot enable them to be used in places where it is difficult to have Palms. The soft green and compact habit, together with the enduring nature of the fronds, renders them most useful. When grown in a 6-inch pot the plants are very useful for vases, but they must on no account be allowed to get dry at the root or they soon suffer. *Lygodium japonicum* is usually grown in gardens under the name of *Lygodium scandens*. For decoration it is most useful, for its slender climbing stems may be employed in a variety of ways. When grown in small pots the growths can be trained round pier glasses and like places. They are also useful for table decoration and for hanging baskets. The fronds are very leathery and stand a long time in water, which is a great advantage. At one time no Ferns were so much in request for decoration as *Adiantums*. Either cut or in pots there was always a demand for them, but since the *Asparagus* has become so popular there is not the same call for *Adiantums*. Still, as pot plants, particularly in a small state, they are much in request, and thousands are sold daily in our markets. Being of such easy culture and accommodating themselves to all sorts of places, they are sure to remain in favour so long as there is such a rage for small plants. When well grown they make nice subjects for decorating rooms, but they must on no account be allowed to get dry at the roots or be stood in the draught, or the fronds will soon shrivel up. Fine specimens may be grown in the course of a few months, particularly if well fed with manure water. As to soil, they are not at all particular so long as it is of a light, sandy nature. *A. cuneatum* should not be grown in too much heat, neither ought the plants to have a dense shade, or the foliage will be of very little use for cutting. *A. gracillimum* ought to be grown fully exposed to the sun to make the fronds hardy if they are to be of any value. All the species are more or less valuable for decoration, though none are so popular as the above.

H. C. P.

KITCHEN GARDEN.

QUALITY IN BRUSSELS SPROUTS.

PROBABLY no winter green vegetable causes more disappointment than Brussels Sprouts. The chief annoyance is their growing out into what may be termed miniature Cabbages instead of young, medium-sized, hard nuts. Errors in cultivation are generally responsible for this state of things, and I am convinced the majority of batches are sown too early. I never could see the force of sowing Brussels Sprouts say in January, or even early in February, as some do. Even in midland and northern gardens the practice is unprofitable, as more often than not the seedlings remain in the seed-boxes until they become yellow and stunted, as the weather is more often than not too inclement for exposing them in open quarters. When residing in South Notts I once or twice grew an extra early lot of this vegetable, sowing the seed in a Carrot frame in February and finally transplanting early in April. Even on not over-rich ground the sprouts invariably reached maturity early in October, at which date they are seldom asked for in the dining-room. By the time this was the case, a large percentage of them had burst or had lost quality, secondary March open border sowings having to be started on. If these extra early sprouts must be grown more than ordinary care must be taken all round. In the first place, sorts noted for their medium stature and close sprouting habit should be selected, and instead of being crowded in seed box or pan should be thinned out as soon as practicable and pricked into other pans, boxes, or frame mounted on a gentle warm bed immediately the first pair of

rough leaves are formed. In the frame they can be left until the weather allows of their final transplanting being accomplished without suffering, and can, provided crowding is avoided, a somewhat holding soil employed, and exposure by entire removal of lights when fine practised, be lifted with a trowel. These early batches should also have a very firm, rather poor root-run, also a sunny, open position and ample room.

In the case of main winter plots, the season affects them more or less. In wet, sunless summers abnormally large, loose sprouts are the rule, this defect being observable even at shows. Good all-round crops would be made more certain were the young plants treated as many treat winter and spring Broccoli, viz., planting on land free from fresh manure and which has not been turned up for some time. Where practicable, the plot from which this season's crop of spring Onions was taken might be set aside for Brussels Sprouts during the following year, not interfering in any way with the surface beyond cleaning with hoe and rake and drawing slight drills to plant in. Onions being, as a rule, well provided for, the ground would be quite rich enough for sprouts, and the firm condition, while encouraging hard fibrous roots, would likewise retain moisture better and have the additional advantage of a more even temperature, conditions essential for the production of good stocky stems in such a variable climate as ours. NORFOLK.

Beet.—Although generally on ordinary soils Beet is not this season so large as usual, yet I have seen on rich ground plenty of roots full large; indeed, in such ground, although gardeners constantly complain of the effects of drought, yet the crop seems to have been as sturdy and good as at any time. Such are the common results of deep culture and ample manuring. But if we have less large Beets generally, there is plenty of nice sized, fairly clean roots, but many are rather rugged in outline because the soil had been so hard baked. Tops, too, generally have been dwarf. I found in my own trial of Beet that Dell's Crimson, Nutting's Dwarf Red, Cheltenham Green-top, Ash Grove, Sutton's Blood Red, Carter's Perfection, Webb's Satisfaction, and others of the very best garden Beets were very much alike in top-growth, although in ordinary seasons differences in robustness are very apparent. It has not been a fair season to test Beets.—A. D.

Large Onions.—The fine Onions exhibited at a recent Drill Hall meeting from Leicester show that the culture of large bulbs is not only widely understood, but is as widely practised. There are few gardens of any pretensions now in which it is not the rule to raise Onions under glass and plant them out in the spring. Although in the Leicester collection that popular Onion Ailsa Craig figured as Leicester Globe, yet the multiplication of names does not affect its popularity, and it remains yet the very best large solid Onion in cultivation. Intending growers not already supplied should get their seeds at once. The best growers sow usually about Christmas; some rather earlier, some later, but it is a good time to sow the seed. A moderate temperature suffices, as growth is stouter in consequence than is the product of much warmth. Plenty of air and light and just kept growing on, pricking out into shallow boxes thinly when the seedlings are from 2 inches to 3 inches in height, enable very strong, sturdy plants to be ready to plant out in April.—A.

Vegetable refuse for Peas.—I am pleased to know that "H. R." has found amusement in my article on the above subject in a recent issue of THE GARDEN. I did not advise Pea growers to use vegetable refuse in preference to manure; as a fact, in the opening sentences of my remarks I expressed surprise that such fine crops could be

grown without the use of manure. Neither did I assert that the decayed matter from one year's crop dug in would be sufficient nourishment for next year's crops. Does your correspondent seriously imagine that any English gardener would make such a ridiculous statement? I distinctly stated that the good results were obtained by means of heavy dressings of leaves, lawn sweepings and such material which had been kept a year and had been sweetened by being repeatedly turned over. I did not say that vegetable refuse should be buried and manure kept on the surface. My remarks were descriptive and suggestive. I described the way in which fine crops of Peas were grown with the aid of vegetable matter alone, also the way in which a large grower uses manure, suggesting that in this manner young growing crops are likely to be better fed than when the manure is dug in in lumps. I would advise "H. R." to read more carefully that which he desires to criticise.—J. C., *Byfleet*.

Turnip-rooted v. long-rooted Beets.—I am now using an excellent selection of Blood Red Beet, and besides its very handsome appearance in the garden I am constantly hearing of its excellence both from the kitchen and the dining-room. This season my earliest sowings, which are always of one of the Turnip-rooted varieties, did badly, and in consequence I had to use the long-rooted kind before it was half grown, but even then it was excellent and the colour remarkably good. I am not going to run the Turnip-rooted section down, as I have found it useful early in the season, but at the same time Turnip-rooted Beets do not in the majority of cases come up to the other section for quality, and I am inclined to think that, as a rule, we grow too many of them. For the first crop sown either under glass or in warm borders the Turnip-rooted Beet is useful, and though I grew for several years a Globe variety for late summer and autumn use, I have discarded it the last two seasons, growing only the Blood Red for all but the earliest supplies. I feel confident it was a change for the better, though doubtless in some very poor and shallow soils there is room for the shorter roots. It is a case perhaps of growing what suits the soil in individual cases.—H. R.

Asparagus.—Whilst in large gardens Asparagus is usually well grown, in many small gardens it is too rarely seen in good condition. Generally the old method prevails of planting in beds which in the course of a few years under the heavy soiling conditions so common with the bed system elevates the crowns so high, that not only do they soon suffer from drought, but the roots at the sides get cut off hard by the spade in trimming down the sides, are exposed to the air and debarred from extending into the adjoining soil. Very seldom do we see a good breadth planted on the flat, which is much the best, especially where the soil has been deeply worked and well manured prior to planting. Where the sub-soil is of a poor, gravelly nature, it is well to throw out several inches of it from the bottom of each trench as the deep working proceeds, replacing it with fresh good soil and the contents of a heap of well-decayed garden refuse, if such be at disposal. Preparing ground well for Asparagus, a crop that it is intended to leave for many years, is amply repaid later when, with years, growth becomes very strong, as then the weight of the produce is greatly enhanced. The sowing of the seed, raising the plants, and thinning them fairly hard to enable yearlings to become strong enough to plant out for permanent purposes give as little trouble as is needful for Cabbages or other crops.—A. D.

The Potato crop.—A statistician has recently declared that fewer Potatoes are now being consumed than was the case a few years ago. Statistics may be made to prove anything desired, but in this case the assumption is that the public taste is being directed from Potatoes on to other foods. That is an assumption which may be taken for what it is worth. But it is certain that some recent dry seasons have materially affected the productiveness of the Potato plant, and such re-

sult has been seen in the past summer to an unusual degree. We have this year one of the shortest of crops generally, relative to area planted, entirely the product of a most adverse season, yet with very little disease. In such case it can be no matter for surprise if Potato consumption is materially restricted, as already prices rule high compared with those seen in ordinary years at this season. Unless there are large importations, or the crop in the north is exceptionally good, we may expect to find prices very high in the spring. Vast quantities of Potatoes are grown in gardens, especially in cottage gardens and on allotments, that never come into ordinary agricultural returns. But when the crops on these areas are represented, as has been frequently the case this year, with produce of but one-half or one-third of the average bulk, no wonder if the demand for Potatoes on sale is enhanced and high prices follow. Last spring-planted Potatoes suffered as much from prolonged cold and numerous late frosts as from any cause, and the great drought which followed made matters so much the worse. With respect to Potato consumption, it is certain that early spring importations of unripe tubers whilst consumed are vicious food, yet they do increase greatly. At home, in the production of early crops we are handicapped not by lack of proper varieties, or soil, or want of knowledge, but by late, cold springs, which defy all efforts to overcome.—A. D.

NOTES ON TOMATOES.

— I do not think any Tomato superior to Conference for flavour and good cropping. It is a most reliable fruiter, never fails to set well, and the flavour is excellent. I am aware there are larger fruits, but mere size does not denote quality, and even in the market there is now a better demand for a Tomato the size of Conference than larger fruits. As regards flavour and crop, Ham Green runs Conference closely, but it is longer in ripening. Many exhibitors would put a good selection of the Perfection Tomato before any other, but I do not think it superior in any way, and at times it is too large, but the quality is good when the fruits are medium-sized. There are so many varieties of Tomatoes under cultivation that in the notes sent there will doubtless be great diversity of opinion. Some growers have their own selections, and some I have seen are in many cases superior to kinds in commerce. The best outdoor kind I have tried is Laxton's Earliest, an excellent Tomato. This ripens in July, and is of good quality. Earliest of All is also a very good outdoor variety, having fruits of medium size, good colour, and produced in quantity. Ladybird and Frogmore Selected I have found very good grown thus. To these should be added Golden Jubilee, one of the best of the yellow section. This is also good as regards crop and quality, and is a beautiful fruit. In the new kinds of late years, some of the small dessert (or so-called dessert) kinds are good for salads. The best kind for winter and early spring crops is a selection from the Old Red, as I find a corrugated fruit sets best in winter or autumn. Horsford's Prelude is an excellent winter Tomato, but too small. Ladybird, Conqueror, and Conference are excellent for this purpose. I consider the Tomato a vegetable.—G. WYTHES, *Syon Gardens, Brentford*.

— I have tried a good many Tomatoes, but have found none to beat one called The Cropper. Inside and out I have it this year and have never seen a better for setting. It is far before others that I have tried and does well for early and late work. I consider the Tomato a vegetable.—C. TERRY, *Blaston Hall, Uppingham*.

— I think Polegate is one of the best Tomatoes for general purposes. I find it free setting, of good flavour, large and fine for exhibition. I know of no Tomato more suitable for outdoor culture than Earliest of All. Some of the fruits are corrugated, but this is a minor fault when we consider what an abundant cropper it is. It is dwarf, short-jointed and fruits early from the base

of the plant. Perfection and Ham Green Favourite are good kinds for early and late forcing. Frogmore Selected and Earliest of All are also suitable kinds for the same purpose. I consider the Tomato a vegetable.—J. LEWIS, *The Gardens, Swanmore Park, Bishop's Waltham*.

—Hathaway's Excelsior and Perfection are the best. Wheeler's Prolific and Maincrop are the best for outdoors and for autumn and spring. Earliest of All is, I find, the best. The Tomato is used here more as a vegetable than a fruit, and I consider it as such.—JORDAN BLAYNEY, *Huntley Manor, Gloucester*.

—For good flavoured and free setting Tomatoes, with an even and good appearance, I consider Ham Green Favourite, Royal Chester, Perfection and Frogmore Selected as good as any. Polegate does as well as any for outdoor work about here, but as the season is short and uncertain not many are grown, and therefore few varieties have been tried. For winter and early work I have had nothing to surpass Early Ruby, which is a good cropper and generally turns out satisfactory. I have no hesitation in classing the Tomato as a vegetable, although sometimes it may be eaten as a fruit, yet considering the many uses to which it is put in the kitchen, I certainly think it is more in its right place in a collection of vegetables than classed among such as Grapes, Melons, &c.—E. GILMAN, *Alton Towers*.

—The best Tomatoes are Eclipse, Frogmore Selected and Early Chemin. Chemin I find the best for autumn and spring work. I consider the Tomato should be classed as a vegetable.—JOHN CAIRNS, *The Hirsch Gardens, Coldstream, N. B.*

—The only two varieties of Tomatoes I grow are Early Ruby and Ladybird. I find they do well here under glass and out on the open wall and always set a good crop. Winter Beauty is a splendid Tomato. I consider the Tomato a fruit.—JAMES COOMBS, *Englefield Gardens, Reading*.

—There are so many so-called new varieties at the present time before the public that it is difficult, I find, to secure a really true stock or define which is the best. Undoubtedly it is an easy matter to secure a strain producing more even fruit than was possible twenty years ago, but still some of those which fail to find favour because they may be slightly ridged or uneven in outline cannot be beaten for producing heavy crops. During the past three years I have found Frogmore Prolific very satisfactory in every way and have grown it in place of older ones, but having a true stock of Ham Green Favourite, I retain it for its general good qualities. A market grower in this district who grows Tomatoes most successfully and in great quantities informs me that he relies on two varieties only, viz., Chemin Rouge for early spring supplies and Challenger for the main crops. From seeing them growing in his establishment I can thoroughly recommend both varieties. In common with many other gardeners, my experience with Tomatoes commenced long before they had become so popular, a dozen or so plants placed in odd positions against a warm wall being considered more than sufficient to meet the requirements of a large establishment when no one dreamt of considering them anything else but a vegetable. Because the public have acquired a taste for them, and in many instances followed a fashion of eating them raw, does not in any way convince me that they should be classed as a fruit and worthy of a place on the dessert table. I have never yet risked using them for that purpose, and I have an idea that even those who would have us believe that Tomatoes are worthy of such distinction would invariably discard them if they had the choice of Grapes, Peaches, Strawberries, or, indeed, any of our choice fruit. My contention is that a Tomato is as much a vegetable as a Potato.—R. PARKER, *Goodwood, Chichester*.

—Ham Green Favourite, Perfection, Jubilee, The Polegate, Duke of York (not quite free enough), Golden Jubilee (yellow), and Prince of Wales (yellow) are, I consider, the best. Laxton's Open Air and Magnum Bonum are the best for

outdoors, and for winter work the best I ever saw was a selection from the Old Red, as grown and selected by a friend that grows largely for the London market. For early work, Early Ruby, I think, is the best. The Tomato should be classed as a vegetable. For flavour I consider the old Vick's Criterion as good as any.—A. J. MORRIS, *Kingston House Gardens, near Abingdon*.

—Tomatoes are only grown outside. Ham Green and Frogmore Selected give very heavy crops of fine fruits, and are the only ones I rely upon. I have tried many others, but none are so satisfactory as the above. If confined to one variety I should grow Frogmore Selected. I consider the Tomato a vegetable.—WM. CANNIE, *Buttle Abbey, Sussex*.

—The Tomato I would recommend for early and main-crop is Hathaway's Excelsior. I have grown it for many years. None of the newer ones excel it here. I have it in fruit mostly all the year round. I have seen the Tomato shown in a collection of fruit, but I consider it misplaced there. It is a vegetable, and should always be shown as such.—M. MCINTYRE, *The Glen, Innerleithen*.

—I knew of no kinds of Tomatoes that are better for setting and flavour than Ham Green, Chemin, and Perfection. For outside Magnum Bonum is a heavy cropper, but I like the above varieties best. For winter and early spring use Chemin and Ham Green are not easily beaten. Ruby is early, but of a bad shape. I consider the Tomato should be classed with what it is grown and used for, viz., a salad or vegetable. I consider anyone exhibiting Tomatoes in a collection of fruit for dessert should be disqualified. Very few people would care to eat Tomatoes like one would a Peach or Pear, mostly preferring them cooked or cut up as a salad.—J. HILL, *Babraham, Cambridge*.

—I consider Best of All the finest for freedom of setting and flavour. The best outdoor kind is Magnum Bonum. Grown in a small house with other varieties, I have found Best of All set fruit near the bottom and ripen quicker than any other I have tried for early spring use. I consider the Tomato a vegetable.—J. HOAD, *Colworth Gardens, Sharnbrook, Beds*.

—I like Challenger, Early Ruby, Neild's Seedling, and Cheshire Favourite, but for larger fruits and midseason work Perfection, Oxonian, and Duke of York are the best. Perfection and Oxonian I had last year 14 ozs. and 12 ozs., and Duke of York I had 1½ lbs. Ham Green, Challenger, Neild's Seedling are the best outdoors, but for this district I usually grow the plants inside in 6-inch pots, and when there are a few trusses of fruit set by the second week in June they are planted out, and with attention and a genial summer I get some good fruit. Challenger, Neild's Seedling, and Early Ruby I have usually grown for autumn and spring, but this year Oxonian set its first fruit before the previously mentioned ones. The Tomato is certainly a fruit, but can be used either as a fruit or as a vegetable. I know at some shows it is a vexed question, but the difficulty is soon made plain by arranging the schedule accordingly.—JAS. DALY, *Wythenshawe, Northenden*.

—I consider Polegate the best flavoured Tomato, and Frogmore Selected the best outdoor variety, and I also believe it to be the best all-round variety for winter and spring. It sets very freely, and always has given me the greatest satisfaction in point of flavour. The crops of this variety have been wonderful on the walls outside, taking into account our damp climate here. I consider the Tomato a vegetable.—W. A. BOWLES, *Adare Manor Gardens, Limerick*.

—The Tomatoes I have grown and find free-setting and of fine flavour are Best of All, Ham Green Favourite, Princess of Wales, Frogmore Selected, Perfection, Hackwood Park, Early Ruby and The Polegate. The above kinds have all been grown inside and out. I think Hackwood Park, Best of All, and Perfection would be hard to beat for outside work. I find Best of All, Early Ruby, and Hackwood Park three good kinds for winter

and spring crops. Though considered by most people to be a vegetable, in my opinion the Tomato is a fruit.—C. E. MUNDAY, *Nuneham Park Gardens, Abingdon*.

—I consider Eclipse the best all-round Tomato indoors. Eclipse is also the best for autumn and early spring. The Tomato is a fruit, but not a dessert fruit. At shows in a collection of vegetables a dish of Tomatoes stands high with the judges, but no competitor would risk his chance of a prize in a collection of fruit by staging a dish of Tomatoes.—A. CROSBIE, *Buchanan Castle, Drymen, N. B.*

—Our best Tomatoes are Earliest of All, Sutton's Dessert, Perfection, Comet, Conference, and Eclipse. The variety I have found most suitable for early work is Earliest of All. I consider the Tomato a fruit, but one that is used principally as a vegetable.—THOS. WILSON, *Glamis Castle Gardens, Glamis, N. B.*

—I find Ham Green, Chemin and Ladybird the best all-round Tomatoes, with the addition of Conference for outdoors and Early Ruby for winter work. A good type of Perfection is the best for exhibition, but it does not give the same weight of fruit as the varieties already mentioned. Cherry Yellow is a decided acquisition for the dessert and very much appreciated here. The Tomato is decidedly a fruit, and certain varieties are dessert fruits.—BEN. CAMPBELL, *Kingston Gardens, Dorchester*.

—The three most useful Tomatoes that I have yet tried I consider are Challenger Improved, Perfection, and Ham Green Favourite. I cultivate them both in the open and under glass, and find them of a most serviceable size, good in flavour, and excellent croppers, and should I be tied to grow one variety it would be the first mentioned. Cannell's King is too large for general purposes, most people preferring fruits of a medium size. Of the yellow-fruited varieties I prefer Golden Jubilee to any I have yet tested. During the last three seasons I have had excellent results from thirty or forty plants, consisting of the above varieties, out in the open air, grown against a wire trellis facing nearly due south, and planted solely in coal ashes with a little stable manure added, doing equal to those in prepared beds. The stems at the end of summer had the appearance of ropes of fruit, with clusters averaging from six to twelve on each. I should describe the Tomato as a fruit, but most generally utilised in the way of a vegetable, either raw or in a cooked state.—W. SILCOCK, *Hollycombe Gardens, Liphook*.

Tomato Stirling Castle.—One is apt to tire of new Tomatoes, as, like Potatoes, they multiply so quickly, and many of the so-called new kinds are no improvement on older ones. Still, a really good all-round variety is sure to find patrons, as few now confine themselves exclusively to one sort. A few days ago I called on a gardening friend and was shown into a small lean-to house, not a good one for Tomato growing. The Tomatoes, which were in pots, were trained up the back wall. There were two varieties, but the one which struck me most was Stirling Castle. A nice crop hung on the top of the plants, the fruit being of exceptionally fine shape and colour. Stirling Castle is, I believe, better known over the border than in England.—GROWER.

Potato Carter's Snowball.—This is undoubtedly an excellent Potato, of good quality and a splendid cropper, well suited to heavy soils; consequently it should become a standard variety for field crops. The first time I grew it I rather disappointed me, as from some cause or other the increase was but small. This was in a very sandy soil that had been cropped with Potatoes for many years, and the season was a remarkably dry one. As I had seen good accounts of it as a cropper and was aware of its excellent quality, I determined to try it again, this time on heavy soil not long in cultivation, and the result far more than justifies the resolve, for the crop turned out was quite a remarkable one, though Potatoes generally throughout the neighbourhood were a very poor crop indeed, Magnum Bonum hardly paying for the seed.—J. C. T.

THE FALLACY AS TO "MATTERS OF TASTE."

THE man behind the counter often tells us that "it is a matter of taste" if we say a word as to the ugliness of some of his wares, and many other people have the same false idea that obscures all issues about artistic things. If it were confined to the ignorant it would do little harm, but we hear it expressed by men of education. To take a recent instance, the author of "Pages from a Private Diary" (1898) protests against

making a religion of what is purely a matter of taste. Weeds are as natural as flowers. A lawn left to Nature would soon become a meadow. A hedge left to Nature would become monstrous and useless, because pervious. A well-grown Yew tree is undoubtedly a beautiful object, but a Yew clipped intelligently is quite as beautiful; and if a tree will clip, it is not unnatural to clip it.

Here we have some common ideas written by a man of wit, but who in this instance

Robin Hood House, Great Berkhamsted. Engraved for THE GARDEN from a photograph sent by Mr. J. T. Newman.

has not thought of what he writes about; and if we find these notions in such men, how are we to blame the many who with fewer advantages have to study the question of garden design or planting? For this and all artistic questions are only "matters of taste" to those who have not thought of them. The merit of a portrait by Rembrandt and the first Academy daub is not a matter of taste, but of very serious fact. So also we may compare an Elizabethan house with one of the carpenter's Gothic of our century; the sculptures of the Parthenon with the statues in our squares; a symphony by Beethoven with the "Maiden's Prayer"; an English cottage garden, quite simple in plan and full of flowers in their natural forms, with the imitations of very bad carpets (vile in colour and without form) which we now see in French and German watering-places (mosaiculture)!

So far from its being true that good or bad garden design or planting are merely matters of taste, the very first thing we should teach to everyone who has to think of it is that they are matters of fact, truth and observation. The assumption in the paragraph that anyone advised leaving hedges, &c., to Nature does not surely need a reply; but that a Yew clipped intelligently is quite as beautiful "as a well and naturally grown Yew tree" is a statement that could hardly be made save in jest by anyone who has thought the least about tree beauty or natural form of any kind. For here it is not a difference of degree we have to deal with, but a difference in kind, because a clipped tree is a thing without any true form, light or shade, motion or voice. Vast as are the differences above named, between none of them is there so great and hideous a difference as between the divinely given form of the northern evergreen tree, whether of the tree-fringed mountain lawns of Jura, the mountains of the Pacific

coast of North America, or the rocks of Scotland, and the ridiculous results of the distortion of forest trees by man.

Yet the fact that garden design or planting is a matter of knowledge of the natural forms, harmonies and colours of things does not mean that this writer or anyone is not to do what he pleases in his garden. But when he tells us that the judgment which enables us to distinguish a good picture from a bad one is to abandon us before the absurdities seen in our gardens, and too often marring the foregrounds of the home landscape of our country houses, he is leading all who trust him into error. Moreover, individual likes and dislikes are wholly separate from the problem of what is best in a given situation as to design and planting.

The question, like so many others, is made needlessly hard for the student by the

WRITING WITHOUT KNOWLEDGE, which, unhappily, is devoted to it. To practise an art without any knowledge of it is bad enough, but when men *write* about art dealing with so many living things as planting, when clearly they have given no heed to its simplest elements, they do infinite harm in spreading the false idea that it is all "a matter of taste." Of such quotations as the above, in which every phrase is an error or a false assumption, a volume might easily be put together.

One of the commonest and grossest errors is to take the worst possible work, abuse it, and say nothing about the better way.

Deception is a primary object of the landscape gardener. Thus to get variety, and to deceive the eye into supposing that the garden is larger than it is, the paths are to wind about in all directions and the lawns are not to be left a broad expanse, but dotted about with Pampas Grasses, foreign shrubs, or anything else that will break up the surface. As was said by a witty Frenchman, "Nothing is easier than to lay out an English garden; one has only to make one's gardener drunk and follow him about."—THE FORMAL GARDEN.

There is not a word said here of the plain fact that we may have true and artistic ways, as well as stupid ones, of forming paths and getting fine variety of surface by planting, without dotting lawns with Pampas Grass, or of the equally plain fact that we can make walks through lawn or wood or by river in lines of easiest gradation and most convenient access without going through any of the antics above described or in any way violating good sense. There is not a word in the above paragraph which is true of good work in landscape planting.

That bad and ignorant work is done we can no more deny than the existence of the barrel-organ or the Victorian villa, but a man must be blind to the truth who writes thus without knowledge, as there are innumerable instances in every county of picturesque planting without deception of any kind. The true work of the landscape gardener is wholly different; it is to study the natural forms of the ground and keep to the best of them; to have keen eyes for every charm of natural growth and to save it for the future beauty of the place; to know also all the trees of the northern world fitted to adorn it; to make a living picture, in fact—easy to those who have eyes and hearts for the work, but impossible otherwise.

Another like statement of the writer on clipping trees that wearies us by its absurd want of knowledge of Nature is this:—

A clipped Yew tree is as much a part of Nature—that is, subject to natural laws—as a forest Oak; but the landscapist, by appealing to associations which surround the personification of Nature, holds up the clipped Yew tree to obloquy as something against Nature. So far as that goes, it is no more unnatural to clip a Yew tree than to cut grass.

The answer is that we mow turf to walk upon; for the pleasure to the eye of short turf, or for the pleasure of walking on it in the hot days, or for the relief and repose it gives; for by cutting grass short we disfigure nothing, throw no naturally beautiful things into grotesque or ugly forms offensive to the

artist and all who care for true form. Moreover, short turf is *not* an artificial thing, as there are 10,000 natural lawns on the mountains of Europe, short and crisp as ever lawn was seen; set, too, with alpine flowers and guarded by outposts of stately mountain trees.

W. R.

ROSE GARDEN.

TOWN ROSES.

THE indiscriminate purchase of Roses by amateurs for planting in town gardens without any previous knowledge of the varieties most suitable for the purpose invariably ends in disappointment. Then, again, the soil in such gardens, except in very few instances, is not such as the roots of Roses take kindly to, the trees also often being seen occupying northern or sunless positions, under which conditions they only drag out a miserable existence. A lot of rank, unwholesome manure is sometimes dug in, which only makes matters worse, as in town gardens it cannot be got deep enough; consequently, the roots are practically embedded in it—a great evil to an unestablished tree, especially should the winter prove severe. I am aware it is sometimes difficult to procure loam the most suitable for Rose-growing in such localities, yet such should be the aim of the cultivator if only a spit deep is given, so that the roots have the advantage of a fair start. Where the plot intended for planting is vacant and can be turned up and exposed to the weather from the beginning of September to the middle of November, or for the matter of that a whole summer, so much the better. In cases where the staple is what may be termed of fair quality, the wisest course to pursue is to remove half the original and thoroughly incorporate a similar quantity of the new material recommended above. If farm-yard manure is added, let it be lowered out of the way of the roots for the present, as contact with it while as yet there are no new fibres to assimilate it does more harm than good. The position, of course, must be a sunny and as sheltered a one as possible, as cutting winds in spring play havoc with newly-planted bushes just making their first growth, and often permanently cripple the trees. This matter of aspect needs, I am sure from personal observation, to be pressed home to amateurs. Staking and mulching are two points of culture generally ignored by the majority of town planters, and a standard which sweeps to and fro with the wind through the winter cannot be expected to make either rapid or satisfactory headway when spring arrives.

When applying a mulch, however, fat spit manure should be avoided, horse droppings being much more suitable. This allows the water to escape if only, say, a couple of inches are applied, and protects the surface roots from parching winds in spring. Soaking the rooting medium with water during November is also bad practice unless the position is an extra dry one, when the moisture should be given previous to the last layer of soil being laid on. Amateurs, again, not infrequently prune hard the first March, regardless of the strength and general stamina of the tree. Judgment is necessary, the weaker trees needing more leniency in the use of the knife. Last, but by no means least, is selection. Many of the beautiful show and other Roses are altogether unsuitable for town planting. Constitution combined with free growing and flowering

qualities is the principal requirement of Roses for town and smoky localities.

The following dozen will, as a rule, be found to give satisfaction: Alfred Colomb, Docteur Andry, General Jacqueminot, J. Stuart Mill, Marie Baumann, Senateur Vaisse, Hippolyte Jamain, Jules Margottin, Victor Verdier (one of the most reliable town Roses in cultivation), Prince Camille de Rohan, John Hopper, and La France.

EAST ANGLIAN.

ROSES FOR THE SHRUBBERY.

IT is a common fallacy that one must resort to the single varieties if it is desired to mingle Roses with other flowering shrubs. I have a great partiality for single Roses. The exquisite *R. hispida*, illustrated in THE GARDEN of November 18, is one of the loveliest. There are other Roses of a more perpetual-flowering character than the singles and equally vigorous in growth that could be planted in shrubberies, and it occurred to me it might be of some usefulness to planters if a short list of such kinds were given. Of the list I shall give there are some few kinds that would need the support of a centre stake. I should not term such specimens exactly pillar Roses. I believe in allowing the plant plenty of freedom at the base, but an artificial support to the centre is advisable until the bush is able to do without it. What are known as summer Roses make the largest shrubs, with the exception of the newer varieties of *Rosa rugosa*. That the forms of *R. rugosa* are destined to become valuable cannot be doubted. We have varieties now that bear really handsome double flowers. Anyone may see such kinds by visiting the sunk Rose garden at Kew. I am not certain that these varieties can be seen elsewhere. It is to be hoped they will soon be put into commerce. A very fine variety (see GARDEN, October 7) of *R. rugosa* which M. Otto Froebel has obtained at Zurich has flowers resembling those of La France, so that there is no lack of good material if we relied solely upon the *rugosa* hybrids. The great point in their favour is their perpetual flowering character. When many flowering shrubs are devoid of blossom in autumn a shrubbery border would not necessarily be the dull thing it is at present if some of the following perpetual-flowering Roses were intermingled with the other subjects. The forms of *R. rugosa* will develop into bushes 6 feet to 8 feet high. Other perpetual Roses that would reach a height of 6 feet to 8 feet if grown as bushes are Longworth Rambler, Gloire de Dijon, Kaiserin Friedrich, Clio, Germaine Trochon, Margaret Dickson, Waltham Climber No. 1, Dr. Rouges, Rosette de la Legion d'Honneur, Fellenberg, Pink Rover, Marie Lavallée, Mme. Emile Dupuy, Mrs. Paul, Dawn and Ella Gordon.

Moderate pruning is of course advisable. If the plants are relieved of the old wood they will not need such mutilation as is thought advisable by so many people. Doubtless the quality of the flowers would suffer, and one might lose the first blossom by frost injuring the early growth, but I have found the second flowering none the worse. The chief aim should be to secure sound, well-ripened wood. This can be better accomplished by allowing the plants plenty of freedom. Of the varieties that would make fine individual specimens from 4 feet to 6 feet high, I would recommend Mme. Abel Chatenay, one of the loveliest Roses in existence; Caroline Testout, Gustave Regis, Marie van Houtte, Grace Darling, Gruss au Teplitz, Souvenir de Wootton, Robert Duncan, Armosa, Mme. Isaac Pereire, Viscountess Folkestone, Mme. Lambert, Mme. L. Messimy, General Jacqueminot, Gloire des Rosomanes, H. Schultheis, Stanwell Perpetual, l'Idéal, W. A. Richardson and Mrs. Bosanquet. The late Mr. Girdlestone had great faith in *Rosa Polyantha* as a stock, especially to make large bushes. It is surprising what size many Roses assume when budded upon it. For the purpose in view I would strongly recommend it, the more so if the stocks are planted in the desired positions and there

budded. I do not care for the stock as a means of obtaining quality of blossom, but I have proved its value in developing some handsome bushes, especially of kinds not particularly good in this respect.

PHILOMEL.

Rose Comtesse Festetics Hamilton.—Few Roses have been more interesting during the past autumn than the above-named variety. A basketful exhibited at the Crystal Palace fruit show came as a surprise to a great many who were unaware of the existence of such a lovely kind. I have been informed that abroad in countries like Egypt it is a magnificent Rose; indeed I think ere long it must become with us a general favourite. There is just that mixture of tints that appeals to every lover of Tea Roses. The ground colour is brilliant carmine, but there is a rich suffusion of coppery-salmon that immediately arrests attention even when one is surrounded by a host of other kinds. The style of flower resembles that of Ethel Brownlow when the latter has not been freely thinned. Ethel Brownlow, if allowed to grow freely, produces plenty of blossoms, but of only intermediate size, and one can hardly believe that the magnificent specimens now and then seen at the Rose shows are of the same variety. So I believe it will be with the variety under notice. I would rather have a Rose that gave plenty of moderately-sized flowers than merely one or two specimens however magnificent such might be. Comtesse F. Hamilton is a variety that is sure to please, and I cannot understand why it has so long remained in obscurity. It was introduced by M. Nabouland some six or seven years ago.—P.

THE USEFULNESS OF BIRDS IN GARDENS.

THE article dealing with the usefulness of birds on p. 403 is very interesting reading, but to the English gardener several of the birds mentioned are comparative strangers, and one bird in particular, namely, the tomtit, is praised beyond that which in common fairness can be claimed by him. There are those who have written, and still write, favourably of this bird, and the wilful mischief, which is sometimes considerable, is set down as a necessity in the search for insects. By the fruit grower in general such a theory cannot be accepted; the many bushels, both of Pears and Apples annually spoilt by the tomtits just previous to their ingathering reduce them to a curse rather than a blessing to the gardener. It seems sheer nonsense to praise a bird capable of such wanton mischief as the tomtit is. Theorists will say that the numerous and often tiny holes bored in Pears and Apples are made in the search for insect food, but this argument does not find substantiation when he invariably chooses the best kinds and often the largest fruits, leaving others unmolested. As a rule, too, Nature endows animal creation with the rare instinct of being able to trace the whereabouts of their natural food. In the many bushels of spoilt Pears that are annually thrown out there are very often no insects present, and the same can be said of Apples. The bird is equally as destructive among Peas in summer as fruit in autumn. The theory of the search for insects gets but scant recognition when the gardener finds his supply cut off, the pods being stripped of the seed before they have time to attain a useful size. If insects are what they are in search of, why do they so greedily devour the seed when there are no insects encased? The quotation of the writer of the notes in question which says, "Besides being actively useful, there is nothing to be said against the bird in any way," does not represent the feelings of the English fruit grower. There may be a period of the season when it might do some good in hunting down insects, but the damage which it does much more than counteracts any good it does in other directions.

The cuckoo, on the other hand, fully deserves all that is said of it, for its utility in the destruc-

tion of caterpillar life cannot be over-estimated. To the gardener the cuckoo is a friend. When in their season the Gooseberry caterpillars appear to defoliate his trees, the cuckoo if unmolested quickly makes a clearance, but its shyness is such that it does not often venture into small gardens: hence its merits are neither universally known nor sufficiently appreciated. For several years I have had no occasion to resort to drastic measures for dealing with Gooseberry caterpillars simply because the cuckoo converts them into food before they have time to commit serious mischief. His visits are mostly paid during the early morning or the evening, when all is quiet and he is not disturbed. It might be truly said of this bird that, besides being actively useful, there is nothing to be said against him in any way. Of the tomtit this cannot be truthfully said, and so convinced

holes too much crowding is usually observable, particularly in private gardens. Those who bunch for sale, of course, are less apt to err in this particular, their aim being to make as much of the flowers as possible.—N. N.

FLOWER GARDEN.

MELIANTHUS MAJOR AND M. PECTINATUS.

THE *Melianthus*es are members of a small family of South African plants, and up to the present but rarely seen outside botanic gardens. Any one who has had the misfortune to see them in such institutions as woe-begone plants 3 feet or

Melianthus pectinatus.

am I of this, that I lose no opportunity in destroying all that come within my reach. W. S.

Exhibiting Violets.—I am pleased to note that classes for Violets at Chrysanthemum shows are becoming more general. I would draw the attention of exhibitors to the folly of bunching the flowers up tightly in a close mass. This not only hides the merits of the individual blooms, but destroys all gracefulness. The best way is not to tie the flowers up at all, but to arrange them quite loosely in small glasses or vases just sufficiently high to allow of the outer Violets falling loosely over the sides. Each flower is then seen to advantage. Even in bunching up Violets for sending to a distance or for sprays or button-

4 feet in height, and bearing three or four miserable-looking flowers, must have reluctantly classed them among the great group of botanical weeds. He would, however, be doing them an injustice, as with proper treatment and a little care they can be made really valuable plants for the garden. The family of *Melianthus* includes five species of pretty uniform habit. All are shrubby plants with feathery foliage, which bears some resemblance to that of the *Rosaceae*, from which, however, they are widely separated. The oldest species of the family is

MELIANTHUS MAJOR.—It was brought to Europe in 1688, and is the form most commonly seen in gardens. It is striking by reason of the bright,

strong grey-green colour, which at full maturity covers the whole plant. The large feathery and indented leaves look very handsome in their verdant colouring, and fit it for isolated positions on lawns as well as for mixed planting, in which it is seen to the best advantage. It needs full sun, rich soil, plenty of water, and manure.

M. PECTINATUS, the subject of our illustration, was first introduced from Namaqualand in 1870. It was discovered by Sir Henry Barkly, the then governor of Cape Colony, who sent seed of it to Sir Jos. Hooker at Kew. Sir J. Hooker judged it to be a perfectly new kind, and described it in the *Botanical Magazine* as *M. trimenianus*. Later, however, it was proved to be identical with an older species named by Harvey *M. pectinatus*. One of the plants raised from the seed sent by Sir H. Barkly to Kew found its way to La Mortola, where it very speedily developed in growth, and in the year 1879 flowered and bore fruit for the first time. As an ornamental plant *M. pectinatus* is much to be preferred to *M. major*, and if not quite so quick a grower, it leaves little to be desired in this respect. It forms in a comparatively short time a light, handsome bush with very attractive foliage. The leaves are each 4 inches to 6 inches in length, bright glossy green on the upper side, on the lower side thickly covered with hair. The deeply cut nerves and the well-defined outline give them a particularly handsome appearance. The flowers of both species are borne in upright clusters. Those of *M. major* are borne on strong, long stems high above the plant, and these flower-clusters, with their numerous dull brown blooms against the bright green foliage, form a singular contrast. The flowers have a large calyx, which is somewhat wider in the lower part, and the bottom petals are drawn back. This wide calyx is always filled to the rim with a curious dark brown honey liquor, which exudes with every motion of the flower. In their native habitat these flowers are visited by flocks of small kinds of birds for the sake of this liquid. The flower-clusters of *M. pectinatus* are shorter and the flowers smaller, but brighter in colour. The small petals soon overtop the calyces and form bright red tufts at the end of the clusters. In less favoured surroundings and with scantier blooms these plants are still well worthy of a place in gardens. They grow readily from cuttings, and, moreover, the seed is easily obtainable. In winter they require the protection of a not too moist greenhouse.—*Die Gartenwelt*.

New double Violet James Watt.—I recently saw a fine exhibit of this new Violet, and, although not personally in favour of the purplish shades, think it will soon become popular, as I was informed that it is a very free and constant bloomer, and, what is more, it possesses a rich fragrance. This latter fact, together with its free-flowering character, will ensure its culture by those whose chief aim is profit. What a pity it is the good old Neapolitan is somewhat particular as to soil and situation, as it is undoubtedly the king of doubles when seen in its true character, the colour being so delicate. I hear a very glowing account of the latest introduction in the single section, viz., La France. If, as is reported, it supersedes the now justly popular Princess of Wales it will be an acquisition indeed. At any rate, Violet growers have now a fine selection, and the culture of these beautiful flowers is becoming more and more general.—J. C.

Michaelmas Daisies.—I read with interest on page 390 an article on Michaelmas Daisies by "T. J. W.," and noticed he spoke very highly of *Aster spectabilis*, a variety I have endeavoured to obtain on several occasions, but failed to get it true to name. Perhaps he would be kind enough to inform me where I can procure the true variety. I grow a large number of Asters. Some of the best which I can strongly recommend to all lovers of hardy plants, in addition to the varieties quoted by "T. J. W.," are *cordifolius* Diana, a charming pale lavender colour, height 4 feet; *turbinellus*, violet, tipped rose, a very graceful

late variety, height 3 feet; Walter B. Childs, deep lilac, 5½ feet; Mrs. C. W. Earle, lovely French grey, 5 feet; Nancy, bright pale blue, good habit, 4 feet; Novi-Belgii densus, bright blue, very free, 3 feet; Top-sawyer, large pale blue, 5 feet; levis floribundus, deep blue, 4 feet; St. Brigid, white, very free, 4½ feet; Henryi, bright blue, very distinct and early, 2 feet; Novæ-Angliæ J. F. Raynor, deep red, 4½ feet, large flowers, an improvement on N.-A. ruber; and Pleiad, a little gem, growing only 15 inches high, with bright rose flowers.—E. BECKETT, Aldenham House Gardens, Elstree, Herts.

Sternbergia lutea.—Much has been written of late regarding the blooming of this. I believe it blooms far more satisfactorily in a dry, light soil than otherwise. I doubt its ever blooming with any degree of freedom when frequently replanted unless the bulbs are very strong and placed in a position where the soil gets very dry in summer. I have a big patch upwards of 2 feet across. Some eleven years ago I found this in the same position as now. Then there were only four or five bulbs. From that time till now it has never been disturbed, with the result that it increases rapidly and every year blooms more profusely. This last autumn I counted thirty open and nearly as many unopened flowers on a foot space of this clump. The few first years it scarcely bloomed at all. The position is at the foot of a south wall on the top of the roots of a Rose. Here the soil gets very dry from the Rose absorbing the moisture, while as the bulbs increase they, too, help to dry the soil. Recently when in Norfolk I saw this blooming freely in quite a small state in a light, dry soil. In Dorset I have seen it growing at the foot of a Pear tree in strong soil, and left undisturbed bloom freely.—J. C.

Pyrethrum uliginosum.—A note appeared in a recent issue of THE GARDEN respecting this plant. I quite agree with the writer that the fact of its being such a tall grower is a rather serious drawback; especially is this so when it is planted in narrow borders. The great height to which it then attains makes it appear quite out of place. The writer of the note in question touches on the cutting-down method to induce a dwarfer habit of growth, but mentions that the process causes the flowering to be too late for the blossoms to be useful. I have in some seasons had the young growths cut down in the month of June, and have had them flower well the latter end of September and the early part of October. Locality has, of course, a great deal to do with the success or otherwise of this cutting down, as, although the method answers well here, I can quite imagine that it would throw the flowering too late for the blooms to be of any service in other places. However, where the climatic conditions will admit of the method being practised with profitable results, it makes a considerable difference in the height of the plants and renders them more fit subjects to grow in company with other herbaceous plants when their great height is a serious objection.—A. W.

Border Auriculas.—Whilst there are differences of opinion as to whether the autumn or the spring be the best season for transplanting border Auriculas, on the whole I prefer doing the work in the autumn, and in cutting pretty hard back those root-stems that will always develop in Auriculas, and then when new roots higher up these stems are emitted, the plants remain undisturbed and soon become well established. It not infrequently happens that plants, because so enduring, remain for many years in the same place and become large clumps, yet very ungainly ones, because the stems are exposed. Some good may be done in the spring by giving to each such plant a liberal top-dressing of old pot soil that is rather sandy, as by the autumn these otherwise naked stems may have put forth roots, thus enabling the plants to be hard root-trimmed and replanted in the autumn. Whilst doing well generally in ordinary soil, yet where it is stiff, a good admixture of sand or grit is helpful, and some well decayed manure is so in all cases. Then the individual portion with new roots attached

may be dibbled in to form a clump of some six or more, and thus large patches are soon formed that remain good for two or three years. It is well to fix the soil about the young plants firmly, whether put in singly or in quantity. These Auriculas are so hardy, that neither rain, snow, nor frost seems to do them any harm.—A. D.

FLOWER GARDEN NOTES.

If it is a fact that up to the time of writing (November 1) the rainfall for the year is some 10 inches below the average, the poor display made by perennials that are not at their best on a light dry soil is easily accounted for, and as the amount of rain to hand at this time has only penetrated some 4 inches or 5 inches, there are two points in connection with autumn work on hardy plant borders that may be worth enforcing. First, in all planting to take care that the ground about the plants is well soaked, and second, not to be in too great a hurry with surface-mulchings, as anything placed on the top of the ground will naturally be all against the rain (when it comes) penetrating the soil. Although borders are on the dry side and scarcely in a condition that one likes for planting, it is hardly advisable to postpone this work, for if frost makes its appearance when the present month is well advanced, it may come to stay and prevent further planting until some time in the new year. Among comparatively dwarf plants, the choicer Pinks from cuttings and Carnations from layers were never better, and have been planted. The dry summer was against the Carnations and I was anxious as to a good strike, but they were layered early, well looked after in the way of water, and lifted in capital trim many varieties with a mass of roots that would have filled a 4-inch pot. I may note in the matter of layering that, with the anticipation of a dry time, not so much prepared soil was put round them as usual, not more than an inch in depth. This was a mixture of peat-moss manure well broken to pieces and road sand well incorporated with the soil already round the plants. I should certainly be on the side of those who write favourably of peat-moss manure. It is a capital thing as the principal ingredient in layering soil, as after one thorough soaking the moisture is well retained, the plants root into it remarkably well, and it hangs well about them at lifting time. It should be thoroughly broken to pieces with a fork before mixing with other materials. One special characteristic of the plants this season is that they are good throughout. Sorts sometimes a bit miffy, as Countess of Paris and Ketton Rose, are this year as well rooted as the more robust varieties. The only weak point is a touch of disease in the Clove section. Other front row plants to be strengthened—this is of which occasional large clumps will be made—are a specially selected strain of dark Polyanthus, Geum coccineum, the dwarfier of the Pyrethrums and Dianthus. In all planting arrangements I endeavour to rely chiefly on those things that will be useful for cutting as well as making a good display, with a preference for such as stand well in water and that are favourites in the house. In taller plants, besides those already mentioned, that do well for the centres of borders, and are very acceptable from these standpoints, are Doronicums, Monstretias, Aquilegias, the dwarfier Phloxes, Statice and many others. Our borders were well overhauled last season and not much will be necessary this year; still, in the best regulated plantings mistakes are made, and these will be rectified as far as practicable.

E. BURRELL.

Keeping Gladiolus bulbs.—There are many disappointments attending the culture of Gladioli, and even when the bulbs are lifted and stored for the winter in an apparently sound condition some will now and then go off with a kind of dry rot, these often being the most prized varieties. I think they are often kept in a too dry and airy position, this partially shrivelling the bulbs, which is a great evil, as unless their

plumpness can be preserved till spring, the flower-spikes are sure to be inferior. The best way, I think, is to embed the bulbs in sand or leaf-mould, preferably the former, and not to store them in a draughty place. Occasionally bulbs are left in the ground all the winter, and if frost is not too severe they remain sound, which proves that a too dry, airy shelf is not the best winter quarters.—GROWER.

Spanish and English Irises.—The bulbs of these charming plants are extremely cheap this year, and anyone with a garden ought to grow them. My reason for calling attention to them now is that after this date less satisfactory results will be obtained from planting than if got in at once. The colours are remarkably rich and varied, some of the whites in the Spanish forms being really lovely, as well as the deep blues and a kind of terra-cotta tint not at all common in hardy flowers. They seem to thrive anywhere and in almost any kind of soil, increasing rapidly, and, beyond planting and weeding, giving no trouble whatever.—H.

Strong-growing Violets.—Whilst there can be no doubt that such new varieties as Princess of Wales, La France, California, and other single Violets produce large flowers, they also give very strong foliage. That is not an unmixed good, as very large leafage is not desirable in Violets, and the appearance is not so pleasing as is the foliage of such varieties as Czar, Wellsiana, Victoria Regina, and one or two others that, whilst robust and giving fine and very sweet-scented flowers, yet wear a much neater appearance. Certainly of single Violets we seem to have enough. Whilst the newer introductions give such large blooms, there is no improvement in colour or in perfume.—D.

Double Primroses.—I saw in a market garden last spring a breadth of several hundreds of double white Primroses. This variety is usually held to be the best grower of the section. I saw the same breadth a few days since, or rather its remains, for there could hardly be found one plant worth having. No doubt the long drought and baking sunshine had dried up the plants, although, being near plenty of water, they frequently had a good soaking. We seem unable to grow double Primroses at all satisfactorily in the south. No one cares to be continually replenishing his stock from Scotland or Ireland, and plants obtained from these countries in the winter, if ever so strong, seem to have lost all capacity to grow after one season's exposure here. Even with single Primroses and Polyanthus the best results are obtained by annual sowing.—D.

Verbenas.—The only coloured plate of Verbenas in THE GARDEN previous to the recent one of V. Ellen Willmott was nearly twenty-one years ago, at which time they were far more universally grown than they are to-day. A decade or so previously was, however, their most popular period, and a glance at the list of plants certificated by the Royal Horticultural Society will show that in 1868 no less than seventeen varieties received certificates, while in the four years previous and the two succeeding ones the numbers ranged from eight to eleven. About that time I was in a garden where bedding plants were grown in very large quantities, and as the raising of Verbenas from seed was not then thought of except for the production of new varieties, many thousands were propagated from cuttings every spring. The stock plants were kept as cool and airy as possible during the winter months, and about the middle of February the plants were taken into a warmer structure, where a minimum temperature of 60° was maintained. They soon commenced to grow freely, and directly the young shoots were long enough they were taken as cuttings, shallow boxes being prepared for their reception by filling them with sandy soil. The soil was very lightly pressed down and the cuttings inserted therein. One good watering through a fine rose sufficed till the cuttings were rooted. Till this took place they were kept in a close propagating case in the same structure in which they had grown. The young plants were then hardened off as quickly as

possible and potted into 3-inch pots. Their tops having been pinched out, they formed neat little healthy plants by the bedding-out period. This being the time of long ribbon borders with unbroken strips of one colour, some of the varieties of *Verbena* were of course very popular for the front rows, especially as the disease had not then to be reckoned with. There is, I think, little doubt that it is caused by continuous propagation from debilitated stock, and the way out of the difficulty is to raise one's supply from seed. If disease-proof plants could be ensured, we should doubtless again see *Verbenas* more generally grown, as they form a bright and telling feature during the summer months.—H. P.

WINTER VIOLETS.

I AM afraid Violets in many gardens which lie high and dry, and where mulching and regular vigorous syringings have only been carried out in a half-hearted manner, will be much disfigured and weakened by red spider. I know it was so last season, and those who plant runners from spider-infested plants must pay the penalty. We sometimes read of individuals growing their Violets in open, exposed situations and finding them satisfactory, but my experience has always been that the surroundings must be naturally very favourable, or unmulched, seldom-watered beds are sure to fall victims to their great enemy. I have often noticed that odd patches of Violets, especially Neapolitan, put out here and there and left to themselves have in tropical seasons had a very yellow appearance, while beds occupying shady positions and well cared for have been quite or almost free from insects, and so far as labour is concerned, nothing repays it better than Violets. For many years in succession I grew the double varieties on the same site, being short of ground. Had I depended simply on manure dug in annually I should no doubt have failed, but I made biennial additions of good loamy soil, leaf mould from the Pine stove beds and road scrapings. Every few years also I took out 18 inches deep of the border and replaced it with a similar depth of loam and the above-named correcting materials, which produced a stout, free growth and abundance of bloom. In gardens where only a limited area is devoted to Violets of the double-flowered section, better all-round results are obtainable from the incorporation of the above-named ingredients than common farmyard manure. The latter tends, especially in wet, unseasons, to promote a vigorous growth, it is true, but one which is easily affected by damp and fog in winter. The position I always found best was a border which enjoyed the sun's rays for a few hours only in the morning. One important thing in winter treatment is providing perfectly drip-free pits or frames and free exposure during fine weather. During the prevalence of cutting winds the lights should not be drawn up and tilted, or the young foliage will soon suffer. Frequent dribblings of water are a mistake. A good soaking from summit to base after planting, repeating it in a few days' time, will generally suffice till February, except in extra dry, open winters. There are, I believe, cultivators who mulch the surface of their frame Violets with cocoa-nut fibre in order as they suppose to prevent evaporation and also prevent damping, but I should not care to practise it, as it must exclude air and what sun's warmth there is in winter from the roots. Abundance of fresh air, occasional surface-stirrings, and the removal of all decayed and yellow leaves are necessary. Those whose plants are infested with spider should dip each one in sulphur water before planting, but they had better obtain a fresh stock of runners from a healthy source in spring. J. B. S.

The double Cowslip.—In looking lately over some old volumes of Loudon's *Gardener's Magazine* I came upon some references to this plant. These induce me to inquire if it is still in cultivation. The plant to which I refer is not a Hose-in-

hose Cowslip, but one truly double. Readers of Gerard and Parkinson will have come across the references made to it by these old writers, but, so far as I can recollect, I have seen no mention of it in current garden literature. Under the name of the Double Paigle it appears in the works of both of these writers, in whose day it seems to have been common. I fear it has shared the fate of many old flowers prized in their day, but since neglected, because of the abundance of new plants. The first mention of the double Cowslip in the periodical referred to appears to have been made by that ardent plant lover, the Rev. W. T. Bree, of Allesley Rectory, in the year 1828, in a letter asking if it was still in existence. In 1830 a letter in reply from Mr. R. Errington, of Oulton Park, was published. In this Mr. Errington stated that he had obtained one from a cottage garden and had bloomed it the previous year, and that it was as double as a Rose. This was succeeded by a letter from Mr. Bree, in which he said that he also had succeeded in obtaining a plant. As a garden plant it must have been inferior to some of the single Cowslips, and it is likely that it would not be much appreciated in the present day. As a curiosity and as a plant which would help to link our gardens with those of the fathers of British gardening it would, however, be treasured by some.—S. ARNOTT.

Callistephus hortensis.—I fear "H. P." and "A. D." are confusing two very different things in writing about this species. I say "species" advisedly, as it is found growing in a wild state in China and Japan and as far westwards as Afghanistan. It was first introduced in 1731 to the Jardin des Plantes at Paris by the Jesuit Father d'Incarville. It appeared at Kew the same year, doubtless from the same source. Both English and continental growers soon recognised its value. The results of their labours are now to be seen in the beautiful double forms commonly known in gardens as China Asters, to distinguish them from the Starworts or Asters proper. Like many other plants that have been taken in hand by the hybridiser—the species from which the double Begonias have been developed, to wit—the original species dropped out of cultivation as soon as new forms were obtained from it. Until the *Callistephus hortensis* in a natural form was re-introduced a short time ago, very few people ever dreamt that its progeny had such a parent. The form exhibited at the Drill Hall and figured in *THE GARDEN*, the *Botanical Magazine*, and other periodicals is a true species, and must not be confounded with the degenerate forms of the double China Asters, about which "H. P." and the anonymous correspondent at p. 348 have evidently been writing. It comes quite true from seed, and among the many plants I grew this year I did not see one showing the slightest sign of breaking away. I cannot agree with "A. D.'s" suggestion that a natural species of this kind, even although an annual, should be given a fancy English name.—JOHN WEATHERS, *Isleworth*.

NOTES AND QUESTIONS.—FLOWER.

Dahlias in November.—It is not often that Dahlias are to be seen in full bloom in the middle of November, yet such is the case this season. The blooms are now not only finer, but more abundant than in September, when, although the plants were kept well watered, the buds that were plentiful failed to expand freely. Since a moister atmosphere has prevailed there has been no lack of bloom, and the plants are still growing luxuriantly.—J. GROOM, *Gosport*.

Michaelmas Daisies.—Few flowers have so much increased in public favour as the several varieties of Michaelmas Daisies. Certainly they deserve all the attention that can be given them. When left year after year in poor soil to struggle for life with all sorts of other plants, they do not strike one as worthy of much care, but if set out at wide distances apart on fresh deeply-cultivated soil, they will astonish even those who have grown them for years. During the protracted drought of the present year I had some single plants on extra good soil that defied the drought and made a glorious show in the autumn, while the

old roots in closely planted beds had a difficulty in keeping alive, much less in making a good display of bloom.—J. G., *Gosport*.

Crinum Powellii.—Recently I saw this in good condition at Didlington Hall, Norfolk. It had bloomed abundantly, as could be seen by the number of flower-stems. In the hardy plant garden it was grown in a large bed in a mass. In the kitchen garden I observed a large clump growing at the foot of a warm house. In both places it bloomed equally well, but earlier in the kitchen garden. Some twenty to twenty-five years ago this was grown well in an open bed at the Pine-apple Nursery, Edgware Road.—J. CROOK.

Clematis cirrhosa.—Although I have tried all the principal Clematis growers, no one appears to have young plants of this to dispose of. I suppose the more showy varieties of the Jackmani type, that are now grown by thousands, are more profitable, but one would think with all the increased demand for hardy plants and climbers of all kinds that some specialists would get all the obtainable varieties together. Possibly some reader may be able to say where it is obtainable, for although one of the small-flowered section, it is well worthy of culture by reason of its early flowering.—JAMES GROOM, *Gosport*.

CHRYSANTHEMUMS.

CODDLING CHRYSANTHEMUMS.

THE culture of Chrysanthemums for large blooms for exhibition or home decoration has obtained such a hold on growers of all classes, and the need of early propagation is so generally understood, that it has come to be quite the custom to root the cuttings early in the winter. The consequence of this is that the plants when young—in fact, for the first four months of the new year—are a constant worry to those who have them in charge. They are not sufficiently hardy to stand outside in cold pits, and, where the supply of pits well built and with means of turning on a little heat on cold nights is short, they are removed about from pillar to post during the intervals of cleaning fruit houses, or else kept in structures much too hot for them. In almost every case they are not kept sufficiently cool, and the want of light and air is keenly felt until it is time to place them quite out of doors. Not only is this the case when they are in the small pots, but when the plants are potted in 6-inch pots they are often perforce stood almost pot-thick in deep pits or plant protectors. If only those who grow for exhibition did this, or if these rooted only their show kinds early and the bulk of the decorative stuff a couple or even three months later, not much harm would be done, but the almost universal system of early rooting and subsequent coddling will sooner or later so enfeeble the constitution of these fine decorative subjects that their culture will be far more difficult.

Good cuttings rooted in February come away quickly, and by the end of March may be stood out in quite cold frames, having become well established in 3-inch pots. If required for growing on the single or treble-stem system they will not require stopping, but for bush plants the points of the shoots should be taken when only a few inches high. Being, as it were, brought up hardly these plants are safe outside a good while earlier than those which have been kept hanging about the houses; they are far less liable to contract fungoid and other diseases, and will be quite large enough for decoration. In the case of plants grown on with the show batches, and later cut down with the object of making them branch out, the stems are never so strong, and unless carefully staked as they grow the branches snap out wholesale and are often blown out by wind. But those described above, on the other hand, are much harder at the base of the branches and may be left until almost full grown before a stake is put in. There is, in short, a distinct gain in late propagation for all excepting exhibition kinds. SUFFOLK.

Special prizes at Chrysanthemum shows.—At some exhibitions these are very numerous,

and are largely offered by members of the trade. There is, perhaps, no great objection to this custom, for it helps to swell the prize list and thereby attract competition. While in France lately a new aspect of special prizes occurred to me, and it was made evident by the imposing list of them which was hung up at the door of the Lyons Chrysanthemum show. The special prizes offered here had none of the taint of business interest about them, but, on the contrary, it was more in the light of a generous encouragement to horticulture that they seemed to be given, inasmuch as they came from high places where no hope of ultimate profit could possibly be desired—thus the President of the French Republic gave a Sèvres vase; the Minister of Agriculture, 550 francs and three medals; the Conseil-Général du Rhône, 900 francs; the City of Lyons, 1500 francs; the French Agricultural Society, three medals; the French National Chrysanthemum Society, the English National Chrysanthemum Society, the Italian National Chrysanthemum Society and other societies all joining in the evident disinterested desire to promote the success of the show.—C. H. P.

Disbudded Chrysanthemums.—Disbudded specimen Chrysanthemums are very imposing-looking when well grown, not too formally staked out, and when the right varieties for the purpose are chosen, as there is a great difference in their capabilities to form healthy bushes surmounted by from eighteen to twenty-four flowers each. The flowers such plants produce are a sort of compromise between those grown on bush plants not disbudded and those from plants on which only three blooms are grown, and when the varieties are chosen which fill up their flowers well without becoming too lumpy the result is good. Varieties I have noted as good for the purpose include Vivand Morel, with its sports, Charles Davis, Lady Hanham, and Mrs. J. Ritson; Nellie Pockett, very fine, and perhaps the best of the whites which can be grown in this way; Charles Curtis, a model incurved yellow; Duchess of Eife, incurved white, very fine; Mrs. Mease, which appears to be far and away the best of the Carnot family this year: M. Freeman, bright silvery pink, an old variety which carries its flowers in good condition longer than any other variety I know, and the old, but indispensable W. H. Lincoln, than which a better Chrysanthemum for general purposes was never raised. I have not yet found the ideal crimson for this purpose.—J. C. T.

VARIETIES OF CHRYSANTHEMUMS.

ALLOW me to thank "H. S." (p. 415) for his "Notes on Varieties," as the information contained therein is particularly valuable to many lovers of this beautiful autumn flower. I am perfectly in accord with the writer in considering that size alone carries too much influence, for many of the huge blooms are very ungainly, and, what is more, they are often of a washy, undecided tint. In various catalogues the colours of different varieties are given as pink, rose, rosy pink, rosy lilac, rosy purple, purplish pink, pale purple, and numerous other combinations, whereas there is very little difference to be found among the whole of them. True, an individual flower of one variety may be widely removed in colour from one of the others, but different methods of culture play a considerable part in the tint of the blossoms. One noticeable feature of Chrysanthemum shows at the present time is the scarcity of brightly-coloured flowers, for many stands consist almost entirely of light-tinted blossoms. Pure white flowers are certainly very beautiful, but the same cannot be said of those with a pinkish tinge, which gives the impression of one past its best. So great is the demand for large show flowers that the merits of many of the best varieties regarded from a decorative point of view are apt to be overlooked, and several of the older kinds now almost forgotten are superior in everything except size to many of recent introduction. A few that sug-

gest themselves just now are: Mlle. Lacroix, an extremely pretty white flower; Edouard Audi-guier, crimson-amaranth; James Salter, bluish, like a bunch of loose ribbons; Lady Selborne, pure white sport of the preceding; Bouquet Fait, pink; Source d'Or, golden orange; Criterion, amber; Elaine, white; Jeanne Delaux, rich crimson, for some years a general favourite; President Hyde, golden yellow; Tokio, glowing scarlet-crimson; Buttercup, rich gold; Val d'Andorre, red; Cullingfordi, intense velvety crimson; Reine des Beautés, bright red. Vivand Morel and its sports, Charles Davis and Lady Hanham, are in every respect very beautiful, and the same may be said of Sunflower. Florence Davis is an extremely pretty variety, with long, drooping florets, sometimes slightly twisted. The colour of the flower is white, with the centre deeply tinged with green, which gradually pales as it extends over the bloom. This green shading, however, varies considerably according to the treatment given to the plants. It is less pronounced in Florence Davis than in Mme. E. Roger, but as a set-off the former is a far more graceful flower. The above must not be taken as a complete list, but it may serve to direct attention to a few good old decorative kinds. T.

Chrysanthemum Mme. E. Roger.—This new incurved Chrysanthemum will now be grown by those who favour novelties, but I cannot say I care much for these greenish white flowers. From what I have seen of it it does not appear to be a very good doer, the general build of the flower being far from compact. Perhaps culture and time will improve it. Decided colours are, I think, preferable. Speaking of these, I am glad to find that really beautiful variety Val d'Andorre still grown by some. The colour is so distinct and pleasing that where plants are grown for conservatory or room decoration this variety cannot well be dispensed with. It is fortunate that while many of these beautiful varieties are discarded by exhibitors, gardeners and others who want to make an attractive display in the drawing-room and on the dinner-table wisely retain them.—J.

Undisbudded Chrysanthemums.—I am pleased to find that numbers of people, while allowing the monstrous exhibition Chrysanthemum bloom its due merits, are nevertheless much attached to the smaller, more naturally-grown blooms, especially for cutting. It is surprising what a number of amateurs and even cottagers adjoining large towns now grow creditable batches of plants for the adornment of their small green-houses, many of them home-made. In many large bay windows also beautiful groups of Japanese varieties may be seen artistically arranged. Few of these are disbudded, but, being grown in comparatively small pots and not highly fed, all or most of the side buds open and keep up the display for a considerable time. For garden decoration these are by many still preferred, and it would not, I think, be a bad plan for the National Society and others to offer prizes for this class of cut blooms.—B. S. N.

Chrysanthemum Comte de Germiny.—I was pleased to see this, a favourite variety of mine, referred to by a correspondent, who also praised the weakly growing, but beautifully coloured Jeanne Delaux, a variety which cannot be surpassed in its season for arranging in vases and glasses. I used for many years to grow a number of Comte de Germiny for decoration in January, and by keeping them out under canvas as late as possible and giving them cool, shady quarters when housed, the plants never failed to give an abundant supply of their graceful feathery blooms at the period named. For these late cuttings, however, it is utterly useless to grow the plants under the feeding system. Small rather than large pots, a holding loamy compost containing a small percentage of bone-meal, and hard potting are essential, the growth topped once, and the position during the summer months an open sunny one, avoiding the least crowding.

Comte de Germiny is not subject to mildew like some sorts blooming after Christmas.—C. B. N.

NOTES AND QUESTIONS.

Chrysanthemums in open air in December.—Seldom have we had a season when these gave so much satisfaction in the open as this year. It is not unusual to have a good display in the open during the early part of November, but there will be many gay patches of these against walls well on to Christmas if severe frost keeps away. I have now (early in December) fine masses of Julie Lagravere standing in an open border and that fine single kind, Mary Anderson, against a wall. I noticed a day or two ago several of the old kinds, such as Tokio, making a fine show against a farmhouse wall.—DORSET.

GARDEN FLORA.

PLATE 1252.

TORCH LILIES.

(KNIPHOFIAS.)

(WITH A COLOURED PLATE OF K. TUCKER.*)

WHILE the bracketed generic name here cited is the more recently adopted one by botanists, it will take many years before the more generally employed term *Tritoma* falls into disuse. Not many gardens of note are without some of these showy perennials. Of their uses, much, if not indeed all that is worth advancing, has been said from time to time. Thus it is that culturally little remains to be said of a family that almost all may grow with a very full measure of success. One thing, however, may be noted with advantage. It is the danger accruing to the plants from a soil over-rich in humus. A very common piece of advice is that these plants delight in very deep and well-enriched soils. The depth of soil is naturally a highly important matter, and many things respond most liberally for such care. The question of enriching, however, is quite another matter, because if heavy doses of manure are given it is more than likely that the plants becoming over-luxuriant will be among the first to suffer, if not to succumb altogether to our English winter weather. It is not of course a question of soils too fully charged with manure; there is an innate tenderness in constitution all round, and which is not remedied, even if at all modified, in any of the numerous progeny that has been raised during recent years. Encourage the root-fibres down as deeply as you may into good bodied soil. If the soil is in need of manure, use it by all means, always, however, at a safe distance from the roots. Big clumps of these plants send roots down to an astonishing depth. The more heavy class of soils rarely requires manure to the same extent as light soils, but instead, when planting a bed of *Tritomas*, mix plenty of old mortar or brick rubbish, burnt clay, ballast or the like with the ordinary soil. This is always of assistance and frequently helpful to the plants.

Of more than passing importance is the depth at which these things may be planted. Indeed, I regard this as of considerable importance, deeply planted specimens frequently passing through a trying winter safely when shallow-planted groups will suffer materially. By deep planting it is intended that the junction of leaf-blade with root-stock shall be kept 6 inches below the surface. In such case, even though the main crown is destroyed by severe weather, the side shoots are usually safe at the depth named. The best season for breaking up old clumps and planting these Torch Lilies

* Drawn for THE GARDEN in Mr. Perry's nursery at Winchmore Hill by H. G. Moon. Lithographed and printed by J. L. Goffart.

PROTEA SP. (1871)

is early in the year, say March or very early April. Autumn, and late autumn particularly, is not a good time, because few, if any, new roots are made during the winter months. If, however, from any cause, such as re-making a border, plants have to be moved in autumn, the foliage must be left intact. Owing to a mistaken notion of tidiness, these plants are at times reduced to a veritable stump 9 inches or a foot long and planted thus. Should a severe winter, or even an average one, follow, many of these plants will perish. Where a good collection of these Torch Lilies is grown it will be prudent to anticipate severe weather and protect the plants. Here, too, for protection avoid all manures, particularly those of a close, wet, heavy nature. All such do harm rather than good. Where leaves can be gathered dry, or nearly so, these form an excellent protection. Coal ashes may be used in some instances, but such do not benefit all soils, though their value for protection is in many cases excellent. Four inches thick of ashes would make a good covering that could easily be removed in March or April ensuing. Anything that will admit air rather freely and not decay readily is the better covering for such plants. Big isolated clumps are best tied up to stakes, inserting dry Bracken or Heather among the leaves as the latter are gathered up. The great destroyer of big clumps is snow settling in the hearts of the plants, and as these are not easily replaced they are worth protecting. Some kinds are less hardy than others, and the newer hybrid kinds show no improvement in this direction.

There is, perhaps, little hope of securing a perfectly hardy race of these Torch Lilies, though much may be done by selecting the hardiest flowered types for future operations. The hybridist would do well to avoid such sorts as *K. caulescens*, usually less hardy and useful than many. On the other hand, something may be done to encourage a later-flowering race of these by raising seedlings between *K. Nelsoni* and that most brilliant late kind *K. R. C. Affourtit*. These two have long tubular blossoms of rich colour, and spikes are freely produced; indeed, for fine effect the latter will require some beating. The least attractive, perhaps, are those with very short tubes and long protruding stamens and anthers, the real attraction being in the colour of the tubular blossoms, and the longer these are the finer the effect. The introduction of kinds with much shortened racemes of flowers should not be encouraged. Some of these are remarkable for their short, stumpy character, that alone prevents their making a lengthy display. The more extended racemes, on the other hand, continue long in good condition.

A very good and attractive sort, *K. Tucki*, is given in the accompanying plate. The variety is of good habit, with fine, almost Yucca-like foliage of a glaucous hue. It grows to nearly 5 feet high when well established, and possesses a value of its own by reason of its early flowering. Indeed, this is one of its chief attributes, which is not likely to be overlooked by those engaged in raising cross-bred forms of these plants. This variety flowers quite early in June and is frequently seen before that month opens. This is very early for a Torch Lily, and the plant is valued accordingly. E. J.

Veronica La Seduisante.—This shrubby variety of Veronica, which is of continental origin, must be assigned a place among the best of its class. Two years ago it received an award of merit from the Royal Horticultural Society, and since then has become more popular. It is

of a free, bushy habit of growth, and the long spikes of flowers, borne in great profusion, are of a rich bright purple, while the whitish anthers are very conspicuous against the rest of the flower. In the more favoured districts of England these shrubby Veronicas are valuable outdoor shrubs, but where this is not the case they form a welcome addition to flowering plants for the greenhouse at a time when variety is none too plentiful. They strike very easily and form dense, wig-like masses of roots. For this reason they can be lifted with but little check; hence they are often planted out during the summer, taken up, and potted early in the autumn.—H. P.

STOVE AND GREENHOUSE.

NERINE FOTHERGILLI MAJOR.

AMONGST autumn-flowering greenhouse bulbs this holds a foremost place. This *Nerine* blooms naturally about September, and when

Nerine Fothergilli major. From a photograph sent by Mr. J. Crook, Forde Abbey, Chard.

desired the season may be prolonged by forwarding or retarding the growth, as the case may be. It may be grown one or more bulbs in a pot, but from ten to eighteen in a big pot, as here illustrated, make a brave show. When used singly in vases, or in a group mixed with Ferns, this *Nerine* will be found very useful. Many look on this and other *Nerines* as difficult to manage. I do not find it so. I grow them in pots 6 inches wide and upwards. The one here illustrated is 9 inches in diameter. About every two or three years I shake the bulbs out just before they begin to grow, potting up the large bulbs one or more in a pot; the smaller ones are selected and grown on. The soil used is good sound loam and peat, with enough sand and broken charcoal to keep the soil open. When the blooming is over they are placed on the shelves in a cold house close to the glass and kept growing all

through the winter. When the foliage has ripened off water is withheld, and they are placed on a high shelf in a cold Peach house, and do not receive a drop of water through the summer. In the autumn when the bloods begin to show, water is given, increasing this till the ball is moistened well through. Should the pots be very full of roots, a little manure water is given when growing and as the spikes increase in height. Large, well-ripened bulbs, as here shown, produce large heads and with stems 2 feet high. The success of this, as in many other bulbous plants, depends on being well ripened. It is unwise to begin watering the bulbs till you can see the flower-spikes.

Forde Abbey.

J. CROOK.

Heliophila scandens.—This very uncommon though decidedly pretty climber is just now flowering with great freedom in the succulent house at Kew, where each recurring autumn it is very attractive. This *Heliophila* is a native of South Africa. It is a free yet slender twining plant, clothed with simple pointed leaves and bearing in great profusion its pretty sprays of white blossoms, the only colour being just a suspicion of red at the base of the flower. It is well worth more attention as a climbing plant for the greenhouse, for the number of those in flower at this time of the year is decidedly limited. This *Heliophila* does not require any special treatment, growing well in a mixture of loam, peat, and sand. The position at Kew, where it is fully exposed to the sun, is particularly favourable to the production of blossoms, and if shaded the results are hardly likely to be so satisfactory.—H. P.

Zonal Pelargoniums.—Formidwinter flowering these are now so generally grown that there is no need to recommend them for the purpose. Easily and very cheaply grown and the brightest flowers of the season, they are plants for everybody with a greenhouse. One of the best lots of plants I have seen was at Ickworth during the week, a span-roofed house being filled with plants, each one a perfect little specimen and presenting in the mass a glorious blaze of colour.

Among the brightest were Donald Beaton and John Forbes, the former an especially fiery scarlet, the latter with very fine trusses, but neither quite up to the standard for form. Among the doubles I noted the comparatively old Grand Chancellor Faideherbe, a kind that has never been beaten in its own colour, though this—dark magenta—is not the prettiest in zonals. Those that are best for the purpose indicated are the bright round-flowered kinds, of which Chas. Mason and Mr. Wm. Bealy are types. The improved F. U. Raspail, again, under its many names is an excellent double, and those even who are not fond of bright colours in the ordinary way are usually pleased with such as these in winter. Ample sun, light, and air winter and summer and proper cultivation are the principal requirements.

Pinguicula caudata.—This pretty Butterwort is a native of Mexico, of easy culture, and an exceedingly pretty little plant. For this

reason it ought to be more grown than is the case at present. The plants grow in small tufts of light green leaves and the rosy pink blossoms occur singly on the ends of the tallish spikes. The plants thrive best in a compost consisting largely of peat fibre and clean, freshly-gathered Sphagnum Moss with which a plentiful supply of crock dust and silver sand has been mixed. In order that an abundant supply of water may be given, a small pot should be nearly half filled with crocks as drainage, while larger ones may have a small pot inverted over the bottom and the intervening space filled up with crocks. Unless provision is made in some such way as this the soil is very apt to get soured by the continuous watering which is really necessary for this plant. The atmosphere of the house in which it is growing, too, ought to be well charged with moisture, as progress without this must of necessity be slow. A cool fernery or a house devoted to Mexican and New Grenadan Orchids suits it better than a warmer temperature. There are many ways of propagating it, seeds, cuttings, or leaves being used, and although it is not exactly a plant to grow in quantity, a few specimens have a very distinct and pleasing appearance at this time of year.

