IN spite of many different ways of treating this *Dendrobium*, very few growers can say they are really successful with it, and I am inclined to think that in many cases where the plants have gone on well for a time this has had more to do with the plants themselves than any special treatment to which they have been subjected. Plants collected at the proper time—and this, of course, varies with individual species—are always better the first season and longer-lived afterwards than are others that have been collected too early, *i.e.*, before the growths are properly finished, or too late. In the latter case the eyes at the base of the stems break into growth, and it is well known that secondary growths, or back-breaks as they are termed, never make such good progress as do the natural first-formed ones. This individual species does not usually arrive in bad condition, but, as is well known, it flowers at once upon the new growths when made, and in many cases the plants are collected before this happens, and the first thing they do is to flower. The fact of the flowers being produced and kept on until they fade before the plant has had time to establish itself is enough to account for the plant starting weakly and never again taking a proper hold of the block, basket, or whatever is used for it. The best plan I know of to establish *D. formosum* is to attach the plants to blocks of some kind and place these in a hot, moist house where they will obtain ample light. If flowers appear they should be rubbed off, and then the energies of the plant will be devoted to the production of good roots, which will establish the plant and strong young growths. Although the block treatment seems rather poor, perhaps, after the first season, I am of opinion that if only plenty of moisture is present in the atmosphere the plants are safer there than anywhere. On more than one occasion I have sunk the blocks in baskets or pots, filling up with compost, but I have nearly always found that after a year or two they go wrong, while others kept to the blocks alone keep going though the growths may not be so strong. *D. formosum* likes a good rest after flowering, but, unlike the deciduous kinds, it does not need to be placed in very cool quarters. There is no need, in fact, to remove it from the house where grown if other tropical Orchids are included. Although the flowers of *D. formosum* are useful for decoration, they are not so pretty as are those of many others in the genus, but they make a good display at rather a quiet time of year for Orchids. H. R.

Oncidium undulatum.—When well grown this is a very fine plant, and one that certainly should be included in all collections of cool-house Orchids. After the prevalent tint of yellow in the genus, beautiful as they all are, a change in colour is very welcome, and in this we get a very distinct one. The sepals are brown, the petals white, with brown markings, and the lip has a bright rosy purple tinge tipped with white. It is not uncommon for the spikes to attain 4 yards or more in length, and they have a very pretty effect if allowed to ramble somewhat loosely about the foliage and stems of Palms or Tree Ferns in the

conservatory. It will be necessary of course to see that they are not exhausted, as the long flower-spikes take many months to form and constitute a severe strain even upon the strongest plants. The roots of *O. undulatum* are large and vigorous, they seem to delight in rambling about over rough lumps of charcoal and crocks, so in preparing the compost, let these be in plenty and let the pots be large enough to take them easily. When repotting set the leads rather low to counteract the habit the plant has of rising above the compost. When the young roots appear from the base of the forming pseudo-bulbs, these should be covered up with a little fresh compost, or insects will probably find them out and eat the points before these reach the compost. It may be kept in the cool house all the year round and always moist at the roots.

Cattleya Whitei.—This is one of the most beautiful of the natural hybrid Cattleyas. It is always interesting to note an additional form of a scarce plant wherever it may make its appearance. *C. Whitei* has been for many years one of the rarest of the natural hybrid Cattleyas. The original plant was sent to Messrs. Hugh Low and Co. from Brazil by their collector White, who is said to have found it growing on the same tree as *C. labiata* Warneri and *C. Schilleriana*. This plant afterwards passed into Mr. Gaskell's collection, near Liverpool. The flowers were described by Reichenbach as being of medium size. A plant was recently noted in flower in the collection of Sir Frederick Wigan at Clare Lawn, East Sheen. The flowers measured upwards of 8 inches across the petals, each petal being upwards of 2 inches broad. The sepals are of a deep rosy purple suffused with a peculiar bronzy tint. The ground colour of the petals is similar to that of the sepals, with some white at the base, the whole surface heavily veined with a darker shade of purple. The lip is open in front, as in *C. Schilleriana*. The whole of the front lobe is bright crimson-purple with a heavily fringed margin, the side lobes rose-lilac tipped with the purple of the front lobe. At the base there is some yellow, which is suffused and longitudinally lined with brownish purple. The plant carrying a two-flowered raceme has the intermediate characteristics of *C. Schilleriana* and one of the *C. labiata* group. It may be noted that the plant differs not only in size, but also in the published description, from that of the original plant, but the general characteristics are undoubtedly the same. It is a grand addition to the Cattleya family, and it is to be regretted that such a fine plant does not appear more frequently.—H. J. C.

NOTES AND QUESTIONS.—ORCHIDS.

Odontoglossum hastilabium.—The flowers of this are quite distinct from those of any other *Odontoglossum*, and although it is not much grown at the present day, it is certainly worth a place in the best collections. From an almost spherical bulb it throws up spikes 4 feet and upwards in length, and these continue in flower a long time owing to the blossoms not opening simultaneously. The sepals and petals are greenish white, barred with purple, the lip white, stained with purple-rose.

Zygopetalum Mackayi.—There are some really fine specimens of this useful winter-flowering Orchid in Colonel Heyworth's garden at Chadacre Hall, the pseudo-bulbs finishing up of immense size and flowering with freedom annually. There is no doubt that, in common with several other old-fashioned Orchids, this is more frequently met with in good condition in places where no particular attention is paid to Orchids and where they are grown in plant stoves than where Orchids are specially cultivated.

Masdevallia infracta.—This is a singularly formed and very pretty species, the tube and sepals varying in colour from yellowish and white to purple. It is quite distinct from any of those of the showy flowered kinds, like *M. Harryana* and its allies, and is not much grown. It is a Brazilian species, and is therefore found a long way from the usual *Masdevallia* country, and, like one or two others, it likes a temperature a little higher than the coolest house in winter, with the freest ventilation possible under the circum-

stances and ample light. In summer it can hardly be kept too cool, and must be screened from the sun.

Masdevallia leontoglossa.—To lovers of quaintly formed and coloured species this singular and rare species will appeal. It is named from a likeness which the lip undoubtedly bears to the tongue of some of the large quadrupeds. The leaves are about 6 inches high and the flowers of mostly a pale yellowish green, with more or less confluent spots of purple on the lower sepals, the upper triangular segment lined with rosy purple. About the lip are many short hair-like papillae of a deep port wine colour.

Lælia elegans Masteri.—In this variety, which is one of the prettiest of the light forms, the sepals and petals are nearly pure white, with a faint streak of rose only at the base of each. The lip is margined on the side lobes with violet-purple, which, in addition to the usual bright blotch in front, gives the flower a distinct appearance, the colour-marking being so well defined. *Lælia elegans* in its many forms is one of the most useful of Orchids, and it certainly keeps up a longer display than almost any other.

Cattleya guttata Leopoldi.—Occasionally plants of this species throw up remarkably fine spikes of bloom, and when they do so there are few finer kinds in the section to which it belongs. The growth is erect and forms quickly, and the spikes often contain eighteen or twenty flowers. The sepals and petals are brownish green, with crimson spots, and the lip is broad and handsome, bright amethyst-purple. It flowers at once upon the newly-forming stems, and should, if possible, be kept at rest after the flowers are past.

Epidendrum aurantiacum.—In habit this plant closely resembles a Cattleya, and under cultivation it will be found to thrive if treated as advised for these plants. The flowers appear from the apex of the last-formed pseudo-bulb, on peduncles containing about twelve. They are small individually, but very bright and pretty, the colour orange-red, with a few greenish yellow markings. *E. aurantiacum* is a strong-rooted plant, and if grown to a fairly large size should have abundant drainage, as well as rough lumps of crocks and charcoal in the compost.

Oncidium maculatum.—Once very popular this old species is now very seldom met with. The branching spikes rise about 18 inches high and contain a large number of flowers, each about 2 inches across. Very variable in its markings, it is usually some tint of yellow or greenish yellow in ground colour, more or less closely covered with chocolate-brown spots. The plants should be grown in a free, open compost in the coolest part of the Cattleya house or with the Mexican *Lælias*. Plenty of water is necessary while the growth is active, occasional light syringings being helpful.

Dendrochilum filiforme.—Those who have nice specimens of this pretty Orchid now in flower should be careful not to have them checked by being placed about in draughty passages or rooms, or by being dried at the roots. The pseudo-bulbs at the time of flowering are only partially grown, and any check in the nature indicated will of a necessity show itself in small bulbs and weak flower-spikes another year. Very pretty are these little spikes of yellow blossoms, and from their appearance when in bloom, the plant has been called the Golden Chain Orchid. The best position for it is one close to the roof glass in a warm house.

A NOTE FROM MUNCHES, DALBEATTIE, N.B.

LYING in a mild corner of S.W. Kirkcudbrightshire, near the Solway, and in a mild and equable climate, Munches, the estate of Mr. Wellwood H. Maxwell, has long been known for its trees, shrubs, and flowers. In the course of a long and busy life Mr. Maxwell has always had a keen interest in plants, and the result is now to be seen in the extensive and varied collection which I had recently the pleasure of visiting. Possibly only an expert in trees could do justice to the trees and shrubs, but anyone to whom gardens are familiar could not but feel keen pleasure in the many beautiful specimens to be seen. Many shrubs seen, as a rule, of small size have been so long at Munches that they have attained large dimensions and show their true character. Notable among these are some superb *Retinosporas*, justly pointed out with pride. *Sciadopitys verticillata*, the Umbrella Pine, twenty-five years

planted, is now 15 feet high, and flourishes in the peaty soil in which it is grown. *Cryptomeria japonica elegans* is very beautiful also. Very beautiful also was a good specimen of the white Douglas Fir (*Abies Douglasi* Stairi), raised originally at Castle Kennedy. It is rare, but, as Mr. Maxwell said, need not be so little seen, as a large proportion of seedlings comes true. Fine also was *Picea Engelmanni*. Some noble specimens of *Wellingtonia gigantea* gave one much pleasure, while a magnificent Scotch Fir of great age could not fail to impress one with its rude grandeur. There are many beautiful conifers, to which only the pen of a specialist could do justice.

Among the noteworthy things are the Maples. Many forms of the Acer are represented, and the collection is especially rich in the Japanese Maples. Some were imported direct from Japan, and a number have now attained a good size, so that their beauty can be more fully realised. The silver variegated Maple (*A. Negundo argenteum variegatum*) is represented by two of the tallest specimens I have ever seen. Space will not permit of further reference to the trees and shrubs save a passing mention of the Cornuses, *Viburnums*, Birches, and to the fine masses of *Parrotia persica*, beginning to colour for the autumn. The collection is particularly rich in variegated, dark-leaved, and weeping forms of the various trees.

The glass structures are particularly interesting to those who care for out-of-the-way plants such as one does not, as a rule, see outside botanic gardens. There are numerous out-of-the-way flowering, fine-foliaged, and fruiting plants such as would take long to see and to write of. I observed the fine *Datura Knighti* on the roof of one of the houses with an *Ipomœa*, which appears to be *I. Leari*. It would, however, take too long to comment upon a collection which includes not only old and generally neglected plants, but such as the recent *Acalypha Sanderi*. Indoor and outdoor fruit was plentiful and generally good, pleasing features being the Pears in the orchard house, the Guavas, the edible Passion Flower, the Capo Gooseberry, and a capital crop of Grapes.

The flower garden gives as much evidence of catholicity of taste as the houses. A small garden which occupies the site of the old house of Munches is planted with a good variety of herbaceous plants, supplemented in autumn with annuals. As is general in the district, the hardy annuals are poor, and they are much missed. Among the flowers grown are *Alstroemeria chilensis* and *A. aurantiaca*, which do well. *Delphiniums*, *Campanulas*, *Poppies*, and other border flowers of merit share with choice and pretty shrubs this small garden.

In the large garden one saw many Cactus and single Dahlias, some capital Asters (a little smaller than usual on account of the drought), good Stocks, and a number of *Gaillardias*. Carnations do not succeed well, but the Margaret Carnations take the place of the more highly prized named varieties. Sweet Peas were good in an open portion of the garden, but nearer the walls they were not so satisfactory. Among the perennial plants was *Gentiana lutea*, which had given a grand spike of flower several feet high and was in seed. It is, as is commonly the case, a shy bloomer at Munches. *Rudbeckia laciniata* Golden Glow was represented by a fine plant, and in the woods *Veratrum* were giving good spikes and blooming freely. *Gazania* were glowing in the sun, and a group of *Crozy's Cannas* was finely in flower. Perhaps the most interesting thing to a hardy plantsman was, however, a line of ten or a dozen plants of *Incarvillea Delavayi*. Raised from seed sown about five years ago, they seem to be yearly increasing in size and vigour. The plants have this year given an average of four spikes each. The bloom was over and the plants were in seed. A spike I measured was 52 inches long, and one can understand how well worth seeing these plants must have been. Munches is, indeed, one of those places which are difficult to tell about, not because of lack of

material, but because of its superabundance. It is the result of long years of care—care inspired by its owner's love for the beautiful works of Nature as displayed in trees and flowers.

S. ARNOTT.

STOVE AND GREENHOUSE.

HYACINTHS IN POTS.

THE foundation to a successful flowering of these, as with other spring bulbs, should be made in the autumn, by potting at the proper time, so that a plentiful supply of roots may form before any kind of forcing is started. I have known the bulbs potted late in the season and plunged straight away into heat, with, of course, anything but good results. In such a case the blooms usually rot instead of grow, and if they do show signs of life, the trusses hardly push up clear of the bulb. September is a good month for potting Hyacinths, and those that are required for forcing should be so treated early, following with later batches. The soil used is loam two parts, not sifted, good dry, rotten manure one part, which may be passed through a sieve, and half a part of grit. I use road-sweepings obtained after a heavy storm in preference to sand, because they are coarser and tend to keep the soil open. This compost is prepared by being thoroughly mixed, and if very dry, watered to make it in a medium state of moisture, that it may be properly handled. Five-inch pots are used for one bulb, and three bulbs are also put into pots of 8-inch diameter. These latter make showy specimens for the conservatory. In this instance, too, I am careful to select each of the three bulbs about even in size, so that there shall not be an odd look in the spikes of blooms.

The larger pots may be well drained, but one piece of crock is all that is required in the smaller. Fill these with soil and press the same down firm, but not extra tight, then scoop out a hole with the fingers to take each bulb. This is a small detail, but the practice of pushing the bulb down into the soil is bad. The part under the bulb becomes too firm by so doing, and when it starts making roots it is liable to be forced out of the earth by that process. Do not water the bulbs after potting. This is not necessary when the soil is moist. Stand the pots on a sound bottom of ashes in a frame if possible. One might then easily put the lights on later in case of much rain. Cover the bulbs, pots and all to a depth of 6 inches with cocoa fibre. This material is lighter and better than ashes and the latter may contain sulphur, which would be detrimental to growth. The Hyacinths are thus placed in the dark to make roots and not tops, and they may be practically forgotten for about six weeks. After that time examine them. Should growth be so forward as to exhibit the blooms in a small state in the cluster of leaves, remove the pots at once from the fibre; if left longer there would be danger of rotting. Gradually bring the growth to the light. This may be done by placing inverted flower-pots over each bulb for a few days. An ample supply of roots should be noticed by their running out of the drainage hole and on the surface of the soil. If in this condition, one has obtained the secret, if any, in the proper development of Hyacinths. Many think that big bulbs must be had to produce large spikes, but I prefer medium-sized, well-ripened ones, and depend more upon plenty of roots.

It is not advisable to allow frost to penetrate the frames. This cripples the growth, and for this reason it is better to remove the pots to greenhouses where fire-heat is only used in

severe weather. The shelves near the glass are a good position. Here a sturdy growth is assisted. Little water is needed, although I would not let the soil become over-dry. Steady, cool progress is best for Hyacinths, and generally they do not force well. A few kinds, however, may be had in bloom so early as January. Blanchard and La Tour d'Auvergne, two whites, the one single, the other double; Amy, red; Charles Dickens, blue, also the pink variety of this, are a few kinds better than the rest for forcing. Use tepid water; this even when not forcing, as the roots are easily checked. Also use no stimulant whatever before the blooms show colour, the object being to keep the leaves as low as possible. This period reached, I feed the plants at each watering with soot water and nitrate of soda alternately. What is required is something to quickly push out the bells to their utmost size.

There is a great deal of waste in connection with spring bulbs. They can hardly be made to produce blooms the second year equal to the first, but very nice useful spikes can be had by not neglecting the bulbs when the flowers are past. We usually find the roots stood in some out-of-the-way part of the garden and forgotten. If rain comes with regularity all is well, but when this is not the case the bulbs perish. Cut the flower-stems off the moment they have passed perfection, then stand the pots in a sunny position. Keep the soil regularly watered until the leaves die down naturally. The bulbs may then be shaken from the soil, dried, and stored for use again in autumn.

The following are the names of a few sorts found most reliable. They are single. Double Hyacinths are less showy and useful. Whites, La Grandesse, Mont Blanc; blush-white to rose colour, Princess Amelia; pink, Charles Dickens, Moreno, Fabiola, Koh-i-nor (semi-double); light to dark red, Robert Steiger, Lord Macaulay, Vurbaak, General Pelissier; blues, Czar Peter, Queen of the Blues, Charles Dickens, Lord Derby, King of the Blues, Grand Maitre. King of the Blacks, very dark, is always admired. Ida and King of Yellows are good of the last named shade. H. S.

ACHIMENES.

SOME time ago I was pleased when visiting Carron House Gardens, Norwich, to see such a fine batch of Achimenes there in full beauty. Unfortunately, they have of late years fallen into disrepute, a deal of time and trouble being expended on subjects far less useful and ornamental. One used to see them exhibited in large bush form at the London shows, these being grown in pans. One of the chief points in their culture is preserving the corms in a plump condition during the winter. I have known them stored away in boxes of silver sand and kept in a cool place, the corms under this treatment keeping sound and plump till wanted in spring. Others turn the pots on their sides after the growth has died down in autumn, keeping them in the greenhouse through the winter. The time of starting must depend entirely on the date at which the plants are wanted to flower. If in May, place them in heat in January; if in June, February, and so on; March and April potting securing flowering batches in August and September. Some growers place the corms in the pots in which they are to flower, others preferring to start them rather thickly together in pans or boxes and finish off afterwards. Both systems no doubt have their advantages. Thorough drainage is imperative, as Achimenes cannot endure a waterlogged condition, yet require

frequent supplies of moisture when in full growth. Some growers pass the soil through a rather fine-meshed sieve, but I prefer rubbing it down with the hand, preserving all the fibre, as these plants enjoy a free, open root-run. A light fibrous loam, with a fifth part cow manure reduced to the condition of fine mould, leaf-mould, and coarse silver sand will grow them well. An ordinary plant stove suits early batches best, but they must have a light position tolerably near the roof glass, a slight shade being given from the full force of the sun. This shade is also necessary in order to prevent scorching, which is very apt to occur by the sun coming on the moist foliage early in the day. Draught also quickly makes its mark, for which reason front air ought not to be given till June. Early closing, coupled with copious overhead syringings, is essential to a free and rapid growth, and when grown for exhibition the young plants should be pinched when from 4 inches to 5 inches high.

For exhibition, wide pans are the most suitable, but for ordinary purposes pots $4\frac{1}{2}$ inches or 6 inches in diameter are best. When well established, weak manure water made by steeping a bag of sheep manure in a tub of water may be given three times a week. As soon as the bloom shows itself, plants occupying a warm stove temperature should be removed to a somewhat cooler one, as flagging and partial collapse will follow any sudden removal from a stove to an airy conservatory or exhibition tent. For later batches cooler treatment answers best, and Achimenes may be retarded for a considerable time by placing them in a house with a north aspect. C. N.

Vallota purpurea.—The brilliantly coloured flowers of the Scarborough Lily come in most useful for conservatory or room decoration at a time when the variety of pot plants in bloom is rather limited, and as it is of very easy culture it is surprising it is not more largely grown. Some good turfy loam and a little leaf-mould and sand are all it needs, and pots about 6 inches in diameter with from five to seven good strong bulbs will make a good show. The bulbs may be kept two or three years in the same pots, as they do not like too frequent root-disturbance; in fact, one finds old clumps that have not been repotted for years flowering splendidly.—J. G., Gosport.

GARDEN FLORA.

PLATE 1238.

TALL-GROWING HYBRID HERBACEOUS LOBELIAS.

(WITH A COLOURED PLATE.*)

THE beautiful free-blooming and almost hardy forms of hybrid Lobelias figured on the accompanying coloured plate are hardly done full justice to as to size of their individual flowers in this illustration, as the flowers of most, if not all, of them are considerably larger in my beds this season than they were when the drawing was made last year. Monsieur Rivoire, of Lyons, has done more for the improvement of this class of Lobelias than any other raiser, though to Mr. Campbell, gardener to Lord Ardilaun, we are indebted for Firefly, one of the brightest and largest flowered in cultivation. Of the varieties figured on this plate the one on the left is named Rivoirei, and is an extremely beautiful variety and quite a new break as to colour; the next is Ibis, quite one of the most beautiful and free-blooming of them all. The dwarf one is a pretty little miniature form named Belle Bordure. The

* Drawn for THE GARDEN by Miss Tisdall in Mr. Guibleton's garden at Belgrove, Queenstown, Cork. Lithographed and printed by J. L. Goffart.

very dark one is *atropurpurea*, one of M. Rivoire's seedlings. The pure white form is a very free-blooming form of the syphilitica section of the family named *Papillon Blanc*. The crowns should be divided in the spring and quickly increase. W. E. GUMBLETON.

THE WEEK'S WORK.

KITCHEN GARDEN.

TURNIPS—LATE SOWING.—If the first sowing of Chirk Castle or other favourite variety was made when advised, the crop will now be ready for thinning. Allow ample room between the plants, as without a free circulation of air satisfactory results cannot be expected with Turnips which are to stand the winter. Crowded plants have flabby foliage, which is sure to suffer if the winter is severe. Make now a final sowing of Chirk Castle, and this will afford good sized bulbs during December and January, and likewise tender green tops, these being esteemed in the dining-room for a change. Should the Turnip fly show itself when the seedlings appear above ground, as it sometimes does even at this advanced date, liberal dustings of soot and lime must be given; at the same time a little guano may be added, which will stimulate growth as soon as rain comes.

CABBAGES.—In large gardens where extra early sowings of spring Cabbage were made, the plants will by this time be large enough for transplanting. In dry seasons like the present the advantage is seen of having a firm root run. On newly-turned ground plants do not become established nearly so soon, and drought very soon affects them. Where, however, the plot has now to be prepared, let it be deeply dug and well enriched with manure from the farmyard or piggery. I would not advise, even where ground is scarce, planting on sites recently occupied by Cauliflower, or attacks from the mite which so often injures the latter crop may be apprehended. It is a capital plan to sprinkle a little fresh lime on the surface, digging it in with the manure, also a little soot. These ingredients will not only stimulate growth, but also assist in eradicating the greatest enemy of autumn-planted Cabbage and Coleworts—the underground grub. If these early batches of Cabbages were pricked off from the seed-beds on to a spare plot when large enough to handle they will now lift well, a good ball to each being obtainable. On no account lift the plants without previously giving a good soaking with water through a rose. This should be administered the day previous. If the weather is dry and this precaution is not taken, the bulk of soil will leave the roots and flagging, with probable loss of lower leaves, follow. Plant with a trowel, allowing a space of 2 feet from row to row and 18 inches between the plants. Plant in drills of moderate depth, water home, and draw a little soil round the collars to prevent evaporation. Some water the drills the day before, which is a good plan in dry summers. Plants resulting from seed sown about August 20 will now be ready for thinning. When far enough advanced I would advise the pricking-off system even in the case of these successional batches.

MICHAELMAS CABBAGE.—This term is applied to plants grown in some localities for coming into use at the end of September and during October, secondary transplantings from the same seed-bed resulting in nice white heads during November, these being delicious after having been subjected to a few keen frosts. These batches should now receive one or two good waterings with liquid manure, no matter how copious the rains may have been, as at this stage they draw much nourishment from the ground. Keep the Dutch hoe moving between the rows not only with a view to eradicate weeds in their infancy, but to admit sun and air. Where old fly or caterpillar-infested plants are growing near at hand, they must be cut hard back and allowed to make new growth, or

the pest will probably find its way to the younger beds.

GENERAL WORK.—The Dutch hoe should now be put through all growing crops for the last time, as, in spite of absence of rain, night dews have induced many tiny weeds to spring up. If this batch of weeds is left alone and the winter proves mild, the probability is that the seeding stage will be reached, which is an evil. Any late-planted quarters of winter stuff if yet unearthed should be done at once, for the double purpose of steadying the plants against rough winds and protecting from frost. Where practicable, cut now a quantity of the common Bracken, and when by occasional turning it has become well seasoned, cart home and stack. This will prove invaluable in winter for covering Celery ridges, Globe Artichokes, and for protecting Lettuce, Endive, and other crops in frames and pits. J. C.

FRUITS UNDER GLASS.

PEACHES AND NECTARINES.—Midseason houses will now be cleared of fruit, and every chance should be given to the trees to ripen off their foliage slowly and naturally by providing plenty of air night and day and by keeping off insects with a free use of syringe or garden engine, the latter for preference, as in houses of good size syringing is apt to be done in a slipshod fashion and with less force than a good engine will give. It is a great boon to Peach and most other hardy fruit trees grown under glass if they can be exposed for the few autumn months to full air and the night dews, which seem to greatly invigorate them, and to this end I would always recommend medium-sized houses from which the lights can be removed at this time of the year, provided the houses are so constructed as to be practically drip-proof when the lights are in use. If any planting is contemplated in the Peach houses, it will be advantageous to prepare a heap of compost for the purpose beforehand, and sufficient should be got ready now, or as soon as the opportunity to prepare it arises, to serve for all the planting that is to be done in any of the houses, as the ingredients used get better toned down when well mixed in bulk some weeks before the trees are planted. Recently when writing of early Peaches I went rather fully into the subject of replanting and the soil which I preferred for the purpose, but I may repeat, in short, what the ingredients are, viz., good, sound fibrous loam chopped up into cubes about 2 inches square as the staple, mortar rubbish in quantities varying with the nature of the loam, but sufficient to ensure porosity, lime in the slaked, powdery state, and burnt earth from the garden smother. I use no animal manure, but add a few crushed bones when the border is made entirely inside. If turfy loam is only to be got in limited quantities, almost any ordinary garden soil can be used to make up the deficiency, provided it is sweet.

POT TREES.—The present is an excellent time for potting on any of the orchard-house trees that may need it and which have been cleared of their fruit, whether these are Peaches or any other of the mixed occupants of the ordinary orchard house. Trees which have reached their limit as to size of pot or other receptacle need to be carefully managed, as the balls must be slightly reduced in size and the roots carefully pruned in order to make room for new compost. Those which can be afforded more room will only need a slight disturbance of the soil round the outside of the ball, using for the purpose a pointed stick, which should be kept clear of any large roots. The crocks, too, should be removed carefully so that the ball may be placed low enough in the new pot. Cover the drainage with tough turf, cut thin, and ram the new soil in round the ball as firmly as possible, as with the soil in good condition as regards moisture it is not easy to over-do the ramming. Of course, the old ball should have a good soaking of water some hours before potting takes place. If the newly-potted trees could be placed under cover, kept shaded and syringed for

a few days, they will be grateful for the attention and will hold their remaining leaves without any assistance of water at the roots until the latter begin to be active again, after which the trees may be returned to the open air and treated in common with those left undisturbed.

POT FIGS.—I like to pot up early Fig trees much earlier in the year than this, but those who intend adopting the usual practice of autumn potting should not leave it any later. Similar soil to that recommended above for other fruit trees will be found suitable for Figs. In the case of trees which have not well filled their pots with roots it will be advisable to remove a good bit of the old soil to make room for the newer and sweeter compost, which should induce better root action. All the pot stock of Fig trees should now be in the open air and in a good sunny position, but the pots should be protected from the full force of the sun-heat by covering them with litter or some other such protective material.

MELONS.—The bottom-heat in which the late crop of Melons is growing will now need careful regulating so that it does not drop too low, as a lowering of the temperature about the roots, risky at any time, is doubly so now, and would certainly result in watery, ill-flavoured fruits, even if it did not stop them from swelling altogether. Very great care is also needed in watering as regards the temperature of the water used, which should be above that of the bed or the soil in which the plants grow, the method of its application, keeping it well away from the stems of the plants, and in the quantity used, which should only be sufficient to moisten without absolutely soaking the soil. After the Melons begin to net, heavy soakings are dangerous, as the fruits are almost sure to split before they ripen, and they will then be useless. Shut up the house quite early and avoid syringing late in the afternoon, as the leaves ought to be dry before night. Atmospheric moisture may be kept up by sprinkling the floor and walls as often as necessary, and this should be sufficient without any overhead syringing after mid-day. The things to be avoided with Melons, at this late date especially, are checks—on the one hand, by lowering the temperature about the roots, and on the other, sudden impulses by heavy waterings. Keep all lateral growth stopped back closely and frequently, so that the foliage of which the plants are divested at any one time is thin. Weekly fumigations up to the time of the fruit netting are necessary to keep down fly.

BANANAS.—Those plants which are showing for fruit should be well fed with liquid manure at each watering, and excessive humidity of atmosphere must be avoided. Ventilate the house for a few hours daily, but always keep the tropical habitat of the plants well in mind. If any of the stock has reached what ought to be fruiting size without showing signs of fruit it will be best to keep them a little on the dry side for a week or two until the spikes appear, after which more liberal treatment is desirable. Where there is room for a fairly continuous supply of plants and it is thought advisable to pot up more suckers this year, these should be detached as soon as they get big enough and potted up, plunging the pots in bottom heat at once, so that a goodly quantity of roots may be formed before winter. Later stock, or that which generally gives the yearly supply of plants, may be left attached to the parent plants until after the turn of the year. A good sucker plant taken off when the parent has ripened its fruits and carefully treated until established will generally make a plant of the best sort for fruiting next winter or spring at a time when the supply of good home-grown dessert fruits is at its lowest ebb, and if this is the only crop of Bananas needed, forward suckers may be sacrificed with advantage. CORNUBIAN.

Leaves prematurely falling.—A lesson may now be learnt with regard to the manner certain trees and shrubs can endure the exceeding heat and drought. Lilac bushes, ever a dense mass of

roots, are affected everywhere, and in thick shrubberies still worse. The Horse Chestnut even in some isolated positions has been quite a wreck for a long time, shedding its leaves abundantly as though in mid-autumn. Black Italian and Lombardy Poplars also are great sufferers, though the chief among them all is the common Sycamore, and this is either dead or dying in many instances. Long ago the foliage was curled completely up and now hangs lifeless upon the almost lifeless twigs. White Thorn, too, is suffering. Most serious of all, however, is the way many early Apples are suffering from lack of moisture, the fruit no larger or but little larger than it was some weeks ago. This, coupled with failure or partial failure in other kinds, makes a very disastrous whole where much land is given up to fruit culture.

FRUIT AND VEGETABLE CROPS.

WESTERN.

Batsford Park, Moreton-in-Marsh.—For the past two or three seasons the Apple crop has been light, and this year it is even worse, most of the orchard and many garden trees being without fruit. There was by no means a profusion of Apple blossom generally, and frosts were very destructive to the flowers on many other kinds of fruit trees. Some garden pyramids are bearing satisfactorily, the best being, as in previous years, and which rarely fail to bear, Stirling Castle, Tower of Glamis, and Warner's King. White Transparent, Lord Suffield, Cockpit, Worcester Pearmain, and Ribston Pippin are fairly good, and a few others are bearing lightly. Cox's Orange Pippin and Blenheim Orange are this season almost failures, which is a great loss, the latter being much grown in the neighbourhood. Pears are scarce, excepting a few varieties which are bearing an average on pyramids, namely, Beurré Clairgeau, Beurré d'Amanlis, and Gratioli of Jersey. Clapp's Favourite, Thompson's, and Durondeau have a few fruits, but most of the other best varieties, including wall trees, have scarcely any upon them. Blossoms on wall fruit trees suffered a good deal from frost, especially the best and most prominent ones. Fortunately, some nearer the walls escaped, and the crops have proved better than could at one time have been expected. Peaches outside have for two or three years been much blistered and unsatisfactory. The best are Royal George, Bellegarde, and Princess of Wales; and of Nectarines, Violette Hâtive and Pitmaston Orange. Apricots were rather small, possibly because of the best flowers having been killed, but of good quality, Large Early and Moorpark being the varieties. Plums in the open are generally very scarce. On walls we have to protect the buds with netting, and this may have helped to preserve the flowers from frost, as the crops on many trees are an average, notably Rivers' Early Prolific, Purple Magnum Bonum, Pond's Seedling, Kirke's, Nectarine, Victoria, Webster's and Purple Gages. Cherries are not a heavy crop, but fairly clean and of good quality, especially Morellos. The trees of dessert varieties do not succeed so well. Strawberries did well, but the season was somewhat short on account of excessive heat and drought. Fortunately, the flowers escaped injury by frost and the crop was heavy and the fruit of excellent quality. Royal Sovereign, Keens' Seedling, and President are most largely cultivated, with Vicomtesse H. de Thury and Sir Joseph Paxton in addition. Monarch and Leader (the latter a compact grower and heavy cropper) and the Gunton varieties were also grown and proved very serviceable, the two first being early and the others useful for late supplies. Raspberries were better than was expected considering the very hot, dry weather when they were ripening. Gooseberries were plentiful where the buds were protected from birds. The crop is chiefly in demand here while green for cooking. Red, White and Black Currants were very good, the fruit clean and of a good size. Walnuts and other

nuts fairly plentiful. Blackbirds and other birds have been very numerous and unusually troublesome in the garden, finding their way through nets wherever there was fruit beneath, and doing a great deal of damage even to green Apples, Pears, &c. Possibly continued hot and very dry weather prevented them finding other food.

Early Potatoes have been somewhat small, but clean and free from disease; midseason and late ones also look well up to the present. Asparagus was an excellent crop; Broccoli stood the winter well and was plentiful; summer Cauliflowers suffered from drought and have been much injured by caterpillars. Early Peas did wonderfully well, but a good many of the midseason ones were a failure, mildew and thrips attacking them during hot, dry weather. Globe Artichokes were early and very plentiful, the plants being favoured by a mild winter. Tomatoes outside are promising to bear heavy crops, and Celery, Brussels Sprouts and winter greens generally look much better than last year, though all will be improved by more moisture in the ground and atmosphere. —J. GARRETT.

Eatington Park, Stratford-on-Avon.—The frosts we had late in May made great havoc in many gardens, especially those near the water. The Strawberry crop was very light; Raspberries, Currants, and Gooseberries average crop; Apples average; Pears scarce; Apricots, Peaches, and Plums almost a failure.

Vegetables in general are good. Beans (Kidney) are late, owing to having been cut down by frost: early Potatoes are small; Peas abundant. —W.M. HAYLOCK.

Poltimore Gardens, Exeter.—Apples average and good. Plums very thin, with the exception of trees in sheltered positions. Pears in the open suffered from the frost, consequently a very light crop. Peaches and Nectarines are very good. The trees suffered much from blister, and some varieties not noticed before have suffered from mildew. Morello Cherries are good; other kinds thin. All small fruits are abundant. Apricots very few. Cob nuts light crop; others good. Potatoes are very promising at present, and early varieties heavy crops. Peas so far have been remarkably good. —T. H. SLADE.

Orchardleigh Park, Frome.—Apples are a very poor crop in this neighbourhood, in some orchards none at all. I have a nice crop of Keswick, Lane's Prince Albert, Frogmore, and Bramley's Seedling on some young trees in a sheltered part of the garden, but the majority of older trees are quite bare. Pears are a light crop, but of good quality. Apricots, where covered with glass and thick canvas when in bloom, are a good crop; Peaches good; Plums and Cherries much under average. Small fruits have been an average crop; Currants good; Gooseberries middling; Raspberries abundant, but small, owing to drought; Strawberries an excellent crop.

Vegetables are up to the present excellent. I have had heavy crops of Peas; Broccoli and early Cauliflowers have done well; later sorts are suffering now from the hot and dry weather. Shallots have done well, but Onions have mildew badly. Brussels Sprouts and winter greens planted early are looking well. Potatoes, first and second early, are only a medium crop. Late sorts at present are looking well, and, if rain comes soon, likely to be a heavy crop. —F. CLARK.

Rood Ashton, Trowbridge.—The season has been fraught with many disappointments both as regards fruit and vegetables in this neighbourhood, but perhaps the most signal failure is found in Strawberries, which have furnished but a small supply, and the quality not up to the usual standard. Frost and drought both contributed to this failing, the latter probably the greater share. Apples in some cases have a full crop; others a very partial crop. Stirling Castle, as usual, needs severe thinning so thickly has the fruit set, as also does Court Pendu Plat. Ribston Pippin, Golden Noble, King of Pippins, Cobham, Leyden Pippin, Cox's Orange, Tower of Glamis, Rambour Franc, Stirling Castle, Gravenstein, Bismarck, Cellini, Dumelow's Seedling,

Annie Elizabeth, Duchess of Oldenburg, Court Pendu Plat, Lord Grosvenor, Worcester Pearmain, Adams' Pearmain, Requette du Canada, Peasgood's Nonsuch, Hoary Morning, Warner's King, The Queen, Beauty of Bath, Cockle Pippin, Syke House Russet, Ecklinville, and Cox's Pomona are carrying the best crops. Pears are less satisfactory even than Apples, for though the trees bloomed splendidly and appear to have set well, wholesale dropping has changed the aspect materially. What Pears there are have a contracted look about them and are undersized. Beurré Clairgeau, which was a mass of bloom, is almost bare of fruit, and the same may be said of many others. The most freely fruited include Emile d'Heyst, Fondante de Bihorelli, Soldat Laboureur, Bezi de Veterans, Beurré d'Amanlis, Dunmore, Ne Plus Meuris, Beurré St. Louis, Beurré Hardy, Doyenné Boussoch, Seckle, Countess La, Louise Bonne of Jersey, Althorpe Crassane, Brown Beurré, and Amandine de Rouin. Plums are the lightest crop I have known for several years; the only sorts that can be said to be carrying an average number are Pond's Seedling, Grand Duke, Blue Gage, and Prince Englebert. Kirke's, Jefferson, Victoria, Coe's Golden Drop, Orleans, Early Prolific, and Washington, as well as the Gages, are thinly fruited. Cherries, both Morello and dessert, have fruited well; so have Peaches, despite the sharp frosts that occurred while they were in flower. Apricots are thin; so are Figs, the fruiting points having been damaged by frost. Gooseberries are about half a crop; Currants, both Red and Black, full; and Raspberries above the average.

Vegetables have given much trouble from the spring frosts and drought. Since the beginning of June the rainfall has been short and sun-heat considerable. Under these conditions Peas have podded prematurely, and the late summer crops will be uncertain. Early sowings did remarkably well. Potatoes are much under-sized, and many are now ripening prematurely. Late Potatoes are healthy, but not so vigorous as usual. Disease appeared among the first earlies in June, but not to any serious extent. Onions are swelling freely, and as yet without mildew or maggot. Cabbages were late and singularly deficient in flavour and tenderness when cooked. Early Cauliflowers were good; later ones without artificial watering are poor in growth. Dwarf and Runner Beans are making good growth, but the latter are late in podding. Marrows are plentiful, as also are good Carrots. Asparagus was never better either in quality or quantity than this year, nor were Globe Artichokes. Lettuces were very fine in early summer, but are giving some trouble now. —W. STRUGNELL.

Crichel, Wimborne.—Fruit much under average owing to late frosts. The following suffered, viz., Peaches, Nectarines, Apricots, Strawberries, Red Currants and Cherries.

Vegetables generally are good, but have a tendency to develop prematurely, owing to hot and dry season. —P. ISHERWOOD.

Staunton Park, Staunton-on-Arrow, Hereford.—With but one or two exceptions there will be but a very light crop of stone fruit. On the other hand, Apples and Pears promise a very heavy crop. Strawberries have done well this season, especially Royal Sovereign, and bush fruits generally have been good.

I found Asparagus rather later this spring, but Peas are quite up to the standard, and I have no cause to complain about the vegetable department. On the whole, everything will be equal or better than last season. —THOMAS H. WINSKILL.

Frome, Somerset.—On the whole this cannot be described other than a most unfortunate season. Late frosts, cold winds and summer drought have all conspired against the poor fruit growers, and on all sides we hear complaints of the scarcity prevailing. Writing of the district generally, I may state that Apples are fruiting well in a few instances, while the crops are of the lightest in others. Cider fruit promises to be very plentiful in places, and if the rain comes too

late to swell this to a good size it is likely enough that the cider made will be less in quantity than anticipated, but superior in quality. In some gardens bush trees of Lord Grosvenor, Stirling Castle, Duchess of Oldenburg, Cellini, Ecklinville and Warner's King are bearing heavy crops, and I have met with a few good trees of Cox's Orange Pippin, Newton Wonder and Ribston Pippin. In my own case the trees suffered from spring frosts, and there is only a sprinkling of fruit on any of the trees. Pears are much scarcer than Apples, and in low positions are a complete failure. In the orchards the commoner small varieties, including perry Pears, are carrying good crops, but of choice fruit there will be very few indeed to gather. Plums are quite as scarce as Pears, but it is worthy of note that those two old favourites, because the most reliable, Early Rivers and Victoria, are carrying good crops in places. Cherries have done well both against walls and in the open. Apricots are producing better crops than anticipated. Hereabouts they were in flower during a very cold time, 14° and 15° of frost being registered, and it would have surprised no one if an utter failure had occurred. Peaches and Nectarines are also doing well, and good crops are borne on most of the trees. Gooseberries have been fairly plentiful, or a good average crop, and the dry weather has been greatly in favour of ripe fruit. Currants, Red and Black, were a good average crop, and Raspberries above the average, though quickly over. Strawberries were disappointing. All the early flowers were killed by frost, and as a consequence of this and hot and dry weather, early, midseason, and late varieties were being gathered from at much the same time. This meant a short season. No variety stood out pre-eminently good.

A backward spring and a dry, hot, early summer have not been good for vegetables generally. Potatoes have been somewhat undersized from the first, and the main and late crops are so much affected by the drought and great heat that the crops will be light. Most of the other root crops are beginning to fail, Onions raised in boxes and planted out being the most promising crop of all. Peas were late and are collapsing wholesale. Runner Beans are also in a poor plight, especially on poor, unmulched ground. There is every likelihood of the winter crops being much under the average, as not much planting has been done. Vegetable Marrows and Tomatoes are the most promising crops.—W. IGGULDEN.

Longfords, Minchinhampton, Glos.—The fruit crops here are the worst I have had for fifteen years. Peaches, Plums, and Apples are very scarce; the spring frosts played havoc with the blossom, but the trees are clean and healthy. Apricots and Figs are a failure; Pears a moderate crop on Winter Nelis, Marie Louise, Glou Morceau, Doyenné du Comice, Jargonelle, and Pit-maston Duchess. Small fruits were plentiful and good. Strawberries Royal Sovereign, President, and Scarlet Queen excellent; Raspberries Superlative and Fillbasket, two prolific varieties, are good; Black and Red Currants and Gooseberries also good.

I have had a good supply of the following Peas: William I., Veitch's Earliest Marrow, Criterion, Autocrat, Telephone, and Ne Plus Ultra, still one of the very best main-crop Peas, but the dry weather is telling on them now. First and second early Potatoes are good and free from disease.—W. DRIVER.

Kingston House, Dorchester, Dorset.—Fruit crops, with the exception of Apples and bush fruits, are under average in this district. Apples are a heavy crop, and the quality good. Tom Putt, which is very much grown about here, has an enormous crop. Pears are less than half a crop; very much cracked. Plums are a failure except a few standard varieties such as Victoria and Orleans. Dessert Cherries are fairly good; Morellos very poor. Apricots are an average crop; quality good. Early Peaches and Nectarines were practically a failure; midseason and late varieties average, quality good. Brown

Turkey and Brunswick Figs on walls seldom fail to give good crops here. This season there are not ten where there used to be a hundred. Mulberries are a heavy crop, and Walnuts are good. Small bush fruits are over average; Strawberries under average, and the season very short.