ARISTOLOCHIA ELEGANS.

Of really pretty stove twining and climbing plants we have none too many, and this is one that may with advantage be added to most collections. It is easily grown where a proper atmosphere and temperature are maintained, is of a pretty habit, and its flowers are decidedly handsome. There are several in the genus that bear flowers too large to be of any service outside the house in which they are grown, but *A. elegans* is a charming subject for cutting for choice decorations, long pieces of the trailing stems with a flower at each leaf axil having a beautiful effect depending from brackets or large vases in the house. The flowers do not last long, unfortunately, but a number are successively produced over a very long season, so their shortcomings in this respect may be easily overlooked. There are several ways of propagating *A. elegans*, but the easiest and best is by means of seeds, which may be sown in early spring in a strong, moist heat singly in small pots. The seedlings should be pushed along as rapidly as possible the first season, and with care may be grown into strong plants in 8-inch pots by the autumn. The growth may be allowed to ramble somewhat at will, as it will be necessary to cut them back rather hard, but it is important that the roots are carefully looked after and large shifts avoided. The object is in the first year to make a good foundation, so to speak, and have a nice quantity of well-ripened stems to cut back to.

During the winter the roots may be kept a little on the dry side, and the plants will be best in a greenhouse temperature. Early in the new year cut out all the weakest shoots and shorten back the bigger wood, placing the plants in a warmer house somewhat suddenly to induce them to break freely. When the young shoots are starting, the plants may be repotted and given a brisk stove temperature. When a little growth has been made the flowers will be seen forming in each leaf-axil, and they will continue to appear as long as growth is well maintained. The shoots require something in the way of a trellis to lay hold of, and have a habit of twisting about that is very pretty, but this plant is seen at its best on a roof in a fairly capacious structure, rambling at will among pillars or tie-rods.

Salvia splendens grandiflora.—For keeping up a bright display in the conservatory from early autumn until Christmas the above is one of the best plants we have. Nothing could exceed in brilliancy the long racemes of crimson-scarlet, the tube and calyx being equally bright. Unfortunately, the flowers soon drop when exposed to a change of temperature; therefore it cannot

be recommended for cutting, though if carefully gummed the flowers will hold on fairly well. It has found some favour among florists, but I should more strongly recommend it for those who have to keep up a bright display in conservatories. There is little difficulty in the culture of this useful plant. If a few plants are well cared for through the winter they will give plenty of cuttings early in the spring. I like to take the first cuttings as soon as they are ready and these will give good strong cuttings later on. The best plants are obtained from the strong growing tops, which if put in about the end of May will make fine plants by the autumn. By taking the tops of young plants it is easier to keep the plants free from red spider, which is their greatest enemy. The plants may be grown on during the summer in a cool frame or out-of-doors. I like to have them where they can be sheltered from wind and heavy rains. Potted in a rich loamy compost and grown on without any stopping, they make fine pyramids if given plenty of room, and will come into flower early in September. If given sufficient pot room and liquid manure from time to time, the same plants will continue in bloom for a long time.—H.

Abutilon Golden Fleece.—A correspondent recently brought this excellent variety before the notice of readers of THE GARDEN. Abutilons generally should be more frequently grown, as it is astonishing what a quantity of bloom a well-established planted-out bush will produce. Pot plants are most useful in their way, but they are generally needed for ordinary furnishing, much cutting soon spoiling their appearance. Nothing equals well-grown specimens planted in the border of a cool conservatory or carriage court. Good drainage must be afforded, as liberal supplies of moisture are needed, and during growth frequent doses of farmyard liquid. A good holding loam, with a fourth part of peat, leaf-mould, and coarse sand, forms a very suitable medium. Overcrowding must be avoided and moderately hard pruning practised each year, say in January, lessening the water supply at such periods. Few things produce a better effect used for dinner-table decoration. The yellows and whites mixed look charming, as they also do lightly arranged in tall vases or glasses, no other foliage but their own being needed. Plants raised annually are perhaps the best—that is where a good-sized batch is grown in pots. Clean, healthy cuttings strike readily during February. They must be kept as near to the roof-glass as possible, or they soon assume a leggy appearance and become weakly. In June a sheltered position out of doors on a bed of coal ashes in the full sunshine is best, feeding carefully from the time 6-inch pots become well filled with roots. Plants in 6-inch pots are the most useful, and when thus confined, a fifth part worm-free manure should be added. One stopping when from 5 inches to 6 inches of growth have been made is sufficient. Removal under glass should take place at the end of September.—C.

ARRANGEMENT OF STOVE AND GREENHOUSE PLANTS.

DURING the winter months a different arrangement of plants grown in our greenhouses and stoves is more necessary than during the summer. In many instances the roofs of the houses are more or less covered with creepers of various kinds in summer. Not only does this improve the health of these plants, but they throw a slight shade, for which plants of other kinds grown on the stages are grateful. But just now it is important that all the light possible should reach the latter, and it is no longer possible to leave the creepers in position on the roof; indeed, it would not be advisable in all cases, for some stove climbers are very easily injured by cold, and the few inches from the glass are not sufficient to prevent the penetrating influence of severe frosts. I have frequently seen fine plants of *Cissis* discolor lose every leaf from this cause, and *Clerodendrons* are easily injured in the same way.

Where a large number of *Caladiums* and other deciduous plants are grown, the decay of their foliage allows other plants in the same house to be spread out a little and as well make room on the stages for those that have been growing on the roof. *Dipladenias*, *Allamandas*, *Stephanotis*, and similar kinds may have a little of the surplus wood removed and be twined round a few stakes placed in the pots, so that they take up far less room.

One point it is necessary to remember, and that is that as soon as the growing season again commences the plants must again be untied, or in a very short time they will be in a hopeless tangle, and to separate them will mean breaking the shoots. The growth will have become so well ripened, that the position of the plants in winter while at rest is a secondary consideration, and they must make room for such sun-loving subjects as *Ixoras* and *Crotons* in the stove, and *Pelargoniums*, *Cyclamens* and others in the greenhouse. Ferns, again, when grown with other plants like ample light now, and if the collection includes, as it often does, a few of the more generally cultivated Orchids, let these also have the benefit of all the light at command. Plants of a bulbous character that are now resting should not be entirely forgotten, for many of them are the better for the slight amount of moisture, notably such Aroids as *Caladiums*, *Callas* of sorts and others. The plants should be stood where they can be looked over occasionally, and placing them near to hot-water pipes, where they dry up rapidly and suddenly, should be avoided.

GROWER.

THE WEEK'S WORK.

KITCHEN GARDEN.

FORCING RHUBARB.—The earliest stools of Prince Albert and other easily excited sorts which were placed in the Mushroom house the third week in November are now moving into growth and will furnish usable sticks before Christmas. About the 13th of this month place a second similar lot in warmth. A portion of the permanent open-air bed should now be covered, either with proper Rhubarb pots or tubs with the bottoms knocked out. These should then be built round with a sufficient bulk of fermenting material, previously prepared by turning in order that rank steam may escape. Leaves and stable litter in the proportion of three parts litter to one part leaves may be employed. If any fear exists of the supply running short in the ordinary forcing house but where time is not a desideratum, nothing equals a bed of leaves only, as these retain the heat to the last, and weak stalks through excessive heat need not be feared. The best example of forced Rhubarb I ever saw was a good-sized bed of the true Prince Albert. Stout stakes were driven in round each stool so as to form a square; round these hay-bands were closely wound, small lights being laid over each, and Oak and Beech leaves well trodden into the intervening spaces. A little litter was then spread over the whole surface, a few extra forkfuls being laid on the lights. Thus treated the stools could be easily examined at intervals, and when growth was advancing, if the weather was mild, a little air was admitted by moving the lights on one side. A second bed was grown by its side so that they could be forced and rested alternately. This is really the best way of forcing Rhubarb I am acquainted with and good flavour is obtained. A good deal of mischief is wrought by piling up huge mounds of hot stable manure, which often literally stews the crowns before the evil of overheating is discovered. Where it is intended to form a new bed in spring, good-sized healthy pieces having a couple of crowns may be broken off the stools as lifted and laid in leaf-mould in some convenient corner ready for planting in February or March. The sooner the ground is prepared the better, as a good rich root-run is essential and time is necessary to allow the manure mixed in trenching to decompose and the

ground to settle. When the plants are put into newly-dug ground in spring, it often happens that the roots get an insufficient supply of moisture, particularly should the summer be a dry one; consequently, only a poor growth follows. For the sake of quality as well as quantity, a change of ground should be given every five or six years. When extra large sticks are required for exhibition, a thick layer of rich manure should be placed beneath the stools. Liquid manure may also be given with impunity as soon as the plants become established.

CARDOONS.—Where the latest batch of Cardoons is still in the ground they should now be lifted and placed in a cool, dry shed or root-store. Get as much soil as possible to the balls when digging them up. Where room is scarce I have known gardeners keep Cardoons for a considerable time by suspending them from the roof. Provided the winter is mild, they may be left in warm soils if well covered with Bracken, but in damp, low-lying situations they will not stand it, and at any time much wet is liable to ruin the centres. Those already in store must be looked over occasionally, and any that show signs of decay used at once. The root-room generally must likewise be attended to at regular intervals for the same purpose, as it is surprising how quickly decayed roots contaminate the rest.

SWEDS TURNIPS.—Many people do not seem to know the value of these roots for a change in the dining-room; indeed, some people prefer them to white Turnips. It must be remembered, however, that those only from good, rich soil must be selected, and these not too large, or the flavour is apt to be strong. It is fortunate when Swedes are appreciated, as their use prolongs the supply of other vegetables. Where in the southern counties the earliest Rosette Coleworts are showing signs of splitting, they may be kept for some time by lifting with a little soil attached and laying them in a cool, open shed in semi-dry soil. When rain gets into these split heads and frost follows, decay soon sets in. Besides, as soon as they are removed from the ground, the latter can, if need be, be turned up for exposure to frost and wind.

ROUTINE WORK.—In fine, dry weather opportunity should be taken to clear off any exhausted crops and to get the manure wheeled on to all vacant plots at the approach of frost. In cases where the ground will not be dug or trenched for the present it is a good plan to tip the manure in heaps of large dimensions and to throw a little soil over it. This prevents the properties from escaping, and where near the mansion is not so unsightly. Gas-lime may now be safely dug in, not only into plots which are to be sown with Spinach, but also into those to be planted with Cauliflower, Cabbage, Beans—indeed, the whole garden will be benefited by an occasional dose of it to rid it of grubs and purify it generally. Perhaps the most effectual way of applying gas-lime on plots where sowing or planting will not take place till April or May is to turn it up very roughly and then to sprinkle gas-lime somewhat thickly over the surface. It is then gradually washed in by winter rains, and the whole depth of soil gets a more even share of it than when it is dug in at once. After a few dry, windy days get the walks of the kitchen garden swept and rolled again. This will solidify them for the winter, and no more rolling will be needed till spring. In unfavourable weather also shorten stakes which have decayed at the bottom, these being just what one wants for the dwarf Peas on early and second early borders. Pegs and labels either for writing on or numbering may also be made.

J. C.

FRUITS UNDER GLASS.

EARLY PEACHES.—The weather up to now having been so warm and fine, Peach and Nectarine trees which have been forced for early work for years in succession appear almost ready to commence growth, so that with present weather conditions continuing fire-heat will be unnecessary, and all the artificial warmth needed will best be

given by making up a nice bed of the leaves and litter already prepared for such purposes. This bed need not be a big one to commence with unless we get a quick change to frosty nights, and may be added to and turned later on as occasion arises. The aim should be to keep the night temperature down to about 45°, rising to 50° by day without sun-heat and the usual allowance of 10° higher with sun, and on cold nights it will be better to allow a fall to 40° than to raise it higher by firing. Just at present it is impossible to keep houses so low, but it is not the rise given by an abnormally high outside temperature that does harm; the harm comes from high temperatures produced artificially, and there is no doubt that this often occasions a stubborn start and also bud-dropping, though my theory is that bud-dropping is, except to the few varieties with a bad reputation for losing their buds, due principally to dryness at the root in the autumn or early winter. A certain amount of humidity in the atmosphere is necessary to a good start, but this should not be brought about so much by heavy dampings down as by careful manipulation of the ventilators—that is to say, by admitting just sufficient air to keep the atmosphere wholesome without causing sharp draughts. Gently dewing over the trees now and then with the syringe is helpful, and this, with the evaporation from the hotbed, will provide just the amount of atmospheric moisture necessary, provided only a little circulation of air is kept up. To open the ventilators widely enough to set up a strong current of air and then to stop a lot of water about to counteract its drying effects is wrong. Of course, one must be guided in these matters by local influences, as the treatment necessary for low and small houses would hardly be applicable to loftier ones and those which contain much greater cubic space. The conditions advised above should be maintained up to the time the flowers expand, after which a drier atmosphere should be kept up with as free a circulation of air as the outside conditions warrant.

EARLY VINES.—Where there are no pot Vines grown to give the earliest supply of Grapes, it is often necessary to start a house of permanent Vines to produce a crop at the earliest possible time, and though I do not advocate starting houses before Christmas except under such compulsion, very fair Grapes may be grown year after year from Vines started early in December, though the start they get over those which are put to work with the new year is only a question of days rather than weeks when it comes to ripening the crops. The difficulties in early forcing of these permanent Vines are accentuated when one has to depend entirely on outside borders, for these, unless protected in some way, get cold with winter snows and rain. I do not believe in making up a hotbed in the old-fashioned way for such borders, but I certainly believe in the virtues of a good thick covering of leaves (the drier the better) for them, as these will gently ferment and prevent the borders from getting really cold. They also thaw the snow and prevent the water from the latter from reaching the roots in a chilling state. A thin coating of leaves that is anything under a foot thick is practically useless, as it gets sodden long before the weather and the rains get warm, and the covering to do much good should be at least 2 feet in depth. Fortunately, very few people now trust to outside borders alone, for there is one great element of danger in forcing Vines planted outside and brought through holes left in the brick or woodwork, this being that the sap sometimes gets frozen at the collar, this arresting growth and producing disastrous results. To prevent this freezing, either bury the stems with the leaf mulch or bind them round thickly with hay bands, filling up at the same time all crevices round the stem where it is led through to the inside. Inside the house one may make up a gentle hotbed as advised above for Peaches. Insect-infested Vines should have one more weak dressing of Gishurst before starting them, then the house may be shut up and treated generally much the same as the Peach houses,

except that from 5° to 10° more heat may be given. As a guide to the time required, it may be advisable to say that those Vines generally used for forcing will take a little more than five months in which to perfect their crop if started at this season. Syringe the Vines two or three times a day when starting them, but beware of too much moisture later on when growth commences, for an excess of moisture leads to flabbiness of foliage, and this in its turn is a precursor of trouble in the shape of leaves that will not bear the summer sun and which drop prematurely before they have done their season's work of plumping up the buds for another year and bringing the wood to full size and a ripened condition.

STRAWBERRIES.—For very early work I have found no Strawberry to equal the old Vicomtesse Héricart de Thury, which is one of the best for setting and certainly the best early for flavour. Its fruits are not large, but this is no detriment, as all the large varieties are poor when forced so early as this. A batch of plants placed now in a pit on a bed of fermenting leaves, the bottom heat of which is about 75° and the top heat 55°, will come away gradually and well, as the roots will be active before top growth commences, and this will tend towards sturdy spikes of blossoms. The pit should be clean and the glass bright, with the plants set well up to it. Before starting the plants dip them in a solution of weak soft soap and sulphur water to prevent mildew; then, after the surface soil has got dry, ram well to close the soil home to the pots. Syringe daily and fumigate at regular intervals, about twice in three weeks or so, to keep down fly, which prevents the blossoms from opening freely and cripples the foliage. CORNUBIAN.

ORCHARD AND FRUIT GARDEN.

LATE PEARS.

THE present season has been a peculiar one in many respects, but in none have its effects been more marked than in the ripening of Pears. We have had seasons before when the fruit has ripened prematurely, but I never remember late varieties being in use at this time of the year. In some seasons Hacon's Incomparable, Van Mons Leon Leclerc, Beurré Diel, Passe Colmar, and the like are not ripe till December, and I have had them keep good till January. This season most of them were early in October and none of them remained good to the end of that month, though they were allowed to hang on the trees till the leaves had begun to change colour. Beurré Rance, Easter Beurré, Jean de Witte, Knight's Monarch, Beurré d'Aremberg, Glou Moreau, Josephine de Malines, Ne plus Meuris, and many others of the so-called late varieties have all ripened long before their usual time. There is very little difference in this respect as regards the stock the trees are grafted on, but of the two the fruit from trees on the Pear have ripened the latest. It is rather disappointing, when the fruit is so scarce, to have it ripen at this season, for long before Christmas I shall not have a Pear left. It is not only those that were grown against walls that have behaved thus, but those from pyramids and bushes are alike ripening long before their usual time. In this respect also there is but little difference between young and old trees. We have had two or three very dry summers, which have, no doubt, had a serious effect on the roots of the trees, and this may in some degree account for this premature ripening. Here, during June, July and August, only 2½ inches of rain fell, nearly half of which was on the two first days in July. The fruit, though of fair average size, has not the flavour it would have had provided more moisture had been afforded when swelling should have been

most rapid. During the month of August the ground was very dry, scarcely a particle of moisture in it, and only .37 of an inch of rain fell in this district, scarcely enough to lay the dust, and it was not till the last day in September that the surface had become moist, which was too late to have much effect on the fruit. H. C. P.

Buxted Park, Uckfield, Sussex.

Apple Gascoigne's Seedling.—This is a very fine-looking Apple when the trees can be induced to fruit freely, but I recently neted a nice healthy-looking lot of young trees on which fruit was scarce, and the grower assured me he had taken very little fruit from them, though other kinds had done well. This coincides with my own experience of it, but as my trees are very young I had not expected much fruit. It certainly is not an Apple for restriction treatment, but I am hoping that by giving it its head it will eventually prove fruitful.—H.

The Pershore Plum.—There is probably no more free-fruited variety than this in cultivation, besides which the tree is an excellent grower and does well in many soils where less hardy kinds would not flourish. Cooked it is of most exquisite flavour, the cooking apparently bringing out a richness that is not present in the raw fruit, no matter how well ripened. It and Victoria are two of the freest fruiting Plums known, and both should be profitable kinds to plant. A firm soil is one of the principal requisites in cultivating these and other Plums, and they both do well here on the grass.—SUFFOLK.

Pear Beurre Bosc.—It is not often this Pear is mentioned, but although not one of the choicest as regards flavour, few sorts possess a better constitution or are more suitable for growing in small gardens, as it crops prodigiously. I believe acres of Beurre Bosc are grown in Kent for market, its fine shape, long and tapering, together with the handsome russet skin, commending it for the purpose. Neither is it at all a bad flavoured sort when the trees get plenty of sunshine. I once saw it in grand condition near Melton Mowbray, in Leicestershire, and what pleased me as much as anything was the fact that the soil was very heavy, approaching to clay in fact. It was in bush form and the fruits were heavy and handsome. Amateurs and others possessing small gardens who cannot afford to plant shy or slow-bearing Pears should make room for at least one or two trees of Beurre Bosc when planting.—EAST ANGLIAN.

Pear Hacon's Incomparable.—A short time ago I read a note on this Pear by a gardener residing in the north of England, and was especially interested in his remarks, as I once had two trees on south and south-east walls and was much annoyed at their behaviour. After waiting patiently for, I suppose, six or seven years without a single fruit I destroyed them. Had my garden been of a heavy, clayey nature and growth gross, I should not have wondered so much at their barrenness, but the rooting medium was such that the majority of Pears did remarkably well. The writer of the note in question states that Hacon's Incomparable is a most useful good-flavoured fruit, in use in December, but adds, the tree is many years before it bears fruit. After reading his remarks I almost wished I had not removed the trees, as perhaps a year or two more would have brought them to a permanent fruiting state. There are other sorts which take a long time, and these may be tolerated in large gardens, but where space is limited gardeners are apt to get impatient.—J. B. N.

Apple Bismarck.—"J. G." speaks of this new Apple as having done well this season, and accords it all-round praise. He is fully justified in so doing, as I regard Bismarck as one of the finest and most useful cooking Apples in cultivation. As an exhibition variety it is unsurpassed, having size, symmetry, and colour to recommend it. Bismarck will also hold its own as far as

keeping is concerned against most other varieties in use at the same season. Although not strictly a late-keeping Apple, it comes into use at a most acceptable time of year, viz., after the ordinary run of Cedias is getting past or becoming light in weight and losing flavour. Another important recommendation for Bismarck is its early bearing, quite young trees in any form giving a nice lot of fruit. As a bush or espalier—more particularly the latter—it is a great success, and the market grower also finds it first-rate as a standard. Not a few of the larger cooking Apples, notably Warner's King, Alexander, Peasgood's Nonsuch, and Bramley's, often tire the patience of the grower by the slow rate at which they commence cropping.—GROWER.

Late Figs.—An interesting note recently appeared on Figs for late supply, the writer asserting that they could often be had good late in October. This I have myself proved, but in such cases it is necessary not only to grow them under as cool, airy conditions as possible up to the end of September in ordinary seasons, but also after

Marseilles will be found the best Fig for extra late supplies.—J. C.

APPLE COX'S ORANGE PIPPIN.

This is undoubtedly the finest flavoured Apple grown. This was abundantly shown by the many times it obtained the flavour prize at the Horticultural Society's meetings some years ago. Although opinions are agreed on this point, the same cannot be said as to its hardiness and cropping. In some soils it bears freely, while in others the opposite is the case, more especially in the case of young trees or trees that are pruned yearly. Many growers find it very tender when in bloom. In this garden trees in exposed positions have had their blooms destroyed, while other kinds, such as Prince Albert, Claygate Pearmain, &c., have escaped. This season a bush tree in such a position, 9 feet high and as much through, had not two score of fruit on it, although full of good flowers. Another tree of the same description in a sheltered place had six pecks of splendid highly coloured fruit, and several soakings of manure water brought the fruit up to a large size. Such fruit commands a good price in the market early in the year.

This kind is most frequently seen as a pruned tree. As a standard it has much to recommend it. I have three large trees in this form in our orchard. They are from twenty to thirty years old. In this form they do well, generally producing plenty of bloom, and although they are not favourably placed, as our position is very low, when the season is a late one I generally get a good crop. This year two of the trees had well-nigh all the bloom-buds destroyed by the birds, the third being in a position where they got disturbed by people passing. This tree produced an enormous crop, as is shown by the branch here illustrated. This was cut from the tree about the middle of September. The fruit was of medium size and very highly coloured. I keep these orchard trees regularly thinned. The soil in this orchard is a strong holding loam. As it is close to the river Axe it is often covered with water. Fruit from these orchard trees is not so large as from bush trees in the garden, but it is more highly coloured and has more russet on it. Regarding keeping, I find fruit from

A fruiting branch of Apple Cox's Orange Pippin. From a photograph sent by Mr. J. Crook, Forde Abbey, Chard.

both forms of trees about equal. When stored in close cases or on shelves in a cold, damp fruit room it retains its flavour till well into March. J. Crook.

Forde Abbey.

Pear Aston Town.—Replying to "B. S. N." (p. 398), there are two different Pears known under the above name. In 1837 I was a lad with my father, then gardener at Beckett's Park, and there two nice trees produced good crops of fine fruit, ripening at the end of September. They were thickly covered with brown russet, suffused with red on the side exposed to the sun, of excellent flavour, and kept fit for use for about a month. At the gardens at Coleshill, Berks, in 1841, I found several trees under that name, the fruits much smaller, paler and more ovate. The fruit was quite worthless, frequently rotting on

that date to apply a genial artificial warmth by means of hot-water pipes. This is necessary to impart flavour. Some sorts, such as Brown Turkey, Osborn's Prelific, the Ischias, and a few others, can, by judgment in starting them for the first crop not too early in the season, be induced to finish off their second lot of fruit at the late period referred to, but I think the finest flavoured October Figs I ever tasted were gathered from a tree of White Marseilles grown in a tub in a cool, somewhat heavily built greenhouse. The tree came into growth very gradually, as no more heat was employed than was absolutely needed to exclude frost; consequently the fruit which was produced on the current year's growth was formed late. The tree was very vigorous, which perhaps accounted for the fact that no fruit ever formed on the extremity of the previous year's wood, but Negro Largo seldom does this. I think White

the trees. As the place was being renovated they were destroyed and I lost sight of the Pear. In 1864, being in charge of a large hop and fruit farm in Kent, I found several trees of both kinds growing and fruiting in the plantation. They ripened at about the same time, but there was little colour on the worthless kind.—RICHARD BUTLER, *St. Dunstan's, Regent's Park.*

Staging white Grapes at shows.—It is an almost universal custom to cover Grape stands with white or pink paper. At the late Chrysanthemum show held at Frome an exhibitor departed from this old custom, and, instead of using the conventional pink tissue paper, chose black velvet plush. The gardener intimated, in response to exclamations from the interested bystanders, that it was his employer's idea, and certainly the colour was enhanced on a black ground over and above that of other exhibits displayed on pink. Black-covered stands, however, are not likely to add to the general effect of the exhibition stages, notwithstanding individual Grape bunches are seen to better advantage. This is the first instance I have seen where such a dark material has been associated with Grapes. There is no reason why it should not have been chosen, especially when it is remembered that similar material is used to display cut flowers in bouquets and other devices, and which it does to undoubted advantage. The beautiful amber tint in the Grapes under notice was more conspicuous than I have ever seen in bunches placed on pink-covered boards.—W.

FRUIT AT NORWICH SHOW.

OF late years East Anglian gardeners have given a good account of themselves at the Crystal Palace and other large shows, therefore I was quite prepared to find a good display in the various fruit classes at the recent Norwich show. It has been said that Norfolk is the home of the Alicante Grape, and certainly some of the finest examples I have seen were produced in that county. The leading exhibits at Norwich were of a high order of merit, size of bunch, berry, and general finish being all that could be desired. I cannot, however, see the use of having a class for Black Hamburgh at November shows, for, as in the Norwich case, the bunches shown are generally inferior and foxy in colour. Of course, the flavour is there, but the show-going public now-a-days expects to see imposing bunches highly finished. I noticed several very creditable lots of Lady Downe's, a Grape which, in spite of the inability of certain growers to master its defects, is invaluable where a late spring supply is desired, as, owing to the thickness of the skin, decay, even in the most unfavourable winter weather, is the exception if ordinary care is taken. What pleased me most were the Apples, the number of dishes, together with the size and finish of the fruit, speaking volumes for the soil, climate, and all-round attention the trees had received. Cox's Orange I never saw finer or more richly coloured, and it was highly gratifying to me to see plates of such neglected but delicious varieties as Margil, American Mother, Lemon Pippin, and Lord Burleigh. I used to see the last shown well years ago at Lincoln, the soil in that neighbourhood suiting the more capricious Apples. In a trade collection I noticed Cornish Gillyflower in addition to the above, but these small, comparatively unattractive varieties stand little or no chance in competition with the newer, more showy section. What I advocate is a separate class for flavour, say six dishes and one dish. This would, I am sure, bring a keen competition and prove of great service to intending planters. Nearly all of these so-called capricious Apples may be successfully grown by working them on the Paradise, planting in a non-clay soil in a somewhat elevated border in which the usual correctives, such as ground mortar rubble, burnt garden refuse, and charcoal, abound. No Apples give such satisfaction in the dessert. Another thing I noticed at Norwich was that the flat, indented varieties, both in the dessert and cook-

ing section, were, except in a few instances, superseded by the deeper or more conical sorts. The marketable and dessert or cooking qualities may be all that is desirable, but exhibitors should not include too many of them in their collections. Notable amongst this class are Baumann's Red Reinette, Court pendu Plat, Fearn's Pippin (a certain-cropping and very valuable Apple), Cox's Pomona, and The Queen. The Blenheims were, except in one or two dishes, undersized and lacking colour. Probably the fruit was taken from young trees. By far the largest and best are produced by aged trees, everyone knowing that the Blenheim is slow in commencing to bear. Bismarck was poorly represented, few trees at present probably having been planted in that quarter. I know of no cooking Apple which bears in a younger state. I saw several dishes of what, though possibly a very old variety, was quite new to me, viz., Nutmeg Pippin, a small, somewhat conical, dingy-coloured Apple. Perhaps some reader can give an account of it. Another discarded Apple was well shown; I refer to Lemon Pippin. I suppose this is not now planted in one garden out of ten. Why, I know not. It yields abundantly, being most useful at and after Christmas, and preferred by some to any other for mince-meat. Some years ago fine old trees existed about Bromley in Kent. I do not think it appreciates a cold soil.

Coming to Pears, had I been asked to choose one of Mr. Allan's first prize six dishes I would, having quality in view, have selected Passe Colmar. By many it would have been regarded as the weakest because the smallest dish, but an expert knows what is beneath the skin. By the way, why not, as I have suggested with dessert Apples, have a class where such sterling flavoured sorts as Thompson's, Passe Colmar, Doyenné du Comice, and others could hold their own? While inspecting the stewing Pears a gentleman intimated to me that he was afraid this class was not sufficiently appreciated, and I quite agreed with him that few things are more delicious than a dish of properly stewed Catillac. The fruit is best when placed in a syrup in a jar, and covered down, in a not too fierce oven. NORWICH.

STONE VERSUS BRICK WALLS.

MOST gardeners know that the worst form of wall to deal with for fruit growing is one built of stone, particularly limestone. Stone was more extensively used in the construction of walls in country districts in olden days than at the present time. Such walls are very difficult to train trees to, particularly when the trees are fastened by means of the time-honoured shreds and nails, because, the stones being of varying thicknesses, the courses are so irregular that it is well-nigh impossible to make good work in the training. The best way to deal with such walls is to wire them, fixing the wires so that there is just room enough to pass the tying material conveniently round the wire. If this is done, there is but little space between the trees and the face of the wall, and the objection raised by many to the draught caused when the wires are some little distance from the wall is then done away with. Another thing which tells against a stone wall is the fact of its being so much colder than one constructed of brick. Sandstone is not so cold as limestone, it is true, but neither is so suitable nor so capable of absorbing and giving out heat as are bricks. I know a garden where some Peach trees were planted against a stone wall, and in spite of the border being carefully made and the trees receiving every attention afterwards they were a failure, yet when a fresh lot was planted in another part of the garden against a brick wall having exactly the same aspect, they succeeded remarkably well. When dealing with a wall of this description a few years ago I was puzzled to know what to do to render it less cold, not only in appearance but in reality, and after thinking the matter over I decided to colour it. In a large tub a sufficient quantity of lime was slaked to yield enough wash when

diluted with water to wash the face of the wall. Venetian red was then added to render the wash, when dry, the colour of a new brick. This was applied with whitewash brushes, and was well worked into the joints and crannies of the wall, the trees being unloosened for the time being. There was a wonderful improvement in the general health of the trees the first year, and they have since succeeded so well that the wall is now kept coloured. The colouring, if mixed and applied in the manner described, lasts a long time, or only requires to be done about once in every seven years. It is a cheap and effectual way of dealing with cold stone walls when they have to be utilised for the growing of fruit, and if the mixing of the wash is carefully done and not made of too glaring a colour, it greatly adds to their appearance as well as rendering them of greater utility. A. W.

CAPRICIOUS PEARS.

AMATEURS frequently err in planting Pears for which the soil and situation of their gardens are not at all suitable. Happily, there is a good assortment possessing such hardy constitutions, that they can hardly be planted in the wrong place, nor can the soil well be too heavy provided it is not actually stagnant. Glou Morceau is free and fertile enough when its roots are working in a warm loamy compost, but I have found it one of the worst sorts for strong loams resting on a clayey bottom. A neighbour of mine had such a garden lying low, and he could not induce Glou Morceau to do well for long together. The fruit was small, and in wet, sunless seasons much cracked. In my own garden two miles away, and consisting of a light open soil in a somewhat high-lying position, the same Pear grew to perfection. Winter Nelis has similar likes and dislikes, a cold, retentive root-run usually producing undersized, cracked fruit. Some of the best looking and most highly flavoured fruit of this the last-named conditions. In the neighbour's garden referred to Thomson's was a special favourite, but though considerable pains were delicious Pear I have seen were from trees growing in a sandy, not very deep soil. As a rule, the flavour of fruit from such a medium is far superior to that from trees growing in strong soils. The delicious Thomson's is another somewhat capricious variety, and succeeds best under taken with it, it seldom produced fruit of good all-round quality. Sometimes amateurs are induced to plant Beurré Rance, hoping to have ripe Pears in February and March, but unless the root-run is warm and thoroughly well drained and the position either a west or southern one, small, inferior, and often cracked fruit will be the result. Baron de Melo is not at home in all soils, and I confess I have never been able to make much headway with it. Cracking was its chief fault when I grew it as an espalier. It should have a wall and a warm, sweet, well-drained border. It is then a good dessert Pear of handsome russet appearance. Of course, where labour and material are at command much may be done to ensure success with these capricious varieties by raising the border and incorporating therewith a good percentage of light loamy material together with abundance of opening material, such as wood ashes and old mortar or plaster refuse. EAST ANGLIAN.

Keeping late Grapes in winter.—Many gardeners are somewhat handicapped in keeping their late Grapes when cut from the Vines in December or January in order that the latter may be pruned, as they have no proper place for standing the bottles after the bunches are placed in them. I have known gardeners obliged to stand them on boards or brick-kerbs in airy vineries, and although they have kept well enough for a time, partial shrivelling eventually occurred. A plan I once adopted with perfect success was to lay a number of Mangold roots on a fruit room shelf close to the edge, the turned-up portion of the latter keeping the roots in position. The bunches with the usual length of lateral attached were then taken

to the fruit room as cut, the lateral being thrust into the Mangold. Each bunch hung down over the edge of the shelf and could easily be examined for bad berries. The berries remained plump and sound for a considerable time. I once kept some late Plums in the same way until the middle of November. A portion of wood was detached with the Plums hanging on it and thrust into the Mangold.—C. N. N.

Root-pruning.—Excellent advice is given, both by Mr. Prinsep (p. 369) and "A. W., Stoke Edith" (p. 411) on that most necessary operation, root-pruning, without which it is absolutely impossible to keep young and vigorous trees in a fruitful state. This is the more often necessary in land of good depth, and which has a sand or clay bed beneath it. Both are very alluring to tree-roots, and no matter how good or how well cultivated the surface may be, they are sure to find their way into it more or less deeply, unless checked by root-pruning. Much disappointment comes from fruit-tree cultivation if this work is

attention in winter, and, as "A. W." points out, the earlier this is carried out the better. It is best done as soon as the leaves fall, but it is not always convenient then to carry it out, and it is better to do it late in winter than not to do it at all.—W. S.

TREES AND SHRUBS.

TAMARISKS.

(TAMARIX.)

AMONG hardy shrubs the Tamarisks are remarkably distinct in the peculiar feathery character of the growth. No other woody plants we can grow outside are capable of producing quite the same effect as they do, an effect of which some indication is afforded by the accompanying illustration. Of all the shrubs that can be grown close to the sea there is none so useful as

driven into the ground will root pretty much the same as Willows do under similar circumstances. Although often described as semi-evergreen, they are, except possibly in the extreme south and south-west, deciduous, shedding not only the leaves, but the smaller branches as well.

To judge by the number of names that appear in catalogues, one might conclude that there were somewhere about a dozen hardy species in cultivation. As a matter of fact, there appear to be about five true species of Tamarix and one of Myricaria (a very closely allied genus) at present grown here. The Myricaria is often called Tamarix germanica. The leaves of all the species are minute and scale-like and the flowers are produced in small spikes.

T. chinensis is a comparatively new introduction, and has been distributed from some nurseries as **T. japonica plumosa**. It is not quite so

The Tamarisk at Kew. From a photograph by G. Champion.

neglected. With large trees it is by no means a light undertaking. It is useless digging an open trench around the tree unless deep burrowing roots are searched for, and severed immediately beneath the stem. It often happens that a straight tap-root descends directly from the bole of the tree and assumes large dimensions, and, unless this is cut through, no good comes from the pruning of the other roots in checking the excess of vigour. Hard pruning aggravates this tendency, and, if continuously practised, fruit is and may be looked for in vain. Such trees may bear if the vigorous leading shoots are not shortened in the winter, but the head simply thinned to admit the sun. Apples, more particularly the large cooking varieties, keep badly when the trees have their roots deeply embedded in the subsoil, and the size and quality of Pears are not equal to those of those produced from trees whose roots are nearer the surface. Generally in gardens of large or small size in which fruit trees are grown there are found some, if only a very few, that need root

the Tamarisk. Exposed even to the fiercest gales it thrives, provided the winters are not too severe. The common Tamarisk (*T. gallica*) can no doubt be cultivated well to the north of Britain, especially near the sea on the western side, but it is undoubtedly seen at its best in the south-west of England and in localities with similar climatic conditions. I know of no place where it is used so extensively as at Abbotsbury, in Dorsetshire. Here it is not only grouped in various places in the garden, but there is a long avenue of it leading to the house. This avenue was very charming when I saw it in September, but must have been doubly so when in flower a month or two earlier.

Provided they have a deep, moist, not too clayey a soil, the Tamarisks thrive admirably in the south of England, whether near the sea or not. They are very easily propagated by cuttings. Stout stakes cut from *T. gallica* and

hardy as *T. gallica*, although allied to that species. It is the plant that fills the foreground on the right hand side of the illustration. It has very plumose branches, and is the most graceful of these hardy Tamarisks. The flowers are pink.

T. gallica.—This, the common Tamarisk, is found wild on the south-west coast of England, in France, North Africa, &c. It is a shrub 5 feet to 10 feet high, or a small tree 20 feet high. The flowers are pale pink, and borne on short cylindrical spikes in summer. *T. anglica* is one of the numerous forms of this species, which vary in stature and to some extent in hardiness according to the climate of which they are native. *T. africana* and *T. algeriensis* are names that have been given to the African forms of the species. The "Treasury of Botany" gives the following interesting information in regard to this shrub:—

The stems and leaves abound in sulphate of soda, and it produces in Arabia a substance considered by the Bedouins a great dainty, and called by them "mann" or "manna" from its outward resemblance

to the manna of Scripture. In the month of June it drops from the branches upon the fallen twigs and leaves, which always cover the ground beneath the tree, and, being collected and cleaned, is eaten with bread. Some travellers suppose this substance to be not an exudation from the tree, but the produce of an insect that infests the Tamarisk.

T. hispida (syn., *T. kaschgarica*).—According to M. V. Lemoine, of Nancy, who has been distributing this new species during the last few years, it was discovered by Roborowsky in Central Asia. Its introduction to this country is too recent for much to be said as to its value. It is certainly distinct, the foliage being of a very glaucous hue. "The leaves are very small and imbricated on the stem after the fashion of *Veronica lycopodioides*, and its inflorescences are of a rosy carmine, brighter than in the other species in cultivation" (Lemoine). It flowers in autumn.

T. tetrandra is very like *T. gallica* in general appearance, but, as the name implies, it is distinguished by having four instead of five anthers. It is quite hardy, growing and flowering freely near London. The flowers are pinkish white. A native of the Caucasus.

Myricaria germanica is very nearly allied to *Tamarix*, and often figures in nursery catalogues under the latter name. It differs in having ten stamens to each flower. The branches are erect, rather sturdier than in the true *Tamarisks*, and the leaves are of a pale glaucous hue. The flowers are white or rosy and appear in June. It is a native of various parts of Europe and Asia, and, although not wild in Britain, has been in cultivation here for more than 300 years.

W. J. B.

Caryopteris mastacanthus albus.—The typical *Caryopteris mastacanthus*, with its pale blue blossoms, has attracted an unusual amount of attention during the present season, as the hot weather we experienced throughout the summer was particularly favourable for the production of its pretty flowers. Now Messrs. Veitch announce a white-flowered variety, which will doubtless be considerably sought after. The two or three mild winters we have had have been favourable to this *Caryopteris*, as it is not very hardy.—T.

Abutilon vexillarium.—This occurs among the ornamental shrubs of October on p. 402, but it is only in the favoured South Devon climate that it can be looked upon as hardy, though it is certainly less tender than was at one time supposed, for it used to be regarded as a climber for the stove or warm greenhouse. The specimen from which the drawing was made for the coloured plate in *THE GARDEN* (now nearly ten years ago) is still at Kew on the low south wall of the economic house, and though somewhat curtailed to what it was at one time, yet in the middle of November there were many expanded blossoms still upon it. The bright yellow petals of the freshly-opened flowers stood out very conspicuously from the red inflated calyces, thus forming a cheerful picture during a dull autumn day. Considering that this *Abutilon* is a native of Rio, it is strange that it should prove so hardy in this country.—H. P.

Yew tree poisoning.—A case similar to that recorded by Mr. Ryder happened here last year, when a young and valuable horse died from eating but a few shoots that he cropped off a stunted Yew bush growing in a clump of shrubs. In trying to reach the Yew the horse broke the top wire of the fence, but after all it only ate about half a dozen pieces altogether. Death took place soon afterwards—in fact, almost before anyone was aware that the horse was ill. I always make a point of having Yews cut well back every now and then in the shrubberies at the points where there is any likelihood of cattle being able to reach over the fence, and this precautionary measure prevents accidents occurring. There is no antidote to Yew poisoning, but some hold the opinion that if the animal, whatever it may be, is prevented from drinking water for some few hours after eating the Yew it takes no harm, but I cannot verify this.—A. W.

ORCHIDS.

COCHLIODAS.

This is not a large genus and some of the few species included in it are not at all well known, but most of them are extremely pretty plants and often give a welcome bit of colour when little else is in flower. They all belong to the cool section and, like the New Grenadan *Odontoglossums*, are not at all satisfactory unless carefully treated. They are all dwarf pseudo-bulbous epiphytes, and under cultivation are not happy unless the roots have something tangible to take hold of. In the middle of a large pot or basket they are lost and will never be satisfactory, but when the roots are almost crowded in, and each one can reach the sides of whatever the plants are growing in, then they can be freely watered and the plants will be satisfactory. Air and light are very necessary to their well-being, so much so that our long dark winters make their culture very difficult unless the houses are kept clean and the plants well up to the light. In summer when the sun is strong and powerful the conditions must be quite reversed and heavy shading and frequent damping must be allowed. By this means only can the temperature be kept sufficiently low. It is not always easy to do so even with all our care, but let the house be pleasantly cool and the plants be placed in such a position that they get the full advantage of the ventilation, and they will usually thrive. In almost every detail of compost and watering the culture is the same as for the *Odontoglossums* above referred to, and anyone successful with these may take up the culture of *Cochliodas*. The best-known kinds are:—

C. Noezliana, one of the most recently introduced and a showy and pretty species. The flower-spikes are semi-pendulous and many-flowered, the individual blossoms about an inch across, bright orange-scarlet, with a yellow centre to the lip. This was introduced to this country by Messrs. Charlesworth and Co. in 1891.

C. rosea is often labelled *Odontoglossum roseum* and bears shorter racemes of smaller blossoms, the colour being a bright rosy carmine. It is not a good grower, and though discovered by Hartweg in Peru as far back as 1840 it was not introduced to this country until 1866, when it was imported by Messrs. Backhouse and Co. The same firm was instrumental in the introduction of

C. sanguinea, a showy and useful species that is not so common in Orchid collections as it used to be. The longer racemes of flowers are of a delicate rosy pink shade.

C. vulcanica is one of the best, and has shining rose-coloured flowers produced on racemes about a foot in length. It is a native of Ecuador, long known to botanists, but only introduced to British gardens in 1872.

H. R.

Cymbidium Traceyanum.—About the beauty of this Orchid there can be no question, and it is now getting quite plentiful and cheap, so it is bound in time to take its place as a popular kind. I recently noted an immense plant of it imported as *C. Lowianum*, of which the owner was naturally not a little proud. Its culture is equally as easy as that of *C. Lowianum*, and the roots delight in a substantial compost of loam, peat fibre and Sphagnum in about equal proportions. The plants should be given ample room in the pots and be grown in a cool, moist and shady house, this suiting them much better than a strong heat. Although the flowers are large and lasting, no harm accrues to the plants by their being allowed to remain, always provided the latter are healthy and well established.

Phaius grandifolius.—This, often grown in places where no Orchid collection, as usu-

ally understood, exists, thrives quite well in an ordinary plant stove. The earliest plants are now in flower; indeed, it is in bloom more or less for half the year at least where a number of plants are grown. On strong plants the spikes are over a yard high and the individual flowers are 4 inches across, white externally, reddish-brown within. Good fibrous loam with its equal bulk in peat and a little chopped Sphagnum make a good compost, a liberal sprinkling of crock dust and finely-broken charcoal being added, as well as some rough lumps, to ensure aeration of the bulk. A stove temperature all the year round and plenty of atmospheric moisture are necessary, and the young growths should be thinned a little when the plants are starting.

Zygopetalum Mackayi.—The large and sweetly-scented blossoms of this species look very pretty when associated with those of *Calanthe Veitchi*, and both, being easily-grown, free-flowering kinds, may be had in quantity for a mid-winter display. The plant likes plenty of root room and a substantial compost in which good fibrous loam forms a part, this being more lasting than peat-fibre, and therefore requiring less frequent renewal. As the roots of this species greatly dislike being disturbed, this is a very marked advantage, and the vigour of the specimens is kept up by top-dressing and ample moisture supplies. As the spikes usually appear in the forming bulbs, no distinct resting season can be arranged, but there is usually a little steadying up after the bulbs are complete. Fine specimens of this Orchid with a dozen or more spikes of flowers make a magnificent show at this dull time of year.

Ornithocephalus grandiflorus.—This, the only species in the genus in general cultivation, is an extremely pretty Orchid, bearing arching, many-flowered spikes of yellowish flowers of very peculiar formation. The habit of the plant is a fair guide as to its requirements under cultivation, most dwarf plants like it preferring a light position and not too large a rooting space. Small wood baskets suspended from the roof of a house kept at a rather higher temperature than the cool house suit it well, and as the plant has very small pseudo-bulbs in comparison to its size, the water supply should be kept going more or less all the year round, a slightly drier atmosphere usually sufficing for the resting season. The roots are not particularly strong, so it is necessary to keep the compost fairly thin and the opening material should be in small rather than large lumps.

Cattleya citrina.—It is not often this pretty species is seen in flower at this time of year, but I noted a nice plant of it during the week. The flowers and habit of *C. citrina* are so distinct from those of all other *Cattleyas* that anyone unacquainted with it would have a difficulty in saying to what genus it belonged. It is a delightful plant, and the pity is that so few can be said to be really successful in its culture. In the *Cattleya* house under similar conditions to the *labiata* and other forms it would not be a success, and its natural habit of growing apparently upside down must be respected and provided for. The temperature of the cool house suits it best, and the likeliest method to grow it successfully is to place it on rather bare trellised rafts, with the points of the growths looking downwards, this being evidently a natural means of protection to the centres of the young growths from damp. *C. citrina* usually begins to grow when other Orchids are resting, so that from the time the flowers are past in summer until the growth is again on the move the plants ought to be kept rather on the dry side. New, sweet material should as often as necessary be packed around the bulbs without disturbing the roots, equal parts of peat fibre and Sphagnum Moss being suitable.—H. R.

NOTES AND QUESTIONS.—ORCHIDS.

Cœlogyne speciosa.—This is one of the most distinct *Cœlogyne*s and a very interesting and beautiful plant. The flowers occur a few together, and are

remarkable for the beautiful crest on the lip. They are large, and light brown on the sepals and petals. The plants should be allowed more warmth and atmospheric moisture than most of the *Colognes*, thriving well in a full Cattleya temperature with plenty of moisture all the year round. It is a native of Java, where it grows at a considerable elevation.

Oncidium sarcodes.—I have received a fine form of this from "C. C." for a name. It is one of the best of the yellow *Oncidiums*, bearing fine pendent or horizontal spikes, the ground colour of the blossoms a bright shining yellow overlaid with deep chestnut markings. It is very free-flowering, and a useful kind deserving of all attention. It does well in baskets or pans in an intermediate house suspended from the roof, the compost consisting of equal parts of peat fibre and Sphagnum. Water must be plentifully supplied as long as root action is brisk.—H. R.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

THE meeting on Tuesday last was held under most disadvantageous conditions, thoroughly typical of London weather at this season of the year. The hall, never too bright and cheerful, was on this occasion dull in the extreme. Why such dreary colours are allowed to preponderate in such a building is quite inexplicable. Instead of dark colours predominating, they should be light, bright, and clear. This, of course, is not under the management or control of the Royal Horticultural Society; if it were so, no time would be lost by the executive in remedying the present dismal appearance of the building.

The show itself was an exceedingly bright and effective one, being only marred by the surroundings already alluded to. As might be expected, the exhibits placed before the floral exceeded those of the two other committees. *Chrysanthemums*, as a matter of course, were conspicuous. Of these, a thoroughly representative collection, strong in singles and small flowers of the decorative Japanese section, with not a few excellent examples of the large-flowered varieties, came from Earlswood. A fine selection of singles also came from Altrincham, making a brave show. A well-grown and profusely flowered group of the best kinds of *Bouvardias*, the plants dwarf and sturdy, came from Tunbridge Wells. From Chelsea came a splendid box of the javanic *Jasminiflorum* hybrid *Rhododendrons*; these were most varied in colour, whilst the trusses were large. These are grand flowering plants for the temperate house at this season of the year, whilst their value within the fog radius is also a strong recommendation. A large group of coniferous plants, several of which had been grown within the suburban area, came from Richmond. These, if not so highly coloured or bright as those grown further afield, are, however, the best to choose for smoky districts, being already inured to it. *Begonias*, chiefly *Gloire de Lorraine*, came from two sources, both north and south of the metropolis. This variety beyond any question is of the utmost value for winter decoration. A large and varied group of *Yuccas*, remarkable alike for variety and sturdy growth, was also noted. The Orchid committee had before them several plants of interest, notably the superb exhibit of *Calanthe* hybrids, most varied and in brilliant colouring, from the Burford Lodge collection. Some excellent examples of *Oncidiums* came from Brussels, the individual blossoms being of unusual size. A few capital hybrid *Cypripediums* were also exhibited, to one of which a first-class certificate was awarded, which of itself is sufficient evidence of its value.

The labours of the fruit committee were not in any sense laborious. Of *Tomatoes*, some very finely grown examples came from Reading, better than which no one could possibly desire even in the summer season, being well coloured and of good average size. Neither *Apples* nor *Pears* were in strong force by any means, but of *Grapes* there were some well-finished examples both black and white. At this season of the year it

would not be at all an inappropriate innovation if some well-trained examples of fruit trees were sent to these meetings with a lecture upon the various methods of training in force in this country and upon the Continent too.

Orchid Committee.

First-class certificates were awarded to the following:—

CYPRIPEDIUM HERA VAR. EURYADES.—The top part of the dorsal sepal is white suffused with deep purple, the central portion covered with large rich purple spots with some smaller ones towards the margin. At the base the spottings are deep brown; the petals are pale green, suffused with brown at the top, spotted on the lower half; the lip deep brown, shading to greenish-yellow. This had previously received an award of merit as *C. Euryades*. It has wonderfully improved. From Sir Trevor Lawrence, Burford, Dorset.

CATLEYA MAGGIE RAPHAEL (C. aurea × C. Trianae).—The petals are pale yellow with some tracings of purple on the outer edges, the sepals deep yellow, suffused with reddish-purple over the whole surface. The front lobe of the lip is bright purple suffused with crimson-purple through the centre area and the throat, through which there are tracings of yellow lines. It is a distinct hybrid, having the intermediate characteristics of both parents in the flower and habit of growth. From Mr. H. S. Leon, Bletchley Park, Bletchley, by whose gardener, Mr. Hislop, it was raised.

Awards of merit were adjudged to the following:—

SOPHRO CATLEYA CHAMBERLAINIANA (Sophronitis grandiflora × C. Harrisonia).—In this the sepals and petals are deep scarlet-crimson, veined with a tinge of purple; the front lobe and outer margins scarlet, mottled with yellow, the whole of the base yellow. The shape of the lip is that of the *Sophonitis* parent much enlarged, and it is here it differs from *S. C. Calypso*. From the Rt. Hon. J. Chamberlain, by whom it was raised.

ONCIDIUM FORBESI MOORTBEEKIENSE.—This is a large form of the type, the flowers being 3 inches in diameter and beautifully round in form. The yellow mottling on the margin was in striking contrast to the deep brown of the other portions of the segments. A plant with a thirteen-flowered raceme came from Messrs. Linden, Brussels.

ONCIDIUM VARICOSUM LINDENI.—This is a pretty form of this well-known species. The flowers were smaller than in the variety *O. v. Rogersi*, but the blotch on the disc was larger and of a deep reddish brown, covering the central area. From Messrs. Linden.

CYMBIDIUM LONGIFOLIUM.—The flowers have the intermediate characters between *C. cyperifolium*, *C. Traceyanum*, *C. grandiflorum*, and others of this section. The petals are pale green, longitudinally lined with deep brown; the lip white, with a few brown spots and a line in the centre; the side lobes veined with reddish brown. The cut spike carried eleven flowers. From Mr. J. S. Moss, Winter's Hill, Bishop's Waltham.

Sir T. Lawrence sent a large group, the most prominent feature being the fine display of the deciduous section of *Calanthes*. The best varieties among these were *C. Veitchi splendens*, a grand form with rich rose-purple segments and a large white eye on the disc. This was in striking contrast to the white variety, *C. V. lactea*. Another dark variety was the lovely *C. burfordensis*, distinct both in colour and the shape of the flowers from the *Veitchi* section. *C. Victoria Regina* is a fine variety with white and pale rose flowers. These contrasted well arranged between the dark forms. *C. bella* has deep rose flowers, with a white band around the dark purple disc. In *C. versicolor* the sepals and petals are pure white, the lip white, suffused with rosy pink in front of the bright yellow disc. *C. Bryan* with its white flowers stained with deep crimson on the disc is a bold form, remarkably free in habit. *C. revertans* is a dark form of the *C. Veitchi* section. *C. Clive* is a dark variety, with a white disc on the lip. *C. wylamensis* is a white form, with a small purple disc. *C. nivea* has pure white

flowers, except the yellow on the disc. *C. amabilis* is a beautiful pale lilac form with compact spikes. Other *Orchids* included were a finely grown plant of *Cypripedium Spicerianum* carrying fifteen flowers. The lovely dark *Cypripedium Statterianum (C. vexillarium × C. Spicerianum)* was also included; also a well-grown plant of *C. Fowlerianum*, differing from the original form, and more nearly resembling *C. Chapmani*. The lovely *Dendrobium cymbidioides*, with its raceme of white and brown flowers, was well represented. *Vanda Sanderiana* was shown in a cut spike of ten highly coloured flowers. *Odontoglossum blandum* was well represented by two racemes of flower. *Oncidium cuculatum*, *Masdevallia hieroglyphica*, *Cirrhopetalum Lowi*, and other botanical *Orchids* were included. A silver Flora medal was awarded. Mr. J. S. Moss sent a cut spike of one of the darkest forms of *Cymbidium Traceyanum* we have seen. Mr. J. W. Thornton showed a pretty form of *Cattleya Euphrasia*, the sepals and petals pale lilac, the whole of the front lobe and margins of the side lobes rich crimson-purple with prominent white and yellow veins through the throat. Mr. R. J. Measures sent a variety of *Cypripedium Leeanum* of the *C. L. giganteum* section with seven flowers. Mr. H. F. Leon showed *Cattleya Preciosa* var. *Hislopi*, the sepals and petals pale lilac, the front lobe of the lip rosy lilac, mottled and suffused with deep crimson. The white and purple lines characteristic of the *C. Luddemanniana* parent are very pronounced in the throat. The Rt. Hon. J. Chamberlain sent *Cattleya Mrs. Endicott (C. Loddigesi × C. maxima)*, the lip having the veinings of *C. maxima* with some yellow at the base, with the intermediate characters of the two parents in the habit of growth. The Hon. Mrs. Albert Brassey sent six finely grown plants of *Calanthe Veitchi* and three plants each of the lovely *Calanthe vestita rubra* and *C. v. r. luteo-oculata*, the whole showing good culture. Mr. Leopold de Rothschild, Gunnersbury House, showed three cut flowers of the white *C. Harrisonia candida*.

L'Horticole Coloniale, Ltd., Brussels, showed in addition to the form certificated five other varieties of *Oncidium Forbesi* and *O. varicosum Rogersi*, very poorly coloured on the disc. Mr. J. McBean, Cooksbridge, sent a very finely spotted yellow ground form of *Odontoglossum Andersonianum*. Mr. H. A. Tracy sent a pale, but large-flowered variety of *Cymbidium Traceyanum*. M. C. Vuylsteke, Ghent, had two of his hybrid *Odontoglossums*, *O. crispum-Harryanum* and *O. Harryano-crispum*, which had been previously certificated. They partake of the intermediate characteristics of the parent species, from which the names are derived, both in growth and also in the flowers. Messrs. J. Veitch and Sons sent a good form of *Cypripedium Minos*, a beautiful secondary hybrid, in which the influence of *C. Fairrieanum* can be plainly discerned. Messrs. F. Sander and Co. sent a small group consisting principally of *Orchids* of botanical interest and a few hybrids. *Phalaenopsis Sanderiana*, with its deep rose flowers, was very attractive. A good plant of *Cattleya exoniensis* with two flowers and *Lelio-Cattleya Wilsonia*, the sepals and petals deep rose, the front lobe of the lip rich crimson-purple, with the purple lines through the throat, were also shown.

At the commencement of the business of the Orchid committee, the chairman (Mr. H. J. Veitch) drew the attention of the members to the sad loss the committee had sustained in the death of Mr. W. H. Protheroe (head of the firm of Messrs. Protheroe and Morris), Mr. Veitch pointing out the many useful services Mr. Protheroe had rendered to horticulture in general and also to the genial and kind-hearted manner always so readily displayed, and which endeared him to all who were brought into contact with him. Mr. Veitch also pointed out that this is the third loss the Orchid committee had sustained within the last few months—Major Mason, Mr. Sidney Courtauld and Mr. Protheroe. So sad an experience was without parallel since the Orchid com-

mittee had been established. It was decided that a vote of sympathy and condolence should be conveyed to the widow and family of the deceased.

Floral Committee.

The following received the award of merit:—

CHRYSANTHEMUM OSCAR.—This is a single-flowered variety with somewhat short, firm, and sturdy petals, the colour a bronzy orange-red. From Messrs. W. Clibran and Sons, Altrincham, Cheshire.

CHRYSANTHEMUM MME. R. CADBURY.—Notwithstanding pure white kinds are now numerous, this latest addition will be warmly welcomed. It is quite snow-white, the blossoms as a whole exceedingly full, the florets in their imbricate character drooping over each other from a slightly flat summit. The purity, the great substance of the florets generally, and strong, self-supporting peduncle are noteworthy. From Mr. H. Weeks, Thrumpton Hall, Derby.

Wretched weather and counter attractions elsewhere notwithstanding, the Drill Hall contained quite a good representative display on this occasion, among these a capital assortment of well-grown shrubs from Mr. John Russell, Richmond, occupying the floor in the centre of the hall. Of sombre hue generally, the greater sombreness of the surroundings and, not least, the ever-present fog prevented these being seen to advantage. In the way they were arranged, however, it was possible to see every one. The examples were also of good size, compact and well grown, particularly so if the plants had been grown as shown and to their present dimensions at Richmond. This much, which was not stated, is of importance to planters of such things, because it reveals what may be accomplished in a district naturally low and suffering from fog and smoke. Some of the most noticeable were the various forms of *Retinospora*, *R. filifera*, *R. plumosa*, *R. pisifera*, *R. squarrosa*, and the golden forms also of the two middle sorts. *Taxus Dovastoni aurea pendula*, *T. baccata erecta picta*, *T. fastigiata aurea* were in nice plants, and *Picea Parryana glauca* showed well its fine character. *Juniperus japonica aurea* and *J. sinensis aurea* were as usual very pleasing, while the varying *Cypresses* were not least in adding their value to the whole group. From the same source came a fine lot of *Yuccas*, medium and small-sized plants being mostly shown. These included *Y. aloifolia variegata*, *Y. flaccida*, *Y. stricta*, *Y. elegantissima variegata*, *Y. plicata* and *Y. monstrosa*, the last bearing a strong resemblance to *Y. gloriosa glauca*, a very fine and by no means common plant. These *Yuccas* attracted a good deal of notice, due largely to their rare appearance at these meetings. A silver-gilt Flora medal was awarded. The Messrs. B. S. Williams and Son, Upper Holloway, and J. Peed and Sons, Roupell Park Nurseries, each had a group of the well-known *Begonia Gloire de Lorraine*, the plants in the former being fine bushes smothered with buds and blossoms, though it was evident the great enemy, fog, had visited them. The plants from Messrs. Peed and Sons were of varying sizes, much smaller than in the previous lot, and had escaped the bad influences of the fog. Small Ferns were used among the plants generally. A group of *Cyclamen* from Messrs. Low and Co., Enfield, occupying two sides of a table at one end, attracted some attention by the size and vigour as well as the freedom of flowering. Some pure white kinds were very charming, the segments being of more than usual length. The feathered strain was also in evidence, and likewise those with fimbriated margin. The palm for beauty, however, is still retained by the best forms of the typical *Cyclamen*. There were at least two hundred—probably many more—of these plants, and these had but just started on their season of flowering, scores of buds being visible just under cover of the thick leathery leafage. This alone is a token of good culture (silver Flora medal). Messrs. Clibran and Sons, Altrincham, Cheshire, had another extensive array of single *Chrysanthemums*, the colours

being much varied. Of these it is not to be expected with the few florets comprising a bloom that they travel well, and for this reason the best side can scarcely be seen after a long journey. As a whole, however, they were showy and pretty in some instances. The following are some of the more distinct: Mrs. Norris, yellow, very nice shade; Nora Davies, a single Source d'Or so far as colour alone is concerned; Oldfield Surprise, white; and Oldfield Gem, orange. Lord Methuen we consider identical with Earlswood Beauty, a fine pure white that gained honours a year ago. It is a very pure flower, and possibly the largest white single yet raised. Amy Fletcher, white, and very free, but not so good in form nor so exceedingly pure as Earlswood Beauty; Mrs. E. Coward, pale orange; Lady Paget, white, tinted rose; and Miss Mabel Pennington, a pretty pink shade, were also included. Silver Banksian medal was awarded. Mr. W. Wells, Redhill, Surrey, also had a group of *Chrysanthemums* in variety, but which would have been better for much more space. Several kinds in this lot were of undoubted merit. Admiral Sir J. T. Symonds, yellow, and nearly single, a very fine mass of bloom, is an invaluable variety for home decoration; Hairy Wonder, very fine; Robert Laird, white; Francois Pilon, a rich yellow Japanese; R. Hooper Pearson, M. Fatzer, a good light yellow; Earlswood Beauty, single white; Mrs. C. Bown, white, with greenish centre, a good decorative sort; Purity, a fine single white; Framfield Beauty, rich crimson; Labrier, a late-flowering white, broad petals; Mrs. A. E. Stubbs, single white, very pure; Golden Star, soft yellow single; Mr. E. G. Whittle, a rosy pink shade, very pretty and distinct; Toorong, a kind not unlike Globe d'Or, of a crimson-red shade with a pale gold reverse, are but a few in this group taken at random. Others of the spidery section, many good singles, and some excellent blooms of Japanese as well as the Japanese incurved, were also shown. The table was flanked right and left with pot-grown groups of the plants as well (silver Banksian medal). Of more than ordinary interest, and certainly of more than ordinary merit, was the group of *Bouvardias* in pots from Messrs. Cripps and Son, Tunbridge Wells. It cannot, however, be said that the plants occupied a good position, for the floor of the Drill Hall on a dark and dull December day is the least suited to a group of dwarf-flowering pot plants of such as *Bouvardias*. It is not clear either, with so much tabling to spare, why the tables rather than the floor space were not occupied. The plants certainly were well grown for the size of pots, namely, 5-inch, and well flowered, yet we think their merit was not determinable in such a position. The same plants on a table, opened out by small Ferns occupying the interstices, would have revealed the clean and healthy examples they were, and generally have created no mean impression of their importance. Most of the leading varieties, single and double, were shown, the plants bushy, sturdily grown, and abundantly flowered. A bronze Banksian medal was awarded. The Messrs. Veitch and Sons, Ltd., Chelsea, staged a nice assortment of their hybrid *Rhododendrons*, in which some good colours are seen. The yellow sport from *Chrysanthemum Western King*, which is named Genl. Sir W. P. Symons, was shown by Messrs. F. Robin and Son, Guernsey. The blooms sent were rather small, due probably to an attack of the so-called rust, the colour being the most pale of all yellows—indeed, rather a cream than a yellow. A so-called sport of *Chrysanthemum* from Mr. J. Riddell, gardener to Mr. E. J. Johnstone, Rougham Hall, Bury St. Edmunds, appears to be identical in all ways with Mr. E. G. Whittle, an American variety received a year or two back. As no parent was given of the sport it is possible an error has been made somewhere. A very beautiful lot of double *Violet Marie Louise* in bunches came from Lady Ashburton, The Grange, Alresford, Hants (Mr. D. Allen, gardener), and received a cultural commendation; the colour was very

fine and the blossoms large also. Some two dozen ample bunches of these ever-popular flowers received a good deal of attention.

Fruit Committee.

The exhibits before this body were unusually few. The chief one was a collection of three varieties of Grapes, four bunches of each, two being shown on hoards and two on plates in front. The varieties were Mrs. Pearson, very good for that variety; Black Alicante, fair clusters; and very good Gros Colman. A few small *Cocos Weddelliana* were used to dress the collection. This came from Mr. J. Ryder, gardener to the Countess of Limerick, Hawkswick, St. Albans. A small silver medal was awarded. Mr. Notcutt, of Woodbridge, sent a good dish of his stewing Pear, Winter Orange, which received an award of merit in March last. In relation to this Pear and the handsome stewing Pear Double de Guerre, to which an award of merit was made at the previous meeting, Mr. Crowley, the chairman of the committee, who was requested to have both Pears stewed, reported that he had found Winter Orange to be rather gritty and lacking in flavour, whilst the fruits of Double de Guerre had soft, smooth flesh and better flavoured. A good-sized round seedling Apple named King of the Hollow came from Mr. F. M. Bradley, Peterborough. The fruits bore some resemblance to those of Wellington, but the eye was less open. The flesh was soft, but lacked both acidity and flavour. A small conical Apple of no merit sent for name by Mr. Giles, of Reading, was pronounced the Lady's Finger, or a seedling of similar appearance. Messrs. Sutton and Sons, Reading, sent three boxes of gathered fruits of the new Tomato Winter Beauty. Each box contained thirty-five fruits, all of good colour and well ripened. The fruits are at this time of the year rather flatter than in the spring, and, of course, are not quite so large, but are quite devoid of corrugation. A plant 3 feet in height in good fruit, the latest on the clusters promising to be ripe at the end of January, was also shown. This was of the same batch as those from which the fruits were gathered, and was from seed sown at the end of July last. The committee desired to see fruits, if possible, both in January and February, that the winter-cropping qualities of the variety might be fully tested. From the society's gardens, Chiswick, came two bundles of Salsafy roots and tops. These were from a sowing made last spring in the usual way. The varieties were the ordinary (the roots large and a good deal forked), the other, Mammoth, having, oddly enough, roots less in size, but straighter and cleaner, presenting an admirable stock. The seed had been supplied by Messrs. Watkins and Simpson, Tavistock Street, Strand.

NATIONAL CHRYSANTHEMUM SOCIETY.

DECEMBER 5, 6, 7.

THE last of the present season's series of shows of this society was held in the Royal Aquarium, Westminster, on the above dates. The competition in most classes was all that could be desired. When viewed from its value as a means of bringing into prominence sorts specially adapted for late display, the present effort cannot be considered a success. A careful survey of the whole of the exhibits showed without a doubt that many of the blooms, bright, pleasing and varied though they were, were varieties similar to those shown a month earlier, and in the present case somewhat out of character. The trade displays and one specially fine group of miscellaneous flowering and fine-foliaged plants, arranged in a most artistic manner on the floor of the building, contributed largely to the success of the last of the 1899 series of shows. There were in all twenty-four classes for competition of a varied kind.

OPEN CLASSES.

The leading class for twenty-four Japanese *Chrysanthemums*, not less than eighteen varieties and not more than two of a variety, was contested

by no less than six exhibitors. Those gaining premier honours came from Mr. R. Kenyon, gardener to Mr. A. F. Hills, Monkshaws, Woodford Green, Essex, who had a good all-round lot of flowers, and some particularly good. The best were Julia Scaramanga, a large flower of a bright bronze colour, somewhat uncertain; Joseph Chamberlain, rich crimson; Mons. Chenon de Leche, exhibited in varying colours; Mlle. Gabrielle Dabrie, a lovely Malmaison-pink colour; Mrs. Barkley, the new bright rosy mauve Japanese; Helen Shrimpton, a new rosy crimson with erect petals; Rivers H. Langton, the new yellow sport from Mrs. W. H. Lees; Matthew Hodgson, an invaluable bright reddish crimson flower; Nellie Pockett and Mrs. Geo. Carpenter. Second prize was won by Mr. D. Williams, gardener to the Earl of Faversham, Duncombe Park, Helmsley, York, who had a very bright clean lot of blooms. Only one lot of blooms was set up in the class for twenty-four bunches of Chrysanthemums, any varieties, in which pompons were allowed. We noticed nice flowers of Phœbus, Mme. Carnot, Julia Scaramanga, Mrs. Mease, Caas, Davis, and Graphic. This exhibit contained several bright and pretty flowers of clear and rich colour, but they were badly arranged and the varieties unnamed. This came from Mr. Henry Perkins, gardener to the Honble. W. F. D. Smith, M.P., Greenlands, Henley-on-Thames. No less than five entrants were found in the class for twelve Japanese, distinct, the leading stand containing a fine lot of blooms for so late in the season, and they also were represented by a nice array of colour. This came from Mr. R. C. Notcutt, Broughton Road Nursery, Ipswich, his blooms claiming notice being G. J. Warren, Amiral Avellan, General Roberts, Master H. Tucker, President Bevan, and an example of Mrs. Mease, the primrose sport from Mme. Carnot, but in the present case almost white. Second honours fell to Mr. J. Sandford, gardener to Mr. G. W. Wright-Ingle, North Finchley, N., who had smaller, but clean and pretty blossoms. Mrs. G. W. Palmer, Julia Scaramanga and Mme. Carnot call for notice. The flowers in the class for six blooms Japanese, distinct, were pleasing, those staged by Mr. Henry Perkins being placed first. They included Mary Molyneux, G. J. Warren, and Mrs. Mease. Mr. R. Kenyon was a capital second, the new yellow J. R. Upton, Mrs. Barkley, and Surpasse Amiral standing out conspicuously. The incurred blooms were good, the only class for twelve blooms in not less than six varieties, and not more than two of a variety, bringing out five stands, making a pleasing contrast to the Japanese flowers. A good first was found in Mr. F. King, gardener to Mr. A. F. Perkins, Oak Dene, Holmwood, Surrey, who had a nice lot of blooms for so late in the season, including Miss Phyllis Fowler, a pretty pale yellow; Louisa D. Black, a deeper yellow; The Egyptian, a massive mahogany-coloured flower; C. B. Whitnal, and Bonnie Dundee, orange, shaded rosy bronze. Second prize was awarded to Mr. Thomas Robinson, gardener to Mrs. Lawrence, Elsfeld House, Sittingbourne, whose blooms of King of Orange, Bonnie Dundee, Mlle. Lucie Faure, and Countess of Warwick were conspicuous. The four entries in the class for twelve bunches Japanese, three blooms of a variety in each bunch, made a pleasing display. In this case Mr. Kenyon was again to the fore, showing large blooms of good form and colour, Matthew Hodgson being remarkable for colour. Mr. R. C. Notcutt was second with smaller, though neat and pretty flowers of good colour, Beauty of Thrumpton, a pretty rosy purple; Snowdon, a white with notched petals; Golden Gate, Mrs. Maling Grant, Matthew Hodgson, and Le Grand Dragon calling for notice. The four competitors staging six bunches Japanese made a welcome display. In this case Mr. Perkins was first, and again his exhibit was unnamed. He had, however, good blooms of G. J. Warren, Julia Scaramanga, Mme. Carnot, and Golden Gate, making a bold exhibit. Second honours fell to Mr. J.

Tullett, gardener to Mr. G. Alexander, Warley Lodge, Brentwood, Essex, whose bunches of Vivand Morel, Graphic, and Julia Scaramanga were deserving notice. The singles were charming. The class for six bunches of large-flowered single varieties, six trusses only of one variety in a bunch, not disbudded and distinct, made a very pretty display set up, as they were, loosely in jasper vases. This is a decided improvement on the old method of arranging these in trebles on boards. Mr. J. Tullett was first, showing Effie, Victoria, a lovely creamy primrose; Purity, Miss Brown, Earlswood Glory, and Rudbeckia. Second prize was awarded to Mr. G. W. Forbes, gardener to Mme. Nicols, Regent House, Surbiton. His blooms of Earlswood Beauty, Yellow Giant, John Arters, and Earlswood Glory were excellent. For six bunches small-flowered single varieties there were three exhibitors, and arranged in vases their decorative value was most pronounced. Mr. Tullett again led in this class, showing freely grown, undisbudded sprays of Mrs. D. B. Crane, Nelly, Nora, Mary Anderson, Guernsey Sunset, and Magenta. Mr. G. W. Forbes again followed, his vases of Mrs. Mist (splendid rich colour), Mary Anderson, and Florrie (deep cerise-pink) calling for special mention. A new class for six bunches of decorative, spidery, thread-petalled, plumed, &c., Chrysanthemums in not less than three varieties was represented by one collection only. This was a pretty exhibit, and came from Mr. W. C. Pagram, gardener to Mr. J. Courtenay, The Whins, Weybridge, Surrey. His varieties were King of Plumes, deep yellow, with notched florets; Sam Caswell, a deep pink, with thread-like petals; Mrs. Carter, lovely primrose-yellow, the best of the thread-petalled sorts; Jitsujetui, pink and white, thread-petalled; Cheveux d'Or, golden yellow, and Houpe Fleuri. The decorative exhibits were fairly numerous, and contributed in no mean measure to the interest of the meeting. For a large vase of Chrysanthemums arranged with any kind of foliage, grasses, or berries there were five exhibitors, and these were displayed on a table by themselves. A vase of somewhat poor artistic design, in which the blooms, &c., were very indifferently disposed, secured first prize for Miss C. B. Cole, The Vineyard, Feltham. A superb vase, undoubtedly meriting leading honours, was placed second. This came from Miss Easterbrook, The Briars, Fawkham, Kent, who used freely-grown sprays of Mrs. Filkins, Snowdrop and Primrose League, small-flowered pompons, also using in the most appropriate manner Asparagus with the brightest green tints. The hand-basket of natural autumn berries and foliage was a welcome change. In this case Miss Cole was again placed first, with a very pretty basket arranged in the lightest possible manner. Miss Easterbrook was again placed second, with a basket of berries of a most representative character. The wealth of berries in this case was nothing short of remarkable, and these were deftly associated with foliage, &c., giving a beautiful finish to the whole. The feathery heads of the Traveler's Joy entwined around the handle were distinctly pretty.

AMATEUR CLASSES.—DIVISION A.

There were but two competitors in the class for twelve Japanese blooms distinct, the prizes in this case being offered by Mr. C. W. Richardson and confined to single-handed gardeners. Mr. C. W. Perrin, gardener to the donor of the prizes, Sawbridgeworth, Herts, was placed first for a very nice board of blooms. Simplicity, Graphic, Etoile de Lyon, still a useful flower late in the season; Julia Scaramanga, Australie, Silver King, a coarse flower even at its best; and G. C. Schwabe call for notice. Second prize was awarded to Mr. A. Hoonery, gardener to Mr. G. H. Cox, The Grange, East Barnet, who had smaller blooms and poorer in quality. Mr. W. Perrin again led for twelve Japanese distinct, but in this case with blooms of poorer quality. Graphic was exceptionally good, and others deserving mention were General Roberts, Etoile de Lyon, Joseph Chamberlain, Silver King, and

G. C. Schwabe. Second prize was awarded Mr. Henry Love, 1, Melville Terrace, Sandown, Isle of Wight, for a stand showing a distinct falling off. No less than six entrants for six Japanese blooms distinct were forthcoming. Mr. Pearson was again first with large, clean, and neat flowers, Silver King, Etoile de Lyon, and Graphic being in good form. Second place was awarded Mr. E. Ryman, gardener to Mr. C. Sopper, South Park, Reigate, Surpasse Amiral, Master H. Tucker, and Vivand Morel serving him well. For a large vase of Chrysanthemums, arranged with any kind of foliage and berries, &c., the five competitors made a brave show. A really handsome arrangement of Japanese and incurred flowers associated prettily with Eulalia fronds and Asparagus secured first prize for Mr. H. Pestell, gardener to Mr. F. S. Wigram, Elston, Bedford. There was a blemish, however, in this vase; on one side the finish had been neglected, showing painted-green stick supports. A pleasing combination secured second honours for Mr. F. Bush, gardener to Mr. W. T. Lister, Rose Hill, Totteridge, Herts, who had a large deep blue vase of Japanese flowers, making an artistic combination, sprays of Asparagus Sprengeri giving a neat finish.

AMATEUR CLASSES.—DIVISION B.

These classes were well contested. Six entries for six Japanese blooms, not less than four varieties, found Mr. W. G. Prudden Clark, York Road, Hitchin, leading. His blooms of Vivand Morel, C. W. Richardson, Mrs. Mease and a richly coloured bloom of Charles Davis were his best. Mr. F. Durant, Ware, Herts, was second, a good bloom of General Roberts standing out conspicuously. For six bunches of any varieties, out of five competitors Mr. G. C. Farmer, Leeds Abbey, Maidstone, was first, nice bunches of Mons. Chenon de Leche, Le Grand Dragon and Mme. Carnot being noticeable. Mr. W. G. P. Clark was second, Etoile de Lyon serving him well. There was a goodly array of vases in the competition for one large vase of Chrysanthemums. A pretty little vase of medium-sized flowers exhibiting a nice blending of colours and bright green foliage placed Mr. Clark first. A more noble and handsome vase of flowers secured second position for Mr. A. Taylor, 5, Vernon Terrace, East Finchley. The decorative effect was spoilt by the too free use of foliage of too deep a shade of green. For miscellaneous plants there were three classes, but in one instance only was an exhibitor forthcoming. The prizes were good and should have been sufficiently tempting even so late as the present. For a collection of flowering plants, arranged with small Ferns on a table 9 feet by 6 feet, a very beautiful display secured first prize for Mr. David Gibson, gardener to Mr. B. Johnstone, Coombe Cottage, Kingston-on-Thames. In the centre was a huge cone-shaped mound of winter-flowering Begonias, interspersed with Roman Hyacinths. The base of the table was pleasingly arranged with Cyrtipediums and other Orchids in variety, Primulas, Cyclamens, Carnations, Chrysanthemums, Roman Hyacinths, &c., finished with small Cocos Weddelliana and Ferns.

MISCELLANEOUS EXHIBITS.

As usual at this season, these exhibits were numerous. One of the special features of the show was a very large group arranged on the floor of the building, containing Chrysanthemums, Cyclamens of high quality, winter-flowering Begonias, Roman Hyacinths, Calla æthiopica, Heaths, Orchids, superb Poinsettias, each of these arranged in an undulating manner and charmingly set off with Crotons in variety, beautiful examples of Dracena Sanderi, Cocos Weddelliana, and other fine-foliaged plants. An irregular and pleasing front edging of Moss and Panicum variegatum made up a magnificent exhibit which left nothing to be desired, and reflected the highest credit on the exhibitor, Mr. John Fleming, gardener to Sir H. Pigott, Bart., Wexham Park, Slough, Berks, to whom a gold medal was awarded. Gold medals were also

awarded to Mr. Norman Davis, Framfield, Sussex, and Mr. H. J. Jones, Rycroft Nursery, Lewisham, S.E. The former used large vases, neat and dainty hand baskets, &c., filled with new and choice sorts. Specially noticeable were King of Plumes, Mignonette, Mrs. Filkins, Tuxedo, Sam Caswell of the decorative sorts, Mme. R. Cadbury, a clear ivory-white, Western King, Mrs. Barkley, and other leading Japanese novelties. Mr. Jones had large vases in variety, huge cornucopia hand-baskets, besides other receptacles, each filled with great taste. Of the newer Japanese sorts we noticed Florence Molyneux, the finest novelty of the season; R. Hooper Pearson, the Buttercup-yellow flower; Mme. Philippe Rivoire, Lewisham Belle, and numerous other good things. A new single named Edith, white, flushed rose, is a fine acquisition. Crotons, Palms, and Begonia Gloire de Lorraine were each pleasingly associated. Messrs. H. Cannell and Sons, Swanley, Kent, as usual, had a magnificent display, embracing no less than sixty-four bunches of their superb zonal Pelargoniums, each of the finest quality. Chrysanthemums of a representative character and winter-flowering Begonias secured for them a silver-gilt medal. From Mr. R. Owen, Maidenhead, came a large table of Chrysanthemums in vases, a huge lyre of artistic merit, and no less than twelve boards of a dozen flowers, embracing new and choice Japanese and incurved varieties (silver medal). Mr. W. J. Godfrey, Exmouth, Devon, also had a large table of Chrysanthemums chiefly of a decorative character. Winter White, King of Plumes, Mrs. Filkins, and Sam Caswell called for mention (small silver medal). Mr. J. Agate, Havant, Hants, staged a dozen flowers of his new white Japanese Florence Molyneux, which called forth much praise, and from Mr. J. Williams, 4A, Oxford Road, Ealing, W., came a most dainty table decoration, in which pink Chrysanthemums were largely used with suitable foliage. These were arranged in his silver-plated rustic ware.

FLORAL COMMITTEE.

First-class certificates were awarded as follows:—

J. R. UPTON.—A very large Japanese variety with long drooping florets of medium width and slightly curling at the tips; colour deep golden yellow. Exhibited by Mr. J. R. Kenyon.

EDITH.—A single variety of large size, having rather broad flat florets; colour deep rosy pink, centre yellow. Shown by Mr. Pagram.

NOTES OF THE WEEK.

Pelargonium Lady Newton.—This is an excellent kind for winter work and quite distinct, the colour of the blossoms being pale salmon with an edge of scarlet, a by no means frequent combination. The variety is likewise very free and the trusses of large size and well filled with large individual blossoms. The clear edge of scarlet is very striking when seen in fair quantity, and is moreover generally decided in its character.

December flowers.—With this I send you a few December flowers. It would be tedious to make a list of all that are still in bloom, but certainly what I send does not comprise one-half of what is even yet in flower, keeping the garden bright and gay, even without the lovely berries of the *Pernettyas* and similar plants.—A. KINGSMILL, Harrow Weald.

** Among the flowers sent were *Arbutus*, *Ceanothus*, *Pentstemon*, New Zealand *Veronica*, Wall-flower, *Fuchsia*, *Colchicum*, *Hellebore*, &c.—ED.

Chrysanthemums Snowdrop and Primrose League.—The two charming little pompons, the former white and the latter yellow, are useful late kinds, and just now are at their best. To see them at their best they should not be disbudded. Quite recently I saw a number of blooms of Snowdrop which had been severely disbudded, the charming miniature character of the flowers being thereby lost. The blooms are admirably suited for the smaller receptacles used for indoor decoration.—D. B. C.

Chrysanthemum Western King.—This is valuable as a late kind. Although generally known as

a midseason variety, it has a greater value during the earlier half of December. It is one of the purest white Japanese sorts, and has not been so freely cultivated as it deserves. At the time of writing plants which were propagated during April and May last are now in full bloom. They were potted into 8-inch pots and allowed to make a natural break. Each plant is carrying some six to eight blooms, and the plants are also beautifully dwarf. The variety retains its foliage well.

Chrysanthemum Chatsworth.—Perhaps the most exquisitely finished flower of this variety that has yet appeared was included in the beautiful lot of blooms shown by Mr. N. Davis the other day at the Aquarium winter exhibition. Early blooms of this kind, both last year and again this season, have not been all that could be desired, much less have they approached to catalogue descriptions of the flower. In the instance now referred to the central part was superb, and toning down to a most delicate pink above the reddish shade of the lower florets, together with its fine build and form generally, made it what it was—one of the very finest kinds shown. Usually this variety is not seen of such depth as was noted in this instance.

Basket Begonias.—While much attention is directed to the employment of Begonias as pot plants, for which staking and tying are greater or less degree necessary, it is to be hoped that their value for hanging baskets will not be overlooked. For this purpose in winter no variety is so bright and cheerful as *Gloire de Lorraine*, with its loose, extended wreaths of blossoms. The variety, too, is especially good when so isolated that no other plant touches it. Even as a pot plant this greatly conduces to the retention of the foliage not only to the pot, but in reality almost clinging to it. For basket work and suspending generally avoid large receptacles, so that a general furnishing of the exterior of the basket will be brought about.

Tanacetum argenteum.—This pretty and compact alpine Tansy is a very continuous bloomer when given a position somewhat raised from the ordinary level and where good drainage is secured. In its day it produces a good white sheet of blossoms, and carpets the earth with a compact silvery patch of leaf growth. The plant is of quite easy culture, the ordinary treatment accorded to such plants suiting it quite well. Loam and leaf soil, the whole made rather gritty, with the addition of old mortar or brick rubbish, are well suited to it, better than the closer class of soils that do not so readily admit of a free passage of moisture. A few days since plants were quite showy, but the last severe frost has crippled it.

Colchicum Sibthorpi.—I have to thank Mr. Kingsmill for writing to tell me that the flowers of *Colchicum Sibthorpi*, mentioned in THE GARDEN of November 25, were not from plants which had been established. I have now had this fine Meadow Saffron for several years, and I find that it blooms a considerable time before the recently planted corms gave flowers at Harrow Weald. The information kindly given by Mr. Kingsmill may have the effect of preventing any misunderstanding on the part of those who might purchase this noble Meadow Saffron under the impression that it flowers in November. The latest to bloom here is one I have as *Decaisnei*, but it is far inferior to *Sibthorpi* in size, colour, and beauty.—S. A.

Aralia Sieboldi variegata in flower.—I have a nice variegated plant, about 4 feet high and 6 feet in diameter, with six spikes, in bloom in the open air here. Eighteen years ago I had a plant too large for the conservatory, and determined to plant it in the open. I chose a place on the east side of a shrubbery and 50 yards from the west side of the house. The soil being London clay, I made a large hole and put in a quantity of brick rubbish, and on this placed about 18 inches of vegetable mould. In this I planted the *Aralia* in May. It was then 8 feet high. It grew well and flowered each autumn, generally before frost, until the severe frost of 1895, when it was much injured, but recovered.

It has bloomed the last two years, and is well in flower now.—RICHARD BUTLER, *St. Dunstan's, Regent's Park.*

Saxifraga apiculata.—Though well known as one of the earliest flowering of its race, it is not usual that such flowering begins while the old year is still with us. This is so, however, at the present time, and it may be said, perhaps, unfortunately, as in the event of sharp frosts or even the present wet and frost combined it is not likely the now apparent show of flowering spikes will escape without injury. A slight protection may be of assistance, especially if the protection is afforded in such a way that the head of the plant is kept dry. This may be readily accomplished by a sheet of glass sufficiently large to cover the tuft being raised by strong wire supports, so twisted into shape that the glass may be inserted and thus throw off the rain. Usually, if dry overhead, the frost is not particularly harmful to such things, while the reverse is often attended with bad results.

Galanthus Rachelæ.—Here this Snowdrop has been the pioneer of the genus, although, as mentioned in THE GARDEN of December 2, its flowers soon fell victims to the greed of the slugs. This Snowdrop is considerably earlier than *Galanthus Elsæ*, which we also owe to Professor Mahaffy, who brought the two from Greece in 1886. It is now some years since Mr. Burbidge kindly sent me a bulb of this rare Snowdrop, but, unfortunately, it shows hardly any increase. Like *G. corcyrensis* and *G. octobrensis*, it is rather weak in growth and does not possess the robustness of the common Snowdrop nor even that of its companion, *G. Elsæ*. I have never been able to get seed from *G. Rachelæ*, but I have now two seedlings of *G. Elsæ* which have reached a flowering stage. They will not, however, be open before the end of December if the weather keep open; should frost come they will be later still.—S. ARNOTT, *Dumfries, N.B.*

Saxifraga Cymbalaria.—Among the few plants which are yet in bloom is the dainty little *Saxifraga Cymbalaria*, which is also one of the prettiest carpeters of the time. The plants now in flower are the progeny of those which bloomed earlier in the year, but have now been cleared away. They are not flowering so profusely, it is true, as they will do in the coming spring, but one cannot but welcome and enjoy the little golden stars on the close carpet of glossy green leaves. It is almost amazing to see how quickly this Saxifrage increases in favourable soils and positions. Last spring I took a few small plants from another part of the garden and placed them in a shady corner in rather heavy soil. They flowered well, and now the seedlings from them threaten to be too numerous, but will form a carpet I would not like to be without for covering the ground below the bulbous plants which will bloom in spring. I would like to draw the attention of others to this valuable little Rock-foil, so unlike many others.—S. A.

Tulipa Sprengeri.—Admirers of the Tulip would see with pleasure the coloured plate and accompanying notes on this in THE GARDEN of December 2. I am grateful to M. Hoog for the information he gives about it. Perhaps a few words upon it as it behaves in my garden here may be of use to others in the British Isles. It has flowered here for at least two, and I think three, seasons. The first year it came into bloom no later than some of the more tardy Tulips, but this I attribute to its having been ripened off early in a warmer climate. This year, however, it was the latest of all the Tulips. Although, as M. Hoog justly remarks, we need not particularly care for a display of Tulips in June, yet one finds its cups give us a pleasing variety at the time. It is distinct enough and pretty enough to deserve the space it occupies. One thing that I have observed is that it is unusually slow in its progress from the time that it shows its bud until the flower opens. I may mention that I grow *Tulipa Sprengeri* in light soil and in full sun. It is left in the ground and not lifted and dried off

annually.—S. ARNOTT, *Carsehorn, by Dumfries, N.B.*

Begonia semperflorens gigantea.—It would appear that very little description is necessary here beyond the descriptive varietal names, but as a fact the plant is so much removed from the smaller-leaved and much more compact typical kind, that some may regard it as not related thereto. Taller in growth, larger and more fleshy leafage, and fewer, if much larger, blossoms, are among the chief characteristics of the giant form. It is, however, so good and distinct in character and so continuous in its flowering, and winter flowering especially, that one may expect good out of it in the endeavour to establish a distinct race of winter-flowering *Begonias*. Despite the fact that already there is tangible proof of securing such a section in one direction, it does not follow that with the fulness of material at disposal in this remarkable genus such a section may be established in one way only, and certainly the *B. semperflorens* would seem almost suggestive of the very work itself. In any case the combination of a third species or kind may enhance the interest, if not the beauty, of such a group the end of which is not yet.

Thin carpets over bulbous plants.—Perhaps one of the most difficult things to obtain quickly is that thin and very desirable carpet over bulb areas that, while affording the needed protection from pelting rains and the like, will not become sufficiently dense to choke the plants as they try to emerge therefrom or to form a nesting place for slugs and other like pests. The usual way is to prick out small bits of the plants at a few inches apart, or even much less. In this way, however, the resulting carpet is too dense and often gappy. A way to avoid this is to get the area ready and take a patch of *Sedum Lydium* or *S. hispanicum* var. *glaucum*, first breaking it up into rather small particles, then, taking it in a sieve to the required place, shake the sieve evenly all over the surface. With a little care quite an even groundwork may be made over large areas not easily covered in other ways, and this at little cost. A little fine soil sifted over the *Sedum* after it has been thus sown and gently firming all with a spade will complete the work. It is a good time for such work to be done now, as with the moisture in the soil the *Sedum* quickly takes fresh hold. Hot, dry banks may now be furnished on this plan for another season at little cost.

Chrysanthemum R. Hooper Pearson.—Those who have grown it will, I think, agree with me that it is one of the finest introductions of recent years. No yellow *Chrysanthemum* could be of a richer shade, the nearest approach to it in colour being the old incurved *Jardin des Plantes*, and its lasting powers are marvellous, both on the plants and cut. In type it belongs to the incurved Japanese, but it has none of the formality presented by the more globe-shaped varieties of the type. An acquisition to the exhibition big bloom section, it is even more so when grown without dishudding, as it produces well-developed and most vigorous sprays. I have at the time of writing plants struck early in July potted into 5-inch pots, and now carrying as many as eight flowers on the single stems, which are only about 2 feet high. Dishudded plants struck at the same time are carrying one big flower each at the same height. All my plants this year are on single stems, but, judging from their healthy appearance and the capacity they have for making a good number of cuttings of the right type, it should soon become well known and universally grown, and I have no hesitation in saying that it will become one of the most popular of bush varieties for flowering rather late—that is, towards the end of November and through the greater part of December.—J. C. T.

Lavatera assurgentiflora.—Some time ago Dr. Stuart kindly sent me from his garden at Chirside flowers and young plants of *Lavatera assurgentiflora*, which he had raised from seeds sent from California. On November 25 a bright and gathering of flowers and leaves arrived from

Dr. Stuart, and so pretty and fresh do they look that I cannot resist the temptation to refer to them. These flowers, it must be remembered, are not from under glass, but are from an open wall with a western exposure. Dr. Stuart tells also that they were grown 400 feet above sea-level and in a windy, exposed situation. It is, I think, doubtful if this uncommon plant can be trusted to stand the winters of Berwick or other northern counties in the open, but those who have the accommodation might lift it and winter it under glass. This is the treatment recommended by the sender of the plants earlier in the year. I believe that *L. assurgentiflora* is rather tall in growth. It is, so far as one can judge from the material available, a handsome plant with its fine Vine-like leaves and its bright flowers, which are almost crimson in their colour. I hope to have the satisfaction of blooming my young plants next year, and afterwards of testing the hardiness of one of them in the course of the succeeding winter. From the appearance of the plants I am hopeful that *Lavatera assurgentiflora* may be harder than has been thought.—S. ARNOTT.

Carica Papaya (common Papaw).—Some very fine examples of this may be seen in fruit in the conservatory at Gunnersbury House at the present time. The seeds were sown in February and the seedlings planted out in March, the object being to keep growth going briskly and so endeavour to bring the fruits either to perfection or as near this as possible. How far success has attended the efforts is not yet fully apparent, but a few days ago many fruits were of large size, some fully 6 inches or 7 inches long and probably 3 inches in diameter. The ends are somewhat equally tapered, and the dark olive green colour would suggest some time before the fruits were fully ripe. Externally the fruits are rendered rough by deep, almost longitudinal depressions, while the method of hanging to the tree displays them fully. The fruits appear in the axils of the leaves, and the latter, long since mature and fallen, leave the fruit suspended by a short stalk. The plants in question must be fully 12 feet high, the erect stem-like trunk perhaps nearly 2 inches in diameter at the base. It is interesting to note the abundant fruiting right away to the summit of the plant, though there is very little hope of these small fruits ever maturing. All the same, they exist in numbers, many being no larger than a half-ripe Fig. Not of the least importance when growing is the handsome palmately-divided leaves borne on long terete petioles, the leaves occurring alternately, or nearly so, on the stem. Though usually regarded as stove evergreens, the plants referred to have shed many of the lower leaves, and would appear best treated on the lines of a stove annual, though, to secure a more general fruiting, even an earlier start than here stated may be desirable. On the Gunnersbury plants there are at least a dozen fine fruits, to say nothing of numbers of medium and small ones.

BOOKS.

CATALOGUE OF PLANTS IN ABBOTSBURY GARDENS.*

We have here a neat little book containing the names of the plants cultivated in one of the most beautiful and richest gardens of our day. The fashion of printing lists of plants grown in large gardens was more commonly followed a few generations ago than now. Such lists are not only of present interest, but may be of value in the future. Abbotsbury is almost wholly an outdoor garden, having no hothouses.

The weather in West Herts.—A warm week with two cold nights, on the second of which the exposed thermometer registered 12° of

*"Catalogue of Plants in Abbotsbury Gardens," By "M. I.," assisted by Joseph Benbow. Privately printed.

frost. This is the lowest reading shown by this thermometer since the end of March. At 2 feet deep the ground is now about 3°, and at 1 foot deep about 5° warmer than is reasonable. Since the beginning of the month rain has fallen on three days, but to the total depth of less than half an inch. November proved a very warm month; indeed, the warmest November since 1888, or for eleven years. On no night did the thermometer exposed on the lawn show more than 10° of frost. Rain fell on nine days (a small number for the month) to the aggregate depth of 3½ inches, or more than half an inch in excess of the November average. The distribution of the rainfall was, however, peculiar, no rain at all falling after the 10th. The record of bright sunshine fell short of the mean for November by about ten minutes a day. The most noteworthy feature of the past month was the small amount of moisture in the air. In the last fourteen years there has been only one other November with an atmosphere so generally dry.—E. M., *Berkhamsted.*

LAW.

XL All Vaporiser.—Messrs. Jacob Wrench and Sons (Limited), London Bridge, were summoned last week before the Lord Mayor at the Mansion House by the Pharmaceutical Society for on November 7 unlawfully selling to Harry Moon a certain poison, to wit, a vegetable alkaloid called nicotine, in contravention of the Pharmacy Act, 1868. Mr. Vaughan Williams, who appeared for the Pharmaceutical Society, said the article sold to Mr. Moon, who represented the registrar of the society, was a vaporiser to be used in greenhouses for the destruction of insect life on plants. One drop of the article put into the mouth of a rabbit killed it in twenty-one minutes. The label stated that the article should be kept in a safe place out of the reach of children. Dr. Stovenson, analyst to the Home Office, said that he had analysed a bottle of the article, which was called the "XL All Vaporiser." It was a solution of nicotine and camphor in diluted alcohol. The bottle contained enough to kill thousands of people if it were swallowed. In reply to the Lord Mayor, the witness said that three, four, or five drops, if taken, would be fatal to human life. The Lord Mayor said he was satisfied that this was a poison within the meaning of the schedule. Mr. Avory: It is an important question. Will you state a case? The Lord Mayor: Certainly. The Lord Mayor imposed a fine of £5 and £10 10s. costs on the first summons, and a nominal fine of 10s. on other two summonses, and the costs of the summonses. He hoped that in the meantime the sale of the compound would be stopped. Mr. Avory: As far as my clients are concerned they have already discontinued it. The Lord Mayor said he did not wish to prejudice the case, but he would suggest that the bottles sent out should be called in.

OBITUARY.

Mr. W. H. Protheroe.—We regret to announce the sudden death of Mr. W. H. Protheroe, who, as a senior member of Messrs. Protheroe and Morris, auctioneers, of Cheapside, was widely known and universally respected. The deceased has not of late years enjoyed the best of health, but the end during the early hours of Saturday morning last was quite unexpected. The deceased was in the fifty-fourth year of his age, and his loss will be felt throughout the United Kingdom and in those portions of the Continent to which he had been a visitor.

Names of plants.—A. E. W.—1, *Swainsonia galegifolia*; 2, *Ficus repens*; 3, send better specimen; 4, *Justicia*, send in flower.—A. Kingsmill.—1, *Elaeagnus pungens*; 2, *Campanula persicifolia*.

ORCHARD AND FRUIT GARDEN.

STRAWBERRIES, NEW AND OLD.

I HAVE read with some interest recent remarks in THE GARDEN on Strawberry culture, and two things have struck me. One was the statement that if late Strawberries could be grown profitably in the south they no doubt would be grown, and it is suggested that they be given a north border. The other statement was that the Elton Pine is too late to produce runners that will fruit the following season. With regard to late varieties in the south and north, all that need be said is that late Strawberries ought to be late anywhere, north or south. It is not the season that makes the difference; the plant itself is late. Elton Pine will come in earlier in the south than it does in the north, but it will be just as far behind the earlier kinds as it is in Scotland. As to the Elton Pine being a late grower, I augmented my own stock this year from Forfarshire, N.B., and although the plants had not been specially layered, but were just self-rooted runners, I expect them to fruit next year by the look of the crowns, and if they had been prepared and got sooner there would have been no fear at all of them fruiting next August and onwards.

As regards kinds of Strawberries, I have strong doubts about a number of the newer kinds. I would like to ask where a better grower, a more prolific kind, or a finer well-coloured berry could be found than in the old Keens' Seedling, now about 100 years old? It is a sort I have never seen surpassed for forcing, general crop, or for preserving, and I have seen it do equally well on poor sandy soils in England and on loamy soils in Scotland. There are, however, a few soils on which it is not fertile, growing rampantly, and one of these is the rather poor, cold soil that lies above the coal in South Yorkshire. In several gardens lying not far apart there it had to be given

up. Generally speaking, however, it is still one of the very best and trustworthy. Dishes that I have seen of it exhibited in Edinburgh and elsewhere in March and April have never been surpassed. I am quite certain that some of the new kinds are inferior to Keens' Seedling, and I have known it all my life and seen most of the others. Some of the new sorts are impostors. Noble, for example, was only tried to be thrown away, as it was neither fit to eat nor to preserve and was one of the worst of travellers. Then Latest of All, we have just had shown, is not a late Strawberry at all.

The one Strawberry that has succeeded Keens' Seedling most generally is Héricart de Thury, and those who find it a success should stick to it. I have tried every likely kind and have kept to it for the maincrop ever since it came out, always propagating from my own stock, and never missed a crop except when frost caught the flowers. No Strawberry is worth much that has not good foliage and is not hardy, and these qualities H. de Thury possesses. It keeps its foliage green throughout the winter almost as well as Keens' Seedling, and that means a good constitution. The fruit reaches a size to satisfy anyone, and when thoroughly ripe it is an excellent dessert kind. It is also much liked for preserving, having a bright colour. The next best to Keens' among old sorts is British Queen. I never forced any other for a late crop, and it has never been surpassed for exhibition. Many years ago Mr. McEwan, of Chiswick, used to show it very fine, and the late Mr. Tillery, of Welbeck, used to show dishes of it at York that have not been beaten for size, colour, and quality. The fault of British Queen is that it is a poor grower, and in dry soils is eaten up with red spider. It must have the warmest spot in the garden and a moderately heavy but permeable deep rich soil. Give it these, do not plant too thinly, and there will be no fear of a crop of fine fruit, which the grower may show anywhere with success. Add to these sorts the Elton Pine, and the list cannot be easily beaten.

Newer kinds introduced since many gardeners can remember are Sir Charles Napier and Sir Harry, two good prolific sorts, but a little erratic and inconstant. Dr. Hogg was of the British Queen type, but a shy bearer. James Veitch was good to eat, but not reliable for general crop; but Veitch's new Perfection is a good grower, throws up a fine truss of flower, has also fine foliage and is a distinct sort. I lost the whole crop last year by frost when the plants were in flower. Royal Sovereign is well spoken of, and I have planted a lot of it this autumn beside Vicomtesse Héricart de Thury, and so far I must say it is by far the weaker grower of the two.

A word about early varieties. In the lists there is, I see, a King of the Earlies (Laxton), which means, I presume, that it is the earliest but I venture to say that it has no more claim to be so described than Latest of All has to its name. The earliest really useful Strawberry (for perhaps the last fifty years or more) is Cuthill's Black Prince. I forced it regularly for about twenty years, and never found one to match it for a fine crop, coming in late in February and in March, while outdoors it came in before any other early sort tried. The fruit is not large, the largest seldom exceeding 1½ inches in diameter, but it is finely coloured and nicely flavoured. The plants require about half the space necessary for the stronger growers and much fruit can be got off a small space.

J. SIMPSON.

Pear Beurre Diel decaying.—I was rather surprised on being told by a friend at Norwich show that his fine examples of Beurre Diel Pear all went soft and useless at the beginning of November. This is, I think, no doubt attributable to the season, although fruit of the same variety was exhibited at the same show in a perfectly sound condition from several other gardens not far distant. This would seem to indicate that soil has something to do with it. Probably also those which decayed prematurely were from wall trees, the others from pyramids or bushes. Such instances, at any rate, prove that an extra

sunny season is not quite the best for finishing up Pears, a certain rainfall being indispensable for communicating to the fruit that virtue necessary not only to perfect flavour, but also to keeping. The Beurré Diel I tasted at Norwich show was the freest from grit and most juicy of any I have seen.—J. B. S.

Apple Cornish Gilliflower.—I think that all who are acquainted with the merits of this Apple will agree with the editorial comment on the specimens sent by Mr. Burrell. I consider it quite equal as regards flavour to Ribston and Cox's Orange, while it is superior to either in keeping qualities. With me it would keep in good condition until March, but I have but few fruits left of it after the turn of the year. I grow it as a bush on the Paradise, and if it does not bear a heavy crop it fruits very regularly. I contributed a dish of this variety to the Hereford show a few weeks back, and the fruit was pronounced by many to be the finest samples they had ever seen of it. Were I about planting a new collection of Apples, one or two trees of Cornish Gilliflower would most certainly be included. There is no difficulty whatever in its cultivation; the only thing, as the editor truly remarks, is to beware of cutting away the fruit-buds which form so freely on the tips of the young shoots.—A. WARD.

Apple Margil.—It is very seldom now-a-days that one either sees or hears of this delicious Apple. Of course, the reason is that it, like its relative, Ribston, is liable to canker, and is, under rough-and-ready treatment, anything but a robust grower. All the same, such is its value as a dessert Apple, that the pains necessary to ensure success with it amply repay the cultivator. No one having a low situation and retentive soil need plant Margil with any hope of success, but where the garden is well drained and the soil fairly warm and friable this Apple will succeed worked on the Paradise. The trees should be planted near the surface, rather mounding up the soil somewhat than sinking the roots much below the surrounding level. Bush trees are the best, no further pruning being required than balancing any irregular growths and keeping the centres open. Any spare soil from the frame or compost yard, together with burnt refuse, wood ashes, and road-scrappings, are welcomed by the roots of this and other tender Apples if worked carefully and firmly amongst them at planting time.—J. C.

—This Apple was well exhibited at Bury St. Edmunds, and it is one of the best dessert kinds. It is quite large enough for dessert, and its flavour seems to be between that of Ribston and Cox's Orange Pippin. I know of no other kind, in fact, that so nearly approaches this the best of all Apples for flavour. Margil is not perhaps the best of growers, its somewhat twiggy habit as well as its liability to canker on very ungenial soils being against it. In fairly light and workable soil if planted properly and the roots kept up there are few kinds that will give greater satisfaction.—H.

Apple Cox's Orange Pippin.—The season seems to have been an unusually good one for this the best of all dessert Apples, and I do not remember a season when so many fine dishes have been staged. Possibly in some instances shortage of crop has made the individual fruits finer, and, if so, this should be a lesson to those who even now persist in leaving their fruit as thick on the trees as it is produced, a host of little scrubby specimens that never can be of any good, robbing the better-placed and larger fruits of their sustenance. Want of time for thinning is no excuse, for when they are left on they are gathered, and it is no more trouble to take them off when young. Although Cox's Orange Pippin will often produce a few extra fine fruits on espalier trees, it seems much more at home when allowed its head and delights in a light sandy soil. Much the finest and most prolific tree of this variety I have ever seen grew in the light red soil above sandstone in Gloucestershire, and many first prize dishes

were gathered from it. It was a standard and never root-pruned, and, in fact, little branch-pruning was necessary.—H. R.

Pear Emile d'Heyst.—I am glad to see "A. W." has a good word for this Pear. As a bush or pyramid it is excellent in every respect, the tree moderate in growth, free bearing, while the fruit is of very good quality, and does not go rotten so quickly as many early winter Pears when it has reached a matured stage. With me it has been much undersized this year owing to the drought. I certainly do not claim for it a quality equal to Marie Louise, but those who depend on the bush or pyramid tree for their crop will find this much more reliable than Marie Louise. In some soils this is scarcely worth growing as an open-air tree. A fault of the higher-class Pears grown as pyramids is the difficulty that comes from wasps and birds. Unless carefully protected, few sound fruits remain by the time they are ready for gathering. In the case of small trees it is a different matter. On the walls I do not find either birds or wasps give much trouble, though why it should be so it is not easy to say, unless it be that there is ample for their needs on the large bush trees in the open, and even then it is curious that this should be so when one is so closely contiguous to the other. Does "A. W." find this to be the case in his garden? I have noticed the same thing here for several years.—W. S.

PEARMAIN APPLES.

THE Pearmain is a very distinct type of Apple, and it owes its name to the peculiar formation of the fruit. Nearly all the varieties are conical in shape, the height of the fruit greatly exceeding the width at the base. Some are tapering and others are bluntly formed at the apex, and, generally speaking, all have a symmetrical appearance. They vary from large to small, and consist of both cooking and dessert varieties. Some come into use in the autumn, others in the early and midwinter months, while others are late keepers, and if properly stored may be had in good condition late in the months of April and May. With regard to colour, some are very brilliant, while others again are nearly green, or have only a dull reddish flush on the side exposed to the sun.

The two most beautifully coloured in the whole section are the Worcester and Scarlet Pearmains. The latter is not often met with now, but the former has become a universal favourite both with private and market growers for early supplies. Large quantities are grown every year and sent to the various markets, where they realise high prices, the returns being very little less than are obtained for Peasgood's and other high-class Apples. Mabbott's Pearmain is another highly coloured sort, which in point of flavour surpasses the two previously named. This Apple has a distinct open eye, very much like Blenheim Orange. It is medium-sized and keeps late. Claygate does not carry so much colour, but it is larger and more richly flavoured than either of the preceding. The colour in this case is greenish, which changes to yellow when the fruit is fully ripe, and on the sunny side the skin is suffused with dull red. Another conspicuous feature is the whitish-grey dots with which the surface is besprinkled. It is a true Pearmain-shaped Apple and will keep in capital condition until late in March. As a standard it bears regularly and crops heavily. Herefordshire or Royal Pearmain is a well-known variety that grows to a large size. It succeeds well either as a standard or bush, and on the former style of tree very handsomely coloured fruits are to be obtained. This Pearmain is largely cultivated both in the county of Hereford and adjoining counties, and is very much appreciated by some people as a dessert fruit for winter use; in fact, I know of one person who gives it the preference over Cox's Orange. Its season is from November to March, but it will, I am afraid, hardly keep so long this season. Adams' Pearmain, which is essentially a Hereford-

shire Apple, is widely known and extensively grown both for private consumption and market. This does not grow so large as Royal Pearmain, but is equally as handsome. The shape is very distinct, the fruits tapering off very much towards the apex, and, with the exception of the next one to be named, more so than any of the Pearmains. The colour is yellow, well-grown specimens being covered nearly all over with dark crimson, and they have very conspicuous greyish dots sprinkled all over the surface. London Pearmain is very similar, only smaller, the colour brilliant red instead of dark crimson, and sprinkled with very numerous greyish dots. Both are excellent, richly flavoured Apples, and are in season from November to the end of January. As standards they bear very heavily, but they may also be cultivated in any other form with success. Old Pearmain, which is considered to be the oldest Apple in cultivation, is another well-known highly-flavoured sort and largely grown in the county of Hereford. Some magnificent specimens of this Apple which were grown in the district between Ledbury and Gloucester were exhibited at the great Ledbury fruit show some eleven years ago. It is in use from now until the end of the year, and does well as a standard. Blue Pearmain, as the prefix denotes, is of a blue or purplish hue in colour, but is otherwise a very excellent Apple. This used to be exhibited in fine form at the Hereford shows by Mr. Wright when living at Glewston Court. It is in season from the end of the year until April. Hornead's is quite the opposite in appearance from those already named, as it is nearly, if not quite, green in colour and large. Its chief merits lie in its being an excellent cooking Apple and the fact of its being a long keeper, as it remains in use until March. Mannington's is a pretty dessert Apple and very high flavoured. The surface of the fruits is covered with light brown russet, and on the side next the sun it has a bright red cheek. It is a good keeper and succeeds well grown in bush form. Ribston Pearmain is a yellowish-coloured fruit, with a few patches of russet on the surface, with a dull or brownish red cheek on the sunny side, somewhat like Ribston Pippin. It is at its best about Christmas and is a rich, good-flavoured Apple. Lamb Abbey Pearmain is an excellent variety to grow in a garden as a bush. The fruit will keep in a cool store until Apples come again. The fruits are small and green or greenish yellow in colour and the skin is covered with a red flush also in a warm season. It has a crisp-eating flesh and is of very good flavour. Winter Pearmain or Duck's-bill is another popular sort hailing from the south eastern and southern counties. It is also known as Sussex Scarlet Pearmain and Winter Queening, but is distinct from the Hereford Winter Queening. It is a medium-sized fruit and very prettily coloured, it being good either for cooking or dessert, and will keep if required until April. Another variety named Baxter's Pearmain is a very old sort that used to be grown much more extensively than now. It is a very free bearer, and an old tree which at one time occupied a position in the kitchen garden here used to carry heavy crops with great regularity. It may be used either for the kitchen or table, and is something like the Old Pearmain in appearance. Next comes Grange's, which is something like Herefordshire Pearmain and is a first-rate dessert Apple, in use from the end of the year until the end of March. Then there is the Golden Winter Pearmain, which many consider to be synonymous with King of the Pippins. According to my experience, the only similarity is the flavour, which is almost identical, otherwise there is a wide difference in the size of the fruit, which is of a true Pearmain shape and much larger. The fruits are also of a beautiful golden colour, with a red cheek, but they never take on the amount of colour that King of the Pippins does.

The above include the best known varieties of Pearmains. I have not included Orange Pearmain. This is, I think, going out of cultivation. It is a pretty-looking fruit, but at the best is only

second-rate in flavour. It was this fact that induced me to discard it, otherwise it is a great bearer. There are a few other sorts, such as Christmas Pearmain, Barcelona, Balchin's, Gidley's, Rushock, Loan's, and Russet Table Pearmain, all of which have good reputations both for flavour and good keeping qualities, but I am unable to speak of them personally. A. W.

Cutting back Raspberries.—I have been much interested in the correspondence on this matter because it is one upon which opinions differ. So far as I can see, the argument in favour of cutting back canes at the time of planting is to ensure stronger growths from the base, and the argument against the practice is that by carrying it out the next season's crop is needlessly sacrificed. I quite agree with "W. S." that the energies of strong canes if allowed to fruit the first season become used up and they produce little or no sucker growth. At the same time a grower who wants fruit does not like the idea of sacrificing the whole of the first season's crop. The best plan then is to adopt the middle course, which consists in planting the canes rather closer together than usual and cutting back every other cane. Those cut back will have every chance of producing strong canes for subsequent fruiting, and those left to nearly their full length will produce some fruit. If the strain is too much for them and they send up no sucker growth, they may be cut out in favour of the canes from the cut-back plants.—H. H.

Plum Coe's Golden Drop.—I have to-day (November 18) seen some remarkably good specimen fruits of this useful Plum which have been kept in a fruit room in the ordinary way like Apples, and I could not help thinking what a boon a lot of fruit like this would be. It is a little remarkable that this Plum is not more generally grown, for it is really of excellent quality and prolongs the season in a remarkable manner. It is too much the custom to place it in a poor position and closely prune the breast-wood in every season instead of allowing it a little liberty. The trees when young are given their head too freely; then, when they have about filled their space, the branches are topped, the summer shoots are pinched, and every bit of new wood is taken off in winter. Better by far be content with a less rapid progress at first, even going to the extent of root-pruning if need be—at any rate, pinching the vigorous top growth. Then the trees would eventually be more evenly balanced; the tops would not show such a disposition to run away in front of the lower portions, and a few new shoots could be found room for annually in fan-trained trees at any rate, bringing with them increased root-action, and, therefore, greater vigour to the trees as a whole.—H. R.

Pear Beurre Superfin.—I was interested in Mr. Ward's account (p. 410) of the variation in the skin of Beurre Superfin Pear, and have the same experience, with this difference, however, that I find situation and aspect have some influence in the matter. I have on a south wall a large horizontally-trained tree which produces very fine, smooth-skinned fruit of a pale lemon colour when ripe. Another fan-shaped tree on a wall facing S.E. has its fruit much deeper in colour, some fruits being beautifully flushed on the sunny side, but, like the others, quite smooth. On an east and north-east wall the difference is very marked, both cordon and fan-shaped trees having their fruit quite russet, and in some seasons very rough, although the flavour, as Mr. Ward says, is quite equal to that of the finer and smoother-skinned fruits. I have a keen recollection of noticing the change of type brought about by double grafting in some specimens exhibited by him at our Hereford show last year. I believe, too, that they are later in ripening, which is a considerable gain, lengthening, as it does, the season of so fine a Pear. On p. 411 Mr. Ward does well in drawing attention to the need for more root-pruning as a means of greater yield in fruit. I have had to resort to it

in the case of some young trees planted round the vegetable quarters here three years ago. Without doing so in a rich soil I might look in vain for anything like a crop.—E. Fox, *Garnons*.

American blight, woolly aphid, &c.—Among the many obstacles which the forester and gardener have to contend with in the successful cultivation of their timber and fruit trees are the ravages of injurious insects. These, from the subtlety of their operations and the obscurity of the life-histories of most of the species, have always proved a troublesome matter. Various remedies, such as petroleum, sulphate of copper, arsenic, coal tar, &c., have been found quite capable of killing or arresting the progress of such pests, but, unfortunately, they have proved dangerous, if not positively harmful, to the health of the trees by not only destroying the outer bark, but often penetrating to the cambium, the more liable to injury of the two, with the inevitable result—the destruction of the tree itself. I have tried many of these with disastrous or indifferent results. One composition, however, I have found to be efficacious both as a preventive and as a cure for the American blight (woolly aphid, woolly bug), bark scale, Larch aphid, red spider, and other pests of similar habits. This is Ahlbottn's composition. It is a treacly fluid, which I apply to the trees with a brush, painting the affected parts thoroughly over. All excoriations on the bark that offer a favourable lodgment for the ova of the insect are treated with extra care. I may add that a second application is very rarely found necessary. It is inexpensive and can be procured from any seedsman, and, while perfectly harmless, has an antiseptic and healing effect on gnawed or otherwise damaged bark.—OMEGA.

YOUNG AND OLD PEACH AND NECTARINE TREES.

THE note from "H.," commenting on a previous article contributed by another correspondent, contains some instructive reading (see GARDEN, p. 395). There are several points therein to which I, as a fruit grower, attach particular importance, as they are of great practical value to the grower of the Peach under glass. The first of these is where "H." alludes to the wisdom of having a reserve stock of trees on hand outdoors, where, of course, the wall space can be spared and the locality suited to outdoor Peach growing. There is nothing new in this I am aware, as such advice has been tendered over and over again in the pages of this journal, but is it acted upon as often as it might be? The importance of making such a provision cannot, I think, be over-rated, and where much Peach forcing is carried out it means a great saving in point of time and also prevents loss of crop. There is just the same liability for losses to occur among Peach trees grown under glass as there are outdoors, and sometimes a tree has to be discarded, perhaps, through its being an unsuitable variety or from other reasons, and when these losses have to be made good by young trees bought in from a nursery, it need hardly be mentioned that several seasons must elapse before such arrive at full bearing condition. Under such circumstances if there is a reserve from which trees may be taken whenever necessity arises there is no loss of time or of crop if the lifting is properly performed. The following case may be mentioned in support of this. Last season I had occasion to lift a full-sized tree of Lord Napier Nectarine to replace one that had become worn-out indoors. This was done just before the fall of the leaf, and great care was taken to have a good ball of soil attached to the roots. The tree when partly planted was well watered home and allowed to remain a few hours to settle down before finishing off. In the spring it flowered well and set a good crop of fruit. This was thinned down so that about eight dozen remained, which the tree perfected; the fruits swelling to a fine size and finishing well. To show how little effect the lifting had on the tree, the latter also made plenty of good wood in addition to carrying a crop of fruit. This latter case

is not a solitary instance, as I have done the same thing many times previously with Peaches as well as Nectarines, and so well does it answer that I contrive to have trees of suitable varieties growing against walls outdoors, that can, if required, be lifted for this purpose at any season. With regard to the age of the trees, I am not at all particular as to whether they are five, ten, or fifteen years old, so long as they are healthy and well furnished with bearing wood, as such will, with proper care and attention, yield good crops of fine fruit for many years afterwards. The advice "H." tenders with respect to the right period at which to lift and subsequent treatment, together with the construction of shallow and narrow borders rather than deep and wide ones, is well worthy of the attention of all about to plant either Peach or Nectarine trees under glass, and if adopted no misgivings as to the result need be feared. A. W.

Stewing Pears.—Most varieties of dessert Pears are good for stewing when approaching ripeness, and some have advanced this fact against the culture of cooking kinds. But it is a mistake not to grow the latter, for in seasons of scarcity of both Apples and the best Pears these often have good crops, and they are then, of course, doubly useful. Catillac is a capital stewing kind, thriving well in almost any description of soil and situation, and, when well placed, giving remarkably fine, clean fruit. St. Germain is large, but not, I think, of the same quality when stewed as Catillac.—H.

The Quince.—The Quince is now so generally used as a stock for working the choicer Pears on that its use as a fruiting tree is in a manner lost sight of. Good cooks know well enough how to make use of as many Quinces as can usually be supplied, and are always glad of them. Again, it is one of the prettiest of all fruiting trees, the bright green tint of the leaves and the pretty blossoms being well set off by the spreading semi-pendulous habit. No tree is easier to grow or more able to take care of itself, and, like the Medlar, it ought to be planted in the pleasure grounds. Quite large trees of it can be transplanted with ease and certainty at the time the leaf is falling, and it may be quickly and easily raised from cuttings.

Pear Aston Town.—"B. S. N." asks for information respecting this now little-grown but highly flavoured autumn Pear. The following may, however, be of interest both to him and others. Aston Town Pear is, I believe, still to be met with in the county of Hereford, where it is, I think, chiefly grown in the form of standards. Some years ago this variety was exhibited at one of the Hereford fruit shows by the late Mr. Piper, of Ledbury, in excellent condition, and if my memory serves me rightly, this variety won the first prize for the best flavoured Pear in the show, certainly on one occasion. Mr. Piper informed me that the tree which produced these fruits was growing against his house, but I cannot now remember the aspect. I well recollect tasting this Pear at Mr. Piper's invitation at the time it won the prize for flavour, and found it a most delicious buttery fruit. It is well figured in the "Herefordshire Pomona," no doubt from specimens supplied by Mr. Piper, as the latter gentleman and Dr. Bull were very intimate. The fruits bear a strong resemblance to Eyewood, another old variety now seldom met with, and which used to be somewhat extensively grown hereabouts.—A. W., *Stoke Edith, Hereford*.

Pear Flemish Beauty.—"Norfolk," in a short note on this Pear, alludes to the fact of his not having grown it on the Quince stock. It may, therefore, interest him to know that I have a good-sized pyramid of Flemish Beauty on the Quince which bears remarkably well and also makes good growth. The fruits, too, are superior in flavour to those produced by trees on the Pear stock, they are quite as large and are much more handsomely coloured. The dish of Flemish Beauty I sent to the Chiswick Pear

Conference was gathered from this tree, and that year the fruits were brilliantly coloured and fine in size. Trees of this variety if worked on the Pear stock are not very suitable for garden culture unless, as "Norfolk" says, they receive careful attention, it being such a strong grower. If its roots are kept curtailed it will succeed, but if neglected in this particular the results are disappointing. If proper attention cannot be bestowed on the trees in the way of root-pruning, the better place for them is the orchard, where they can grow away unrestricted, unless there should be sufficient room in the garden for the branches to extend outwards and upwards. The difficulty can then to a great extent be overcome, as the fact of their being allowed to make free growth tends to the exhaustion of superfluous energy and eventually leads to their becoming fruitful. Even then an examination of the root system would become necessary, in case some of the strongest might descend into the subsoil, which would have a tendency to render the fruits insipid and flavourless.—A. W.

NEGLECTED PLUM AND PEAR TREES.

WHAT is the proper treatment of a row of neglected Plum and Pear cordon trees as to cutting and pruning? Should all the old wood be cut out?—M. D., *Bedfordshire*.

* * * The first thing to be done to cordon trees in a neglected condition should be to cut away to within one or two eyes of their base all shoots of the present year's growth, except perhaps the upper or leading shoot, which may be left on to further extend the main stem, if such extension is desirable. The new shoots alluded to above may be readily recognised by the absence of side growths and by their Willow-like appearance, for the growth having been neglected there will of course have been no summer pruning or pinching to cause them to break into more than one lead; therefore it will be safe to cut all shoots of this nature back almost close to where they sprang from or to where the simple stem becomes divided into the short, stubby growths, bristling with buds, which are known as fruiting spurs. This leaves us only wood more than one year old to deal with, and how much or how little of this wood should be left is a difficult matter to advise about without seeing the trees. If the neglect has only been for one year there should not be much more to do, unless perhaps in the case of the Pear trees the fruiting spurs may have become too thick and would be better for thinning. This ought only to be undertaken by an expert, but "M. D." may do it himself, for it is not a difficult matter when a little intelligence is applied. It may be taken for granted that all the fat brown buds on short stems are fruiting buds, and that probably at least one-third of these will bear bunches of flowers, most of which will set fruits if the weather is favourable. When we think that half a dozen fruits to a foot-run of a cordon tree would represent a heavy crop of a medium-sized Pear, we can readily see what a lot of wasted force there is in allowing a hundred blossoms to be borne in a space only sufficient to carry a dozen fruits, and it is a fact that the reduction of spur growths on trees thickly laden with them strengthens the blossom-buds left behind and helps us to better fruits. The reduction of spur growths is carried out in two ways. If they are long and straggling they may be shortened back, leaving from six to ten buds on a spur. If they are very thickly placed on the main stems it is advisable to cut half of them out bodily, the result being a new crop of spurs at the same point, which will be ready for fruiting in a year or two, when they should take the place of those now left and which can then be cut away in their turn.

Turning to Plums, we have to put up with a more straggling spur growth, for, except in the case of a few varieties, the fruit-spurs are not borne so close at home or in such clusters as those of the Pear, and the amount of pruning, beyond cutting back the young wood, which would be safe could

only be determined on the spot. Cutting back the spurs to their base would result in the production of a lot of new wood that would probably remain fruitless for years, as fruiting-spurs are slow to form on Plums. "M. D." should proceed with caution this year and watch carefully the progress of the trees as regards the production of flowers and fruits, basing the future treatment as regards pruning on his observations of results next year. During the summer it will be advisable to pinch out the points of strong growths two or three times during the season. If "M. D." could get some advice from an expert on the spot, especially as to recognising fruit-buds from wood-buds, he would find it very helpful.—Ed.

Pear Olivier de Serres.—This is one of the best late Pears. It succeeds well on a south wall as a cordon, and fruits from such trees generally ripen perfectly if they are only allowed to hang as late as possible and afterwards stored in a cool fruit room. From here they should be brought into the Pear room proper to ripen as required. If placed in the Pear room as soon as gathered they invariably ripen prematurely. The fruit is medium-sized, roundish in shape, and flattened at the stalk and crown. The skin is covered with rich brown russet when fully exposed; when shaded it is a greenish yellow. The flesh is white, buttery, sweet and juicy, with a fine rich flavour.—A. W.

Filberts and Cobnuts.—These are not only generally planted in out-of-the-way places, but also frequently neglected for years together in the matter of pruning, thinning, and removing rubbish which impedes the ingress of sun and air to the roots. Neglected trees are sometimes taken in hand all at once, receiving such a dressing with billhook and pruning-knife that a severe check is given. In such cases I would advise a gradual diminution of superfluous wood, extending it over several seasons, and when once the bush is got into shape preserve an evenly balanced condition by a little annual attention. That more sunshine and light than are usually accorded Nuts in general are necessary is proved by the heavy yields of Kentish plantations, the occupants of which are often restricted to so many main branches, spur-pruning being carried out. In any case the trees from first planting should be freely thinned, all useless sprays, of which there is generally a considerable percentage, being entirely cut away. An open, sunny position, the ground beneath and around being kept free from grass and weeds, and in dry summers a mulch applied are the conditions needed to secure the best results.—C.

NOTES AND QUESTIONS.—FRUIT.

Pear Forelle, or Trout.—This is a handsome medium-sized November Pear. The skin is pale yellow, bright red on the side next the sun, and regularly freckled with small grey dots. The flesh is white, half melting, juicy, sugary, with a perfumed flavour. It is a good hardy variety, succeeding well either as a standard or bush, and is a good cropper. It was formerly much grown in gardens, but is not seen so frequently now.—S. E. P.

Pear Passe Colmar.—This is one of our best December Pears. The tree grows and crops well, whether as a bush or horizontally trained against a south wall. In the latter case the fruits come larger, with a much clearer skin. Grown in the open, the fruits are smaller and are coated over with a rich brown russet—a sure indication of rich flavour. It is in use from the third week in November till the middle of December.—A. W.

Apple Newton Wonder.—The value of this variety is hardly appreciated as yet, but it will be a popular and useful kind without a doubt. Its handsome appearance and excellent quality, taken in conjunction with its long-keeping habit, are sufficient to ensure it a place, but it is also a very free-bearing kind, and in a neighbouring garden has fruited well this season and last, neither of which years has been remarkable for the quantity of Apples produced.—SUFFOLK.

Pear Beurre d'Anjou is a sort of great merit, and is highly recommended for orchard cultivation.

The tree grows and bears well, and the fruit will keep in good condition in some seasons till near the end of the year. The fruits are large and fine-looking, roundish in shape, with a smooth, yellowish green skin, sprinkled with brown dots. The flesh is white, tender, juicy and sweet, with a perfumed flavour. The tree succeeds equally well either as a cordon, bush, pyramid, or standard.—A. W.

Pear Marechal de la Cour.—This Pear succeeds well as a pyramid in the open ground. If grown as a cordon on a south-west wall and well cultivated, the fruits grow to a very large size. In shape the fruits are pyriform, and the skin is almost completely covered with russet, which is rather rough to the touch. The flesh is white, melting and juicy, with a fine sprightly flavour. It is in season during November, and may be had as late as the middle of December if stored in a perfectly cool place.—S. E. P.

Pear Marie Louise.—A superb dish of this Pear was staged at the Bury St. Edmunds Chrysanthemum show, not at all over-ripe and each one of perfect form and colour, with the bright russet tinge peculiar to this Pear. This dish was quite a contrast to some of the others shown, which were quite rotten. As long as exhibitors are allowed to take prizes with such fruits so long will they be forthcoming, but they are a disgrace to any show, and should have been thrown away or eaten weeks before.—S.

Gros Maroc and Gros Colman Grapes.—I have read with great interest the notes on early and late Grapes (p. 354). My opinion is that Gros Maroc is a better Grape in point of flavour and colour than Gros Colman, and in a house I recently saw the two Grapes were growing side by side. The superior quality of Gros Maroc could well be seen, the berries being very large, the colour of Damsons, and carrying a dense bloom. Gros Colman was far behind in colour and watery and poor in flavour compared with Gros Maroc.—A. E. WARNE, *Elstree, Herts*.

Lime and Cherries.—It has frequently been remarked that Cherries might be grown more largely than they are, and that other counties could share with Kent the profits from this important crop. Kent holds the monopoly of Cherry culture, and the cause, I think, can be traced to lime. It is obvious that Cherries like lime, and if this does not exist naturally in the soil and means are not adopted for supplying it artificially, it would be better to plant other fruit trees. Some of the best Cherry orchards I know are on land where the chalk is found within a few inches of the surface, so that practically the trees are growing in it.—H. H.

Pear Durondeau.—This, one of, if not the highest coloured Pear in cultivation, grows to a large size. The flesh, which is white, is very juicy and richly flavoured. It is a splendid dessert Pear, ripening at the end of October, and keeping quite three weeks afterwards in good condition. After arriving at maturity in warm districts the tree will grow and bear well in the open garden as a bush on the Quince, when it is exceedingly prolific, but in colder districts it should be grown against a west wall. It should prove a valuable Pear to grow for market, as its handsome appearance, large size, and fine flavour would be sure to attract buyers.—A. W.

Apple Bramley's.—Shapely and well-ripened fruits of this Apple are very handsome, and it is one of the best late cooking kinds, excellent either as a sauce Apple or for baking, but it is not always so free as may be desired. As a rule, I think, it fruits best on a light or medium soil, and it certainly dislikes very close forms of training. The fruits keep well and are always acceptable in the kitchen. Bramley's is a very strong grower, and when young trees on the free stock are planted they will in all probability require somewhat severe root pruning and the soil made as firm as possible about the roots. I noticed some very nice specimens of this Apple at Ickworth recently.—H. R.

Pear Althorpe Crassane.—This well-known and highly-esteemed Pear was raised by Mr. T. A. Knight. The fruit is medium sized, roundish and irregular in outline, with a pale green skin, which becomes dark brown on the sunny side, and the whole surface is sprinkled with minute white dots. It is an excellent Pear, and should be allowed to hang as long as it will, and then be stored in a perfectly cool room. There it will ripen to perfection and keep for a long time. I have frequently had it in good condition in the middle of January when so stored. If placed in the warm Pear room it comes into use during November and the beginning of December. The tree is a vigorous and hardy grower, bears freely, and succeeds well either as a standard or bush.—S. E. P.

MENABILLY.

IN a county so favoured by its position and its climate as Cornwall there are many excellent gardens containing treasures in the way of plants but seldom met with elsewhere. Even in that favoured county gardens like that at Menabilly are very rare, and many of the plants cultivated there cannot be seen anywhere else; at least, not in the same perfection. Menabilly, the property of Mr. J. Rashleigh, is situated about a mile and a half from Fowey, and perhaps $2\frac{1}{2}$ miles or 3 miles from Par. From the Fowey side a most pleasant carriage drive winds through extensive woodlands and valleys, the owner's taste, and especially his love for beautiful plants, being apparent everywhere, and the arrangement of the plants entirely without that stiff formality which jars upon the feelings of those who love Nature in her simplest forms.

All the year round a visitor to Menabilly—provided he is a lover of plants—will find something to interest him, and most probably something he has never seen before. In the spring-time thousands of Daffodils and other bulbous plants dot the grass; in summer, flowers and flowering shrubs of every description adorn the grounds. Among the late or autumn-flowering shrubs are many thousands of Hydrangeas which abound everywhere, and nowhere else have I observed their handsome trusses of flowers of a deeper shade of blue. Even in winter the attractions of Menabilly are manifold owing to the great variety of rare evergreens—Dracenas, Palms, coniferae, and last, but not least, its Bamboos, which include every variety that is known to succeed in Great Britain. The illustration (p. 480) depicts a group of *Gunnera manicata* and *Osmunda regalis* (Royal Fern), which is passed on our way through the drive mentioned above. There are larger *Gunneras* in Cornwall, but it is questionable whether any of them occupy a more telling position than the group here illustrated, which grows on the fringe of a stream.

Bamboos are everywhere, and the specimens most conspicuous for their size and graceful beauty are *Arundinaria nobilis*, *Phyllostachys viridi-glaucescens*, *Arundinaria nitida*, and others. Not far from the house is a Bamboo garden proper, which is the pride of its owner and the envy of his friends. The love of the owner for his plants is manifested by the careful way in which every plant is labelled by an inconspicuous, but indestructible tablet of zinc. Among the gems of the collection are the true *Arundinaria falcata*, which is but seldom seen out of doors, and varieties like *Arundinaria nobilis*, *A. nitida*, *A. gracilis*, and *Thamnocalamus Falconeri*, which are never seen in the midlands in such a state of perfection as at Menabilly. Magnificent specimens with canes considerably over 20 feet in length may here be seen of both *Thamnocalamus Falconeri* and *Arundinaria nobilis*. Other rare varieties here grown most successfully are *Phyllostachys violascens*, *P. heterocycla*, *P. macrosperma*, *P. verticillata*, &c. The house, which is covered with beautiful creepers, looks out upon an extensive undulating lawn covered in spring by thousands of Narcissi and sheltered on either side by choice trees and shrubs. In the distance the sea is distinctly visible, and it is probably this fact which suggested the name of the "Spy-glass," by which this undulating valley is known. Near the house is a very fine specimen of *Dracæna australis*, which was photographed when in full fruit and is illustrated herewith.

The Palm walk is some 150 yards in length and planted alternately with *Chamærops excelsa* and several varieties of *Dracenas*. The

Dracenas were very fine specimens, 12 feet to 15 feet high, but the severe blizzard and extremely cold winter some five years ago crippled many of the plants, which were partly cut back, while others had to be replaced. Here again the grass in spring is studded by a wealth of Narcissi and other bulbous flowers. Not far from the Palm walk, and in a well-sheltered

ance of *Hydrangeas*. How fine an effect may be produced by these plants may be judged from the illustration (p. 484) representing *Hydrangea Hortensia* on a bank.

Conifers also play a most important part in this part of the grounds. There are few coniferae unknown at Menabilly, whose owner has devoted to this class of plants much tender care. Conspicuous among rare conifers is *Arthrotaxis laxifolia*, known as the Jointed Yew, from Tasmania. The specimen illustrated (p. 477) has bright green foliage and is 18 feet or 20 feet in height. *Pinus Montezumæ* (see illustration on p. 481) is probably the finest specimen of its kind in Great Britain. It was planted by Mr. Rashleigh in 1874, and it was then only 2 feet high, but measured 25 feet in height and 5 feet in girth in 1894. At the present time this handsome native of Mexico is of course still much larger and its needles are 9 inches to 10 inches in length. Of other handsome coniferae I will only mention the elegant *Taxodium distichum sinense pendulum*, and fine specimens of *Podocarpus Andina*, *Sciadopitys verticillata*, *Larix Kæmpferi*, and a host of others too numerous to mention.

Rare shrubs of all kinds also form a most important feature among the treasures of Menabilly. I noticed a fine bush of *Raphiothamnus cyanocarpa*, which is a native of Chili and has formed a specimen about 18 feet high by 12 feet through. It has dense, Myrtle-like foliage, and at the time of my visit was covered with a mass of berries the size of a pea and bright violet-blue in colour. *Leptospermum scoparium* is another interesting plant. Though a native of New Zealand, it appears to be quite at home at Menabilly, where it has developed into a shrub about a dozen feet in height, and where both its very small Myrtle-like leaves and its reddish lilac flowers are very attractive. *Parrotia persica*, with its drooping habit and its fine leaves just turning scarlet and yellow at the tips, was also an object of great beauty at the time of my visit; nor must I omit to mention the Japanese climbing *Hydrangea* (*Schizophragma hydrangeoides*) some 30 feet high, and clinging like Ivy to the stem of a tree. Its flowers are flesh coloured, and appear in flat cymes some 5 inches or 6 inches in diameter. A Tasmanian "Devil's Pepper-bush" (*Drimys aromatica*) forms a bush about 13 feet in height, and interesting also are *Colletia cruciata*, 10 feet high; *Pittosporum Colensoi*, about 11 feet; *Ligustrum coriacaemum*, and many others.

Dracæna in fruit at Menabilly, Cornwall, August, 1899.
From a photograph by G. A. Champion.

part of the woods, is a deep depression devoted to Tree Ferns. There are eight or more specimens of *Dicksonia antarctica*, evidently feeling very much at home and receiving but very little, if any, protection during winter. At the other end of the Palm walk are numerous choice hardy shrubs, and again we notice an abund-

beautiful plants at Menabilly is an excellent collection of *Rhododendrons*, mostly of the Himalayan or Sikkim type. The extensive fruit and kitchen gardens as well as the flower garden and pleasure grounds generally are under the care of Mr. Bennett, who is well acquainted with all the plants and their history.

F. W. MEYER.

KITCHEN GARDEN.

PRESERVING ROOTS THROUGH THE WINTER.

It is easy to preserve roots during the winter when one possesses a special place for the purpose, but as everybody cannot afford a suitable root-house or a cellar, in most cases one has to be content with putting the roots into any kind of cellar or into a clamp in the garden. Under such conditions the roots keep fairly well, but there is always the risk of losing some through dryness or rot. There is, however, an easy means of protecting roots from frost. It is little known and deserves to become common, as it is within the reach of all and is specially fitted for preserving Beetroot, Carrots, Celery, Cabbage, Turnips, Parsnips, winter Radish, &c. It should be carried out in the following manner:—

In a part of the garden sheltered as much as possible—along a wall preferably—choose a well-drained rather light soil for the reception of the roots, and having lifted these with care, cut off the leaves half an inch or so from the collar. Select a dry day and dig a trench 3 feet or 4 feet wide, more or less deep according to the length of the roots, and place them in it in a vertical position and so that the collar is on a level with the soil. The roots must not touch each other. The first line completed, fill up the trench and stamp the soil well down over the roots; then open a second trench at a distance of 6 inches or 8 inches from and parallel to the first, and so on with other trenches. The vegetables should be covered as far as the collar, except Turnips, of which the fleshy part should be left above ground.

In private establishments it may be more convenient to employ another way, which permits of the placing together of the kinds of roots for which there is most frequent demand. Thus, instead of digging the trenches across, make them lengthways, putting in a certain number of the most commonly needed vegetables, such as Carrots, Turnips, and in less quantity Celery, Beet, Radishes, Parsnips, so that on opening a trench across one may find a few of each sort of vegetable. This makes it unnecessary to re-open the trench at different places or uncover it in several directions.

On the first appearance of frost, cover the whole surface of the plot, and for about 12 inches to 16 inches around, with dry leaves or manure about 8 inches deep. If the cold increases, double the depth of the covering so as to prevent the soil from becoming frozen. Whether the soil has frozen or not can be ascertained by thrusting a stick through the layer of leaves or manure. In time of thaw remove the covering with a fork, but hold it in readiness for replacing on the first occasion. In winter and until the spring, unless there is very severe and prolonged frost, vegetables can be taken out as required by simply removing the covering of the trench and lifting them with a spade or fork, replacing the covering afterwards.

We find this plan of wintering vegetables very successful in the case of Milan Kale and Broccoli, the plants being placed in lines with the heads inclined to the north, after having previously removed the large outer leaves. In frosty weather we protect the ground with worn-out matting, covered with manure or leaves, and uncover during thaws.

The gardener who can spare empty frames in winter (as frequently happens) may simplify operations greatly by planting the roots in

lines in well exposed beds in boxes, covering these over with the frames and matting during frost. It is well to surround the boxes with manure also if the cold is very severe. In these conditions the work of removing the vegetables is easier and cleaner.

In addition to its extreme simplicity, this plan of wintering vegetables has the great advantage of keeping the roots as fresh and sound as if they had been gathered in season.—*Revue Horticole.*

Globe-shaped Beet.—I saw a breadth of globe-shaped Beet on trial at Chiswick in 1898 which greatly pleased me. Last spring I procured seed of this variety with the view of giving it a trial in the gardens here. As is usual when novelties are sent out, the seed supplied was none too plentiful, but by economising it to the fullest extent and sowing two seeds only about 1 foot apart, several rows of plants were ultimately secured. These have done well, the roots being quite true in shape and like those grown at Chiswick. Some were pulled for use during August and September, and the remainder were lifted and clamped a fortnight ago. When cooked the flesh is of fine colour, very tender, and of good flavour. In my opinion it is so superior to any of the flatter forms or Turnip-rooted Beets, that the latter will therefore not be grown another year.—A. W.

Tomato Ham Green.—I have grown nearly all the so-called new kinds, but for general crop I find nothing to surpass Ham Green. What we want is a variety that produces plenty of nice smooth fruits rather under than over a quarter of a pound each. The colour of this variety is all that can be desired, and I think that if a vote were taken on a dozen varieties of the best-known Tomatoes, Ham Green would head the list—at least amongst growers for profit. Culture has a more marked effect on the Tomato—at least in a short space of time—than on many other fruits or vegetables, for it is such a strong rooter and gross feeder, that it shows in a few days the effect of applications of artificial food. During the past season I had plants of Ham Green Tomato that produced beautiful even-sized fruits, about six to the pound, for some distance up the stems, but on giving a few good doses of guano the fruits took on quite a different character—in fact, quite unlike the first gatherings. On ceasing to give stimulants, the latest gatherings were of just the shape and size that are most sought after by the public.—J. GROOM, *Gasport.*

Corrugated versus smooth Tomatoes.—I think too much importance is attached to the smooth varieties of Tomatoes, that is, where the produce is required for cooking. It may be fancy on my part, but I think the corrugated varieties have the best flavour, at least as a rule. Is there yet a better flavoured Tomato than the old Dwarf Orangefield? I think not. More than that; were I planting simply for home use and could ensure a true strain, I would, if confined to one variety, grow Orangefield. Laxton's Open-air, another rugged-looking fruit, is of excellent quality, and the crop I saw last autumn in a private garden trained up stakes was enormous. Carter's Outdoor belongs to the same section and is a most reliable variety. In looking over the very interesting and instructive notes on Tomatoes in THE GARDEN I was pleased to see Mr. Challis and one or two others speaking favourably of Regina. As a smooth, handsomely shaped, heavy cropping Tomato either for indoor successional work or in the open air, I know of few to equal it.—N. N.

Flat v. sloping borders.—From the point of view of the fruit trees, "A. W." is doubtless quite right in his argument against sloping borders, but in the kitchen garden small beds raised to the sun are very useful. Not only do the young growing crops get the full advantage of the sun, but when these are thrown up in the open the small bank formed at the back of each

materially protects them against cold winds. Where the position is exposed, beds for sowing small early salads, especially Radishes, followed on the same ground by young Carrots, and later by Parsley, may be thrown up 3 feet wide in a crescent shape, the back facing north and east, the front south and west, and they are very valuable. In gardens facing the south and protected by good walls, all that is necessary is to let the beds run east and west in a straight line. Besides forming a wind-break, the back of each bed forms a convenient place to rake any covering material used into on fine days. This plan is much affected by market men in the west of England for the crops referred to, and with excellent results. It may be followed with advantage in private gardens having a light soil for the culture of the crops named, also for early Lettuces and Turnips, all this saving frame room in spring.—H. R.

Coal ashes for Potatoes.—"G. H. H." and "W. S." are both perfectly right as to the abuse of coal ashes for Potatoes, but in my note I recommended them for mixing with the compost used on Potato ground in conjunction with other things, and as an addition I can very strongly recommend coal ashes, if only as an opening medium. As to their having no manurial value, I consider this at least not proven, for who has not noticed the way almost every description of plant roots into coal ashes, the roots ramifying freely, the plant in many cases being improved in health? When used fresh and in the ridiculous manner mentioned by "W. S.," coal ashes are undoubtedly injurious; so they are as a covering to bulbs after potting, but when moistened and weathered, as they would be if used as I recommended, they are good for either purpose. Not only this, but the scabby appearance of Potatoes grown with coal ashes in the soil is not always due to the presence of these, unless, as I say, they have been used fresh. Most of the cottagers hereabouts, and in many other parts of the country for that matter, are in the habit of throwing ashes and all the manure they can get into a heap and dressing their gardens and allotments with the mixture. Many of them grow exceedingly good and clean samples by this judicious use of a waste product.—H. R.

Winter greens.—But a few weeks since market growers were congratulating themselves on the almost luxuriant appearance of all descriptions of winter greens resulting from the earlier autumn rains. In every direction Brussels Sprouts, Savoy Cabbages, Kales, Coleworts, &c., were then looking so well as to lead to the belief that the anticipated scarcity resulting from the long drought of the summer would not exist. But the intervening weeks seem to have wrought a distressing change, as it is now complained that aphid is so rife in all descriptions of green stuff, that large breadths have been rendered not only unsaleable, but are being destroyed. The best thing to be done in such cases seems to be to turn sheep on to the breadths and let them eat up green stuff and insect pests. After the very heavy rainfall earlier in November it was naturally thought that all descriptions of vegetation had been pretty well cleansed. But the reverse seems to have been the case, for later dry weather has helped to breed the aphid wholesale, and their presence is now far in excess of anything old vegetable growers can remember. No doubt the visitation is due to a legacy of the dry season which bred these insects and enabled them to re-breed in the most liberal way. Aphid-infested green stuff is of course unsaleable. Those who have purchased such matter have found that there is no means of cleaning the vegetables without literally pulling all to pieces, and even then the labour is great. It is hoped that this trouble is not widespread. It seems to be bad enough in West Middlesex.—A. D.

Onions.—A great quantity of Onions has been hawked about the streets of our county town during this autumn, and the vendors seem to experience but little difficulty in getting rid of them. The persons selling them appear to be French sailors, and they come by rail, no doubt,

from some of the nearest seaport towns. The Onions are neatly roped together, each rope being from 3 feet to 4 feet long, and they carry them on long poles balanced on the shoulder. From what I have seen it is mostly people attending the market who become customers, but I have not been able to ascertain the prices at which they are disposed. They must be grown at a very cheap rate indeed to enable them to be brought

of Onions might be grown, and to have to buy them from the foreigner is, to say the least, anything but creditable. While writing on Onions I might here remark on the excellent firm condition of the home-grown bulbs this season. They are not so large as usual, through the effects of drought and not having had them thinned out quite so much as in former years, but the aggregate weight is quite as heavy. They should keep well, but

Arthrotaxis laxifolia at Menabilly.

to this country, to be afterwards hawked about in the manner described, for the men's travelling and other expenses have to be provided for out of the proceeds of the sales. There should not be the slightest necessity for Onions to be imported into such a country district as this, as all that is required for home consumption and a very great deal more might easily be grown at home. On the fertile soil which is so suitable for Hops, cereals and fruit in abundance splendid crops

unfortunately, through their having been ripened up so thoroughly, but little or any tops remain on them to enable their being tied and afterwards roped. This is a favourite method of mine of keeping Onions for late use, but it will be but few that will be suspended this season. The alternative is to keep the bulbs thinly spread out and as cool as possible, and to give them a turn over on wet days or whenever opportunity offers.—A. W.

EARLY POTATO CULTURE.

Few things in the kitchen garden require greater care and skill than the production of good crops of early border Potatoes. Some ignore it, asserting that results do not justify the time and labour incurred, but in reality a half-hearted method of culture is generally responsible for failure. Of course, in low-lying damp situations and in gardens having cold subsoils, early Potato production is practically impossible unless more than usual pains are taken; indeed, in the best situated gardens and in warm, genial soils it is no child's play. One of the most important points in early Potato culture is early preparation of the plot and the incorporation of sufficient opening material to secure a speedy and free root-action. I like to keep the border well elevated, adding the necessary ingredients, such as Mushroom manure, burnt refuse, sweepings of walks and drives and wood ashes. Strong farmyard manure is best omitted at this period, being used later on for successional crops on the same border. I like to ridge the border up to the action of frost and wind, levelling it previous to planting, say in March. This exposure ensures the crumbling of all lumps, kills insects, and sweetens and improves the soil generally. A south aspect is the best and shelter from cold cutting winds imperative, such working much greater mischief in the earlier stages of growth than ordinary frost.

The preparation of the seed tubers is of great importance. Some think sprouting to any degree unnecessary, and even injurious, but while having a decided objection to placing the seeds in intermediate houses and forcing the sprouts unduly, I know from experience that tubers having short, stubby growths when planted mature earlier, if not better crops than seed minus growth. Of course, to bring seed from a warm Peach house or vinery and plant at once in open-air positions is to court partial failure, yet such is often done. From the moment the seed-tubers of extra early Potatoes are sorted from the eatable ones in summer, they want careful watching. I cannot say I am in favour of spreading them out on the ground in order to become greened and, as some think, matured. It may do when the object is pot culture, as then potting or boxing usually takes place in December and early sprouting is not such an evil. The open-air exposure referred to induces, I think, early autumn sprouting, the new growths if left on being far too forward for March planting, their frequent removal, on the other hand, of necessity materially weakening the tuber. The best way is to lay them out thinly in quite cool shady quarters, examining them at intervals and if possible arranging them in boxes for convenience sake. The short-topped early sorts grown now-a-days will need no forcing to form sprouts sufficiently long for March planting, but if any assistance is needed the warmth of an ordinary sunny greenhouse will suffice, a few days' confinement in a cool frame or pit previous to planting further hardening them. Even when desirable to lift eatable tubers at the earliest possible date it is not wise to adhere to any particular date for planting. The general condition of the weather and ground should decide this. I have before advocated planting shallow and drawing slight mounds over the drills, as these extra early short-haulmed varieties do not root deeply. A little leaf mould and fine loamy soil well mixed strewn over the seed favour a good start and prevent decay. From a couple to three growths to each tuber are sufficient, producing as much foliage as can be properly exposed to sun and air, even when crowding the rows is avoided. Rough-and-ready protection in spring is better than none at all, but it can hardly be expected that a few evergreen boughs, although effectual in the case of Cauliflower and Peas, will save the tender susceptible growth of Potatoes from maybe a dozen degrees of frost. Wood is cheap, and a home-made rough frame with cross rails is easily erected and can even remain up permanently. Cheap stout canvas, oiled to preserve it from the weather, forms the best covering, care-

ful and constant attention being paid to covering and uncovering. NORWICH.

Greens and caterpillars.—Usually we expect to get rid of the caterpillar plague when the cooler weather sets in. Only the other day, the middle of November, I examined a breadth of Brussels Sprouts, and was surprised to find the plants badly infested with caterpillar. No time has since been lost in getting them picked off. Aphides are also giving trouble this season, particularly among Brussels Sprouts. Here and there I have observed plants less healthy and vigorous than the rest entirely covered with aphides, which also infest the sprouts up the stems and render them unfit for use. A few sharp frosts would, of course, put an end to these plagues. In the case of sickly greens stricken with aphides the best plan is, I think, to pull them up and burn them.—H. H.

Shortness of winter Turnips.—The summer and autumn drought rendered the growth of Turnips almost impossible in gardens short of water and where the soil is of a light description. These troubles if they came alone might be surmounted to some extent, but it was not to be, by reason of the intervention of the Turnip fly. Frequent dustings of lime and soot in a dry state had no material influence, and Elder boughs brushed over the surface in the early morning—usually a good preventive—failed in many cases this season. The seedlings, even before they have fully developed the seed-leaf, disappear as if by magic when the ground is overrun with these destructive pests. The result of this is now felt in the scanty crop of roots available for daily use. It is only from favoured districts from which a supply comes. I cannot recall another season when there has been such a poor crop, or such a general outcry from growers and consumers of the dearth of good Turnips.—W. S.

Marrows without manure.—It seems to be a generally accepted, and I may add old-fashioned, theory that Marrows to succeed well must be grown on a manure heap, or, failing this, they must have a heavy dressing of farmyard material applied to the ground before planting. Doubtless good Vegetable Marrows are grown by such treatment, but to say they cannot be cultivated well without it is a fallacy. In the past two dry seasons I have succeeded in growing heavy crops of Marrows without manure and also without water. I put out a number of Marrow plants that had been raised in pots on an open, fairly retentive piece of ground that had been done moderately well for a previous crop. The result in both seasons far exceeded my expectations. The plants did not make the giant leaves and sappy growth which are often the result of strong manure, but the shoots were sturdy and short-jointed. By cutting the fruits as they attained to a serviceable size the plants were relieved of the extra strain, and they continued bearing heavily till frost destroyed them.—H. H.

Celery Major Clark's Red.—This variety of Celery is hard to beat for general purposes, especially for use after the end of November. This season late Celery ought to keep particularly well, as, owing to the absence of severe frosts, it has been easy to leave the soil low on the ridges. But it is not safe to leave it any longer, and if the earlier mouldings have been properly done it is very little trouble to finish all off neatly. I usually make the men use a garden line, twisting this around each head as they go, as this enables two men to work at the row, one each side, and prevents the sticks being beat or the earth finding its way down to the heart. It is less trouble than either tying up each head with raffia or setting a man to hold each, in which case only one side of the ridge can be done at a time. The kind above named has abundance of good outer leaves, and though requiring more room than the very dwarf varieties, is well worth it. The rows should for late work be 4 feet apart, and these, if possible, ought to be got out very early in spring so that they are well weathered. The small

plants may then be pricked direct into the trenches, and such I always think keep better than those which are pricked out and again transplanted when large.—H.