Vegetables, in spite of the prolonged drought and a light soil, have been well up to the average, but the drought is beginning to tell on the Brassicas and late Peas. Potatoes are a heavy crop, the tubers rather small, quality excellent; all roots heavy and clean. Early and second-early Peas have been extra good. Late Peas, notwithstanding deep cultivation and heavy watering, look far from promising. Tomatoes out of doors on walls and espaliers are ripening off heavy crops. I have tried over twenty varieties side by side, and find Chemin, Ham Green, Ladybird, and Conference in the order named the heaviest croppers and the most useful.—BEN. CAMPBELL.

Shobdon Court, Hereford.—The general outlook is very good. Small fruits, Nuts, and Apples are above the average. Strawberries have been abundant. Pears, Plums, and Apricots are not so plentiful; still, many trees of these are carrying good crops, especially cordon Pears on walls.

Peas, both early and mid-season kinds, have done well, and up to now no trace of mildew on the later varieties. Onions, Carrots, Beetroot, and, indeed, all root crops, could not very well look better, and all the Brassicas are growing apace, giving promise of a good and bountiful supply for autumn and winter use.—THOS. PLUMB.

Inwood House, Henstridge.—The fruit crops in this part vary; some are very fair, while others are poor. Apples are good in some gardens, while in others not far away the crop is poor. Pears are good, and an average crop of fine fruit. Peaches and Nectarines are very good. Apricots are below average, owing no doubt to the frost when in bloom. Plums are also below an average. Nuts are a poor crop in most places. Strawberries have a fine crop and above an average, Royal Sovereign being the best. This is a fine Strawberry for forcing, and also outdoors. Gooseberries are fair in most places, but not quite an average. Currants, Black and Red, are very good. All small fruits are fair.

The vegetable crops around here are looking well, Potatoes especially. Early Potatoes have been very good and of splendid quality. The late and mid-season ones are looking well, with no disease as yet. If disease keeps away there ought to be a wonderful crop, that is if we get one more soaking of rain to carry them through. The small local shows have caused labouring men and cottagers to take more interest in their allotments and gardens by looking after vegetables and growing them well and keeping them clean.—T. WILKINS.

The Gardens, Doddington, Chipping Sodbury.—Fruit of all kinds is unusually scarce this season except Currants of all kinds and Raspberries, which are above average and good.

We have good crops of Potatoes, and vegetables of all kinds have done well.—W. GREENAWAY.

Batheaston, Wiveliscombe.—Strawberries, Gooseberries, Currants, and Raspberries have been very abundant. Apples are a good average crop. Plums and Pears are very scarce.—R. J. CARTER.

Tregothnan, Cornwall.—The fruit crop here and in the district is in most cases good. Apples are plentiful; Pears rather thin; Cherries (Morello) good; Plums, with the exception of Victorias, thin; Peaches good average; Strawberries, Raspberries, Gooseberries, Red, White, and Black Currants all above average.

Vegetables are suffering badly from want of rain. Early Potatoes are good; Asparagus very fine; early Peas and Broad Beans good, but later sowings of both are badly infested with mildew and the crop very poor; dwarf French Beans are good, but Scarlet Runners are dropping from want of moisture; Onions, both Tripoli and spring-sown, are very good. Roots and green

crops will be very poor unless we get early showers.—WM. ANDREWS.

Frampton Court, Dorchester, Dorset.—Apples are very thin in this neighbourhood. What there are on the trees are looking well and promise to be fine, the trees being healthy and clean. The same remarks apply to Pears. Cherries are considerably over the average; Plums much under average, but promise to be good as the trees are perfectly free from insect pests. Peaches and Nectarines on south walls are quite a failure, but those on a west wall are fairly well cropped. Red, White, and Black Currants are all bearing good crops and of fine quality. Gooseberries are rather under the average, caused by birds taking the buds during the winter. Raspberries are bearing a good heavy crop, but the fruit is small; Bullaces and Damsons are a failure; Mulberries and Medlars are bearing good crops. Strawberries have been an enormous crop in these gardens, but in the neighbourhood there is no end of failures, all stating the cause to be the frost which we had at the time they were in flower.—W. J. HARVEY.

Ashton Court, Clifton.—In the early spring when fruit trees were in bloom there was great promise of an abundant crop of all kinds of fruit. Unfortunately, it did not set, as nearly all fell to the ground. In this district Strawberries have been far below the average, many growers not having gathered enough to pay working expenses. I have seen some beds that were planted three years ago that have not produced any fruit worth gathering; the plants simply dried up, not having recovered from the effects of last August and September's drought and heat. Raspberries also are an under average crop. Many canes have died outright and the fruit is small generally. The season for this fruit will be very short. Gooseberries and Currants are very plentiful, and in some gardens the bushes are breaking down with the weight of fruit, which is of good quality. Apples, Pears, and Plums in this neighbourhood also are below the average. Codlins generally have a crop, but other kinds are light.

The season for vegetables has been, and still is, very trying. The early Brassicas were badly infested with blight. Turnips, Spinach, and many other crops have no chance of growing unless plentifully supplied with water. Potatoes up to the present look well, and the early kinds have yielded good crops. Parsnips, Carrots, and Beet also look well, but I am afraid they will all be small unless they soon have rain. Peas grow well, but their period of gathering will be short. Runner Beans are looking well, although the young Beans are beginning to fall off.—H. NOBLE.

Mount Edgcombe, Plymouth.—In this district the fruit crop is a very good one. Currants, Gooseberries and Raspberries are heavy crops; Strawberries and Cherries good; Apples heavy crop, require a lot of thinning; Pears medium; Peaches and Nectarines fair; Apricots not grown, soil too light.

All vegetables are good, Peas especially so, and where all crops are looking well it is difficult to select any as worthy of special mention.—S. J. RICHARDS.

Cowley Manor, Cheltenham.—Apples are very scarce; the only variety I have carrying a crop is Keswick Codlin. All the other varieties bloomed well, but the late frosts caused the bloom to fall. Pears are very scarce. A great many varieties have none at all. They bloomed well, but were also affected with the frost. We had frost as late as the end of May. The first bloom on the Strawberries was destroyed by frost, but we have had a very fair crop of what may be termed second fruit. Royal Sovereign, British Queen and Scarlet Queen are the varieties I depend on; Royal Sovereign forces well. Red Currants, Black Currants and Raspberries are very good. Gooseberries were rather scarce; I think the frost is the cause of it, as they bloomed well. Plums are almost a total failure.

Vegetables have done well. I got most of my winter stuff, such as Broccoli, Brussels Sprouts and all sorts of Kale, planted at the latter end of

May, so it has got well established. My first spring-sown Cauliflowers (Early London) have done well. Onions, Carrots, Beet and Turnips are doing well. Potatoes are a good crop. My Peas have done better this season than ever.—JOSEPH MADDOCKS.

Abbotsbury Castle, near Dorchester.—Fruit is generally scarce, owing to late frosts and very chilly nights. Apple, Pear and Plum trees were bedecked with blossoms, which failed to set.

Early Potatoes were in many instances a failure, but with recent rains late crops promise an average supply. Here in this somewhat favoured locality Chemin Rouge and Comet Tomatoes promise well out of doors, the former setting very well.—JOSEPH BENBOW.

Trelissick, Truro.—The Apple crop is a very partial one, some trees carrying heavy crops while others have few or none. All the trees are, however, making most vigorous growth and in a fine healthy condition. Pears are a light crop. Pitmaston Duchess on young trees is truly grand,

Early and midseason Peas were all that could be desired, but the abnormal drought has destroyed all chances of late crops, and I am afraid there will be a great scarcity of winter stuff from the same cause.—W. SANGWIN.

FERNS.

ADIANTUM FORMOSUM.

THIS beautiful Fern, which is well shown in the illustration, is a native of Australia and New Zealand, but does not appear to be widely distributed, being found in one locality only in each country. The large spreading fronds are of a deep green with a bright surface, and are produced freely from thick, spreading, underground rhizomes. Where space can be given it makes large fronds, and when confined to small pots forms a compact plant. It should be

good condition throughout the winter. I have found it one of the best to withstand the effects of fogs and damp atmosphere. A. H.

SOWING FERN SPORES.

If spores are sown during the autumn, a good supply of seedlings for early spring work is ensured. Although Fern spores may be sown at any season and good results obtained, it is from those sown either early in the spring or during the autumn that success is best obtained. It is during the summer and autumn that spores should be collected, for those matured during the bright sunny weather invariably prove more prolific than those produced during the dull, damp winter months. As much depends upon collecting the spores at the right time as in the sowing and after treatment. It is not an uncommon error to suppose that the fertile fronds will hold their spores for an almost indefinite period, with the result that the fronds are often taken after all the best spores have escaped. Take *Pteris argyrea* as an instance. The true spores are black, and they drop from the fronds as soon as the spore cases are open, but there still remain the spore cases, and when these are rubbed a lot of fine brown dust is obtained, which may by chance contain some good spores, but all the best will be gone. This applies to all Ferns in a more or less degree. In collecting Fern spores it is interesting to note the various shades of colour. The *Adiantums* vary; some (as in *A. scutum*) are yellow, others vary from pale brown to black (*A. cuneatum* is brown and *A. æmulum* almost black). The true spores of *Osmunda palustris* are bright green, of *Dicksonia antarctica* bright yellow, and if taken at the right time very abundant. In the *Gymnogrammas* (gold and silver) the spores are almost black. Generally a good deal of the coloured powder comes off with the spores; but if lightly shaken on a piece of paper the dark (true) spores will be found underneath the yellow or white powder. I might give other instances, but the above will be sufficient to help those who have not had much experience or have not given this matter proper attention. Another important matter is in collecting spores to take them from plants which have been isolated as far as possible from others

Adiantum formosum.

all trees doing well. Plums are a very poor crop. The Czar and Victoria are the only sorts that have done fairly well. Cherries of all sorts are a complete failure. Peaches and Nectarines are carrying heavy crops, which with a liberal supply of water to root and branch promise to mature well. I began picking Early Alfred on July 12, and shall finish with Sea Eagle about the second week of October, having a continuous supply from start to finish. Strawberries were a moderate crop, Royal Sovereign being the best. Sir Charles Napier is a great favourite with me, but did not do so well this hot summer. Bush fruit is abundant and good. I am still (end of August) gathering splendid Gooseberries and Red Currants from under permanent wire-net protection, which I should not like to be without after ten years' experience.

Vegetables have been exceptionally good, especially Peas and Potatoes. Of the latter, Myatt's Ashleaf, Windsor Castle, Syon House Prolific, Up-to-date, and Champion are my favourite sorts.

potted in a rough, porous compost consisting largely of fibrous loam and leaf-mould. For large specimens pans are preferable to pots, as the spreading rhizomes require more surface room than depth. It may be recommended as one of the most useful Ferns for the cool greenhouse. It also succeeds well in a higher temperature. Although nearly hardy, the fronds get blackened if exposed to a low temperature while in a growing state. I may add that it is one of the best for treatment under the patent process for preserving the cut fronds. *Adiantum Birkenheadi* is a very distinct variety of garden origin. It was raised by Messrs. Birkenhead. The fronds grow more erect and the rhizomes do not spread so freely, otherwise it would suggest some affinity to the above, the fronds having the deep green shade and the pinnules the finely-serrated margins. It succeeds well under cool treatment and keeps in

which produce spores freely. I like to take the fronds as soon as the spore cases begin to open. Although it is generally supposed that Fern spores will keep for an almost indefinite time and under various conditions, I am quite satisfied that they are very perishable, and although under favourable conditions they may retain their vitality for a considerable time, there is great risk in using spores which have been kept long, especially if they have been damp. I prefer to have new spores when possible, or for spring sowing those collected now may be relied upon, but they should be properly dried and then kept in a cool, dry place. If more attention were paid to collecting and keeping spores under proper conditions so many failures would not occur.

SOWING THE SPORES.—In preparing the pots, the chief thing is to get some good yellow loam, which should be quite free from worms and other insects, also from seeds of any weeds, for when these spring up they often damp off, and cause the damping to spread over the surface of the

pots and destroy the spores. Five-inch pots are the best size to use. They may be filled firmly to within about an inch of the rims. No drainage is necessary; in fact, it is better not to use any, as the most important point is to keep a regular moisture. Filling the pots with loam and standing in saucers of water will ensure this. After the pots are filled they should be well soaked, and then surfaced over with powdered charcoal and crock-dust, or for the *Aspleniums*, *Platyceriums*, or others which root on the surface, some *Sphagnum* may be added. This should be carefully picked over, and all weeds, &c., removed. It must be chopped up very small, and then rubbed through a fine sieve with some sand. After damping the surface the spores may be sown. It is essential to avoid sowing the spores too thickly. If they have been saved with care, the slightest dusting over will ensure a good crop, as when sown too thickly they choke each other. If a number of sorts are to be sown at the same time, the pots for each should be removed from the others to avoid the spores spreading. If this is not done, all the pots will produce a crop of the free-growing sorts. With due care most of the varieties may be raised comparatively true. When choicer sorts or those that are slow to germinate are sown, I like to avoid having any of the free-growing sorts about, for even with the greatest care it is impossible to avoid some spores spreading about. After the spores are sown, the pots may be placed in a shady position and covered with glass. Although the direct rays of the sun must be avoided, light is essential. This point must not be overlooked, for I believe failure often occurs through keeping the pots in a dark, heavily shaded position. I have frequently noticed when the pots have stood partly under a slope that the spores germinate freely where the light falls on the pots, while they remain dormant where they get less light. The glasses should be removed and the condensed moisture wiped off before the globules have got large enough to drop off on to the surface of the pots. No surface watering should be given after the spores are sown, but the saucers may be filled up from time to time as they require it. It is not necessary to keep them constantly full; in fact, it is better not to do so, or the soil may become too wet. With a little experience it is easy to tell when the pots are sufficiently moist. They must never be allowed to get quite dry. As soon as the pots are well covered with the prothalli, they may be taken off in small patches and pricked off into pots or boxes which have been prepared with a surfacing of more suitable soil for the young seedlings to root into. These will require dividing again about the time the first tiny fronds appear. Where Ferns are grown it will often occur that numbers of seedlings spring up under the stages and on the walls, or even on the surface of the pots. I now have a fine crop of *Gymnogramma Alstoni* on the surface of some pots which are suspended to the roof. Although this sort of thing may often occur, it is not safe to rely on it where a large stock is required, for it will generally happen that the sorts least needed are the most abundant.

A. HEMSLEY.

A double *Gypsophila paniculata*.—Until a fortnight or so ago I was unaware of the existence of a double variety of the graceful *Gypsophila paniculata*. Such may previously have been in existence, but if so I have not heard of it. At the time alluded to a gardener near London who has charge of a large collection of hardy flowers wrote me, stating that he had raised a double form of this favourite flower. This letter has been followed by the raiser kindly sending me a spray of the flowers, which quite corroborate what he said regarding it. The blooms are quite double, but although doubled are not so heavy-looking as to be ungraceful. Possibly they may not be light enough to take the place of the single form, so largely used for cutting, but their greater substance and more lasting properties will give them advantages in other respects.

The double *Gypsophila*, when introduced, ought to find a place in good gardens, not to the exclusion of the typical form, but as a novelty of considerable beauty and merit.—S. ARNOTT.

FLOWER GARDEN.

BURMESE LILIES.

WITHIN the last ten or a dozen years several new Lilies have been introduced into our gardens, principally from China and from Upper Burmah. Of these, the one that has made itself most at home in our climate is the Chinese *Lilium Henryi*, which is rapidly becoming established in various parts of the country. The Burmese Lilies, on the other hand, must, in most districts at least, be regarded as greenhouse plants, under which conditions they are decidedly attractive, as they are so very distinct from any others in cultivation. Interest in the Lilies from this region was aroused when on September 11, 1888, Messrs. Low, of Clapton, first showed *L. nepalense* in flower. It is very questionable if any plant submitted to the floral committee of the Royal Horticultural Society throughout the year excited so much interest as this Lily, which was then awarded a first-class certificate. No one seemed to know what *Lilium nepalense* was like (even our botanical authorities differed), and when shown by Messrs. Low and proved to be so distinct and withal so beautiful, the attention of everyone was directed to this charming addition to our Lilies. The stem of *L. nepalense* is usually tall and slender, while the base thereof is more woody in texture than in most other species. Roots from the lower part of the stem are also pushed out but sparingly. The flowers in general appearance bear a certain amount of resemblance to those of *L. Szovitzianum*, but in colour they are distinct from those of any other Lily. The centre of the flower, that is to say, the basal half of the petals, is of a rich chocolate-purple tint, while the recurved portion is yellow. Individuals vary in their depth of colouring, while in some the dark portion extends over a greater part of the flower than in others. *Lilium sulphureum*, the next introduction, has proved itself the most amenable to cultivation of the Lilies from that region and the hardiest of this group. Besides the specific name of *sulphureum* this is also known as *L. Wallichianum superbum* and *L. ochroleucum*. Under this latter name it was well illustrated in THE GARDEN, October 1, last year, the specimen shown flowering in an open border in a Dorsetshire garden, where the bulbs had stood for over two years. In the neighbourhood of London I have not succeeded with it permanently in the open ground, but under glass it is a very beautiful Lily. It possesses so many distinctive features that there is no danger of confounding it with any other species. The great number of its long arching leaves, the bulbils in the axils thereof, and its large, massive flowers, borne on the top of a stately stem from 5 feet to 7 feet high, combine to render it one of the most imposing of Lilies. The trumpet-shaped flowers are of a distinct ochre-yellow in the interior, the recurved portion of the petals being milk-white. The blooms are usually flushed on the exterior with purple, which varies in density according to the position in which the plants have grown. Under glass, as a rule, this species flowers during the month of August, but the season of blooming is considerably influenced by the time the bulbs are imported, their condition, and after-treatment. Where protected from the

sun's rays the flowers of *L. sulphureum* remain fresh longer than most members of the Eulirion or tube-flowered group. *Lilium Lowi*, another of the Burmese Lilies now in flower, has pretty drooping blossoms, in colour white, spotted more or less with purple in the interior. The outside of the blossom is slightly tinged with green, and there is just a suspicion of the same tint along the midrib inside. Two other species from Burmah were described about the same time, but it is questionable if they are now in cultivation. They are *L. primuminum*, once shown under the name of *L. claptonense*, and *L. Bakerianum*, which I have never seen.

The bulbs merit a passing notice, for though the plants are widely dissimilar in all other respects, yet the bulbs are very much alike. True, some individuals may be selected with almost certainty; but, on the other hand, many bulbs intermediate in character crop up, and until they grow one cannot be positive with regard to them. As Lilies, in some cases at least, grow together and are dug up when dormant, probably without an opportunity to note them when in flower, they are sometimes sent to this country in a mixed state, the two kinds generally represented being *L. nepalense* and *L. sulphureum*. Strange to say, many bulbs of the Neilgherry Lily (*Lilium neilgherrense*) can scarcely be distinguished from these just mentioned. The Neilgherry Lily is now getting scarce, for it is not very amenable to cultivation, and collectors have played havoc with it in its native habitats. It is also more than probable that the same will have to be written concerning the Burmese Lilies before many years. If these last are treated as greenhouse subjects the bulbs should be potted as soon as obtained in a compost consisting of equal parts of loam and peat, with a liberal admixture of sand. The pots must be well drained and the bulbs potted at such a depth that the upper part is covered with from 1 inch to 2 inches of soil, according to the vigour of the bulb. Only sufficient water should be given to keep the soil slightly moist till the roots are active, when they can be treated more liberally. During the growing period they should have a light, airy position, otherwise the stems will run up weak. T.

Lantanas in the flower garden.—A generation or so ago, before the mortality which now frequently prevails among *Verbenas* had made its appearance, they were largely employed for bedding, and given a warm, fairly dry season they were very beautiful. Now, however, they are seldom met with, but their place bids fair to be taken by the different *Lantanas*, of which a particularly dwarf free-flowering race has sprung into existence of late years. In Battersea Park they are used with good effect, the plants being pegged down to cover the surface of the bed, and they are flowering with great freedom. A form with brilliantly coloured blossoms is there, and very attractive it is. For the embellishment of the greenhouse at this season they are also very useful, being easily grown into neat little bushes that will maintain a succession of bloom for a long time. They can be readily wintered in an ordinary greenhouse, and should be kept fairly dry during that season, but, given an intermediate temperature, many of them will bloom more or less at that period. The plants that are kept in that excited state throughout the winter do not, however, grow away in the spring with the same vigour as those that have rested during the dormant season. Their propagation is a simple matter, as cuttings of the young growing shoots strike root very readily in the spring, so that there is no difficulty in working up a stock. There are numerous varieties whose blossoms range in colour from white, or nearly so, to pink, yellow, scarlet, and crimson.

The change in the colour of the flowers after expansion is very noticeable. In the tropics these Lantanas increase at such a rapid rate from seed, that in many districts they form veritable weeds.—H. P.

FLOWER GARDEN NOTES.

HARDY FLOWERS.—In common with everything outside, hardy flowers have suffered severely from the prolonged drought (exceptionally prolonged, I think, here in West Surrey), and had not beds and borders destined for their reception been thoroughly well done in the autumn, the flowering season would have been very short. Experience of the soil and subsoil has led to the use of cow manure in large quantities at the autumn planting, and this in dry summers is a wonderful help. In a recent note I mentioned a very pleasing effect produced by a mixture of purple Stocks with *Sisyrinchium striatum*. This lasted remarkably well, and when the spikes of the *Sisyrinchium* were removed the pleasing grey of the foliage contrasted nicely with the Stocks. One of my very best beds this year, at any rate just at present, is a mixture of *Montbretias* with *Gypsophila paniculata*. The contrast is wonderfully pleasing and there is nothing unnatural in the combination, two points, I think, that go very far towards securing the best results in flower garden work. Both were autumn planted, the one selected corms obtained from a mass lifted on an outlying border and the other from seed sown in April, 1898. For the benefit of those who have not as yet tried the perennial *Gypsophila* from seed, I may note that seedlings throw the stronger panicles and are later in coming into flower, the season of this most useful plant naturally being more sustained. *Pentstemon barbatus*, also from seed sown at the same time as the *Gypsophila*, has also given a very pleasing display. Individual blooms are not large, about the size of those of *Cuphea platycentra*, but many spikes are thrown up from each plant and the flowering season is well sustained. Alternate batches of this and *Statice latifolia* make a charming bed. One of the best combinations I have tried is a mixture of the above-named *Statice* with plants of *Tamarix gallica* if a little special attention is given to the well-known seaside plant. It should receive similar winter treatment to that given *Hydrangea paniculata*—viz., all weakly growth should be cut clean away and strong shoots well headed back. Long graceful shoots are thereby obtained, which will afford splendid material for large vases as well as being very ornamental on the border. Where the stock of *Statice latifolia* is short, a batch can be raised from seed, the seedlings varying considerably alike in size of panicle, size and colour of the bloom and in time of flowering. Another plant to associate with the Sea Lavender that is just now at its best is *Galtonia candicans*. All the above hardy plants noted as having afforded this year a very satisfactory display are fairly tall, and it may be mentioned that for large beds or borders they are more satisfactory than things of dwarf habit, especially as forming a good centre for borders or for isolated beds on turf, but if the latter are on a small scale there are many hardy things that may be used that cannot fail to give very pleasing results. A mixture of *Geum coccineum* and the clear white *Pink Albino* made a very pleasing bed. The season, unfortunately, was against the long display generally afforded by the *Geum*, and it was more quickly over than usual. A little taste in the planting of Carnations is always productive of good results; thus a mixture of *Hayes' Scarlet* or *King Arthur* with *Mrs. Eric Hambro* makes a very bright bed; so also do fancies of the *Cardinal Wolsey* and *Lady Ardilaun* types, apricots and buffs like *The Pasha* and *Carolus Duran*, and the pinks in many different shades. Writing of Carnations reminds me to note that as the weather continues very dry, constant attention in the way of watering will be necessary, and it is advisable to see this is carefully done so that the soil is not washed away from the layers. *Sweet Williams* were short-lived, but the dwarf

Antirrhinums in various shades last out well where attention is given to the prompt and constant removal of seeding spikes. This latter operation has in fact been more than ever necessary this year with all kinds of hardy flowers. It was only in this way, coupled with occasional soakings, that a continuous display could be maintained.

Claremont.

E. BURRELL

Leucojum autumnale.—This delicately beautiful little Snowflake has once more come into bloom to make us feel how delightful are its simple charms when contrasted with the glow and luxuriance of ordinary autumn flowers. It is a welcome day when one sees its first blossoms open. Compared with those of the Spring Snowflake—*Leucojum vernum*—they are tiny, but their beauty is more elegant and almost ethereal

Eremurus Elwesi in Mr. Hindmarsh's garden at Alnbank, Alnwick.

in its charms. Here, in spite of its apparent want of robustness, it is certainly as reliable as any flower in the garden, and never fails to come into bloom very late in July or early in August. The silvery whiteness of the flowers is accentuated by the chocolate colouring of the flower-stems and by the little tinge of red at the base of the segments. One is always led to think that this autumn Snowflake is not sufficiently known, or it would never be absent from gardens, especially in those where the dwarfier flowers are prized. I believe the few failures I have heard of have arisen from the time at which the bulbs were obtained being too late, and that they had made top growth without emitting roots. Early in July is about the latest time to procure dry bulbs, unless they have been kept very cool.

Leucojum autumnale is one of the bulbs which ought to be kept in stock by nurserymen in pots, so that it could be planted with safety at any time. I feel sure that a panful or a group of pots filled with it in bloom and exhibited at one of the leading shows would help to popularise one of our most exquisite autumn flowers.—S. ARNOTT.

EREMURUS ELWESI IN THE NORTH.

A FEW notes on *Eremurus Elwesi* as grown in my garden may interest some of your readers, more especially as it is apparent that it thrives with a little attention in a climate that one would think might be unsuitable to such a plant. The photograph, which was taken on June 16 last, shows two flower-spikes 8 feet high, the inflorescence covering the upper portion of 4½ feet. The plant is growing in free loam in a sheltered spot, where it has been since the autumn of 1897. When planting, care was taken not to bury the crown, and the roots, being very much like a star-fish, are therefore necessarily close to the surface. It is somewhat peculiar in its manner of growth, as it dies down in August and shoots slightly in October. The crowns are then covered with a piece of glass supported about 6 inches above the surface of the ground, but not closed, so as to keep the soil about as dry as possible without creating heat. In March the crowns, which have remained practically dormant during the winter, push upwards, and the massive leaves, some 6 inches in diameter, expand, forming at their bases perfectly tight receptacles for water, and in the centre of these the flower-spikes appear and rapidly extend in length.

It is necessary to prevent any water collecting in these leaf cups. To avoid this I have adopted the plan of fixing up a cap glass, supported on the points of a tripod of Bamboos and heightened as occasion required until the flower-stems are sufficiently grown and further precaution is rendered unnecessary. As will be seen, the plant requires attention, and this has been intelligently bestowed on it by my gardener (Mr. A. Law), and it is worth some trouble to succeed with such a subject. Last year there was one crown only and one flower-spike. I hope next year there may be four. In speaking of climate, of course it must be remembered that there has not been a prolonged severe frost during either of the two last winters.

W. T. H.

Alnbank, Alnwick.

Omphalodes Luciliæ.—From more than one point of view this is quite unique—unique in the exceeding delicate beauty and charm of its blossoms, and equally so in the peculiar combination afforded by the pretty glaucous foliage. It is not easy to find a good descriptive term for the colour of the flowers of this fine Navel-wort. Possibly for its wonderful profusion of flowering for months together it is one of the most remarkable of alpiners. It is, however, a plant that must ever be dealt with in a more or less stereotyped sort of way, particularly so in respect to division of the roots. At any time, however, this operation is fraught with difficulty, and on no account should be attempted at all except in spring, the months of April or May especially, and the latter of these two if the season be late and growth backward. Far better than risk its increase by division—which in any case cannot be very great—would it be now to carefully watch for every seed that ripens, and so increase the stock this way. It is so good indeed and so rare, that it may well be worth while to fertilise it in order to secure a good crop of seeds, taking care not to

gather them before signs of detachment appear. It is quite possible some of the seedlings will not retain the very striking glaucous-tinted leafage of the original, but, even bereft of this, they will assuredly prove both interesting and beautiful. Perhaps the nearest approach to its colour is the palest sky-blue, over which is a shade of silvery grey, and with age a suspicion of delicate lilac. It should be grown in deep gritty soil, loam, and good peat, quite free of manure, and be kept fairly moist in summer.—E. J.

PARK AND WOODLAND.

THE MOUNTAIN PINE.

(PINUS MONTANA.)

THE Mountain Pine offers the greatest diversity of habit. Sometimes its form is that of a very straight tree, of which the narrow, tapering, always pointed top is composed of branches in whorls, slender, and thickly covered with dark green foliage, making a thick covert. In this form it can attain in 160 to 200 years a height of upwards of 80 feet and a circumference of between 4 feet and 5 feet, but more often it stops short of these dimensions. Sometimes the branches which grow nearest to the ground take a vertical upward curve, and, like the branches of a candlestick, surround the principal stem with secondary stems, forming whorls like it and oftentimes equalling it in height. The result is a bushy, many-stemmed tree green from the base upward. In other circumstances the stem of the Mountain Pine remains very short, and its tortuous branches spreading abroad by interlacement with those of adjacent trees form inextricable undergrowths.

The root system is composed of several tracing main roots, and there is no principal tap-root. The bark in structure resembles that of *P. sylvestris*, except that it never exhibits in the upper portion of the stem the slender bright red-ochre-coloured constantly detaching scales characteristic of *P. sylvestris*. The bark of the Mountain Pine is, on the contrary, as thick in the upper part of the stem as at the base. It is, moreover, of a uniform grey-black colour, and is thickly strewn with resiniferous cells.

The young plant appears generally with seven cotyledon leaves two or three weeks after sowing in the spring. Although its length of life is great, fructification begins at about the age of ten years and remains abundant and continuous. The Mountain Pine is spread over Central Europe, of which it never leaves the high mountain regions. It is met with in the Pyrenees at an altitude of 8200 feet; very rarely is it found so low as 3772 feet in the Western Pyrenees, where it is very common, and where its lowest limit is as a rule 5248 feet. Into the plains of northern regions it never descends. It inhabits a zone which succeeds to that of *P. sylvestris* and which blends in its upper limits with those of the Larch and the Swiss Pine. It grows in all soils whatever the formation, and whether dry, moist, marshy or even boggy. Although in the last conditions named the vegetation is sickly and very slow and the form of the tree generally defective and straggling, it is only on soils of this nature that it is met with (almost exclusively) in the Jura and (always) in the Vosges. In the Alps and Pyrenees, on the contrary, it grows in all kinds of soils, even those which are dry or only cool. Abundant rains in the season of vegetation and an atmospheric humidity capable of imparting the necessary coolness to soils predisposed to dryness appear to be the principal

conditions of vegetation in the Mountain Pine, which resists the most rigorous frosts and stands in no need of a very high summer temperature.

The species is far from being devoid of interest; it forms by itself alone on the high Pyrenean regions (Western Pyrenees, High Pyrenees, Ariège, and Haute-Garonne) extensive forests. It is a useful tree for planting at great altitudes, serving to form screens and to raise the level of forest vegetation, which at many points shows a ceaseless tendency to sink.

The wood of the Mountain Pine much resembles that of *P. sylvestris* in northern regions, having the same white sap wood and light red-coloured heart. The annual growths are thin. Neither heavy nor hard, it is very soft to work, easy to cleave, and is much sought after for building and also as fuel. The timber of the military buildings at Mont Louis, which date from Louis XIV., is of Mountain Pine in a perfect state of preservation. The density of the wood varies between 0.441 and 0.625. Popular medicine makes use, in Germany especially—under the name Balm of the Carpathians—of a turpentine taken from the Mountain Pine and resembling that of *P. sylvestris*.—*Flore Forestière*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 29.

THERE was a marked falling off in the extent of the exhibits at the meeting on Tuesday last, and the same remark applies to the attendance, if in a less degree. Those firms who regularly support these bi-monthly meetings deserve every credit; without such, an occasional show might fall off to a serious extent. Just at present it is well known that the metropolis is not crowded; many of the best patrons of gardening are away for the time being.

Three notable groups were staged on Tuesday last, that from Messrs. Veitch and Sons composed of Pitcher Plants, grand specimens in the best of health, bearing a profusion of pitchers of large size for the varieties, being finely coloured too. An exhibit like this is an educational one from the standpoint of hybridisation. The arrangement, too, was good, the groundwork of Maiden-hair Fern being quite appropriate. At the end a choice selection of hybrid Orchids was grouped. Mr. May had another of his characteristic arrangements, in which Ferns and Campanulas with Abutilons and Acalyphas were tastefully blended. Another group from Messrs. Wills and Segar, who seldom stage at these meetings, was composed of fine-foliaged plants only. Choice Palms (seldom seen) with Alocasias in the finest varieties, and suitable carpeting material made a good display. Orchids were not, on the whole, numerous; a few good Cattleyas, as Hardyana and its allied forms, were in evidence. Fruit was not largely shown by any means, and vegetables, too, were scanty.

Orchid Committee.

An award of merit was given to **CYPRIPEDIUM CAPTAIN HOLFORD**.—A hybrid derived from the intercrossing of *C. superbians* and *C. hirsutissimum*. It is fairly intermediate in its characters between the two parents. The dorsal sepal is white on the outer margins, shading to green through the remaining portion, with some tracings of purple in the centre. The whole surface is heavily veined with dark green and covered with numerous miniature purple spots. The lower sepal is greenish white, veined with numerous green lines; the ground colour of the petals pale green at the base, suffused with rose-purple on the margin and over the top half, the whole being thickly covered with prominent purple spots. The large lip is deep purple-brown,

shading to green at the base. From Messrs. J. Veitch and Sons, King's Road, Chelsea.

Messrs. J. Veitch and Sons were awarded a silver Banksian medal for an interesting group of hybrid *Lælio-Cattleyas*, illustrating in most instances the usefulness of hybrids that are derived from crossing species flowering at various periods of the year. Included were several forms of *L.-C. callistoglossa ignescens* (*C. Warscewiczii* × *L. purpurata*), the sepals and petals pale lilac, the lip deep crimson-purple, veined with a darker shade. It has also some yellow markings through the base of the throat. In *L.-C. Nysa* (*C. Warscewiczii* × *L. crispata*) the sepals and petals are delicately tinted with rose, the whole of the front lobe of the lip deep crimson-purple, heavily fringed and margined with white, the side lobes pale rose, shading to bright yellow, with numerous deep purple lines through the base. *L.-C. Phryne* (*C. Warscewiczii* × *L. xanthina*) has the sepals creamy white, suffused with yellow, the petals almost white, the front of the lip deep rose, suffused with a darker shade of purple in the centre; the side lobes yellow, with traces of purple at the base. *Phaio Calanthe Imperator* (*P. grandifolius* × *C. masuca*) is a distinct hybrid, the sepals and petals deep rose, the lip of a bronzy tint, with some yellow and brown through the disc. Messrs. F. Sander and Co. sent a collection of Orchids, including a finely-flowered plant of *Oncidium divaricatum*, two good plants of *Dendrobium formosum giganteum*, a good variety of *Aerides Lawrenceæ*, and *Cypripedium callo-Rothschildianum*, derived from and having the intermediate characteristics of the species indicated in the name. In *Lælia pulcherrima* the sepals and petals are pale lilac, the ground colour of the lip similar, suffused and veined over the front lobe with deep rose-purple, the side lobes pale lilac, with some yellow at the base.

Sir F. Wigan sent *Cattleya Warscewiczii* (gigas) Prince of Wales. This is one of the most distinct and beautiful forms of this species we have seen. The sepals and petals are of fine form and substance, deep rose, the broad lip rich crimson-purple, except the yellow discs and lines through the throat. The plant carried a four-flowered raceme. A good form of *C. Hardyana* was also included. Mr. G. W. Law-Schofield, Newhall Hey, Rawtenstall, sent a large-flowered variety of *Cypripedium Juno* and *C. Veitchi-Morganæ*, a hybrid derived from the species indicated in the name. The petals are broader and more spotted than in *C. Morganæ*. Mrs. Masoo, The Firs, Warwick, sent a dark form of *Cattleya Harrisonæ* and *C. superba splendens*. Mr. Coleman, Gatton Park, Reigate, showed a fine form of *Cattleya Hardyana*, the lip exceptionally dark and the sepals and petals fine in form and substance. *Houlletia odoratissima* came from the same collection. Mr. H. S. Leon had *Lælio-Cattleya bletchleyensis* (*L. tenebrosa* × *C. gigas*), a distinct and desirable hybrid, having the intermediate characters of the parents. The sepals and petals are deep rosy lilac, the lip rich rose-purple, suffused and veined with a darker shade, the side lobes similar, with some white lines at the base. Mr. H. F. Simonds, Woodthorpe, Beckenham, sent two good forms of *Cattleya Hardyana*. Mr. A. J. Keeling, Bingley, sent *Cypripedium bingleyense* (*C. Charlesworthii* × *C. Harrisianum*), showing the influence of both parents, *C. Charlesworthii* predominating. Mr. E. Kromer, Bandon Hill, West Croydon, sent a good form of *Miltonia Regnelli*. Mr. W. Cobb brought *Zygopetalum Protheroeanum*, a distinct form of *Z. crinitum*, with dark brown sepals and petals and a deep blue lip.

Floral Committee.

The following obtained the award of merit:—

ROBINIA INERMIS ALBO-VARIEGATA.—A pretty white variegated form of a well-known plant, possibly containing too much white and too little green to mark a strongly constituted variation or even to form a permanent variegation. As shown, however, the plant is distinct and good. From Messrs. Cripps and Son, Tunbridge Wells.

GLADIOLUS JAMES H. VEITCH.—Evidently a vigorous kind with handsome salmon-scarlet flowers, the throat lined with white and spotted crimson, with just a touch of yellow beneath. From Messrs. Veitch and Sons, Chelsea.

DAILIA (CACTUS) MRS. STEPHENSON CLARKE.—A very distinct and striking form, the base of the petals pale golden and the tips of an orange-scarlet hue. From Messrs. Cheal and Sons, Crawley.

DAHLIA (CACTUS) MRS. J. H. LUSCOMBE.—A pretty rose-mauve shade with white centre, the florets strongly recurved and well fluted. From Messrs. J. Cheal and Sons.

CANNA BEAUTÉ POITEVINE.—An intense crimson-scarlet, the petals of good substance. It is said to be very useful for the flower garden. From Mr. T. S. Ware, Tottenham.

POLYGONUM BALDSCHUANICUM.—This is quite a recent introduction and certainly one of the most important of this genus. It is a free grower, quite hardy at the base. Even when the top is cut down it breaks away quite vigorously from below, and when established produces a veritable mass of its white flower clusters, that in a certain stage give a suspicion of pink colour. As a cut flower it is excellent. Its greatest value, however, is in the garden, where its neat, almost elegant habit will quickly render it a favourite among plants of semi-climbing tendency. Samples were shown both by Messrs. Barr and Sons and T. S. Ware, Tottenham, the latter also having small growing plants.

Two of the most important groups at this meeting were Pitcher Plants from Chelsea and fine-foliaged plants from Messrs. Wills and Segar. Both groups were very fine in their way, the examples choice and particularly well grown. In the former the Messrs. Veitch and Sons brought some of their finest examples, the plants well grown, the pitchers particularly fine, and in several instances finely coloured also. In the majority the examples were veritable specimens, and created not a little admiration by reason of their general excellence. Some of the finest from a decorative standpoint were Amesians, obtained from Rafflesiana and Hookeri, a splendid piece carrying some thirty fully developed pitchers, which, hanging down on the extended petioles, gave ample evidence of the former as one parent. Another splendid example was a red variety of Mastersiana with three dozen fine pitchers. *N. mixta*, too, with seventeen, was very fine, and quite equal was *N. mixta superba*. *Burkei* was in fine colour, bearing nearly two dozen handsome pitchers, while an equal number of handsome pouches depended from *Morganæ*. The finely coloured *N. Mastersiana* type was in grand condition, almost blood-crimson. *Curtisi superba*, *Wrigleyana*, *formosa*, *intermedia*, *Sedeni*, *Balfouriana*, *Chelsoni*, *Dicksoniana*, and *Hookeriana* with thirty pitchers were all in grand form. Not the least attractive was the well-marked *N. bicalcarata* from Borneo, the pair of spines from which it obviously derives its specific name being quite prominent. The plant carried but two pitchers, but these and the broad extending foliage were an ample attraction in this comparatively rare kind. The whole of the plants were in large baskets or pots, and the splendid vigour and general condition are but another proof of how well the wants of these picturesque plants have been studied by the Messrs. Veitch. Arranged in a bed of Ferns the value of these things was enhanced. A silver-gilt Flora medal was awarded. The other group referred to, from Messrs. Wills and Segar, On-low Crescent, South Kensington, was also very fine, the examples here being well chosen and of high order. The manner of arranging was in groups, small groups encircling a large Palm or the like, the effect being good. Among the best plants were *Licala grandis*, a really noble piece, very distinct in aspect generally; *Livistonia rotundifolia*, a capital plant, well grown and furnished; *Stevensonia grandifolia*, and *Martinezia caryotaefolia*; all these were prime examples and of rare size. The group was singularly rich in *Alocasias*, *A.*

Sanderi, *A. Thibautiana*, *A. Rodriguesiana*, *A. argyrea*, *A. Sedeni*, and *A. mortefountainensis* being among those shown, and all more or less distinct. A fine piece of *Curculigo recurvata variegata* was in good colour, and, again, a capital group around one of the Palms consisted of *Draena Goldiana*, nice plants 2 feet high or thereabouts. The remaining plants were *Crotons*—only sparsely used, however. As a rule the opposite is the case, and too much of this colour the result; such plants indeed require to be used sparingly, otherwise the brilliant tones usually seen run away with the real beauty and effect of much that is far more useful in decoration. We were pleased to see *Crotons* in the minority in this case, yet enough were used to light up the group. These, with *Aralia Veitchi*, *Begonia Arthur Mallet*, the variegated Pine-apple (*Ananassa sativa variegata*), and a few smaller things in the margin, formed a most pleasing and really effective whole. Much taste was displayed in the arrangement (silver-gilt Banksian medal). Mr. H. B. May, Dyson's Lane Nursery, Edmonton, again showed his *Campanula isophylla* variety, this time, however, in its natural or trailing habit. In this way it is even more beautiful than when tied up, for the mass of flowers trails here and there in the most effective way. Quantities of this and the white *isophylla* were shown side by side amid a considerable variety of small Ferns. Other plants included in Mr. May's group were *Asparagus Sprengeri*, the very showy and beautiful *Abutilon Golden Fleece*, also very finely flowered; *Acalypha Sanderi*, surrounded by variegated *Eulalia*; the pretty *Begonia Dregei*, with its numerous nearly white flowers; and *Bouvardia Humboldtii grandiflora*, which is said to be an improvement on the old form so long grown. The variety mentioned has larger flowers certainly, but the same weakness attends both—the liability to fall over in the truss. A variety of this plant that would be proof against this would be an acquisition (silver Banksian medal).