Cabbage Old Essex.—By the courtesy of Mr. Beesley, of Denbies, I have received a dish of Cabbage under the above name, interesting to me as having been introduced from Claremont to the neighbourhood of Dorking more than seventy years ago and grown there ever since. It is a small, firm Cabbage, of conical shape, of very mild flavour, so much so that it is evident our forefathers from this standpoint had quite as good an article as we can produce to-day. Mr. Beesley tells me he sows it with the Coleworts about the middle of June, and has an abundance of small firm heads right away till Christmas from the first cutting. It should be equally serviceable for February sowing to furnish summer cutting. As 15 inches each way is plenty wide enough to plant, it should be an ideal Cabbage for small gardens. Among the small quick-growing Cabbages, I have not met with one just like this, and shall be glad to know if it is still in commerce.—E. BURRELL.

Brussels Sprouts.—I have had an opportunity this year of trying many (so-called) different varieties of Brussels Sprouts, and have come to the conclusion that in the majority of cases there is very little to choose between them. It would be well if a thorough trial of the same could be made at Chiswick with the view to determine the best types and the many synonyms. Personally I much prefer a dwarf strain, say not more than 30 inches or so in height, always provided, of course, that the stems are well clothed with firm, solid sprouts. The tall-growing varieties may be very well in sheltered situations, but if exposed they are, unless well earthed, very likely to blow over, materially affecting the well-being of the plants besides giving an untidy appearance to the quarter. A good strain of Scrymgeour's Giant is, I think, still one of the best to grow. The extra size of the sprouts may be objected to for some purposes, but this might form the bulk of the crop, and the variety known as the small French be grown for special requirements. This is a tall-growing sort well clothed throughout with exceptionally solid sprouts. In common with most things, the Brussels Sprouts suffered this year from the protracted drought. They were a long time from the planting in making their growth, and during this spell of inaction aphids got a tight hold, making them dirty and necessitating a good washing before sending them into the kitchen.—E. B.

Late Broccoli.—In a season when the earlier planted green stuff had difficulty in making headway, and in many cases is smaller, less productive at present, and likely to be so, it is gratifying to record a signal success with late Broccoli, which never looked better, and which, given a favourable winter, is likely to furnish some very fine heads. Having a light, sandy soil to deal with, the Broccoli has been planted for the last ten seasons on ground previously cropped with late Potatoes. In this particular instance the Potatoes were lifted rather late in the autumn of 1898, the ground well loosened between the rows, and left, save for occasional attentions with the hoe, until the plants from the May sowing were ready. It had settled down dry and hard, necessitating the use of a short crowbar to make the holes. Sufficient space was left after the plants were filled in to allow for a thorough soaking of water, and although from the time of planting until late in October we had no rain, they came away well and covered the ground, presenting just the appearance one likes in a brake of late Broccoli, viz., a close, sturdy habit with big, stout stems and vigorous foliage. It may be noted that care should be taken in crowbar planting not to make the holes too deep, as if this is done the soil is not always well settled about the roots. The three best for general excellence are Maincrop, Champion, and Miller's Dwarf Late White. In these days when new sorts are

annually offered in such profusion, the last-named of the above trio is apt to be neglected. It is, however, a very good variety, dwarf, compact, and hardy, yet vigorous in habit and throws very fine heads.—E. BURRELL.

ORCHIDS.

NATURAL HYBRID ORCHIDS.

(WESTERN SECTION.)

THE Western section of natural hybrids in most cases surpasses in point of usefulness and beauty those which have been previously dealt with as the Eastern section, and is, therefore, from a garden point of view of far more interest than most of the Old World products, and in point of value among the most cherished and highly prized among Orchid experts.

BIGENERIC NATURAL HYBRIDS.

One of the earliest of the natural hybrids to make its appearance was

Lælio-Cattleya elegans, discovered in 1847 on the island of Santa Catherina. It has since been collected, and is now frequently imported from other localities of Southern Brazil. All the forms were originally distributed, and are perhaps best known in gardens at the present day as *Lælia elegans* when referring to the varieties with deeply coloured flowers, while the lighter tinted varieties are recognised as *L. e. alba* and *L. e. Schilleriana*. In the district above referred to three well-known species occur, and, in certain localities at least, they grow intermixed. These are *Lælia purpurata*, *Cattleya Leopoldi*, and *C. intermedia*. It is interesting to compare the characteristics of the offspring with the combined characters of the two parent species. In growth some of the pseudo-bulbs bear a single leaf, as in *Lælia purpurata*, and others a pair, as in the *Cattleya* parent, while in shape they are intermediate, or incline towards one or the other parent. The same remark applies to the flowers both as regards shape and colour. There can be little doubt as to their origin, and the distinctive characteristics are plainly visible. The dark varieties, or *L.-C. elegans* proper, are derived from the intercrossing of *Lælia purpurata* and *Cattleya Leopoldi*. The light forms originally distributed as varieties of *L.-C. elegans* have been proved under artificial hybridisation to have their origin in *Lælia purpurata* and *C. intermedia*, and are now described as

Lælio-Cattleya Schilleriana. The white form originally appeared in 1855 in the collection of Consul Schiller, of Hamburg. The original form had white flowers and an obscurely three-lobed lip, the front lobe and tips of the side lobes amethyst-purple, a purple line along the disc and a little yellow in the throat. Around the original form many variations are grouped, which is less numerous than in *L.-C. elegans* have been more misunderstood. *Lælia elegans alba* (*THE GARDEN*, vol. xvii., p. 132, t. 218) belongs here. *Lælia Wolstenholmia*, *L. Stelzneriana*, *L. Mesuresiana* and *L. e. Warneri* must also come under this heading as varieties of *L.-C. Schilleriana*. It is worthy of note that neither of the parents was known at the time of the advent of *L.-C. elegans*. Other bigeneric hybrids between the closely allied species *Lælia* and *Cattleya* have since made their appearance.

L.-C. albanensis was supposed to have its origin between *C. Warneri* and *L. grandis*. It appeared with Messrs. F. Sander and Co., St. Albans. The sepals and petals are light rosy-mauve, the front lobe of the lip rosy-crimson with some radiating veins through the margin, which is rosy-lilac. The side lobes are also rosy-lilac with some yellow at the base and brownish-purple small lines through the throat. The parentage has been confirmed by the flowering of a hybrid at Brussels.

L.-C. amanda originated with Mr. W. Bull. It is a supposed natural hybrid between *C. inter-*

media and *L. crispa* or *L. lobata*. The sepals and petals are pale rosy lilac, the front lobe amethyst-purple, with a lighter margin, the side lobes rosy lilac, shading to yellow, with radiating reddish streaks through the base. *Cattleya Rothschildiana* is a synonym of *Lælio-Cattleya amanda*.

L.-C. Gottoiana is derived from the intercrossing of *L. tenebrosa* with one of the *C. labiata* section, probably *C. Warneri*. The flowers are nearly as large as in *Cattleya Warneri*, the petals narrower and more acute, and their colour as well as that of the lip is a uniform bright rose-purple. There is a little deeper colouring on the disc of the lip, but the yellow blotches so familiar in the throat of the *Cattleya* parent are quite obliterated. It was first exhibited on June 23, 1891, and was awarded a first-class certificate by the Orchid committee of the Royal Horticultural Society, coming from the collection of Mr. E. Gotto, Hampstead Heath, having been imported as *Lælia tenebrosa*. The variety *L.-C. G. rosea* appeared later with Messrs. F. Sander and Co.

L.-C. Pittiana is a supposed natural hybrid between *Cattleya guttata* Prinzi and *L. grandis*. The sepals and petals are creamy white, tinged with rose, and having a few minute dots of crimson; the front lobe of the lip rich crimson-purple, the remaining portions nearly white. It is a most distinct hybrid.

L.-C. Oweniæ is a supposed natural hybrid, having *L. Perrini* as one of its parents. It has dark rose-coloured flowers and the tube of the lip white. A plant was exhibited by Mr. G. D. Owen at the Royal Horticultural Society's meeting, August 23, 1894.

L.-C. Porphyrites was brought by Mr. J. Day from Brazil in 1884. The presumed parents are *L. pumila* and *C. Dormaniana*. The sepals are greenish purple, petals pale purple; the lip has its front lobe rich purple, with a white disc, the side lobes light purple, becoming almost white at the base.

These comprise all, or nearly all, the natural hybrid *Lælio-Cattleyas*. They include many beautiful varieties, and will form subjects of interest for the hybridist to determine definitely what are at present only suppositions as regards the parentage.

NATURAL HYBRID LÆLIAS.

Lælia Crawshayana is undoubtedly a natural hybrid between two of the Mexican species, five of which appear to grow almost together. These are *L. anceps*, *L. albida*, *L. furfuracea*, *L. autumnalis*, and *L. majalis*. *L. Crawshayana* is probably derived from *L. albida* and *L. autumnalis*. The sepals and petals are bright rose-purple, the front lobe of the lip deeper purple, veined with a darker shade of purple, the side lobes purple, shading to yellow towards and through the base. It first appeared in the collection of Mr. De B. Crawshay at Sevenoaks, and has also made its appearance in other collections since.

L. Eyermaniana is a supposed hybrid between *L. majalis* and *L. albida*. It first flowered in Messrs. Sander and Co.'s nursery at St. Albans, but has since proved to be fairly distributed.

L. Finckeniana is one of the rarest and most distinct of this section of natural hybrids. It first flowered in the collection of Mr. C. W. Fincken, Hoyland Hall, Barnsley, in 1892. It is no doubt derived from *L. albida* and a white form of *L. anceps* of the *L. a. Dawsoni* section. The sepals and petals are pure white, the ground colour of the lip also white. The front lobe has a crimson-purple blotch, and the side lobes are striped with radiating purple lines. It was awarded a first-class certificate by the Orchid committee of the Royal Horticultural Society on December 12, 1893.

L. Gouldiana is a supposed natural hybrid between *L. autumnalis* and *L. anceps*, but has appeared in such large quantities that it seems almost impossible to be of hybrid origin. It has

the undoubted intermediate characteristics of the two species, and is too well known to need description here.

L. leucoptera appeared with M. Peeters, of Brussels, in 1884. It was described by Reichenbach as *L. Crawshayana* var. *leucoptera*. It is more probably a hybrid between *L. albida* and *L. furfuracea*.

L. venusta is another hybrid of this section, having the intermediate characters of *L. furfuracea* and *L. autumnalis*. It first appeared in Messrs. J. Backhouse and Sons' nursery at York, afterwards passing into the Downside collection of Mr. W. Lee, where I noted the plant in flower.

L. lilacina has pale lilac sepals and petals, the side lobes of the lip white, marked with purple lines on the inner side, the front lobe bluish-white, with a purple blotch in front. It is supposed to have its origin between *L. crispa* and *L. Perrini*.

L. Wyattiana is probably extinct. It is supposed to have been a cross between *L. crispa* and *L. lobata*; the sepals and petals white, the front lobe of the lip deep purple, becoming yellow through the base of the side lobes. It appeared in Mr. Neville Wyatt's collection at Cheltenham.

NATURAL HYBRID CATTLEYAS.

Cattleya Brymeriana is a supposed natural hybrid between *C. superba* and *C. Eldorado*; the sepals and petals are rosy purple, stained with white, the front lobe of the lip deep purple, shading to yellow on the disc, the side lobes mauve-purple, shading to yellow at the base. It was introduced through Messrs. H. Low and Co. and named by Reichenbach in 1883. Of

C. Hardyana, the parentage has been confirmed by Mr. N. Cookson. It is one of the most beautiful of all the hybrids. It is very variable and must be fairly plentiful, judging from the manner in which plants have turned up among importations of *C. Warszewiczii* (*gigas*) and *C. Dowiana aurea*, from which species the hybrid has its origin. The characteristics of the species are wonderfully combined in the offspring. It is much sought after and a valuable plant.

C. Massaiana is a form of *C. Hardyana*.

C. intricata is a supposed natural hybrid named by Reichenbach between *C. guttata* and *C. intermedia*.

C. Krameriana is supposed to have its origin in *C. intermedia* and *C. Forbesi*. The sepals and petals are bluish, suffused with pink, and pale green above; the lip bluish, reticulated in front with rosy purple.

C. Measuresi has its supposed origin in *C. Aelandiæ* and *C. Walkeriana*.

C. Patrocinii has the intermediate characteristics of *C. Loddigesii* and *C. Leopoldi*. It first appeared in the collection of Herr Rucker-Jenisch at Hamburg.

C. reoplendens, which originated with Messrs. H. Low and Co., Clapton, has the intermediate characters of *C. guttata* and *C. Schilleriana*, from which it is supposed to be derived.

C. venosa is a distinct hybrid. The combination of *C. Harrisoniæ* and *C. Forbesi* has a quaint effect.

C. Victoria Regina, a charming addition to the natural hybrids, is supposed to have its origin in *C. Leopoldi* and *C. labiata*. It was introduced through Messrs. F. Sander and Co. in 1892, and has since turned up in other collections, although the plants originally distributed proved to be in the majority of cases nothing more than *C. Leopoldi* and *C. granulosa*. In the hybrid the flowers have the exact intermediate characteristics of these species. Another closely allied variety is

C. Imperator, exhibited by Messrs. Linden, of Brussels, as *C. Le Czar*. It received a first-class certificate October 27, 1896. Particulars will be found in THE GARDEN certificated list of plants for that date. It has larger flowers and the lip is more deeply divided than in *C. Victoria Regina*. It is a supposed hybrid between *C. labiata* and *C. granulosa*.

C. Whitei has its origin no doubt in *C. Schilleriana* and *C. labiata*. The sepals are deep rose,

tinged with olive-green; petals deeper in colour; the front lobe of the lip purple, with deeper purple veins; the side lobes pale rose-purple, with some yellow at the base. It was introduced by and named after White, one of Messrs. H. Low and Co.'s collectors. A plant of this lovely natural hybrid from the Clare Lawn collection of Sir F. Wigan, which was thought to differ from the original variety and received an award of merit as *C. Whitei* (*Wigan's* var.), was recently exhibited at the Drill Hall. H. J. C.

CATTLEYA HARRISONIÆ.

THE fine mild autumn has been all in favour of *Cattleyas*, and this beautiful old species has been, and still is in many instances, flowering with all its accustomed freedom. Really good forms of it are exquisite Orchids, and few can compare with them for beauty. Even the poorest form is well worth growing, and its culture is fairly easy when once the leading principles of Orchid growing have been mastered. All the erect-growing *Cattleyas* with thin stems show a disposition to weakness if allowed to remain long in a close or worn-out compost. They are vigorous enough as long as everything is kept sweet and open about them, but if the centre of the plant, for instance, is allowed to get bare, so that the new material can only be placed about the sides, there will never be another healthy root there, and the best thing to do is to break the specimen up into so many pieces and set each growing on its own account, or else re-moss it after removing the old and decayed portion. One thing is absolutely necessary in thus making up plants. All the young growths should as far as possible be selected of about the same strength, while any exceptionally strong or very weak ones may be kept and potted singly.

Very often by these means plants that have been languishing for years may be brought back to a thoroughly healthy state, and the small, weak bits that are removed at the time go on and improve, eventually reaching flowering size themselves. I have in so many instances lately seen plants of this species doing well on blocks of Tree Fern stem, that I cannot but think there is something specially suitable to *Cattleya* roots in this material. One seldom sees a really unhealthy plant of any *Cattleya* upon it, unless, of course, it has been very badly treated in some other way or is covered with insects, and the semi-rambling habit of *C. Harrisoniæ* especially fits it for this method of culture. Respecting position, it is a native of Brazil, and the useful intermediate house suits it admirably. It must be kept well up, so that the plants get to the full the advantage of sunlight and air, for all the year round it delights in sunshine, provided it is not sufficient to harm the foliage. A little uncertain in its flowering season, *C. Harrisoniæ* should have the pseudo-bulbs well ripened after the flowers are past, and from this until spring should if possible be kept dormant.

Lælio-Cattleya Statteriana.—This is a fine winter-flowering hybrid, and we could do with a great many more like it. The original form was raised from *Cattleya labiata* and *Lælia Perrini*, and although it is a variable hybrid, I think the majority of the forms I have seen more nearly resemble the *Lælia* parent, a potent factor in hybrids wherever it has been used. The sepals and petals of a fine form now before me are rose, the lip with a dense purple front lobe and white and yellow throat—a lovely flower. Its treatment may easily be deduced from a study of its parents, both well-known kinds.—H. R.

Cypripedium Leeanum.—As a garden plant there are even yet few among the hybrids to beat

this, its large, clear-cut blossoms, with their fine dorsal sepal, being as showy as any in the genus. Its capital constitution is all in its favour, small bits of it soon growing into fine plants when properly treated. Like all hybrids of the older class, the flowers in different plants vary a great deal, this being on account of the many different varieties of the old *C. insigne*, from which it has been raised. But a poor *C. Leeanum* hardly exists, for every one is useful to grow for cutting from at any rate. It thrives best in an intermediate house, with ample moisture supplies all the year round.

Dendrobium sanguinolentum.—Although this species has been known for over fifty years, it is not even now by any means common; indeed, it is seldom seen. Chiefly towards the end of the tapering pendulous stems the flowers are produced in short racemes of two or three. The colour of the sepals and petals is pale yellow, with the ends blotched more or less with purple, while the lip is also blotched with purple. It likes ample heat and moisture, and, in order to ripen the growth, may be suspended from the roof in medium-sized baskets, well drained, with a compost of equal parts of peat and Moss. It is a native of Ceylon.

Odontoglossum Cervantesi punctatissimum.—In this variety the pretty rosy pink markings, as seen in most others of the species, are thickly placed over the whole surface of the sepals and petals, and in a good form the individual flowers are large and of great substance. Unfortunately, it is not plentiful, but it is just one of those things that may turn up among any importation of the species in numbers, and thus bring the price of it down. Its culture is the same as for the type, and it likes a small pan suspended from the roof in the cool house. The roots should not be severely dried at any time, and frequent small additions to the compost are necessary to keep the pseudobulbs from rocking about.

Oncidium cheiroporum.—This charming little plant is again in flower, and it is one of the brightest of those that bloom now. As a garden plant it has obtained a bad name, but this is in some instances the fault of those who have it in charge. Many of these cool *Oncidiums* cannot stand the same winter cold that *Disas* and *Masdevallias*, or even *Odontoglossums* can, and it is much better to keep the cool house at a minimum temperature of 50° than to let them be injured.

Except in the very coldest weather this would not necessitate heavy firing, and would certainly not be sufficiently high to harm any other plants. A great variety of Orchids could be safely wintered in such a house. *O. cheiroporum* should not be given a large receptacle or much compost, as large plants of it are seldom seen. Owing to its liability to damp, the pans or baskets containing it should be kept well up in the house and the usual compost of peat-fibre and Moss suits it well. If the pans are well drained so that it soaks easily away, ample moisture supplies are necessary, but such a small-growing plant is easily injured by an overdose of water when the compost is not perfectly drained. It is a native of Chiriqui, and was introduced in 1850.

Stock-seed scale on Orchids.—At this time of year this troublesome insect makes its presence known, and I know of no other insect that will so quickly run over a collection of Orchids. One day the plants may be apparently quite clean; the next, or at least a few days after, the young growths will be overrun with this scale, which takes its name from the silvery lining all round it

as seen on the seed of Stocks. Fortunately, although of such rapid increase, it is far more easily got rid of than any other kind. It is the only scale that is injured by fumigation, and even if sponging is resorted to it falls off at a touch, quite unlike the small brown, tightly-clinging scale that affects *Aerides*, *Vandas* and *Cymbidiums*. Again, it does not appear to seek the under side of the leaves so much as some other insects, so that its work is nearly always in sight. Were it otherwise it would indeed be a foe to be reckoned with, for it rapidly eats the very life out of any plant if allowed to remain. No Orchid is safe from its ravages, and although it thrives much better and quicker on soft young growths, yet it is not particular if these are not to be had. *Cypripedium barbatum* and *C. venustum* seem to be particularly tasteful to it, and wherever the least sign of it is noted, remedial measures must be taken without delay.

Stokesia cyanea.—Mr. S. Arnott at page 447 speaks of the inability to flower this plant in the north, while admitting its success in Devonshire gardens. This at least may be expected, though I was not aware it was generally flowered even in that favoured locality. Near London I have never been able to flower it myself, nor, indeed, have I

lateness of the flowering and the sparsity of flowering plants as much as the colour of Stokes' Aster that for several years I raised batches of root cuttings of the plant for this purpose, and by planting in groups in a sunny spot in the rock garden obtained a nice display, though by no means the fulness of its flowering. The same class of plants will give a good return when liberally treated as pot plants, by being plunged in the open and taken to the greenhouse in late September. No plant is more easily raised from root cuttings than this, and none give less evidence of such growth when left alone.—E. J.

GARDEN FLORA.

PLATE 1253.

MECONOPSIS HETEROPHYLLA.

(WITH A COLOURED PLATE.*)

This is a Californian annual which was introduced to Kew two years ago, when it flowered for the first time in the herbaceous garden and ripened seeds. It flowered freely again this year in the rock garden and again ripened seeds freely. From this we may conclude that it is a useful addition to hardy annuals. It was dis-

Royal Fern and Gunnera at Menabilly.

seen a single instance where its blooming may be regarded as accomplished in this part. The most that is obtained is a flower-head or two, certainly not a general flowering of the principal as well as the lateral heads, which, of course, would take some time. The nearest approach to a flowering in my experience has been obtained with frame-protected plants during winter, that is, established pot plants that had been raised from root cuttings during the preceding winter. The lateness of flowering is in no small measure due to the lateness of the plants in the open starting into growth in spring. Where the plants have remained in the rock garden or border all the winter unprotected there is usually damage to the chief growths, that at no time are numerous from the root-stock. When this occurs the season's growth is more or less dependent on a lateral growth bud at the root-stock, and its start is hampered by the damage done to the previous main growth. By protecting the plants in frames during winter, the leaf-growth as well as the crown or heart is retained, and an earlier flowering has resulted by these means. It is to the

covered in 1833 by David Douglas. Although widely distributed in North America, it is not common anywhere. According to Sir Joseph Hooker, *M. heterophylla* is the sole American representative, as *M. cambrica* is the sole European, of a genus which is well represented only in the loftier Himalayas and the mountains of Western China. The best of them undoubtedly is the blue Himalayan Poppy, *M. Wallichii*, a coloured plate of which was published in *THE GARDEN*, vol. xix., 1881. Although described as perennials, I find that all the eastern *Mecopopsids* are biennials. To maintain a supply of them it is therefore necessary to make an annual sowing of seeds. *M. heterophylla*, in addition to its annual character, has also a distinguishing one in its leaves, which are pinnately divided, whilst in all the other species they are entire or lobed.

MECONOPSIS HETEROPHYLLA

THE WEEK'S WORK.

KITCHEN GARDEN.

FOR a number of years I used to sow my first early border Peas in January or early in Feb-

plunging the pots in a cold frame. The labour of this is not great; the principal thing needed is plenty of air, as the soil needs very little water until the growth appears. I prefer pots 3 inches or 3½ inches in diameter, draining them by placing a small portion of teased loam or a little leaf-

should be plunged to the rim in either ashes, leaf mould, or cocoa fibre, and the lights put on at night when cold. Chelsea Gem is still one of the best early sorts, and the good old Stratagem if sown at the same time is very hardy, and follows close on the heels of Chelsea Gem. Another capital medium height Pea possessing a grand constitution is Wordsley Wonder. It is surprising how this variety will yield under good culture, the individual Peas also being much larger than the majority of white-seeded varieties. The interior of the frame should be examined each morning, as a single mouse will ruin a whole batch in a few days if not detected. I have known Furze branches to be pegged down round the sides and ends of the frames with good results, as mice do not seem to appreciate them. Be careful when watering to thoroughly moisten the soil.

PREPARING FRAME POTATOES.

—It is now quite time tubers of such early forcing varieties as Sharpe's Victor and Ring-leader were placed in order in shallow boxes and given comfortable quarters in a greenhouse or other tolerably comfortable quarters not far from the light, in order that new sprouts may come away strongly and reach the length of half an inch by the second week in January. This is much better in all ways than postponing it until a week or two before they are required for planting, and then forcing them unduly in a warm Peach house or vinery. Formerly I used to cover the bottoms of the boxes with half an inch of leaf-mould, but do not now, as I found the tubers often rooted into the compost, and if not taken out and planted in the nick of time, got such a hold that in freeing them from it many young fibres were torn off. A sprinkling now and then with the syringe to prevent over-dryness will be all that is wanted.

FORCING LETTUCES. — Where plenty of Lettuce in spring is imperative, it is well to sow now seed of any of the small Cabbage varieties and to prick out the seedlings on a gentle hotbed at the end of January. Sow in a pan or box, placing the same in an intermediate house, thinning out as soon as the young plants can be handled, and elevating them close to the roof-glass to ensure a stocky growth. Two good varieties for sowing now are Perfect Gem and Golden Queen, and a pinch of that excellent sort All the Year Round may also be sown. From a two-light frame, raised on a bed of warm leaves and surrounded by linings, very useful hearted produce may be cut in April. Lay on the surface 6 inches or 8 inches of

good garden soil. Of course, plants put into frames in autumn will after average winters afford an ample supply, but as one never knows what weather is in store, it is always best to be on the safe side, salad being so important.

SEAKALE CUTTINGS.—As each batch of Seakale

The Mexican Pine at Menabilly.

ruary, using small pots and placing them in a warm Peach house or vinery until they had grown an inch, then in a cooler house for, say, a fortnight, finally placing in a cold frame to harden off. I have now abandoned that plan, and sow about the middle of December, standing or rather

mould over the crocks. Employ a good stiff loam kept porous by a free addition of road grit. Avoid thick sowing, as crowded plants not only smother each other, but the roots become so entangled that much damage is done if the balls are divided at planting time in March. The pots

is prepared for forcing, the root thongs should be saved and cut into lengths some 6 inches long, laid in a box or frame and covered with sharp, fine soil to induce an early callus and sprouting. When sufficient has been saved for the earliest batches, the rest may be laid in out of doors, the foot of a south or west wall being the best position. Some lay them in roughly at trimming time and cut them into lengths later on, but this makes growth later and is no saving of labour. I still think the old variety unsurpassed for very early forcing, as it seems to start into growth more readily provided the crowns are well matured. Lily White is a grand Seakale and looks very delicate when dished up for table. Those whose stock is still confined to the original should certainly procure Lily White.

EARLY RADISHES.—It is possible to obtain nice tender Radishes early in the new year by sowing now on a mild hotbed and covering with a frame. In making the bed do not use rank stable manure, as the least excess in bottom-heat causes a spindly growth and invariably ends in failure. Use all leaves, tread firmly, and allow about 6 inches of light open soil for a rooting medium. Sow French Breakfast and Wood's Frame, or other favourite early sorts, thinning out very freely as soon as practicable, as coddling, even for a few days, ruins Radishes at this period. Growers about London sow now and cover the beds with litter, but this means a great amount of labour, the latter having to be removed each morning when the weather is fine and replaced at eventide. Of course, success or otherwise largely depends on the season, as in very sharp or snowy winters the crop cannot be satisfactory.

J. C.

FRUITS OUTDOOR.

THE ORCHARD.—Pruning in the orchard consists mostly in thinning out branches and spray growths, as alluded to in my recent notes on the treatment of bush and trained trees, but even here it does not do to treat all varieties alike, as Apples vary in their methods of bearing. Some few, such as Blenheim Orange, Lady Sudeley, Margil, and a few others which do not occur to me at the moment, but which may be discerned on the spot by the observant grower, carry many of their flower-buds on the extremities of rather long spray growths, the cutting away of which in the trim way in which we can treat other sorts would interfere greatly with their cropping capacities; consequently these must be left in a rather rougher condition, more especially while they are young. Closer spurs come with age even to such varieties, and then the knife can be used more freely. Orchard trees are often planted far too thickly, or, rather, left unthinned too long, and one often meets with instances in which such strong growers as Blenheim Orange, Wellington, Warner's King, Cox's Pomona, Reinette du Canada, &c., are only allowed the same amount of room that King of the Pippins, Cox's Orange, Manks Codlin, and Fearn's Pippin are given. The remedy for this state of things is the drastic one of cutting out of the way of the strong growers anything which interferes with their natural spread and doing this before they come to meet, as they will never become handsome or fertile trees if they are curtailed in any way by cutting them back to prevent their spreading, and thus keeping two or more trees on the space that one should occupy. One good big tree of Blenheim Orange, for instance, is worth at least four smaller ones that have been kept cut back from want of room. It may not be necessary to cut the surplus trees out altogether right away, but the point I wish to make is that the best placed and most thrifty trees should be selected to become the permanent occupants of the ground, leaving them untouched as to spread of branches, and the others should be cut back hard enough to give all the room wanted by these permanent trees and ultimately removed altogether. Were I about to plant an orchard I would be guided as to distances by the sizes reached by good specimens of the varieties chosen in the neighbourhood, commencing on the

north side with the vigorous sorts and working southwards, lessening the distances according to the closeness of the natural habit, but always allowing plenty of room for a full-sized tree. After having filled the permanent sites, one could then fill up between with some of the short-lived, early-cropping varieties that would pay for planting and for their room before the time came for their removal. Good varieties for this filling-up would be Lord Suffield, Stirling Castle, Early Julien, Manks Codlin, and King of the Pippins, or the under-crop might be from bush fruits, which would do well and pay well for years without becoming a nuisance. An orchard planted on these lines would require but very little pruning beyond branch-thinning at any time, and one would have the satisfaction of knowing that the permanent trees could not become too crowded at any time. Some years ago I took charge of an orchard in which the grouping system had been carried out, and though this system is the best when the spacing is intelligently applied, I found that all the varieties were planted at 12 feet apart, and one part of the orchard contained nothing but Blenheims; consequently before these reached fruiting size half of them had to be cut away piecemeal to allow room for the others. Had they been planted alternately with varieties coming quickly into bearing, all would have paid for themselves in their turn, but, as it was, those which had to be sacrificed only gave trouble all through and never bore a bushel of fruit, while wasting room and labour.

CLEANSING.—After having finished thinning, cleansing the trees should be the next important thing. If they have been much pestered with insects, the best application that can be given will be the caustic soda and potash solution so universally recommended. This is fatal to insect life and frees the bark from all mossy growth as well, leaving it bright and clean. Of course, for the insects the application should be thorough, and the solution is best applied through a sprayer or a garden engine, for a syringe slips about in one's hand and cannot be used comfortably. If mossy growth alone is the only trouble, then I prefer dusting the trees with freshly slaked lime, applying this on a foggy day, when it will stick to the branches. As a cleanser, lime is no more effective than the solution alluded to above, but I prefer it from its manual value, as I never yet found an orchard or a fruit plot of any kind that would not be the better for a dressing of lime on the surface, so that one need not mind a little waste in applying it, as that which falls to the ground will do good in other ways. When the trunks and branches of the trees have been dealt with, attention should next be turned to the roots—that is to say, all trees on grass should have at least all the coarse grasses and weeds, such as Nettles, Sheep Parsley, &c., forked out and destroyed. The finer grasses may be left, as they will not do so much harm, but where labour is sufficiently plentiful, it would be best to keep a clear surface round the trees as far as the branches spread. This is often done with young trees and neglected afterwards, but quite old trees would pay for it, especially those which show signs of loss of vigour, as a clean surface slightly broken up with a fork to let in moisture will reinvigorate them and help to keep them going for years longer than they otherwise would.

GREASE BANDING.—Bandages put on and smeared with cart grease, as recommended some weeks back, should be gone over again, giving a fresh application to the bands, as the grease gets hard and loses its efficacy after exposure to the weather. Neglect of these later applications has caused some to doubt the virtues of banding, as their trees have still been infested, but the insects remain active till quite late in the year and do not all seek their winter quarters till the weather becomes really wintry.

LABELLING, &c.—One of the interesting things in gardening is the knowing what one has and where it is, and those who have not some system by which they can tell this, lose much of the pleasure they might get. Labelling is the most

common way of dealing with the matter, but except in the case of wall trees, where the labels can be nailed to the walls and not fixed to the trees themselves, it has very many disadvantages which need hardly be specified here. The most durable labels for wall trees I know are strips of lead with the names stamped on them. But better far than any labels is a system I have applied now for many years to fruit trees under my charge; this is to have a rough plan of the plots on which each tree station is under number. A key to the plan is kept in which the names as well as the numbers are entered, and also any particulars of changes, space being left for such particulars as dates, &c. If one cuts out or heads down and regrafts a tree, this may be specified in a few words and the names of the substitutes entered; indeed, anything which takes place in connection with the trees may be set down where one has it at one's finger-ends whenever it is necessary to refer for facts. I have found this a great help, and commend the system to all as one far safer than that of labelling. It may take some years to fill out correctly, but the necessary researches and the pleasure of clearing up doubtful points more than compensate for the little trouble entailed.

CORNUBIAN.

STOVE AND GREENHOUSE.

CARNATIONS IN WINTER.

DURING the next two or three months Carnations may be said to be at rest—that is, the hardier or border kinds. The layers have rooted well where propagating was done in July and August, and the young plants are mostly in their permanent quarters for next year's flowering. Autumn planting has great advantages, inasmuch as one may get the young stock established before hard weather sets in, and at the first burst of spring new growth goes on without a check. If planting has been delayed, I prefer to do it now rather than wait until March, provided the ground is not in a soddened state. Yellow-ground Picotees appear too tender to go through severe weather unscathed, and I prefer to pot this class and give them the shelter of glass until the spring. With Carnations outside it is important that they shall be kept free of weeds. Frost, too, damages them only in one way, it is apt to lift the plants out of the earth when a thaw takes place. It is advisable therefore to see that each one is trod in firmly. One should look over the stock occasionally for maggot. Its whereabouts are indicated by white lines in the leaves, generally in the centre of the plant. Such leaves come away from the plant readily and the enemy may be lower. I use a long needle to probe into the heart of the stem, not resting until the maggot is caught. It is a light yellow coloured insect, with a very hard skin, but one that beginners in the cultivation of the Carnation must become acquainted with and spend the necessary time to catch. Except this there are indeed few troubles with outdoor plants in a soil that does not become over-wet.

With plants in pots a great deal more care is required. What one has to guard against is dampness. If in frames, therefore, where the bottom must necessarily be moist, the lights should be taken off whenever the weather is favourable. In such structures the plants will scarcely require water for weeks together, the roots doing best when on the dry side. Cool, span-roofed houses are preferred to frames for wintering Carnations in pots. They are here more under one's observation, and can be easily treated. Water is needed more frequently, but the atmosphere may be kept dry, by always having plenty of ventilation. Except to keep out dense fogs I never quite close the houses. Green-fly is sometimes troublesome. This is removed by the aid of a soft brush or by fumigating with the usual tobacco preparations. Carnations are easily managed plants if such simple rules are followed as above stated, yet there are few plants more readily spoiled by bad treatment. Undue

moisture and a close atmosphere will bring spot in the leaves. It is not a deadly disease, perhaps, but it disfigures the plants and may require the entire removal of much of the growth. This, of course, is a check. An over-supply of water will cause the roots to decay, these being hair-like and tender. It is well to be prepared with soil long before the time for potting. I do not, however, set so much value on the advice that the same shall be mixed as I do on the wisdom of getting it under cover. Loam of good quality and leaf-mould, besides rotted manure may be obtained now, as potting into the flowering size will be started at the end of February. I find it necessary, in the case of a few kinds which are difficult to root, to place them in a slightly heated house. Here there is no danger in sprinkling the leaves daily to make up for the loss in evaporation. This watering should be done in the morning. So soon as the plants become established remove them to cooler quarters. H. S.

Isoloma Vicomte A. de la Combe.—This is one of the best varieties for winter-flowering. It may be propagated from cuttings, and these put in in the spring make nice plants for flowering the following autumn and winter. Grown in an intermediate house it makes a dwarf, compact plant, the thick, woolly, ovate leaves have a red shade on the margins, the flowers are bright red, with a yellow throat, spotted with a darker shade of red. Many of this class of gesneraceous plants would be much appreciated if grown under cool treatment. They all like a rich, open compost, and after the pots are filled with roots, liquid or artificial manures may be used freely. Some of the finest Gloxinias I ever saw were planted out on an old hotbed and had no artificial heat whatever.—A. H.

Daphne indica.—This makes a very pretty little shrub for growing in cool houses, and its charming blossoms are freely produced when the plants are healthy. But owing to the somewhat sluggish root action at this time of year and later on until quite late in the spring the plants are very easily overwatered. Every endeavour should be made in summer when the plants are able to stand moisture to get a strong, yet hard and well-ripened growth into them, but too often they are neglected until just before they are wanted; then, of course, they are not equal to the demand made upon them. Good, strong, vigorous plants will stand being kept on the dry side if it seems to be necessary, but it is the weak, badly rooted bits that turn yellow and lose their leaves when overwatered or dried in the least. The best time to repot is after the flowers are past, and by keeping the roots on the dry side a little and damping the heads freely, nice healthy shoots will be produced. When a fair head of young leaves is produced the plants are safe, and may go outside to a frame or plant protector, the roots a little out of the scorching rays of the sun, but the foliage and stems fully exposed. Like other hard-wooded plants, this *Daphne* and its varieties dislike soils very heavily impregnated with lime, but this need not make cultivators go to the other extreme and use all peat, which is bad for the roots when decayed.

Eucharis amazonica.—Had "E. J." read the whole of the correspondence re this plant he would have seen that it was just the market method of forcing it into flower time after time that I deprecated. Just as much I dislike the method of having the *Eucharis* in flower the greater part of the year. When the plants bloom naturally and well once a year they have done as much as need reasonably be expected if the plant is grown simply for its true beauty and worth. The system of running private gardens as cut-flower factories takes away a lot of the pleasure of those who own and those who look after them, and when, as in the case of the *Eucharis*, a lovely plant is sacrificed to the demand for cut flowers, I maintain that it is a distinct loss. Their true form is never seen in market gardens or in private places where the

forcing conditions prevail. There is as much difference as there is in a Lily of the Valley forced into flower in November and the same gathered from outside in May. One is a beautiful vigorous plant with stout, glossy leaves, the other pale, weak, and debilitated-looking. This was my point in the original note; the answer to a correspondent is all that "E. J." seems to have read. Market methods need only be brought into private places where large demands exist, and then I have nothing to say against them.—H. R.

SOLOMON'S SEAL FOR FORCING.

Of all hardy plants this is, I consider, the easiest to force into flower of them all. It responds very quickly indeed if forced in a brisk heat, which, however, has certain drawbacks, inasmuch as the stems then become unduly long. If grown simply for cutting this is not of any great moment, but if wanted for arranging with other plants they should be forced rather more slowly. The resulting plants are then not only more dwarf and sturdy, but the flowers open more slowly, last longer, and give off a very delicate perfume. The latter, which much resembles that of the Hawthorn, is much appreciated by many people, and a few potsful of plants placed in a house quite scent the air with their fragrance. That the Solomon's Seal is of greatest service from Christmas and onwards need hardly be pointed out, but to keep up such a supply means that a considerable number of crowns must either be grown or bought in. It is as easily grown as forced, is not at all fastidious as to the class of soil it is grown in, nor very particular as to position. A piece of ground or a border about 9 feet wide and 40 feet long would furnish a fine lot of crowns, and if the border is divided into three equal portions, there would always be one lot ready for lifting each year for forcing. The roots after being forced should be saved and planted again in the same or another piece of ground, when at the end of two years they would again be available. It is a good plan to dig in some manure before planting, as the rhizomes form such a host of hungry feeding roots, they soon impoverish the soil if this is not done. A position facing south is the best for growing Solomon's Seal for forcing, as the crowns then ripen up early, but if such is not available, a south-easterly or westerly aspect would do. Forcing is a very simple matter. After lifting and potting up the roots they may at once be introduced into heat. If wanted to flower quickly, a brisk bottom and top-heat is needed, otherwise the gentle heat of a bed of leaves, such as is oft-times made up in a forcing house, will suffice. The pots should be plunged rather deeply in the leaves so that the crowns also are covered with them, which keeps them uniformly moist and greatly facilitates their starting into growth. After they have made from 5 inches to 6 inches of growth, gradually inure them to the light and place near the glass to prevent growth from becoming spindly. When the flowers begin to develop and open, and if not required for immediate use, remove the plants to a cooler place. As the season advances, less warmth is required; in fact, the heat of a vinery or a Peach house then suffices. A. W.

NOTES AND QUESTIONS.—STOVE.

Carnation Mrs. L. de Rothschild.—Through the kindness of a friend, who gave me a few cuttings of this variety of Carnation, I have been enabled to grow a nice lot of plants which are now flowering very freely. Its beautiful salmon-pink flowers are much appreciated here, and the stock will therefore in due course be further increased. It is such a free bloomer, and a good grower withal, that it appears to be one of the most easily cultivated of all the winter-flowering Carnations. Those having to supply Carnations in quantity at the present season should grow a good number of plants of this variety, which will not, if well grown, fail to give satisfaction.—A. W.

TREES AND SHRUBS.

ABIES GROWING AT OCHTERTYRE, NEAR CRIEFF.

Abies amabilis.—A tree planted in 1889 is now a fine plant. A number of smaller ones planted since are equally fine. It is a very desirable variety to plant as single specimens.

A. balsamea.—Growth vigorous, and never affected here by frost. It is said to be tender in some places. The specimen here is about 15 feet in height.

A. brachyphylla.—Hardy, and one of the best. The plant here has not done so well lately, but I attribute this to its having too much surface water during wet weather.

A. bracteata.—This variety has not been quite a success here. Some of the smaller plants look as if they would make more satisfactory growth.

A. cephalonica.—This is handsome till it reaches upwards of 30 feet high, when the leaders give way and the side branches grow vigorously. The plant put out in 1855 cones very freely here.

A. cilicica (true).—This is yet small, but is growing freely.

A. concolor.—As an ornamental variety this is an acquisition and grows rapidly here.

A. firma.—This plant is very healthy. It is late in starting into growth. The plant here is 9 feet high.

A. concolor violacea.—The plant here 5 feet high is growing vigorously. It is a more desirable variety than *concolor* for ornamental planting.

A. Fraseri will not grow here, although it has been tried several times.

A. grandis.—There are two large specimens here each 60 feet high and quite distinct; one has a softer green foliage and does not bear cones, while the other has shorter leaves and a more rigid form of growth, coning annually. Unfortunately, the cones are produced very near the top.

A. lasiocarpa (Hooker).—There are several plants of this the true variety, but are all more or less of an unsatisfactory nature here, only one plant having grown freely.

A. Lowiana.—This grows very freely. There are no large specimens; a few about 12 feet high.

A. homolepis.—A most distinct variety and altogether different from *A. brachyphylla*, which some growers consider synonymous. The largest plant is nearly 20 feet high and grows freely.

A. magnifica.—A beautiful variety, growing very rapidly. The largest plant is 25 feet high, but has not yet borne any cones.

A. nobilis grows rapidly and forms beautiful specimens. The largest plant, over 70 feet high, was blown down six years ago. From this I had raised hundreds of seedlings.

A. nobilis glauca.—None of the plants here are so distinct as I have seen in other collections, yet they are of a constant character and equally robust.

A. Nordmanniana.—There is a large number of this, and all growing into beautiful specimens, and still free from aphids.

A. numidica.—This has failed to grow here. **A. pectinata** does well as a forest tree. A number of fine trees were cut some years ago.

A. p. fastigiata pyramidalis.—So named by Mr. Dawson, of the Arnold Arboretum, Boston, U.S.A., who pronounced it the finest specimen he had ever seen. It is never found in catalogues; it is perhaps the handsomest conifer we possess here; possibly the most distinct.

A. Pinsapo.—A few are growing very satisfactorily and are fine specimens, but the oldest trees seem to be affected by a sort of canker, a good number of dead branches having annually to be cut out.

A. Pinsapo glauca.—There are two beautiful small trees, each 8 feet high. For grafted plants they are highly satisfactory.

A. sachalinensis.—This, planted in 1889, is now 10 feet high. Apparently it is unsuitable for this locality.

A. sibirica.—This grows very badly, yet very healthy. It is not a desirable variety, except for a collection.

A. Veitchi.—Grand in form and growth, and when more plentiful and better known it will no doubt be freely planted.

A. Webbiana.—This is one of the most distinct and beautiful of conifers, but it has several times been very much cut by late spring frosts.

A. Webbiana Pindrow.—This grows equally as freely here as Webbiana, but is liable to suffer similarly from spring frost. It is not such an similarly from spring frost.—GEORGE CROUCHER, *The Gardens, Ochertyre, Crief, N.B.*

A note from Dublin.—Mr. Moore, writing from Dublin on November 9, says:—

It has been a fine season in Ireland, one of the best I ever remember, and the brilliant colours of the foliage of many plants and trees even now make a handsome ending to the season. *Rhus Cotinus*, *Rhus cotinoides*, and *Berberis Thunbergi* were the three brightest in colour, but there were dozens of other trees and shrubs that were very lovely. *Pyrus nigra*, *P. arbutifolia*, *Euonymus alatus*, *E. europæus*, *Spirea prunifolia*, *Enkianthus japonicus*, and the hardy *Azaleas* have all been brilliant.

SHRUBS IN BLOOM IN SOUTH DEVON.

ABUTILON VENILLARIUM has borne its crimson and yellow pendent blooms, and bids fair to continue its somewhat diminished display, should severe weather not intervene, until the new year. *Ceanothus Gloire de Versailles* has been bearing a few of its pale blue bloom-clusters, and the leafless *Winter Sweet* (*Chimonanthus fragrans*) has already opened the first of its scented stars. The Mexican *Orange Flower* (*Choisya ternata*) is in some gardens blossoming freely, as is *Cytisus racemosus*, while *Colletia cruciata* has its spiny growths thickly covered with minute white blossoms. The *Habrothamnus* still shows a drooping cluster of crimson tubular blooms, and the double *Jew's Mallow* (*Kerria japonica fl. pl.*) is bearing against a cottage wall its orange-hued blossoms. The *Laurustinus* is slowly coming into flower, and the great standard *Magnolia grandiflora* produced a few ivory-white scented chalice until mid-November. The shrubby *Vernicas* are blossoming freely, and here and there *Yucca gloriosa* rears a stately flower-spike. Of climbing plants, *Jasminum nudiflorum* has been one of the most effective, having spread a sheet of gold over cliff-face, trellis and wall, while it creates a particularly harmonious picture where it is associated with *Cotoneaster microphylla*, whose crimson berries are now at their brightest. A cottage in the neighbourhood of Plymouth, covered from ground to eaves with the *Cotoneaster*, through which the shoots of the *Winter Jasmine* twined, presented a pretty and unique appearance in mid-November clad in its winter mantle of crimson and gold. With everyone planting climbers for spring and summer effect, or, as in the case of the *Virginian Creepers*, for their autumnal colouring, the man who is content to forego the charms of profuse blossoming and fragrance during the heyday of the year in order that his walls may assume their fullest beauty as *Christmastide* draws near, when the charms of

the earlier flowerers shall have vanished, is a public benefactor, and should merit the esteem of all who love a spot of bright colour in the dark December days. *Convolvulus Cneorum* has borne some expanded blooms, and the oval orange fruits of the *Passion Flower* illuminate the dark foliage with their bright festoons. The *Lapageria*, both the red and the white variety, has been blooming well on a north wall in the open during the whole month, its trails of pendent, waxy blossoms being thrown into high relief by the dark background of stone and foliage. *Solanum jasminoides* is still in profuse flower; indeed it is difficult as yet to mark any decided decrease in the number and size of the bloom-clusters that reached the zenith of their beauty and luxuriance towards the close of August and commencement of September. During the following month a marked change will doubtless be seen, but in

THE ARTISTIC PLANTING OF TREES.

ONE of the most false and stupid assertions ever made is that garden design is possible without garden knowledge. It is so wrong that it could only have been made by one who had never faced the realities of the subject and its extent. Many people are so glad to be in a garden of any kind, out of the rush and noise of our towns, that almost any triviality passes for garden design, and conventional things are accepted as pretty without regard to what would be right in the place. We may see the *Wellingtonia* planted within a few feet of a window, and trees planted in

Hydrangeas at Menabilly.

mild winters a good sprinkling of flower-clusters is carried into the new year, and in the present year it was not absolutely flowerless until the second week of February. One of the prettiest sights of the month is *Clematis Vitalba*, the *Traveller's Joy*, which, growing in graceful freedom in hedgerow, wood and shrubbery, garlands tall evergreens with feathery skeins now silver-grey in colour, hangs in tangled loops from the lofty branches of the giant *Ash*, or veils the straggling hedge-top in a billowy cloud of softest grey. S. W. F.

NOTES & QUESTIONS.—TREES & SHRUBS.

Vitis inconstans in fruit.—This handsome climber is at the present time making a fine display of its beautifully coloured little Grape-like bunches of berries, of a lovely blue colour, that were so hidden by lovely crimson foliage as to be quite overlooked until the foliage dropped. The hot, dry summer gave a very intense colour to the foliage, and is probably responsible for such highly-coloured berries, for I never remember seeing them so plentiful before.—J. GROOM, *Gosport.*

conditions in which it is impossible for them to grow to any good effect; and when we consider the hundreds of kinds of trees that have to be planted, it is no wonder that men, busy in other ways, should make many mistakes in planting. But when we come to deal with garden design on the part of professional men, so low a standard should not be accepted; and a high one is unattainable without a knowledge of the garden art itself, and especially of the loveliest gift of Nature to the earth—its trees.

Of all the different questions which the landscape gardener has to deal with, trees are the most important. A knowledge of them is an absolute need, as they grow in gardens, pleasure grounds, parks, and woods; not only the ordinary "wood" of the country seat, but also in real old woods of the coun-

try, like those in Sussex and many other parts where long-established native woods exist. This knowledge is not only essential for good planting, but also from an artistic point of view. How a tree grows in a park or pleasure ground is often different from the way in which it is massed in woods; and it is as important for the landscape planter to know one expression of its beauty as the other. Take the Oak—how mistaken anyone might be as to its planting who knew only one expression of its beauty! The Oaks in Sussex are quite distinct in aspect from those of Warwickshire—trees by the roadsides and in the parks. Yet the Oak, set close in a Sussex wood, with many silvery columns rising out of underwood, or Primroses, is as beautiful as anything in Warwickshire. Then, again, we have the shattered old Oaks of Sherwood, and the stately Oaks which sow themselves on the banks of many rivers, which are as handsome as any in a park, and interesting as having placed themselves. And these are but a few examples of the variation of form of one tree, showing the need for the study of trees in Nature, and not in books.

From so much variety of form occurring in one tree, we may judge how much the many trees of the northern and temperate regions of Europe, Asia, and America may influence the beauty of a landscape, and how much they have to learn who would deal with them rightly. The art of planting trees with good effect is a far higher question than that of the mere divisions and plans of the ground round a house. The Birch is beautiful in many forms, but I never had a true idea of the beauty of a Birch wood until I saw woods in Northern Germany, with nothing visible but silver stems. Trees vary with every condition of altitude, soil, and climate; and there is no way of knowing them but by actual study in many different places, not only for their cultivation, but for their beauty.

The better we know the aspects of trees in Nature, the more easy it is to do right work in park or pleasure ground. Take the common pinetum as seen in many country places. Its effect is rarely good, owing to the way in which the trees are dotted about. An acquaintance with the Pine woods of the northern world should save us from that weak way of planting, each tree labelled and set out by itself as a specimen. A much better way would be to mass and group trees that we know to be hardy. Worse still is it when, instead of keeping these Pines in the pinetum, they are scattered about the foreground of the house. Some of the most beautiful houses and home landscapes in England are marred by this practice of scattering trees in the foreground, very like those in front of a child's Noah's ark. Artists and those who look much at form see the error at once. The artist cannot tolerate what the gardener may think perfection; and the artist is right. The shape of the conical conifer, always ugly as compared with the trees of our own country, is only natural to them when young.

If we travel in countries where these Pines abound, we find that they grow rather closely together, or, if not, that the extinguisher is by no means their true form, and that they shoot up into handsome and finely-coloured stems, sometimes over 100 feet high without a branch; so that Nature and art show us that the crinoline shape is wrong, dear as it may be to the ordinary planter.

Many country houses are marred by this way of planting, and the evil is increased through the laying-out of grounds by people whose main idea of tree form is that of "fixed points," to be always clipped—the most inartistic idea that could be conceived by man. It is a delusion to suppose that there is anything Old English in this common mode of planting conifers. The Irish Yew is a mere sport quite of modern origin, and most of these ill-shaped or ugly conifers that we see stuck about grounds are of recent introduction. The view from the house to the park, and from the best parts of the park to the house, is often marred by this error, which no man knowing the natural grouping of trees would commit. The forms of the fine English trees in our parks are as good as those of any trees on earth, and should not be obscured by stupid planting. All exotic conifers should be grown in woods or groups, where they will not interfere with the good effect of trees finer and more precious to us than they can ever be.

Look at the stiff clumps of trees in iron rings which disfigure nine out of ten of our country seats. A more inartistic way of planting could not be devised; and if our plantings were made by people with the least idea of the beauty of trees in Nature, we should never see such clumps, but trees massed in natural groups or colonies, easier to manage in every way, and in which they would really shelter and help each other. Plantations might often be formed best in pieces of ground difficult to cultivate, or soil that is useless save for trees. The thin "skippy" belts of trees which we see everywhere, and which are always useless for game protection or effect, would never be thought of by anybody who has studied trees in Nature. The best planter might be forced to make such a belt for a shelter in exposed ground; but generally it is much better to use inferior land, or land difficult of approach, or too much exposed or too poor for arable crops, but which, when planted as a wood, would some day give us at once good effect and timber.

The best effect and good cultivation may go together, and the knowledge we may gain in a wood will often help us well. Take the common Spruce, a tree which does not usually do well in the south of England, which starves on the hills and is diseased in the heaths of Surrey, or the cool forest hills of Sussex, yet we see it planted everywhere, and even sometimes made into hedges and clipped by those who probably think one tree is about as good as another for clipping or any other use.

Even in our own limited tree flora of Great Britain a good deal depends upon the soil in which we put a tree, and we have not to deal with the tree flora of Britain only, but with that also of Europe, Northern Asia, and America. Trees of the Pine tribe have been so extensively introduced that many of them may have to be dealt with in quantity by the landscape gardener, and for planting them aright no book knowledge is a substitute for the actual knowledge of the tree, both in the wild and cultivated state if possible. W. R.

NOVEMBER IN SOUTH DEVON.

MILD as have been the Novembers of the two preceding years, the past month has attained an even higher average temperature, and the foliage of such Dahlias as were not injured by the early October frost has remained green throughout the entire month, while in sheltered spots plants of Heliotrope are as yet unscathed. Towards the commencement of the month a couple of short-lived gales denuded the trees of much of their glowing leafage, but even in the concluding days of November the autumnal tints had lost but little of their decorative value. In the hedges the leaves of the Brambles are here purple, here blotched with crimson, while now and again the berried skein of the Bryony gleams—a spot of vivid scarlet. The berries of the wild Guelder Rose were still in evidence at the commencement of the month, when the coral-pink of the Spindle Tree was here and there to be seen, and in the garden the Strawberry Tree (*Benthamia fragi-tera*) was thickly set with its crimson fruits. The Hollies are exceptionally bright, being loaded with berries. The birds have already commenced to attack the haws and haws, and the thrushes congregate by dozens round the fruiting Ivy that garlands many an old tree-trunk. The rooks are busy with the acorns of the Ilexes, and each morning may be watched from the windows hovering over a tree not 30 yards distant and tearing off the acorns. Early in November a few swallows were still to be seen. The last fortnight of the month was a period of most perfect weather, a time of gentle breezes and sunny hours, very similar to the delightful "St. Martin's summer" that we experienced during the preceding month. Some people, by the way, confound "St. Martin's summer" with the "Indian summer," but the latter is much later, coming when the trees are leafless, and in Canada generally follows closely upon the "Squaw's winter," a period of heavy snowfall, which, however, does not freeze, but rapidly disappears, and is often succeeded by a spell of placid, halcyon days, to which the name of "Indian summer" has been given.

In the garden the Sweet Alyssum clothing the high bank, though not the unbroken expanse of flower that it has been through the two preceding months, is still in bloom. The first of the Poppy Anemones has already opened its petals, those being of a rich violet hue, but unopened buds hard by show that ere long scarlet and white will soon be added to the soft purple. Aster grandiflorus has been especially decorative this year, the early October frost, which was exceedingly partial, not having harmed it, and during the early part of the month its large purple, golden-centred star flowers thickly set on their rigid bloom-sprays have created a telling effect in the garden. The Valerian (*Centranthus ruber*) is here and there in bloom on the rock ledges, showing spots of pink, white, and red against the mantling Ivy. The giant Christmas Rose (*Helleborus altifolius*) has been in profuse bloom since the commencement of the month, its snowy chalice, sometimes as much as 4 inches across, being often held on spotted footstalks considerably over a foot in height. *Coreopsis grandiflora* was still bearing a fair quantity of golden

blooms at the commencement of the month, and *Cosmos bipinnatus* has produced its single blossoms above the elegantly cut leafage, though in lessened numbers, up to the close of the month. Scapes of some of the *Crinum*s are yet to be seen in certain gardens, and the autumnal-blooming *Crocuses* have begun to create a bright display. The *Cactus Dahlias* were at the commencement of November still bearing a sparse show of glowing blossoms, and here and there an occasional pale blue *Delphinium* spire or a scattering of large golden stars of *Doronicum plantagineum excelsum* Harpur-Crewe was to be seen. *Erigeron speciosus* bore a few of its yellow-centred mauve stars into the early days of the month, and the Mexican Daisy (*Erigeron mucronatus*) after a blossoming period of six months was still in bloom in dry, sheltered positions.

Hardy Fuchsias held their flowers, though in gradually lessening numbers, up to the conclusion of the month, and *Gaillardias* and *Gazanias* retained their bright blossoms in many a garden, while not a few deep blue flowers of *Gentiana acaulis* were to be met with, and the *Helichrysum*s gave spots of colour here and there. A few of the perennial *Sunflowers* retained their golden blossoms until the opening days of November, and the great *Hydrangea* bushes, the tint of whose gradually paling flower-heads became less effective as the weeks wore on, were still not without a certain decorative value. *Hypericum Moserianum* has borne its yellow blossoms, and the delicious Algerian Iris (*I. stylosa*) as well as its white variety, that commenced to flower before the close of October, is now coming into fuller bloom, and will continue to blossom uninterruptedly, should a mild winter be experienced, for another five months. No more lovely or fragrant flower than this Iris is available through the dark winter days, while the blossoms last well in water if they are cut before the buds expand. In light, porous soil in the south-west the plant increases at a prodigious rate, some gardens where it was unknown five years ago, and into which a few tubers were introduced, now containing large patches of this valuable Iris. The *Kniphofias* still show an occasional fiery spear-head of blossom, and the *Marigolds* brighten the cottage gardens with their orange, saffron, and pale sulphur, while the *Paris Daisies* are not flowerless, and *Physalis Alkekengi* and *P. Franchetti* display the globes of their orange-scarlet calyces, some of those of the latter variety being of immense size in comparison with those

of the earlier introduction. *Scabiosa caucasica* has produced a few of its porcelain-blue flowers during the early days of November, and the *Winter Flag* (*Schizostylis coccinea*) has created a brilliant effect where planted in large clumps. This plant, like the Algerian Iris, succeeds best in a porous compost. *Sparmannia africana* has been in flower in a sheltered nook, and the *Winter Daffodil* (*Sternbergia lutea*) has borne its golden, *Crocus*-like blossoms. *Stokesia cyanea* produced its purple flowers well into the month, and the *Periwinkles* have also been blooming. Of these, the double variety of *Vinca minor* is particularly charming, the blossom to a casual observer having much the appearance of a *Marie Louise Violet*. The white variety of this *Periwinkle* is also a chaste and pretty flower, and the pale lavender-blue *V. acutiloba* presents a fair picture when covered with a profusion of its delicately tinted blossoms. *Zauschneria californica* was still bearing its vermilion blossoms at the commencement of the month, the same colour being afforded by

the flowers of great bushes of *Salvia splendens* that have remained in the open undisturbed for some years, and which bloomed throughout the entire month. S. W. F.

FLOWER GARDEN.

IRIS SOFARANA.

Of the fascinating group of *Cushion Irises* about a dozen species are now in cultivation, a large number of which have come from Syria and the Holy Land. The subject of this note and of the accompanying illustration is also an inhabitant of these countries. Its discovery dates from the spring, 1898, when a collector of the firm Van Tubergen, of Haarlem, found it growing in the Lebanon at an altitude of 4500 feet to 5000 feet, near the highest part of the railway to Damascus, in the neighbourhood

Iris sofarana, two-thirds natural size. From a photograph sent by C. G. van Tubergen, Jun.

of the village Ain Sofar. Dried specimens sent home gave the impression of its being a very dark-coloured variety of *Iris Lorteti*, the collector being in fact sent out with the special commission to secure among other things a good supply of this handsome plant. During the month of May the collected rhizomes came into flower in Messrs. Van Tubergen's nursery, and on its proving to be an absolutely different plant from *I. Lorteti*, specimens were forwarded to Professor Foster, who proposed for it the specific name of *Iris sofarana*. The rhizome of this new Iris is short and stout and the leaves remarkably broad, so much so as to resemble an ordinary bearded Iris. When in a young state they are of a pale green. The scape reaches about a foot in height, bearing a large flower of noble proportions and outline of the sombre, subdued greyish combination of colours which this remarkable class of *Irids* usually has in its

flowers. Of the standards, the ground colour is a creamy white with innumerable thin purple veins, and dotted all over with the same colour. The falls, which are very large, are of the same ground colour, but here the markings are much bolder, and they fuse together in the centre into a nearly black, large central blotch. A few long black-purple hairs are scattered over the central portion of the fall and over the inner portions of the flower. Altogether it is a very welcome addition to this fascinating group and well worthy of cultivation.

Although, unhappily, it cannot be said that we have already successfully solved the highly interesting problem of growing these *Irises* to perfection, yet their cultivation cannot be too strongly recommended to the many whose gardening ambition cannot be satisfied with the ordinary run of garden flowers.

Haarlem, Holland.

JOHN HOOG.

***Tropæolum tuberosum*.**—To those who may intend trying this very handsome climber, my experience of it as grown for many years in Suffolk may be useful. The soil of the garden was sandy and light, and I found that a sunny position did not suit the plant at all, but it grew admirably on an east wall and where it seldom got a glimpse of sun, as there was a grove of tall Beech trees within 50 yards on the eastern side and a fine old Cedar close by on the south. A length of about 20 yards of wall was covered thickly to a height of 16 feet, and for months, quite up to the end of autumn, the plants were clothed almost from the ground with innumerable red and yellow flowers. I was much interested in Mr. Day's account of its behaviour at Gallogway, as the capital results I had with the plants mentioned above led me some years ago to recommend it to him, and I believe I am right in saying that I sent him the tubers from which his present stock originated. The method of treatment which I gave the plants was similar to that recommended by Mr. Day, except that in my case it was not necessary to add sand to the soil when planting, but I quite think sand would be most useful in soil of a heavier nature. For training on walls I found no plan so satisfactory as straining thin string from the top of the wall to pegs pushed into the ground near the tubers. The twining shoots would climb up these strings very quickly, and I was careful to have strings enough to prevent much entanglement of growth till the top of the wall was reached. The increase of tubers was great every year, but I never tested them for their edible properties.—J. C. TALLACK.

Tropical Water Lilies in the open air.—Under this head "F. W. B." asks if the *Victoria regia* has ever bloomed in the open air in England, and cites a reference bearing on this subject and the practicability of a repetition where there is clean warm water from a factory, &c. If any reader contemplates the culture of the *Victoria regia* in the open air I would strongly urge him to use the variety *Trickeri*, as it succeeds in a temperature 10° cooler than *V. regia*. At Benning, D.C., U.S.A., V. Trickeri came up spontaneously in a pond where the plant had been grown the previous year, the seed having been in the pond during the winter when the thermometer registered 17° below zero. These seedlings made their appearance on the surface in June, and although the past summer was not what is regarded as hot, but rather the reverse, the plants made good growth, and on August 24 produced the first flower, and continued at intervals until October. The largest leaf measured 4 feet in diameter, not counting the turned-up rim. At Riverton, N.J., more than 100 miles north of Washington, numbers of *Victoria* plants came up under like conditions, and several of them flowered in September and early in October. These plants were not subjected to any artificial heat whatever. Where plants had been raised indoors and planted outdoors on

June 1 without artificial heat, they produced flowers in July. The leaves of the same plants attained a size of 5 feet 6 inches in diameter, and the turned-up rim 7 inches. Under the same conditions *V. regia* has not shown signs of a seed germinating, and a plant raised indoors and transferred to summer quarters under like conditions has in some cases proved a failure and others have done fairly well, but in no case could comparison be made. While such conditions do not exist in England, yet it is possible to heat an artificial pond outdoors either by exhaust steam or hot-water pipes to a temperature of 75° to 85° at no great expense during June, July, and August, or later.—W. TRICKER, *Riverton, N.J., U.S.A.*

CHRYSANTHEMUMS.

EXHIBITING LARGE BLOOMS IN VASES.

It is satisfactory to find that at almost every Chrysanthemum show worthy of the name at least one class has been devoted to an arrangement of large Chrysanthemum blooms in vases, though of a limited nature in most instances. This, however, appears to be the beginning of the end of staging large blooms on boards, and although for one or two reasons it may be desirable to retain a few classes in which blooms of high quality may still be exhibited in what has hitherto been considered the orthodox method, those who appreciate the large blooms for their decorative value must rejoice that a change has at last set in. In the newer method of exhibiting blooms in vases, the diverse forms and pleasing variety of colour are likely to be represented in such a way that each point attains the prominence it deserves. The curious and quaint forms of many of the handsome Japanese blooms by the older method of exhibiting are rarely seen, although boards for staging Japanese blossoms were enlarged a few years since. By the arrangement in a free and easy manner of, say, half a dozen huge blossoms in a vase the whole of each bloom is seen and the greatest possible effect thereby gained. The great vase class at the National Chrysanthemum Society's show in November last may fairly claim to have been the chief competition of the season. The first prize lot of twelve vases, each containing five blooms, was arranged with exquisite taste, and a fine display they made. The second prize lot was also very fine, but the flowers appeared to lose something by their arrangement. The quality in each case was high. A curious feature of the display was the exceptionally large number of white, pink, and other pale-coloured kinds. It appeared to be a case of selecting varieties developing blooms of exceptional size, and as these are less frequently seen in Japanese blooms of crimson, orange, and other rich shades of colour, the more bulky, but less pretty blossoms were more often seen. If this and similar classes are to be repeated next season, it may be well to consider the advisability of a proper representation of the richer colours as seen in the Chrysanthemum. A display of this kind should be far more interesting than that made up of colours of a washy kind chiefly. Excellent though this display of Japanese Chrysanthemums in vases was, it appeared to lose somewhat by its uniformity. The society was exceedingly fortunate in having loaned to it a very large number of deep olive-green vases, well suited for the purpose, but by confining each exhibitor to the use of these the display lost much. Something more original was wanted to make the display effective; and as

uniformity of the exhibition boards in the past has made Chrysanthemum shows appear somewhat monotonous, those responsible for change in these displays should endeavour to avoid a similar result by not laying down hard-and-fast rules as to the kind of vase to be used. The executive no doubt had a good reason for keeping each exhibitor to the use of vases of one pattern, as by their use they were all placed on an equal footing. Why cannot exhibitors be allowed to bring their own vases? This will probably be answered by some that the cost of acquiring new vases and the expense entailed in getting them to the exhibition are more than they can bear.

The object in drawing attention to the kind of vase used is to induce those responsible for forming schedules of prizes to leave this an open matter. Some persons may say that the character of the vase used would secure too large a share of attention from the judges; in fact, this has already been put forward. That a pleasing diversity in the character of the vase used would enhance the display, and also be the means of seeing the blossoms at their best, is undoubted.

The incurred blossoms are also very effective when arranged in large vases, their stiff and rigid character being less pronounced in this way than when set up on boards. The impetus given to this section during the last two or three years by the acquisition of several large and handsome sorts has also given us greater variety in colour. The large-flowered Anemones and their more fantastic Japanese rivals, with long tasselled florets, make superb exhibits when set up in vases. As at present exhibited their beauty is to a considerable extent lost, and those who have not seen blossoms of these types arranged in vases of medium size have no idea of the beautiful effect they produce. Pompons and Anemone pompons when not too crowded are also charming. The unnatural method of exhibiting three large blooms of these miniature kinds, altogether out of character, on boards is to be deplored. A few dozen sprays in correspondingly small vases would be very convincing as to their value for decoration. The same remarks apply to both the large and small-flowered single varieties.

Within the next few weeks Chrysanthemum growers all over the country will be preparing their prize lists for next season, and a break away from old and somewhat useless methods of exhibiting the Chrysanthemum should be encouraged.

D. B. CRANE.

Good old Chrysanthemums.—I was highly gratified to read in the interesting notes on Chrysanthemums in Waterlow Park the names of several good old varieties which I was afraid were quite extinct. For instance, those three beautiful compact sorts Mrs. G. Rundle, George Glenny and Mrs. Dixon are mentioned, and although many larger flowered sorts adapted for exhibition exist, few if any are prettier or better growers. At one time specimen plants of these sterling sorts were exhibited at the London shows sometimes carrying from 80 to 100 neat heads of blossom. Indeed, if judicious feeding and good all-round culture are given, the individual flowers will reach considerable dimensions, and their colour and symmetry are so good. For ordinary home decoration few can beat them in the incurved section, and whatever the season is, one can rely on an almost total absence of blind or malformed flowers.—C.

Chrysanthemum cuttings.—At this time of year when growers of Chrysanthemums are busy propagating for next year's supply, it may not be out of place to call attention to the great superiority of cuttings that are produced by

plants grown on the planting-out system, as practised by market growers, over those from pot plants grown all the season with the aid of highly concentrated foods and flowered as a rule in artificially heated houses, so as to get them into bloom at a fixed date. Doubtless many of the evils that Chrysanthemums suffer from at the present day are traceable to the unnatural conditions that prevail during the earliest stages of the cutting's existence. The market grower, who goes in for large quantities of one kind, grows his plants as a rule in the open ground and with much more natural surroundings, and when the time comes for lifting and replanting under glass every plant will be found to have quite a colony of underground shoots, which soon make splendid cuttings. I feel sure that if many private gardeners were to plant out any kinds that they have any difficulty in getting good cuttings from under the pot system, they would find it repay the trouble.—J. GROOM, *Gosport.*

Bush Chrysanthemums.—Many of the large show varieties are not suitable for other purposes, and growers who wish to have a few pot plants for decoration may often be puzzled to know what selection to make. During the present season at Messrs. Veitch and Sons' and at Mr. H. J. Jones's I saw some very pretty little bush plants in pots that would be useful either in a conservatory, in a house, or even where flowers for cutting were wanted. Freedom of growth both in foliage and bloom are the chief requisites in such plants. Among these plants were Wm. Tricker, Emperor of China, O. J. Quintus, and Mrs. Wingfield in various shades of pink. Crimsons were well done in J. Shrimpton and Wm. Seward. Bronzes were a little more numerous, there being some good examples of Mme. la Comtesse Foucher de Careil, Charles Davis, and Source d'Or. Of whites, some good plants were shown of Souvenir de Petite Amie, Mme. Carnot, Louise, Mlle. B. Pigny, Lady Selborne, Mabel Williams, White Clinton Chalfont, and White Quintus. Yellows were free and good, the best being October Yellow, Cloth of Gold, Yellow Lady Selborne, Amiral Avellan, W. H. Lincoln, Rycroft Glory, and Sunbeam. Rycroft Scarlet is a very bright, effective variety for the purpose, and so, too, is the newer Etoile de Feu. Dr. Sharpe does well, and so do Margot, M. William Holmes, and Nellie Brown, which need no description and are peculiarly adapted for this purpose.—C. H. P.

Calvat's novelties.—Although most of M. Calvat's seedlings have been seen during the present season in good form, and some of the oldest still remain very popular with English growers, yet the 1899 series have not been quite so common as might have been expected. One of the first of this year's novelties to be seen was Mme. Lucie Recoura, a large, broad-petalled Japanese of a dark shade of carmine-amaranth, with silver reverse. Soleil de Décembre was well out by October 20, and is a large Japanese incurving type of flower with broad florets something like Oceana; colour deep canary-yellow. M. H. Martinet is also a Japanese of good build, the colour a rich shade of crimson-red with a bronzy yellow reverse. Mme. A. Rey is one of the most promising of its kind. It is of the Japanese type; colour rosy lilac, reverse silvery. Princesse Bessaraba de Brancovan is a very large white Japanese, close and compact in build. W. Wells, although represented by the raiser as an incurved, was certainly a Japanese when seen here in England for the first time. It has broad florets, and the colour is a rich old gold. Mlle. Jeanne Lieber, rosy white, shaded lilac, is a large flower. Eliane, which already has been mis-spelt Elaine, is of good size, but the florets are rather thin and sharply pointed. The colour is best described as straw-yellow. All these were fully out by the third week in October, showing, as most of his seedlings do, a tendency to earliness, which the seedlings of many other raisers do not. Chrysanthémiste Lemaire is a large incurving Japanese with pointed florets, the colour a deep velvety crimson-red and reverse of bronzy yellow. Zephoris is a large Japanese, and one of

the most promising in the set. It has flat, pointed florets, and is a very full flower, the colour pure pale golden yellow. Mme. C. Terrier is a pearly rose; Professeur Jacquinet, a hairy Japanese, pale lilac-mauve; Lydia, a Japanese incurved, rosy lilac, reverse silvery pink; Mon Petit Jean, a dark yellow not met with this season, but shown pretty freely in medium form at Lyons.—C. H. P.

SOME NEW CHRYSANTHEMUMS.

THE season being now over and all visits to the trade displays, floral meetings, and exhibitions at an end, I have been looking over notes taken during the season and find that novelties are, perhaps, more numerous than ever. Many of them are so fine that they would have taken a leading place a few years ago, but now-a-days the mere number seems to swamp many a variety that would otherwise come to the front, for, no matter how good they may be, there is not room for all. Among some of the best of the season's novelties are the following, all of the Japanese section:—

Edith Pilkington.—Very long, drooping, medium-sized florets that are curly and twisted; colour pure pale canary, deepening to golden-yellow in the centre.

Miss Alice Byron.—Very fine flower of large size and great substance, globular in form. The florets are very broad and closely and compactly arranged; colour pure white.

J. R. Upton.—An Australian seedling of great merit. The blooms are large and the florets of great length, but medium width, and slightly curling at the tips; colour deep golden-yellow.

Kathleen Rogers.—Large blooms, of incurving form, with broad grooved florets; colour pure white.

M. Louis Rémy.—A pure pale golden yellow sport from Mme. Louis Rémy, one of the numerous sports from Mrs. C. Harman-Payne, similar in size and form to the parent.

Amateur J. Le Chaplais.—Immense spreading blooms; the florets are grooved and of good width and substance; inside colour deep reddish crimson, reverse golden bronze.

Mrs. A. H. Hall.—A fine massive built flower, very large and globular in form, with grooved florets of medium width; colour deep orange-yellow, shaded golden bronze.

Florence Molyneux.—Also a very large flower. Its build is very close and compact. The florets are of good width, twisted and grooved and incurving; colour white.

Mrs. Alfred Tate.—A fine golden chestnut-bronze sport from Etoile de Lyon. The florets are long and flat and the form is almost identical with that of the parent.

Lord Ludlow.—Very large; florets long and drooping and very broad; colour pale lemon-yellow, slightly striped.

Soleil de Decembre.—An early bloomer. It is incurving in form with very broad florets; colour deep golden yellow.

Princesse Bessaraba de Brancovan.—In this the florets are of medium size, being close and compact; colour pure white, slightly tinted green.

Lord Salisbury.—Florets of great length, medium width and curling at the tips, a closely-built flower; colour canary yellow of a very pure shade, dusted carmine.

Miss Elsie Fulton.—Large blooms with broad grooved florets, curling at the tips, a deeply built flower; colour pure waxy white.

Miss Maud Douglas.—Broad florets, good sized flowers, pale rosy amaranth with reverse of silvery pink.

Mme. Von André.—A pale sulphur sport from Mutual Friend, and similar in size and build.

Lily Threlfall.—Deeply built and closely incurving flower with medium-sized florets; colour creamy white.

Eastman Belle.—A very useful early variety of large size. It is a deep crimson and gold sport from President Borel. C. HARMAN-PAYNE.

Exhibiting single Chrysanthemums.—A complaint was recently made that these most charming of all Chrysanthemums when ordinarily staged in boxes and in trebles at shows are presented in a flat, formal way that gives to the blooms an objectionable appearance. The same remark applies to pompons as usually shown, in trebles on boards, although perhaps in a less

degree. Single flowers are necessarily flat, and when thirty-six in trebles are presented on an ordinary dozen show-board, every effort seems to be made by the exhibitor to have every bloom as flat and level as possible. Would it not be much better to have classes for six varieties, six blooms of each, set up in dwarf vases or glasses, with some foliage amongst them? In a very pretty exhibit made at a recent Drill Hall meeting evidence was furnished of the pleasing way in which in such vases pompons could be presented. Singles would no doubt look even more pleasing because they are light, more graceful, and better suited to this form of arrangement. Probably the exhibitor prefers boards and boxes for his flowers, but when the best effects from flowers at a show have to be obtained, the exhibitor must vary his methods to suit more advanced needs.—A. D.

Late Chrysanthemums.—With the approach of Christmas the majority of large-flowering show Chrysanthemums are over, and a considerable gap is left in the conservatory and show houses. The care now bestowed on varieties that are either naturally late in expanding or that can be retarded by late pinching or keeping under canvas in the open air until very late in the autumn, has led to the Chrysanthemum being now regarded as a winter as well as an autumn flower. There are now long lists of varieties published that are said to be suitable for Christmas supply, but so far I find very few of the later introduced sorts that surpass some of the old well-tried kinds. At present the best whites are Niveum, L. Canning and Princess Victoria. These are of excellent habit, throw up plenty of good strong cuttings, and with anything like reasonable care may be relied on to come in at the time required. Yellows are now in as much request as whites, and W. A. Lincoln is still a good reliable sort. Christmas Gold is, as its name implies, of a beautiful golden yellow, and that good old orange kind called E. G. Hill is, without any special care, at its best at Christmas. Monsieur Bergman is of a beautiful bright yellow, but is not naturally so late as the preceding. There are several varieties with dark flowers, notably the old Cullingfordi, that may be had late by special culture, but few of them are naturally so late as the white or yellow kinds above named.—J. G., Gosport.

Chrysanthemum Hairy Wonder.—I cannot quite agree with "H." when he says we rarely see this variety, although his remarks concerning the hairy section in general are correct. Of all the hairy novelties introduced since the advent of Mrs. Alpheus Hardy, the one bearing the name of Hairy Wonder is the oftenest seen and is the best. At nearly all the metropolitan parks it has been shown in very good form this season, and it looks like remaining long after the others have gone. The next most popular variety appears to be Louis Boehmer. Looking over my notes for 1899, it is surprising how few of these hairy novelties are now grown. Three years ago M. Nonin had a large number in his group at the Paris exhibition, and they were certainly well done, but when I visited his nursery last month I only found one variety worthy of note, and that was a new one called Myrto, of a pretty shade of soft pink on a silky white ground. At Lyons there were very few, *Enfant des Deux Mondes* (white), *Leocadie Gentils* (pale yellow), and Louis Boehmer being all that were noted. At the nurseries and parks round London, White Swan, Esau, and Calvat's new Professeur Jacquinet were about all I came across that were sufficiently striking to make a note of, and this is rather curious, because only two or three years ago the Southwark Park collection contained a large number of hairy varieties which excited some interest. They may, of course, be there still, but my visit being made early in the season may account for my not seeing them.—C. H. P.

Hardy Chrysanthemums.—It appears to me that S. Arnott, in THE GARDEN of December 2, requires something in Chrysanthemums that will never be obtained. The choicer kinds are hardy

enough to go through our usual winters, but the blooms cannot be expected to withstand the effects of frost. I usually put out in the open ground several plants of each of the popular kinds for stock and allow them to bloom outside—at least, they bloom if frost does not spoil them. This season throughout November one might have cut bushels of quite clean, highly-coloured blossoms of all shapes that withstood moisture readily. Of course this (Surrey) is a somewhat favoured locality for gardening, although in my own particular neighbourhood slight early frosts are common. The only valuable outdoor Chrysanthemums are, to my thinking, the early-flowering ones, and here there is room for improvement certainly, although there are now many excellent sorts which flower abundantly through September and October. The well-known Mme. C. Desgrange is a model in habit of growth—so short and bushy—and in freedom of flowering. Rycroft Glory is another splendid type in every respect, save that it is rather late and is therefore apt to be caught by an early frost. Ivy Stark, Harvest Home, Mme. Marie Masse, Lady Fitzwygram, Mons. Dupuis, Ambrose Thomas and G. Wermig are a few other sorts that are of sturdy growth and abundant bloomers. Source d'Or blooms beautifully in the open in the south of England if the autumn be not unusual in its severity, and this season a yellow variety, Soleil d'Octobre, was especially fine with me. William Seward and William Holmes gave a wealth of rich crimson blossoms. Col. W. B. Smith, Vivand Morel, Charles Davis, Lady Haaham and Lady Byron were also first-rate, but I would not care to recommend them for outdoor culture generally without shelter at flowering time. I remember some years back seeing all the best varieties of those days in full flower in the open. This was near the sea. Possibly many who are favoured by such a position might now enjoy abundance of the choicer Chrysanthemums of to-day were they to take the pains to try them.—H. S.

NOTES OF THE WEEK.

Chrysanthemum Fleur de Marie.—The purity of this fine white Anemone sort is almost proverbial, yet it is not grown so freely as it deserves. Being dwarf in habit, too, it is especially well suited for pot work for decoration.

Hibiscus Archeri.—The blood-crimson flowers of this plant render it a most striking ornament just now in the greenhouse; it would prove undoubtedly so were the blossoms produced with greater freedom. The rich shade of colour and the pretty fringed form of the flowers alike assist in rendering it most attractive. The plant is of sparse habit and rather tall. A coloured plate of it appeared in THE GARDEN of May 6 of the present year.

Heliphila scandens.—This pretty climber is singularly adapted for a cool house, particularly such structures as the conservatory with lofty roof. In these places the plants may be allowed to trail naturally, or in a measure so, from the rafters, and when in flower give the prettiest results. The species is also a reliable one for winter flowering, and the pretty panicles of white blossoms appear stronger when the plants have a fairly free root-run.

Notes from a Cornish garden.—I have had the same difficulty as your correspondent from Gosport in obtaining *Clematis cirrhosa* and the very similar *Clematis balearica*. I first saw the former at La Mortola in perfection, and this year came across a house near Bovey Tracey where *C. balearica* covered the whole of the west side. The two plants have only reached here, thanks to the kindness of friends, and I see every cutting of a bundle sent from Ireland in September has grown well, while of a plant of each put in at the same time, *C. cirrhosa* is now coming into bloom. *Galanthus cilicicus* has been in flower here for three weeks.—C. R.

Cypripedium insignis at Syon.—Just now a very fine batch of this old plant may be seen in these gardens. A good-sized lean-to house is set apart here for the cooler kinds, and of these the above is a prominent member, the whole of one side being occupied with large plants. A large number are in 9-inch and 10-inch pots, and now that the plants are well in flower

are making a goodly display. The very fine foliage, too, is an indication of rude health. As here grown, with but sufficient warmth to exclude frost and maintain a healthy surrounding, the plants are naturally late flowering; indeed, this much is the design of Mr. Wythes, who in this fine plant has a most reliable midwinter Orchid, that so coolly grown is capable of greater endurance in a cut state.

Iris stylosa.—Already in the more sheltered positions this valuable winter Iris has begun its flowering. The only position that is at all likely to provide a supply of flowers in mid-winter is one where the plants receive the benefit and protection of a warm wall, that adjacent or even part of a greenhouse or stove suiting well. In some such place a narrow border may be planted with this winter Iris and be found of much value when such flowers are scarce. The protection thus afforded goes a long way to making the plants evergreen, this in turn also helping the flowering.

Roses in December.—The Tea and China Roses have continued to bloom fairly well throughout the entire month, and their delicately tinted blossoms in vase and bowl have afforded a charming foil to the Chrysanthemums that almost monopolise the indoor decoration of November. The single white Macartney Rose has flowered during the whole of November, and in the middle of the month I saw a large plant growing over a low wall on which were nearly four dozen expanded blossoms. This plant commenced to bloom in June, since which time it has not been flowerless for a single day.—S. W. F., *Plymouth*.

Rhododendrons flowering in the open.—It is, perhaps, either owing to the earliness of the variety generally or this and the comparatively mild, open autumn, that a large bush of the above has come into flower at this time. The plant is a large one, possibly 6 feet or more through, and is growing in one of the beds devoted to these things at Kew near to the large Palm house. It is a white-flowered variety, and the earliest buds had become quite prominent, and thus showed clearly at a short distance. The circumstance is unfortunate in the end perhaps, as the chances of a good spring blossom are to all appearance destroyed.

Crassula lactea.—This winter-flowering succulent is not nearly so largely grown for warm greenhouse decoration as it deserves. It is not at all fastidious as to soil, as any ordinary potting compost suits it, provided there is an ample supply of coarse sand mixed with it to make it porous. Cuttings struck early in the spring and grown on during the summer months, and afterwards well ripened up in a frame, flower well the following winter. The plants, being of dwarf habit, come in extremely useful in the winter season both for room and conservatory decoration, when their pretty spikes of white flowers at once arrest attention.—A. W.

Chrysanthemums in the west of England.—As has been the case during the past three seasons, these have added much to the brightness of the November garden, and their deep crimson, orange, gold, sulphur, white, pink and rose tints enliven many a cottage plot with rich colour. In these cottage gardens many old-fashioned varieties are to be found, such as the incurved Mr. G. Glenny and Mrs. G. Rundle, the golden Jardin des Plantes, never excelled for colour except, perhaps, by the recent introduction Modesto, the Christines, the deep maroon-crimson Julie Lagravere, Peter the Great, Val d'Andorre, of a striking chestnut hue, and many others.—S. W. F.

Canarina campanulata.—This very distinct plant is only rarely seen, a fact largely due, perhaps, to the few flowers produced by even strong tubers. Just now an example in flower may be seen at Kew, the somewhat extended growth indicating a rather warm temperature. The flowers are distinctly bell-shaped, drooping, and of a vinous red tone beautifully veined within. One of these large bells is situated at the extremity of the lateral branches, and as much by its position as the colour at once attracts atten-

tion. With cool treatment or in a cool greenhouse the plant is more dwarf and sturdy, the more or less fleshy or succulent stems firmer. It is rare indeed that it may be described as free-flowering.

Cestrum aurantiacum.—Though scarcely coming under the designation of climber, this distinct and pretty coloured flowering plant is useful in the warm greenhouse at this season of the year. The golden-orange colour of the flowers—a shade of colour rarely seen, in fact—is quite distinct. The plants, however, require to be of a good age before flowering freely, and when this occurs but little pruning will be necessary. A mixture largely of peat, with a fourth part good loam, and some brick rubble freely added together with sand, will suit it well. Careful watering, too, is very necessary, as an overdose or a wet condition of the soil at the root is often attended with injury. If planted out, but little water will be required at this season.

Violet La France.—One can scarcely agree with "D." (p. 456) when he says the newer Violets give "no improvement in colour," &c. Surely the above-named surpasses all else in the single kinds in depth of colouring, or if not, what would "D." consider among older kinds to be on a par with it? I know nothing that can compare with La France in this respect, and we can only hope when raisers tire of giving single kinds of good size they will turn their attention to the foliage. In this latter respect it would doubtless prove a great gain could we but get a fine single kind with a habit of growth similar to that of Marie Louise. Unfortunately, it frequently happens that single-flowered kinds in more things than Violets possess a rather strong habit, and this may take some time to correct, to say nothing of overcoming it altogether.

The Chrysanthemum rust has increased during the past year, and even in the open air many collections are affected, while under glass the disease has in some cases had disastrous effects. Where gardens are at present free from this scourge the greatest care should be taken that the home stock should be exclusively relied upon for purposes of propagation, and that no cuttings from outside sources should be admitted. In this manner the infection may be warded off, though very possibly, in course of time, spores of the fungus may be carried into the garden and contamination take place. How long immunity can be assured by isolation it is impossible to say, but in view of the rapid spread of the disease, such a course is well worth a trial, and I am anxious to see for what length of time a healthy collection located in a valley a good quarter of a mile from the nearest plants of the same race, and which it is intended shall be kept rigidly isolated, will remain clean.—S. W. F.

Erigeron speciosus superbus.—Sharp frost has reached us at last, and among the flowers to which we shall have to bid a long farewell is *Erigeron speciosus superbus*, which has given us its second crop of bloom. It is difficult to speak too often or too favourably of this plant, which is yet absent from many gardens in which it would form a veritable treasure. I have been told, I admit, that it does badly in some gardens. Why this is the case one is at a loss to know. I have seen it doing well in even colder and less promising places than those in which it is said to have failed. Either for garden decoration or for cut flowers it is worth more than the little trouble it gives to secure a profusion of its violet-purple flowers, much of whose beauty consists in their narrow petals. Its fault for the garden consists in its need of support, unless in a position protected from wind; it soon gets blown down, and then the blooms come with bent stalks, which make them difficult to arrange to advantage when cut.—S. A.

Begonia socotrana.—Pretty batches of this plant now in flower at Kew in the No. 7 range afford visitors a good idea of comparison with at least one of its offspring, viz., *B. Gloire de Lorraine*. The colour and the form of the blossoms in these two are singularly alike, while the nearly

orbicular leaves of the former are quite obliterated in the progeny. Nor, indeed, is there much to be seen of the other parent, *Begonia Dregel*, beyond the generally closely-formed habit. The rather fleshy leaves of *Gloire de Lorraine* in part point to the above-named, but in no other respect. That it should have so closely inherited both colour and form of the flowers while renouncing all else of the one kind is both curious and interesting. At the same time, the lovely baskets of *Gloire de Lorraine* are a picture of colour and beauty at this dull season, pointing to its great value for brightening the warm conservatory and other such places at this season, when, with the collapse of the Chrysanthemum, so much brightness is wanted.

Kniphofia Tucki.—As "E. J." says on page 459, one of the chief attributes of this Torch Lily is its early flowering. In brightness of colouring it is not to be compared with some of the hybrid Torch Lilies which are now so numerous, and which form useful plants in their own time. *Kniphofia Tucki* is, indeed, deficient in colour, and could stand some improvement in this respect. It is, however, the earliest, with perhaps the exception of *K. Rooperi*, which in some localities seems to bloom more or less throughout the year. It is, however, even more deficient in brightness than *K. Tucki*, although, as already remarked, the latter could with advantage be improved upon. I do not know that we have much need of early-flowering Tritomas, as there is no lack of material at the season in which *K. Tucki* blooms, but they can be advantageously used in some places. It is possible to have a surfeit of Torch Lilies, and if we had them throughout the summer we would probably tire of their stately spikes. *K. Tucki* proves fairly hardy without protection.—S. ARNOTT, *Carsehorn, N.B.*

Sedum brevifolium.—The interesting notes advocating the use of *Sedum Lydium* and *S. hispanicum* var. *glaucum* as thin carpet plants, for which they are admirably adapted, lead one to remember that one hardly ever sees any mention of the very beautiful little *Sedum brevifolium*, one of the dwarfiest of the genus. One of its features is the tone of its colouring, which has been well described in "Hardy Flowers" as a "pinkish mealy tone." The truth is that one can hardly find terms accurate enough to depict the precise colour of its foliage. For some years there was a very pretty form grown in the Royal Botanic Gardens of Edinburgh as *S. brevifolium* var. *Pottsi*. This variety is probably there still, but I must have failed to observe it on any of my recent visits. This has a greater variety of colour and tint. I am always puzzled to know why this little Stonecrop does not succeed in my garden, where so many increase so freely as to become rather troublesome. Probably there is too much moisture in the air. It appears to do well at Edinburgh, where the climate, if colder, is drier.—S. ARNOTT.

Crocus hyemalis.—I have never been able to understand why the typical *Crocus hyemalis* should be so difficult to obtain while the variety *Foxi* is easily procured in some quarters. Possibly we have no great reason to regret this, as the drawings of flowers of the type give an impression that it is not so pretty as Fox's Winter Crocus, whose black anthers give it a most distinct character. Still, collectors of these flowers like to have an opportunity of comparing the actual flowers instead of being satisfied with a drawing, however well done and however truthfully coloured. I must confess that I have never been able to obtain the type of this Crocus. When it was ordered, Fox's variety was always sent instead. I have seedlings from seed purchased under the name of the type, but these have not bloomed, and as corms from the same source gave flowers of *C. h. Foxi*, one has little hope of getting the type among the seedlings. As it is said to be a common species in its own country, it is strange that it is so scarce in the trade. It is unfortunate for the future of *Crocus hyemalis* in our gardens that it is so easily spoiled by rain. Unless protected overhead it soon be-

comes a shapeless piece of pulp devoid of beauty. Protection is easily given, but the true place for it in our climate seems to be in a frame or in pots in an alpine house or cold greenhouse.—S. ARNOTT.

XL ALL VAPORISING COMPOUND AND THE PHARMACEUTICAL SOCIETY.

It is strange that the XL All compound should not have been attacked before now. How is it that the Pharmaceutical Society has left it alone until it has become known to practically every gardener in the kingdom, and has become all but indispensable in the garden as an insect destroyer? It has been suggested that had not the trade in this gardener's requisite developed to its present proportions, the attention of the council of the Pharmaceutical Society would not have been drawn to it by its members. Why this sudden discovery of the fact that the XL All compound is a preparation which contains a percentage of nicotine, and why the fear that some one will drink it when it is manufactured and sold expressly for fumigating greenhouses? Why has it taken six years for them to discover that this is so dangerous after it has been sold by nurserymen, seedsmen and florists for this length of time without a single accident? To all unbiased minds the answer suggests itself.

It appears that neither the Pharmaceutical Society nor its members have any control over the sale of carbolic acid or its preparations, and these can be freely purchased anywhere for domestic use, and seem to stand about some households quite unguarded. If this and other poisons of a similar character can be and are sold for household purposes without any restrictions, surely the horticultural trade may claim the right to sell a preparation of nicotine for use (quite apart from the dwelling house) in greenhouses which in nine cases out of ten would be stored in an outhouse in the garden. It is the opinion of many that all interested traders who have suffered from similar jealous and needless interference at the hands of the Pharmaceutical Society should organise a society of their own to watch over their interests and bring their grievances before Parliament at the earliest date possible with a view to getting the Act of 1868 amended, so as to enable agents other than pharmacists to sell poisonous preparations for technical purposes (in the manufacturers' original packages) to the trades and professions which in the ordinary course of business it should be their legitimate right to supply, of course under necessary restrictions. The Pharmacy Act of 1868 as affecting the sale of poisonous preparations for technical purposes does not appear to be understood by one and all alike. It must be clear to all but the most nervous people that the skill of a pharmacist is not at all necessary to sell a farmer a tin of sheep dip. Why, then, should not the farmer be able to get his sheep dip from the same source of supply as his other farm requirements?

Again, why should a gardener not be able to order his fumigating material or weed-killer from his seedsman together with his bulbs or seeds, thus saving the expense and annoyance of having to obtain one requisite from one source and one from another? Next we shall hear of nurserymen and seedsmen being prosecuted for selling any kind of insecticide.

I shall be glad to receive communications and suggestions from anyone who is willing to join such a movement as is above indicated.

G. H. RICHARDS.

128, Southwark Street, London, S.E.

The conference mania.—Every opportunity is now seized upon for getting up an anniversary festival of some sort, and now the innocent Sweet Pea has furnished an excuse for one. At a recent meeting held in Edinburgh it was agreed "That it is advisable to organise an exhibition of Sweet Peas in London in July, 1900, in order to celebrate the bi-centenary of its introduction to

Great Britain," and that a conference of admirers and growers of Sweet Peas be convened for the purpose of classifying the varieties into groups of colour and form. Another reason for this needless proceeding is shown in clause 5, which the preliminary committee has drawn up: "A banquet and other social observances as may be deemed advisable!" If we are going to have a bi-centenary and a banquet to memorialise the introduction of every popular flower, we shall have a lively time. Sir George Lewis said a memorable thing in declaring the world would be an agreeable place if it were not for its amusements. We may now add, to our sorrow, that it will become to many people a very hard place if the busybodies who get up these needless functions on such slender pretences are not controlled in some way by the sober-minded public. The notion that a conference is needed for the classifying of the Sweet Pea into "groups of colour and form" is not true, and is very silly, to boot.

PUBLIC GARDENS.

Rochester pleasure ground.—The Dean and Chapter of Rochester have declined to sell the freehold of The Vines in that city to the corporation. They have, however, granted another lease to the corporation which continues the use of the ancient vineyard of the monks as a public pleasure ground.

A new park for Brighton.—The town council will shortly be recommended to purchase a new park for Brighton, which we learn is obtainable for a reasonable sum. It is situated to the north of the town, just outside the boundary, and is 190 acres in extent, or more than three times the size of Preston Park.

Tudor House, Bromley.—The Parks and Open Spaces Committee again recommended that the house at Bromley Recreation Ground, known as Ratty's House, should be cleared away and the site laid out as part of the recreation ground. The matter has twice before been before the council, and on each occasion the recommendation of the committee to demolish the house has been referred back.

Open spaces.—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., Mr. C. J. Stevens presiding, it was reported that the Local Government Board had assented to the proposed contribution by the Willesden District Council towards the Dollis Hill scheme, and that steps could now be taken to complete the purchase of this estate of 98 acres as a public park. The secretary stated that the Brockwell Park Extension Committee, upon which the association was represented, formed for securing the addition of 42 acres to Brockwell Park, at a cost of £72,000, had been actively engaged during the month in approaching various South London vestries. Lambeth had agreed to subscribe £15,000, and it was hoped that Camberwell, Newington, and St. George the Martyr, Southwark, would also become contributors. It was decided to render help in the laying-out of a children's playground in Sumner Road, Camberwell, and to take steps to oppose any Bill that might be introduced for enabling the Battersea Latchmere allotment land to be used as a building site, the land having been formerly part of a common. It was reported that the attention of the various county councils in England and Wales had been drawn to the Commons Act, 1899, a clause in which, promoted by the association, conferred upon all county councils the powers of the London County Council in regard to providing open spaces themselves or assisting local authorities to do so.

National Dahlia Society.—A committee meeting will be held by kind permission of the Horticultural Club in the club room at the Hotel Windsor, Victoria Street, London, S.W., on Tuesday, December 19, at 2 p.m. Agenda: Report for 1899, schedule for 1900, financial

statement, and other business.—J. F. HUDSON, Hon. Sec.

Royal Horticultural Society.—The last meeting this year of the above society will take place next Tuesday, the 19th inst., in the Drill Hall, James Street, Westminster, when the Fruit, Floral and Orchid Committees will meet as usual at 12 o'clock. Election of new Fellows at 3 p.m.

The weather in West Herts.—A great fall in temperature took place during the past week. On the 7th the highest reading in shade was 54°, or 10° above what may be regarded as a seasonable temperature; whereas five days later the shade temperature never rose higher than 31°, which is 13° colder than is seasonable. On four consecutive nights the thermometer exposed on the lawn showed from 10° to 12° of frost. The temperature of the soil has fallen considerably during the week—indeed, as much as 10° at the depth of a foot. The ground is at the present time at about an average temperature at 2 feet deep, and about 3° colder than is seasonable at 1 foot deep. There was a little rain at the beginning of the week, and on the morning of the 15th the ground was covered with snow to the average depth of 1½ inches. During the last eight days there have been altogether only about two hours of clear sunshine, and on four of these days no sunshine at all was recorded.—E. M., *Berkhamsted.*

Portlandia grandiflora.—I regret to have to inform you that the plant figured in THE GARDEN of September 30 from a photograph sent by me was wrongly named. It was received by me under the name of *Portlandia grandiflora* some years ago from a reliable source, and it never occurred to me to doubt the nomenclature, and thinking it a well-known garden plant I never examined it botanically. It was recently pointed out to me that the corolla tube was of quite a different shape from that in the figure of *Portlandia grandiflora* in the *Botanical Magazine*, and on examining the plant carefully it was apparent that it could not be a *Portlandia*, but rather a *Brunsfelsia* or some allied genus. Mr. Watson has now identified it as *Brunsfelsia undulata*, of which there is a figure in the *Botanical Register*, pl. 228. It is a most beautiful plant, and I trust your illustration will cause it to be more generally grown. I have never met with this species before, though one or two others of the genus are not uncommon in nurseries. It is not even mentioned in Nicholson's "Dictionary of Gardening."—R. H. B.

OBITUARY.

Mr. Alfred Outram.—We regret to announce the death of Mr. Alfred Outram, who expired suddenly at his residence in Moore Park Road, Fulham, on Friday last, the 8th inst., aged 52 years. Mr. Outram was born in Lower Tooting and had been connected with gardening from his boyhood. He started in the once-famed nurseries of Messrs. Rolleston and Sons, Tooting. From there he went to Messrs. Veitch and Sons, of Chelsea. He next entered the service of Messrs. B. S. Williams and Son, of Holloway, with whom he remained over twenty-two years. For some time he was connected with Messrs. Sutton and Sons, of Reading. Hosts of friends will sympathise with his widow and family in their great bereavement.

Clematis cirrhosa.—Mr. Groom (see p. 457) will, I think, have no difficulty in obtaining this plant from Mr. T. Smith, Daisy Hill, Newry, Ireland, in whose catalogue he will find many other more or less unusual and interesting plants.—G. PIM.

Names of fruit.—*Bury St. Edmunds*.—1, Calville Rouge; 2, Annie Elizabeth; 3, Winter Peach; 4, Downton Pippin; 5, Lamb Abbey Pearmain; 6, Kedleston Pippin.—*C. H. Percival*.—Apple Scarlet Nonpareil.

Name of plant.—*W. A. G.*—*Cassia floribunda*.

ORCHARD AND FRUIT GARDEN.

PLANTING FRUIT TREES IN HEAVY SOILS.

GIVEN a light or medium soil with ample drainage, planting suitable trees and the attainment of good all-round success are comparatively easy matters. It is in dealing with heavy, retentive soils that the inexperienced so often meet with failures. So-called economy often means increased labour and outlay in the end, and it is far wiser to plant a dozen or two trees only after due preparation of the ground than to rush headlong into planting for planting's sake. I believe that plots which can be assigned to fruit culture entirely without any regard to a grass surface for cattle or sheep should be trenched, or if too shallow for this operation, turned up one spit deep in autumn or early winter and allowed to remain unplanted till the following November, the improvement effected in the soil by such treatment and the consequent greater speed and freedom with which the roots of the newly-planted trees lay hold of the rooting medium warranting it. During the summer, whether weeds and rubbish make their appearance or not, several harrowings or scuffings with five-tined forks should be given, no barrier then existing to a speedy completion of planting when the proper date arrives. Of course, where the loam too nearly approaches clay to allow of an effectual escape of surplus water, draining the plot, however small, by means of drain pipes must precede trenching, nothing being so detrimental to free and short-jointed growth as a cold, stagnant root-run. In the case of clay subsoils overlaid with only a medium depth of passable loam, it is well where labour is plentiful to lay the surface on one side, burn, say, the next 12 inches, and, the burning completed, mix the two together, adding as well road scrapings, mortar rubble, charred wood, or burnt garden refuse. Where capital has been scarce I have known this

plan adopted for, say, a space of 6 feet round where each tree is to stand, first placing a few inches of clinkers over the bottom to act as drainage. This will suffice for a few years, when, if need be, a further similar addition may be made. I am opposed to adding animal manure as a rule to heavy composts at planting time, provided the staple is not of a hungry nature, as it almost invariably ends in the formation of rank, long-jointed wood, which even root-pruning frequently takes years to remedy. Assistance by surface mulchings can always be given. I have always advocated the use of stations composed of tiles, slates, or similar material to check descending tap-roots and induce the fibrous portion to take a horizontal course near to the surface, where they will reap the full benefit of sun and air. A foot from the top is a good distance at which to fix these. In extra strong, cold mediums, bush trees, or at any rate those worked on the Paradise in the case of Apples and Pears on the Quince, are imperative. These naturally root nearer the surface than Crab and Pear stocks, and, if necessary, the mounding system can be adopted with bush trees, as high winds have less effect on them than on tall standards.

By the mound system I mean keeping the roots well up almost on the surface and forming mounds over them. This plan has often been attended with capital results where the soil has been shallow, poor, or gravelly. A very important thing when dealing with the above sites is early planting. As soon as the trees can be safely lifted the work should be done, then they get a good root-hold before bad weather sets in. Neglect planting until, say, the middle of December or later, and the roots remain inactive till spring, which is an evil almost, in fact, as bad as spring planting. Firm planting of Vines and Peach trees is generally deemed imperative, but how often are many fruit trees left in at least a semi-loose condition? Provided abundance of correctives is incorporated, Apples, Pears, and Plums can hardly be made too firm,

and for this reason it is necessary to catch the soil in just the right condition—on the dry side. The final treading should be given previous to the last layer of soil being laid on. The supporting stakes should also be inserted soon after the tree is in position, as the compost can then be rammed around it piecemeal and firmness secured. Hammering the stakes in when planting is completed is unsatisfactory in more ways than one. It sometimes happens that trees in heavy soil are considered safe from drought, and are therefore left even in a dry summer to take care of themselves, but I have known fine trees ruined by neglect of this simple operation, and perhaps even left unmulched, when one moderate soaking in April or May would have sufficed. Sometimes cold soil orchards also occupy exposed positions, in which case some varieties are more certain to succeed than others. The following varieties of Apples should in such cases be included: Lord Grosvenor, not liable to canker like Lord Suffield; Golden Spire, unsurpassed for cold, damp situations; Seaton House, an Apple which is gradually gaining favour; Lady Henniker, Northern and Yorkshire Greening, and Sturmer Pippin. NORFOLK.

Birds and wasps attacking Pears.—In answer to "W. S." I am sorry to say that my experience with regard to Pears on walls being injured by birds and wasps is quite contrary to his, as here they attack the fruits in just the same manner as they do those in the open garden. As soon as the fruits are fully grown and the flesh becomes at all sweet they commence their depredations, and the last few seasons I have been compelled to net the trees as soon as the earliest sorts begin to ripen. This keeps off the birds, but is, of course, useless for preventing wasps doing harm. With regard to the wasps, I have conducted a regular crusade against them for the past few years, and the men told off to search out their nests have been so successful that several hundreds have been destroyed. Wasps in consequence were much less numerous last summer, but birds, owing to a scarcity of food, attacked

the Pears in a most determined manner, and it was only nets that were in good order and free from rents that would keep them at bay.—A. W.

Peach Prince of Wales.—I was pleased to read "A. W.'s" note on Prince and Princess of Wales Peaches. One seldom meets with the former, but I do not know a more reliable variety. Its shape is, perhaps, less perfect than that of some others, but colour and flavour are all that can be desired. "A. W." gives his experience of it as grown on an open wall. I have only grown it in a cool lean-to Peach house, where it never missed a crop, large numbers of tiny fruit having to be removed annually. One distinguishing feature of this variety is its exceptionally small flowers, which, however, are always furnished with a large amount of pollen, this being very useful for fertilising less certain sorts growing by its side. I think Prince of Wales should be included in all late houses where room can be found.—GROWER.

Strawberry Duke of Edinburgh.—What has become of this Strawberry? Some fifteen years ago it was a favourite with many, especially in the midlands. I believe it was one of Dr. Roden's seedlings, and although never, so far as I am aware, a market Strawberry, was esteemed in private gardens for its handsome appearance and good flavour. There were, if I remember rightly, two Dukes of Edinburgh, Dr. Roden's being the better. I remember what fine dishes of this Strawberry Mr. Edmunds, of Bestwood, used to show at Nottingham and elsewhere, he himself telling me that it was one of his favourites and did better in the Bestwood soil than most others. Is it because the Duke was not a sufficiently prolific kind or capricious that, like many others, it has fallen, or nearly so, out of cultivation?—J. CRAWFORD.

Pear Doyenne du Comice is next to, if not equal to, Marie Louise in point of flavour and general excellence, and is in season till the end of November. The fruits, which grow to a very large size when well cultivated, have a yellow russet skin when grown out in the open on a bush, but of a clear lemon-yellow, heavily flushed with red on the sunny side, when grown on a wall. The tree makes a fine prolific pyramid on the Quince, and a few cordons worked on the same stock should always be grown on a south or west wall in order to make sure of a crop should the trees in the open garden fail. Trees on the Pear produce fruits equally as large as on the Quince, but their skins are greener and lack the bright red flush already alluded to. With regard to flavour there is no difference whatever, and the same remark applies to their bearing capacities.—S. II.

Apple Flanders Pippin.—It is very singular how well some varieties of Apples will succeed in one district and not in another, and with, perhaps, but a few miles separating the two. The Apple named above comes under this category, for in the Easton, Ledbury, and Putley districts of South Herefordshire it is a marked success, while here at Stoke Edith, only four miles distant from the last named district, it neither grows so large nor is it so beautifully coloured. Mr. Coleman always entertained a very high opinion of this Apple, and in no other part of the country have I seen it succeed so well as it does in the above-named districts. There is something in the nature of the soil no doubt which causes this marked difference, and this same variation in the character of Apples, Pears, and other fruits is no unfrequent occurrence in other parts of the country. Some remarkably fine specimens of Flanders Pippin were exhibited at the Hereford show in November last. It is an excellent cooking market variety and succeeds best when grown as a standard.—A. W.

Unnailing outdoor Peach trees.—This is usually done with a view to retarding the trees, keeping them away from the wall in spring until the fast swelling buds make it imperative that they are again fastened up. But there are other distinct gains in removing the trees. For instance,

although in many cases the shred used decays before the branch has swollen sufficiently to do much harm, in others the wood is bound and the circulation of sap impeded, an impossibility where the trees are taken down annually. Again, insects of all kinds like the shelter of the shred, and when winter approaches they seek all such places. Of course they are disturbed when the shreds are removed in taking down the trees. But the greatest advantage of all is the ease with which one may get all round the wood for cleaning purposes, and this should be an all-sufficient reason for removing them annually. Trees badly affected with red spider, for instance, can never be cleaned properly by applications of insecticide from the front alone. Their progress is hindered, but they are not thoroughly cleared, and in the warm corners on the back of the trees they have a capital breeding ground, the young insects coming out in thousands in spring to feed on the tender foliage, and green fly finding suitable hiding-places until the foliage is ready for them.

OUTSIDE V. INSIDE BORDERS FOR VINES.

My attention was lately drawn by the gardener here to the fact that in one viney, which had a new inside border of turf and bones a few years ago, the Vines did not seem to relish the food provided for them, but turned their roots to the outside border. This is a mass of rootlets. Can you suggest a cause, and, if so, a remedy?—H. PENRY POWEL.

** In very few instances has the making of both inside and outside borders really worked well, and, all things considered, providing both must be regarded as an expensive fad not warranted by results. In building an early viney I would take every precaution, including that of forming the front walls with cement instead of mortar for fixing bricks or stones to keep the roots inside. I would also have the roots of mid-season and late Vines confined to an inside border. This arrangement has its drawbacks in many instances. The difficulty is presumably met by constructing the house in such a way as to admit of the Vines rooting in or having access to both inside and outside borders. The brickwork in front consists of a series of arches, but as the start is usually made with an inside border only and the arches are temporarily bricked up and ordinary soil banked up against these, sometimes the original programme is actually carried out, the arches being opened and outside borders completed in due course. Whether this is done or not, the result is much the same—the roots find their way through the walls, and so rapidly do they increase, that in the end few root-fibres are to be found in the inside borders. When the soil outside to which the roots have access is of a nature to benefit the Vines, their owner need not worry about the fact of the inside border being deserted, but should much cold clay abound, then bad times are in store, shanking and other evils following. That once happened in connection with the famous Longleat Vines. Once a single root finds its way through a wall into soil of any kind it quickly commences to spread and thicken, flattening between the bricks and swelling abnormally on the outer side. In far too many cases inside borders are mismanaged. They are much trampled on nearly all the year round; they are literally burnt up in the vicinity of hot-water pipes; in many instances are made sloping from the front walls, and gradually become so hard that neither moisture nor air can properly penetrate them. What may be thought heavy applications of water or liquid manure may be given, but how much of this reaches the roots? Inside borders should be made level to facilitate watering; the hot-water pipes distributed evenly through the house, not massed just in front of the position usually assigned the Vines. There should be as little trampling

on the borders as possible, and if this cannot well be avoided, the surface of the border ought to be carefully loosened prior to each watering, or as often as found solid, while water should be applied as often as the border is found approaching dryness. Too much or too little water is injurious, and occasional weak supplies of liquid manure or surfacings of special manure are far safer and more effective than a few stronger doses. It does not injure the Vines if the border is probed deeply at places in order to be able to determine whether either water is required or enough has been applied. A mulching of short strawy manure is of the greatest service to an inside border. It prevents a rapid loss of moisture, saves the surface from becoming unduly hard and dry, and attracts the roots to the surface where they can easily be kept active. If these lines are followed, Mr. Powel's Vines may yet be induced to take fuller possession of the inside border, but the roots will always have a predilection for the outside.

Should it be thought desirable to have the roots inside, measures must be taken to bring this about. Probably there is a considerable number of old roots in the inside border, and if it had been worn out I would have advised removing all the old soil, shortening these old roots, and laying them evenly through a width of good new compost. The border not being stale, all that need be done is to remove the surface of the border to the extent of burying many of the top-most roots, and after notching the more woody portions in places, either relaying them all in or top-dressing them, according to circumstances, with a mixture of fresh loam, leaf-soil, partially decayed stable manure, fine mortar rubbish and burn-bake (the residue from a slow fire) in equal parts. A mild hotbed on the top of this when the Vines are started would hasten root action considerably, and in any case a mulching of strawy manure should be given. If kept properly supplied with moisture, borders so treated this autumn or winter should be well occupied by roots before the leaves fall next autumn, when all the roots that run out may safely be cut away close up to the wall or, in the case of archways, sufficiently inside to admit of bricking up. Afterwards keep the front wall bared on the inside, or otherwise the old troubles will quickly recommence. Root action is the most brisk after the crops are matured and before the leaves fall, and if the outside roots are cut off in good time the inside border will be more fully occupied by root-fibres. Vines treated in this way have produced improved rather than lighter crops the following season.—W. I.

Pear Glou Morceau.—This is not what may be termed a generally popular Pear, as it is not good in all places alike. However, where it does succeed it is one of the best large-fruited varieties we have for January use. To have it in perfection it should be given a south wall, allowing the fruits to hang as long as it is safe to do so before gathering and storing them. The tree makes a perfect cordon on the Quince and bears remarkably fine fruit. It also succeeds on the Pear stock, and may be trained either fan-shaped or diagonally, but, according to my experience, the fruits are not then so highly flavoured as those produced by trees on the Quince. I have not grown it in the open for some time past, as although the trees cropped fairly well the fruits always cracked, and were otherwise blemished, while the trees were subject to canker. By growing a good few trees on walls, as indicated above, a good supply of fruit, and that of the finest quality, can invariably be secured for January use.—S. H.

Protecting fruit trees from rabbits.—Many are the methods employed for preventing rabbits and hares from damaging the stems of newly-planted Apples, Pears, and Plums. Some of the rough-and-ready dressings are effectual enough, provided they are renewed sufficiently often. I think, however, that nothing is better, all things considered, than enveloping the stem

of each tree with ordinary wire netting. Most people keep the wire from 9 inches to a foot from the stem and let the bottom into the ground an inch or more, but where rabbits are numerous they will sometimes burrow beneath and reach the bark. If, as a correspondent lately remarked, the base of the protector is turned outwards several inches and then firmly embedded they seldom find their way beneath. A better, or at least as good, and much easier way is to allow the netting to go within a couple of inches of the stem. Join the two ends securely by means of a pair of pincers. Rabbits do not like the movement of the wire when touched, and rarely scratch beneath it; in fact, although I have practised this mode of protection for many years, I never remember the least damage being done. It takes a very little time to do fifty or a hundred trees if the pieces of netting are all cut off previous to starting the job.—J.

SLOPING FRUIT BORDERS.

"A. W." recently penned some interesting remarks on this subject, and is correct in stating that the sloping border, particularly when the angle is a very sharp one, entails much labour in dry summers. All the same, the roots must be influenced by the sun's power to a far greater extent under such conditions than when occupying flat or nearly flat borders. The great thing is to draw the line at moderation, then if the surface is kept in a loose condition, what rain does fall will find its way in, being pretty evenly distributed, and artificial applications prove effectual. On sloping wall tree borders evaporation is far more rapid than from flat borders, but more often than not a heavy shade is created by the growth of various dense-growing vegetables, which is, of course, an evil in itself in more ways than one. To give fruit trees the best chance no crop should be allowed on the border, this being nicely mulched with any spare material, such as old Mushroom manure. Only in large gardens can this system be carried out. In regard to watering sloping fruit borders, I have seen medium-sized dams formed by ridging the soil up, say every 3 feet or so, in order to check the water and secure its entrance to the border. Sloping borders are, in my opinion, imperative in the case of early vineries and Peach houses, and the old-fashioned style of elevating them considerably has much to recommend it. With a view to this, new vineries and Peach houses should be built above the ground level and entered by steps. It is in this style of forcing house that I have seen the best and most constant crops of early Peaches and Grapes, the reason being that the root-run is immensely calculated to produce and preserve in the best condition a host of fibrous rootlets, all other conditions being equal. Of course such borders require judicious management through the hot summer weather which often follows the ripening of the crop.

EAST ANGLIAN.

Pear Winter Nelis.—This still retains its position in the front rank as a highly-flavoured variety for midwinter use. Its season I find depends a great deal on where it is stored. If placed directly in the Pear room when gathered it oftentimes ripens at the latter end of November and early in December, but if stored in the cooler atmosphere of the Apple room it then comes into use at Christmas and lasts into January. This is the latest period that I have ever had it. I gather my best fruits from cordons on the Quince stock, they often being twice the size of those produced by trees on the Pear. On the Quince it is a vigorous grower and produces an abundance of fruit-buds, so much so that every now and again it becomes necessary to thin them out somewhat severely. Root-lifting is also requisite every few years to keep the trees in good bearing condition. Winter Nelis also succeeds well fan or diagonally trained, and is then very productive. The merits of this Pear are so good and so generally well recognised that one or more trees,

according to demand, should find a place in every garden.—S. E. P.

Apple Duke of Devonshire.—Until I saw this Apple shown at Norwich in November I had not met with it for several years. I believe it is more common in Scotland than on this side of the Border; indeed, I was once informed that the Caledonian Society always included in their schedule a class for Duke of Devonshire. The colour is pale lemon, sprinkled over with russet. The flavour, however, together with its long-keeping powers, is its chief recommendation. Like a few other of the best dessert kinds, it must be allowed to hang on the tree as long as possible to secure it in its best form, and such are its merits, that it well repays the trouble of casting a net over the tree to protect from birds, which are very apt to make incisions close to the stalk. I would advise all who think of adding to their list this winter to give Duke of Devonshire a trial.—NORFOLK.

A profitable Black Currant.—Amateurs and those having little experience in fruit culture are sometimes at a loss to know what Currant to plant for profit when the extent of ground at command is limited and only one variety can be accommodated. I should have no hesitation in recommending Lee's Prolific. Were I confined to one sort only this would, I think, be my choice. I well remember it first being sent out by, I think, the late Mr. Lee, of Hammer-smith, and how delighted an old gardener I was serving under, and who was very partial to Black Currants, was when the trees he planted bore their first crop. I know Champion or Baldwin's Black is much thought of, and it is doubtless an excellent Currant. In some parts of Kent it appears to do better than any other. Lee's has a good constitution and will be found a generally good doer. In large gardens both may well be planted.—NORWICH.

Caustic alkali solution.—In THE GARDEN of October 28, 1899 (page 343), there is an article, "Is potash a cure for canker," and a caustic alkali solution is recommended for application to the cankered surfaces. I should deem it a favour if you will kindly state the strength of the solution to be used, that is, the amount of caustic potash to the pint of water.—R. L.

* * * You cannot do better than apply the soda mixture, made as follows: A convenient vessel in which to prepare the mixture is an ordinary paraffin cask holding on the average about forty gallons. In this cask 4 lb. of caustic soda should be first dissolved, using hot, soft water. Take care that the boiling mixture does not touch the skin or the clothes of the person mixing. In another vessel dissolve 4 lb. of pearl-ash, also using hot, soft water for this purpose. Mix this with the other and fill up with water. The mixture will now be ready for use, and may be applied through a sprayer or a garden engine. It is better not to use a syringe, the solution making it slippery and difficult to hold. See that every part of the tree is well dressed.—ED.

Apples on walls.—On the south coast one would hardly expect to find much wall space allotted to Apples, seeing that nearly all kinds come to perfection in the open, but so greatly has the Apple increased in favour of late years that we find it taking up a good deal of the wall space that used to be occupied by Apricots, Peaches, or Figs, and usually with very good results. Not only is this the case in large gardens, but in small ones, where the enclosing walls are not in many cases more than 6 feet or 7 feet high. For Apple trees trained horizontally such walls answer well, and the produce of young trees of such kinds as Cox's Orange Pippin and other dessert kinds that I have seen during the past few years would seem to justify the owners in planting fruit trees that very rarely fail to crop. As a rule owners of small gardens make very little profit by growing the choicer fruits on their walls, but with the Apple they can hardly fail, and if they get really good kinds to start with and treat them well the produce will be

quite as profitable as the produce of choicer but less certain fruit trees. There is a great demand for highly-coloured Apples, and if Emperor Alexander, Hoary Morning, or Lady Sudeley be grown on sunny walls they will be worth quite as much as Apricots. Cordon Apples take so little space that one may fill up spare places very profitably with them.—J. G., Gosport.

Fruit rooms.—Fruit rooms are often constructed in very unsuitable positions and in a way not at all calculated to preserving Apples and Pears. Fruit rooms should never have a position facing south nor yet be lofty. When facing the sun the interior during October and November often becomes far too hot, causing a too speedy ripening of the fruit, which quickly decays, or at least loses flavour. Even when facing north or east, lofty fruit rooms become too dry—a great evil. One of the best fruit rooms I know of is constructed behind a high bank of earth facing the north. It is entered by a descending tier of steps, has a heavy thatched roof, and is amply ventilated. In this room autumn-ripening Apples have been kept for two months after the same sorts gathered 100 miles further north, and which had been stored in ill constructed, dry rooms, had decayed, and this in spite of the fact that the fruit in the first-named house ripened a fortnight sooner. The chief need of a fruit room is a cool temperature that does not fluctuate, this enabling late sorts to retain their weight. So long as actual freezing does not take place the fruit will take no harm, and it is always better to cover with a slight layer of dry Bracken, hay, or Oat straw in case of sharp weather than to subject the fruit to fire heat. All the same, every fruit room should be furnished with a stove for use in such winters as that of 1894. I have always laid sheets of coarse brown paper over the shelves on which to lay tender-skinned sorts, but thick-skinned, firm, long-keeping Apples are best laid, not too thickly, on bare shelves, which ought to be latticed, so that a free current of air may pass through the fruit.—EAST ANGLIAN.

NOTES AND QUESTIONS.—FRUIT.

Apple Court pendu Plat.—This excellent midwinter Apple has so far been a failure on my heavy soil, and I think it is probably due to the stock. I was assured it was on the Crab, but of this I was doubtful when planting the standards, and the behaviour of the trees favours the idea. On a light soil it did well with me, and though not one of the most vigorous growers, was always healthy and clean-looking. It is one of the best of dessert kinds now in season.—H.

Pear Marie Louise is the finest-flavoured Pear in cultivation. Several trees should be grown in every collection, and in different positions in order to ensure a crop. It succeeds well in standard and bush form in warm districts, but in colder ones it should always be grown against a wall having either a south, south-west or western aspect. As cordons on the Quince the trees are exceedingly prolific, but the largest and highest-flavoured fruits are obtained from double-grafted trees on the Quince and trained either fan-shaped or diagonally. The crop should never be gathered all at one time, but at intervals of a week, when a much longer succession is ensured.—S. E.

Pear Beurre de Jonghe.—This is a medium-sized but first-class Pear, ripening about the end of December or the early part of January. Its merits are so good that it is deserving of a position on a south or west wall. When better known it will, in my opinion, be more largely cultivated. As a cordon on the Quince stock it is very prolific and grows vigorously. The fruits have greenish yellow skins, with brown russet spread more or less all over the surface, and are regularly formed. The flesh is white, most agreeably flavoured. This Pear will remain in good condition for some time after arriving at maturity. It should be in every collection where the shelter of a wall can be afforded it.—A. W.

Pear Beurre Hardy.—This is essentially a November Pear, and a good one too. Its appearance is rather uncommon, especially in a season when an abundance of sunshine is experienced. The side of the fruit exposed to the sun then assumes a deep bronzy reddish tint, and this contrasted with the greenish yellow colour of the remainder renders well-

grown samples very handsome. The fruits grow to a large size, particularly on a wall-trained cordon. Fine examples can also be had from pyramids on the Pear stock; in fact, it succeeds so well in the warmer districts grown in this way that it is almost unnecessary to give it the protection of a wall. It is a very heavy cropper, and is a vigorous and hardy grower. If buried in quite dry sand and kept in a cool place, fruit may be had quite a fortnight later than the usual time of ripening.—A. W.

CHRYSANTHEMUMS.

CODDLING CHRYSANTHEMUMS.

THERE is a deal of truth in the concluding words of "Suffolk" at page 457 under the above heading, and unless for exhibition, as pointed out, there is no gain in all this extra early propagation. Even where the plants are grown entirely for home use—and good flowers are a necessity—there is no real need in beginning their propagation in November or even December. One has but to put the matter intelligently to the test to find out what really serviceable blooms can be had even from April and early May-struck cuttings; indeed, some of the best blooms of that still fine yellow *Jardin des Plantes* I have seen were grown from cuttings inserted early in May in a manure frame containing Cucumbers. Anxious to secure dwarf plants and as leafy as possible, I selected some strong cuttings and dibbled them into sand in the frame mentioned. They were not long in rooting, and so well did the roots take to the leaves and manure of which the hotbed was composed, that I put the young plants at once into 5-inch pots, which were speedily occupied with vigorous roots. Not long after the plants were in their final pots—8-inch, I believe. I grew about a score of this kind in this way, and the blooms were a surprise to all who saw them. Most of the plants carried three, and one or two four, blooms. I do not say these were exhibition blooms, though I have seen much smaller on boards set up for that purpose, while in colour they were splendid of the kind, and in not a few instances superseded those from plants much older. This is twenty years or more since, and to-day we have dozens infinitely better suited to late propagation than the above kind. But with late propagation there must not be the fatal mistake of late stopping also, or the blind shoots will be more apparent than blooms. I am not greatly in favour of much stopping for the production of so-called bush plants, and consider that a few more plants with less pinching would give much better results and a far greater number of useful blooms to the grower. That well-known kind *W. H. Lincoln* is splendidly adapted for free-flowering, and plants in 8 inch pots I have had carry from forty to four dozen capital blooms without being stopped at all. These plants were grown thus some five years ago. My stock plant then was a solitary one, and not a good one at that, as it produced but five very small and weak cuttings. These were secured in two lots, and, fortunately, all rooted, but made little attempt to grow; so much so, that they were shifted bodily into larger pots more with the thought of securing stock than aught else. Presently, however, a start was made, and the plants were not interfered with beyond good culture, no pinching or stopping being done. Early in the autumn the plants began to develop wonderfully, and being only in 8-inch pots required every attention. Finally, they reached about 3 feet 6 inches across, and bore the flowers above stated. I am strongly of opinion that some sorts resent

much stopping of the shoots, and in such kinds as *Lincoln*, *L. Canning*, *Lady Lawrence*, *Golden Dart*, and others it can certainly be overdone. That useful white, *Petite Amie*, is always good for a dozen flowers on terminals without stopping at all, flowers, too, that no gardener who had them at command would despise. I believe, too, that the freest flowering kinds are those that most quickly fall into disuse, simply because they resent the one-to-three-on-a-plant system. Both *Mrs. Fogg* and *Golden Dart* are far from good, with a few blooms, the latter simply wretched, but with a dozen on the terminals it is one of the most graceful I know. E. J.

CHRYSANTHEMUM SPORTS.

MANY choice new varieties have been obtained by sports. Notable instances will be found in *G. J. Warren* and *Mrs. Mease*, from that queen among *Chrysanthemums*, *Mme. Carnot*; also *Charles Davis* and *Lady Hanham*, from another kind scarcely less beautiful, *Vivian Morel*. In these cases the new colours are rich, and in other respects the sports have qualities to make them as popular as the parents. But this is not always so, and not a few of recently-introduced varieties obtained by that means are anything but improvements on their respective types. *Mrs. J. W. Barks*, from that fine yellow, *Edith Tabor*, is dull in its bronzy shades and has the appearance of the parent in decay. *Pride of Stokell* seems a long time in getting the vigour of *Pride of Madford* with me, and I fear the new-comer will never be so highly esteemed as is the parent. *Eastman Belle* is a deep-coloured sport from *President Borel*, a variety now discarded. *J. E. Clayton* is a yellow *Eva Knowles*. The type is valuable because of its distinct amber tint; therefore, a yellow is not worth growing, because we have others of the shade better in bloom and of shorter growth. *Lord Aldenham* is a yellow sport from *E. Molyneux*, notable for its rich combination of crimson and gold; otherwise it is now considered uncertain. A yellow, therefore, from such a kind cannot be recommended. *Mr. A. Barrett* is a variety obtained by the sportive habit of a popular but by no means handsome exhibition *Chrysanthemum*, *Mrs. C. Harman-Payne*. The new kind has rose and buff tints, instead of the pink seen in the type. *M. Louis Rémy* is a yellow sport from the same parent variety. This is a fairly good one, as it seems less coarse than the type and yet of great size. *Mr. R. T. Simpson* is a rosy bronze shade of *Julia Scaramanga*, which is late flowering and rather uncertain, and, apart from a nice shade of bronzy buff, there is little in it that is especially attractive. *Rivers H. Langton* is a very light yellow sport from *Mrs. W. H. Lee*. The type is a fine show flower, but the plant is tall and ungainly and withal uncertain. A really excellent variety is *Mme. Von André*. This is a primrose-yellow sport from *Mutual Friend*, a variety rightly esteemed for its size and charming formation of its florets. Perhaps this is the only one among recent sports one would add to the choicest selection of *Chrysanthemums*. *Mrs. Alfred Tate*, a rosy yellow form of *Etoile de Lyon*, is good in its way, but so few manage to grow the type presentable for show that I fear the same difficulties will present themselves with the newer form, although both may be excellent for the supply of cut blooms in quantity late in the year. The last I noted was a light yellow variety from *Western King*, which, like its parent, will be useful as a late-flowering sort for market.—SPECIALIST.

— Most of the new sports this season strike me as being rather poor and but little or no advance on the parent forms. The best are undoubtedly *Mme. Von André*, the pale sulphur sport from *Mutual Friend*; *Mrs. Tate*, a deep, warm golden terra-cotta sport from our old and long-standing show variety *Etoile de Lyon*; *Mr. A. Barrett*, rosy-buff sport from *Mrs. C. Harman-Payne*, and *J. E. Clayton*, a yellow

sport from *Eva Knowles*. There is also a yellow sport from *M. Chenon de Leché*, and *Eastman Belle* is a crimson and gold sport from *President Borel*. *M. Louis Rémy* is a yellow sport from the white *Mme. Louis Rémy*. There are also one or two sports from the old *La Triomphante*, but these have only been useful as bush plants. In the same way *White Quintus*, which sported from a medium sized pinkish Japanese *O. J. Quintus*, may also be useful.—C. H. P.

Chrysanthemum R. Hooper Pearson.—For decoration this has an undoubted future before it, the habit of its growth and magnificent colour of the blooms to my mind making it one of the finest introductions of recent years. It has been, and still is, praised as an exhibition flower by some, while others say it is too small. Its qualities, however, are such, that even if it suffers from lack of size for exhibition specimen blooms, it will claim a foremost position as a decorative plant and become a prominent market variety. The plant has an erect growth, dwarf and self-supporting, and the blooms, deep yellow with a suffusion of orange, are very effective. Being new, its present cost will prevent it becoming universally grown as a decorative kind during the coming year. At the late *Frome Chrysanthemum* show one specimen plant of this received a greater share of attention than any other individual exhibit, and there were, it may be said, many others of exceptional merit.—W. S.

Chrysanthemum C. W. Richardson.—While a great many flowers were past their best at the mid-winter exhibition of the National *Chrysanthemum Society*, held at the Aquarium on December 5, 6, 7, this variety was represented by several beautiful blooms, and it was, I think, one of the most desirable varieties there exhibited. From the profusion of long, curling florets, this forms in most cases a beautifully-shaped bloom, while its rich golden-yellow colour gives it an immeasurable advantage over the many kinds with pale or washy tints. I have never noticed it so prominent as it was at the meeting referred to. This variety received a first-class certificate from the National *Chrysanthemum Society* on November 25, 1896, so that it is quite an old kind as *Chrysanthemums* go now-a-days. I have attended this mid-winter exhibition for several years, and I think the one just held contained more blooms that were past their best than I ever noticed before. It may be that one was more than usually critical, and the excessively mild weather and fogs had doubtless affected them, but, at the same time, the varieties were much the same as those exhibited a month previously, and the idea that this December exhibition would encourage the raising of later-flowering varieties has not apparently borne fruit.—T.

NOTES AND QUESTIONS.

Chrysanthemum Mrs. Langtry.—Single varieties are slowly making headway in popular estimation, and rightly so. The wonder is that it should not have been so long ago, because in them grace and refinement are both prominent features that ought to have been more freely recognised. *Mrs. Langtry* is by no means a new kind, but it is, all the same, as pretty as many newer ones. The flowers, small and Daisy-like in character, are borne on freely branching heads. For cutting or as a decorative plant in small pots *Mrs. Langtry* is particularly fitted. Its colour is white, which with age becomes tinted with pink, and in either state it is equally desirable.—W. S.

Chrysanthemum Miss Rose.—The exceptionally mild autumn has been an ideal season for outdoor *Chrysanthemums*, none of which among my outdoor collection has been more admired than *Miss Rose*. There was scarcely a comparison between these outdoor plants and those in pots under glass, the flowers of the latter being pale in colour and smaller. It is exceedingly free-flowering, and quite as remarkable for its dwarf habit, and both as a pot and border plant is a most desirable sort to grow—that is, to those who admire the single varieties. I have never before seen the flowers so fine or so large as on these border-grown plants. These, it may be said, were grown on a warm, sunny border.—W.

KITCHEN GARDEN.

MUSHROOMS ALL THE YEAR ROUND.

THE accompanying illustration shows rather less than one-third of the ridge-shaped beds contained in the Bromley Mushroom Farm, Kent, their total length being upwards of two miles. These beds are all in bearing, and new ones are being constantly made at the average rate of 20 yards per week. Mr. C. W. Gedney, the proprietor, is better known as an angling author and writer on natural history than as a gardener. He tells us that he first began Mushroom culture in the open by planting spawn along some headlands. This proved very successful, and when a large orchard at

soon—before the temperature has fallen below 80°—and then blame everyone except themselves. Given good spawn and the right temperature of beds, he finds it as easy to grow Mushrooms in the open all the year round as it is to grow Cabbages. With a good coating of nice clean stable litter, frost and snow will do no harm and the crops will grow in spite of them. Of course there is a great deal of difference in the results dependent upon good, bad, and indifferent spawn. Good spawn will keep a bed in bearing for twelve months, whilst poor spawn will not last as many weeks. In this Bromley orchard spawn-making goes on regularly every week all the year round, the result being that nothing but fresh bricks straight from the “hatching

Garden has returned nothing under 1s. per lb. since September 7. A good many have fetched 1s. 6d. per lb., but the average for the past three months would be 1s. 2d. in London. Manchester, Liverpool, and other big centres do not average quite such high prices, but these markets are not quite so particular about size and quality. Mr. Gedney sends his best to Covent Garden, and has got 1s. 6d. per lb. when field Mushrooms were selling retail in the shops at 3d. per lb. It is all a question of quality, and it is the greatest mistake in the world to grow anything but the best. Small and medium-sized “Mush” realise much better prices than large ones.

There are three grades known in the trade: “buttons, cups and broilers;” cups fetch the

Winter Mushroom culture in the open air. From a photograph by Geo. Champion in Mr. Gedney's garden at Bromley, Kent.

Bromley came into his possession he there started growing Mushrooms on ridges on a very small scale for his own household. The orchard was choked up with old and much-neglected Currant and Gooseberry bushes, and as these were grubbed up their places were taken by Mushroom beds. There were some early disappointments, the result of the first year's working showing a balance on the wrong side. But there were the assets of beds in bearing and others yet to bear, besides the value of exhausted manure. It is as well to thus make it clear that in Mushroom growing on a large scale the beginner must be able to await results. The failures of most amateurs, according to Mr. Gedney, arise through their being in too great a hurry. They spawn their beds too

house” are used. Bricks that are stored and dried will assuredly perish in the drying if the mycelium has been over-developed in the “hatching house.” This is where the amateur suffers, because such spoilt bricks will appear to him to be full of spawn. So they are, but the spawn is dead. Mushroom-growing and spawn-making are very fascinating occupations, especially when one can get say 10 cwt. per week at this time of year.

What about prices? He admits that they have been good this autumn, but they were bad all through the summer, when he found it better for some weeks to make ketchup instead of sending to market. What would be the average price this autumn? His ledger showed that his principal London salesman in Covent

most money. How long does it take from the planting of the spawn to the cutting of the first Mushrooms? That is one of the glorious uncertainties of the business. Mr. Gedney has had them in a month from spawn straight from the “hatching house,” and has, with dry spawn, waited six months before they put in an appearance. A fair crop per yard run for Mushrooms grown in the open, according to Mr. Gedney's plan, he puts at 20 lbs. The large specimens are worthless for market, and only go into the ketchup tub. He used to grow a good many weighing from 1 lb. to 1½ lb. until he made his own spawn, and thus developed a strain that produced Mushrooms of the size and quality which command top prices. We import an immense quantity of French Mush-

rooms to this country grown in the catacombs of Paris, but they are wretched, dry things, utterly lacking in the fleshy and juicy qualities of our English outdoor garden Mushrooms. He gets a few indoor Mushrooms in the "hatching houses," where he develops the spawn, but there is no comparison between these tasteless, spongy Mushrooms and those grown in the open. The coddling of Mushrooms in stifling sheds and heated houses is an utter mistake. Mr. Gedney has gathered them in the open when he had to turn the snow-coated litter off the beds in order to get at the crop.

VISITOR.

Stachys tuberosa.—How little is now heard of this nice little tuberous-rooted plant. Does it arise from prejudice on the part of the gardener, or dislike on the part of his employer or on that of the cook? Most certainly the little tubers when properly grown, cleansed, and cooked are very nice. Even Salsafy, called in France the Vegetable Oyster, is here a vegetable that is tolerated in the garden, but seldom asked for in the kitchen. We ought to as heartily welcome the tubers of *Stachys tuberosa* as we should the pods of the delicious Butter Bean, and should doubtless do so did we only have them properly sent to table.—A. D.

Potato Carter's Snowball.—Having grown this Potato for several seasons, I was pleased to see the note in its favour from "J. C. T." This season it has been the heaviest cropper amongst half a dozen maincrop varieties, turning out a heavy weight of fine well-shaped Potatoes in spite of the dry season. It should be said of Snowball, however, that it is a tall grower, and on this account it is perhaps more suitable for the field than for the garden. With me this season it has grown taller than Up-to-date, and though I was inclined to regret this at the time, I was more than satisfied when the roots were lifted. Another point in favour of Snowball is its excellent quality, and in this respect it differs from some other vigorous-growing kinds.—H. H.

Early stump-rooted Carrots.—The excellence of Early Gem Carrot was recently noted, and, having grown it myself, I can corroborate what the writer says in its favour. For many years I made a speciality of early vegetables, Carrots included, and forced early in the new year in frames raised on gentle hotbeds. I grew Early Gem as soon as it was sent out, sowing it early in February alongside of that good, richly-coloured Carrot, Nantes Horn. If I remember rightly, Nantes Horn was ready for drawing some ten days or a fortnight before Early Gem, this forming a good succession. A few years after, however, Market Favourite was introduced, and one trial convinced me of its superiority. For years I grew it, usually drawing bright, tender roots with little core and of excellent flavour slightly in advance of Nantes.—J. C.

Long versus short Carrots.—Many gardeners pride themselves on the length and perfection of their winter stock of Carrots, and in good Carrot ground this may afford some satisfaction, but I have come to regard these long roots with much less favour than in the past. In the long tapering root there is a deal of waste in the course of preparation for cooking compared with the shorter stump-rooted kinds, of which there are a good many. This season I sowed some of both sections for winter use, and in extent of yield, labour of lifting and storing, and their utility, I find the stump-rooted sorts the better. The labour of lifting the long-rooted Carrots is considerable when a large extent of ground has to be dug, and so is the covering up of the roots when they are laid in outdoors, as I prefer to do. They do not keep well in "pits" indoors unless they can be covered up with sand or other non-conducting material; they shrivel before the winter is over, and in this state they give rise to complaint from the kitchen. Laid in the open ground in layers

and protected with leaves and litter when severe weather threatens, they keep sound and plump, and may be drawn upon as required for use. The Early Nantes turned out a remarkable yield of heavy roots, clean, shapely and bright. Veitch's Model also is a fine winter Carrot, and these and others of the same section will replace the long ones with me in future.—W. S.

Parsnips.—These roots invariably winter best if left in the ground where grown, because they then keep so much more plump and juicy. But their chief trouble when hard weather prevails is discoloration and injury to the shoulders, which are often much exposed to the atmosphere. If alternate rows in a bed or breadth be lifted, some soil can be ridged over those rows left in the ground, and thus the shoulders are well protected. The lifted roots can either be laid in thickly into sand and be stored in a shed or cool cellar, or, and I think best, be laid in thickly into the ground beneath overhanging trees, as with a few leaves strewn over them in such case no harm from frost results, and the roots are invariably more restful and keep fresher. Parsnips seem to be very good this year, but this remark applies chiefly to those field-grown, and not to those long, leggy roots sometimes 30 inches in length that are frequently grown in gardens. These are not nearly so nice when cooked as are harder-grown roots.—A. D.

Is the Tomato a fruit or vegetable?—Whether the Tomato should be correctly termed a fruit or vegetable is a matter of opinion amongst growers. I have taken some interest in the notes which have recently appeared from gardeners, and notice that opinions are very much divided. Some consider the Tomato a fruit, others contend that it is a vegetable; another says it is a fruit, but not a dessert fruit; and again it is given as an opinion that it is a fruit, but usually classed as a vegetable. One grower says it should be classed with that which it is grown and used for, and in reading one note after another no really definite result on this vexed question can be arrived at. It seems to be generally allowed that, speaking from an exhibition point of view, the Tomato is out of place amongst the fruit, its proper place being among the vegetables. This, coupled with the fact that the Tomato is rarely placed on the dessert table, seems to suggest that its proper place is amongst the vegetables.—H. H.

NOTES AND QUESTIONS.—KITCHEN.

Tomato Stirling Castle.—I do not think any Tomato superior for general purposes, both indoors and out, to Stirling Castle. I agree with "Grower's" remarks on the above variety (p. 452). I have grown it very largely both inside and out this year with good results. It is of medium size and an excellent setter. I have tried a goodly number of varieties here, and I hope next year to confine myself to the following varieties: Earliest of All, Stirling Castle, Ham Green Favourite, Conference, and Challenger. I consider the Tomato a vegetable.—S. KNOWLES, *Pylewell Park Gardens, Lynton.*

Tomato Royal Chester.—I notice that in the "Notes on Tomatoes" which have appeared in THE GARDEN recently, a considerable number of varieties are recommended, though, so far as I have observed, only one reference is made to the variety named above. Mr. E. Gilman speaks well of Royal Chester, and he has every reason for so doing, considering how well he grows it at Alton Towers. When visiting these gardens some time ago I was struck with the excellence of a house of plants of this variety, which is a heavy cropper and produces large, well shaped and extremely fleshy fruits. The variety is a free setter and the fruits contain very few seeds. The notes which have appeared in THE GARDEN also give an idea of the great variety there now is amongst Tomatoes.—G. H. H.

Frost in cold frames.—In the south we are now experiencing the sharpest pinch of weather we have had for several seasons, and the protection of plants in cold frames has become a ne-

cessity. It sometimes happens at these times that the protective material is not sufficient, and the frost penetrates into the interior of the frame. If the next day happens to be sunny and the desire to give the plants the benefit of it by removing the covering is carried out, the result will probably be disastrous and frozen leaves will at once become limp and lifeless. Before removing the covering from frames after a sharp frost it should first be ascertained whether it has caught any of the plants, and if so, light should be excluded by not removing the covering material. By keeping the frames covered till the frost has departed there is not nearly so much fear of plants being permanently damaged as if exposed to light and sunshine while the foliage is in a frozen state.—H. H.

STOVE AND GREENHOUSE.

THE PHILODENDRON IN FRUIT.

The accompanying illustration is from a photo taken at the doorway of a small tropical house, 40 feet by 20 feet, in the garden of Mr. Thos. Fletcher, Grappenhall, Cheshire. Although every plant is grown in a separate pot to admit of thorough cleanliness and prevent the harbouring of vermin, the pots are conspicuous by their absence from view; in fact, the whole arrangement is an attempt at the reproduction of a tropical jungle on a small scale. The collection is a very mixed one, and includes Pitcher Plants, fruiting Bananas and Pines, some rare Caladiums, Crotons, &c. Perhaps the most uncommon plant is the Philodendron in fruit seen at the top left-hand corner. This is growing in an 8-inch pot some 30 feet away, but this is assisted by the rope-like roots thrown down from the top of the house. This plant has ripened four to six fruits each year for the past five years. It is now carrying two bunches of seven fruits each, which appears to be a very unusual crop.

Croton Eugenie Chancier.—Among the brightly coloured Crotons this variety is just now very conspicuous, supplying as it does a shade not much represented among them. It is one of those forms with moderately broad foliage, the leaves being each about a foot or 14 inches long and 3 inches wide. The ground colour is a rich olive-green heavily veined and in some instances almost entirely suffused with bright orange-red, a tint that is particularly effective during the dull winter days. It has not the extreme grace and elegance of the narrow-leaved forms, but as a brightly coloured plant for the stove it merits high rank.—H. P.

Brightness in the winter.—Nothing is more acceptable during the dull days of winter, when flowers generally are scarce, than the bright scarlet bracts of *Poinsettia pulcherrima*, and where much decoration has to be done they are practically indispensable. Under artificial light they are very effective, and in conjunction with spikes of Roman Hyacinths make very pleasing decorations. Dwarf plants in small pots raised from cuttings in the summer are most useful for table decoration. The best plants of *Poinsettias* are those which are kept during the growing season in a cool temperature. *Poinsettias* are often grown in a stove temperature, and though under these conditions the bracts may possibly be obtained a little larger, the plants are invariably tall and lanky, disposed to lose their lower leaves and not nearly so lasting for decoration as if they had been grown under cooler conditions.—H. H.

Lily of the Valley in flower.—At one time it was considered a good test of a person's skill in handling Lilies of the Valley to have an ample supply for Christmas, but now, owing to the practice of retarding the crowns beyond the normal period of flowering by keeping them in a

freezing chamber, they may be had in bloom at almost any time of the year. Thus the quantities of fine flowers that one sees in the florists' shops during the autumn are the product of crowns that would naturally have flowered in the spring of the year. The same applies to most of the blooms that are met with at Christmas-time, for the forcing of such crowns is an easy matter, all that is needed being to place them under conditions favourable to growth. They then quickly push up both leaves and flower-spikes. Before this practice was in vogue the earliest ripened Berlin crowns were obtained and potted as soon as possible, which in a general way would be by the middle of November at the latest. Then they were plunged in bottom-heat in a close propagating case, and generally commenced to quickly grow in a more or less regular manner. Sometimes, however, the first batch absolutely refused to start, in which case they were taken out and

the habit and general appearance of *B. Lynchiana*, but is not so liable to run up tall and naked, the intercrossing of *B. semperflorens* having influenced it in this respect. Another variety known as *gigantea carminata* is much in the same way. If struck in the spring and the plants are grown on cool (and sturdy during the summer they form effective bushy plants in pots 5 inches and 6 inches in diameter by the autumn, and in a warm greenhouse with a little care they will maintain a succession of bloom for months. Older plants may be grown into large specimens if desired, but generally speaking the smaller ones are the more useful.—T.

Repotting Cyclamens.—Reference was recently made to potting Cyclamens, but I think comparatively few are put into their blooming pots at such a late period of the year. I presume the batch spoken of was the produce of seed sown in autumn, 1898, as the majority of cultivators

desirable dark colour. For feeding, nothing, so far as my experience goes, equals ordinary farm-yard liquid. The old plan of standing Cyclamens behind north walls is losing favour. The best position, I think, is in frames turned towards the north, but in an open, sunny position.—B. N.

HYBRIDS OF BEGONIA SOCOTRANA.

It falls to the lot of very few classes of plants to attract so much attention as did Messrs. Veitch's exhibit of the several varieties of hybrid Begonias obtained from *B. socotrana*, which formed such a prominent feature at the Drill Hall on November 21. Their great value for winter blooming was well exemplified, and collectively they were seen to much greater advantage than in the case of isolated examples. Again, that such a grand display was furnished by plants grown within the smoke-laden London area is another great point in their favour, as plant culture within half a dozen miles of Charing Cross becomes more difficult year by year. With these Begonias and the Javanese *Rhododendrons*, two groups of plants that may be almost said to have been created at Chelsea, a grand yet uncommon midwinter display could be formed, as the same temperature is suitable for both. When *B. socotrana* was first introduced it was confidently anticipated as likely to be of great service to the hybridist, and this has proved to be the case, though we had to wait a little while for the first of its progeny. This was

John Heal, which was obtained by fertilising the flowers of *B. socotrana* with pollen from a crimson-flowered tuberous-rooted variety known as *Viscountess Doneraile*. Only one seed germinated, which flowered in 1885, and was named John Heal. It was awarded a first-class certificate by the Royal Horticultural Society. This variety was distributed in 1888, all the plants having been propagated by cuttings from the original specimen. It forms a freely-branched plant, with oblique foliage, instead of the peltate leaves of *B. socotrana*, while the flowers, which are borne on loose gracefully disposed peduncles, are single and of a rich rosy carmine colour.

Adonis, distributed in the same year as the preceding, originated from an orange-scarlet tuberous-rooted variety of the summer-flowering Andean section, which was fertilised by pollen from *B. John Heal*. This is a vigorous-growing, freely-branched plant with deep rose-coloured blossoms, which are in some examples as much as 3 inches

View in the conservatory at Grappenhall, showing *Philodendron* in fruit. From a photograph sent by Mr. T. Fletcher.

another lot potted in their place. When the flower-spikes commenced to push up they were still retained in the propagating case, as the humid atmosphere was favourable to growth. As the flowers opened more air was given to prevent damping. The retarded crowns are now as a rule brought on in a close, moist atmosphere.—H. P.

Begonia semperflorens gigantea rosea.—Since this Begonia was first sent out (now some fifteen or sixteen years ago) we have had many other kinds put into commerce, but for general purposes this still holds its own as one of the very best, and for greenhouse decoration during the winter and spring months it is invaluable. This variety is one of the innumerable hybrids that we owe to M. Lemoine, of Nancy, who announced it as a cross between *B. Lynchiana* (Rozezi) and *B. semperflorens*. It is in every way a better garden plant than either, having more

who sow say in February find a 4½-inch pot sufficiently large for flowering the plants successfully in, judicious feeding being of course resorted to. My practice for years was to sow the seed in August or early in September, and to keep the seedlings in the pans until the following March, or, in the case of forward batches—the result of a mild winter—February; then pot off and grow in an intermediate house till May. An ordinary greenhouse, light in character, then received them, from which they were removed to cold frames in June. As a rule I used to flower these autumn-sown plants in 4½-inch pots. The chief thing is to get a potful of healthy roots, yet to avoid a pot-bound state. Cyclamens are soon upset, and I think that sudden withering of the leaves is often due to the injudicious use of manures. When in full growth a little weak scot water in a clear state, given say twice weekly, will aid in imparting to the foliage the

which are in some examples as much as 3 inches in diameter.

Winter Gem, of which a coloured plate was given in vol. xxxix. of THE GARDEN, was obtained by fertilising *B. socotrana* with pollen from a crimson-flowered member of the Andean race. In *Winter Gem* the single flowers are of a rich crimson-scarlet colour, while the habit of the plant is dwarf and compact. This was distributed in 1891, and was popular for a time, but has since then become comparatively scarce, and is not now included in Messrs. Veitch's catalogue. In 1897 three charming varieties were distributed from the same source, viz.,

Ensign, in general appearance nearly resembling the summer-flowering tuberous race, with semi-double rosette like blossoms of a rich rose-pink colour.

Myra is altogether of looser growth, and readily lends itself to culture in suspended

baskets. The flowers are carmine-rose and borne on long arching peduncles.

Mrs. Heal, a superb variety, bearing a great profusion of rose-carmine blossoms tinged scarlet. The flowers are over 3 inches in diameter.

Winter Cheer, which stood out very conspicuously among the varieties shown on November 21, is of more recent date, and was only distributed in the spring of the present year, though it received an award of merit in the winter of 1897. This is of short, sturdy growth, with foliage a good deal in the way of *B. socotrana*. The flowers, which are produced in small clusters well above the leaves, are over 3 inches in diameter, semi double, and of a carmine-scarlet tint. The latest addition to this section,

Sylvia, received an award of merit on the occasion referred to, so, judging by the others, it will be a year or two before it is distributed. It is of rather erect habit, particularly free-flowering, and the blossoms, though rose or carmine-rose, are tinged with salmon.

These varieties are, I think, destined to form the nucleus of a race which we may expect in time to be almost as universally grown for flowering in the winter as tuberous *Begonias* are for summer blooming. A prominent feature of these *socotrana* hybrids is the length of time the flowers remain fresh and bright, but this is doubtless to a certain extent owing to the fact that they expand during this dull period of the year.

The culture of these *Begonias* differs principally from the ordinary tuberous-rooted section in the time of the year at which they grow and bloom. Thus they go to rest after flowering, but must not be too much parched up at that period. Then towards the end of the summer they must be shaken clear of the old soil and repotted in light, open compost, such as members of the tuberous section delight in. The temperature of a warm greenhouse, that is, a maximum of 60° to 65°, will suit them well during the autumn and winter.