Messrs. Paul and Son, Old Nurseries, Cheshunt, had a nice lot of cut Roses in boxes, mostly arranged in batches of each. Those thus shown were William Allen Richardson, Mrs. Grant, Kaiserin Augusta Victoria, the beautiful novelty Mr. J. B. M. Camm (a Noisette of exceptional form), Mme. A. Chatenay, Maman Cochet and the beautiful white kind side by side, Mrs. G. Dickson, Mrs. Laing, and Caroline Testout, many being in capital form considering the time of year and the great heat. A great variety of *Althæa frutex* was shown, the many colours testifying to the beauty of this shrub. *Kalchaueria paniculata*, yellow, and the Water Hyacinth (*Eichornia crassipes*) were also shown (silver Banksian medal). Messrs. Sander and Co., St. Albans, brought plants of *Acalypha Sanderi*, *Dipladenia Sanderi*, a pretty kind so far as the flowers go, but apparently a poor grower; *D. atropurpurea*, with very rich maroon flowers and very dark; and *Calla leucocantha*, cream, with a coloured base, not clear or generally attractive. It is said to have been raised from *C. Elliottiana Rossi* and *C. albomaculata*. From Long Ditton the Messrs. Barr and Sons sent hardy flowers in variety, *Phlox Toreador* (salmon) and *P. Lawrence* (white) being good in their way; *Lilium speciosum* vars., *L. Henryi*, *Spartium junceum*, *Statice*, *Torch Lilies*, *Lathyrus latifolius albus*, *Paygelius capensis*, *Gaura Lindheimeri*, *Hemerocallis aurantiaca major*, *Eryngium* of sorts, *Gaillardias*, and one or two of the *Aster acris* forms. Some good bold groups of Sunflowers were also seen (silver Banksian medal). A large group of hardy things, with Dahlias of several sections, came from Mr. T. S. Ware, Tottenham. The Cactus and pompon kinds were very attractive, the former including such as *Magnificent*, *Mrs. Wilson Noble*, *Keyne's White*, *Colonel Wilson*, *Firebrand*, *Standard-bearer* and others. Among hardy things we noted *Erigeron speciosus grandiflorus*, *Cimicifuga racemosa*, *Phytolacca decandra*, *Torch Lilies*, *Helenium grandiflorum striatum*, *Pampas* and other grasses, *Sundewers*, *Heliopsis levis*, some pretty Bamboos, and a few Lilies of the *auratum* group.

Cannas were also very largely shown at one end and materially assisted the display (silver Banksian medal). A very interesting lot of New Zealand plants was contributed by Messrs. Veitch and Sons. These were *Senecio compactus*, *S. rotundifolius*, *S. Greyi*, some half dozen species of *Pittosporum* (all more or less distinct), *Olearia moschata*, *O. nummulariæfolia*, *Alectyron excelsum*, *Plagianthus betulinus* (a graceful plant), *Melaleuca ericæfolia*, *Aciphylla squarrosa*, &c. None of the plants were in flower, but in many kinds the habit was very distinct. The Messrs. Veitch also set up two pieces of *Diplopappus*, *D. leptophylla* having a silvered look, and *D. Vanvilliersi* of a golden hue, approaching *D. chryso-phylla*. Mr. P. Fry, Addington, West Malling, had a group of *Fuchsias* evidently raised from *F. corymbiflora* and *F. fulgens*, all the plants of very low stature as shown. A very beautiful golden *Retinospora*, *R. obtusa aurea Crippsi*, came from Messrs. Cripps, Tunbridge Wells; the plant is obviously distinct from *R. o. aurea*, but the committee desired to see it side by side with that form.

From Sir Trevor Lawrence, Dorking (gardener, Mr. Bain), came a beautiful lot of herbaceous Lobelias, including *Crimson Gem*, *syphilitica rosea*, *igneæ Firefly*, *Carmine Gem*, *British Maid*, a pale salmon-pink, the largest flowered of any of these, though wanting in the spike, which does not fill up readily or well; *sessiliflora*, a good and distinct blue; and *Queen Victoria*, very fine. The last is the green-leaved form and still one of the very finest, as it is also one of the most pronounced of the whole group. Cut flowers of *Clanthus Dampieri* were also shown in some quantity. Another plant, one of the old-fashioned class of a semi-hard-wooded character in *Crocea latifolia*, came also from Dorking. The example was finely grown and flowered, the axils being furnished freely with the purple-pink flowers. *Euphorbia corollata*, a Spurge with numerous small white blossoms, also came from the same gardens. It is scarcely a plant for cutting, but for mixing in the sub-tropical beds in the open it may prove of some service.

Fruit Committee.

From Messrs. G. Bunyard and Co., Maidstone, came a box of remarkably fine and well-coloured fruits of *Lady Sudeley Apple* from trees twenty years worked. It was remarked that as the trees age they become more fruitful and the size of the fruit increases. From the same source also came bunches of fruit of the Japanese Wineberry to show its free-fruiting and some preserve made from the berries, but seeds seemed to greatly predominate. Mr. W. Cross, Wisbech, sent fine and fully ripe samples of his new *Apple Early Victoria*. The committee, however, thought the previously granted award of merit sufficed. A fine Melon of thick white flesh and handsome form came from Mr. Hurford, Catel, Guernsey. The inner flesh was found to be too soft and the outer hard, also indifferently flavoured. Another fruit named *Foster's Seedling* came from Mr. Foster, gardener to Mr. R. Neversen, Hendon. The flesh was scarlet, but being over-ripe, had become unpleasant. A dish of superb *Jargonelle Pears* came from Mr. Neville, gardener to Lord Chesham, Latimers, Bucks, grown on a south wall and on clay soil on chalk. Mr. W. Mitchell, Farnham Royal, Bucks, sent a dish of a fine *Blackberry*. An award of merit to it as *Mitchell's Seedling* was granted in 1897. He also sent a dish of *Filberts* as *Mitchell's Seedling*, but it was regarded as no better than other varieties in commerce. Very finely-coloured fruits of *Peach Hale's Early*, grown on a wall at Balmae, the Countess of Selkirk's residence, Kirkcubright, Scotland, were sent by the gardener, Mr. W. McGuffoy. They were of fair size, and considered to be excellent examples of *Peaches* from the open wall so far north. Messrs. Harrison and Sons sent fruit and fruiting sprays of the so-called *Raspberry Strawberry*, *Rubus palmatus* (*sorbifolius*), also some preserve made from the fruits. This tasted sweet at first, then later somewhat astrin-

gent. The fruits, though fine, handsome, and richly coloured, seemed to be less palatable than are ripe *Arbutus* berries.

Several varieties of Potatoes came from Mr. F. Escombe, The Gardens, Penshurst, Kent. They had been grown on a heavy loam. Most of the samples were much scabbed, and the sender desired to learn the cause and a remedy. It was agreed that the primary cause was less the presence of manure than the absence of lime in the soil, and a fungus created the skin excrescences. It was advised that a liberal dressing of fresh lime be applied to the soil a few weeks before Potatoes are again planted; also that soot and wood ashes be used freely in the furrows when planting. Mr. Escombe was asked to report the effects of such dressing next year. A letter was read from Mr. Harrison, gardener to Miss Thrupp, Merrow House, Guildford, who gave as the name of the Melon conditionally granted an award of merit at the previous meeting Harrison's Hardy Scarlet. He also gave information as to treatment, showing that he had grown his plants quite exposed during the summer for several years. Messrs. J. Cheal and Sons, Crawley, sent heavily fruited plants in pots of an outdoor grown Tomato much resembling the Old Red. The fruits were of uneven and ungainly shape, and were not considered so good as some other popular outdoor varieties in commerce. It was, however, resolved to try the variety at Chiswick next year with others as an outdoor variety. Rather flat samples of what was named *Chemin Rouge* Tomato, but differing from the recognised form of that variety, and, oddly enough, from those on a bunch of green fruits sent, came from Mr. Broom (gardener to Mr. F. Lucas, New Barnet). Messrs. Dobbie and Co., Orpington, sent preserved Red Dessert and Golden Nugget Tomatoes, very rich, but over-sugared; one half the quantity of sugar would have sufficed. Thirty-four varieties of Onions, nearly all of outdoor spring sowing, were shown by Messrs. Harrison and Sons, Leicester. The samples were, for the season, exceedingly good, and the varieties seemed to be fairly true to name. The globe-shaped varieties were fine, and included bulbs of Ailsa Craig and Excelsior from winter sowings, Banbury Cross, Bedfordshire Champion, Prizetaker, Straw Yellow, and Danver's Yellow, the richest coloured of that hue. The finest rounds and flats were Rousham Park Hero, Nuneham Park, The Aristocrat, and Yellow Rocca; and of the Tripoli section, Pink and White Lisbon, Red Italian, Red Naples, and Globe Tripoli; of reds, Market Favourite, Blood-red, Crimson King, and Crimson Rocca; and of small or early white varieties, White Queen, Nocera, and Marsala. A silver Banksian medal was awarded.

On the proposition of Mr. G. Bunyard, seconded by Mr. P. Crowley, the chairman, it was resolved to have forwarded to the relatives of the late Mr. T. F. Rivers, a vice-chairman of the committee, a vote of sincere condolence with them through Mr. Rivers' death, as also of profound regret from the committee with which he had been so long identified. It was further agreed that in relation to the lamented death of M. Henri Vilmorin, the council of the society be invited to submit to the Fellows at the next meeting a resolution of condolence, as the deceased was one of the most distinguished of continental horticulturists.

NATIONAL CHRYSANTHEMUM SOCIETY.

On Monday evening last the executive committee of this society held its first meeting of the present season at Carr's Restaurant, Strand, Mr. Percy Waterer occupying the chair. There was a large attendance, and after the minutes of the previous meeting had been read, the secretary, Mr. R. Dean, announced that the society had to mourn the loss by death of several of its supporters, viz., Mr. George Fry, of Lewisham, Mr. T. W. Girdlestone, and Mr. J. T. Saltmarsh. Mr. Harman Payne also announced the death of one of the society's honorary Fellows, M. Henri de Vilmorin.

The chairman reported on the subject of a new design for the society's medals, and Mr. W. H. Lees having resigned his position on the classification and schedule committees, it was resolved that Mr. Godfrey, of Exmouth, replace him on the former and Mr. Howe on the latter. Mr. P. Waterer and Mr. Harman Payne were elected as delegates to the meeting of the horticultural section of the British commission for the Paris exhibition of next year.

A report was read from the floral committee containing several alterations in the floral regulations. A sub-committee was appointed, consisting of Messrs. Taylor, Simpson and Moorman, to conduct the details of the annual dinner, which will probably take place towards the end of November.

Thirty new members were elected, and local societies at Bideford, Southend and Wellingborough were admitted in affiliation.

NOTES OF THE WEEK.

Dipladenia Santei.—The medium-sized flowers of this species, while not equal to those of *D. amabilis* or the like, are certainly very beautiful and delicate in colour—a soft rose-pink. It is unfortunate that the species, judging by a plant seen at the Drill Hall this week, is a poor and weakly grower.

Bouvardia Humboldtii grandiflora.—Nice batches of this were brought to the Drill Hall on Tuesday by Mr. H. B. May, but, so far as could be determined, the variety is scarcely so free-flowering as the older form. If this is characteristic, the slight increase in the size of the flowers will not prove a great gain.

Abutilon Golden Fleecy.—The golden flowers of this plant are of a very distinct hue, such as can hardly be compared with gold usually as a colour. All the same, it is a very beautiful shade and showy, while the great freedom and profuse flowering of the variety in every way fit it for use in the conservatory, the greenhouse, or even in beds in the open air.

Sunflowers.—Notwithstanding the great heat there is promise even now of a good display of these things now that a little rain has come. But there is a superior look in those plants that have been either planted quite early this year or only been in position for one year. Older clumps are greater sufferers, showing the wisdom of periodical planting with such of these as is possible either in autumn or quite early in the year.

Tritoma Uvaria.—I enclose a photograph of a bed of Tritomas growing here. There are four large groups, one in each corner of the each court, which make a magnificent display when in bloom during the autumn. The severe winter frosts try these plants if left unprotected. In November I always give the beds a good covering of long stable litter, which is taken off in March and a good dressing of half-rotten manure given them.—G. J. SQUIBBS, *L'Angelwynn Hall, Oswestry*

Lobelia Queen Victoria.—Since the introduction of this fine kind many varieties have been added to the group, and while many of these are possessed of considerable merit, few, if any, have surpassed this kind from an all-round point of view. This is particularly true of those nearly allied in colour, for while many are distinct and even more vivid, few surpass the old variety in habit or in freedom of flowering. Unfortunately, it has not been an ideal year for these moisture-loving plants, and in some gardens they are quite a failure.

Tropæolum speciosum.—One hears so many complaints of the difficulty of growing *Tropæolum speciosum* that it may interest some of your subscribers to learn how it will grow if left alone. A Spruce Fir hedge about 10 feet high and 40 feet long in my kitchen garden is covered with it. My gardener put in a small number of the roots at the back of the hedge some years ago and it has never been disturbed since. It has rambled all over it back and front, and when in flower is very beautiful. The blue berries later on are also very fine.—H. HAMILTON, *Pimmore, Daljarrock, Ayr, N.B.*

Thrips on flowers.—This season thrips have been unusually abundant, and in the dry weather which has been prevalent they have destroyed the beauty of a number of plants. Gladioli have

been especially infested by them, and it is very disappointing to see how soon the flowers become spoiled by the swarms of thrips which cover them.—S. A., *Dumfries, N.B.*

Crowea latifolia.—This old-fashioned plant, which was brought to the Drill Hall on Tuesday last by Mr. Bain, gardener to Sir Trevor Lawrence, Dorking, in capital condition, served to remind not a few of the times when hardwooded and allied subjects were freely and well grown. Indeed, this *Crowea* was usually among the exhibition plants of thirty or forty years ago, but, like not a few others equally good, it has been put aside for the time being. That such plants will occasionally appear to refresh the memory there is little doubt, and if as well grown as the example now referred to, will be welcomed by old gardeners, if not indeed by those of the modern school.

Nepenthes at the Drill Hall.—It is doubtful whether, from a cultural point of view, finer specimens have ever been shown at the Drill Hall meetings than those brought by the Messrs. Veitch on Tuesday. The plants were splendid examples of their kind, and it mattered little whether species or garden hybrid, the same excellence prevailed throughout. The pitchers were in not a few instances like huge goblets. Great vigour and great freedom also appeared to go hand in hand with these striking and picturesque plants. Fine examples bearing twenty to thirty, and in one or two instances three dozen, fully-developed pitchers were noted in many cases.

Polygonum baldschuanicum.—It is gratifying to see this beautiful climber coming into notice. The neat and attractive habit, together with the mass of blossoms produced over so long a period, will suggest the varying uses to which it may be put. In two collections of hardy things the plant was noticed at the Drill Hall this week, and there is no doubt that a stock will be quickly forthcoming, most probably from seeds. The propagation of the plant by cuttings has hitherto in some instances not been a success, though it is extremely probable that layers would root and thus form large plants quickly. Should this prove to be the case, there is ample material provided by a large plant to produce a hundred, and in this way a plentiful supply would soon be forthcoming. For covering balconies, rustic poles or the many ill-shaped or decrepit trees and shrubs one is constantly seeing, this plant is well suited.

Notes from a Cornish garden.—*Gladiolus Senateur Volland*, flowering here for the first time, has attracted much notice. *Eucomis punctata* has given us nine flower-spikes and is greatly improved by having been shifted last autumn. The clump has been here some forty years, and seldom gives more than four flower-spikes. *Senecio pulcher* has had forty-five flowers on one plant, and *Cyananthus lobatus* over fifty flowers on one plant. *Rudbeckia Golden Glow* has maintained the character lately given it in THE GARDEN, and now this week R. Autumn Glory is out, and will take the place of R. maxima. R. purpurea seems likely to last in flower a long time. A *Solanum* sent here as arboreum is flowering for the first time. One or two visitors have told me it is not this, but no one has decided what it is. *Callirhoe involucrata* and *Tournefortia heliotropioides* are flowering profusely in the rock garden.—C. R.

The old Crimson Clover.—In reference to "N. N.'s" article about this being so rarely met with, I was surprised to hear how badly it does in most places and so little grown. Here at L'Angelwynn it does well. I grow it in large quantities, and it flowers very freely during the season. I am also able to save seeds from it every year and get some very pretty shades of crimson. Most of the seedlings come true to the old stock. I think most of the failures can be attributed to late layering and late planting, so that the plants have not time to get established before winter sets in; consequently they are lifted out of the ground by the severe frosts and never

pressed back into position when the thaw comes, and so they perish. I always finish layering by the first week in August, then by the end of September they are nicely rooted and ready for re-planting. I prefer leaving some to flower the second year, as I get a greater profusion of bloom for cutting from two-year-old plants.—G. J. SQUIBBS, *Llangedwyn Gardens, N. Wales.*

Lathyrus latifolius albus.—Very few hardy climbing plants can surpass this for freedom of flowering. This is particularly true where the plants are old and well established. A very remarkable instance of this plant came under notice quite recently in a market nursery which runs beside a deep railway cutting. The limit of the company's property is marked by their usual four-barred fence and posts, and to make the most of the fence, or rather the space at disposal, plants of the Everlasting Pea had been planted at a few feet apart along an extensive line of some 300 yards or 400 yards. The plants were merely looped to the fence by strong cord, and have for many weeks in succession provided an untold wealth of blossoms, and of not a little value, seeing the cost of production is trifling. The plant in question is such a favourite, that private gardeners might imitate this method even if on a smaller scale. There are certain positions in almost every garden where a sort of floral fence such as this suggests would not only prove attractive, but valuable, for long sprays of flower and foliage could be cut intact, and these of a pretty and useful kind. In such positions the plants if given room root deeply and give but little trouble.

Tritonia rosea.—One generally finds this catalogued as *Montbretia rosea*, and it has also been known as *Tritonixia rosea* in addition to other names. That given above is that now recognised at Kew. I think a note upon it as a hardy garden plant may prove useful to some. This remark is, however, made subject to the statement that its beauty is, perhaps, better seen as a cut flower than when growing in the garden, where its rather pendulous habit does not show the flowers to advantage, and where its soft rosy pink blooms are made less effective by contrast with the more gaudy hues of so many autumn flowers. In its general appearance it is not particularly like our better-known *Tritonias* or *Montbretias*, as it is of much looser and more graceful habit. The flowers are of a pretty shade which I have ventured to call "rosy pink," although it has been described as "rose-red." It has been under my observation in South-west Scotland for several years, and appears to be hardy if planted with the crown of the corm about 3 inches below the surface of the soil. It has been in my own garden for about three years without protection of any kind, and is now increasing at the roots besides giving plenty of bloom. Not its least recommendation is the length of time it flowers; here it blooms some time before *Tritonia Pottsi* and the hybrid *Montbretias*, and continues to produce its flowers as long as they do.—S. ARNOTT, *Carsehorn, by Dumfries, N.B.*

Helianthus decapetalus.—A dry season has, with all its disadvantages, the compensation of enabling us to see some plants under a new and more pleasing aspect. The Ten-petalled Sunflower—rather a misnomer, as the number of petals is irregular—is one of those. It appears to revel in the drought and in the brilliant sunshine which has of late been so overpowering to many. I have been particularly struck with the beauty and apparent happiness of a clump lifted in spring in the course of some garden alterations. A portion was replanted, but the remainder, with what soil was attached to the roots, was set down on the top of a part of the vegetable quarters so that someone might have it. It has remained all the summer, and is now much more beautiful than the plants which were properly planted in the borders. This has been a little surprising to me, as I have found that some of the Sunflowers not only resent drought, but are even much weakened by a continuance of dry weather. The flowers of *H. decapetalus*, although

comparatively small when compared with those of *H. multiflorus*, are light and graceful. A few arranged loosely in a glass or vase look very well in the house. They last well in water if cut before the disc flowers have quite expanded. They are, moreover, so freely produced that one has no compunction in cutting them, as is sometimes the case with plants which do not give a succession of bloom.—S. ARNOTT, *Carsehorn, by Dumfries, N.B.*

Antholyza paniculata.—One is glad to observe that this distinct-looking plant is gradually finding its way into good gardens, where it will do much to induce others to grow it in groups. Casual observers think it a *Montbretia*, and although those who notice plants more carefully see much difference in the general appearance, one is not surprised at the mistake. It belongs to the same natural order—that of the *Iridæe*—and those who wish for a full botanical description cannot do better than refer to Mr. J. G. Baker's "Handbook of the *Iridæe*." It is not named in the "Dictionary of Gardening." Botanical descriptions do little, however, to bring home to those who care for flowers the effect produced by the paniced *Antholyza*. Its broad, plaited leaves are very beautiful and effective, and even when the plant is not in bloom almost invariably attract notice. Then when in flower the deep crimson blooms are so formed and arranged as to give a distinct character to the plant, that is to those who can detect the by no means small differences between it and the *Montbretias*. This *Antholyza* is a native of Natal, where, Mr. Baker tells us, it was first gathered by Gerard. One has some difficulty in saying how far it is hardy in our districts. In such it would be well not to plant the corms until spring the first season, and to cover the place in after winters with litter, but in this district one does not find this necessary, and clumps increase almost yearly in size and in grandeur.—S. ARNOTT, *Carsehorn, by Dumfries, N.B.*

OBITUARY.

M. HENRI DE VILMORIN.

WE greatly regret to announce the death (suddenly) on August 23 of the best known figure among the horticulturists of Europe, M. Henri de Vilmorin, known to many of our readers for his public work as well as in the intimacy of private life. M. Vilmorin was one of a family of several generations devoted to horticulture, and to whom we are much indebted for their publications as well as excellent cultures in their always interesting gardens at Verrieres and elsewhere. His father having died young, he himself took his place at the head of the firm at a very early age, and well he acquitted himself of that task. He also continued the scientific studies in agriculture and horticulture to which his father had devoted his life. These included the improvement of wheat, oats, beetroot for sugar, vegetables, hardy plants, &c.

Among the numerous works left by M. Henri de Vilmorin may be mentioned "The Best Wheats," the first important one published in 1880; a pamphlet, "The Best Wheat to Cultivate," read at the Millers' Congress in Paris in 1887 and in the winter of 1890-91; a methodical and synonymous catalogue of all the Wheats composing his collection; "Experience of Growth of the Different Wheats," communicated to the Botanical Society of France; "The Best Potatoes," read at the general agricultural meeting at Paris in January, 1890; "The Methodical and Synonymous Catalogue of Potatoes," being the personal collection of M. H. de Vilmorin; "Vegetable Garden Plants," a very important and extensive work, in which vegetables of all kinds and varieties are fully described; "Plants for Extensive Cultivation, with descriptive notices of the use, quality, and cultivation of different kinds of forage and cereals, whether for commercial or eco-

nomical purposes." There also appeared a note from M. de Vilmorin in 1879 on his "Experiences regarding the origin of vegetables." This was sent to the National Society of Agriculture in France. "Study on Wheat Mildew: its nature, favourable conditions for its propagation, and the best means of fighting it;" "The price Wheat cost the U.S. of America," a report of the mission entrusted to M. de Vilmorin by the administrative council of the Agricultural Society of France; and "Flowers of the French Riviera," published in 1893 in the journal of the Royal Horticultural Society. "The Chrysanthemum: its history and culture in France and abroad;" "Vegetables for cultivation on a large scale," paper read at a conference held at the Agricultural Congress of Troyes, in June, 1892. M. de Vilmorin was an important member of the Council of the Society of Agriculturists of France, of which he was the founder. He was vice-president of the Botanical Society in 1881 and president in 1889. He received the *lauréat* and gold medal at the meeting of the agriculturists of France in 1882 for his researches on the cultivation of the Beetroot for sugar. He also wrote papers on "Temporary Meadows," on "The Culture of Tobacco," "An Account of the Varieties of Oats," "Pasture Grounds," "Wheat Culture," "Choices of Plants for Pasture," "The Amelioration of the Beetroot Industry," "Early and Late Seeds of Wheat," "Potato Cultivation," "Cultivation in America," and "A Study of *Lathyrus sylvestris*."

M. de Vilmorin was also a contributor to a large number of horticultural and agricultural journals in France and other countries. He was French representative of the Government at the International Exhibition at St. Petersburg in 1899, and a Chevalier of the Legion of Honour. Like most of his family, he was a very good English scholar and a frequent visitor to our country.

The weather in West Herts.—Still another warm week and the eighth in succession. On four days the temperature in shade rose above 80°, and on the 25th ult. reached 87°, or exactly the same reading as was registered by the same thermometer ten days previously. On the 29th ult. the highest temperature was 67°, which is only a few degrees below the average for the time of year. Nevertheless, so persistently warm has the weather lately been, that even this moderate reading caused that day to be remarkable as the first cool one for over five weeks. The ground is not quite so warm as it was a few days ago, but at the time of writing is still 6° warmer than the average both at 1 foot and 2 feet deep. Rain fell on two days, but the total measurement amounted to less than a quarter of an inch. No measurable quantity of rain-water has now come through either percolation gauge for a month. On the 25th ult. the air was singularly dry throughout the day, and at 3 o'clock in the afternoon the difference between the readings of an ordinary thermometer and one with its bulb kept constantly moist amounted to as much as 19°, indicating a very low degree of humidity indeed for so late in the summer.—E. M., *Berkhamsted.*

BOOKS RECEIVED.

"Cultivated Roses." Illustrated. W. H. and L. Collingridge, 148 and 149, Aldersgate St., E.C.

Climbing Roses.—Will someone kindly tell me if any, or all, of the following Roses would climb posts 11 feet high and then run along 11 feet on an arch across a path: *Laure Davoust*, *Charles Lawson*, *Kaiserin Friedrich*, *Mme. Alfred Carriere*, *Rêve d'Or*, *Vivid*, *Coupe d'Hebe*, *Gloire de Bordeaux*, *Desprez à fleurs jaunes*, *Blairi No. 2*, *Mme. Plantier*, *Souvenir de Mme. Metral*?—S.

Names of plants.—*M. M.*—*Carthamus tinctorius*.—*S. T.*—1, *Rosa caroliniana*; 2, *Geranium Eudresi*.—*Mrs. Wood.*—*Colutra cruenta*.

Name of fruit.—*Oakenhead and Co.*—Apple Hawthornden.

FLOWER GARDEN.

NYPHLEA STELLATA IN THE OPEN AIR.

ON page 151 of THE GARDEN of August 19 Mr. Burbidge records the interesting fact that *Nymphaea stellata* is flowering in the open air at the present time at Carton, Kildare, in Ireland, without the assistance of warmed water or shelter of any kind. This is not, however, the first time that this has happened in the British Isles. Two years ago I saw *N. stellata* var. *zanzibarensis* in flower in the garden at Buckham Hill, in Sussex, at the end of September or the first week of October. It had been flowering there freely without any protection of any kind during the summer, nor was the water warmed in any way. It was growing in a small pool in a position naturally sheltered and sunny, the sloping banks of a rock garden rising round the pool. *N. s. zanzibarensis* has smaller flowers than the variety of *N. stellata* to which Mr. Burbidge probably refers as flowering at Carton, and it is also much darker in colour, even the anthers being shaded with bluish violet. It is a richer looking flower than *N. stellata*, though fine forms of the latter, such as the lovely pale blue Berlin variety, are probably more beautiful. It may be said that the forms of *N. stellata* and *N. s. zanzibarensis* that are met with differ very much in quality, particularly the latter variety. It is comparatively rare, I think, to find the rich intense blue with the violet anthers that we associate with the true form of *zanzibarensis*. Perhaps this may be explained by the fact that it is usually treated as an annual and raised year by year from seed, when, of course, deterioration frequently occurs. I saw quite recently a large batch of seedlings of this variety; several were in flower, but one was decidedly superior to the rest, much richer in colour. It is not surprising to hear of the flowering of *N. stellata* in the open air in this country without assistance other than that afforded by Nature when *N. zanzibarensis* has previously done the same, for the difference in the conditions which are favourable to them correspond to the differences between the climates of the river Nile and Zanzibar

respectively, or more generally to the difference between North-east Africa and the eastern part of Central Africa, in which places these varieties are to be found. I only know of one other instance of the flowering of blue *Nymphaeas* without assistance or protection on this side of the Channel, though it has been an ordinary occurrence for years past in Southern Europe. The second case has occurred in the garden of Burford Lodge, Dorking, where so many choice plants and flowers are to be found. Last year Mr. Bain planted *N. stellata* in a tub sunk in the ground and grew it in the same way as he grows the hardy coloured Water Lilies. It flowered well when treated in this way. This year Mr. Bain has gone a step further and has flowered *N. s. zanzibarensis*, treating it in the same way as the other kinds, no protection being afforded nor any circulation of warm water through the tubs being maintained, though the roots would derive a little additional warmth from the fact that the tubs are sunk in the ground.

Last year I saw *Nymphaea stellata* flowering fairly well in the pond at Kew, which has been specially constructed for the growth of the hardy Water Lilies, but I believe that this pond is provided with a supply of warm water from the pipes of some hothouses in the vicinity. At Gunnersbury House *N. stellata* has flowered in a tank in the open air both last summer and this summer. The tank is supplied with warm water from the pipes of an adjacent range of pits, so that a bottom temperature of about 70° F. is maintained. No protection is afforded in the summer, but a glass frame was placed over the tank during the winter months. Under these conditions the blue *Nymphaeas* flourish exceedingly, so that more than half a dozen flowers may frequently be cut from a single plant. *N. s. zanzibarensis rosea* is flowering in this tank at the present time as well as *N. stellata*, and bears exceptionally large flowers. Last summer *N. Daubneyana* flourished in this tank, and continued to flower until Christmas under the glass frame. It continued to grow in that position, until this year it was moved to the lake and placed amongst the hardy varieties, but it has not flowered yet. It is a very distinct variety, much paler than

N. stellata, as we should expect from the fact that it is a hybrid between the latter and a white variety.

Though we cannot from these facts conclude that blue Water Lilies may be grown successfully during the summer months wherever the hardy kinds flourish, still it should encourage all enthusiastic growers of *Nymphaeas* to make experiments to test the possibility in their own case. Strenuous efforts are being made to raise a hardy blue Water Lily, but it now appears that, without waiting for this to be achieved, some at least of our beautiful water gardens may have their charms enhanced to a high degree by the culture of varieties waiting to be used. Charming as are many of the new varieties given to us by M. Latour-Marliac, none are more beautiful than the better forms of *N. stellata* and *N. s. zanzibarensis*, both of which are very pure in colour.

Except for the pretty little Forget-me-not that haunts the banks of our native rivers, blue is the colour most wanting at present in our water gardens. We have the *Eichornias*, *crassipes* and *azurea*, but these are so tender that their beauty is rarely seen, and *Pontederia cordata* is not a very effective plant. This makes *N. stellata* all the more welcome, and it is to be hoped that it will prove as successful in many instances as it has already done in a few.—J. F. HUDSON.

— In THE GARDEN of the 12th and 19th ult. I was interested to see mention made of hothouse Water Lilies flowering in the open. Mr. Alfred Wallace states that he has heated the water artificially. I do not find this to be necessary, though in a tank in the Orchid house the flowers of *Nymphaea stellata* and *N. zanzibarensis* are larger than those grown out of doors, where there are flowering here *N. stellata*, the pale blue, *N. zanzibarensis*, the dark purple-blue, and *N. Devonensis*, the crimson, all named as hothouse *Nymphaeas*. These are put out into the open pond in May or June, and taken up in October or November, though during that long and severe winter about five years ago a plant of *N. stellata* left out by mistake lived through the cold and budded, but did not fully flower the following autumn. Together with these there are several kinds of

hardy Water Lilies of different colours and the pretty little yellow *Limncharis Humboldti*, which I brought from Madeira and have found to be hardy; in fact, it spreads almost too much. I hear surprise expressed that Arum Lilies should do well in ponds in the open. I find them quite hardy, and they flourish and flower well. The three hothouse Lilies require a sunny situation even more than the others.—E. H. THURLOW, *Buckham Hill House, Uckfield, Sussex.*

Petunias.—These have gained much favour during the last few years. Thirty years ago named varieties were held in esteem by the majority of gardeners, but all at once they seemed to fall into the background. Though comparatively easy of culture, there are a few important details which must be observed if success is to be achieved. I think better results are obtainable if the plants are not raised too early in the season, as when in full bloom at midsummer the flowers frequently become distressed from a tropical sun. The cooler dewy nights and mornings suit the plants admirably, and if the beds are mulched and well supplied with moisture, the root-run being rather poor than rich, a long succession of bloom will result. Too rich ground induces a gross, barren growth. A sandy loamy soil kept cool and moist by a liberal and timely mulch is what Petunias like.—C. N.

Blue Verbenas and white Stocks.—There is one thing about seedling Verbenas which particularly strikes me, and that is their vigorous habit of growth. The flowers obtainable from the best strains are very large and the colours good. A week or so ago I saw a grand bed composed of white East Lothian Stock and blue Verbenas, the latter having a white eye. There was an entire absence of stiffness about the arrangement, and the fragrance of the Stocks was delicious. I think Verbenas are often subjected to too much heat. It is all very well to place the seed-pans in a fair heat till germination takes place, but after this an intermediate house is the most suitable till the seedlings are fit for potting off. After this an ordinary greenhouse temperature is what Verbenas like until it is safe to harden them off either in cold frames or pits. Well treated, Verbenas not only bloom profusely, but over a long period; indeed, till cut down by frost.—B. S. N.

Tricolor Pelargoniums.—I read with interest "A. D.'s" note (page 131) on this once very popular class of Geraniums. I have never grown Mrs. Harry Cox, referred to by him, but feel sure that it must be an excellent variety if, as "A. D." says, it surpasses Mrs. Pollock. The latter is a grand variety when well grown in a not too warm, moist atmosphere and fully exposed to sun. It should have an open, sunny position in the flower garden, and should not be planted in a very rich soil. A poorish root-run prevents grossness and secures rich colour. I lately saw Mrs. Pollock in a spoiled condition through being repeatedly fed with liquid manure, the plants being grown quite out of character and the colour very poor. Years ago in Essex I used to bed out Lady Cullum and Sophia Dumaresque, both gorgeous-leaved varieties, the former a good bedder, but I have seen neither of these for some years. At one time also there was a class for tricolors at most exhibitions, and a good deal of skill was needed to produce good-sized trained plants, but these were always much admired.—J. C.

Clematis integrifolia.—The beauty of the more effective *Clematis heraclefolia* var. *Davidiana*, better known, perhaps, as *C. Davidiana*, is apt to cast still further into the shade the old *C. integrifolia*, already too little grown. This, should it happen, will be unfortunate, as the latter has many good qualities, although brilliancy of colouring cannot be included among them. One may go through a good many gardens without seeing it, and I find that a number of people who see this *Clematis* in flower have not met with it

before. This is not due to its novelty, as it was in cultivation in 1596, but simply to the neglect into which many old flowers fell in the rage for bedding out. As already indicated, it is not brilliant in colour, yet one finds its deep blue hooded flowers with white centre appreciated in the garden as well as coming in usefully at times with other flowers when cut. It is one of the non-climbing Clematises with herbaceous habit, and is said in books to grow from 1 foot to 2 feet high. The type grown almost everywhere appears, however, to attain to a greater height, and even in this dry soil and in a dry season it becomes considerably taller. This year—one not particularly favourable to the growth of plants—it is a little over 4 feet high, and one has seen it at least a foot more in some gardens. When exposed to wind it requires staking, but is a somewhat difficult plant to fasten to a support without destroying its beauty in some degree. There are several varieties of this Clematis. One of these, raised by M. Lemoine, of Nancy, has been named *pallida*, and the same eminent hybridist has given us some hybrids of which *C. integrifolia* is one of the parents. There is, I believe, a white variety, but this seems to be rare, and I cannot at present find it in any catalogue I have at hand. *C. integrifolia* may be grown from seeds or increased by division, but the latter is not an easy process, as it forms a very hard root-stock, difficult to divide without lifting the whole plant. Although not showy, *C. integrifolia* is a pleasing plant over a considerable period.—S. ARNOTT.

FINE-FOLIAGED PLANTS IN THE FLOWER GARDEN.

BESIDES what is termed sub-tropical bedding when Palms and other tender plants are brought out in summer, we have a number of very suitable plants for flower garden decoration that are much more quickly and easily grown. The flowers of many of these are quite inconspicuous, but that is a minor detail for their very striking foliage makes up the deficiency, while if boldly and effectively planted they are more lasting and equally as beautiful as the best of flowering plants. A plant that has fine foliage, a handsome contour, and very pretty flowers is the Thorn Apple, and the fruits are also very striking. Perhaps some growers have been afraid of its poisonous properties, but a good deal of this is simply alarm. I do not remember a prettier combination with the Stramonium than one I planted some years since and that was *Gladiolus Brechnleyensis* with a good scarlet kind of the *gandavensis* type to follow. How often one hears complaints from gardeners of all these large beds to fill and no big stuff to fill them with. The plant named is as pretty as anything for a large bed and the number of plants that go well with it is very great. It is simply a good green and white and its fine tubular blossoms alone would make it worth growing. *Datura Stramonium* is without a doubt a very much neglected plant, and worth a trial in places where room for wintering bedding plants is scarce, and where pretty and natural effects are liked better than stiff or glaring arrangements. The Castor-oil plant is better treated by gardeners, but even it has not had the attention it deserves. It is more tender than the last-named, but the metallic-looking bronzes and steely greens in various of the named kinds are fine in positions where more showy plants would be out of place. To get the proper effect from a *Ricinus*, the plants should be carefully grown and hardened previous to setting out and never starved. Then, if planted sufficiently far apart, they will make immense specimens with rich lustrous foliage, quite different from the lanky bits so frequently seen in flower gardens. The more recently-introduced *Nicotiana sylvestris* is, I think, going to prove a very valuable aid to those who like the kind of gardening mentioned. Even on quite a poor soil here its leaves are already of very striking proportions, and all who have seen it in flower speak very highly of it. The foliage is the

thing, of course, but when joined with beautiful flowers the plant is all the more worthy. Cannas, again, are well known and beautiful plants for the purpose, and although it is a little outside the scope of this note, I would like to mention a pretty bed I saw recently. This was composed of rather tall well feathered plants of *Grevillea robusta* with a fairly thick carpeting of the new *Rudbeckia Golden Sunset*, an inaptly named, but very pretty annual.

It is necessary in all arrangements where large-leaved plants are used to make the soil good. A rich soil at first and repeated waterings until the plants are established are needed, then when the roots get hold of this, progress is very rapid, and the summer sun brings out to the full the beauty of the leaves. Unless the plants are made self-supporting much of their beauty is lost, but this is easy, and the effect is much more lasting than the majority of floral bedding arrangements.

LATHYRUS DRUMMONDI.

"R. D." speaks of this as being related to *L. rotundifolius*. I have always been under the impression that these names were synonymous, but, if not, can "R. D." say in what way the two plants differ? The Pea I have grown for a good many years under the name of *L. Drummondii* is very bright in colour, but it cannot be called scarlet. It is distinct in colour from any other flower I am acquainted with, and for this reason I find that it invariably attracts the attention of visitors who see it for the first time. My stock plant is about 5 feet across, and never exceeds 6 feet in height. It was planted about ten years ago, and would be twice the size it now is had I not used it freely for propagating from. Although this Pea blooms with great freedom, it yields seeds very sparsely, and unless these are sown at the right time they will not germinate. This is the reason why such a distinct and ornamental hardy flower is not more frequently seen. When I first came into possession of this Pea I wished to obtain a good stock of young plants, and naturally had recourse to seeds, but I could not get enough and tried root cuttings, which I found much more satisfactory. The seeds of this *Lathyrus* are harder than those of any plant I am acquainted with. They are so hard that they might easily be mistaken for pebble stones. When kept until spring they remain in the soil until the following year before germinating, and frequently will not come up at all. If sown in September and kept in a frame or cool house, nearly every seed will come up in the early portion of the year. The young plants should remain undisturbed until the following spring, when if set out in good soil they will bloom the following July. The first lot of plants I raised in this way I set out the first season and they would not go away into growth, many of them eventually dying. Those of your readers who want something distinct for conservatory decoration in early spring should grow this Pea in pots. It will bear gentle forcing, and plants in 8-inch pots, 3 feet high and as much through, have a fine appearance when in full bloom.

Byfleet.

J. CORNHILL.

Cactus Dahlias for garden decoration.—The small spring-struck bits sent out by nurserymen and Dahlia specialists may be all very well for feeding up strongly and getting a few large show flowers from, but for garden decoration there is nothing like splitting the old roots up into two or three and planting these out into prepared stations after gently starting them. The plants make rich masses of foliage and flowers that are very pretty, though in some seasons the Dahlia season is short. The Cactus varieties are prettier far than the show or fancy section, and even the little pompon varieties have not the same graceful habit and flowers. But there is a danger that in seeking after size our raisers will give us varieties absolutely useless for the purpose. Some five or six years ago a new half-dozen was sent out from a well-known firm who make the raising of

Dahlia a speciality, and these came into my hands the next season. Not one would throw a single flower above the foliage, but underneath the large leaves the blossoms were really magnificent. I am not one of those who think that a well-developed bloom of anything, be it a Chrysanthemum or Dahlia, is necessarily ugly, but I do think it is a mistake on the part of gardeners who do not grow for exhibition to use these new kinds for garden decoration. I admire a well-grown, large Cactus Dahlia immensely, and this is more than I can say of either the show or the fancy kinds, which, no matter how large or well grown, can never be called pretty. But for making a display in the garden I never grow any a second time that hide their beautiful flowers under the leaves.—A GROWER.

NOTES AND QUESTIONS.—FLOWER.

Cactus Dahlia Fantasy.—This variety pleases me more this year than it has done before. It is wanting in one thing—that is, a longer flower-stem. The arrangement of its petals is so light and distinct from that of any other, that in a cut state it has quite a dainty look surrounded by Fern. The colour is deep coral-red.—H.

Euphorbia corollata.—If not an attractive species to the eye at first sight, there is certainly a use for this free-flowering Spurge if arranged among fine-foliaged things in beds in the open ground. This is so not only by reason of the blossoms, but, perhaps, even more so on account of the greyish foliage and the general tone throughout.

Geranium Crystal Palace Gem.—This golden-leaved Geranium has stood the test of time, and is still about the most popular of its class. It is a capital grower and has a very striking appearance in a mass. True, the individual flower-truss is small compared with that of other sorts, but the colour is delicate, and on a fine sunny day the golden foliage shows off to advantage.—J.

KITCHEN GARDEN.

WINTER TURNIPS.

OWING to the protracted drought there will be few breadths of winter Turnips sown at this date, at any rate in the southern parts of the country, and in large places where quantities are needed some means must be adopted to secure a crop. It is an easy matter to get the seeds to germinate, but not so easy to assist growth afterwards. I adopt various means. Doubtless the best is to damp the plants overhead at night. The fly does not like moisture, and if it can be kept at bay there will be fewer losses. With August approaching the end we get cooler nights with shorter days, and the moisture will be retained longer. Should the fly make its appearance, it is advisable to dust over after watering with wood ashes mixed with fresh soot. This mixture is distasteful, sticks to the plants and will keep growth active. A much richer soil may be used in such seasons as this for Turnips. I find that by using cow manure moisture is better retained in a light, porous soil and there is a gain in sowing in deeper drawn drills than usual. In deep drills the tender seedlings get more shade and are less affected by drying winds, and as the plants bulb it is an easy matter to fill in the drill by hoeing or raking. When once the land gets well moistened by an ample rainfall growth will be rapid owing to the great warmth in the soil, so that large sowings need not be made in the way advised, merely small ones to keep up the supply. Land should be held in readiness for later sowings. I do not think Turnips are needed larger than a cricket ball, and if sown in September the roots will be large enough. Small roots keep better, are sweeter, and more solid. Should there be

any deficiency, it will be well to sow a few rows of the Early Milan type for present use. These do not keep, but they provide roots weeks in advance of the winter kinds, and a small quarter can be covered over, so that germination is more rapid. Now is a good time to sow the yellow-fleshed Turnips, as these are hardier, keep longer, and the quality is equal, indeed often superior. One I grew last season named Yellow Perfection is of great value as a winter Turnip on account of its small top and quick growth. This sown early in September will be ready in October. Golden Ball and the older Orange Jelly are both good. In the white section for keeping, no variety I have grown is equal to Red Globe. In the north the Green-top Stone varieties find most favour for summer and the yellow-fleshed for winter. G. WYTHES.

Forwarding open-air Tomatoes.—Should rainy weather set in, plants bearing ripening fruit should be protected by means of odd spare lights in order to prevent cracking; indeed, where the fruit is only in a half-developed state the same covering will be instrumental in hastening it on to maturity. From henceforth it will also be best to abandon the use of stimulants, this tending to promote growth rather than to hasten on the fruit. Keep all laterals closely pinched off, and thin out, though with discretion, the old foliage where at all crowded. It must be borne in mind that where lights are used no rain can reach the plants, so that regular supplies of water must be given, especially where the plants are in pots plunged in the border.—C.