The varieties above enumerated by no means exhaust the list of desirable kinds for which we are indebted to *B. socotrana*, and of them, the first place must be assigned to M. Lemoine's *Gloire de Lorraine*, which for the last three or four years has been certainly grown more than any other *Begonia*. This, which was first distributed in the spring of 1893, has given rise to valuable sports, viz., *Caledonia*, a pure white counterpart of the type, and Mrs. Leopold de Rothschild, which is more compact and with flowers of a more decided pink than the ordinary form.—T.

The excellent varieties of new winter-flowering *Begonias* that have been evolved from the well-known *Begonia socotrana* crossed with the tuberous *Begonia* are not merely novelties of themselves; they mark the advent of a new race of these plants, the end of which it is not possible to surmise. In view, however, of the remarkable strides made during recent years with the tuberous-rooted section, it is quite possible that great and rapid improvements will result in the present new class. Even now the kinds that have already made their appearance are possessed of much merit—at least, in so far as showiness and freedom of flowering are concerned. The kind called *Winter Cheer*, for example, is all that could be desired in a plant in a 5-inch pot. Such habit as this possesses is exactly suited to cultivation under glass, and even if the flowers do not become larger than those of present-day sorts, there is ample in the new-comers to appreciate and to admire. Of course, the flowers will of a surety increase in size. All the same, we may yet express the hope that no attempt will be made to secure blossoms of dinner-plate proportions to rob the present types of the pleasing grace and beauty they now possess. Freedom of flowering should ever be an important item, and how

pleasing a result may be secured by quite small blossoms we need go no further than the well-known *Gloire de Lorraine*. Mention of this recalls the fact that John Heal, one of the new winter-flowering kinds, is possessed of a habit of growth (not of blossom) that reminds one of the plant named. This, it appeared to me, would make a very fine kind, for freedom of flowering was a chief point with it and its small leafage pleasing and distinct. *Ensign* is another very effective kind, erect in growth, the foliage ample and good, and flowers abundant. No less good is the newer kind called *Sylvia*. This, while possessing much the same habit of growth as the two named, except that it is slightly dwarfier, is of quite a novel shade of colour, a sort of salmon-rose largely predominating. Another called *Mrs. Heal* has scarlet flowers, and these are also larger. One of the earliest of the race is *Myra*, in which a loose and straggling habit prevails. This may have its uses all the same, and for baskets or brackets and the like will be esteemed. As pot plants those previously mentioned appear the best. All the same, it is well to see the earliest as also the most recent kinds side by side, if only to secure a correct idea of the progress made. The progress, too, is evident, and the Messrs. Veitch and Sons merit all praise for thus providing beautiful and free-flowering plants for winter work, and, above all, plants that are apparently of easy culture and likely to succeed in the fog-laden atmosphere of our large towns.—E. J.

POINSETTIAS.

THESE are among the brightest subjects we have for decoration at the present time. The only drawback is, they will not stand exposure to the cold, more especially when used as pot plants. This fault may be remedied to some extent by gradually reducing the temperature. They will then stand well if the thermometer does not fall much below 40°. When cut I find the flowers last much better if the ends are dipped in hot water as soon as cut, this preventing bleeding and sending the sap up to the bracts. I have had them last in good condition for fully three weeks, and I believe I might say a month; while on the other hand I have seen them droop the same day as cut when the sap has been allowed to run down, and sufficient care has not been taken in regard to exposing them to a sudden change.

There are several distinct varieties, the result of raising seedlings. Of the red varieties, I do not know of any that have been distinguished by names except one called *carminata* and the double form, *pulcherrima plenissima*. The variety shown at a recent meeting of the Royal Horticultural Society by Messrs. Cripps and Sons is one of the best forms I have seen, though not quite such a brilliant scarlet as some. The white variety is worth mentioning. It is more difficult to manage than the red, but when well done it makes good heads of bracts and forms a nice contrast to the bright colours.

In the culture of *Poinsettias* these grown for cutting may be propagated early, say in May, and though they may run up tall, if potted on and treated liberally they make much larger heads of bracts. For dwarf plants strong cuttings put in early in August will make the best plants. The most important point is to get strong cuttings. The tops may be taken from those propagated earlier, but as the stem is hollow between the joints, care must be taken that they are cut off quite close below a joint, one leaf may be removed, and the cutting put in just deep enough to keep it firm. If done carefully and put into the close pit before they get withered, they will start away without losing a leaf. One of the greatest difficulties is to keep good foliage, but if these late-struck cuttings are carefully attended to they will retain their leaves and make dwarf plants. They should be grown in a moderate stove temperature and kept up as close to the glass as possible, and no shading should be given. As soon as the bracts begin to

form more heat may be allowed. The early plants may be grown in a cold frame during the summer and will do well, but if left out when the nights begin to get cold, though they may not appear to take any harm, the leaves are sure to fall off soon after the plants are placed in heat. H.

IUCULIA GRATISSIMA.

THIS fine greenhouse plant, when it is grown at all, is usually grown as a climber, or at least attached to a wall. Why it is so treated it is difficult to say, for it is very fine when grown as a bush, flowering much more freely than when given a large root-run such as is usually afforded wall plants. I recently noted some nice little bushes about 3 feet high covered with the clusters of rosy flowers, and thought them wonderfully pretty. It is much easier, too, to keep such plants free from insects than others growing on walls and trellises, where it is often difficult to get all round them with the syringe. A little closer pruning, of course, is necessary than when growing on a wall, and the best time to carry this out is the present, or, rather, as soon as the flowers are past. Let the roots get fairly on the dry side before cutting back, and it will be found that little more root-moisture will be required until the plants are again started. Some growers try to strike the prunings, but personally I have never succeeded in doing so. This *Iuculia*, like a number of other hard-wooded plants, requires to be drawn out a little, as it is termed, before the growth is fit for making into cuttings. For instance, just before the plants begin to grow naturally, place them in rather warmer and moister quarters and ply the syringe about the heads. This will cause them to break freely, and when the shoots are about 3 inches in length the tops may be taken off for cuttings. In order to avoid their shrivelling before being inserted the cutting-pots may with advantage be taken to the propagating case, especially if the potting-shed is draughty. Water them thoroughly at once and plunge in a medium bottom heat. If carefully tended and never allowed to flag, a fair percentage will be sure to root, but at the best it is rather a difficult subject. The old plants when they start may, if cuttings are not needed, be grown straight away, the shoots thinned a little if necessary, and any extra strong ones may be pinched out; this is not often needed. A warm and moist greenhouse temperature with ample light suits it best, and the compost should be lasting, free, and open rather than rich. Equal parts of peat of good quality, loam, and leaf-mould, with plenty of sand and a few lumps of charcoal or crocks, will suit it well. The young plants mentioned above may be grown on in a good light with the older ones, and by occasionally pinching to divert the sap and cutting a growth out here and there to keep them thin, they will soon make flowering plants.

Ardisia primulæfolia.—This is a very pretty and distinct species of *Ardisia* whose most prominent feature, like the commonly-grown kinds, is furnished by the brightly-coloured berries. It forms a sturdy stem little more than an inch high, while the corrugated leaves, which are disposed in a horizontal manner, are each about 6 inches long and of a deep green tint. The entire plant thus forms a flattened whorl of leaves a foot or a little more in diameter. The bright red berries, about the size of peas, are borne in closely-packed rounded clusters from twelve to twenty in a cluster on stems about a couple of inches long, so that the entire plant seldom exceeds a height of 3 inches. As the bunches of berries are slightly drooping, they are not seen to quite so good advantage as if they were more upright. For all this, *A. primulæfolia* is decidedly attractive, and as an edging to a group of plants it presents a pretty and uncommon feature. From a fine-foliaged point of view a second species—*A. mammillata*—at once arrests attention, the pale green ovate leaves being so thickly puckered all

over the surface that they present the appearance of being covered with small wart-like elevations, and as a whitish hair springs from the centre of each one, the entire leaf has quite a hoary appearance. The scarlet berries are very attractive, but are usually partially hidden by the ample foliage. By far the best-known member of the genus is *A. crenulata*, which was introduced from Mexico quite early in the present century. It may be treated either as a greenhouse or stove plant, the usual method being to grow it in the latter structure, as it makes more rapid progress therein; then, as the berries ripen, the plants are removed to the greenhouse, as in the lower temperature they remain fresh and bright for a longer period than would otherwise be the case, and they can then be used for the decoration of the dwelling-house. Apart from the berries, the dark shining green leaves of this *Ardisia* are very ornamental. The white-berried form of this, though distinct, is less showy than the type.—H. P.

ORCHIDS.

BASKET ORCHIDS.

A GREAT deal of the charm of Orchid flowers lies in their quaint and fantastic forms and the delicate, semi-transparent texture of their component parts. These are never so well shown off, so to speak, as when the plant bearing them is on a level with or above the line of vision, while pendulous species and varieties seem especially attractive. Most of these are grown in various contrivances that for convenience sake are all termed baskets. But not only are baskets useful from this point of view; there are certain plants that thrive well in this class of receptacle that are hardly strong-rooted enough for pot culture, yet prefer a little compost about them to bare blocks of various kinds. The freedom with which air enters by the spaces between the rods or wires, and the amount of light that reaches the leaves and stems of the plants are all points in favour of basket treatment, many plants difficult to grow in other ways thriving well in them. Another attribute of basket culture frequently lost sight of is its utility in bringing back to a state of health weak plants of a vigorous habit of growth. Many a choice bit of *Dendrobium*, *Vanda*, *Cattleya*, or *Laelia*, and even *Cypripedium* has been recovered from a state almost of collapse by being transplanted temporarily from a badly-drained mass of compost to the more healthy conditions mentioned above. I could give many instances of this if it were necessary, but would rather advise anyone who has unthrifty plants to try the experiment for himself, and will instead mention a few plants that are peculiarly adapted to basket culture.

No plants are more so than the *Dendrochilum* or *Platyelinis*, and few Orchids are more beautiful than a well-flowered specimen of *D. glumaceum* or *D. filiforme*. A grand subject is the former with its scores of racemes arching and depending in rich profusion from the bulbs that produced them, lasting long in beauty and filling the house with fragrance. A very open-meshed basket or rough compost is not necessary for these plants, as they are surface rooting in a way, and when growing need a large quantity of moisture. A plan with perforated sides nearly filled with drainage suits this class well. Quite a different style of plant is *Saccolabium giganteum*, now in flower in most collections. This and many allied plants in the *Vanda* and *Aerides* tribe like basket treatment. The compost should be rough, and it is hardly possible to have the rods too far apart, provided always that the basket is strong

and rigid. Again, we have *Masdevallias* of the *Chimera* group. Their quaint and singularly formed blossoms push out of the sides of the compost, and are often lost when the plants are grown in pots. In baskets they look best, and thrive in a compost in which *Sphagnum* plays a large part. The *Stanhopeas* and *Acinetas* are purely basket plants, and, owing to their peculiar habit of pushing their flower-spikes down into the compost, some rough lumps of charcoal or burnt clay should be introduced around the bottom and sides, or possibly many of the spikes will never see daylight. Some kinds, notably *S. eburnea*, are in the habit of pushing directly downwards; others, such as *S. tigrina*, are more apt to push laterally. So far I have not even mentioned the beautiful species of *Dendrobium* that are so suitable for this method of culture, or the sweetly-scented and pretty *Odontoglossum citrosmum*, which is useful for growing in no other way. To touch ever so lightly on a tithe of those suitable would take up far too much space.

There are one or two common sources of danger that have to be avoided. When hanging, as they are frequently allowed to, from eyes screwed or driven into the rafters, condensed moisture from the latter often runs down into the compost, or, worse still, into the hearts of the plants. In winter especially this water is very cold, and many fine plants have been ruined by it. If a brass rod is screwed to the rafters at right angles to them and running the length of the house, the baskets may be hung on this between the rafters, where they are out of danger. The baskets, too, where possible ought to be suspended over walks and paths. Where they overhang choice plants from compulsion, they should always be allowed to drip for an hour or two after dipping before being replaced. Dipping is much preferable to any other form of watering for baskets, as it is more thorough, it makes insects very uncomfortable, and drives out stagnant air from about the roots. H. R.

Oncidium Cavendishianum.—The colour of the blossoms of this fine winter-flowering species is very bright, clear, and telling, being a chrome-yellow with a hardly perceptible tinge of green that serves really to brighten rather than otherwise. It is such an excellent grower, that all should include it in their collections. Having no pseudo-bulbs, it does not require any distinct dry resting period, yet after the spikes are past until the growth again commences a great amount of moisture is required. For temperature the intermediate house suits it well, and the compost must be very rough and contain a good proportion of *Sphagnum* Moss. Ample moisture when growing, and consequently perfect drainage, are necessary.

Ada aurantiaca.—There are several brightly tinted Orchids now in flower, and though the individual blossoms of this species are small, in the mass they are very showy and as good as any in the colour. Quite a long succession of flower may be kept up by growing sufficient stock of it, as some plants are sure to be later than others. A native of New Grenada, the temperature of the *Odontoglossum* house will suit it well, but when healthy and vigorous the roots will thrive in larger pots and a rougher compost than most *Odontoglossum*. It is well suited, in fact, if treated like *O. grande* and similar kinds. Thrips are sometimes troublesome, and should be kept under by vaporising the house occasionally and sprinkling a little sulphur about the young growths.

Masdevallia amabilis.—Though one of the commonest, this is one of the prettiest of the showy flowered *Masdevallias* and a first-rate garden plant. The leaves and habit are the same as in *M. Harryana*, and the bright crimson and orange of the flowers are remarkably fine. In

spite of all that has been said against it, I still hold that autumn potting is safest for these showy flowered *Masdevallias*. It is not cold that harms them under cultivation, but too much heat. They come from some of the coolest regions that Orchids are found in, and it is difficult to keep them cool enough in an ordinary English summer. One never need fear the results of our winters, for as long as the house is kept at 45° or 50° the *Masdevallias* will take no harm. Besides, if taken in hand at the proper time, the plants are well established again before winter. During the summer it is wise to allow the *Sphagnum* Moss to grow somewhat freely about the surface of the compost, as it keeps the base of the stems cool and is a good index as to the condition of the compost as to moisture. Frequent fumigation is necessary in order to keep down yellow thrips.

NATURAL HYBRID ODONTOGLOSSUMS

THE next largest section to the *Cattleya* family among the Western section of natural hybrids are the *Odontoglossums*. These are about eighteen in number, and they form in many instances useful and desirable additions to our cool house Orchids.

Odontoglossum Adrianæ is one of the latest introductions. When first named it was said to have been raised by Messrs. Linden by crossing *O. crispum* and *O. Hunnewellianum*. It is quite intermediate between the parents named, the flowers white, densely spotted and margined with yellow on the sepals and petals, these in some of the forms being suffused with rose-pink. The lip is white, except the yellow disc, and covered with numerous small brown spots. This hybrid has since appeared in many importations of *Odontoglossums* in this country. Several of these have been exhibited at the Drill Hall meetings of the Royal Horticultural Society and will be found described in THE GARDEN reports of certificated plants. There can be no doubt as to its being a natural hybrid.

O. Andersonianum first appeared with Messrs. H. Low and Co. in 1867 or 1868. It is supposed to have been a cross between *O. odoratum* and *O. crispum*. It is difficult at times to distinguish it from some of the starry varieties of *O. crispum*, but in the majority of cases the separating lines are clearly defined. It is, therefore, to be regretted that Messrs. Veitch in their *Orchid manual* should have classed *O. Andersonianum* as a variety of *O. crispum*. *O. Ruckerianum* is not distinguishable from *O. Andersonianum*, and must therefore be classed only as a variety of that natural hybrid. The only difference the *Odontoglossum* experts now attempt to set up is the fact of the rose suffusion being found in *O. Ruckerianum* and not in *O. Andersonianum*.

O. aspersum is supposed to have been derived from *O. Rossi* and *O. maculatum*. It has the intermediate characters both in the flower and habit of growth. In the variety *O. a. violaceum* the flowers are suffused with deep rosy-violet. Both are distinct and desirable varieties.

O. Cookeanum is supposed to have its origin between *O. gloriosum* and *O. triumphans*. It certainly combines the intermediate characteristics of these species. It first flowered in the collection of Mr. Malcolm Cooke, and was exhibited by him on November 14, 1891. A second plant was exhibited by Messrs. H. Low and Co. on February 9 last.

O. Coradinei (*O. Lindleyanum* × *O. crispum*) has the intermediate characteristics so pronounced, that no doubt can exist as to its origin. It has extensive variations, the best forms being worthy of every consideration.

O. Denisoniæ is supposed by some authorities to be the original of the large class now known under the name of *O. Wilekanum*. It is supposed to be derived from the crossing of *O. luteo-purpureum* and *O. crispum*. I recently examined the only existing record of *O. Denisoniæ*, and to my mind it is not distinct from *O. crispum*, and is

totally different from the plant in cultivation as *O. Wilckeianum*.

O. elegans (*O. cirrhosum* × *O. Halli*) first appeared with Messrs. Veitch in 1871, Reichenbach describing it as "one of those quasi-meteoritic rarities." It has the intermediate characters of the supposed parents and is a distinct variety. It has since appeared in different collections and may be found under several names.

O. excellens, the only natural hybrid up to the present that has had its parentage verified by artificial hybridisation, is derived, as was supposed, from the intercrossing of *O. Pescatorei* and *O. triumphans*. It first cropped up as an imported plant in Sir T. Lawrence's collection, and has since made its appearance on several occasions, generally along with *O. Pescatorei*. It was artificially raised by Mr. Seden. Mr. Thompson, of Stone, and others have since been successful in flowering home-raised hybrids.

O. Galeottianum (*O. Cervantesi* × *O. nebulosum*) first appeared among an importation of *O. Cervantesi* with Messrs. H. Low and Co. The flowers are white, with a few reddish brown bars at the base of the petals and some yellow streaks on the crest of the lip.

O. Horsmani (*O. Pescatorei* × *O. luteo-purpureum*) is a distinct and pretty hybrid, with sulphur-yellow and brown spotted flowers. It first flowered in Messrs. Wallace's nursery at Colchester in 1879.

O. Humeanum (*O. Rossi* × *O. cordatum*) has the distinct characteristics between these species. It is a distinct and desirable variety, worthy of every consideration. It first flowered in the collection of Mr. Burnley Hume, and was described by Reichenbach in 1876.

O. Schroederianum is a unique *Odontoglossum* in Baron Schröder's collection. It is supposed to have been derived from *O. Pescatorei* and *O. tripudians*, the flowers being white, with mauve blotches.

O. vexativum (*O. maculatum* × *O. nebulosum*) appeared in Lord Londesborough's collection at Norbiton in 1876, but seems to be lost to cultivation.

O. Wilckeianum (*O. crispum* × *O. luteo-purpureum*).—This hybrid has been the cause of more controversy than all the others put together. It is a difficult matter to decide where *O. Wilckeianum* finishes and *O. crispum* begins. In fact, some growers suggest that all the so-called spotted forms of *O. crispum* are of hybrid origin. The distinguishing features of *O. Wilckeianum*, as known to us in gardens, are so marked, that little difficulty is found in identifying the plant. In very few of the species is so great a variety to be found as in *O. Wilckeianum*. Flowers are met with in different shades, from yellow and brown markings to white grounds with purple spots, and what is of still greater importance to the grower is the fact that with but few exceptions the varieties are worth growing.

O. Williamsianum (*O. grande* × *O. Schlieperianum*) has the brown and yellow flowers of *O. grande*, and is said to combine the numerous characteristics of the latter. It was described by Reichenbach in 1881. H. J. C.

Odontoglossum Sanderianum.—In size of flower or width of the segments this pretty *Odontoglossum* cannot compare with many others in the genus, but it is free-flowering and a very useful plant that should be grown by all. In growing it one or two points need consideration: in the first place, like all dwarf kinds, a large pot and a lot of compost are unnecessary, and being a strictly cool-house species it will have to be kept well up to the light and air and fairly moist all the year round. In a dark house and large pot the plants dwindle away rapidly. Although not so susceptible to injury from over-flowering as the larger-flowered kinds, it is better to be on the safe side with it, and especially on weak plants to remove the spikes after a week's flowering. The blossoms of *O. Sanderianum* are

pale yellow, with reddish spots upon the segments, and they are delicately scented.

Phalænopsis Stuartiana.—Whatever may be the opinion of metropolitan growers as to the advisability of getting these lovely Moth Orchids to flower in winter, there can be no doubt as to their beauty and utility in country collections. This is one of the best of them, and the spikes of sulphur flowers with red spots are very beautiful. A native of the Philippines, it thrives with the warmest section of the genus and is a very good grower. Fairly large perforated pans or baskets, well drained, and a compost chiefly of Sphagnum and charcoal suit it well. No water should at any time be allowed to reach the foliage, but ample moisture in the atmosphere and at the roots is essential. All changes of temperature should be brought about in a gradual manner, not hurried, as the sensitive foliage is easily injured, though possibly it may not show the injury at the time. The dropping of the leaves in spring that is sometimes so troublesome is often caused months before by some check to growth, the axils of the leaves shrivelling, and the fluids, more than usually active in spring, pushing them off. Regular and constant treatment then all the year round is the easiest way to ward off this trouble.

NATURAL HYBRID ONCIDIUMS.

It is remarkable how sparingly natural hybrids appear in this one of the most extensive of the Orchid genus. This is no doubt accounted for by the fact that the different species are particularly local in their native habitats. It is rarely indeed that more than two varieties are known to grow together, and these cases are extremely limited. One of the most distinct and beautiful of the intermediate forms that has yet appeared is

Oncidium Gardneri (*Forbesi* × *dasystyle*).—This was originally described by Lindley as a species allied to *O. crispum* and *O. Forbesi*. It was first collected by Gardner on the Organ Mountains in 1836. It does not appear to have been cultivated until Messrs. Kollisson received plants from M. Pinel in 1846. It has since appeared in British gardens at long intervals under different names. *O. prestans*, *O. elegantissimum*, *O. flabelliferum* and *O. Pollettianum* are probably derived from the intercrossing of the species which are now identified in the production of *O. Gardneri*. Though differing as varieties, they have in most instances the intermediate characteristics of the parents above mentioned.

O. pectorale (*Forbesi* × *Marshallianum*) first appeared in the collection of Mr. J. Wentworth Buller, of Exeter, in 1840, and was described by Lindley in that year. It was imported with *O. Forbesi*. It has since appeared in several collections, and leading botanists have been misled into describing it under different names. In 1885 a plant flowered with Mr. Bull which Reichenbach described as *O. caloglossum*. In 1887 *O. Mantini* appeared in the establishment of M. Truffaut at Versailles. In THE GARDEN, xxxvii., p. 325, Gower describes *O. Larkinianum*. In vol. i., "Orchid Review," Rolfe describes *O. Marshalliano-Forbesi*. Though differing somewhat as varieties, there is not sufficient difference to merit distinction from Lindley's original description.

O. hæmatochilum was originally described by Dr. Lindley in 1850 from a plant in the nurseries of Messrs. Loddiges. It was not until Mr. T. T. Potter, St. Ann's, Trinidad, pointed out in vol. iii., "Orchid Review," the fact of *O. luridum* and *O. Lanceanum* growing together with the intermediate form, *O. hæmatochilum*, that the possibility of its being of hybrid origin occurred. After duly considering the facts before him and the material at hand, Mr. Rolfe came to the conclusion that it must in future be regarded as a natural hybrid. I have since seen plants in flower, and have no doubt as to the intermediate characteristics of the offspring.

O. Wheatleyanum was first described by Gower (THE GARDEN, 1893, p. 227) as a new species. On November 13, 1894, a plant was exhibited and received an award of merit from the Orchid committee of the Royal Horticultural Society from the collection of Mr. F. Wheatley, Teignmouth, Devon. In the "Orchid Review," vol. iii., p. 6, Mr. R. A. Rolfe points out the technical differences that exist between *O. Gardneri* and *O. Wheatleyanum*, and concludes that it is probably derived from the intercrossing of *O. crispum* and *O. dasystyle*. The original description by Gower in THE GARDEN of above date is as follows:—

A very beautiful *Oncidium*, which appeared with Mr. F. Wheatley, Ringmore, Teignmouth, having been purchased as an imported plant with two or three others as *O. Gardneri*. It bears a raceme of upwards of thirty flowers. The sepals and petals are marbled with reddish brown on a lighter ground, and the lip golden yellow, edged with brown, and a deep crimson area at the base. H. J. C.

NOTES AND QUESTIONS.—ORCHIDS.

Dendrobium bigibbum.—When this showy little *Dendrobe* flowers as late in the year as this, it is exceptionally useful either for cutting or mixing with other kinds in the Orchid house. The deep magenta-purple of the lip in many of the better forms is very striking. It thrives in ample heat with *D. Phalænopsis* and others of the Australian kinds, and should be grown in small pans close up to the light.

GARDEN FLORA.

PLATE 1254.

IRIS ALBO-PURPUREA.

(WITH A COLOURED PLATE.)*

This is a new addition to the Apogon division of the genus *Iris*, typified by *I. pseudacorus* and *I. levigata* (Kämpferi). In general appearance it is not unlike *I. hexagona*, a handsome species, widely distributed in the Southern United States, but, unfortunately, not hardy here except in such favoured localities as Cornwall. It is grown in the temperate house at Kew, where it is an attraction when in flower in early summer. *I. albo-purpurea* may be a native of Japan, or it may have been introduced and accidentally mixed by a nurseryman there with *I. levigata*. Its history is given in the following extract from Mr. Baker's description of it, published last year in the *Botanical Magazine*:

A few plants of this fine new *Iris* were imported from Japan, mixed with a quantity of *I. levigata*. Till they bloomed the two species looked very like one another, but when the flowers came out this caught the eye at a glance by the outer segments being much deflexed and the inner ones erect, whilst in *I. levigata* all the six spread horizontally at one level, a character very unusual in the genus *Iris*.

Both *I. albo-purpurea* and *I. levigata* were in flower together in damp ground by the side of the lake in front of the Palm house in the Royal Gardens, Kew, from the middle to the end of June, by which time nearly all the other *Irises* had faded. *I. alba* is a synonym of *I. florentina*, which is very different from the plant here figured, the name of which is a composite one, not *alba* var. *purpurea*.

W. W.

Jasminum nudiflorum.—So common is this old *Jasmine* in some districts, that it passes almost unobserved and unadmired. Yet even where plentiful it is worthy of more than a passing glance, especially when grown in conjunction

* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by J. L. Goffart.

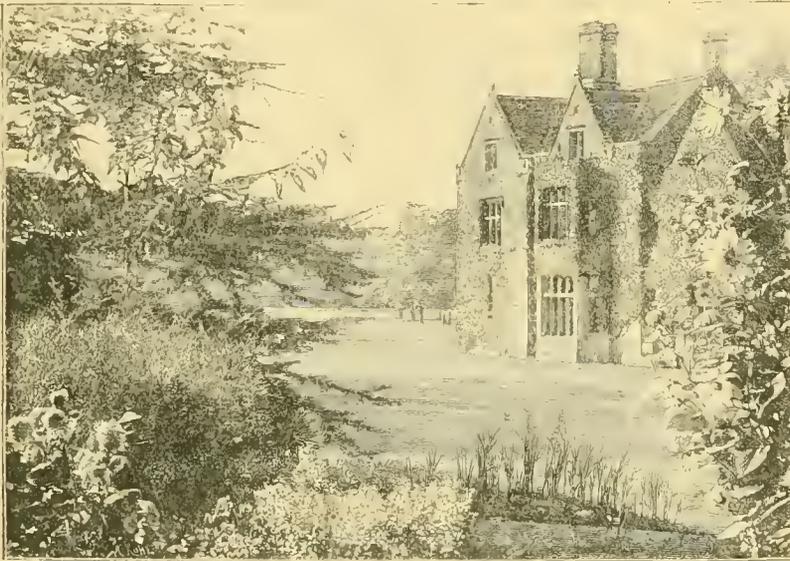

IRIS ALBA PURPUREA

with other plants whose foliage will make up for the bareness of the branches of the Jasmine. This year it is unusually early, and, I think, unusually fine. I have it now in bloom clambering among the branches of an old evergreen Rose, whose leaves make its soft yellow flowers doubly attractive. It does not seem the best position it could have, as it is facing east by north-east, with little to intercept the cold winds which come across an arm of the Solway some five miles or more in width. Yet it appears to thrive and bloom well yearly, although I can hardly remember it being so pretty in any previous year. No attempt is made to train it in a formal way, and this is possibly, or rather probably, one of the causes of its beauty among the branches and leaves of the Rose. Full exposure otherwise it seems to like.—S. ARNOTT, *Carsethorn, by Dumfries.*

FLOWER GARDEN.

A LAWN GARDEN IN GLOUCESTER.

THE freedom of vegetation and the natural toss of branch and leaf about this simple English house may well compare with the

Chambers Court, Tewkesbury. Engraved for THE GARDEN from a photograph sent by Mrs. Ward, Tewkesbury.

engravings (or diagrams rather) of the pattern garden, usually of a hard, ugly kind, with which the foregrounds of houses are not only marred, but in which the very vegetation itself has to conform to the pattern-monger's notions of "design." Whether in winter or in summer, the effect of this garden and gardens of like kind is very much more consoling to the artistic eye than the pattern garden, especially, perhaps, in autumn and winter when the forms and colours of fine trees and plants help to make up for the lack of colour in the summer garden.

Chambers Court, the residence of Mrs. J. E. Ward, is in the valley of the Severn, in Worcestershire, facing the Malvern Hills. The present house of grey stone was rebuilt fifty years ago and is now nearly covered with *Vitis inconstans*, which puts on a most brilliant crimson, something in soil or aspect

making it peculiarly vivid. The lawns are very picturesque, from the number of large evergreen shrubs planted about them, and herbaceous plants flourish, particularly those in a border under a south wall in line with the house.

PYRETHRUM ULIGINOSUM.

THE cutting down of this and other very tall perennials naturally does not find favour with all. At the same time it must be very clear that without the dwarfing the uses to which the above may be put are much modified. I believe this dwarfing originated with myself many years ago, and was brought about more by the exigencies of the moment than aught else. I was planting a bed for stock very late in spring, and orders having been heavy, my supply was limited. At this time growth had considerably extended, and, rather than see the long tops droop and perish in the strong sun-heat—for the plants had been broken up considerably—I cut them down to within a few inches of the earth, placing no value on the flowers at all. The treatment was not what one would recommend, but so vigorous a plant was not slow in recovering. I was more than surprised at the result. The pieces planted were

over, in any case in my experience. Indeed, my one object in cutting down a part and leaving a part was purposely to test this very point, and as I experimented on a bed about 50 feet long and 5 feet wide, the evidence was very clear.

This dwarfing is a matter that should prove of value to many not only with small gardens, but others who have to make a display in autumn in various ways, on the lawn or the like. Take, for example, a bed of this a dozen feet across; what a display it would make. At the same time bold groups in their full height may still have their place in the herbaceous border, and so on. The whole of the Starworts are amenable to the same treatment, these, too, giving much better masses of bloom than cuttings and the like inserted late to encourage dwarfness. Those who value specially late things in this way will find that lateness in flowering is best secured by late annual planting in conjunction with the cutting-down system. Among plants best suited to cutting down which I have tried, Starworts, Sunflowers, Phloxes (*decussata* group) and the above are worthy of mention. In saying this I am far from the idea of minimising the value of our tallest and boldest autumn flowers, and the only object I ever had was that of providing a more extended use for such, and securing their inclusion in many gardens and positions from which height alone hitherto excluded them. E. H. JENKINS.

Hampton Hill.

The Willow-leaved Ox-eye (*Bupthalmum salicifolium*).—Anyone in need of a hardy, dwarf, free-flowering plant should grow the above. A large clump produces great quantities of golden yellow flowers, which are like miniature Sunflowers in appearance. They are most useful for cutting and last in good condition a long time. Like most herbaceous plants, it is all the better for being lifted and broken up every few years. If this is not done the centre of the clump becomes impoverished, and then produces flowers of poor quality. I have never tried it, but should imagine it to be a good hardy plant to grow for summer flowering, particularly for dotting about in large beds where the mixed style of bedding prevails.—A. W.

Open-air Mignonette in November.—Too frequently late-sown batches of Mignonette get cut off by sharp autumn frosts while as yet they have been of little service. Yet where room is abundant it always pays to sow a late bed, as in exceptionally fine autumns the produce is most useful—more so, in fact, than at a season when Mignonette is common in every garden. I think the Giant Crimson strain the best for late sowings, and the ground should be in good heart. Thinning out the plants freely when young is also important, each one standing quite clear of its neighbour. Only last week I saw a beautiful lot in excellent condition in a market garden, and I have no doubt it is being turned to good account for cutting. In private gardens a bed of this description, if occupying a clear position, is deserving of a covering of garden lights to preserve it from the weather.—C.

Callistephus hortensis.—I fear there is much unnecessary fuss being made about this obviously single Chinese Aster. That it is a good garden plant one and all who have seen it frankly admit. That it is likely to become a popular plant and be grown freely by all who garden at all there is ample proof, particularly as it is sure to be cheap and as easily raised as any other of its race. But to assume that it is so much superior and quite a different thing from what Mr. J. Weathers is pleased to term "the degenerate forms of the double China Asters" is quite another matter. Assuming that the plant referred to is the true original kind, but re-introduced, what is there to prevent the cultivated forms reverting to as nearly as possible the original state? More than one writer has spoken of or in some way or other referred to the superiority of the so-called species, but the distinctions are not pointed out in any clear or convincing form.

single stems, and had they so remained, a single stem only would have been made that year. The result of the cutting down, however, gave several breaks from each stem—so numerous in fact, that I rubbed off quantities and allowed at the most half a dozen to remain, some of these taking the lead for themselves. The most surprising part of all was the flowering, which was but a trifle behind the usual time, and instead of a plant 6 feet high the bed revealed a mass of pure white rather under 3 feet high. Even though I had a much more numerous display of blooms, these were still of their usual size, and I at once saw a new and extended use for one of the most showy of autumn flowers. I believe I mentioned the fact at the time. The following year I acted experimentally, cutting back early in June about half my stock and allowing the other part to grow at will. The result of this was that both flowered together, not a day separating the earliest blooms on both portions or the display at its best in the mass. The only difference was the dwarf lot had many more flowers, thus creating a splendid effect, all of which is to be seen and fully admired at 3 feet high. It is naturally assumed that the cut-back plants would be later. This is not so, how-

Much very naturally in such re-introductions of long-lost plants has to be taken for granted, for of all things the most impossible in herbaria is to preserve the colour of such things even for a much less period than 170 years nearly. I have seen one or two batches of the plant, I have seen those grown in the long border at Kew, and I have carefully noted all the exhibits of the flowers sent to the Drill Hall. On one occasion quite in early autumn there were also many single *Asters* of varying colours, and among them shades and forms so nearly identical that it would be a difficult task to separate them. This much, however, was obvious, that one name would apply to all save and excepting the shades of colour. And why the one is a species pure and simple and all else but "degenerate forms of the double China Aster" when all have descended from the one originally is somewhat of a mystery. Surely it is possible that among the blue shades, which are many, there will be found single kinds that it is not possible to separate either by habit or colour from the plant referred to. Mr. Weathers says his stock comes "quite true from seed," but much the same may be said of the many varying types of this race. Should this single kind, however, persistently retain this characteristic in the face of the many groups and sections evolved out of the plant originally introduced, it will be but evidence against it.—E. H. JENKINS, *Hampton Hill*.

Epiphyllums.—It is difficult to know why these beautiful plants are not more grown. The amount of bloom produced by a healthy plant is remarkable, and the plants are very elegant, though quaint-looking when out of flower. Besides the older species, which have long been known in our gardens, there are several new varieties that should increase the popularity of the genus, some of which have been figured from time to time in THE GARDEN. It is usual to graft the *Epiphyllum* on the *Pereskia* at various heights, but I consider they are far prettier when grown entirely on their own roots and allowed to droop naturally about the pots or baskets in which they are grown. True, grafted plants give far less trouble in repotting and other cultural details than do those on their own roots, but I think the latter are worth the extra trouble. The idea that all the *Cactus* family live and thrive best on the poorest and most sterile of soils and with hardly any water is a mistake, for if healthy plants and healthy roots are there they will stand a fairly liberal supply of moisture while growing, and a compost consisting of good fibrous loam and peat, with plenty of broken charcoal or sandstone to keep it well open. During the period of rest, of course much less moisture is necessary—only sufficient, in fact, to prevent shrivelling.

TROPÆOLUM TUBEROSUM.

MR. TALLACK'S surmise (p. 486) that the original tubers of this climbing plant were sent here by him is correct, and I may add it is but one of several most interesting and beautiful subjects by which this garden has from time to time been enriched from the same source. Some of these were received during the time that Mr. Tallack held an appointment in Cornwall, and although the climatic differences which exist between that favoured county and Scotland were too great for the well-doing of a few, yet the majority made good progress and have added considerably to the wealth and importance of the hardy plant department here. Furthermore, a quarter of a century's mutual friendship and regular correspondence with Mr. Tallack have resulted, as may be readily supposed, in the gaining of many useful hints and observations, apart from the many concise, clear, and practical articles on a great variety of subjects which for years have so frequently appeared in the pages of THE GARDEN and other papers from his pen.

There is one point in connection with *T. tuberosum* that, so far as I am aware, has not been touched upon during this correspondence, viz.,

the attractiveness of the tubers themselves. These when fully grown are from 4 inches to 6 inches in length with rather deep sutures in which are numerous eyes or cavities. The ground colour of these when dug is dull yellow, plentifully streaked and blotched with crimson, which as the tubers ripen becomes intensified, when they are really very pretty, more so than any other bulb or tuber, that I am acquainted with. The edible qualities of the tubers have often been mentioned, but I have never put them to the test, although in places where the plant thrives it could be done without much sacrifice of the stock, for in good soil and positions these are produced almost as freely as early kidney Potatoes. Ten days ago, when severe frost was anticipated, all our clumps were lifted, the doing of which presented an excellent opportunity of observing the effect that diverse soils and situations have upon the size and increase of the tubers. In this soil appears to have most influence for good, as where the same was well prepared and of a light sandy nature the tubers were the finer, whether the position was well exposed to the sun or otherwise. In some cases where leaves and other vegetable matter had collected and decayed about the stems and foliage, the tubers were found to be protruding above the soil, and the colouring of these was much more distinct than in those covered by the soil.

Galloway House, Garriestown, Wigtownshire.

NOTES AND QUESTIONS.—FLOWER.

Naturalising *Cypripedium Calceolus*.—I have secured, by kindness of Mr. Heinrich, some extra good seed of this scarce native plant. If any plant lovers living in a likely neighbourhood (chalk soil and woodland) would like to endeavour to naturalise it, I shall be happy to give them small packets so long as my supply lasts.—H. SELFE-LEONARD, *Guildford*.

Strong-growing Violets.—In a recent note on single Violets it was stated that the foliage of several of the latest introduced single kinds was so large as to be ungainly and ill adapted for use in bunching the flowers. I think so too; in fact, I think the flowers themselves individually will, if they go on increasing in size, soon assume the form of vulgarity. I am much afraid size is being considered at the expense of fragrance, and exclude this latter feature from the Violet, and what is it? To have single Violets the size of Pansies, yet minus fragrance, may be all very well for the hunter for novelties, but the true lover of this beautiful flower prefers a variety half the size if the perfume be there.—C.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

FIGS.—Those having to depend on planted-out trees for giving the earliest crop should now be thinking about making a start with those intended to give a crop in May, and where the trees are well furnished with well-ripened growths and with roots confined to inside borders there is more satisfaction to be gained from them than there is from a houseful of pot Figs, and a greater weight of crop can be had from them. Of course, there may be more anxiety when one has to depend on one or two trees only, but I have never found any crop more certain than that of the Fig when the roots are under control and the head trained close to the glass. In such positions Brown Turkey forces as well as the softer-fruited varieties now so much in vogue for forcing, and, taking all things into consideration, there is no Fig so valuable as this well-known variety when treated as the principal occupant of the house and given the best position in it, instead of having to take a secondary place on the back wall of a house with the roof devoted to some other crop. The Fig, not being a gross feeder, except during the summer months, and enjoying a poor root-run at other seasons, should not be subjected to the annual manurings and

top dressings considered so essential to the welfare of many other fruits. All the feeding it wants can be better given in the form of liquid manure later on. For the present all that will be necessary is to see that the border is not dry, or if it is so, that it gets a good soaking before being put to work. Trees that have been infested with bug should again be carefully gone over in search of stray insects, as the Fig is difficult to clean during the growing season. It may be necessary again to say that strong insecticides must on no account be used on the young wood of the Fig tree, and I attach far greater importance to vigilance and a quick eye on the part of the man or men told off to do the work than on the efficacy of any special insecticide, as I have not found one of these preparations which can be used strong enough to kill bug by contact alone that will not injure the wood of the tree. If feasible, a nice bed of leaves and manure should be made up inside the house to assist in keeping up a genial temperature and atmosphere without the aid of a great deal of fire-heat, and this is especially essential now when we are just approaching what usually is the coldest part of winter. To commence with, a minimum temperature of 55°, or even of 50° in case of very sharp weather necessitating hard firing to reach the higher temperature, will be sufficient until the young fruits show that they are swelling away, after which the night temperature may be gradually raised a few degrees at a time. The trees may be syringed over once or twice daily, but the water used should be tepid and applied more in the form of a dew than in that of a deluge, more especially at the afternoon syringing. Very little ventilation will be needed in the Fig house for some time to come, as the young growth is susceptible to injury from cutting draughts. The general rules applied to forcing Vines are equally suited to Figs. Late houses should be put in order, all arrears of pruning and cleaning finished up as soon as possible, and the trees should be tied into position, as there is less danger now of injuring the embryo fruits from rubbing than there will be later on.

CHERRIES.—The Cherry is a most excitable tree and may readily be forced for ripe fruits early in May; indeed, its excitability forms one of the chief dangers in forcing it, as anything like driving is resented by the flowers failing to set and by the fruits dropping soon after they have formed. This should be borne in mind and acted upon by only allowing a minimum temperature of from 40° to 45° at the time of starting and allowing only a few degrees rise at a time up to the time of stoning, after which it is only safe to allow any actual "forcing" of the fruits. A close atmosphere, too, must be avoided, as this neither flowers nor fruits will stand, so that it will readily be seen that progress must at all times be slow, and that even an occasional over-heating of the pipes or a temperature too high will do irreparable damage. Another thing to be rigorously avoided is dryness at the root, for the Cherry likes water when the drainage is effective, which it always should be. No other tree is so susceptible to the attacks of aphides, and these should be watched for from the very first, as they develop with the buds and do great harm if left alone; consequently periodical fumigation must take place frequently. Ventilate little or much, according to the weather, daily, but do not neglect the little at any time after the buds are moving.

POT VINES.—Those started before the middle of November should now be breaking nicely, and if the break is regular all along the rods, there should be no further delay in tying them up into position, as there is less fear of breaking or damaging the shoots now than there will be when they have become more forward. Any which are breaking irregularly and weakly towards the middle of the rods must, however, be kept in the bent position for a while longer to strengthen the weakly breaks. When it can be seen which are the most likely looking growths, the others may be rubbed off, reducing

the breaks to the number required to furnish the Vines without crowding, but the final disbudding should not take place until the embryo bunches can be distinctly seen, as it is not always the most promising-looking breaks that carry the best bunches. The minimum temperature of the house may be raised to 60° with the usual rise of 5° by day, and these figures may be kept up until the Vines are in bloom, when a further rise will be necessary. The Vines will not yet require much water, as there is but little call on the roots during the early stages of growth, and it is easy to make the mistake of over-watering. At the same time, they must not be allowed to get absolutely dry. I do not advise the continuance of overhead syringing after growth has really commenced, and depend on supplying the proper amount of humidity with the evaporation from the hotbed, coupled with occasional damping down.

PINES.—In the Pine houses there will not be much to do outside of the usual routine, but it will be as well to look over the stock of Queens prepared for fruiting next summer and which have been kept on the dry side and slightly cooler for resting purposes, selecting the most forward and starting them again for providing fruit in June. These plants should be given a good soaking of water, and the bottom-heat should be raised with a view to giving them the necessary impetus to grow. Succession stock should be kept on the move without absolutely forcing growth. Cover the houses and pits nightly with some warm covering material such as frigi domo, or two or three thicknesses of mats, which to be really serviceable should be dry when put on. They are then welcome aids to the fire-heat.

MELONS.—Very early Melons are not particularly easy to manage, but if they must be had it is necessary to sow the seeds during the very dullest time of the year; consequently extra precautions must be taken to prevent the seedlings from becoming drawn during the early stages of growth. Some plunging material should be brought up close to the glass, though not out of reach of the bottom-heat, and in this the seed-pots should be plunged after sowing. Sow seeds singly in 2½-inch pots, giving no water until they have germinated and appeared above the soil. A high temperature, *i.e.*, as near 70° as possible, should be given, and all available light will be required at all stages after germination takes place.

CORNUBIAN.

KITCHEN GARDEN.

HOTBEDS.—By the time this calendar appears many gardeners will be thinking of making the first hotbed. If made up now, any excess of heat will have a chance of escaping by the first week in January. Those who may have to produce new Potatoes, Horn Carrots, and Radishes in April take care to collect leaves in quantity early in autumn, and if stable litter has to be used to mix and sweat them previous to using. Beds that are made up hurriedly with fresh litter material invariably cause no end of trouble, as, although owing to a sudden lowering of temperature out of doors the bottom-heat declines to what is considered a safe figure, they as suddenly rise on a return of mild weather, and in spite of airing by night as well as by day, growth appears far too soon and is weak and spindly. It is astonishing what a moderate amount of heat is required to start the tubers and maintain growth in a healthy condition, and any slight deficiency in the bottom-heat can be made good, should sharp frost intervene, by building up linings to the top of the frames. Still, it is advisable to have the beds a foot higher all over than is necessary for the successional ones for February plantings. The great point in building hotbeds is to put on moderate layers of leaves previous to treading, otherwise they will be spongy, and when the soil is thrown in the frames will sway on one side, which, to say the least, looks very unworkmanlike. Let the linings be well trodden and

beaten with the back of a five-tined fork at frequent intervals, or they soon collapse when weight is put upon them. If in a few days the heat of the beds is not excessive, the soil may be thrown in, and when warmed through the tubers planted. A somewhat light loamy compost rendered porous by the free admixture of old Mushroom manure, and, if not in very good heart, enriched by a sprinkling of some approved fertiliser will form a safe and lasting medium. Farmyard manure I do not approve of in the culture of Potatoes in frames and pits, as at this sunless period of the year a consolidated stem growth cannot be secured if such stimulants are used. It is easy to supply the roots with liquid manure when the tubers have formed later on. A depth of about 9 inches of soil is a good one, this being increased somewhat when the slight earthing up is given. The less earthing is practised with early Potatoes either under glass or in the open air the better, as it can only have one effect, that of excluding sun and air at a time when these important agents are scarce. Planting completed, admit air in small quantities daily when warm, as there is sure to be a certain amount of steam generated, which is best liberated, otherwise it condenses on the sash-bars and then drips into the soil, which is an evil. A few words must be said respecting varieties. There are several good newer sorts, but I should be sorry to discard Ringleader. As a rule one can rely on a large percentage of good-sized tubers at each root, and it is of good colour and table quality, Ninety-fold and Early Racehorse also being good, but, as previously intimated, much depends on culture. For successional planting a month later I have found Puritan and Sutton's Seedling both respond readily to frame culture, only, of course, being strong-growing sorts, sufficient room must be allowed between the soil and the glass, and pegging the growths resorted to. Only some two, or at the outside three, growths should be allowed on each tuber, as sun and air will be excluded. It will pay those who have spare ground close up to a south wall to prepare it now for the reception of a few early Potatoes in February. In such a position the young, tender haulm can be protected by means of canvas mats, old bags, or litter from night frosts. I do not advise sprouting the tubers to any great extent for this planting, as sometimes the growths get a check. If the sprouts are just formed that is sufficient.

CARROTS.—Christmas is a good time to sow in a two-light frame elevated on a gentle warm bed one or more varieties of extra early Carrots. For the first drawings there is perhaps yet nothing to beat Parisian Forcing, but for the principal crop in frames and pits my experience is that Market Favourite, a stump-rooted variety of great excellence, is unsurpassed. This sort has also a small core compared with some others. I have usually been able to draw it ten days or so in advance of the good old Nantes sown at the same time. The latter, however, is a brilliantly coloured, richly flavoured Carrot, and may do better with some than other sorts. In regard to the distance between the rows, if no other vegetable, such as Cauliflower, Lettuce, or Cabbage, is to be sown in the same frame, 9 inches will suffice. The one great evil in associating Carrots and Cauliflower is that the latter wants almost complete exposure to the air while as yet the former are too young and tender to stand it, and if once young Carrots become stunted through a check they seldom start again. I have often given Carrots 12 inches between the rows, and sown broadcast early Radishes, such as Wood's Frame or French Breakfast; the joint crops then do very well.

J. C.

California winter notes.—The winter of 1899-1900 will long be remembered in California for its extreme mildness and beauty. We have had several hard years of short rainfall and severe frosts. Now we have an autumn so far

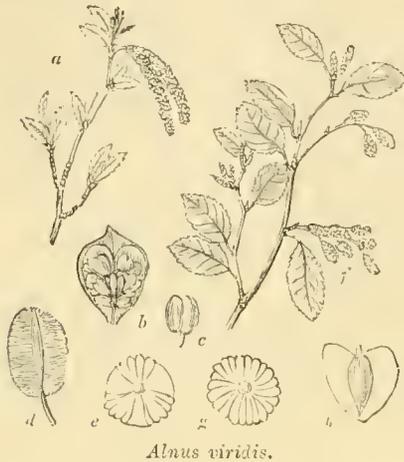

without frost, rainy, and job filled with much sunshine, as most of the rain has fallen at night. The following notes taken during a journey over California will show the character of the season (November 20-26). Near Sacramento, the capital of the State, I saw a field of wheat headed out and ready to be cut. This grew on unploughed land from the grains of wheat falling from the header last August or September, and sprouting with our early rains. At Chico, in the Sacramento valley, nearly 100 miles north of Sacramento, hardly a deciduous tree has begun to shed a leaf. Some Cherry blossoms are to be seen in the orchards; *Acacia cyanophylla* is fairly well in flower. In the region around the bay of San Francisco white *Heliotropes* and *Nasturtiums* are in full bloom. Roman *Hyacinths* left in the ground in naturalised clumps are showing colour, and will be in flower in a few days more. All the spring bulbs appear to be a month in advance of the ordinary season. The Kai Apple (*Aberia caffra*), described in Von Mueller's "Select Plants for Extra Tropical Culture," &c., comes to its greatest perfection at Santa Monica. A plant there (five years old) is 6 feet high and quite as much across. It grows on a dry and rocky slope facing south, and on November 24 when I examined it the bush was heavily laden with large yellow fruits of better quality than elsewhere produced in California. A very fine jelly was made from some of these fruits. This plant promises to have a distinct value for hedges on such barren soils as this, but it does not endure much frost. *Stanotonia hexaphylla*, an interesting broad-leaved evergreen Vine from Japan, fruited at Santa Monica in 1896 and again this season. *Schinus terebinthifolia*, a fine large-leaved Pepper Tree introduced from Brazil, has now fruited in the fourth year from seed.—C. H. S.

TREES AND SHRUBS.

THE ALDERS.

FRINGING the banks of the rivers and brooks and growing in marshes throughout the whole of Europe, Asia northward from the Himalayas, and North America, as well as on the Chilian Andes, the Alders are often the most frequent of trees, and contribute in no small degree to the beauty of the landscape. According to the ideas of the individual botanist as regards specific rank, the genus contains from about fifteen to more than double that number of species, many of them furnishing well-marked varieties and most of them being known in cultivation. The habit, too, varies considerably, some of the kinds never getting to be more than bushes, others often attaining a height of 70 feet or 80 feet; indeed, under different circumstances the same sort will often run through all the intermediates between a small bush and a large tree, as, for instance, our native Alder, which on high hills does not reach a quarter the height it attains in the richer soil of the more sheltered valleys. In some places this is largely grown to produce charcoal for the manufacture of gunpowder. The timber is soft and of no great value, but it is extremely durable when buried under ground or immersed in water. In Holland it is extensively used for forming piles, and its adaptability for this purpose has been recognised from a very early period, Pliny calling it "eternal." According to Vitruvius, the city of Ravenna was built upon it, and Evelyn states that the celebrated bridge of the Rialto at Venice was built on Alder piles. About a century and a half ago enormous numbers of plants were imported from Holland to Scotland at a considerable price and planted in large tracts of moist land. Boucher, who records the fact, informs us, however, that no returns suitable to the labour and expense in-

curred were received. The common Alder does not seem to have been regarded with much favour by many writers as an ornamental tree, although it is one of the finest of aquatic trees; indeed, Gilpin places it, after the Weeping Willow, as the most picturesque of all. With

Alnus viridis.

Gilpin Sir Thomas Dick Lauder fully agrees. He says:—

It is always associated in our minds with river scenery, both of that tranquil description which is most frequently to be met with in the vales of England and with that of a wilder and more stirring character which is to be found among the glens and ravines of Scotland. In very many instances we have seen it put on so much of the bold, resolute character of the Oak, that it might have been mistaken for that tree but for the depth of its green hue. The river Mole may doubtless furnish the traveller with very beautiful specimens of the Alder, as it may also furnish an example of that species of quiet English scenery we have alluded to, but we venture to assert that nowhere will the tree be found in greater perfection than on the banks of the river Findhorn and its tributary streams, where scenery of the most romantic description everywhere occurs.

An advantage the tree doubtless possesses over many deciduous ones which affect drier situations is its tendency to retain its foliage after they have shed theirs. There is, how-

Alnus glutinosa.

ever, a great deal of difference in this respect among the numerous species and varieties, several of the varieties of the common Alder being in good foliage after that of the type has fallen. Although in a state of Nature most of the Alders are found where their roots can at all times command an abundant supply of moisture (and under such conditions they reach their fullest degree of development), they will

grow well in all but the lightest and driest soils. I believe that all the species known already in cultivation fruit freely in this country, and can be most readily propagated by means of seeds. The numerous very strange and ornamental varieties require to be reproduced by layers—a very easy process—or propagated by grafts, using the common Alder or other vigorous kinds as stocks.

Common Alder (*ALNUS GLUTINOSA*) has a wide geographical range, being found wild throughout Europe, North Africa, West and North Asia to Japan. It has black bark and rounded, somewhat wedge-shaped leaves, wavy at the margins, and deep green both above and below; these when young are, as well as the young shoots, covered with a glutinous substance, whence the specific name.

The following are the most striking varieties of this species:—

Hawthorn-leaved common Alder (*A. G. VAR. ONYACANTHIFOLIA*) is a dense-habited bush or small tree with leaves much smaller than those of the preceding, resembling in a marked degree those of the common Hawthorn.

Oak-leaved common Alder (*A. G. VAR. AUREA*) has leaves exactly the size and shape of those of the species, but of fine golden yellow colour. In suitable situations it does not scorch, and although it is of somewhat slow growth, it is a shrub decidedly worth growing in the choicest collections.

Red-veined common Alder (*A. G. VAR. RUBRO NERVIA*) is a vigorous grower, with the habit and leaves of the type, the leaf-stalk and midribs being, however, a bright red.

Large-fruited common Alder (*A. G. VAR. MACROCARPA*) differs from the typical *A. glutinosa* principally in its larger fruiting catkins and bolder leaves, and also in its more vigorous mode of growth.

Fern-leaved common Alder (*A. G. VAR. IMPERIALIS*) is a distinct and handsome tree with elegant drooping branches and Fern-like leaves, which are more deeply cut than those of the next variety. In some nursery catalogues it goes under the name of *Asplenifolia nova*.

Cut-leaved common Alder (*A. G. VAR. LACINIATA*) has deeply pinnatifid leaves which, from their tendency to open out quite flat, give to the tree a totally distinct aspect from that possessed by the last named variety, in which the leaves are very often concave and the lobes always longer and narrower. As to the origin of this, Loudon quotes Thouin, who in the year 1819 in the "Nouveau Cours d'Agriculture" states that the cut-leaved Alder was first found by Trochereau de la Berlière, and planted by him in his garden near St. Germain, where the stool still remains from which all the nurseries of Paris have been supplied with plants, and probably all Europe. There is also a variety with variegated foliage, and another, *Alnus emarginata* (Willd.), with nearly round, wedge-shaped leaves, dark green, with an edging of light green.

Bearded Alder (*A. BARBATA*) is by some regarded as a variety of *A. glutinosa*. It is a native of the Caucasus, being found on the western side of the Caspian Sea. It differs widely in its foliage from the common Alder, its leaves being pointed, having more or less doubly serrated margins, and often attaining a length of 6 inches or more by a breadth of 4 inches or $4\frac{1}{2}$ inches; on the upper surface they are dark green. The most striking characteristic of the plant is furnished by the bright red-brown hairs which clothe the midrib and principal veins on both surfaces of the leaf, and are so marked as readily to catch the eye.

Oblong-leaved Alder (*A. ORBONGATA*) is a large shrub or low tree from South Europe and North Asia, introduced by Miller in 1749. It has obtuse, somewhat egg-shaped, glutinous leaves, the axils of the veins being naked on the under side. Loudon says the finest tree of this sort of

which he has knowledge was one in the Glasnevin Botanic Gardens, which in 1834 was 30 feet high.

Heart-leaved Alder (*A. CORDIFOLIA*), sometimes also called the Neapolitan Alder, is a very distinct and handsome South European tree; its leaves being nearly or quite smooth and of a glossy green, a shade or two lighter than those of

Alnus incana.

the common Alder, give it almost the aspect of a Poplar. It is a fast growing tree with light coloured bark, and from its fine pyramidal habit it is very effective either in groups or as a single specimen. It remains in good foliage some time after most Alders are leafless, and is perfectly hardy in this country. The flowers are produced in March and April before the development of the leaves. The date of its introduction to this country is 1820.

ALNUS NERVOSA differs from this in its more rounded leaves, which are not so decidedly heart-shaped at the base; it, however, seems to grow quite as quickly as *A. cordifolia*, and to resemble it considerably in other respects.

A. SUBCORDATA is another Alder, a native of the Caucasus, which is also referred to as a variety of this species; its foliage is, however, very much larger and bolder, darker green, and its general aspect is widely different from both *A. cordifolia* and *A. nervosa*. Its leaves measure about 6 inches long by 4 inches wide, whilst those of the two others just mentioned are about 3 inches long by 3 inches wide; the relative length, too, of the leaf-stalks is different, those of *A. sub-cordata* being much shorter than the others.

Hoary-leaved Alder (*A. INCANA*) is one which will attain a good size even in dry localities, and which as an ornamental tree is well

Alnus glutinosa laciniata.

worth growing. It, as well as its varieties, is easily recognised by the smooth greyish bark of the stem and twigs and by the grey-green under surface of the leaves. In shape the leaves are ovate, pointed, with margins primarily divided into coarse teeth, which are themselves serrulate. In size they are about 4 inches long by 2 inches wide. It is found wild in North America (where it is known as the Speckled Alder), and is pretty widely distributed throughout the north temperate zone. The best of the varieties which

have at various times received names in different nurseries, &c., are as follows:—

A. LACINIATA, a noble tree, with handsome foliage somewhat like that of *A. glutinosa* var. *imperialis*; the leaves are often from 6 inches to 7 inches long.

A. SUB LACINIATA has smaller leaves with deeper primary divisions than *A. incana*, the secondary teeth, too, being much more evident.

A. PINNATIFIDA when casually examined seems to come extremely near the last-named, but for gardening purposes it is quite distinct; it is of slightly different habit, and the form, size and serration of the leaves render it well worthy a varietal name.

A. GLAUCA has prettily serrated leaves (the petioles of which are reddish), deep green above and glaucous beneath. This, one of the most beautiful kinds of the genus (according to Michaux), forms a tree in the United States from 18 feet to 20 feet high.

A. ANGULATA differs from *A. glauca* in its leaves being green underneath, and in its having green, not red, leaf-stalks.

Saw-leaved Alder (*A. SERRULATA*), a shrub from 6 feet to 10 feet high and a native of North America, makes a very pretty bush with its deep green foliage. The three following, which are sometimes classed as varieties of *A. serrulata*, nevertheless differ from that very considerably.

A. AUTUMNALIS has handsome leaves 6 inches long by about half that width, doubly serrated at the margins.

A. RUGOSA has leaves rather smaller than the last and more rugose.

A. LATIFOLIA has large rounded leaves, sometimes sub-cordate at the base, and with crenulate, weakly serrated, decidedly wavy margins. They measure about 5 inches or 6 inches in length by 3 inches or 4 inches in breadth.

Curl-leaved Alder (*A. UNDULATA*), a native of North America, was introduced in 1782 by the Hudson's Bay Company. It is a small shrub, not growing more than 3 feet or 4 feet high in the swamps of the mountainous regions where it is found wild, though Willdenow states that in 1811 a tree in the Berlin Botanic Garden had reached the height of 15 feet.

Birch Alder (*A. ALNO-BETULA*) is a handsome bush found wild in the mid-European and Italian mountains. It flowers in April (often in March) and produces a plentiful crop of very pretty catkins. The leaves are egg-shaped, pointed, and the same deep colour on both sides. In a state of Nature it only grows about 5 feet or 6 feet high, but in cultivation makes an elegant little tree about double that height.

Oriental Alder (*A. ORIENTALIS*) is a quick-growing tree, with noble leaves measuring often 9 inches to 10 inches long by about 5 inches broad. This, a native of North and East Asia, is still somewhat rare in collections, but it deserves to be much more generally known, its pyramidal habit and enormous ovate, acuminate leaves giving it quite a character of its own.

Japanese Alder (*A. JAPONICA*) is a most distinct shrub, with lance-shaped leaves 4 inches or 5 inches in length by 1 inch or 1½ inches broad, the margins of which are slightly serrulate. In colour the upper glossy surface of this pretty sort is a shade or two lighter than in most other Alders, the whitish veins being very conspicuous on the light-coloured under surface.

Trees at Corsham Court.—On the lawn at Corsham Court, Wilts, the residence of Lord Methuen, there are a few unusually fine specimen trees, some of which in their character of growth are very remarkable. The most noteworthy of these is a cut-leaved Plane. This is a noble tree, having a circumference of 20 feet at 3 feet from the ground and a spread of branches extending nearly 140 feet. This branch-growth does not extend from the bole or stem itself direct, but the lower ones touching the ground in a pendulous manner have rooted and given rise to an independent outward growth in every direction. One branch in particular at the point where it joins the tree would measure perhaps 6 inches

or 7 inches in diameter: beyond and where it rises from the soil it forms quite a heavy tree. It has a height proportionate to its great breadth. Whether this pendulous nature is an outcome of the nature of the soil or the surroundings is not easy of explanation; it is a characteristic not confined to one tree or variety. Copper Beeches are very fine in growth and leaf, and one of these has quite a broad base from the extension of the ground-rooted branches. Horse Chestnuts and Cedars both sweep the ground. One of the finest Elms I have ever seen is here. At 3 feet from the ground it measures 20 feet round; higher up it is considerably larger, and to the eye presents a great mass of solid timber. There are other noteworthy specimens, including an *Abies excelsa*, very old and from 80 feet to 90 feet high. The Tree of Heaven (*Ailanthus glandulosa*) is striking even when without leaves, its growth being so distinct and noble. There are also a very fine Tulip Tree and *Salisburia* of lofty stature. A *Catalpa* close to the house is a wreck, but its prostrate stem has many smaller branches growing freely, and in close contiguity is a flourishing specimen that has arisen from a natural layer. This was separated not long since from the original, and would now appear to have had no relation to its aged parent. —W.

THE HARDY SPECIES OF SMILAX.

COMPARATIVELY few species of this genus can be grown out of doors, but they are almost all evergreen, and all are so distinct in character that they merit attention. *S. herbacea* can be grown as an ordinary herbaceous plant, but with this exception, they require, in all parts of the kingdom, the most favourable position that can be given them. They are most suitable for walls, but several may be grown over large tree roots or may be trained over Spruce trunks, requiring in this case the most sheltered position that can be found. In some cases it is not the low winter temperature that kills, but rather the insufficiency of summer warmth that prevents development. The subject of the accompanying illustration is absolutely hardy, but only on a wall or wooden fence can it attain the beauty of which it is capable. In such a position it is really very ornamental. The naming of the species is exceedingly difficult. In referring to herbaria, specimens are sometimes identical except for some one feature, the value of which it is impossible to determine, and specimens in one or two cases more nearly match what they could not possibly be than anything else. Certainly the genus is very variable, and from the same plant very unlike specimens may sometimes be gathered. From an old stump of the present plant, low down beneath the dense growth, I have gathered specimens which are almost identical with specimens of *S. Bona-nox*, from which, on the whole, it entirely differs. I have made repeated efforts at Kew to name this plant, but have failed to match it, unless with a specimen named *S. hispida*, which this could not be. The genus was monographed by the late Prof. A. de Candolle, and I am indebted to Prof. C. de Candolle for kindly comparing specimens with those in his late father's collection. He informs me that it cannot be identified with any one of them. Since, therefore, it cannot be identified, I propose for garden purposes to call it *S. Cantab.* It may conveniently be connected with the Cambridge Botanic Garden, and no descriptive name could be given that would not equally apply to some other species. It may yet prove to belong to some already described species, but to name by the monograph referred to requires the female flowers, and as this is a male plant there is no hope of identification until it can be matched with some authentic living or dead specimen.

The cultivation of the genus is not at all difficult. All the kinds respond to good soil, and if the soil is not good it should be made so. If suitable cuttings can be got they will usually strike, but there is sometimes difficulty in rooting them. The plants may sometimes be divided, or pieces may be taken off, which readily make plants, and this is usually the surest method of propagation for hardy kinds. The following are the more hardy kinds of *Smilax* cultivated in this country:—

Smilax aspera.—This is a well-marked species, with angular and usually prickly stems, reaching a height of about 5 feet, or even 10 feet. The leaves are ovate-hastate, cordate at the base, the principal veins with a few prickles and often the margin as well. In colour they are dark green, with flecks of white on the upper surface. The flowers are whitish and fragrant. It is a native of South Europe, the Canaries, &c., and is represented by numerous forms.

S. a. var. Buchananiana.—With this variety I am acquainted only by a specimen at Kew. It has a long leaf, with numerous marginal setae. I do not find the name in books, but the plant is distinct and is probably a native of India.

S. a. var. maculata.—Under this name a very neat-habited plant was formerly more common than it appears to be at present. It is marked by a dense growth of slender stems, reaching a height of about 3 feet and bearing leaves of small size, so dark as to be almost coppery in colour. The plant to which the name belongs is a native of India.

S. a. var. mauritanica is a distinct variety, if, indeed, the plant is not even worthy of specific rank. It has angular stems, which, under favourable circumstances, reach a considerable height. The stems and branches have few prickles, and they are rare on the leaves. It is a handsome plant, native of the Mediterranean and the Canaries. An illustration of *S. aspera* var., regarded as approaching this variety, will be found in the *Gardeners' Chronicle*, December 20, 1884, p. 785.

S. Bona-nox (Bristly Green Brier).—The root-stocks have large tubers; the stems are terete or slightly angled, the branches often four-angled; the leaves are usually deltoid-hastate, green and shining on both sides, and their margins are fringed with needle-like prickles. Stout prickles are also scattered over the stems. This species appears to me easily distinguished among other cultivated kinds by the green, deltoid-hastate leaves, which are fringed with slender prickles. *S. Bona-nox* hastata is a form with pronounced basal lobes. It is a native of North America.

S. China (China root).—This species is not evergreen. It has a large and edible fleshy root. The stems are terete, here and there furnished with strong sub-recurved spines. The leaves are ovate-retundate and glossy, the young ones abruptly narrowed and acute at the base, at length cordate at the base, cuspidate or even retuse at the apex. It is a native of China and Japan.

S. Cantab.—For many years this has been cultivated in the Cambridge Botanic Garden, and the accompanying illustration shows well what it is from a garden point of view, as grown against a shed facing west. It is evergreen. The strong shoots reach a height of about 12 feet or more. The stems are round, armed with strong, straight green prickles three-eighths of an inch long; the branches are slender, nearly tetragonal, and are usually without prickles. The finer leaves are nearly deltoid in shape, cordate at the base, and without the petiole are usually rather broader than long, measuring about 5 inches in length and 5½ inches in breadth. They are five-nerved, with one or two extra nerves in the basal lobes, papery in texture, green on both surfaces, with a few spots of grey on the upper surface, and along the margin are a few small prickles not conspicuous, but easily felt by the hand. The smaller leaves are often as broad as long, but they tend to be narrower and to be less cordate at the

base. The male flowers are fragrant, produced on umbels of about eight to twelve; the peduncles are about as long as the petioles, or rather longer. The stamens are six in number, and the anthers are about half the length of the filaments. This plant is, perhaps, nearest to *S. rotundifolia* among the harder kinds, but the leaves differ distinctly in shape. A plant I believe to be the same is grown by Canon Ellacombe as *S. China*.

S. excelsa.—According to a description this is a high-growing species with sub-quadrangular branches, the older ones slightly angled and punctate. The leaves are broadly ovate, acute, sub-cordate at the base, seven-nerved, usually unarmed, but with petioles and veins remotely acute, the margin thinly erose-denticulate. The anthers are more than half the length of the filaments. It has red berries. It is a native of Eastern Europe, Persia, and the Azores.

S. glauca.—The height of this plant is about 3 feet. It has terete stems, branches and twigs angled, armed with rather stout numerous or scattered prickles, or may sometimes be without any. The leaves are partially persistent, ovate, acute or cuspidate at the apex, sometimes cordate at the base; they are glaucous beneath and sometimes above. Native of N. America.

S. herbacea.—I am not sure that this is worth cultivation outside of a botanic garden, but it is easily grown as an ordinary herbaceous plant and is sure to be interesting. It is the Carrion Flower of North America, growing from New Brunswick to Ontario, and south to Florida, Louisiana, and Nebraska. It is native also of Japan. The tubers are numerous, short and thick, the stems unarmed, usually branched, and bearing ovate or lanceolate leaves with numerous tendrils. Its herbaceous habit distinguishes it from all others in cultivation.

S. hispida.—This is quite a distinct plant on account of the stems, which are usually thickly hispid with slender straight prickles. The leaves are ovate, thin, and green on both surfaces, and with even or more nerves, the margins usually denticulate. It is a native of North America.

S. laurifolia.—A high climbing species, the stems round, armed with strong straight prickles, the branches angled, mostly unarmed. It is evergreen, and the plant is easily recognised by its leathery, bright green, three-nerved leaves, elliptic or oblong-lanceolate in shape. It is a native of North America. A fine specimen of this I have seen in Canon Ellacombe's garden at Bitton.

S. pseudo-China.—The lower part of the stem is armed with straight, needle-like prickles, the upper part and the branches mostly unarmed. The leaves become leathery when old. They are ovate, often narrowed about the middle or lobed at the base, seven or nine-nerved and green on both sides, sometimes denticulate on the margin. It is a native of North America and the West Indies.

S. rotundifolia (*S. caduca*, *S. quadrangularis*), Greenbrier.—A high climbing species with large, thin and nearly round leaves. The stems are terete and the branches and young shoots often four-angled. The prickles are stout, scattered and sometimes a little curved. This is a handsome strong-growing species, and I have had fine specimens from Mr. Burbidge, of the Trinity College Botanic Gardens, Dublin. It is a native of N. America.

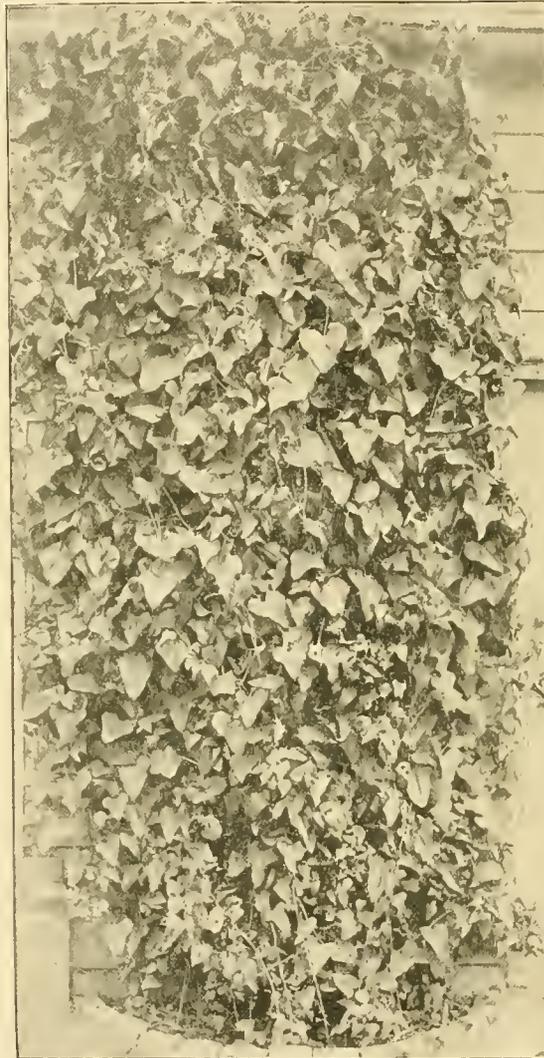

S. tannoides.—Under this name at Kew in the Bamboo garden is a plant of very satisfactory qualities, growing freely and illustrating well how such a plant may be used to ramble over tree stumps and help to make a mass of picturesque vegetation. It has the habit of a free-growing *S. aspera*, and at the time of my visit was bearing numerous black berries. The leaves are very nearly ovate, and to my recollection are without the broadened base common to *S. aspera*. M. Alphonse de Candolle does not allow the name *tannoides* to stand, and I have not been able to satisfy myself that this plant can be either of those to which *S. tannoides* is referred. It might be *tannifolia*, but that species is described as

having an annual stem, which this does not seem likely to possess.

S. Walteri has stems angled, prickly below, the branches usually unarmed. The leaves are ovate or ovate-lanceolate, cordate or sub-cordate. The berries are bright red, but I am not aware that they are produced in this country. It is a native of N. America. R. IRWIN LYNCH.

Cambridge.

Clerodendron trichotomum.—Though this *Clerodendron* may be of no value as a flowering shrub in Scotland as mentioned on p. 367, yet in the southern portion of England, including the London district, it can usually be depended upon to bloom well, and in this stage it is very orna-

Smilax Cantab in the Cambridge Botanic Gardens. From a photograph sent by Mr. R. I. Lynch.

mental. The white flowers which protrude from inflated red calyces after the manner of some of the tender kinds, are disposed in an open panicle, and being at their best in early autumn, form a very attractive feature, as so few shrubs are then in bloom. A hot summer such as the last is particularly favourable to flowering. Before they drop the leaves often become suffused with bronze. The second species alluded to in the same article as *C. Bungei* is perhaps more generally met with under the specific name of *fetidum*. It also flowers around London, particularly after a hot summer, but is at its best at the foot of a south wall or some similar spot. This species is totally distinct from *C. trichotomum*, the stems being only of annual duration, but of a sturdy nature,

and will reach a height of 4 feet to 5 feet. The large heart-shaped leaves are decidedly ornamental, while the bright rosy red blossoms are closely packed together in a terminal head. The flowers are sweetly-scented, its specific name of *fetidum* being derived from the unpleasant odour given off by the foliage if bruised or roughly handled.—T.

FERNS.

FLOWERING FERNS.

ANEMIAS.—It is to the Anemias that the term flowering Ferns is usually applied, but there are others which may be included under the same heading, and though the title may not be strictly correct, the peculiarly distinct manner in which the fertile portion of the fronds is produced certainly gives the appearance of flower-spikes. The Anemias, though not of much use as market plants, should be found in all collections. Most of them may be raised from spores, which, if collected at the right time, germinate freely. When seedlings are plentiful they may be grown several together in a pot or pan. They should not be bunched up together, but put in singly at equal distances apart, say about six plants in an 8-inch pan, or one older plant with fertile fronds in the centre and some younger seedlings round. Compared with most Ferns they are short-lived, or if grown on they lose much of their beauty after they have made some fertile fronds and the basal ones die away. Many Ferns lose much of their beauty after they attain to a certain size. There are none more difficult to keep after the second or third year than the Anemias, which require stove treatment, a rough, open compost, and to be grown in moderately sized pots.

Anemia phyllitidis is the most useful, and this is grown to some extent for market, but only as quite small plants before the fertile fronds appear. The young fronds are of a fresh pea-green, and in the variety *fraxinifolia* the name is very appropriate, as they have much the colour and texture of Ash leaves.

A. ciliata has very woolly fronds. When well grown it is one of the prettiest, but it requires some care to establish good plants.

A. rotundifolia, which was re-introduced by Mr. Bull a few years ago, is one of the most distinct, the drooping pinnate fronds reminding one of *Adiantum lunulatum*. A young plant is produced from the caudate termination. The young fronds have a pretty bronzy brown tint. In the fertile fronds the two lower pinnae grow erect as in other varieties. To grow this well the plants should be stood upon inverted pots or suspended. I have not yet raised seedlings, but it is easily propagated by rooting the young plants which are produced on the fronds.

A. Dregeana is a South African species of dwarf habit with a tufted crown. It makes a compact plant, and may be grown in a lower temperature.

A. villosa is another pretty form with very woolly fronds, and *A. adiantifolia* may be mentioned.

There are upwards of two dozen species besides varieties, but I doubt if there is half this number in cultivation at the present time.

I find in the Kew list of Ferns there are only six given, but they have no doubt added *A. rotundifolia*, which was not in commerce at the time the list was published. In the list from the Cambridge Botanic Garden only one is given—*A. phyllitidis*.

OSMUNDAS.—The most useful variety of these for pot culture is

***O. palustris*.** It finds some favour as a market plant. In a small state it is very pretty, and when well grown makes a well furnished plant for a 4½-inch pot, and as it is fairly hardy and evergreen, it is useful for winter work. The young fronds have a bright bronzy red tint, which is most conspicuous in the stipes. This comes freely from spores, but these should be collected while they appear to be quite green. The true spores are green when ripe, and although the prothallia begin to grow in a few days after they are sown, it is some time before the first frond starts.