Scarcity of salads.—I never knew such a scarcity of Lettuce at this season of the year owing to the great heat and drought. There is no lack of Lettuces in the north, but, I fear, few of them reach the London market, as in shops a short distance away from Covent Garden good Cos Lettuces are selling at sixpence each; indeed, even at that price they are difficult to obtain. In Newcastle I saw an ample supply of excellent Lettuces. We can grow Endive fairly well, and this is a boon in such seasons. This is best grown where sown in light land. Lettuce would be more plentiful if grown thus, as the transplanting breaks the tap root and the plants make poor progress afterwards. Anyone who can sow a quick-growing variety, such as Golden Queen, on a north border will have good heads for early autumn supplies, but the land must be well enriched before sowing.—S. H. B.

Pea Dwarf Ne Plus Ultra.—Is this our old friend Omega, one of the late Mr. Laxton's very best flavoured Peas, that is posing in the eastern counties under the above title? Omega is 2½ feet in height, and except in its dwarfness has always been regarded as a reproduction of the old and favourite Ne Plus Ultra. But the other day I heard some eminent gardeners referring to Omega as a late variety in the highest terms. But we may also class Autocrat, probably the most popular late Pea in commerce, as a Ne Plus Ultra also, for the pods bear close resemblance to those of the old variety and have the same colour and sweetness. It is rather dwarfer than Ne Plus Ultra and generally a better cropper, but in the case of any of these high-flavoured, sugary Peas much depends on how grown. Deep soil, ample manure, plenty of room, frequent waterings, and mulching do wonders.—A. D.

The autumn Broccoli crop.—Those who had land at their disposal and were able to plant this crop early will reap the benefit, as I note in the southern part of the country there is a much poorer lot of plants than usual where these followed other crops, such as early Potatoes or other vegetables. Those who have to double crop the land, and they are many, will in such seasons as this have had a trying time, as the Potato crop was later than usual. This delayed planting, and with the great heat and drought plants since

that have made slow progress. I fear in the southern parts of the country there will be a poor supply of autumn Broccoli, as, though these plants have stood much better than the summer Cauliflowers, both are much alike and are affected by drought sooner than other vegetables. The plants on a firm soil are much healthier than on a loose one; indeed, in the latter they are poor and will not pay for labour. This shows the advantages of well working the soil in winter and planting when it has well settled down. The autumn Broccolis need a richer root-run than those which have to stand the winter.—S. H. B.

Dwarf Kidney Beans.—This has been one of the worst seasons probably ever known for these Beans. Literally everywhere they seem to have been of somewhat stunted growth and eaten up with spider. I made an effort to obtain in two diverse places trials of some twelve to fourteen varieties, but failure has resulted. Though not sown early, growth was remarkably slow, doubtless owing to the coldness of the soil and atmosphere. No matter what variety, all proved alike. Whilst the edible produce has been moderate, the seed crop should be a small one. I notice that Mr. Wythes speaks highly of the climbing Kidney Beans as showing so much more of robustness. That is due first to the fact that all these Beans are naturally climbers, and, being so, find natural help to grow in the support sticks furnish; and second, because the foliage is so much removed above the soil, it suffers less from radiated heat, and therefore less exposed to the attacks of spider. Even further, the foliage gets much more of light and air, and that, again, promotes robustness and health. Certainly a good row of staked Beans, if not sown thickly, once the plants have started climbing, get a good soaking and are well mulched with long manure, get help that cannot well be afforded to dwarf Beans. Almost always these latter are sown too thickly. For all ordinary outdoor varieties the seed should be 6 inches apart, and strong growers, like Canadian Wonder and Magnum Bonum, should be sown fully 9 inches apart. All the dwarfs are of very dense, branching habit, and sown thickly the plants soon crowd each other unduly. The climbing forms, whilst habitually sown more thinly, do not branch materially, but run up into the light and air; hence their greater cropping powers.—A. D.

WINTER AND SPRING SALADS.

THERE is always a brisk demand for salads in the spring, and to provide materials at that season we must sow now, and even then with our variable weather we cannot depend upon an open-air supply. As most growers are aware, Lettuce, the salad most in demand, is difficult to winter. Many growers have not glass at their disposal to winter plants, and if they have not it is useless to try to keep Lettuce of any size after November. For a winter supply it is by far the best plan to lift full-grown plants, keeping them as cool as possible and just free of frost. Those who have fruit cases will find these structures useful, as though thrown open for the fruit trees, there is just enough shelter to preserve the plants. For many years I planted in August a row of Lettuce between each row of late Celery and lifted these with a ball in October into a Peach case, placing the plants on the bed close together. They lasted for months treated thus; indeed, the plants grew freely after housing. Of course, cold frames will do for the plants for winter protection, but here damp is their great enemy. I prefer to place the larger plants in the house or case, putting the later sown or small plants into the frames. Treated thus, growth is more certain and there is less decay of leaves. These plants will give an early spring supply and follow on those lifted from the open ground in the autumn. Many who do not shelter under glass forward a crop early in the year by sowing in January in heat and growing on in frames, but the supply is much later than from autumn-sown plants, as, take the quickest variety I have grown, the Golden Queen,

it is the end of April or middle of May before the plants are large enough for use.

I now come to the open-air culture, and would advise this in every case. Now is the time to sow. It is essential to get as sturdy a plant as possible, and to do so I advise an open border, sowing thinly. I put out a goodly number of plants in front of fruit houses in October, the largest plants from the seed-beds being used. They are lifted with a dibber, and in planting made as firm as possible; indeed, the ground is trodden if at all light before planting (not dug). Here one may reckon on half the plants pulling through a reasonable winter, but those who have frames at command will do well to plant some out here, as they will have these to fall back upon in case of severe weather. Often the smaller plants in the seed-beds are not much injured when those planted out are killed. For earliest supplies the Cabbage varieties are the first to turn in, and for autumn sowing, Lee's Immense, Hammersmith, Hardy Green, and Brown Dutch are the hardiest kinds, and in the Cos section the Bath or Brown Cos, Brown Sugarloaf, and Hicks' Hardy White are among the best. For some years I have grown a small, compact Cos variety called Intermediate, a cross between the Cos and Cabbage, and a remarkably nice variety for winter work or frame culture, owing to its size and hardness. In winter there is no lack of Endives. The Bata-vian Round-leaved is the best for winter work. Endive well repays frame or house protection treated as advised for Lettuces, though I have wintered medium-sized plants of this variety under walls. Endives, like Lettuce, force well early in the year under glass, the Green Curled being the best for this purpose. I have also grown Endive in pots and got a fair return, but there is less demand than for good Lettuces. Many could have tender Watercress by sowing seed in winter and growing on, finally planting out in the shade and giving ample moisture.

G. WYTHES.

Vegetable Marrows.—Although useful as a variety, I can never understand why Vegetable Marrows are made so much of, especially at small local shows. Every exhibitor who has the least convenience must grow and show a pair, and no class is watched more keenly. With shows that occur in July it is a good deal of trouble for a cottager who has no frame to produce them, and yet their value as a food product is very slight. There is something very interesting in growing them, and this, I suppose, must account for their popularity among the class referred to. It is a pity that they do not go in for a nice shapely, small Marrow instead of immature specimens of large kinds.—H.

Potato Renown.—"Norwich" writes very favourably of a Potato under the name of Renown. Will he say whose Renown, as there are two in commerce? One was put into commerce some twelve years since from Bedford, and the second one by Messrs. Webb and Sons. Both are main-crop varieties, both rounds, and, so far as my experience of them has gone, both excellent. Dean's Renown was raised by crossing Magnum Bonum with pollen from the handsome and excellent Woodstock Kidney—of all varieties known for the past twenty-five years, probably the best to furnish pollen. "Norwich" seems to have been more favoured for rain than we have been in the south. Generally Potato breadths are very thin and weak, the tuber prospects being indifferent.—A. D.

A Pea insecticide.—At a recent meeting of the fruit and vegetable committee Mr. J. Crook, of Forde Abbey Gardens, Chard, sent up a few plants of tall Peas in two small bundles to show the effects of an insecticide known to him as spine in the destruction of thrips. These insects have been destructive to Peas this year beyond all precedent, and anything that would help to check the depredations of these pests would be heartily welcomed. The plants in both cases showed that for 2½ feet in height and before the

spraying took place the foliage was quite eaten brown, but for 3 feet above the leafage was very fresh and green, slight evidence of the solution on the foliage only being visible. I know nothing of this insecticide beyond Mr. Crook's statement, and do not know who is interested in it. But I should like to see it tested at Chiswick another year, for there Peas generally suffer very much from thrips, because the atmosphere is so heated.—A. D.

SMALL EARLY SPRING CABBAGE.

To have an ample supply of good Cabbage in March and April one must now sow for that purpose. The chief drawback with the very early plants is that some kinds bolt so badly if sown too soon. Again, sowing at this season is greatly influenced by the weather, as delay in planting will mean later cutting. Of course, at the early season named a large Cabbage is not needed in private gardens, and any variety that will closely follow the winter kinds such as St. John's Day is of great value. To obtain an early Cabbage, a few years ago I crossed a good type of Rosette Colewort with a spring variety and with good results, as though the produce is small, it is of excellent quality, very hardy, and does not run to seed. This may be sown at the end of June and will turn in the end of March, or sown a month later, is earlier than the ordinary spring kinds.

Sutton's April is one of the best I have grown for earliest cutting. This sown even in August will be earlier than some kinds sown in July. Few kinds have a more compact growth than the April, and it is well named, as all the plants raised the last week in July may be cleared in April and Ellam's follow on, so that there is no break in the supply. In a severe winter the growth of the April is rapid. I plant it rather close—15 inches apart always. This allows of many plants being placed on a small space, and it is wonderful how reliable this variety is, as scarcely one in a hundred runs. I have grown Little Gem, also Little Pixie; both are good, but of the three I prefer the April, as it turns in so true to time. Little Pixie is a little later, but of equal quality. Little Gem is more useful sown for autumn supplies. There are other kinds doubtless well worth a trial, but I have selected those named on account of their reliable qualities.—G. W. S.

Feeding Asparagus.—There is a great demand upon the manurial constituents in an Asparagus bed now that the stems are getting large and tall. This may be met by occasional soakings of liquid manure or by sprinkling at the rate of 2 ozs. to the square yard superphosphate and salt. I used this manure two years ago and again last year, and it seems to suit the Asparagus well; indeed, there are few crops it does not suit. The better the stems of the Asparagus are nourished the finer the produce will be next season, and where growing in a very exposed place or in any position where the stems are likely to fall about, these should be supported in some way. A few Pea stakes thrust into the bed at the time cutting is relinquished for the season is a good protection, and a stout stake at intervals of 6 feet, with a line of tar string all round, is an additional support. Seed-bearing is weakening, and if time can be spared a little of this should be removed by taking the side branches off with a knife. Anything in short that can be done now to ease the plants and enrich the beds where they are growing will be well repaid by the increased size and earliness of the crop next season. Many growers mulch and feed liberally early in the summer, but now is the time to do so.—GROWER.

Runner Beans.—I have some fifteen varieties of runner Beans on trial this season, and so far the best seem to be Lightning, The Czar, Mammoth Scarlet, and Best of All, and if either of the two latter were selected to grow with the two first-named, three finer runners could hardly be desired. Lightning is a stringless-podded variety almost round in shape and very fleshy.

As its name implies, it does its work very quickly and is one of the first to come in. It also possesses the merit—no slight one by the way—of setting well in dry weather. The Czar is a white-flowered variety of excellent constitution, very even in shape, and a large, handsome Bean. Mammoth Scarlet is, I think, the best scarlet-flowered variety on trial. All three are good croppers, but the fact of Lightning setting so freely puts it absolutely at the top from this standpoint. The season during the past fortnight has been very trying for runner Beans, especially on light, dry soil. The advantage under such conditions of sowing in trenches and giving a heavy mulching of manure is very apparent. This, however, in an exceptionally dry time is hardly enough to keep the plants going satisfactorily, and I have been compelled to resort to the water-barrel and the liquid manure tank.—E. BURRELL.

Late Peas.—Late Pea crops are very precarious, owing to the variable character of our autumns. Good, tender, sweetly-flavoured Peas in October are so highly appreciated in the dining-room, that any extra trouble to secure such is well repaid. These late rows are often neglected, and where tall sticks are not forthcoming, the haulm is allowed to fall about. Such vigorous growing varieties as Ne Plus Ultra and British Queen will in dry seasons soon drain the soil of all moisture, mildew making its appearance. Where ordinary height stakes only are in use and the haulm has grown above them, I would advise cutting it off at that point rather than allow it to fall down and thus smother the younger pods and blossom. By all means mulch liberally and give a good root drenching once a fortnight with farmyard liquid, and should mildew gain a footing, use some well-tried exterminator. Anyone possessing a few good fruitful rows of late Peas will do well to use means to prevent mildew making its appearance at all. To three pounds of unslaked lime and four pounds of sulphur add one gallon of water and boil all together for forty minutes. When settled pour off the clear liquid and bottle. Use in the proportion of half a pint to three gallons of soft water. If owing to the stakes having been placed too far apart the haulm is falling through, place some stout rods horizontally along the rows on both sides, securing them to one another here and there with stout twine.—J. C.

Hearting Lettuces.—The passing season has been a very trying one for all descriptions of Lettuces. Not only did the heat and drought seem to favour early bolting, but there seem to be many stocks of Lettuces in commerce that need very little help in that direction, for they bolt off even under favourable conditions. It is evident that in the matter of stocks there is much divergence, and it would be a good plan could we have a thorough test made of all varieties in commerce as to their hearting and standing properties. Some years ago there was in commerce a stock of the Paris White Cos named Alexandra that stood long after hearting before it bolted off to seed. I wonder whether that stock is now existent. There was one grown at Chiswick during the present season under some other appellation that closely resembled the Alexandra. Whilst judging gardens in the Witley district of Surrey I came upon a remarkably fine stock of a Giant Green Cos, not the Giant White or Mammoth Cos, that hearted in finely. I have nowhere this season seen a better one of this type of Lettuce. Generally the Giant White Cos forms, although very noble looking, yet failed to heart in under the influence of the drought. Cabbage Lettuces generally have been more satisfactory than Cos Lettuces, but in many cases I found the stocks of these to have bolted early. Of course, cottagers cannot give their plants the same high culture and ample watering that gardeners do, but all the same I think few crops just now are scarcer in gardens than are good Lettuces. It is very unfortunate that in hot, dry weather when salading, and Lettuces especially, are most needed these best of all summer salads should be so difficult to obtain good.—A. D.

SOME RECENT FLOWER CREATIONS
IN CALIFORNIA.

MORE than forty years ago a few nurserymen and gardeners in California began experiments in seed-raising, and propagated accidental seed-

ling yellow species. For several years past Mrs. Shepherd's Cosmos beds have shown more decided breaks towards new shades and forms. She has a strain of dwarf and very early Cosmos; another of giant and larger-flowered ones. The yellow Cosmos exhibits similar

With proper thinning, such flower beds maintain a brilliant display. One summer, while in Mrs. Shepherd's garden, she showed me a Cactus fruit of great beauty and superb quality. This very attractive novelty (shown in the illustration) ought to find a place in the fruit markets of the world. It was as large as a Peach, dark red in colour, and possessed a higher flavour than any other Cactus fruit with which I am acquainted. The parent plant is the well-known *Cereus colubrinus*. Blossoms of this were hand-pollinated with the scarlet-flowered *Phyllocactus Akermanni*. Seedlings are being grown, and much is expected of this hybrid, though none have yet bloomed. Although this Cactus fruit is covered with spines, it breaks open when ripe, and is much easier to manage than the fruits of the *Opuntias*.

It would be difficult, if not impossible, to give a complete list of Mrs. Shepherd's introductions. One of her earliest successes was with Cannas, and her *Canna* hybrids continue to appear. She has sent out Carnations, Poppies, Dahlias, Roses, Chrysanthemums, and, in fact, good varieties of all the garden flowers. Her well-established reputation as a hybridiser rests in great measure, however, on a set of superb fibrous-rooted *Begonias*, which seem to possess a very high value for the flower garden in some districts. I have seen many of these, and have grown several of the best. Nothing else in the *Begonia* line out here is so stately and permanent. Mrs. Shepherd writes to me from Ventura, under date of August 6, 1899, saying of her new strain of *Begonias* :—

They are almost trees, with grand brilliant leaves and immense clusters of flowers, tropical in their splendour. A new one, *Marjorie Daw*, is a very rapid growing climbing variety; parents, *Begonia rubra* × *B. glaucophylla scandens*. The latter is a much more delicate and creeping variety, yet its influence is seen strongly in the offspring. . . . *Marjorie Daw* is like *rubra* in cane-like growth, size and shape of leaf, in the long stems and size of the flowers; it is like *glaucophylla scandens* in its climbing habit, the red circle at the joints of stems, and partly in the shape of the leaf. The flowers of *B. rubra* are red and those of *B. glaucophylla scandens* are salmon-pink. *Marjorie Daw* has very large flowers, in spreading panicles; in colour a sea-shell pink with white spot on the ovary. The flowers are much larger than those of either parent. It grows rapidly, throwing out vigorous shoots that in five or six months reach a height of

New seedling *Cosmos* from Mrs. Shepherd's garden at Ventura, California. From a photograph sent by Mr. C. H. Shinn.

lings of merit. Some new *Roses* were brought out as early as 1860, I remember, and several growers produced excellent seedling *Geraniums*, *Verbenas* and *Petunias*, which were shown at state and county fairs. This summer I visited the noted Morse seed farms near Gilroy, where I saw many acres of Sweet Peas and other flowers. This company has brought out a long list of charming novelties. Such seed-growers as the Morses, of Santa Clara and Gilroy, such hybridisers as Luther Burbank, of Santa Rosa, such nurserymen as John Rock, of Niles, and such collectors as Carl Purdy, of Ukiah, have made places for themselves high on the list of our horticultural leaders. It is an interesting fact that those who know most about California give Mrs. Theodosia B. Shepherd, of Ventura, who began this work in 1873, a very high place among the raisers of new flowers. Her recent creations appear in many American and foreign catalogues, and her small but beautiful town garden on the cliffs of Ventura, hardly a bow-shot from the ocean, is yearly visited by many pilgrims. I have seen it at several seasons, and it is a marvellously crowded workshop. Mrs. Shepherd's local reputation as a florist became national mainly through her success with the *Cosmos*. The illustration shows some of her new seedlings of lacinated varieties and different colours. The dark ones at the left are of the small

variations, and especially fine are the newer and brighter shades of crimson. Her best success comes in many cases from self-sown seeds. In fact, *Cosmos* is as well adapted as the *Godetia* to naturalisation here, as the spring rains are enough to bring self-sown plants to flowering. Self-sown *Cosmos* often sprout by September 15, and of course in the mild Ventura climate grow all winter, beginning to bloom by April, when spring-sown plants must be watered almost constantly. I should think that in the Channel Islands the *Cosmos* could easily be naturalised. At the little flower garden of the Santa Monica forestry station, on the Southern California coast, not only *Cosmos*, but *Coreopsis*, French Marigolds, and a number of other composites, as well as *Eschscholtzias* and *Salpiglossis*, reproduce themselves freely from self-sown seed.

Hybrid fruit of *Cereus colubrinus* × *Phyllocactus Akermanni*.

6 feet. It branches freely, blooms profusely, and would, I believe, reach a height of 20 feet.

A good deal of interest is now being shown in the bulb industry, and California growers hope

ultimately to supply most of the American trade with Daffodils, Hyacinths, Tulips, &c.

CHARLES H. SHINN.

ORCHARD AND FRUIT GARDEN.

LATE STRAWBERRIES.

WHAT has become of our late Strawberries? Why are they not found in the market? To have them early seems to be the only aim of growers, and all the varieties come in with a rush for a week or two and are gone again. I was in a large provincial town lately when it was glutted with this fruit, and about eight days afterwards there was none. In good private gardens there are occasionally a few late varieties grown, but no crop to speak of, yet there need be no more difficulty in having late crops than early ones, and I have no doubt but that good dessert Strawberries in August and September, or even as late as October, would pay as well if not better than early ones. I noticed this season in one of the most reliable Covent Garden Market lists that on June 22 Strawberries per dozen punnets were priced at from 2s. to 5s., and at a proportionate figure by the peck from Kent and Middlesex. By July 15, when the season was approaching its end, the price had risen to 8s. per dozen punnets common sorts, and British Queen to 15s. By July 29 the price for ordinary kinds had risen to from 10s. to 15s. per dozen, and by August 5 Strawberries had disappeared from the market. And this in London! In Paris the supply will be going on till September at least with alpinas, of which more further on. In Scotland the supply goes on later, and late districts in England have late crops, but, whether north or south, the crop may be prolonged much beyond the usual time by culture and the use of the right kinds. Many years ago I remember a plentiful supply of Strawberries being kept up in a large garden in Scotland all through August and into September with late dessert varieties, and after that the supply was prolonged by alpinas on a north border. Strawberries were not wanted sooner, because the owner of the garden with his establishment did not arrive at his seat till the middle of August and left again in October, and the gardener had to meet the demand as well as he could. This he did by planting good breadths of British Queen Strawberry, Bicton Pine, and in greater quantity Elton Pine. Frogmore Late Pine is said to be an improvement on the latter, which is, however, probably yet the best late Strawberry grown. It is a good grower, a prolific bearer, of large size, and good brisk flavour. In the garden I speak of it used to be planted between the rows of the latest kinds of dessert Gooseberries, giving both plenty of room, and the same net covered both crops. To give an idea of the length of the Strawberry season, I may mention that in that garden the Black Prince variety, the best early kind yet produced, came in about the middle of June or beginning of July, succeeded by Keens' Seedling, still one of the very best and most dependable. After these came British Queen, and last of all the Pines, extending the season into September, for it is a feature of the Elton Pine that the fruit ripens long in succession. Since then a generation of gardeners has grown up who appear to know not that there are such things as late Strawberries, and who waste much precious time in running after the new and often useless sorts as fast as they come out. The other day a great Strawberry grower and raiser sent me his

catalogue containing a list of some fifty varieties, including about a dozen new ones. I sent for sample runners of the Elton Pine, and out of all his acres and varieties he could not supply me. One called Latest of All, a reputed cross between Helena Gloede and British Queen, does not deserve its name, and it can neither compete with British Queen for flavour nor with Elton Pine for lateness. It is much the best plan to discount all these much-praised new Strawberries at least 50 per cent. Gardeners will not soon forget the sort called Noble that came out with such a flourish backed by the experts of the Royal Horticultural Society, only to be banished out of every good garden as soon as tested and tried. Now is a good time to plant runners of the Elton Pine or indeed any variety. British Queen I do not recommend as a variety to be relied upon to grow well, otherwise wherever it does grow it will also bear well, and for size and flavour it is still unsurpassed either for forcing or planting out. It likes a rather light, rich soil and a warm situation, but the finest crops I ever saw were grown in the Lothians in the open quarter, but under high culture. It is very subject to red spider, which destroys the foliage, and hence it cannot endure a poor, dry soil. It is, however, well worth good culture, and the fruit would find a ready sale.