O. javanica is another evergreen species, having fronds of great substance. I have never known of a large batch of seedlings being raised of this; the only way I have been able to increase the stock has been by division, but this is a very slow process. I have sown spores on several occasions, but have had little success, a solitary seedling appearing here and there.

O. regalis (the Royal Fern).—This comes freely from spores if they are collected from well-matured plants. I have seen it grown in large batches for market, and in a 3-inch pot it is very pretty—that is, before the first young fronds die off. Being deciduous is somewhat of a drawback. It takes some years to establish the large specimens, such as are seen in their native habitats. This may be grown in any cool shady place either under glass or in the open, but it loves a moist atmosphere, and though it is deciduous, it should never be allowed to get quite dry at the roots.

O. gracilis, as imported from North America, is very pretty. It more nearly resembles *O. palustris*, but has broader fronds and is deciduous. I have never succeeded with spores of this or the other two species, *O. cinnamomea* and *O. Claytoniana*, which come from the same district, though it appears they come freely enough in their native habitats. Like our native Royal Fern, the North American species succeed best in moist, swampy districts, and I believe it is only from plants of advanced age that good spores are procurable. The imported clumps usually retain their vitality, and although the fronds do not go on increasing in size as do those on plants that are well established, there is little risk of losing them when properly cared for.

A. HEMSLEY.

Nephrolepis exaltata is an excellent Fern for dwelling-house work and will stand draughts well.—G. P.

***Alsophila australis*.**—This does not make such a solid stem as the Dicksonia, but is of rapid growth. Seedlings soon grow into large plants. I have never succeeded in raising seedlings from home-saved spores, but imported spores have generally germinated well. With many of the large-growing Ferns it appears to be that it is only from large plants grown in an airy position that good spores are obtainable. This may be grown under the same conditions as the Dicksonia, but requires careful attention in regard to watering. Free-growing plants take up large quantities, and a little neglect will prove disastrous; the fronds shrivel up quickly and cannot be revived, but with care and a liberal supply of manure after they are well rooted they soon make grand plants with large, spreading fronds, and where plenty of room can be given, *Alsophila australis* is one of the most desirable Ferns that can be grown.—A. H.

***Gleichenia circinata*.**—There is hardly a more elegant Fern in cultivation than this when allowed to grow a little naturally, but many people are not satisfied with it in this way, and

prefer to tie it in to balloon or other shaped trellises of wire. Looking round a garden in the neighbourhood recently, I saw a man busily engaged in tying and snipping at a fine plant—"to get it into shape a little," as he expressed it. The least of the harm done by this silly practice is to damage the tender young fronds, while the worst is the spoiling of a very beautiful plant. As a matter of fact, very few Ferns are more easily injured in the young stage than this, and in all cultural details there is need of great care. The rhizomes often push above the surface of the soil, and it is necessary to keep this in a somewhat loose and open condition, so that these may occasionally be pegged down. Where there is room for it, the compost may be added to by top-dressing with a little rough peaty soil, and this answers the same purpose. To support the fronds a few stakes may be placed in each pot—not straight deal ones, but thin branchy bits of Birch or a similar wood. They will be hidden entirely as the plants grow, the older fronds passing through them and preventing the whole plant falling about in an untidy manner.—H. R.

DICKSONIA ANTARCTICA.

This is the most useful of all the Tree Ferns. From young seedlings in 6-inch pots to the giant specimens which are established from imported stems it is always appreciated. One of the finest specimens I ever saw was a home-grown one; though the stem was not a great height, it was very thick. The treatment had a good deal to do with the size of the stem. It had been regularly supplied with a covering of Sphagnum Moss; this not only increased the size of stem by providing material for the roots, but also increased the strength and size of the fronds. Imported stems may be treated in this way with advantage, but the covering should not be too thick. A thin covering of quite fresh Sphagnum from the base of the stem up to the crown is sufficient, and by keeping it moist, but not saturated, the young roots will penetrate and the Moss itself will grow. With the imported stems care should be taken that they are not started in a high temperature, or they will make fronds quickly and exhaust their vitality before they have made new roots sufficient to sustain them. Although the stem should be kept moist, care should be taken not to wet the crown too much until the fronds have made a good start. It takes a long time to establish a stem of any size from home-raised seedlings, but very useful little plants may be had within a year of sowing the spores. The best spores are obtained from the large plants grown in a cool house. If taken at the right time and sown while quite fresh they germinate freely, but I have never succeeded with spores that have been kept for any time. Young plants may be grown on in an intermediate temperature. They should be potted in a compost consisting largely of fibrous peat with some leaf-mould, a little loam, and some sand. Plenty of drainage is essential, and until the plants are well established water should be given sparingly. After the pots are well filled with roots and while the plants are making new fronds clear liquid manure may be used freely. A. H.

Sunlight for Ferns.—I quite agree with the remarks of "C. H." (p. 424) and A. Hemsley (p. 449) on this subject. I have a small intermediate house in which I grow a good many *Adiantums* fairly successfully, and the only shading used is a little whitening rubbed on the glass, and it is only when they are placed quite near the roof that such things as *Adiantum tinctum*, *A. tenerum*, *A. Farleyense*, *Davallia Tyermanni*, *Doodia aspera*, &c., show the lovely red and brown coloration in their young fronds, which is their distinctive charm. When it is desired to use Ferns for dwelling-house decoration I find it a great advantage to let them make their growth in a cool, airy house, such as an unheated vinery, rather than in a close, damp structure. The growth made in the latter is lovely to look

at, but the plant fades the moment it comes into a room, and the same applies to cut fronds. A very large number of *Adiantums*, especially those of the cuneatum and capillus-Veneris sections, make excellent growth in an unheated greenhouse in summer if slightly protected from the full blaze of the sun, as by a Vine on the roof, and, of course, well looked after as to water, but the plants should be put in before they commence to start, otherwise any growth made in the close house will surely be ruined.—G. P.

***Pteris scaberula*.**—Either as a large specimen or a small one in a planted-out fernery or in pots anywhere, this is a delightful species. It always reminds me of the exquisite Killarney Fern, and is, I think, equally precious. The fronds rise from a creeping, wire-like rhizome and are finely cut and very elegant. Unfortunately, it is a difficult Fern to grow, and especially to propagate. It was one of a collection of large exhibition Ferns I had under my charge some years ago, and I tried it in various temperatures, but it was nowhere so satisfactory as in a cold, damp vinery from which frost was just excluded, but which was useless for growing Grapes in. Here *P. scaberula* grew and increased, and the largest plant was in a pan that, judging from memory, must have been at least a yard across, while the rhizomes that grew outside would have made the plant considerably larger. When in full health it must have been well over 4 feet across. Although large plants are useful for exhibition, they are not so pretty as are medium-sized ones in baskets or pans. Propagation, as hinted above, is difficult, and the most likely method to succeed is to wait until the new growths are just starting and endeavour to lift out pieces of the plant with roots and soil attached. For compost it likes something free and open, with plenty of leaf-mould and sharp sand.—H.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 19.

IN extent the meeting of last Tuesday was no doubt the smallest held during the current year. Being so near upon the Christmas season, this is not to be wondered at in the least. What was lacking in quantity was fully atoned for by the exhibits of Orchids, not groups, it is true, but of rarities and new hybrids, which were beyond the average in quality. Two good exhibits of Apples were staged, one by the trade and another from a private source. Several seedling Apples were presented to the fruit committee, one at least of these obtaining an award of merit. The attendance of gardeners was remarkably good, the meeting being in no sense a dull one. As a suggestion is not out of place, the hint is given that at such a meeting collections of berry-bearing plants would have been most appropriate.

Orchid Committee.

First-class certificates were awarded to the following:—

DENDROBIUM SPECTABILE.—This is one of the most distinct and beautiful of the *D. macrophyllum* group. It has been known to botanists for nearly half a century, but it has only been of recent years that plants have been introduced to this country alive. There are now several places in England where plants have been showing bloom for some months; consequently, there has been considerable excitement as to who should be the first to exhibit the plant in flower. This has fallen to the good fortune of Major Joicey, of Sunningdale Park, Berks. The sepals and petals are each about 2 inches long, the sepals half an inch broad at the base, tapering towards the apex. The ground colour internally is buff-yellow, lined and marbled with reddish brown, the petals smaller and much twisted, similar in colour to the sepals. The exterior of both the sepals and petals is pale yellow. The front lobe of the lip is

twisted, white, heavily veined and suffused with deep violet-purple, becoming less coloured towards the base. The winged side lobes are white, closely reticulated with small violet-purple veins. At the base there are three raised white ridges. In the habit of growth it resembles *D. Johnsoniæ* and other members of this section. It is a native of New Guinea and the Solomon Islands, and is a most desirable addition to this section of *Dendrobiums*.

CYPRIPEDIUM LORD ROBERTS (*Charlesworthi* × *Creon*).—This is by far the best of the *C. Charlesworthi* hybrids that have yet appeared. The dorsal sepal is $2\frac{1}{2}$ inches across, white at the top, slightly tinted with rose, becoming suffused with rose-purple and veined with a darker shade of purple towards the base. The highly polished petals are each about 2 inches long, deep purple, suffused with a darker shade of purple on the upper half, where it is also highly polished. The lip is brown, shading to green at the base, the column bright rose. The lower sepal is pale green streaked with purple. From Messrs. J. Charlesworth and Co., Bradford, Yorks.

CYPRIPEDIUM HERA EURYADES VAR. SPLENDENS (*Leocanum* × *Boxalli*).—This is a distinct and beautiful form. The dorsal sepal is $2\frac{1}{2}$ inches across, white, suffused with deep rose-purple through the central area. At the base there is a small area of green with brown spottings. The petals are very broad, deep brown, highly polished and mottled with green; the lip deep brown, shading to pale green. The flowers are quite distinct from those of the variety certificated at the last meeting. From Messrs. J. Veitch and Sons, Royal Exotic Nurseries, King's Road, Chelsea.

Awards of merit were adjudged to the following:—

CYPRIPEDIUM CONCO CALLOSUM.—This has the intermediate characteristics of the species indicated in the name. The dorsal sepal is 2 inches across, delicately suffused with rose, with some yellow and green at the base. The petals are pale green, suffused with rose and thickly covered with minute purple spots. A cut raceme was sent from the collection of Mr. G. W. Law-Schofield, New Hall Hey, Rawtenstall.

ZYGO-COLAX AMESIANA (*Zygopetalum brachypetalum* × *Celax jugosus*).—This is a most distinct and desirable hybrid, having the intermediate characteristics of the parent species. The sepals and petals are green, thickly covered with deep brown spots; the lip white, lined and spotted with deep blue. Two plants came from the nurseries of Messrs. F. Sander and Co., St. Albans.

LÆLIO CATTLEYA WELLSIANA IGNESCENS (*Triabæ* × *purpurata*).—In this the sepals and petals are of fine form and substance, deep rosy lilac, the large lip rich velvety crimson, shading to yellow through the throat. A plant carrying a two-flowered raceme came from the nurseries of Messrs. J. Veitch and Sons.

CATTLEYA ELATOR (*C. Schilleriana* × *C. Mossiæ Reineckiana*).—The sepals and petals are white, faintly tinted with rose, the front lobe of the lip light rose, shading to crimson in the centre, the side lobes rose, shading to yellow, spotted with purple at the base. The plant carried a two-flowered raceme. From Mr. C. L. N. Ingram, Elstead, Godalming.

Mr. W. M. Appleton, Weston-super-Mare, was awarded a silver Banksian medal for a small group consisting of four distinct varieties of *C. insigne*. One of the most curious and interesting was *C. i. Oddity*, with malformed flowers, in which the petals form two extra labellums, giving a remarkably quaint effect. The plant carried five flowers, which have retained their characters for several years. *C. i. Macfarlanei* is a distinct form with a deep brown suffusion on the dorsal sepal. *C. Morteni* (*Chamberlainianum* × *Leocanum Masercelianum*) is a beautiful variety, the dorsal sepal white, suffused with green, and spotted with brown through the central area, the petals green, suffused with purple and spotted with deep brown, the lip rosy purple, highly polished. A

lovely variety of *Lælio-Cattleya intermedio-flava*, bearing two racemes of six flowers each, the sepals and petals bright yellow, the lip purple, shading to creamy yellow, was also included. Major Jeacey sent a finely-flowered plant of *Dendrobium atro-violaceum* and a lovely spike of the white and purple *D. Johnsoniæ*. M. Jules Hye, Lysen, Ghent, sent *Cypripedium* Mme. Jules Hye (*C. Spicerianum* × *C. tonsum*), in which the intermediate characteristics of the species were combined. Mr. J. Gurney Fowler, South Woodford, sent *Cypripedium insigne* Fowlerianum, a variety with a finely spotted dorsal sepal. Mr. Reg. Young, Liverpool, showed a good form of *C. Mines* and numerous other hybrid *Cypripediums*. Mr. J. T. Bennett-Poë, Cheshunt, had a fine cut spike of *Oncidium tigrinum* and a good form of *Lælia anceps*. Messrs. H. Low and Co. sent *Cypripedium* William Lloyd and a *C. venustum* hybrid. Messrs. J. Charlesworth and Co., Heaton, Bradford, sent a grand plant of *Cypripedium insigne* Sanderæ with sixteen growths and six flowers, which were remarkable for size and substance. This is by far the finest specimen of this lovely *Cypripedium* we have seen.

At the commencement of the business of the Orchid committee, Mr. J. O'Brien, in the absence of Mr. H. J. Veitch, drew attention to another sad loss the committee had sustained since the last meeting by the death of Mr. A. Outram. Mr. O'Brien dwelt on the many useful services Mr. Outram had rendered to horticulture both in England and America. The committee desired that their deepest sympathy should be conveyed to the bereaved wife and family.

Floral Committee.

No award was made to any novelty before this committee, while the exhibits may be described as among the smallest ever seen at the Drill Hall. The only group of plants shown was composed entirely of *Chrysanthemums* from Messrs. W. Wells and Co., Earlswood, Redhill. This was largely made up of a good late dwarf white named *Letrier*, the plants being in pots and barely 4 feet high. That the variety possesses the merit of lateness there is no doubt, but *Niveum* is also a good white and may be had in fairly passable condition into January. Mention of *Niveum*, indeed, almost suggests the parentage of *Letrier*, which appears intermediate between it and *L. Canning*. *Letrier*, however, has the blooms well filled to the centre, is of good bushy habit, and in some isolated plants we noted many blooms of which hardly a petal was unfolded. Besides this there were cut specimens of *Golden Good Gracious*, *Mermaid*, white, an Australian kind; *Cheveux d'Or*, of the thread or spidery section; *Sunset*, a fine gold and red-orange shade; a beautiful yellow sport of *Princess Victoria*, of which a solitary bloom was shown; Mrs. J. Thompson, a good white; Dr. Basse, a distinct shade of violet-amaranth, and withal violet scented. Other kinds noted were *Alice Carter*, King of Plumes, *Bouquetiere*, white and rose, and *Sam Caswell*, pink, these last belonging to the so-called spidery section. Some good flowers of Mrs. C. Bown, a capital white, were also shown, making a really pleasing and telling lot for so late a date. All the cut flowers were quite fresh. A silver Banksian medal was awarded. From Messrs. Clibran & Sons, Altrincham, Cheshire, came three or four varieties of single *Chrysanthemums*, including *Lord Methuen*, white; *Lord Roberts*, bronze, almost a single form of *Tuxedo*; *Earlswood Beauty*, white; and *Miss Moffatt*, white. It was not possible to form any correct idea of these, as their beauty and freshness had long since passed. Messrs. Veitch and Sons, Ltd., Chelsea, had a stand of their well-known hybrid *Rhododendrons*, of which *Rose Perfection*; *Princess Alexandra*, white; *Cloth of Gold*, a deep shade of canary-yellow, exquisitely soft and pleasing, and large, handsome blossoms; *Exquisite*, rich golden, a most superb variety, surpassing all else in this way; *Amabile*, flesh; *Maiden's Blush*; the intensely coloured Malayan kind

Little Beauty, and *Balsaminiflorum aurcum*, a double form, being among the most striking. It speaks volumes for the perpetual flowering character of these plants that the Messrs. Veitch are in a position to show them so frequently and in such numbers. The Earl of Ancaster, Normanton, near Stamford (gardener, Mr. J. Butler), exhibited some capital growths of *Lygodium scandens*, the longest being upwards of 16 feet in length. These excellent examples, while in a marked degree displaying the true character of the species, were also noteworthy for the abundance of fertile fronds, fertility being greatest in the uppermost part of growth. Very interesting, too, was the way in which these fertile fronds graduated till the quite barren and much less beautiful fronds were reached on the lower half of the growth. These entire growths are deemed of especial value in decoration. A large flowering spray several feet in length of *Acacia dealbata* was also shown, and may safely be regarded as among the showiest of this somewhat numerous race of greenhouse shrubs.

Fruit Committee.

On this occasion the exhibits before this body, limited as they were, really exceeded those before the other committees, but were chiefly of Apples and a fine collection of Grapes.

An award of merit was given to—

APPLE STANWAY SEEDLING.—A handsome medium-sized conical fruit not unlike *Royal Jubilee* or a good *Golden Spire*. It was shown by Mr. F. H. Kettle, King's Road, Colchester.

A fine collection of sixteen bunches of Grapes came from Mr. C. Bayer, Forest Hill (gardener, Mr. Taylor), including *Muscat of Alexandria*, very good samples; Mrs. Pearson, a large 6-lb. cluster, but showing the brown tinge characteristic of the variety; and two nice clusters of *Trebbiano*. The black varieties were: *Alicante*, well-finished clusters; *Gros Colman*, very fine berries; Mrs. Pince's *Black Muscat*, *Gros Guillaume*, and *Lady Downe's*, the last three in bunches of moderate dimensions, but good for the time of year (silver-gilt Knightian medal). The Earl of Ancaster, Normanton, Stamford (gardener, Mr. J. Butler), staged a collection of sixty dishes of Apples and twenty of Potatoes in variety, the samples in each case being of moderate quality. His finest Apples were *Peasgood's Nonsuch*, *Prince Albert*, *Mère de Ménage*, *Lord Derby*, *Beauty of Kent*, *The Queen*, *Alfriston*, *Warner's King*, *Newton Wonder*, *Bismarck*, *Barnack Beauty*, *Cox's Orange Pippin*, *Wyken Pippin*, *Stirling Castle*, *Blenheim Pippin*, *New Hawthornden*, *Ecklinville Seedling*, &c. The Potatoes comprised several seedlings, also *Sutton's Ideal*, *Ninety-fold*, *Triumph*, *Satisfaction* and *Windsor Castle*, with *White and Pink Beauty of Hebron*, *Syen House Prolific*, *The Bruce*, *British Queen* and others (silver Banksian medal). From Messrs. J. Cheal and Sons, Crawley, Sussex, came a nice clean collection of eighty dishes of Apples, none large, but all in good preservation. The finest samples were *Newton Wonder*, very handsome; *Gloria Mundi*, *Annie Elizabeth*, *Prince Albert*, *Waltham Abbey Seedling*, *Bismarck*, *Lord Derby*, *Chelmsford Wonder*, *Golden Noble*, *Lerinka*, semi-conical, of rich appearance; *Schoolmaster* and *Beauty of Kent*. *Gospatrie*, *Kruger*, *Bess Peel*, *Castle Major*, *Hormeard's Pearmain*, *Mabbot's Pearmain*, *Hoary Morning*, *Duke of Devonshire*, *Golden Reinette*, *Paroquet*, one of Mr. C. Ross's new ones; *Fearn's Pippin*, *Dutch Mignonne*, *Seaton House*, *Winter Queening*, *Cox's Orange Pippin* and *Mannington Pearmain* were excellent (silver-gilt Banksian). Mr. W. E. Parsons, Egham, Surrey, sent *Apple Brothier*, not unlike *Manks Codlin* in form and flesh. *Lord Ducie*, *Tortworth Court*, again sent fine rich-coloured fruits of the Japanese *Diospyros Kaki*, some of which were, if very pulpy, yet pleasantly flavoured. Mr. C. Ross, gardener to Captain Carstairs, Welford Park, Newbury, sent seedling Apples *Miss Annie*, from *Golden Reinette* × *Lane's Prince Albert*, slightly conical and of nice

appearance; *Elsie*, from Peasgood's Nonsuch x Duke of Devonshire, pretty round form; and *Berks Russet*, small, round, highly coloured, not unlike *Ross Nonpareil*, but flesh firmer and better flavoured. The last, a nice, promising fruit, was asked to be seen again next year after another season's growth. Mr. Ross also showed a fine richly coloured sample of the old Northern Greening, in this instance far superior to the new Northern Greening.

National Auricula and Primula Society (Southern Section).—The annual general meeting of the above society took place on Wednesday, December 13, in the Horticultural Club Room, Hotel Windsor, Victoria Street. The statement of the hon. sec. disclosed a very satisfactory state of affairs, sixteen new members having joined during the year, as against the loss by death and otherwise of six. The amount received in subscriptions during the year was £75 7s. 6d., and the amount paid in prize money at the late exhibition held in conjunction with the Royal Horticultural Society at the Drill Hall, Westminster, in April last £56 17s. The balance carried forward to the year 1900 is £20 18s. 9d. It was decided to hold the exhibition for 1900 on Tuesday, April 24, at the Drill Hall, Westminster, under the auspices of the Royal Horticultural Society, a very liberal list of prizes being offered for show Auriculas, alpine Auriculas, Primulas, Polyanthus, and Primroses. The hon. sec. is Mr. T. E. Henwood, 16, Hamilton Road, Reading.

National Carnation and Picotee Society (Southern Section).—The annual general meeting of the above society took place on Wednesday, December 13, in the Horticultural Club Room, Hotel Windsor, Victoria Street, the president of the society (Mr. Martin R. Smith) and a large muster of members being present. The hon. sec. and treasurer reported a very satisfactory state of affairs. Forty-five new members have joined the society during the year, a number considerably in excess of those lost to the society by death and otherwise. Subscriptions received during the year amounted to £301 3s. 6d.; prize money paid at the late exhibition of the society, held at the Crystal Palace in July last, £228 0s. 6d., in addition to three silver cups presented by the president. A balance of £229 11s. 10d. was carried forward to the year 1900. The society now numbers nearly 400 members. It was decided to hold the annual exhibition for 1900 at the Crystal Palace in July next. Several new classes were added to the schedule, and it was also decided to offer a silver cup to the exhibitor gaining most points in the undressed classes as a further encouragement to the amateur members. The sum now offered in prize money amounts to close upon £300, and a silver cup in addition to the three silver cups presented by the president. It was also decided to publish in the forthcoming report a list of flowers that can be shown as yellow ground Picotees and another list for yellow ground fancies, much doubt having hitherto been felt as to which class some of the varieties should be shown in. A packet of choice Carnation seed is sent to all subscribers of 10s. per annum and upwards. This seed is saved from the unique collection of the president, and generously presented by him to the society. The hon. sec. of the society is Mr. T. E. Henwood, 16, Hamilton Road, Reading.

National Chrysanthemum Society.—A meeting of the committee was held at Carr's Restaurant, Strand, W.C., on Monday evening last. In the absence of the chairman, Mr. Thomas Bevan, vice-chairman, presided. After the minutes had been read and confirmed, the secretary referred to the loss sustained by the committee in the death of their colleague, Mr. Alfred Outram. On the motion of Mr. J. Moorman, seconded by Mr. Newell, the secretary was requested to write a letter expressing the committee's deepest sympathy and condolence with Mrs. Outram and family. The secretary announced that at the annual dinner, held on the 14th inst., 112 sat

down. Fruits and flowers sent by friends were duly acknowledged. Mr. A. Taylor's epitome of blooms exhibited at the November show was then read as follows: Blooms, Japanese, 2241; incurved, 618; Anemone flowered, 240; Anemone pompons, 48; pompons, 84; reflexed, 36; and singles, 42, making a grand total of 3309 blooms. In the case of pompons and singles, a bunch of three blooms was counted as one bloom. A vote of thanks to the compiler of these figures was passed. Mr. W. H. Lees wrote wishing to resign his position on the committee at the close of the year. The dinner account after some discussion was passed for payment. The amendments to rules affecting affiliated societies, passed at a recent meeting of the committee, were then read. These will be presented for confirmation at the annual general meeting. The meeting of the classification committee was then fixed for Wednesday, January 3, at 6 o'clock. Mr. Sturrock was elected to fill the vacancy on the schedule committee, caused by the death of Mr. Outram, this committee arranging to commence their labours at the conclusion of the classification committee meeting on the 3rd prox. Reference was made to the reserve fund, which had been but slightly increased during the past year. Three new members were elected.

NOTES OF THE WEEK.

Chrysanthemum Winter White.—This is the name of a very good and dwarf white for December work, a fact that was amply illustrated by some nice bushes of it at the recent Aquarium show. It is evidently a good variety for bush plants, and those requiring a dwarf plant of not more than 3 feet—the plants shown were under this—should make a note of this one.

Rhododendron Princess Royal.—Among the newer hybrids of which javanicum and jasminoides are the original parents this forms a pleasing variety in the pink shades at least. Not only is it useful as a winter-flowering kind, but being also somewhat free-flowering maintains a more or less constant supply of its valuable trusses of bloom through the autumn and winter season. A capital companion to it, though of different tone of colouring, is *Rose Perfection*.

Plumbago capensis alba.—Pleasing as is the blue form of the above popular plant, the above is very chaste and beautiful also. Given more or less freedom for branching and a not too great a root run, this white form may frequently be had in fair quantity over a long season, and when it is desired to carry its flowering on into the winter months, a variety of plants in pots will often meet the wants of the case. Warm greenhouse treatment suits it best, and if only a few trusses are forthcoming, these will be welcome and of much value.

Euphorbia fulgens (*E. jacquiniiflora*).—Few of the more tropical-flowering plants of midwinter are more serviceable than this, and very few so attractive. The large handsome sprays are, perhaps, most conspicuous when the plants have been allowed to develop long arching racemes of its floral bracts, that surpass in brilliancy any other of its genus or, indeed, any other of the many winter-flowering plants. The flowers also last well when grown moderately cool. It is a good plan to plant four or six rooted cuttings of equal strength in a 6-inch pot and grow without stopping. In this way long racemes are secured and an effect not readily surpassed.

Chrysanthemum Mme. C. Desgranges.—It is curious as well as interesting to note the various ways in which the above is rendered in different catalogues of the flower, and more than once it has occurred to me that while there is undoubtedly a right and proper rendering of the name, this at least should and would carry away if once an authoritative statement of the correct way was given. At times it is seen in its full array thus, *Mme. Castex Desgranges*, another rendering is *Mme. des Grange*, while another slight variation is *Mme. C. Desgrange*. There may be other variations, but these occur to me at the moment.—E. J.

* In the National Society's catalogue it is given as *Mme. Castex Desgranges*.—Eo.

Salvia splendens grandiflora.—Those only who know this handsome Sage as a dazzling summer-flowering subject should lose no time in

growing it also for winter flowering. It simply requires a little later stopping and retarding generally to secure a good display through late autumn and often to the end of the year. Indeed, late propagated plants of the original form may quite easily be kept thus late, and with the huge gap that is rendered necessary by the clearing out of the *Chrysanthemums*, such plants as may be kept over become doubly useful. In the dull days of winter the rich scarlet flowers are most telling.

Agave Woodrowi.—It is seldom that any species or form of the *Agave* presents any particularly striking features in its leafage. This kind, however, is not only an exception, but a remarkable one, presenting features that are bound to attract attention. The most striking characteristic of this kind is the milk-white variegation which is so prominent and so well sustained in the plant. Usually when this sort of variegation occurs in any plant it is marked by weakness or a more or less sickly nature. In the above plant, however, there is no apparent sign of any inherent weakness, and the plant is therefore of value. A nice example of this well-marked form is in the large succulent house at Kew.

Senecio macroglossus.—Innumerable as are the species of *Groundsel*, those of climbing habit are certainly in the minority, and the above is at least one, if not a unique one. It is, too, a capital winter-flowering greenhouse plant that requires but little special treatment beyond a fairly free root-run and plenty of moisture at the root during active growth. This freedom of root space is needful for the free growth of the plant, without which its flower-heads will be few and far between. The ray florets are of a distinct buff yellow shade, more yellow than buff certainly, yet of a combined character that is not readily asserted. When growth is free, the glossy, Ivy-looking character of the foliage renders it most distinct and pleasing. It is a native of South Africa.

Chrysanthemum Princess Victoria (yellow variety).—While seedlings of the *Chrysanthemum* naturally produce some of the most beautiful and useful flowers, it frequently happens that to their sportive character also are we indebted for many things equally valuable. The above sport is an instance in point, the original kind being dwarf, free, and late in flowering, and, though not of exhibition size, is undoubtedly of more value by reason of its decorative character only. What is true of the white kind, now so well known, will be equally so of its yellow sport, of which we have so far seen but a solitary bloom. The shade of yellow is a deep one, and its value is thereby enhanced, as the paler shades of yellow deteriorate under artificial light to such an extent that it is not always possible to distinguish pale yellow shades from poor whites or the more creamy shades.

Bouvardia odorata alba.—This beautiful and useful winter flower is all that is implied in its specific and varietal name, and is certainly one of the most charming of all *Bouvardias* for pots. The blossoms, as indeed the foliage also, are allied to the *Jasmine*-flowered type of these plants. It is a bushy and free-habited kind, the blossoms pure white on the one surface, the reverse of a pinkish hue and nearly 2 inches long. These shorter-tubed varieties are less likely to fall over and almost break in the banding, as is often the case with the *Humboldt* varieties, though perhaps less so in the case of *B. H. grandiflora*, the latest addition to these plants. For freedom of flowering, the above and *Parity*, a perfectly white flower of the *odorata* type, are worth every attention. Very rarely are these *Bouvardias* grown to perfection in small lots, and once insects secure the upper hand, the stake hole fire is at once the shortest and safest all-round cure.

Helleborus altifolius (giant Christmas Rose).—Though naturally a rather early kind to flower, frequently in mid-November or somewhat later, this handsome kind is even now in excellent condition. Many of its blossoms are exceptionally fine, and on their fine bold stems are both beautiful, handsome, and picturesque at this usually

gloomy season of the year. Of the value of the plant there is little doubt, and scarcely two opinions of its merit as a garden flower or a garden ornament exist. But it is worth noting, and it is worth repeating with even greater emphasis, that it should be regarded in the light of a garden plant, that its flowers should be valued from the garden standpoint, and not ruthlessly cut and forgotten the moment the blossoms are expanded. Above all things, avoid cutting and trimming its foliage; rather suffer a dead-looking leaf to remain than cut it away, and with it so many inches of good stem that quickly dies to the crown and often carries disease thither.

The conference mania.—The note in last week's issue of THE GARDEN respecting the proposed conference on Sweet Peas for the purpose of classifying the varieties into groups of colour and form is most opportune, and should have the effect of exposing the absurd notion that such a conference is necessary. Regarding the form of Sweet Pea flowers, surely there is little variation in the many sorts to call for the adjudication by a body of admirers and growers, and anyone interested in the flower may find all the variation in colour he may need by confining his selection to a few varieties. Such a conference is quite unnecessary. If it is considered necessary, then by all means let the Royal Horticultural Society take the matter in hand, and also let them have a thoroughly representative trial of catalogued varieties. This would have the effect—and, after all, the only good effect—of bringing into prominence the large number of synonymous sorts.—A GROWER.

* * A trial has already been made by the Royal Horticultural Society of the then known forms of Sweet Peas.—Ed.

Abelia uniflora.—Bushes of this pretty plant when freely grown are among the more acceptable things that may be well flowered in comparatively cool structures. In the cool conservatory, for example, where frequent opportunity is afforded for planting out in good soil, the above is not only a neat, but a most desirable subject, and when in flower, when a faint rose tint is added to the white that predominates in the prettily formed flowers—and a good bush is laden with a profusion of the same—the effect is pleasing. Happily, too, it is one of those beautiful ornaments of the greenhouse that may well escape the never-ending demands of the cut-flower merchant, and in this way all its pleasing beauty and profusion of flowering may long be enjoyed. The plant is not difficult to cultivate, and in equal parts of peat and loam, with sand added, is usually a success. It is worth noting, however, that planting out is far better for its ultimate success than retaining it in a pot, the small amount of soil soon becoming exhausted in such. The plant is quickly sensible of the loss, and shabby plants not infrequently result.

Mr. Harpur-Crewe's double Wallflower.—While the blooming of Wallflowers in autumn and winter is a frequent occurrence, the habit of this double variety to do so seems more pronounced than that of most others. This is no mean advantage, as flowers in the open are by no means so plentiful at the end of November and the beginning (or for that matter the end) of December that we can afford to neglect the few that bloom. Thus I do not think that a reference to the Rev. Harpur-Crewe's double Wallflower will be either unwelcome or unseasonable. Those who do not know it must not picture a plant with the habit of the German double Wallflowers, whose crowded spikes of bloom give quite a different appearance. The one under notice is more perennial in its habit, is taller than they, and has shorter spikes of round, ball shaped yellow flowers. It never seeds and must be propagated from cuttings. These are easily obtained from the side growths, which are produced with comparative freedom. Annual propagation is not necessary, although it ought to be practised so that a reserve may be at hand in case of a hard winter carrying off the old plants. I

should be glad to know from anyone how this Wallflower came to be called "Mr. Harpur-Crewe's." I believe that it has been in cultivation for a very long time.—S. ARNOTT.

Colchicum Sibthorpi.—Established clumps of this are still flowering freely here, and have been doing so for six weeks or more. Some of the deeply coloured forms are very fine. The freest-flowering, and I am almost tempted to say the handsomest of them all, is *C. Bisignani*. Each bulb was a perfect bouquet, the colour soft and lovely. What will probably be a drawback, except in very mild localities, is its habit of sending up its leaves immediately after flowering. They are nearly fully developed now, and if hard weather should ensue, are likely to be injured. The most distinct in flower now is *C. Ritschi*, a shapely pure white flower just held up above the partly-developed deep green leaves, which form a sort of cup below them. *C. bulbocoides* is now a mass of deep rosy blossoms amongst the leaves, the whole only about 3 inches high. A most elegant species is *C. polyphyllum*, with fair sized soft blush-pink flowers, the segments of which are narrow and strap-like, and curl about in the most charming way. It has been in flower for several weeks and is still quite fresh. *Crocus vitellinus* forms just now bright patches of a fiery orange-yellow.—T. SMITH, *Neury*.

Sedum brevifolium var. Pottsi.—From a note kindly sent me by Mr. E. C. Buxton, I fear that I may have led some readers to think that I intended to recommend the use of *Sedum brevifolium* var. *Pottsi* as a carpeting plant. I must admit that a perusal of my note might easily give that impression, although I merely intended to imply that it was the reference in THE GARDEN to the other *Sedums* which recalled this *Stonecrop* to my mind. I hasten, therefore, to make it clear that it was not meant to suggest that it was a suitable plant for carpeting. While one regrets some obscurity of language in writing of this pretty little *Stonecrop*, the regret is not mingled with an opposite feeling, inasmuch as it has drawn from Mr. Buxton some valuable information regarding the needs of a somewhat difficult subject. In his garden it likes to rest entirely on rocks. On one which is very hot and dry in summer it grows very dwarf and in small tufts. On the face of another rock where there are some deep natural fissures it grows 2 inches high, but pieces which fall to the ground and root do little or no good. Mr. Buxton is always so willing to assist others who care for flowers, that I know he will allow me to give others the information he has so kindly sent me. *Sedum brevifolium* *Pottsi* has so long been a favourite with me, that I feel grateful for any hints which will enable it to be grown where it has not done well in the past.—S. ARNOTT.

THE WEATHER IN WILTS.

THE season, indeed the whole year, has been a most remarkable one in many respects, but, speaking more especially of the autumn, this has been most favourable from a gardener's point of view in its relation to outdoor work, mild weather and the attendant wealth of outdoor flowers both in and out of season. I was able to gather very nice fresh Rosebuds until the first week in December, which is most unusual. Chrysanthemums, too, outdoors have been abundant and very good, so much so that growers for the market found them of much less value than is usually the case. Until quite recently Dahlias and Sweet Peas were frequently mentioned, and in my own case they flowered later than I remember them before. Other flowers, too, have been continuous and late, and some, although not necessary or useful because of other seasonable flowers being plentiful, are interesting. In the fruit garden the pruning, nailing, and cleaning of bush fruits have proceeded without much hindrance, and the advantage of pressing forward this class of work is distinctly felt when the change to colder weather sets in. It was unnecessary to

place pot-grown Strawberries under cover until the first week in December; the mildness of the season and freedom from drenching rains were sufficient justification for their remaining outdoors. Neither Rhubarb nor Seakale forced well in their early batches for the same reason, and Asparagus recently lifted for forcing displayed signs of unusual activity in the crowns for the time of year. Some shoots had extended to over an inch where the crowns were situated near the surface, and which, it may be said, for the middle of December is of most unusual occurrence. Cauliflowers and early kinds of Broccoli have been plentiful and very good, as also were full-hearted Lettuce and Eodive from the open ground.

This wealth of unseasonable vegetation now suffers a reverse, frost varying in intensity up to 20°, accompanied by snow, having been lately recorded. The past mildness makes this severe touch of winter keenly felt in every department, and a continuance will make tender vegetables and salad outdoors scarce; those not of tender nature are rendered so by their continuous late growth. In many gardens the summer's drought accounts for a short supply for the present and future requirements of some crops in particular, and to such the severity of the weather change will be most inopportune. The summer, from a vegetable grower's point of view, was one of the worst for many years; seed-sowing and planting were most difficult, more particularly where water was short, and thus the winter's supply is restricted and rendered more so by the present weather.

Wills.

W. S.

The weather in west Herts.—The present cold period has now (20th) lasted thirteen days. On three days the temperature in shade at no time rose above the freezing point, and on five consecutive nights the thermometer exposed on the surface of the snow indicated from 15° to 27° of frost. The reading last mentioned, which was registered on the night preceding the 14th, is the lowest with one exception (December 22, 1890) that I have yet recorded here in December during the fourteen years over which my observations at Berkhamsted extend. At 2 feet deep the ground is now about 2° and at 1 foot deep about 3° colder than is seasonable. On the 13th the ground was covered with snow to the average depth of 1½ inches. This covering gradually diminished, until by the 18th it had been reduced to half an inch, and on the following day almost entirely disappeared. On nine of the last fifteen days no sunshine at all was recorded. The 18th was singularly calm, the mean rate of movement of the atmosphere at 30 feet above the ground being considerably less than a mile an hour. The last Rose bloom of the year was destroyed by frost on the 14th, which is five days later than the average date of its destruction in the previous fourteen years, but seventeen days earlier than last year.—E. M., *Berkhamsted*.

Public commons and footpaths.—A meeting of the executive committee of the Commons and Footpaths Preservation Society was held at 1, Great College Street, Westminster, on Friday, Mr. G. J. Shaw Lefevre presiding. The preliminary report of the secretary, Mr. Lawrence W. Chubb, on the provisions of private Bills to be introduced into Parliament in the coming session showed that power is sought in thirty-five Bills to appropriate common land and open spaces, or to extinguish rights of way. Over 3000 acres of open space will be extinguished in the coming session unless satisfactory terms for the protection of public interests are obtained. On the other hand, no fewer than thirteen local authorities are seeking power to enable the purchase or improvement of open spaces to be effected.

IT is with much regret that I now bid good-bye to the readers and contributors of "The Garden," which with the new year passes into other hands. Ever since its first year the paper has had the sympathy and support of garden lovers blest with fullest opportunities of practising the art; and not even the fierce competition of the cheaper press has lessened their number. From what I know of those who are to have the care of its columns in the days to come, its readers will have good reason to give it the same support as they have given during the many happy and busy years it has been in my hands. The new directors are able and willing to do full justice to "The Garden," and to give more time and thought to the business work of the paper than the growing needs of the "English Flower Garden" and other cares have of late allowed me to do.

The first volume of "The Garden" was dedicated to the memory of a man, J. C. Loudon, who left us a precious possession of books worthy of the art. The 56th volume is dedicated to that of Henry de Vilmorin, one lately among us in the prime of life, and his great loss calls to mind that of many others who have written in its pages or in some way aided and encouraged it: Robert Marnock, J. C. Niven, James Veitch, James McNab, Noel Humphreys, Anthony Waterer, Stuart Low, Frank Miles, David Moore, James Backhouse,

J. F. Meston, Richard Gilbert, the Rev. H. T. Ellacombe, J. McHutcheon, and T. W. Girdlestone.

To these and to many more of the long-lived race of good gardeners who are still alive—among them being Miss Jekyll and Mr. E. T. Cook, who will now edit the paper—I owe a deep debt of gratitude.

December 29, 1899.

ORCHARD AND FRUIT GARDEN.

BUSH APPLE TREES.

I do not think any fruit trees grown in private gardens are more profitable than what are usually termed bush trees. These can be grown in many gardens where space could not be given standards. There are great advantages in growing bush trees, and with these one may include some kinds grown as pyramids if these are grown with a clear stem, as some kinds, notably some of the russets, have a decided tendency to this mode of growth. On the other hand there are some gross growers, and these, even with bush culture, need special culture. By this I mean occasional lifting to check gross growth. With bush trees this mode of culture will generally give good results, as it is an easy matter to check gross growth at this season, and by so doing ensure a full crop next year. Bush trees, even when grown in orchards, are very profitable, as the trees fruit more quickly than standards. I am aware some kinds are not so good grown thus. For instance, I do not advise the Blenheim Orange, which with me is too gross, and much better results are obtained from standards; at least, this is my opinion. There are a few others, such as Belle Dubois, Twenty Ounce, and Bramley's Seedling, which may be placed in the same category.

But so many succeed under bush culture that there is no difficulty whatever in having a splendid collection of trees, and, what is so important to the cultivator, grown thus the trees fruit so quickly and fail so rarely that there can be no doubt as to this being one of the most profitable modes of growing them. To get the best results the trees need feeding. In

many gardens I have noticed the soil is cropped quite close to the stem of the trees. This is not wise. Care is needed in pruning certain kinds, while others crop so freely that very little pruning is needed. Alfriston is one of the best grown as a standard, and we have few better varieties grown in bush form. Like most of the free-fruited kinds this bears a very heavy crop one season and a light one the next, but rarely fails altogether. This I attribute to its late blooming, as the flowers often escape where others are injured. On the other hand, Alfriston is not always reliable. When I lived in the north and had a much heavier soil to deal with, it was not nearly so reliable, and, though a strong grower, in badly drained soils I have seen it canker badly. This variety I grow in quantity, having a row of bush trees on the eastern side of the garden. These, planted from ten to fifteen years ago, give wonderful crops of fruit, and I note, like other strong-growing kinds, their free-cropping is their salvation, as it prevents severe pruning. Bismarck is equally free-bearing, and is not so strong a grower. This comparatively new Apple has now been sufficiently long in this country to test its merits, and it thrives grandly in our light soil. The fruit is handsome, solid, and large. I recently saw this in standard form doing well. It appears to thrive in most soils and situations. This variety was introduced into this country from New Zealand, and is certainly valuable, as my trees fruited freely when only two years old. I prefer it grown as a bush on account of the heavy fruit, which also colours more freely.

There is a great gain in growing some of the best dessert and cooking Apples in bush form, as should any variety fail, it is an easy matter to replace it with one more reliable. Some of our best Apples canker badly when they attain age, but grown in bush form on the Paradise there is less disease. Take Cox's Orange grown in bush form, what splendid quality fruits are secured from bush trees, this variety doing well under this mode of culture, as the fruits can be left on the trees later and a much longer season secured. I am aware it does well as a standard, but with bush trees much finer fruits are obtained and the trees rarely fail to crop. Much the same remarks apply to Ribston; indeed, there is more need to grow this in bush form as on the Paradise stock there is freedom from canker which is

so fatal to standard trees. Sturmer Pippin thrives as a bush, and if the fruits are not gathered too early it is the best late Apple we have, and its Ribston flavour makes it valuable. What a pretty bush Pine Golden Pippin makes and the same remarks apply to the newer St. Edmund, a delicious Apple that does grandly under bush culture. This last is well worth planting, as it is one of the best Russets we have. Such kinds as Rosemary Russet, the Egremont Russet and Claygate Pearmain are all at home grown thus, and the trees give a good return for space occupied.

Of new kinds, Jas. Grieve promises well and is a first-rate bearer in bush form and of good quality. Allington, also a new Apple, is excellent in bush form, and the flavour of well-finished fruits is little inferior to that of Cox's Orange, which it somewhat resembles. Though full early to write about Charles Ross, the new Apple of the year, the raiser informed me it would make a splendid bush. It is a great acquisition and very handsome, though I cannot say I like the way in which it is sent out, paying half this year for a tree to be sent twelve months hence. For orchards, trees on a short leg or stem are preferable, as the lower branches clear the soil. The fruits are readily gathered, and, what is so important, those kinds that are very free fruiters may be thinned and the trees given food, as if on grass it is well to feed, removing if necessary the turf for that purpose.

G. WYTHES.

Apple Margil.—"H." (p. 472) says that this Apple is liable to canker, but I never found it so, though it may, of course, have this characteristic in had or unprepared soils. I fancy the neighbourhood of Bury St. Edmunds suits it, for I always got excellent samples of it while at Livermere, and these were generally bigger than any others which used to be shown at the Crystal Palace shows; but, owing to the best tree being heavily shaded by and close to some large Oaks, I could never get the colour up sufficiently so early in the year, though it came up well later. As regards flavour it is equal to Cox's Orange, but not quite so juicy. Its season is later than that of either Ribston or Cox's Orange, being at its best during the first two or three months of the year, and a few trees of it ought certainly to be grown to form a succession to these more popular varieties.—J. C. TALLACK.

Trees purchased at markets.—In many towns it is getting more and more the custom to employ some third-rate auctioneer to sell off surplus rubbish from fruit nurseries. Varieties quite useless for the kind of tree, badly worked and worse trained, without a bit of packing of any kind round the roots, which are dried up and shrivelled, are purchased at prices very little below what good trees are offered at by nurserymen. Such a custom is bound sooner or later to die a natural death, as few people care to spend money time after time and be disappointed continuously. But love of a so-called bargain constantly tempts fresh customers, and I have sometimes seen gardeners, who of all men ought to know better, attending these sales. It is a great pity, for the trouble does not end with the bad trees. Wherever an Apple or a Pear has a local popularity anything is labelled to suit. Dr. Harvey is one of the most popular of Apples in Norfolk and Suffolk among cottagers and shopkeepers, and I have noticed how often this name turns up in these sales.—H. R.

Apple Cornish Gilliflower.—All who have ever eaten good fruit of this seldom-seen Apple will agree with the estimate of "A. W." as to its being the equal of Cox's Orange or Ribston Pippin in flavour; indeed, I look on it as being the best-flavoured Apple I ever tasted. Certainly it never becomes really mellow, as do these, with age, but it is not everyone who likes a soft Apple, a little resistance to the teeth being considered

an additional recommendation by some people, and these will certainly set a high value on the Gilliflower. I never expect to see it very popular away from the southern and other favoured counties, my experience being that to get it in perfection it, like Calville Blanc, requires a wall or some particularly favoured spot, and, as pointed out by "A. W.," it requires pruning with great care and leaving in a more rugged condition than most Apple trees in order to preserve the fruit-buds which form on the young wood. In a young state it is a very vigorous grower and not free-fruiting, but if allowed to grow and extend itself freely it becomes a fairly free cropper and one of the surest, as it very rarely misses. In Cornwall it used to be highly esteemed for the winter dessert, and kept in good condition well into the spring months. I see that a writer lately classed it among the "small and unattractive" varieties. Small it certainly is not when well grown, and though it is not to be compared with the showy varieties for external beauty, its unattractiveness is only skin deep and does not appeal to the consumer who knows what is before him.—J. C. T.

Stewing Pears.—The recent granting of awards of merit to two varieties of stewing Pears will probably cause some surprise, as no doubt many persons think that there were enough of these hard fruits in cultivation already. But whilst awards of merit may be taken as simply commendatory, and not in the same light as a first-class certificate, yet the two referred to, Notcutt's Winter Orange and the very little-known Double de Guerre, if such be its correct name, shown by Mr. Frank Lloyd, of Shirley, Croydon, in whose garden two trees of the variety fruit most abundantly, are both very free croppers, and if the fruits are not of the huge size seen in Catillac or Uvedale's St. Germain, yet they are large enough for all ordinary purposes, and being so freely produced are relatively more meritorious. The flesh of the latter variety when cut is certainly whiter, softer and less free from grit than is that of the other, but both are excellent additions to the list of stewing Pears. It is too commonly the case that whilst so many dessert Pears are grown in gardens, resulting where there are good crops in great waste, because so many decay before they can be used, relatively few stewing Pears are grown. Certainly it is not too much to expect that at least six of these varieties should be found in any garden, if not more, and that the fruits be held over till after November, in which month good dessert Pears are few, as when properly stewed these otherwise hard, flavourless fruits not only develop wonderful flavour, but are singularly pleasant and delicious. Up to a certain period hard green fruits of any fair-sized variety may be stewed, thus saving the real cooks until later in the winter. We ought to be able to purchase stewing Pears cheaply in the market all the winter. That is not so. The two varieties above-named should be very largely planted, and in time that winter scarcity may be overcome.—A. D.

Pearmain Apples.—I was greatly interested in the article on Pearmain Apples published last week, as it brought to notice some of that section which are valuable though not often seen. Take, for instance, Blue Pearmain. There can be no doubt that this is little known, though it deserves to be in every garden or orchard, and I would strongly recommend its culture. Then, again, Mabbot's Pearmain is not much grown, though it is a most lovely Apple and of good quality. This Apple has one peculiarity that upsets the generally-received idea as to colouring, *i.e.*, that it develops its colour off as well as on the tree, and colours as well in the dark as in the light. For instance, the fruits of perhaps the loveliest dish of this ever exhibited, and which was shown at the Crystal Palace two years ago, were picked green and each fruit wrapped in paper until within a day or two of the show, when they were found to be of the loveliest colour imaginable. Lamb Abbey Pearmain I found to be quite the best dessert Apple for April and May, and I also

found it a first-rate cropper, though the fruits are rather on the small side, but worth all the attention they can get in the way of cool storage for late work. In the Veitch flavour competitions this was preferred to Sturmer Pippin, of which good dishes were exhibited against it. Crimson Queen "A. W." does not include in his list, but while at Livermere I found this one of the most reliable Apples I grew, always cropping heavily on trees of medium size and the fruit handsome, good alike for dessert or cooking, and lasting over quite a long season. I would include this without hesitation in a very exclusive list of valuable Apples to grow. Of Baxter's Pearmain I have not so good an opinion, and fancy it may well be allowed to die out. Hubbard's Pearmain, too, though a good Apple, did not pay for its room, the blossoms being, I fancy, rather tender. Anyhow, it never cropped freely, though mostly well set with buds, and the tree is liable to canker. Christmas Pearmain is a first-rate Apple, and "A. W." would do well to add it to those he already grows, as it is a certain cropper and makes a very good tree.—J. C. TALLACK.

STRAWBERRIES FOR EARLY FORCING.

IN those gardens where the best of conveniences exist for fruit forcing, the earliest batch of Strawberries will have been got under cover some time, but in places where the earliest dishes are looked for from about the end of February to the middle of March, the present is a good time to commence. A well built brick pit in which a good lasting hotbed of leaves can be made up and with a single hot-water pipe round it is a very useful aid to Strawberry forcing. Supposing such an one to be at command, the leaves may be got in and firmly trodden a week previous to starting the Strawberries. For early work strong single crowned plants should be selected, and after cleaning the pots and removing any decayed or broken leaves, each plant should either be dipped in or syringed with some good insecticide. Many of the proprietary articles are excellent, and a good home-made one may be prepared by rubbing up a quarter of a pound each of soft soap and sulphur and adding about a quart of boiling water, agitating it violently and stirring in a wineglassful of paraffin; gradually add another gallon of boiling water and let the mixture settle down. If any oil rises to the surface, skim it off and add one gallon of water to a pint of the mixture for use. A stronger mixture may be used if the plants appear dirty, as it is less likely to do harm now than later.

Having all clean, the pots must be plunged up to the rims in the leaves, and if very cold weather ensues a little warmth may be turned on, sufficient to maintain a night temperature of 45° and a day temperature of 50° to 60°, according to the weather. A good supply of air must be left on night and day. Damp the leaves slightly when the weather is fine, and do not allow the soil in the pots to become dry, though at this early stage the roots will not require much moisture. It will be easily apparent when the latter have become really active; the young growing and feeding points will appear on the surface, and the plants will be found to require more water. Then feeding with liquid manure twice a week may be commenced, and a light top-dressing of soil with a little of a good chemical manure, such as superphosphate, mixed with it should be laid on and watered home. The crowns by now will be showing the divisions that eventually make the flower-buds, and when these can be distinctly seen the plants may go to the house in which they are to fruit; that is, unless there are separate compartments for fertilising and fruit ripening and for the periods of growth and

swelling. This is an excellent plan, and the trouble involved in shifting a lot of plants, though considerable, is in a manner repaid by the extra chance given of a look through them for insects, mildew, and other troubles.

It is quite possible by a little manipulation of the atmosphere to arrange for the plants to begin and finish in the one house. When a fair number are in flower the atmosphere should be kept buoyant and rather drier than usual by admitting more air and giving a little more fire-heat. When the fruits on the majority are swelling the conditions may be rather more exciting, while ripening fruit is always improved in colour and flavour by the admission of plenty of fresh air. From five to seven fruits are ample for each plant in these early batches to carry if they are to be the best of their kind. The feeding with liquid manure should cease directly the fruit begins to colour, and a few bits of forked sticks to raise the fruit from the rims of the pots are advisable.

For the early batches the useful old La Grosse Sucrée is still an excellent variety, Royal Sovereign and Sir Joseph Paxton making a trio hard to beat. The last may be strongly recommended where more tender varieties fail.

ASPECT FOR PEACHES.

WILL Peach trees do on an east or west wall, and which is the better?—C. F. F.

* * The question asked requires consideration as to locality. Soils also would cause trees to fail on one aspect which would do well on another. I would not advise east or west walls in the northern parts of the country, as the best results would be secured on a south wall. But there can be no doubt whatever that your trees would do best on a west wall, as on an east wall, owing to cold winds in the spring, Peach trees blister badly. Only in very exceptional cases would I advise planting on an east wall, these being in the most favourable soils and localities. It may interest "C. F. F." to know that there are cases of successful Peach culture on north walls. The advantages of a north wall are that by planting second early kinds, such as Goshawk, Stirling Castle, Violette Hâtive, Grosse Mignonne, Crimson Galande and Dymond, the season is greatly extended, as the above varieties are mostly of superior quality to the very late kinds, such as Gladstone, Golden Eagle and others, and one gets equally late fruit as well as quality. The bloom is also retarded, and when others on more favourable aspects are destroyed, these escape. Last summer and the previous one were hot and dry in the south; indeed, so hot that Peach trees suffered on both south and west aspects. In such a season trees on an east or north wall would be at home. I prefer the north, as the hot sun so warmed the wall through from the south that the warmth on the north from this was retained, the trees thrived well when those on the south were roasted, as it were, and the afternoon sun on the south side was ample to mature the fruits. It is a question of soil and locality, and in some instances variety also, as it would not do to plant any kind on an east or north wall. What would be a success in the south and west of the country would probably be a failure in the north. I much prefer a west wall to an east, and, though I grow a goodly number of trees on the south, these are for the earliest supplies to follow the forced fruits. Such kinds as Waterloo, Early Alexander, Amsden June, and Hale's Early are often ready by the third week in July, but they lack the quality of the midseason kinds. You did not give any particulars as to varieties you wish for on a west wall. Any of those named above would not fail, and you may with advantage add to their number. Bellegarde is excellent, as also is Barriogton, whilst for later supplies on the same aspect

you would find the Nectarine Peach, Sea Eagle, and Princess of Wales the most reliable, especially the Nectarine Peach and Sea Eagle; indeed, after a trial of most kinds I do not know of better kinds than the last named. On such an aspect by growing the best varieties you may have fruit from the end of July to the end of September, and even later if desired.—W.

Pears keeping badly.—I quite agree with what "J. B. S." says (p. 471) as to Pears keeping badly, and I feel sure that it was the protracted drought that was the cause of it. Although my crop of Pears was fairly heavy, they were so much affected by prolonged heat and drought that they could neither attain their ordinary dimensions nor would they keep sound until the ordinary season of ripening. I find a dull, dripping season with an abundant rainfall necessary to swell off a good crop of Pears. This year no one could tell by a month when any variety would be fit for table. That hard stewing Pear Catillac is rotting as badly as any of the soft dessert kinds, and I can attribute it to nothing else but lack of moisture at the roots.—J. GROOM, Gosport.

Pear Glou Morceau.—This variety, like Chaumontel and many others, is greatly influenced by the way it is treated, and is good or bad according as the culture is suitable or the reverse. In the south and south eastern counties it is often grown as a bush, but in the north it requires the protection of a wall to bring out its good points. It is rather remarkable that in so many gardens in the south one may see early kinds, such as Williams' Bon Chrétien, Souvenir du Congrès, and even Jargonelle, freely planted against warm walls where the fruit and wood ripen really too quickly, and the former to be of good quality must be gathered and finished off in a cool fruit room. It would be far better to grow these on espaliers or even bushes, except say one tree for very early supplies, and to utilise the valuable wall space with those kinds that ripen later, and consequently need the September sun. Glou Morceau at its best is a very juicy and refreshing Pear of good flavour, but unless well ripened, it is not good enough for a first-class dessert. The habit of the tree when given this treatment is all that could be desired, vigorous, yet fruitful, and it should be included in all collections of choice winter Pears.

Grapes Gros Colman and Gros Maroc.—Several correspondents have been comparing these two varieties, but in spite of a certain outside resemblance they are so totally different, that no comparison can be really drawn between them. Your Elstree correspondent notes the fact that he saw the two growing side by side in the same house, and that Gros Maroc was superior. This is no argument against Gros Colman, as the two Grapes require different treatment. In the first place, Gros Maroc, started at the same time as and grown with Gros Colman, would be at its best considerably before it, while to say that the latter was poorer in colour simply shows that it had been improperly cultivated, over-cropped, or was not finished. Gros Maroc is, I will admit, a much easier Grape to grow than Gros Colman, but it is certainly not of better quality. The appearance of properly finished Gros Colman leaves nothing to be desired, and to many people the distinct flavour of this Grape is an advantage, only the fruit must be ripe. It needs a long season and good culture from first to last, while Gros Maroc with its great spreading growths and comparatively small bunches finishes easier and more quickly. Both are useful in their place, but they cannot be compared.—H. R.

Unnailing Peach trees.—The practice of unnailing Peach and Nectarine trees occupying walls, say, in December or January used perhaps to be practised more in bygone years than at present, and I think it has much to recommend it. Some years ago a good old Peach grower living in Suffolk used regularly to practise it with a view to retarding the buds, and so deferring pruning till as late in spring as possible. Cer-

tainly the regular crops of fine Peaches he grew warranted the practice. All gardeners know, or at least those who have had experience with Peaches on open walls, what excitable subjects the trees are, and, strange though it might appear, the more immature the wood is the sooner the trees start in mild, genial springs. Probably this is partly accounted for by the fact that most Peach trees are worked on Plum stocks of some sort, and these are never quite dormant even in midwinter, young quill-like roots being often discovered when trees are lifted for replanting under glass at that date. Of course, the principal object in unnailing the trees is to bring all the shoots away from the bricks, which sometimes become quite warm from the sun's rays even in January and cause the buds to expand. With old trees it is not a very easy task, but it can generally be accomplished by driving a sufficient number of tall, very stout stakes into the alley or pathway facing the trees, and afterwards bunching the branches carefully and fastening them with tar twine, using bandages where there is any fear of undue pressure on the bark.—GROWER.

PEARS RIPENING PREMATURELY.

I CAN sympathise with Mr. Prinsep (p. 461) in the loss he has sustained by such a wholesale premature ripening of his stock of even the latest varieties of Pears. A fortnight or even three weeks is not so much to be wondered at, but for such good keeping sorts as Beurré Diel and Passe Colmar to be ready for use in October is most unusual. Still, in Mr. Prinsep's case the fruit seems to have ripened, whereas in the case of a lot of Beurré Diel owned by a friend of mine the fruit did not mature, but actually decayed in October, and the trees from which they were gathered are always well attended to as regards mulching and watering, so that lack of root moisture was not the cause. I have come to the conclusion that a hot, dry summer is not, as some suppose, the best for finishing off Pears and Apples to perfection. There must be a certain amount of natural atmospheric moisture to develop the juice as well as to impart the finest colour. This is proved by fruit from wall trees well soaked with liquid manure over copious mulchings and liberally hosed as well lacking both these qualities. The variety Jean de Witte, mentioned by Mr. Prinsep, I have never grown, and very seldom do we see it mentioned. Ne Plus Meuris is mentioned, and the superiority of climate is, I think, at once proved by this anything but generally satisfactory variety ripening well at Buxted. I could never induce this Pear to ripen fit for dessert in the midlands, even in the sunniest summers. The tree, a horizontal one, occupying a west wall, bore almost annually extra fine crops of normal sized fruit, but although I always allowed them to remain on the tree as late as possible, they never softened or developed juice. I was advised to put some fruit into a close box and place in a warm Mushroom house, a process which really does assist some varieties to finish, but it made no impression on Ne Plus Meuris, and in the end the tree was grafted with another sort. I imagine it is generally capricious, being so very seldom mentioned either in fruit crop reports or ordinary notes. It may be said that such may be put to a good use for stewing and the tree be made to pay. That may be, but my experience is that as a rule they are not to be compared with the true stewing varieties. I am glad to see Beurré d'Arenberg named in the list. This Pear has been much more frequently spoken of the last two or three years. I consider it ought to be included in all collections, however limited, as although perhaps not quite so rich as Winter Nelis, it is an excellent

substitute where the latter does not succeed and possesses a grand constitution. It succeeds equally as well as an espalier as a wall tree. As a pyramid I have never tried it. Frequently the tree crops so heavily that if thinning is not practised early and liberally, growth suffers in consequence. No amateur's garden should be without at least one tree of *Beurré d'Arenberg*.

J. CRAWFORD.

Apple Gascoigne's Scarlet.—At p. 462 "H." has a short note on the above Apple. There can, I think, be no doubt as to its shyness in cropping, at any rate in a young state, or we should more frequently hear of it. It is some years since it was sent out, and yet how very seldom one meets with it even at large shows. I have heard that it is grown for market in some parts of Kent, where no doubt the soil and climate suit it. "H." rightly remarks, *Gascoigne's* is not suitable for restricted growth. This I have myself proved, having some ten years ago planted it as an espalier and never had a single fruit on the tree, which was healthy and not even rank in growth, as I attended to root-pruning and other cultural details generally considered necessary in order to induce shy sorts to fruit.—B. S. N.

Pear Beurre Bosc.—I was pleased to see this Pear favourably noticed by "East Anglian" (p. 462). Growing on a south aspect, two young trees here produce regular crops, and though the quality may not equal that of *Winter Nelis* or *Dojenné du Comice*, its handsome russet skin, distinct shape and large size make up for any deficiency. It is an October and November Pear, keeps fairly well after it is ripe, and though its season clashes with that of others, it deserves a place in the most select collection. In quality it is much superior to *Durondeau*, at least it is so in these gardens, and though similar in its shape and colour, the latter is not deserving of the same attention. No doubt the largest fruits come from trees on walls, and possibly of higher quality, too; still, *Beurre Bosc* deserves the attention of those who may not have grown it. It is good for exhibition, and, as "East Anglian" says, it should be a good kind for the market. In the west of England it is not, so far as I have seen, much grown for market.—W. S., *Rood Ashton*.

Grape White Tokay.—I have often heard this Grape described as a coarse one, but I think this condition generally arises from the Vine being grown in too little heat. If grown in an ordinary cool vinery and started late in the season the berries never assume anything but a greenish white tint, and the flesh is decidedly coarse. When favoured with a Muscat house temperature and ripened by the first week in September, *White Tokay* is a Grape of no mean order. It will hang in a plump condition long after the Muscats in the majority of gardens have shrivelled. The Vine has a very vigorous constitution, and crops best when growing in a poor compost the reverse of rich. A shallow border composed of medium loam, with a large percentage of mortar rubble and charred wood, produces a hard lateral growth, which matures early and thoroughly, and is the only remedy against barren laterals, so common in the above-named varieties when grown in deep, rich borders and too liberally fed with manure water. Some time ago I saw some very nice bunches hanging on Vines in a garden in the eastern counties. Speaking of late white Grapes, how often is that, to my mind, most useful one, *Trebbiano*, seen in a semi-green state in autumn? whereas when given the warmth and light it needs it takes on a handsome deep amber shade and is very refreshing in February and March.—J. C.

Apple Cox's Orange.—I saw last September the tree of this beautiful Apple from which the branch was cut, the illustration of which was so admirably presented at p. 462. The entire tree, a fine round-headed standard, was fruited all over just as is seen on the branch, and pre-

sented, apart from the great usefulness of the crop, quite a pleasing picture. I fear we too little regard Apple trees from this point of view. Certainly *Cox's Orange Pippin* is not one of the richest coloured of varieties, but when the fruits are for the variety fairly well coloured they are very pleasing. I have seen on bush trees in gardens fruits both larger and more fully coloured than were Mr. Crook's, but none that I have tasted had better flavour. I usually find with this good dessert Apple that great size and high colour seem to have been gained somewhat at the expense of flavour. It has been essentially a *Cox's Orange Pippin* year, and the result of such splendid crops as I saw literally everywhere should be to boom the variety in a remarkable degree. Certainly we have no other Apple in commerce that is at all equal to it for table excellence, and the high flavour which so much characterises it is largely due to its yellowish flesh. But having it, what wonder if after the past season's experience everyone fond of Apples should prefer to plant *Cox's* largely. It seems to have thriven equally well in very diverse soils and conditions. At *Forde Abbey* on a fairly stiff loam, at *Chilworth Manor, Romsey*, on stone-brash, at *Dropmore* on a deep and fairly retentive soil, at *Chiswick* on the porous gravel of *Middlesex*, and apparently everywhere the trees have done well, suffered very little from disease or insects, and fruited alike abundantly. If fewer of the inferior dessert varieties that are so much pushed and far more of *Cox's* were planted, our fruit supply for table would be greatly improved.—A. D.

FIGS IN POTS.

THE finest collection of Figs grown in pots it has been my privilege to see is at the Royal Horticultural Society's *Chiswick* gardens, where presumably every sort worthy of cultivation is represented. I could not help being struck with the remarkable freedom with which the majority were fruiting in the summer, even in quite small pots, especially when it is remembered the length of time they have occupied them. Bone-meal is a great favourite as a fertiliser both for Figs and other fruits, Tomatoes and Grapes in particular, and the freedom with which the roots spread over the surface speaks volumes for it as a fruit tree manure. The collection is so extensive, that it would be utterly impossible to make mental notes of a tithe of them, and time at my disposal did not even permit me to get them otherwise. Their inspection would be an object-lesson to any fruit grower who is interested in Figs. The house seems excellently suited to Fig culture, being span-roofed, well ventilated, wide and lofty.

At *Gunnersbury House*, Mr. Hudson, too, grows a considerable number in pots, though, of course, in this case a smaller number of sorts suffices. It is Mr. Hudson's rule to produce only the earliest batches of ripe fruit and others for late autumn and early winter, midseason supplies not being required. My visit being an autumn one, I found that *Negro Largo* was much in evidence, and in pots, mostly of small size, it fruited freely. Here, too, span-roofed houses, light in structure and well ventilated, were filled with Figs. For later and successional use *Nebian* seemed very free, and *d'Agan* promised to carry on a supply until late in the winter, its fruits being small and hard when *Negro Largo* was ripening freely. Restriction in soil space and high feeding with suitable fertilisers gave splendid results.

There is no doubt that from intelligent cultivation a much longer and regular season of fruiting can be obtained from trees in pots than from those planted out, and as a rule not more than one house is devoted to Figs, except in the largest gardens. Of course, such fine fruit cannot be expected as permanent trees give, but for purposes other than exhibition these smaller fruits are quite as good. There is, too, a greater control over the season when they may be obtainable either from retarding or forcing. It must not be denied that Figs need close and continuous

attention to watering, but if this is compared with the time expended on the suppression of leaf and lateral growth as well as at the root, a very good balance may be made in favour of pots. In too many cases one sees Figs relegated to the back wall of a Peach house, where they simply take their chance, and this feeling is often fostered when ripe fruit is only appreciated by one, or it may be two members of a family.

From pot trees it is easily possible to obtain two crops during the season. It would be scarcely fair to expect more, though it is possible with some sorts to do so, given the treatment necessary. Thus grown, the stopping and training are reduced to a minimum, and a greater certainty of good results follows the pinching of the current season's growth in the production of a secondary fruit crop. Some kinds are prone to cast their early formed fruits prematurely, but to the smaller grower this is not a serious matter, for there are reliable kinds to be obtained that are free from this failing. W. S.

Wills.

Grape Lady Hutt.—Unless of exceptional merit, new Grapes are slow in making headway in the smaller gardens. Where planting is being carried out in large vineries it is not difficult to introduce new kinds. There is no other means that will popularise Grapes so much as the show board. If a new sort possess a distinctness in combination with the other attributes of a good Grape and is brought to the front as a prize-winner, it soon finds its way into private and market gardens. *Lady Hutt*, generally speaking, has not yet supplanted *Foster's Seedling* and *Buckland Sweetwater* as a summer or autumn Grape, and its slowness to be put under trial will give these the monopoly for some time yet. It never will, of course, compete with the *Muscat of Alexandria* in popularity. Neither Mrs. Pearson nor *Golden Queen* have ever become what might be termed favourites. They do well in a few instances and fail in many, and it is just this that makes the progress of other new ones slow. At *Gunnersbury* in September I saw this Grape in bearing, and must say it was a different fruit from what I had expected. Mr. Hudson, however, speaks well of it both as to quality and keeping. It had been inarched on to a *Muscat* stock. As I had both planted and inarched young rods myself on to older ones, I was interested in Mr. Hudson's Vine and his opinion of it. In the shape of the berry, *Lady Hutt* resembles *Buckland Sweetwater*, but its skin is thicker; hence less transparent and better adapted for late autumn use. Its colour is pale as I saw it, but, as this is so much influenced by the soil, structure, and treatment given, it would be impossible for one to obtain its general character from one case alone. I was tempted into planting not from actual experience, but by advice from a very good gardener who had it established, and who described it as a decidedly useful Grape.—W. S.

NOTES AND QUESTIONS.—FRUIT.

Pear Zephirin Gregoire.—An excellent late Pear. Its season is during December and January. This variety will not succeed on the Quince, but on the Pear stock it grows well and makes a fine bush or pyramid and then bears abundantly. It is rather small and roundish in form, but its deficiency in size is made up in its delicious flavour. It has a greenish-yellow skin covered with russet dots and patches, and the flesh is yellow, buttery and very juicy.

Pear Bergamote d'Esperen.—A good and well-known late Pear of excellent flavour. The tree succeeds and bears well grown either as a bush or cordon on the Quince, the fruit from the latter invariably being the larger. The fruits should never be gathered till late, or they will shrivel. It is from medium to large in size, with a thick greenish-yellow skin, mottled with dark brown russet. The flesh is white, juicy, sweet and richly flavoured. Is in use from December to March according to the character of the season during growth.—A. W.

STOVE AND GREENHOUSE.

THE ORANGERY.

THERE is still many an old English pleasure ground graced by a good orangery, and where it happens to be well placed the effect is often good, though the use has to some extent passed. The spread of greenhouses and bedding-out led to the disuse of the orangery in our country, perhaps, more than in any other. In other European countries, however, it remains much longer in use, and the orangeries built many years ago near the great cities of Europe, such as Vienna, Berlin, and Paris, are still in use. One could hardly see a better instance of what is called a survival than at Sans Souci. The cost of the orangery there must have been immense, and still every year the poor, scarecrow trees are dragged out, black sticks with a few leaves on top of them, without the least trace of the form of the Orange tree as it grows in the south, now within a day or two's journey

The orangery at Holme Lacy. Engraved for THE GARDEN from a photograph by Miss Pilkington.

from most parts of Europe. We illustrate this week the orangeries at Kew and Holme Lacy, where there are some of the best forms of that structure, which is still useful in a large garden as the winter home of Myrtles, Verbenas, Oleanders, Pomegranates, large African Lilies, and many other plants. The more the beauty and fulness of our hardy plant flora are seen, the less need there will be for this structure, the more so as the natural plant has always a beauty of habit which we rarely find in anything grown in a tub. The true use of the tub is not to grow for us things we can grow in the open air, but rather plants too tender for our climate in winter, as, for example, the sweet Verbena in many districts and the Myrtle, also the African Lily, which survives in the south of England and Ireland, but is, however, soon stricken if we leave it out in the midlands, the northern parts of our country or in any district away from the sea.

EUCCHARIS AMAZONICA.

I CAN assure "H. R." that I carefully read THE GARDEN week by week; indeed, I have but very rarely missed it since the year 1872, and I was fully aware of his former note in the issue of September 30 on the above. It was not a question of market garden or private garden procedure at all, nor the way the so-called floral decorator uses the flowers of the Eucharis that I took exception to. It was the emphatic advice of "H. R." to so treat the Eucharis that it would only flower from July to September, the interval of all in the year when such things are of least value. Thus it was I suggested "H. R." had a special object in view, and therefore a special demand for the Eucharis at that time. I mentioned that market growers avoided if possible that same interval as a coincidence. At this very time there are hosts of beautiful flowers invaluable for cutting if need be. There is nothing new or remarkable in the Eucharis flowering from July to September; it is seen in market gardens every year, the plants blooming with the greatest freedom, and this in quite cold and freely ventilated houses. It is the ones that usually flower from January to March that do this. But when "H. R." refers to this late summer flowering as though all else was an imposition, he is not merely taking a derogatory

temperature of about 60° at night, and for some months this year had no fire-heat whatever. Indeed, the hundreds of spikes now appearing must have been formed in embryo under the very natural conditions of the past tropical summer. This I regard as a complete refutation of the notion that the more natural flowering is but once a year. The above have been thus grown and flowered twice at least each year during the last ten years, and instead of a weak, debilitated stock it is now more than fourfold the original, and may now be doubled if space permitted. Growing the Eucharis in the greenhouse may prove an interesting experiment, and I think the owners of private gardens require something more than leaves for at least nine months of the year. E. J.

Potting Lilies.—Fashions in plants and flowers change, but not always for the better. I remember thirty years ago what grand pots of *Lilium lancifolium rubrum* and *album* might be seen in private gardens, having been grown more especially for placing in front halls and windows of the mansion. Though various other subjects have come to the front since then, I know of nothing to equal the above for autumn use. These beautiful Lilies will not submit to rough-and-ready treatment when in pots. Good drainage, an open, rich compost consisting of fibrous loam three parts, peat one part, some leaf-mould and coarse sand or grit, will grow them well. Plenty of pot room and thorough drainage are also important. Wintering the bulbs safely is the great point. When left carelessly about in the open unplunged and uncovered, frost and wet are sure to work mischief. They should be repotted directly the stems die down, and not left till spring if possible. Potting completed, a frame, pit, or perfectly cool glass house, or even shed, will form suitable quarters for the winter. Plunge the pots in leaf-mould or ashes, and cover them with several inches of, if possible, the former, as it is light and not so apt to cripple the new growth in spring as ashes. In spring give frame protection. Given unremitting attention to watering with pure water at first, and later on weak farmyard liquid, any trouble taken will be amply rewarded.—F. S. W.

Euphorbia jacquiniæflora.—This plant well repays for careful attention, the long racemes of bright orange-scarlet being so distinct from anything else at the same period. When grown singly it rarely makes a well-furnished pot plant, but a few plants grouped together have a fine effect. With care the roots need not be disturbed, and so arranged they are useful for grouping with other plants. When grown for cutting, planting out may be recommended. Good drainage should be given and a rough, open compost used. I find they do best if planted in a bed where there is a little bottom-heat. An important point in connection with the culture is to take care of the stock plants. After they have done flowering, those required for cuttings should be kept in the stove, giving them a light position. When the bloom is cut about Christmas-time, they generally flower again from the first side shoots, and later on they start into new growth. The best cuttings are those taken when the new growths are about 3 inches long. These may be put in singly into small pots. They require watching, as damping is sometimes troublesome. They should be put into the warmest part of the propagating pit and kept quite close until they are rooted. After they have made a good start they may be stopped, but only the points should be taken off. If taken off too low they are liable to die off. A compost of equal parts of loam, leaf-mould, and peat, with sand added, may be used for potting. The roots are very tender, and great care should be taken not to break the balls. The roots are also liable to die off if watering is not regularly attended to; either extreme is equally damaging. I have seen it grown in a cool house during the summer or in a pit, but the best plants I have had have been grown entirely in the stove. Those grown under cool

view generally, but is minimising the value of one of the finest typical bulbous plants ever introduced to this country. It most certainly is a tropical plant, a term I employ in preference to the indefinite term stove plant. For a stove is what the gardener makes it, and it is here, too, that boundless bottom-heat to roast the roots on the one hand is often found, as also the excessive water supply that such heat renders necessary, that quickly leaves its mark behind. "H. R." is out of touch with the facts when he suggests that market growers "keep their plants over bottom-heat and drive them for all they are worth all the year round." Instead of bottom-heat the largest percentage is grown on open wooden stages, the pipes being a few inches from the ground floor.

Again, as showing what an erroneous view "H. R." has taken, I may say that, instead of weak and debilitated spikes, the spikes of fully grown bulbs will be nearly 2½ feet long, each the thickness of a man's index finger at its base, and carrying an average of six blooms per scape, that measure 4 inches across and often considerably more. Within a stone's throw some hundreds of bulbs are throwing up from a batch that flowered in July last. These are in the comfortable

treatment generally lose their foliage when removed to a higher temperature, which is necessary to open the bloom.—H.

WATERING POT PLANTS.

To keep plants in a healthy condition watering must be carefully attended to at all seasons of the year, and during the winter, when it is necessary to give artificial heat, it requires additional care. Many plants will take even more water than during the summer. This, of course, applies to those grown indoors where shading is used in summer and little or no fire-heat given. I find at this season of the year many subjects are liable to get dry beneath while the surface may appear moist, particularly where plants stand on stages where the heat is beneath, and when once they get very dry at the bottom the best way is to dip the pots, so that the soil may be thoroughly moistened through. With some soils it seems almost impossible to get the water to pass through from the surface when once it gets very dry. Plants such as Heaths, Azaleas, &c., that are potted firmly in peat are difficult to wet through, except by dipping, if they once get very dry. Of course, they ought not to be allowed to get so dry, but it will sometimes happen.

Many Ferns are very deceiving with regard to taking up water. A Farleyense, if in a healthy condition, will take up a quantity of water, and if not carefully looked after it will suffer before it is noticed, for it is the under fronds which go first. I have previously referred to the necessity of giving careful attention to this Fern, and it cannot be too often repeated, for I believe inattention to watering is the chief cause of failure. Excess of moisture is equally damaging, and with plants that are in an unhealthy state it is better to keep them a little on the dry side than otherwise, but with vigorous, healthy plants there will be little fear of over-watering under ordinary treatment.

Palms and other subjects where the syringe is used freely will not be so liable to get too dry, but even these plants may be found quite dry beneath when the surface is moist, and those standing nearest the pipes sometimes do not get so much water from the syringing as those where they do not dry so quickly. Palms, like Ferns, often get over-watered, especially when standing on a moist bottom, but in the winter where much heat is given they may require more water than during the summer.

During the winter months it is one of the most important points in plant culture to keep the roots in a healthy condition, and this can only be done by careful attention to watering. Over-watering will sour the soil, while the other extreme will cripple the roots. It is therefore necessary to give careful attention to watering, and this will ensure the plants being in a condition which will cause vigorous and healthy growth when the season comes round for making a start. Much time is often lost in the spring through plants having been neglected during the winter.—A. HEMSLEY.

— There is, I think, nothing so trying to anyone in charge of a garden as the teaching of young men and boys how to water plants in pots. There is always the idea that so much watering has to be done every day, and this in winter, especially when the weather is dull or wet, is the forerunner of mischief. Time after time when dealing with young beginners I have made them leave the plants entirely alone for several days and then shown them the result, but in most cases the lesson is soon forgotten, and one may

see them giving a plant a spoonful or two of water when it was already far too wet. There are exceptions, of course, but by a great deal the majority of pot plants in winter is over-watered. Some there are that it seems almost impossible to harm in this respect, but with such plants as the various kinds of Pelargoniums the tale is only too plainly told in the yellow-looking points and leaves, and a general indisposition to grow or flower satisfactorily as the case may be. Carnations, again, have been killed in thousands by over-watering during November and the three following months. It would be far better in many cases with the latter plants to give orders that they are not to be watered at all during this period, and I am sure they would come through the ordeal far better than when given over to the tender mercies of the average garden assistant.

Specific directions as to watering that will suit every case cannot, of course, be given. To say nothing of the likes or dislikes of various plants and different methods of potting, there are always the texture and class of soil to be considered. A man who is used to his soil and knows well the plant he is growing can look through the ball, so to speak, and by a quick method of observation and rapid judgment forms his idea as to whether the plant needs water then and there or will wait another day. Several things influence his decision—the length of time the plant has been potted; whether the pot is full of roots or

oes through with a rush to the floor, but it percolates steadily and surely through every inch of the compost, and when the operator sees it trickling out of the holes at the sides and bottom he may take it that that plant has had sufficient to go on with for a time. A good test is the time-honoured one of tapping with the knuckles and noting the sound before watering, and should a doubt then exist, the weight of the pot is the safest test.—H. R.

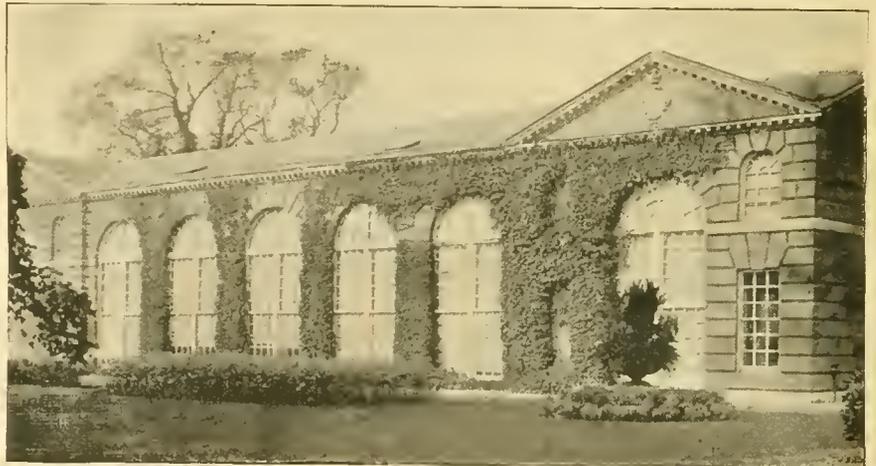

GARDEN FLORA.

PLATE 1255.

DOUBLE-FLOWERED PEACHES.

(WITH A COLOURED PLATE OF PRUNUS PERSICA MAGNIFICA.*)

THE double-flowered Peaches are very old inhabitants of our gardens, having been noticed by Guy de la Brosse in 1636. There are numerous varieties—white, rose, red and deep red—but confusion exists as to their origin, synonyms, and date of introduction. However, they were hardly known until a double rose-coloured variety was figured in the "Flore des Serres" under the name of Pecher d'Isphan, in 1831, vol. x., t. 1. Paxton, in his

An old orangery in Kew Gardens. From a photograph by Geo. Champion.

not; the plant itself; is it a thirsty subject or the reverse? The man who is to do his work expeditiously and correctly has to quickly consider these and other points as he pauses between each plant. All growers of plants know my meaning who have had years of experience in this branch of gardening. Eye and hand have to be trained to work together, and the mind must be quickly made up. A single mistake is not fatal by any means, and to water a plant a day too soon or leave it a day too long is not going to do it any serious injury. It is when these mistakes are being constantly made; when the plant is being watered in dribbles day after day until its roots are sickened and die that trouble ensues. If a plant is dry enough to need water at all it needs a thorough soaking that will last a day, a week, or a month, according to the state of the weather, the temperature, and the condition of the plant itself as to growth or rest.

Supplying water to large specimen plants in pots and tubs requires a deal of care. Here, again, the silly plan of dribbles daily is often practised, and a worse does not exist. Plants properly potted of such kinds as Azaleas, Camellias, and various hard-wooded stove and greenhouse species will not pass the water so freely that it

"Flower Garden," mentions *Amygdalus flore semi-pleno*, also Lemaire, in the "Jardin Fleuriste," t. 238, with a plate. In the Journal of the Royal Horticultural Society, 1848, vol. iii., part iv., pp. 246 and 313, it is stated that the *Amygdalus persica sanguinea flore-pleno* (double crimson) was introduced from China by Fortune. Jacques, in the Journal de la Société d'Horticulture de Paris, April 5, 1849, says that the trees come true from seed—a fact which can be ascertained by leading nurserymen. A strange fact is that these double or semi-double flowered plants produce fruits which, if they have not the fine quality of our cultivated Peaches, are not at all unpleasant to eat. The annexed plate was drawn from a fine tree now growing in the Jardin des Plantes, Paris, under the name of *Pecher de chine à fleurs double rouge vif* (double bright red-flowered Chinese Peach tree), but no record whatever can be found of its origin or introduction in the annals of this establishment.

* Drawn for THE GARDEN in the Jardin des Plantes, Paris, by Mme. Lejeune. Lithographed and printed by J. L. Goffart.

PRUNUS PERSICA MAGNIFICA

The tree is a standard twenty to thirty years old or more, 10 feet to 12 feet high, and thickly covered every spring in March with a profusion of its deep red splendid flowers, producing a beautiful effect. Such a beautiful tree ought to be not only more widely grown, but found in every garden, being perfectly hardy and growing in almost any soil and situation. This original tree was imported from China with numerous other double-flowered Peach trees, amongst them being one producing constantly every year double pure white and double pink flowers on almost every branch.

Referring to nurserymen's catalogues, we find *Amygdalus persica alba plena* (double white), *A. p. flore roseo plena* (double rose), *A. p. magnifica* (semi-double bright red), but none of the above varieties can approach or be compared with the splendid variety represented in the annexed plate as regards the profusion and bright colouring of the flowers. The plate represents exactly the colouring, shape, size, and disposition of the flowers on the tree.—*D. GUIHENEUF, 20, Rue Albouy, Paris.*

— Among the trees that flower before the middle of April, the Almond and the Peach, with their varieties, are some of the most notable. They possess all the tender beauty which is so characteristic of the great *Prunus* section of the Rose family. The Peach as a flowering tree is essentially one for the southern and milder parts of Britain. It is not so hardy or so vigorous as the Almond, neither is it so long-lived as a rule. Flowering in early April and whilst the branches are still devoid of foliage, it requires both shelter and a back-ground to bring out its full beauty. The best effect I have seen produced by the Peach is where a group of a dozen or so trees has been planted on the south-west side of a mass of Hollies. As is the case with several other trees that have been cultivated from time immemorial, the origin of the Peach is doubtful. We associate it most with the East, especially with Persia, whence, indeed, the old generic name of *persica* was derived. But it is now believed to have originally come from China, and some authorities point to *Prunus Davidiana* as the most probable type. If it be so, the Peach must have been greatly modified in other respects besides leaf and flower, for it blossoms at a considerably later date than Abbé David's Peach. In this country it has been cultivated for at least 300 years.

There are several varieties of the Peach in cultivation, of which the best known are the double white and double red. There is also one (*foliis rubris*) with reddish purple leaves and fruits. But, so far as I have seen, the variety which forms the subject of the accompanying plate is the finest. It was, I believe, first put into commerce by Messrs. Veitch. That firm has at any rate shown it at the spring meetings of the Royal Horticultural Society for five or six years past. A first-class certificate was awarded it on February 13, 1894. Of its beauty, the plate will give a better idea than any words can. A variety called *Clara Meyer* has also been highly spoken of.

The name given here is in accordance with *Bentham and Hooker's "Genera Plantarum,"* but the Peach was called *Amygdalus persica* by *Linnaeus* and *Persica vulgaris* by *Philip Miller*, both of which are still applied to it.—*W. J. B.*

Leaves as protection.—In the more distant part of the garden where there are beds of such things as *Tree Paeonies*, *Tea Roses*, *Hydrangeas*, and any kind of shrub usually considered hardy, but still the better of a little protection in very hard weather, leaves form a handy and good pro-

TECTIVE material that may, I think, be used more often. Especially is this the case when there are semi-hardy bulbous or herbaceous plants associated with the shrubs, though in this case the leaves cannot be quite so thickly placed. In very exposed positions their use is hardly to be advised, as they are apt to blow about and make a litter. But if a little wire netting is not objected to, this may be placed around the beds and will keep all tidy. By their decay the leaves form a useful plant food, especially suitable to *Azaleas*, *Rhododendrons*, *Kalmias* and other peat-loving subjects when planted on soil not exactly to their liking. Much of the raking and cleaning that goes on in shrubberies is labour in vain, and might be done without to the benefit of the plants. If the leaves and rubbish were collected and mixed with any odds and ends of soil or manure, and again applied as a top-dressing to the shrubs, then for the sake of tidiness the cleaning up may go on, but to be constantly taking away their natural protection and food without replacing it is wrong.

THE WEEK'S WORK.

FRUITS OUTDOOR.

SINCE my last notes there has been a great change in the weather; frost has been severe, and this, combined with a heavy fall of snow, has practically put an end for the time to work among outdoor fruits, *i.e.*, as regards anything directly connected with root or branch. Such weather gives an excellent opportunity for wheeling out all kinds of mulching material ready for distribution round the roots when a break in the weather comes, or, if there is no snow, spreading may take place simultaneously with wheeling out. I attach very great importance to the supply of good mulching material to almost all trees, especially to those in grass orchards where the roots have to contend for their supply of sustenance with those of the grass and other herbage. Under systematic mulching and careful attention to thinning the branches, the very finest, and certainly the best keeping, fruits may be got from orchard trees, and it is only neglect of these items that brings orchard fruit into disrepute. Perhaps for general purposes the best kind of top-dressing is that obtained from the remains of a fire in which have been consumed prunings and all other waste from the garden. To obtain the maximum quantity and the best quality of ashes or residue, the combustion should be slow, and there is certainly some art in making up the right sort of fire for the purpose. The proper course is to put a good dry faggot upright in the centre of the heap, and then to build up round this all the biggest pieces of wood set on end; then round this again should come the driest of the waste material, leaving the wettest for the outside of the heap, on which may again be packed any spare soil that may be at hand, such as the top soil removed from inside *Vine* and *Peach* borders, as any insects contained in this will be destroyed in the course of charring. A hole should be left at the top of the heap, through which a shovelful of live coals may be thrown on to the kindling material in the centre, and when the heap has got well alight, the only attention required will be to pack on a few shovelfuls of soil or wet rubbish from the outside wherever and as often as the fire burns through the casing. A heap of rubbish dealt with in this way will leave a large proportion of charred, but unconsumed ashes, while the same material thrown together loosely in the ordinary way and set alight will leave practically nothing. Of course, these ashes are far too valuable for a great variety of purposes in the garden to be all used as top-dressing to the fruit trees, but as much as possible should be spared for the purpose and scattered over the surface prior to spreading the mulching material proper, which should consist of the best farmyard manure obtainable at the time, and this should be spread

well over the area containing the feeding roots of each individual tree, not packed close up to and for a few feet round the bole, most of the feeding roots being found some distance away from the bole. A good guide for the application of mulching material is to let it occupy all the surface covered by the branches, then all roots will feel its influence alike. Whether the mulching should be put on thickly or thinly depends to a very great extent on the nature of the soil. Heavy soils in low ground will only require sufficient for feeding, and would be best described as a top-dressing rather than mulching, but with a lighter staple on shallow or raised ground the added material may well be put on to a depth of 3 inches or 4 inches if it can be spared, and will then act as a conservator of moisture in addition to its value as a manure.

STRAWBERRIES.—Strawberry culture has improved of late years in that plants of the current year are planted out in August and gathered from the next year instead of putting out ground layers in April and not fruiting them the same year. There is something to be said for each system, and where labour is scarce and ground plentiful, probably the old system of spring planting is still satisfactory, as it does not entail the amount of care in the preparation of runners that is imperative in the other case if we expect a good crop of fruit the first year, and this expectation is really the only excuse for August planting. To do the plants well the ground should be prepared many months beforehand, so that it may have time to settle, but in the meanwhile it need not lie idle, as an early crop of *Potatoes* or some other thing may be taken off before planting the *Strawberries*, and will leave the ground in better condition for the cropping. If the ground for next year's plants has not yet been prepared, the first opportunity of doing so should be taken, provided the soil is in good condition for working. The best means of preparing the soil in the majority of gardens is to double-dig or bastard-trench it, as in this way it is stirred to a good depth and room is found for two good layers of manure that, with the aid of surface dressings, will keep the plants in good condition for the three years during which they may be expected to carry good crops. The great value of bastard trenching is that while stirring and manuring the soil to a good depth the crude subsoil is not brought to the surface. Of course the methods of digging may be modified to suit the nature of the soil being dealt with, as in some old gardens it is possible to bring up the second and even the third spit to the surface without doing the slightest harm, while in others not so long under cultivation, or with a bad subsoil, to do so would be doing great harm.

FRUIT ROOM.—In the fruit room, space will, unfortunately, be getting almost too plentiful, but advantage should be taken of this fact to bring the remaining fruit into the best positions for keeping it from frost without using fire-heat. I always make a point of emptying the upper shelves first and of allowing a clear space between the walls and the fruit. Heaps of *Apples* and all that have been stored in barrels and boxes to economise room should be looked over for decaying fruits and spread out on the shelves if possible. My own experience is that the best *Apple* store is the one which can be kept fairly dry without much ventilation, and with a temperature not much above freezing point in cold weather. Fixed fireplaces or hot-water pipes for heating the fruit room are an abomination, and should be abolished everywhere, for no amount of care will prevent a fluctuating temperature and an atmosphere that is too dry in places so fitted up. The best means I have found of keeping things right when there is fear of frost getting inside is to light one or two small petroleum lamps in the room, as these can be regulated to a nicety. I recommend ordinary lamps with glass chimneys, as used for lighting in dwelling-houses, rather than anything in the way of oil stoves, as the latter give off bad fumes when turned low and too much heat when turned high. *Pears* when

wanted for dessert should be put into a warm room for a few hours before being eaten. This improves them greatly. CORNUBIAN.

KITCHEN GARDEN.

EARLY CUCUMBERS.—By the time these notes appear it will be time for those who wish for Cucumbers at the end of March and in April to sow the seed. More than ordinary care is needed at this early date in order to secure good all-round results. Those whose houses are under-heated or at all draughty had better wait another three weeks, as, failing ample top and bottom-heat, the tender leaves soon turn yellow and the shoots become hard and stunted. Presuming that a top-heat of from 65° to 70° and a bottom one of 80° can be maintained, no fear need be entertained of a speedy and perfect germination and unchecked growth afterwards. A great point is not to stand either the seed-pots or the young plants too near the roof-glass for some time to come, as if the outside temperature is low and frosty nights prevail, the plants are sure to receive a check, and so long as the glass is kept free from soot and dirt, 18 inches or 2 feet from the glass will not be too far. A handlight should be previously cleaned to place over the seed-pots when plunged in the bottom-heat bed. Sow the seed in small pots in a mixture of light loam, leaf-mould, and a sprinkling of sand, leaving half an inch margin for earthing-up when the plants are a few inches high, as Cucumbers, unlike Melons, always emit a number of roots from the base of the stem. Use the soil in a semi-moist condition, then water will not be needed till the young plants appear. Woodlice and cockroaches must be assiduously watched for, or they will soon destroy the lot almost before they are through the soil. Avoid the too common practice of wetting the foliage daily whatever the weather be; in fact, all moisture for the first three weeks after the young plants appear had better be supplied by vapour alone. Where roof blinds exist it will be well to lower them at eventide during inclement weather, as it is surprising how snug and warm these keep the house and economise fire-heat. Be sure to lay in some nice friable loam to dry in readiness for potting on the young plants in due course, nothing being more detrimental to success than potting Cucumbers in wet or sticky soil. At the first shift some worm-free manure may be incorporated, but the use of stimulants must be modified so early in the season.

SEAKALE IN BEDS.—There is no crisper or better Seakale than that produced by established crowns in the open, covered with pots and leaves. It is best when the individual beds consist of two rows of plants, with a 3-foot alley between. This allows of easy examination when cutting time arrives. The pots being placed, cover with leaves, allowing these to overtop the pots by about 18 inches, making them firm by treading. In exposed positions it is well to lay on the surface a slight covering of strawy litter as a protection against rough winds. Thrust a stout testing stick into the beds, as should very severe weather ensue, an additional covering may be necessary. It is a good plan to cover successional beds with a few leaves—sufficient, in fact, to prevent the surface freezing or from becoming saturated with snow.

VEGETABLES AND FROST.—No risks should be run after this date in regard to laying in a good stock of such indispensable vegetables as Celery, Horse Radish, Jerusalem Artichokes and Turnips, as their quality does not materially deteriorate for several weeks when lifted, provided due care in laying them in is exercised. A cool, airy place and moist soil, where the produce can conveniently be covered with Bracken or litter, are necessary. Laying things in in dry soil or sand is ruinous. They quickly become leathery and lose all quality. See that plenty of crowns of Seakale for forcing indoors is lifted and laid under cover, also plenty of protecting material ready at hand for covering Celery ridges, and Parsnips laid in in sheltered nooks in case of frost or snow.

In case of frost, Savoys, Coleworts and other greens may be effectually thawed by placing them in a comfortable greenhouse a day or two before being wanted. In inclement weather examine closely all roots under cover, such as Carrots, the most susceptible of any root to decay, Salsafy and Scorzonera. The Onion store must also be inspected, any decayed ones removed, and those growing out at the neck laid aside for present use. C.

FLOWER GARDEN.

THLADIANTHA DUBIA.

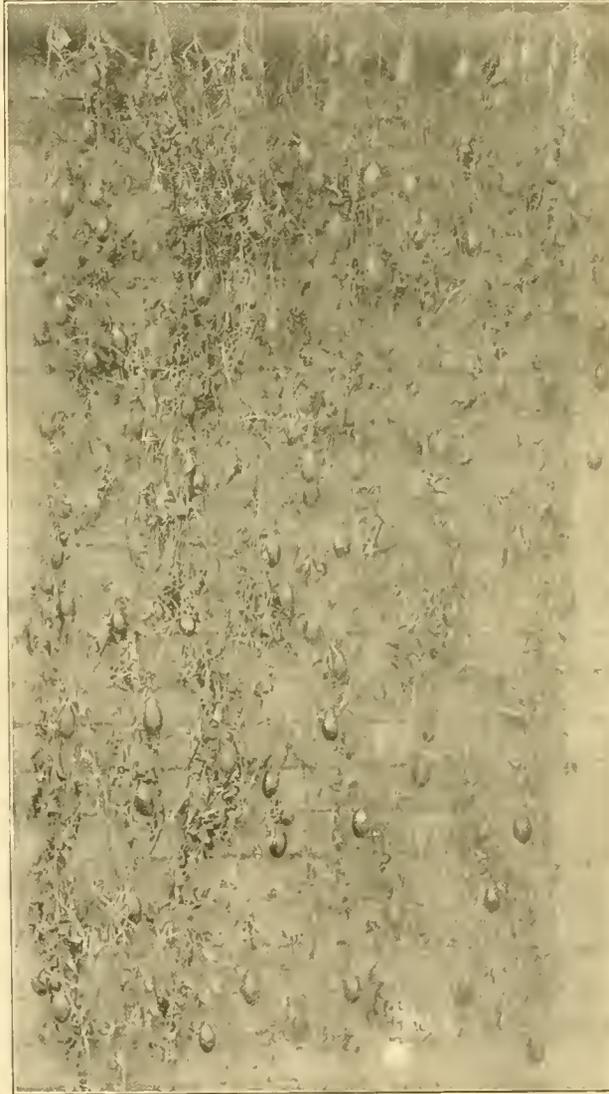

THE fruiting of *Thladiantha* has been a feature at Cambridge for several years past, and as the

exclusively either male or female, and the stock extant has mostly been grown from tubers usually, I believe, of the male plant. I took the trouble, therefore, a few years ago to get both sexes, and now by artificially pollinating the female flowers I get any amount of fruit, the number being limited only by the amount of time available for the work of pollinating. The leaves of this plant are very ornamental, and on this account alone the plant is well worth growing. They die off about the time the fruit ripens, and it may be imagined that the show of fruit is then exceedingly attractive. Some years ago I made an observation on this plant (Bulletin du Congrès International de Botanique et d'Horticulture à St. Petersburg, 1884) which makes it absolutely unique among all flowering plants so far as I have yet been able to discover. It dies down naturally each year, not to a piece of stem, but always to a tuberous root, and never in the course of its life-history does it ever grow up from a stem portion of the plant. It is as if a Dahlia died down every year to a tuberous root without a bud, forming a bud as from a root-cutting fresh in the spring.

The first tuber formed by a Potato seedling is true stem, and the tubers afterwards are true stems, but in this case the only tuber produced by the seedling is a root tuber, and the tubers always afterwards are root tubers. The plant is a native of North China. It is perfectly hardy, and, so far as I have information, will grow in any kind of soil. The specimen illustrated is growing on an east wall.

R. IRWIN LYNCH.

Botanic Gardens, Cambridge.

Thladiantha dubia in the Cambridge Botanic Gardens. From a photograph sent by Mr. R. Irwin Lynch.

fruit is practically unknown, even to those who are well acquainted with the plant, the accompanying illustration may be of some interest. The fruits are scarlet or crimson, each about 2½ inches long by 1¼ inches in diameter, and about 120 hang in the space here photographed—6 feet by 3 feet 6 inches; some rather outside the area had to be drawn in somewhat in order that the full crop of the one specimen might be shown. Why the fruit is rarely seen can easily be explained. The plants are always

they seek to make a speciality of them. There are few professional gardeners who can spare the time, and it is the amateur to whom we must look if the old Rockets are not to become things of the past. Even now the gardens where they are seen are few and between, although some hardy plant nurseries keep up a small stock to meet any inquiries for them. The large white variety, known as the French double white, seems the most plentiful of the lot, but the Scotch double white Rocket is growing scarcer year by year. One sees a solitary plant, or perhaps two or three,

The double Rockets.—Writing of Mr. Harpur-Crewe's Wallflower and the need of its propagation by cuttings recalls to mind the old double Rockets, which were such favourites with the older florists, but are now so little grown. One is not surprised to see these plants so seldom now, pretty though they are. We are no longer dependent upon a comparatively small number of plants, but can make our gardens attractive with an ever-increasing variety of flowers. It is not, therefore, wonderful to find that such plants as the double Rockets are less grown now than of yore. Gardeners, besides, have so many requirements to provide that they are unwilling to take up the Rockets, unless, it may be, that

occasionally in gardens that one passes through. Rarely, however, do we find the long lines which were at one time far from uncommon. A gardener of my acquaintance still speaks with enthusiasm of the lines of some thousand plants he grew at one time in a former situation. I question much if it will be found in greater plenty anywhere than in Ayrshire and in the district around Glasgow, although even there it is rapidly losing ground. I well recollect the pleasure felt by two friends and myself on coming across a stock of some nice young plants in the garden of a clergyman at Kilbarchan. I do not know whether there are any there now or not. Still scarcer is the old double scarlet or crimson Rocket. I know of people who have tried to get hold of this in vain. It still exists, but is, one fears, almost doomed. At times the common double purple Rocket has been grown for it. My own taste does not lie much in the direction of flowers of this kind, but I must confess that I view with regret the possibility of their loss. They were admired by many true lovers of flowers in the olden days. They have their uses still. It will be unfortunate if we have ever to number them among the old plants which were favourites in their day, but have been lost.—S. ARNOTT.

NOTES FROM CARTON, IRELAND, IN NOVEMBER.

THIS is not by any means the best season for a first visit to any garden, but there was more than ample to occupy attention in these charming gardens. The Water Lilies, for which these gardens are noted far and wide, were resting; therefore there was not anything there to feast the eye. One could only imagine how lovely the Marliac and other varieties must look upon the picturesque water with such appropriate surroundings. Mr. Black has advanced further than most of us in his experiments with these Lilies. He finds the strong-growing kinds thrive well in deep water, *i.e.*, up to 6 feet or so in depth. *Nymphaea stellata* during the past season was a decided success in the open water. The common white Arum Lily (*Calla æthiopica*) thrives upon the same water in a marvellous manner, strong growths being above the surface at the time of my visit. The water culture appears to change the season of flowering to the summer months. Near to these Lilies a long pergola has been erected recently, but sufficiently long to have become well clothed with climbers. Another season this will be a delightful promenade in the heat of the day.

No tender bedding plants find favour at Carton, and this fact afforded the greatest pleasure. Instead of such, alpine and bulbs in a wide range of variety receive every encouragement; so also do all kinds of hardy herbaceous plants, both early and late. These latter are massed largely in colours in the kitchen garden. Of conifers, note was taken of several fine Cedars, which, combined with the pergola and the water, were most attractive. These Cedars have still the best years of their existence before them. Forest trees merge into the pleasure grounds in a natural manner, constituting in places the most charming wild gardens possible. A bog garden, which has been a great success, is situated at some distance; hence, as time was all-important, a visit was deferred until a future occasion. There is a large expanse of water upon a considerably lower level, the upper end of which is crossed by the carriage road. Most effective planting has here been carried out down to the water's edge and also upon the islands. Here, again, the natural beauty of the surroundings has not been allowed to suffer in the slightest degree.

Under glass there was a splendid display of *Chrysanthemums* just in season, quantity not being sacrificed for mere size of blooms. The Malmaison Carnation is well grown at Carton, sturdy young plants promising a good return. Climbers evidently find favour, too, Mr. Black's method being to plant out as much possible. The planting-out system has also been followed with decided success in the case of the temperate-house *Rhododendrons*. Orchids are well grown, not in immense quantities of given kinds, but as a general collection, both *Cattleyas* and *Dendrobies* being in evidence; so also was a splendid plant of *Angraecum sesquipedale* of the best variety. The *Nepenthes* at Carton are pictures of health, with a profusion of pitchers; these are grown in a light house and near the glass. Large plants of *Kentias* are grown for decorative uses in a lofty conservatory. Here also was noted *Papyrus antiquorum*—most effective. Fruits under glass are well cared for, Grapes of high-class quality being noted, especially some bunches of Mrs. Pince. Both Peaches and Nectarines are represented by large, well-trained trees. Figs also are of large size and in the best of health. The greater portion of the fruit houses is of the old-fashioned style, with steep roofs, which are not altogether so desirable as those with wider inside borders.

J. HUDSON.

THE CONFERENCE MANIA.

THE GARDEN has rendered a service to horticulture by calling attention to the proposed Sweet Pea conference, which seems to be more useless and unnecessary the more one thinks about it. Those who have undertaken its organisation have truly taken upon themselves a work of supererogation, and it is a pity that their energies should not be devoted to some more worthy object. The increasing tendency of the present age to specialisation is quite indispensable in most departments of activity, but in this case it will degenerate into the formulation of trivial and unimportant distinctions, the tabulation of slight differences in the case of a flower not at all adapted for this kind of treatment. One's feelings find spontaneous utterance in the words, "Pity the poor Sweet Pea." One of the simplest of garden flowers, one of the most popular and one of the prettiest, it claims multitudes of admirers, but any of those who think that a conference, commemoration, exhibition, banquet, &c., are really necessary must be considered to have developed an unwholesome mania for a flower which is by common consent one of the most charming. If the Sweet Pea could express its own feelings on this subject, it would doubtless reveal a deep anxiety that the present proceedings may end in failure through want of financial assistance or otherwise. There are some flowers that are represented by societies devoted to their especial interests—*Chrysanthemums*, *Roses*, and *Dahlia*s, for example—but in each of these cases there is very good reason for a society consisting solely of admirers of the particular flower. Their differences of form and colour are so great, that their admirers can render services to horticulture at large by fixing and developing the best types and improving them where necessary, as in the case of the *Cactus Dahlia* at the present time. What work of this kind is there for a Sweet Pea society to do? Are the individual flowers of the Sweet Pea large enough as now cultivated? Empatically, yes. Does any change in the form of the flower seem desirable? Certainly not. The plant both for the garden and for providing cut flowers is as satisfactory as can be desired. We shall have new varieties with colours different from those already in existence, but this work will go on just as well without any conference and the dire classification of this simple flower into groups of colour and form. To do this in the case of the

Sweet Pea is quite as irrational as it would be for the *Verbena*, *Phlox Drummondii*, *Scabious*, and other similar annuals. H.

ARUNDO CONSPICUA.

THE New Zealand Reed (*Arundo conspicua*) is one of the most graceful of all the grasses, bearing slender, arching, plume-tipped shafts 10 feet or 12 feet in length when planted in deep soil. By those whose knowledge of gardening lore is limited it is usually styled Pampas Grass, but the true Pampas Grass (*Gynerium argenteum*) bears erect and not arching shafts and lacks the delicate grace of *Arundo conspicua*, whose bending plumes spread outward far beyond the furthest limits of its narrow, drooping leafage. The New Zealand Reed attains its full beauty towards the close of July, whereas the Pampas Grass is not at its best until October. *Arundo conspicua* is not so hardy as the Pampas Grass, but a clump I know has withstood the effects of 20° of frost uninjured, though growing in deep retentive loam and in close proximity to water, which has on one occasion, during a prolonged autumnal downpour, covered its roots to a depth of 2 feet. Another highly decorative *Arundo* is *A. donax*, which bears tall pennoned shafts from 10 feet to 14 feet in height, its foliage being of a cool blue-green tint. There is also a variegated form of this plant which is most attractive in appearance, but which is more tender than the type.

S. W. F.

TREES AND SHRUBS.

TREES IN GREENWICH PARK.

CHESTNUT and Elm are the predominant trees in the Royal Park at Greenwich, the majority being of large size and in a rapidly declining condition. Evelyn tells us in his diary that the Elms were planted in 1664, but the Spanish Chestnuts are much older, although one of the avenues mainly composed of this tree was formed at the instigation of Charles II. The old Oak beneath which Henry VIII. danced with Anne Boleyn must in its heyday have been a tree of giant proportions, the hollowed trunk, in which Queen Elizabeth oft partook of tea, being fully 20 feet in girth. The tree is quite dead, and mainly supported by a thick coating of Ivy, which imparts to the majestic trunk a decidedly ornamental appearance. About half way between the Blackheath entrance and the Royal Observatory may be seen several very fine specimens of the Spanish Chestnut, but, indeed, all over the park this tree predominates, the deep gravelly soil being peculiarly suitable for its growth. The fluted trunk of a tree of this kind growing near the entrance to the deer enclosure and nursery measures no less than 23 feet 6 inches in girth at 3 feet from the ground level, and contains fully 180 cubic feet of timber. This is a truly noble tree, but, like many others in the park, it has suffered from the wind and after-neglect of long standing. Another equally fine tree growing by the main avenue leading to the Observatory is admired by visitors to the park, the immense bole girthing 20 feet at a yard from the ground and containing fully 200 feet of timber. The spirally twisted stems, many with immense protuberances at the base and curiously netted bark, are peculiarities of these Chestnuts which have attracted more than passing notice from artists and others. Perhaps the finest Elms are growing opposite the Royal Naval College and upwards towards Vanbrugh Castle entrance to the park, but,

generally speaking, the larger trees are in a very unsatisfactory condition, owing to old age, decay, and neglect. At one time (1660) the Elms must have been of no mean size in some parts of the park, for we learn that Sir William Boreman sold a number at £5 apiece. Of Oaks, the largest trees are in the deer enclosure and near the site of Greenwich Castle, on the Observatory hill. There is a record that some of the Oaks in 1660 were sold for £14 each, so that even at that early date the timber in the park must have been not only large, but of very good quality. In the grounds attached to the Ranger's house, and which were recently thrown into the park, there are noble examples of the Chestnut-leaved Oak (*Quercus castanefolia*), purple Beech, common Hornbeam (finer than any at Epping), Tulip tree, Ailanthus, Amelanchier 25 feet high, and common Hawthorn. The last is one of, if not the largest in the kingdom, the height being 47 feet and the stem girth 5 feet 10 inches above the swell of the roots.

In connection with these trees it might be mentioned that, like the Cedar at Chelsea, trees which once did well at Greenwich cannot now withstand for a lengthened period the deleterious effects of the impure atmosphere to which they are almost constantly subjected. This, combined with artificial drainage consequent upon the making of the Blackwall and other tunnels, has in latter days had a most injurious effect upon the general health and appearance of the trees in the park.

A. D. WEBSTER.

TREES AND SHRUBS CERTIFICATED DURING 1899.

DURING the year 1899 sixteen different trees and shrubs received either first-class certificates or awards of merit at the various meetings of the Royal Horticultural Society. This was three less than in 1898 or 1897, as in each of these years the number was nineteen. Some of the subjects were by no means new, *Caryopteris mastacanthus* being an instance of this. Perhaps the finest plant of all the certificated subjects was that beautiful double Japanese Cherry which was given a first-class certificate on May 16. The following is a complete list, the names being arranged in the order in which the awards were made:—

Prunus persica alba plena.—This is the double white-flowered Peach, a good form of which received a first-class certificate on February 28. The specimens exhibited were, of course, forced.

Azalea mollis Purity.—A variety of *Azalea mollis* or *sinensis* in which the flowers are large and of a very delicate sulphur tint. The upper segments are slightly spotted with a deeper shade of yellow.

Azalea mollis Betsy de Bruin.—The medium-sized blossoms of this are of an orange-apricot tint, spotted on the upper part with brownish crimson. Both these *Azaleas* received awards of merit—the variety *Purity* on March 13, and the other on March 25.

Prunus pseudo-Cerasus James H. Veitch.—Under the generic name of *Cerasus* this charming Japanese Cherry received a first-class certificate on May 16. This honour was well bestowed, as it is one of the finest of this popular race. The deep rosy pink blossoms are double, each about a couple of inches in diameter, and borne in great profusion. The freshly expanded reddish bronze foliage serves admirably as a setting for the charming blossoms. Among other items they are later in expanding than those of their immediate allies.

Acer pseudo-platanus elegantissimum variegatum.—A form of the Sycamore, in which

the leaves are variegated with creamy white. In a young state they are heavily suffused with reddish bronze. The individual leaves are pretty, but variegated-foliaged trees as they grow up have little to commend them. A first-class certificate was awarded this at the Temple show.

Ilex Wilsoni.—A vigorous, bold-growing Holly, with long spined, oval leaves. It is said to have originated from seed, probably from the variety *Hodginsi*. *I. Wilsoni* is reputed to be an abundant berry-bearer. It received a similar award to the *Acer* and at the same time.

Juniperus Sanderi.—Apparently a form of the variable *Juniperus chinensis*. An award of merit was given to this *Juniper* at the Temple show.

Rhododendron Essex Scarlet.—A hybrid *Rhododendron*, bearing compact heads of rich crimson-scarlet flowers, upper petals spotted purple. This variety received an award of merit on June 13, doubtless owing to the extremely rich colour of its blossoms.

Abies Douglasi pumila.—A close, compact-growing form of the Douglas Fir, with pretty bright green foliage. It is said to be a native of Colorado, and must be regarded as one of the most desirable of the smaller conifers. A first-class certificate was awarded this on July 25.

Acer californicum aureum.—A form of *Acer Negundo* in which the leaves are of a pleasing shade of yellow. This colouring is intensified by exposure to the summer's sun. The long wand-like shoots, being of a glaucous hue, add a notable feature. It promises to be a good garden subject, as the tinting is not of that patchy character common to most variegated-leaved trees and shrubs.

Cornus macrophylla.—A vigorous-growing Japanese species of Dogwood, with leaves 5 inches to 8 inches long and 3 inches to 4 inches broad, dark green on the upper surface and very pale beneath. In the autumn the leaves die off brightly coloured with red. The flattened clusters of creamy white blossoms are freely borne. It has not been long introduced, but in Japan is said to form a tree 50 feet to 60 feet in height, with a trunk more than a foot in diameter. The long branches, which stand at right angles to the stem, form distinct tiers, which when thickly studded with corymbs of flowers are particularly noticeable.

Vitis Thunbergi.—A Japanese Vine in the way of *Vitis Coignetiae*, and, like that, remarkable for its autumn tints. *V. Thunbergi* has large wrinkled leaves, deep green above and covered with rusty hairs on the under sides. The leaves are in most cases slightly three-lobed. The last three subjects received an award of merit on July 25.

Cupressus Lawsoniana Wisseli.—A very distinct variety of Lawson's Cypress with several erect leading shoots, somewhat after the manner of *C. Lawsoniana erecta viridis*, but the side branches are disposed at various angles, thus giving it quite a unique appearance. It is a neat, compact form of a pretty glaucous tint, and should be of service for small gardens. An award of merit was given this variety on August 15.

Robinia pseudacacia inermis albo-variegata.—This differs from the ordinary form only in the leaves being freely variegated with silvery white. As shown, it was decidedly pretty, but it is questionable whether it will prove of much real service to the planter, as its variegation appears delicate. It received an award of merit on August 29.

Retinospora obtusa aurea Crippsi.—Among the numerous varieties of *Retinospora obtusa* this must be assigned a prominent position, as it is in every respect a very desirable form. It is extremely graceful in habit, bearing long pendulous thong-like shoots, while the entire plant is of a rich golden yellow. It is said to retain its colour throughout the year, and this, in conjunction with its graceful habit, should render it one of the most desirable of golden

conifers. It was given a first-class certificate on September 12.

Caryopteris mastacanthus.—A now well-known shrub, which was originally sent from China by Robert Fortune in 1844, then lost after a time, and re-introduced by Maries when travelling for Messrs. Veitch in 1879 or 1880. The flowers, which are borne in rounded clusters from the axils of the leaves on the upper parts of the shoots, are of a bright purplish blue, with prominent stamens. Flowering as it does in the autumn, its value is still further enhanced. The excessively hot season was in favour of this *Caryopteris*, which can only be considered moderately hardy in this country. T.

EVERGREEN TREES AND SHRUBS.

MUCH as we appreciate the varied forms and shades of foliage of a good collection of deciduous trees and shrubs, and the effect they produce at various times of the year, I find that without a judicious sprinkling of evergreens our shrubbery borders and woodland walks would not be half so attractive during the dull winter months. If it were not for the cheerful and lively hues of these much of our interest in country rambles during the dull period would be lost. The Ivy-clad ruins of an old castle do not seem to have the same charms when all around is bright and gay with the foliage of other trees as in the winter when these are bare; neither has the common Holly in our hedgerows the same attractions on a bright, sunny day as it has when the berries are ripe and the leaves are glistening with hoar frost. The Pine woods in winter present a different feature in the landscape than in the summer when their closely-set fine foliage does not come into contact with that of more attractive hues. These, however, are only a few of the many features that evergreens possess. There is such a number of Hollies that these alone form a very interesting study, to say nothing of their usefulness as shelter for other less hardy plants. The common variety makes a splendid hedge, as most people know, and will stand clipping better than many evergreens with such large leaves. It is not often, however, that we see a hedge of the yellow-fruited form (*flavum*), but well grown this is very attractive. Not long ago I saw a belt of this about 12 feet high leaved with bright yellow berries, which was very attractive. Then there are so many forms with variegated foliage, and these for the most part are well set with berries, which during the present wintry weather are very attractive. *Laurifolium* does not usually fruit freely, but this year the berries are thickly clustered round the stems, which form a fine contrast to the large light green leaves. Though berries, as a rule, are not so plentiful this season, there are some bushes that are well laden with fruit. The bold foliage of some of the Barberries is very attractive, especially where these do well and are fully exposed. *B. japonica*, or, as it is sometimes called, *Beali*, has very large, deeply-cut leaves, and when grown to a good-sized bush is very attractive from this time onward, as it is one of our earliest shrubs to bloom. *Aquifolium*, too, is most useful for planting under the shade of trees and covering bare patches on sloping banks where little else will grow. This is not at all particular as to soil or situation, though in exposed places on the chalk the foliage assumes a bright colour in the autumn and is much sought after for cutting. It seems rather strange that the *Kalmia* does not find more favour in our gardens. It is one of the hardiest evergreens we have, and, though it will not succeed on chalk, will grow in almost any other kind of soil. The flowers, too, of many of them are very attractive. There is such a variety of forms of the *Andromeda* that these alone would be well worth a piece of ground devoted to their cultivation. There is so much difference in their habit of growth, shape and colour of foliage that one would scarcely think they belonged to the same class. *Arborea*, *Catesbaei*, *japonica*, *speciosa*, *Boribunda* and *calyculata* are all worthy of a

place. Amongst the Box tribe there are also many useful forms that will grow where little else can be planted. On the chalk these thrive in a most remarkable manner; even where there is but little soil to cover their roots plants seem to be at home, while on a deep loam they grow freely. Balearica, with its large shining leaves, is very distinct; there are also several of the variegated forms that are attractive, all of which form neat, compact bushes. Phillyreas are so hardy that no amount of frost seems to injure them, and though not so useful as some other plants, they are very serviceable for planting in exposed places. Being of slow growth, they do not soon become unsightly. Some of the Oaks, too, are very attractive and form dense trees, being very hardy, particularly Quercus Ilex, which withstands the sea breeze better than any other evergreen shrub. There are many others, but mention is made of those which are perfectly hardy and will grow in any part of the kingdom without the least protection. H. C. P.

CHRYSANTHEMUMS.

CHRISTMAS CHRYSANTHEMUMS.

At no time are these flowers more valued than in mid-winter. From a market point of view they then become a paying crop, and no gardener can afford to neglect them. Apart from proper attention to culture, the selection of suitable varieties is of considerable importance, as only a few kinds will prove satisfactory so late in the year. White being the most useful colour, I will take these sorts first. L. Canning had for a number of seasons a great run, and it is certainly a first-rate white when well done. Dwarf in growth, free, and the blooms pure, as well as of good shape, it has every good quality, yet many find it a bad one in the matter of lasting when cut. Many find, too, that the variety in some seasons has a habit of producing blind buds. Thus, faults like these are causing a considerable number of growers to discard it. Niveum is a much better variety, as it is more constant and quite as late as L. Canning. By striking batches of cuttings as late as May, one may get this kind to last in bloom until February. It is very fine when the plants are not disbudded, or rather if the bloom-buds be not thinned. If rooted early the plants should have their shoots topped, otherwise it rarely forms a natural bushy specimen. Western King, a seedling from the last-named, is a very pure white, and the blooms are of fine quality. These incurve slightly, whilst those of Niveum reflex. Both kinds are first-rate for the supply of Christmas flowers. A sort much favoured is Mlle. Thérèse Pankoucke, a free but rather tall grower. The blooms have stiff stems and are elegant in form. Market growers favour this on account of its lasting qualities, besides the other merits. One of the latest and best is Princess Victoria. The plant is strong and forms a good bush, and the flowers last well when cut. Lady Lawrence, an old variety, is still excellent for late flowering. The white is pure and the florets incurve slightly. The plant, however, is not among the easiest to cultivate. Mrs. H. Weeks, a noble exhibition kind, is also useful when grown to produce late flowers, and, like Niveum, it sends forth blossoms a considerable way down its long branches, in which state the plant is very effective in the conservatory. A sort generally known as an early one, Souvenir de Petite Amie, is first-class late in the season from the terminal flower-buds. The plant is so dwarf and free that it has advantages over most varieties we grow. A late pompon, Snowdrop, should not be overlooked. The tiny blooms come so freely as to make it excellent for decoration.

Sports have been obtained from Niveum, Western King, Lady Lawrence, and Snowdrop. They are all light or sulphur-yellow, therefore hardly deep enough in shade of colour to be of much use, more especially under artificial light. The most favoured yellow—at least for market—

is Major Bonaffon. I am not impressed with the formation of its blooms, but the colour is rich and the flowers last and travel well. The florets are short, and incurve. As a plant it is especially dwarf and free. Golden Gate is a favourite late yellow. The blooms are elegant in form and the plant generally has every good quality. Another well-known kind for a late supply is W. H. Lincoln. I like the growth of this, but would welcome a sort of similar habit with better flowers. The colour is rich, but the petals are quill-like and wanting in grace. Phœbus might well be tried for late work. It is first-rate in any form. A few large bush plants of this variety in fine flower I recently noted. This and Souvenir de Petite Amie form a capital pair—yellow and white. King of Plumes should be grown for its lateness and for the wealth of small, elegant blossoms.

Late pink varieties are not abundant. Much the best is Mme. Felix Perrin, which keeps its colour well. The plant is rather tall, but free-flowering. Liability to fade is the fault of most of the crimson-flowered kinds. The old Julie Lagravère is valuable for late flowers, these keeping their deep shade well. The blooms are comparatively small and the plant dwarf and free. G. W. Childs is also excellent. The blooms of this are of pretty form, but the plant wants careful culture. Its roots are tender and will not stand much feeding. J. Chamberlain is a recent variety, which may be tried for late flowering. The colour stands well, and the plant grows freely. Tuxedo is a tall-growing variety, but there are none of a bronzy shade more useful than this late in the year. Master H. Tucker produces blooms of a brown-crimson shade, which lasts well. Although somewhat tall, this kind should not be neglected for late supplies of bloom. Matthew Hodgson, a bronzy red, is a capital late sort. The growth of this is dwarf and bushy. H. S.

NEW CHRYSANTHEMUMS.

Not for some years past have so few novelties in Chrysanthemums been seen. This, perhaps, is partly due to the fact that, properly, a much higher standard of excellence is required than formerly before the award of a certificate is given. Another reason is that many of the best of the French novelties are not placed before the committees the first year, because three blooms must be obtained. Few persons are bold enough to purchase a sufficient number of plants at a very high figure to get these; hence one must see the leading traders' collections to form an opinion as to which of the many new sorts are likely to be improvements upon existing ones. Of English-raised new kinds, Florence Molyneux has been exhibited in first-rate form. It is a white incurved Japanese of immense form, probably the biggest variety of any. I have not seen the plant growing, but one can imagine that it is a sort like Mrs. H. Weeks, requiring a long time to develop its flowers, and satisfactory only when one single bloom is allowed to a plant. Edith Pilkington, yellow, with bronzy tint, is a wide-spreading flower, not unlike Ella Curtis. Mrs. Bagnall Wild has blooms of a pretty shade of pink. These incurve and build up a noble blossom. Vicar of Leatherhead is a yellow variety, the florets drooping and long. It is full and large; thus a useful kind, although it is scarcely distinct from many another. Mrs. A. G. Hall is said to be a seedling from that excellent variety Edith Tabor. The new one, however, has a better habit of growth. It is bronzy yellow in colour, large, full, and graceful in formation. General Symons belongs to a class difficult now to distinguish. It is rather closely incurved and not extra large, so that instead of classing it as a Japanese it is called incurved. Its colour is a pretty buff shade.

Australian and French-raised kinds afford better material than the above in the way of novelties this year, and a considerable number of these will be highly esteemed when better known. Of the

former, G. H. Kerslake Jun. is first-class. It is white, and in shape not unlike Mme. Carnot, but the habit is especially dwarf and sturdy. J. R. Upton is a handsome Japanese variety of a bright shade of yellow. The form of this is drooping. The florets are of great length, and the blooms grow to a large size. It is a sturdy grower. Lord Ludlow is not quite new, but is a variety of considerable importance. The colour, a bright yellow, has a distinct edging of red in each floret. The sort lacks nothing in size and beauty of form, whilst the growth is of a sturdy nature. Walleroo, a slightly incurving form of a purple shade, bears large, handsome flowers when disbudded, and is also excellent if produced in quantity. Of continental varieties, Calvat 1899 is of great beauty. A soft shade of yellow tinted mauve would describe its colours. The bloom is large and rather incurving in form. When sprays of flowers are allowed to develop it is one of the choicest things seen for a long time. Mme. Henri Bernard has blooms of a bright rosy purple, in which white lines run most distinctly. The formation is drooping and a full, showy flower is obtained. Mme. C. Terrier has flowers of a charming rose tint. The florets are long and hang in a graceful manner; the growth of the plant is dwarf. M. H. Martinet is a variety of much promise; colour, a mixture of crimson and gold, as in the well-known, but difficult kind, E. Molyneux. The flowers are large, full to the centre, and especially rich. It is a dwarf, sturdy grower. This should become a popular kind. Although white Chrysanthemums are numerous, Princesse Bessarabe de Brancovan is an improvement in that shade. The quality of the bloom is first-rate, and the growth dwarf and branching. This is likely to surpass that magnificent variety Mrs. J. Lewis. Roselyn is a gain in colour; the shade is violet-red. The blooms are large, of a spreading form, and full and deep, quite a fine type. W. Wells will, I suppose, be classed as an incurved; its shade of amber-yellow is rich and pleasing. This variety is an excellent addition. For growing in sprays it is most striking. Zephoris is a broad-petalled, full, deep Japanese flower of a bright yellow colour. This, like the foregoing novelties, has a dwarf habit of growth, not the least pleasing of the characters noticed in varieties of recent raising. H. S.

Chrysanthemum Mme. R. Cadbury.—This is a distinct advance in all that pertains to quality in a flower. Apart from the striking purity of the white, the flowers are remarkable for substance, the florets being thick and leathery. They are also broad and long, forming a large, recurring-shaped bloom of much richness. There is not a doubt about its becoming a popular late-flowering kind when known. I can only judge of its being a late one from the fact that in each of the past two seasons the raiser has exhibited it in December. Its value, therefore, from an exhibitor's standard may not be so great as it will be to growers generally who welcome choice flowers late in the year. It is an English raised seedling.—H.

Hardier Chrysanthemums.—The note by "H. S." in THE GARDEN of December 16 was not unexpected. Unless I am mistaken, the initials are those of one whose opinions on the subject of Chrysanthemums are of immeasurably greater weight than those of the writer of the present lines. I venture to think, however, that the prospect of the introduction of hardier Chrysanthemums is not so hopeless as he thinks. I am not, I trust, unduly optimistic in attributing to Chrysanthemum raisers the ability sufficient to enable them to give us plants and flowers of greater power of resistance to frost than we have at present. The years during which the Chrysanthemum has been so largely grown under artificial conditions can hardly fail to have had some influence in making its progeny less hardy. Nor can it, one would think, be argued that the developments of the modern Chrysanthemum have made it equal to the older flowers in ability to

stand rough weather. If we are to have plants capable of remaining in flower at a late season, it is only reasonable to think that we must be content to sacrifice something in the way of the magnificence of the flowers produced under glass. I fear that the early-flowering varieties will hardly serve the purpose for which we want the later blooms. There is generally a short spell of frosty weather in autumn, sometimes only for a day or two, but enough to destroy their beauty. What is wanted is a race which will not open its buds until about November. Those who have tried the Chrysanthemum in the open can observe that there are varieties of greater hardiness or having flowers so constituted as to be less liable to injury from frost than others. Is it impossible to raise from these a race which will possess these qualities in a greater degree? I do not think so; but I do not anticipate that success will come from working on the lines which have in the past given results so remarkable. A race of hardier Chrysanthemums would be a boon to thousands.—S. ARNOTT.

NOTES AND QUESTIONS.

Chrysanthemum Miss Alice Byron.—White varieties are so numerous that there hardly seems room for more, yet this one is distinct. It is pure white, large, and solid, the shape incurving. The petals are broad and remarkable for substance. It reminds one of Louise, not the least handsome of Japanese forms, only white and most exquisite in richness and finish. For exhibiting in November the variety should take a leading place, and, now that vase arrangements are coming into use, this introduction gives a variety that would form a chaste exhibit in a vase.—H.

ORCHIDS.

TEMPERATURES FOR ORCHIDS.

It is usually understood that the grouping of Orchids in proper temperatures, classifying them, as it were, and keeping each particular section of a genus to its own house or compartment, are very essential, and likely to lead to their successful culture, all other conditions being correctly attended to. With all the outcry against collectors and nurserymen who withhold the habitat of a species lest rivals in the field should get hold of it, it would appear to be considered a very important point. But when one sees a small collection sometimes and finds plants from all quarters of the globe thriving and flowering in one house, it really seems as if this temperature question had been made a little too much of. It took us a long time to convince ourselves thoroughly that Cymbidiums of the gigantum and Lowianum section were more satisfactory in cool houses than hot ones, yet the fact is now fairly generally accepted. But fine plants have been grown, and still are grown, in heat, thus showing that this particular section is not fastidious as to temperature. Quite recently in a Norfolk collection I saw some remarkably fine basket specimens of Mexican *Laelias* thriving and in the most vigorous condition in the same house as a general collection of heat-loving *Dendrobiums*, *Aerides*, *Vandas*, and a host of others. *Odontoglossum grande*, *O. pulchellum*, and several others were on the back stages in the same house, but it is only fair to add that these and other cool Orchids had been grown outside in a cool pit during the summer.

Then there are many instances that could be cited of plants usually considered to need a great deal of heat, and difficult to grow at that, cropping up in some out-of-the-way place in splendid health in a cool house and *vice versa*. It will usually be noted in these cases that the plants come in for a good deal of watchfulness and care on the part of their owners, and by a

close study of their habits, the growers have been able to anticipate their every want almost in the way of compost and watering. I believe that this close attention—by which I do not mean the silly and reprehensible practice of being always pulling the plants about—on the part of those in charge does a lot to remedy any slight mischief that may occur through the temperature not being suitable. To take Orchids as a whole, there can be little doubt that the temperatures, generally speaking, are kept too high. Some species there are that cannot be grown without heat, but many would be far better in cooler quarters than are at present allowed. H. R.

NATURAL HYBRID MILTONIAS.

WESTERN SECTION.

MILTONIAS, considering the small number of species, have an exceedingly large proportion of intermediate forms. This fact no doubt is explained by the particular construction of the flowers of this genus, rendering them easy subjects for insect fertilisation. One of the first supposed natural hybrid Miltonias was

M. fastava, which was described by Reichenbach in 1868. It appeared to have been lost to cultivation after 1877 until a plant flowered in the collection of Mr. R. I. Measures at Ladymead, East Harting, Sussex. In 1894 a plant was exhibited at the Temple show. It undoubtedly is derived from the intercrossing of *M. spectabilis* and *M. flavescens*. The creamy yellow sepals and petals are rather broader than in *M. flavescens*. The lip is very similar in shape to that of *M. spectabilis* and light purple. The growths are flat, as in the last-named species.

M. Blunti is one of the most beautiful and desirable of the natural hybrid Miltonias. It was sent home by the collector whose name it bears in 1879. It is a supposed natural hybrid, and partakes of the intermediate characteristics of *M. spectabilis* and *M. Clowesi*. The sepals and petals are creamy white with some reddish brown blotches in the central area, the broad front lobe of the lip white, suffused with crimson at the base. The variety

M. B. Lubbersiana appeared in 1877. The flowers are larger and more beautifully spotted than in the typical form. It is a choice and most desirable variety.

M. B. Peetersiana differs from the typical form in the fact of its having *M. s. Moreliana* as one of its parents. This variety has the dull purple suffusion and veinings of *M. Moreliana*, with indistinct bars as seen in *M. Clowesi*. It is a scarce and desirable addition.

M. Binoti is supposed to have its origin between *M. candida* and *M. Regnelli*. The sepals and petals are creamy white, tinged with lilac at the base and barred with light brown; the lip rosy lilac. A plant was exhibited at the Royal Horticultural Society's meeting, September 20, 1898, from the collection of Sir T. Lawrence. The same exhibitor also showed on that occasion

M. leucoglossa, one of the most distinct and beautiful varieties I have seen. It has creamy white sepals and petals, sparingly spotted with violet; the lip white, with the exception of a few purple markings around the crest.

M. Lamarckiana (*M. Clowesi* × *M. candida*) was exhibited at the Drill Hall and received an award of merit on October 15, 1895, as *M. Cobbiana*. It first appeared in and was described from the collection of M. Lamarck de Rossius, president of the Société Royale d'Horticulture de Liege, in August, 1874. In 1893 a variety appeared in the collection of Major Joicey, Sunningdale Park, which was exhibited and received a first-class certificate on August 8 of that year as

M. Joiceyana.—This is not sufficiently distinct to be separated from *M. Lamarckiana*, only as a variety. The sepals and petals are much like those of *M. Clowesi* both in shape and colour; the lip is much larger and broader, the front lobe

white, shading to purple on the basal half. It is a rare and desirable variety. H. J. C.

Cattleya Percivaliana.—Though not so large as many others of the *C. labiata* group, the lip markings on this *Cattleya* are very beautiful and effective. It usually only opens partially until the plants are strong and well established, but when well cultivated and vigorous this fault usually disappears. Its general culture differs little from that of *C. Trianae*. It should be started into growth after the flowers are past and encouraged to finish up early while there is yet time to thoroughly ripen it by exposure to sun and air in autumn.

Cœlogyne Gardneriana.—The pendulous flower-spikes produced by this *Cœlogyne* are very handsome and make a fine display at midwinter. When in good condition the plant grows freely and flowers abundantly, but it is apt to be attacked by insects, especially thrips, if kept in an over-heated or dry atmosphere. It flourishes well in a collection not far from here in the shady part of an intermediate house, and this is the best place to grow it. A free supply of moisture is necessary during the growing season, and the compost may consist of equal parts of peat fibre and Sphagnum Moss. Grow it in baskets in order to show the habit to perfection and see that these are well drained.—H. R., *Bury St. Edmunds*.

Vanda Amesiana.—This very distinct and beautiful *Vanda* is now flowering in many collections, and as a winter-blooming subject would be hard to beat. In its thickened cylindrical leaves it is like a stout form of *V. Kimballiana*, to which pretty species it is closely allied. In an intermediate house the plant will generally be satisfactory, and it should be grown in small baskets suspended from the roof. Here it obtains the full benefit of all the light and the best of the air currents at command, thus producing a solid, free-flowering plant. All these mountain plants like this treatment; they cannot stand being stewed up in a close, badly-ventilated structure, or one in which the air is not constantly being changed. The flowers appear on erect racemose spikes, are fragrant, varying in colour from quite a deep rose-purple to nearly white. After these are past, the plants as a rule take a short rest. I say as a rule advisedly, for some specimens seem always inclined to grow, and can only be induced to rest by force, which is harmful. In their native haunts the plants are said to shrivel considerably, but it is not advisable to go to such extremes under cultivation. Such treatment—by many misnamed rest—is very weakening and harmful to the plants and is unnecessary. *V. Amesiana* is a native of the Shan States.

CHRISTMAS DECORATIONS.

AT this season of the year a walk through the central avenue of Covent Garden Market affords the best possible means of seeing what materials are at our disposal for the embellishment of our churches and our homes. With that tenacity with which we cling to all old institutions, our thoughts turn again to the Holly and the Mistletoe. But now we want choice flowers, delicate exotics, as well as the good old English Holly, and here in the market they are to be found in abundance and much variety—the Arum Lily, whose pure spathe does not confine its chaste splendour to the summer months; Lily of the Valley, whose retarded crowns have sent up many a tender spike to cheer the dark September days, followed by a leaf of sickly green, deprived by lack of sunshine and air of that healthy appearance that is natural to it; Roman Hyacinths and Paper Narcissi, reminding us of the spring days that are to come; early Azaleas and other flowers, with the last of the ever-popular Chrysanthemums, scarlet Geraniums and Carnations to add bright and warm colours to those that are at our disposal.

Nor is the supply of foliage less profuse. Holly, both the red and yellow-berried forms, must be used in quantity. But we have also Berberis foliage, with its exquisite brown and bronze tints. The Box and the Yew must not be forgotten, whilst *Ruscus racemosus* will be found very useful, even for use in large vases with flowers of different kinds. A supply of Pampas Grass plumes will doubtless have been secured in the autumn, and perhaps some of *Arundo conspicua* as well. The common Reed Mace (*Typha latifolia*), and the finer varieties, such as *T. angustifolia*, well mingled with it, produce a very fine effect in large vases with the plumes of Pampas or *Arundo*. Long dried sprays of *Humea elegans* may be mixed with these to add a little colour; they are also in themselves quite graceful. Spikes of *Echinops* and *Eryngium* cut from the herbaceous border in the summer, with as long stems as possible, are very serviceable in the winter months. In a similar way the native Sea Holly (*Eryngium maritimum*) may be used effectively. Its dwarf, much-branched, bluish spikes are very elegant. The dried catkins of the Winter Cherry (*Physalis Franchetti*) can be mixed with any arrangement of the Grasses, &c., that have just been mentioned, in order to give colour if desired. On rare occasions the Stag's-horn Moss is found flourishing so luxuriantly that quite long sprays of it can be obtained, and if carefully dried these can be used for trailing down the sides of large vases. An excursion to parts of the English Lake district would afford an excellent opportunity to secure a supply of this. It should be remembered, too, that *Asparagus plumosus* will last very well for two or three weeks when used in this way and kept dry.

The Ivy has not yet been mentioned. How useful this is always found to be in all kinds of church decorations, whether at Christmas or even during the harvest festival season! What better decoration can be devised for a stone or marble pillar than a narrow spiral of trails of Ivy guided round and round the column like the thread of a screw? How easily, too, the Ivy lends itself to the formation of a frame of foliage round any formal circumference; to enclose a pulpit panel, for example. If any string or wire has to be hidden, nothing is simpler than to use a single piece of Ivy.

In the arranging of our flowers, let us not forget the oft-repeated warning to beware of over-crowding, of mixing many different things together, or of using flowers of a considerable size with short stems and putting them into small specimen glasses, as though they were show Dahlias or *Chrysanthemums* intended for exhibition in the orthodox manner. Suppose that half a dozen *Arum Lilies* are at our disposal—the best effect will be produced by arranging them boldly and loosely with long stems in a large vase, with a little of their own or other suitable foliage. These handsome flowers are only spoiled by being crowded with short stems amongst a lot of other kinds in an undistinguishable mass, or placed in a wreath in a mass of white so that their own outline is lost. To fill a small specimen glass, let us take a few sprays of Lily of the Valley, with two or three of its own leaves. The result is a beautiful yet simple arrangement. *Chrysanthemums* are still to be obtained in various sizes; these are some of the easiest flowers to arrange. Various kinds of foliage may be used with a good result, if only over-crowding is avoided and the colours chosen do not clash. Whites and yellows will be found the most serviceable.

If these simple principles are adhered to, all our churches and homes, rich or poor, may be

made beautiful during the coming days of rest and rejoicing. H.

Potting Ferns loosely.—Where the aim of the grower is simply to get a quick growth irrespective of solidity of texture in the fronds, this may easily be brought about by loose potting and ample warmth. For instance, when bringing on small seedlings or plants from division to a useful size they may be treated in this way, and if slightly hardened by exposure for a few days to a lower temperature and drier atmosphere they will stand fairly well for decoration. Most of the *Adiantums*, for instance, especially *A. cuneatum*, when treated like this make very rapid progress, and the same is true of *Pteris serrulata* and its varieties and *P. tremula*. The latter does not, of course, lend itself to propagation by division to any extent, but the former kinds do, and very rapidly. In breaking up the plants it is well not to shake them out more than can be avoided, simply breaking apart being a better method. Before potting it is as well to lay them out on a moist stage or on a tray, with a little prepared Fern compost, to strike root a little before potting. At first very little water is necessary, but when the roots have obtained a hold on the new material the loose condition of this will necessitate frequent moistenings. In this way a large stock of useful plants may be rapidly grown.

ROSE GARDEN.

ROSES FROM CUTTINGS AND LAYERS.

CUTTINGS of Roses are made in September from branches that, having flowered or not, are already half-ripened. The cuttings are made with three or four eyes—less if need be—and cut very clean below the last eye, and if possible with a heel or enlargement at the base of the branch on the stem which bears it. All leaves are cut down to their petiole. Before, however, making cuttings, a small plot of land should be carefully prepared on the north side of a wall or hedge in a somewhat warm place, though sheltered from the sun, and well mixed with sand to prevent retention of moisture. If bell-glasses are available, the places they are to occupy are marked by pressing them against the soil; in the absence of these, a shallow box covered with a single sheet of glass will answer the same purpose. The holes for the cuttings are made within the circumscribed space with a dibble at distances of a few inches from each other, and the cuttings are inserted to their middles and the holes filled up. The soil is then watered with a fine rose and the bell-glasses or boxes are put in place. The cuttings should afterwards be inspected at intervals for the removal of fallen leaves and dead cuttings, and watered if required. At the end of five or six weeks many of them will have taken root and even commenced to grow. Let them do this with out removing the bell-glasses, so that the backward cuttings may take root in their turn. The growth cannot in any case be other than very restricted, as winter will then be close at hand. The cuttings will pass the winter under the bell-glasses, and care should be taken to surround these with leaves or straw, covering them, if need be, all over to protect them from severe frost. In the spring remove these extra precautions and air the plants a little by lifting the glass. When the slips have begun to put out shoots and the roots are active, remove them to small plots in the temporary nursery, or even at once to the places they are to occupy if this allows of their being attended to. Most of the cuttings will flower in the same summer and afterwards become handsome, lasting plants.

However, all varieties do not root equally well, Teas and Noisettes being somewhat difficult as cuttings, and here layering comes to the amateur's assistance by enabling him to propagate the most difficult varieties. It is extremely simple. The best time to make layers of Rose plants is the autumn. The longest branches are chosen for this purpose. These are laid in in a small trench 4 inches to 6 inches deep and kept in place by means of small wooden pegs. To make sure of and hasten the formation of roots it is well to make under an eye in the buried part on the upper side an incision to the middle of the wood for half an inch or so. This is known in gardening as layering with incision, and is applied to certain plants, notably to Carnations. Layers thus made sufficiently early take root before the winter, or at least form a callus. In the spring or summer, when they begin to shoot, the mother branch is cut first to the middle of the wood, then altogether, and as soon as the plant can support itself it is lifted with its ball and placed in the position it is to occupy.—S. MOTTE, in *Gazette de Village*.

NOTES OF THE WEEK.

Acacia penninervis.—This is one of those having globular heads of flowers and singular-looking as well as decidedly strap-shaped leafage. In many species the foliage, or rather the general effect of the leafage, is very striking and beautiful. In this kind, however, its leafage is more picturesque than beautiful, and here and there its little globular heads, that rather add to a general quaintness of form, are distributed.

Primula Reading Blue.—So far as size and colour are concerned, the above is one of the finest of its race yet raised. It is of the so-called giant race, all of which are notable, not merely for size, but for the fine form of the individual flowers. With these improvements the very desirable quality of sending the spike or truss well above the foliage is a point also achieved, with the result that a handsome pot plant is secured.

Rhipsalis cassytha.—This is a very curious-looking plant, the nearly transparent berries of which may almost be taken for Mistletoe. Rather less in size perhaps and somewhat more clear, there is still a similarity all round that is more than feebly supported by the very position the berries occupy on the nearly or quite succulent stems. It is a curious-looking plant, and little bushes of a few inches high usually carry a fair number of the berries referred to.

Chrysanthemum Owen's Brilliant.—I have at the present time (December 19) some good blooms of the above-named variety not quite full out. It is the darkest crimson variety I have seen. It is of about the same size as John Shrimpton, but grows a little taller. It is very shy of throwing up cuttings, which, perhaps, makes it so scarce, as one hardly ever sees it in a collection of *Chrysanthemums*. It makes a good companion to Golden Gate and Niveum. I fear these medium-sized *Chrysanthemums* are being overlooked for the large-boomed varieties. The medium-sized blooms are the best for cutting, as the petals are not so long, therefore the flowers stand better when cut.—W. DANIELS.

Chrysanthemum Letrier.—The group of this brought to the last meeting of the Drill Hall committee for the present year attracted a good deal of attention. Grown in bush form and not 4 feet high, it appeared an ideal kind both for bush and late work. It would in some respects appear superior to L. Canning, a kind that frequently shows a black eye, which materially detracts from its value as a white flower. In no bloom did we note this defect in the variety Letrier, which, being of the same type as Niveum and L. Canning, usually display this defect quite early.

Chrysanthemum Mrs. J. Thompson.—When grown freely there is a strong likeness between this and that much older and, perhaps, rather later-flowering kind, Lady Lawrence. The

similarity is, however, more on the surface than real, for a touch of the petals reveals the fact that the above is devoid of the paper crispness that is not merely a characteristic of the latter, but that greatly assists to its longevity. For purity, however, the above is well worth noting, and equally so for its lateness. Add to these its better habit of growth and its greater vigour of constitution, and you have many of the requirements of a good late white embodied in one and the self same plant.

Woodwardia radicans.—In large conservatories this handsome Fern is often very striking, the huge and finely arched and well-proportioned fronds stretching out several feet from the crown and again descending to the earth, there again quickly to mature a future crown and plant. The plant is at home in the cool conservatory, and where freely in growth is not easily overdone with moisture. To some extent this much would be assisted by the position the plant should occupy, and this, owing to the nature of growth, should always be elevated. At the same time a large pocket of soil should be provided for the roots, as these, in common with the handsome fronds, are strong and vigorous.

Reinwardtia trigyna.—One thing that renders this plant more than usually attractive is the richness of the golden orange blooms, few of this colour being found among the usual run of winter-flowering plants, and not merely in colour, but equally for the great profusion of flowers is the plant welcome. It is usual to raise stock from cuttings, but anyone able to secure seeds will find the resulting plants of a more vigorous type. Occasionally when the plants are grown under too dry atmospheric conditions red spider attacks result, and these must be guarded against. The cuttings taken from old plants that have been infested will render a renewal more certain, and in any case a watch must be kept over the plants. By growing in cool pits during summer and using the syringe freely there is hope of keeping the pest in check.

Two indispensable Chrysanthemums.—The ordinary gardener who has to supply large quantities of cut bloom has to ignore many of the grand exhibition varieties, which are all very well if disbudded to a single flower on each stem and liberally fed. But, grow the same sorts in bush form or for quantity, practising little or no disbudding, and disappointment is in store. There are two very old varieties which cannot be dispensed with, as, given well-grown plants, one may cut and come again, and for beauty either in the conservatory or cut, few equal them in their respective classes. I refer to Julie Lagravère and the Anemone pompon Marie Stuart. The latter is not only exceedingly beautiful in drawing-room glasses, but such a vigorous grower, that from a spring-struck cutting large bushes may be grown.—C. N.

Fuchsia pumila.—Winter brings to the grower of hardy flowers many doubts regarding the lives of the plants he has obtained under the impression that they are able to withstand the

vicissitudes of our seasons. Many of these plants only bring disappointment in this. Sometimes the first winter proves fatal, but often they only succumb when an unusually severe season comes. Those of similar tastes can do much to aid each other in advising what to grow and what to avoid. The Fuchsias are mostly so graceful in habit and flower, that those which are hardy ought to be more widely grown. Among these may be included the pretty little *F. pumila*, whose slender, dwarf habit and bright flowers render it a favourite plant for the rockwork or the border. It is, we are told, a variety only of *Fuchsia macrostemma*, and it closely resembles in its general appearance the variety *gracilis*, but is dwarfer and smaller in all its parts. I have seen it in a good many districts, and in all of these it is considered as hardy as it is here.—S. ARNOTT, *Dumfries*.

Malvastrum Gilliesi.—One seldom sees this pretty little Mallow-wort even in large collections of alpine flowers. It is, nevertheless, a neat little plant, albeit it does not appear to be long-lived in many gardens. It is, I believe, hardy enough, but I am inclined to think that it requires to be propagated occasionally or the old plants will die out. It is of trailing habit, the trailing shoots emitting roots as in the Strawberry. Old plants appear to become exhausted, especially if the soil is too dry. It grows about 6 inches high, and has pretty, neatly cut leaves and a number of purple-crimson flowers. It is still met with in a few catalogues under the name of *Modiola geranioides*, but *Malvastrum Gilliesi* is recognised as the correct one. I grew it here for several years and found that it did not suffer in winter, but that dry summers were very injurious to it. It requires sun, but I am of opinion it does best with a fair amount of moisture at the blooming season.—S. ARNOTT, *Carse-thorn, Dumfries*.

Epimediums.—At this season one is attracted by the foliage of one of the Barren-worts, which reminds us of their gracefulness in spring and summer. One thinks that a brief note may be serviceable in drawing the notice of some to these flowers, so that they may be remembered when plants are being obtained in spring. The one I observed in my garden to-day is *Epimedium pinnatum*, whose leaves are as fresh and green as if the frost we have had did not come near them. It is a pretty species with clusters of yellow flowers in racemes in summer, and grows in light soil to nearly 18 inches in height. The young leaves of the Barren-worts are prettily coloured and are thus very attractive. *E. pinnatum*, which comes from Persia, is one of the finest of the genus. *E. alpinum*, which is naturalised in Britain, is also pleasing with its crimson and yellow flowers. *E. macranthum*, with white flowers, is perhaps the finest of all, but the dwarf *E. Musschianum*, although not so pure, is one of my favourites. One great merit of the *Epimediums* is the way in which they thrive in shade. Even under trees, where not so many plants flourish, the Barren-

worts seem quite at home. For naturalising in woods they are of great value. I know a bank, by the side of a small lake and under the shade of overhanging trees, on which *Epimedium alpinum* has been established and where it forms a pretty picture against the other vegetation on the bank. These plants prefer a peaty soil, and in such soon increase. They do fairly well in the border, but look their best when planted in a more natural way among other herbage of dwarf growth.—S. A.

Gaultheria procumbens.—We have had several falls of snow, alternated by thaws which have carried away the most of the wintry covering of the flowers. As I write, here and there appear green patches showing objects of interest to flower lovers. On a small level at the shady side of a rock garden and in moist, peaty soil one observes a nice little patch of *Gaultheria procumbens* (the Partridge Berry or Canadian Wintergreen). It is pretty at all seasons, though one usually needs to examine it a little closely when in bloom if he wishes to see the beauty of its waxy-white, drooping, bell-shaped flowers. At this time its attractions are more evident. The flowers have departed, and in their place have come the pretty little berries, whose red colour is so acceptable amid the snow. I believe they are edible, but one feels unwilling to test the statement, not from any fear of the consequence, but because of unwillingness to deprive the plant of any of its beauty. Perhaps the birds will be a little less scrupulous. The red berries are, however, not the only charms of the "Canada Tea," as it is also called, as the leaves are now prettily tinted with red as well. *Gaultheria procumbens* is so dwarf, that even those who have but little space can grow it without its being out of place, while the largest garden can find a place for it in a shady spot in sandy peat or loam. It is, we are told, found in the sandy places and cool, damp woods of North America, and grows there in the shade of evergreens as well. Had it been a now plant, this creeping Wintergreen would have received more notice than it does. The beauty of plants which have been long introduced to British gardens is often unobserved, while we speak with glowing terms of novelties often of less value. *Gaultheria procumbens* came to British gardens as far back as 1762. It deserves to be found in many in which it has not yet a place.—S. ARNOTT.

The lerot.—The lerot, I find, is known in common parlance as the garden dormouse, and scientifically as *Myoxus nitela*. It is well known on the Continent as a destructive pest to fruit. The dormice are not true mice, and belong to quite a different family, being in certain characteristics more like squirrels.—GEO. S. SAUNDERS.

M. Henry de Vilmorin.—Owing to delay consequent on the Christmas holidays, we regret we are unable to publish the portrait of M. Henry de Vilmorin, to whom this volume is dedicated.