PREPARING THE GROUND.—The best plan is to trench the soil two spits deep at least, as the Strawberry will send its roots 3 feet into the soil if they can get down, and in a dry season like the present it will set the drought at defiance because the roots are deep and within the reach of moisture; in fact, this treatment suits all varieties. High culture of the Strawberry, it is known, will nearly double the weight of the crop owing to the greater size of the berries. Early mulching is also almost indispensable in dry soils, and for that purpose there is nothing better than short litter or short grass from the lawn-mower, provided plenty is used. I have often seen a well mulched quarter of Strawberries produce a fine crop in a dry season when they were a failure throughout the neighbourhood. Any manure applied in preparing the ground should not be trenched in deep. It is lost when so applied because the roots are long in reaching it, if ever, and heavy rains carry its virtues away into the subsoil and drains. The ground should first be trenched, and then if farmyard manure is applied it should be dug or forked in afterwards in the surface spit, and after that artificial manures may be applied to the surface in early spring. The constituents of the fruit of the Strawberry consist, according to the best analysis, of over 20 per cent. of potash and soda and a large percentage of lime, phosphoric acid, silica, and peroxide of iron. The three first named are of most consequence, and where they exist the others will generally be present. The lime should be thoroughly incorporated with the soil, and potash may be supplied in the form of kainit as a surface dressing. Manures that suit the Potato suit the Strawberry also, and a plantation of Strawberries may follow a crop of early Potatoes, which are usually off the ground in time for Strawberry planting. The kainit has, like salt, also the merit of attracting moisture from the air. With farmyard manure, succeeded by kainit as a top-dressing, I have seen some remarkable results on Potato crops. Some six rows of Potatoes were dressed with kainit in the middle of a field of 12 acres, all the conditions being equal, and these rows could easily be distinguished from the highway a good distance off by their superior growth, and when lifted the crop was

nearly one-third heavier than that of the rest of the field.

DISTANCE APART.—One important matter in Strawberry culture in both late and early crops is to give the rows plenty of room. Where the foliage of the rows meets during the summer the fruit is shaded, longer in ripening, never so good flavoured, and in wet weather great quantities of fruit rot, being soft. Thick planting also encourages slugs and black beetles (clocks), which hide under the foliage and destroy much fruit. I have seen immense quantities of the finest fruit destroyed by these pests in some gardens. They are the one objection indeed to the mulching of Strawberries, and they are always least troublesome in plantations where the rows are wide apart and where the plants have room all round. Varieties like the Black Prince, which has scanty foliage, may be in rows 18 inches apart, but with all other sorts the rows should be at least 2 feet 6 inches apart, and 3 feet is not too wide for some sorts. The plants develop fine crowns and foliage under such circumstances and the fruit gets the sun, but the rows should run north to south. In making plantations about this season the plants may be put 9 inches apart in the row if they are expected to fruit the following summer, as they should do, but at the end of the first season every other plant should be removed and 18 inches allowed from plant to plant. It is a sheer loss to have the plants thinned the first year, as half a crop may be lost thereby. I cannot too much impress upon cultivators the importance of securing a crop the first year. It is seldom one sees that in gardens, but it is just as easy to have the crop as not. Layer the Strawberry runners in July on a ridge of good soil laid between the rows, stop the runners beyond the layer as fast as they push, and plant out as early as possible in August and not later than September. At all times keep the runners chopped off close in to the stools when they are not required for fresh plantations.

ALPINE STRAWBERRIES.—These fruit during August, September and October in this country, according to the climate. In Paris they are plentiful in August, heaps of fruit being shown in the market. The largest fruits are about the size of a lady's thimble and the flavour is agreeable and refreshing. The late Mr. James McIntosh, gardener to the Duke of Buccleuch at Drumlanrig Castle, was the only one I have known who grew alpinas extensively and successfully. The seed was sown about midsummer and the plants were planted out in August on a north border, but they will do equally well or better on an east or west border in cool localities. Care should be taken to get good new seed, which should be sown on a fine surface of light, nice soil and not covered too deeply. Regular watering is necessary till the plants are fairly up, and when they have made two or three leaves they should be planted out in rows about 1 foot apart. After culture consists in keeping the runners pinched off as fast as they appear so as to secure good crowns on the plants, which will produce abundantly the following autumn. Seed may also be sown in spring in frames, and if the plants are put out in good time they will be strong by autumn, but will not fruit till the following year. Summer-sown and autumn-planted plants are best. At Drumlanrig, at the time I refer to, late and alpine Strawberries, late Gooseberries and late Raspberries used to be regularly supplied to the house for dessert. J. S. W.

Plum Pershore.—Some time ago a little friendly correspondence passed between Mr.

Crook, of Forde Abbey, and myself as to the merits and cropping powers of the above Plum. Just lately I saw and tasted a fine-looking sample in a fruiterer's shop in Norwich. The flavour, though by no means comparable to that of some other sorts, was decidedly better than that of the fruit I used to gather from a warm wall in South Notts. I was informed the consignment came from Devonshire, and there is no doubt that soil and situation make as much difference in the flavour of Plums as of any hardy fruit. Some time ago in a note on Plums in THE GARDEN a Kentish grower criticised the flavour of Pershore, but having to-day eaten some in a stewed state, I am bound to pronounce them excellent.—B. S. N.

Grape Gros Colman.—There is no doubt this fine Grape requires a long season to finish and colour properly, and it must be kept going all the time—that is to say, it is no use to grow it in an early house with other quicker developing kinds, and when the latter are ripe to throw the house open under the impression that any kind of treatment is good enough for Gros Colman when once colouring begins. No Grape is more liable to go foxy under such conditions and none is more trouble to get out of this state. The large berries require a lot of filling out, and to do the variety well it should be grown by itself, or else in company with a hard-skinned Grape like Alicante that is not averse to a long season. Such a house started early, say in February or earlier, will, I believe, produce Gros Colman in the finest possible condition, and it need not be a large house either. Some of the nicest looking and best quality Gros Colman I have seen were grown at Norman Court, in Hampshire, some years ago in a small house with almost upright lights of the Peach case order—not exactly the class of structure one would expect to be suitable. The Vines were liberally treated, had plenty of room laterally, and were grown all the season.—H.

RED SPIDER ON PEACH TREES.

THE remarks by "J. C. B." (p. 114) on the above subject are well worth perusing by those having Peach trees under their charge. "J. C. B." is quite correct in his idea that red spider commences its destructive operations at a much earlier period than many are aware of. In fact, I have seen numbers of the insidious pest on trees in full bloom under glass, that is when the trees had received no winter dressing. On taking charge of a fresh garden I once had such a colony to deal with, but of course nothing could be done till the fruit was set. By that time many of the tiny leaves had quite a brown appearance, and I never thoroughly conquered it that season. Doubtless after mild winters spider often exists on open-air trees, as frequently these do not receive any insecticide during the resting period. But why should wall trees be neglected in this matter any more than those under glass? Then with the former many are afraid to apply the hose or garden engine so early in the season for fear of frost occurring at night while the foliage is wet, or lest the application should cause an attack of mildew, and so the remedy prove as bad as the disease. There is no need whatever at that early date to postpone syringing the trees until the after part of the day, as is the case later on in the season. If even in April a fine sunny morning is chosen and chilled water used, syringing may be quite safely practised immediately after breakfast, as scorching need not be feared and the foliage dries before nightfall. "J. C. B." informs us that his friend at Lake House, Byfleet, uses a mixture of soft soap and sulphur and finds it effectual. I have used quassia extract with very good results, following this with a good washing with clear water the following morning. If trees are in fairly good health and these preventives are proceeded with in time, and continued through the months of May and June at intervals of say ten days, the trees being also well mulched and watered, good crops are rendered pretty certain—at least in

average seasons—and the health and longevity of open-air Peach trees ensured. NORFOLK.

RIPE GOOSEBERRIES.

REALLY good, thoroughly ripe Gooseberries are rarely to be bought, and the owners of the majority of gardens, large or small, are not often favoured with a supply. This is not quite as it should be, as it is certain no hardy fruit is more wholesome or more pleasing to the palate. Immense quantities of Gooseberries are grown in all directions, but the bulk are picked in a green state, and what are left to ripen are eaten by birds and wasps or they crack prematurely. A dry, hot summer suits Gooseberries left on the bushes to ripen, and I never tasted better fruit than were available in all too small

months. Bullfinches were never more plentiful or destructive among fruit buds generally than they were this year, and in many gardens fruit bushes and trees were nearly cleared of fruit buds.

The framework of Gooseberry houses should be moderately strong, as they will occasionally have to bear a great weight of snow. If one rafter has a flaw in it and breaks, the whole of the structure will most probably collapse. It is also of importance that small or three-quarter-inch mesh wire netting be employed, especially along the fronts and sides, small birds finding their way through larger openings. According to my experience, the netting and woodwork offer a certain amount of protection against frosts, and I have seen Gooseberry crops outside badly injured while those under the netting escaped.

There is no necessity to confine these permanent structures wholly to bush fruits. If formed against a wall lean-to fashion, the back wall may with advantage be covered with either Cherries or Plums, with cordon Gooseberries and Currants between them as long as there is room for these. If the house is built quite in the open, the sides should be sufficiently high to admit of all the uprights and supports generally being clothed with cordon Cherries or Plums, while among the low bushes may be dotted standard Gooseberries and Currants. The one drawback to this plan of permanently covering Gooseberry bushes is their liability in some cases to be more over-run by the Gooseberry caterpillar than are those unprotected. This, however, is not a particularly strong argument against the plan I am advocating. The cuckoo is the only bird I ever saw feeding on the obnoxious caterpillars, but it is just possible certain kinds of small birds may eat more of the egg-depositing flies than we give them credit for doing. These small birds can be admitted from the time the buds are too forward till the fruit is ripening by simply providing large netting-covered shutters for the sides and ends, taking these away till they are wanted for excluding the blackbirds. There is also the other alternative of moving and burn-

Gooseberry Green Champagne.

quantities this season. Unfortunately, birds, notably blackbirds, made a dead set at ripe and ripening Gooseberries, and netting over in the ordinary manner proved of little avail against them. Bushes were cleared wholesale in a single day. Years ago I advocated the more general adoption of the plan of growing Gooseberries under light wooden or iron structures permanently covered with galvanised wire netting, and those who acted upon this advice have this season had good cause to be particularly pleased at their decision. It should be remembered that these Gooseberry houses if properly constructed not only save the fruit, but, what is even of more consequence, they preserve the buds from bullfinches and other small birds during the winter and spring

ing the surface soil down to the roots every winter, and with this taking away and destroying the greater portion, if not all the cocoons or fly cases. The surface soil being replaced by moderately rich compost, the double purpose of preventing a bad attack of caterpillar and of feeding the roots has been answered. Other remedies, such as mulching with tanner's bark, surfacing the ground with gas-lime, spraying the branches with quassia or hellebore extracts, and dusting with hellebore powder, are all open to the cultivator to adopt, and in any case it is better to run risks from caterpillars than from birds.

Judges at flower shows will agree with me that as a rule really good Gooseberries are seldom met with on the exhibition table, but it

does not follow that the smaller-fruited varieties are invariably the best. The best I have tasted is, without exception, *Whinham's Industry*. We have been apt to value this variety principally for its reliability as an early variety, gathering the whole or greater portion of the crop in a green state. For the future let me advise those who appreciate good ripe Gooseberries to leave a sprinkling of fruit on all the bushes rather than a heavy crop on a few bushes—a mistake often made with other varieties, with the result that the fruits are under-sized, liable to drop prematurely, and poor in quality. *Keepsake*, another variety recommended for its heavy cropping and the quick growth of young fruit, is also of excellent quality when ripe. *Whitesmith*, also a popular market-grower's variety, has always been regarded by me as one of the best for dessert, and if properly thinned out the fruit attains a comparatively large size. The same remarks apply to *Crown Bob* and *Lancashire Lad*. Only give a portion of the fruit a chance to ripen properly, and the results are bound to be satisfactory. *Snowdrop* and *Antagonist* are both fine white varieties of excellent quality when ripe, and I can also strongly recommend the greenish yellow *Leader*. It will thus be seen that it is possible to grow Gooseberries for profit and yet have some left for eating in a ripe state, the quality of which cannot be surpassed by many of the smaller-fruited varieties of reputed superior flavour.

We ought not, however, to wholly dispense with the smaller varieties, as we are not all market-growers, and there are some seasons when the larger-fruited varieties ripen indifferently well, and also keep badly. *Early Sulphur* is a remarkably heavy cropping variety, ripening early, while the quality is passable. All the *Champagnes*—red, white or green and yellow—are good bearers, and the fruit, though small, is of excellent quality when ripe. By some authorities these are regarded as among the very best flavoured Gooseberries we have. *Keens' Seedling*, a medium-sized early form of *Red Warrington*, is very reliable and good, and I must confess to a liking for the small-fruited *Rough Red*. *Pitmaston Green Gage*, another variety with small fruit, is also of excellent quality. The most valuable of all, whether compared with large, medium-sized or small varieties, is the *Red Warrington*. No other sort hangs so long on the bushes, the quality being good till quite late in the season. I have seen bushes red with fruit in September and October, and, where a long succession of Gooseberries is required, at least half the bushes under a netted-in structure should be of this variety.

W. IGULDEN.

The woolly aphid.—I gather from Mr. Hay's observations respecting the woolly aphid in New Zealand that there the pest most seriously operates on the roots of the Apple trees. That is probably due to the great dryness of the atmosphere there. One naturally wonders how the aphid would fare could the roots now and then be deluged with water, especially strong soot water. But so far as my experience of the aphid is concerned here, it attacks roots but little, and tree stems and branches much. That being so, it is difficult to understand what benefit would result to the trees from the employment of *Northern Spy Apple* as a stock, as it is most improbable that any deterring properties possessed by the stock would equally operate on the tree upon it. But one wonders why, with ordinary care, the woolly aphid should become an appreciable trouble here. Anyone having trees suffering from it has but to spray them once or twice during the season with some powerful insecticide and the trees will be

cleared. But the other day, having been invited to test the merits of a solution called *Abol*, I took it to a large Surrey garden where there are hundreds of Apple trees, but found woolly aphid on one only, a very aged *Blenheim Pippin*. With the aid of a special spraying syringe I gave all the spots of aphid I could see a taste of the liquid, and it settled them rapidly enough. It is but needful to follow up sprayings of this nature two or three times and the pest is easily kept in check. But, after all, it gives little trouble in this country, except where it is left untouched. The past two or three dry seasons have helped the insect very much, but damper summers will check it greatly, as they will many other insect pests.—A. D.

SUMMER PRUNING FRUIT TREES.

I WOULD be much obliged if you could let me know how to do the summer pruning of Apples, &c. All the books I have, tell you to summer prune, but do not say how or when.—R. W. M.

** Early in the summer, or before the shoots are many inches long, all wall trees ought to be gone over, and wherever lateral growths or shoots from old spurs are numerous these ought to be freely thinned out. The same with much-pruned or somewhat dense, bush, pyramid, cordon, and espalier-trained trees, the effect of this being to strengthen and otherwise benefit the reserved growth. Summer pruning proper may commence while yet the topping can be done with the finger and thumb, doing this from the middle to the end of June—not earlier. Very hard topping must not be resorted to, as this when done by too zealous pruners results in starting the basal buds into active growth, the shoots formed being soft and of the wrong character; whereas summer pruning is intended to strengthen the basal buds, some of these ultimately developing into either fruit-buds or short fruiting spurs. The young growths may be topped beyond the fifth leaf on each shoot, and if the tree is vigorous, shoots will be pushed from the fourth and fifth joint in every case. These second breaks should also be topped beyond the first leaf, treating later breaks similarly. At the winter, or, better still, late autumn, pruning all these topped laterals must be shortened just beyond the third bud from the base or below where they broke after topping, leaving a short spur from which one, or at the most two shoots will spring the following summer, fruit-buds developing from the rest. If this treatment is persevered with, all the main branches of Apple, Apricot, Cherry, Pear, and Plum trees will gradually become furnished with abundance of fruiting spurs which are sufficiently short to derive the full benefit of the heat and protection from the walls or fences to which any of them may be trained. This form of summer pruning tends to correct grossness in trees, as when long and strong shoots are allowed to develop, only to be hard pruned in the winter, the principal result is often a greatly increased quantity of sappy wood only.

The older and more common form of summer-pruning consists merely in cutting back all the shoots not required for furnishing after they have developed to their full size and become hardened. Not infrequently this is all the pruning the trees receive, and it is only done when those responsible think it is about time to admit more light to the fruit and to otherwise benefit this. Allowing the trees to grow thus wild through the greater part of the season means so much wasted vigour, and is not conducive to productiveness. The least that can be done is to prune all the laterals directly the wood has become somewhat firm, or, say, not later than the third week in July, shortening them to the fifth leaf, completing the pruning—shortening to the second or third bud from the base—either before the second leaves fall or soon after. This treatment has the effect of benefiting the current crop of fruit and also of strengthening and developing the basal buds, some of which may become fruit-buds during the following summer, fruit-buds in most cases not forming in a single season.

Some cultivators also summer-prune the growths intended to be laid in or reserved as leaders, topping them when about 12 inches in length, but I prefer reserving and laying the strongest in to their full length, winter-pruning only those that require strengthening. What thinning out of shoots may be rightly thought necessary in the case of dense bushes and pyramids is best done in the summer, or while yet the leafage is fresh. Not only can the operator then better decide which ought to be removed, but the timely thinning admits sun and air to the interior of the trees, benefiting what fruit may there be swelling and also tending to develop more fruit-buds. Too often these classes of trees fruit on the surface only. The leading growths on trees that must be kept restricted in size may be topped at a length of 10 inches to 12 inches, and shortened somewhat severely at the winter pruning, but those on more naturally grown trees ought to be more naturally treated, that is to say, should be left intact both now and next winter. Without the aid of diagrams I fail to see how I can more plainly describe summer pruning for the benefit of "R. W. M." and other readers requiring information on the subject.—W. I.

GRAPE FOSTER'S SEEDLING.

FOR flavour this Grape cannot of course compete with such fine kinds as *Muscat of Alexandria* or *Mrs. Pearson*, but there are many growers who have not heat enough for these varieties and are glad to fall back upon a white kind of medium quality easy to grow. In *Foster's Seedling* we have a useful all-round kind that is as easily grown as *Black Hamburgh*, easier to keep in good condition, and though not in the first flight for flavour, yet good enough to find a place in the best collection of dessert fruit. No Vine that I know will bring a heavier crop to perfection, and the only fault of the fruit is a little muddiness in colour, which, however, is not confined to this only. If good-shaped, well-shouldered bunches are looked for, the wood must be fairly strong and well ripened, and the Vine should not be pruned too long. Large bunches may be produced by leaving several eyes and pruning to a very prominent one, but they are seldom of first-rate shape, and the beauty of a good bunch of *Foster's Seedling* lies not so much in its size as in the good shape, and well filled up shoulders are a great help in this direction. *Foster's Seedling* is a rather thin-skinned variety, and on this account should not be grown for keeping late in the season or when it is difficult to keep up a correct atmosphere in the vinery. It is very apt to split if kept either in too moist an atmosphere or a very dry one and watered at the roots, and though far from advocating a system of drying off the roots of any variety, it is a great mistake to let those of *Foster's Seedling* have a lot of moisture when the fruit is ripe. Provided the atmosphere of the house is kept at a nice equable state as regards moisture up till the time the berries are colouring, there will not be much fear of the latter going. It is when moisture is pressed in every day and the heat kept up until colouring commences, and then the dry air allowed to play about the bunches suddenly, that wholesale cracking takes place, and then it is difficult to cut even a fairly good bunch. The plan of tying the leaves back from white varieties has been often recommended, but it is only in exceptional cases that any need for it exists. All white varieties like ample light, and this should be kept in mind during the growing season and the laterals kept thin. The principal leaves then need not be interfered with, but allowed to carry out their proper functions undisturbed.

H.

Peach Sea Eagle.—Though usually looked upon as of second-rate quality, this fine Peach is not really so when well grown and ripened. Its fine form and handsome appearance are very well known, and there was a large number of good dishes of it at the recent show at *Shrewsbury*, notably in the classes for dressed tables. There

are few Peaches that will carry so heavy a crop to perfection as this, and I was reminded of this at Shipley, where a tree was carrying a very heavy crop, though the individual fruits were large and the tree grown on a cross trellis, not the most suitable place for ripening up late Peaches. It is, according to my experience, far before Princess of Wales, and a very useful kind where late fruit is needed.—H.

Plum Victoria.—This deserves its popularity as a good standard kind, useful for dessert or cooking, and one of the most constant bearers in cultivation. The fruit is above medium size, and when properly ripened the flavour is superior to that of many kinds that are thought far more of. In most years the fruit has to be thinned considerably, but there is none of that to do this year as far as this garden is concerned. Still it is the only kind that has a crop at all, and it rarely fails entirely. Most of my trees of it were shifted last autumn, and the season has been rather against them of late, but the trees have made a fine healthy growth in spite of this. This Plum needs a good amount of feeding owing to the immense crops of fruit it annually produces, but it is a mistake to plant it or any other kind on well manured, loose soil. It should contain the proper elements for supporting the trees, of course, but the roots should be made quite firm, when planting and feeding should be done from the surface. Soils deficient in lime should have this added either in the form of rubble at the roots when planting or by top-dressing with newly slaked lime occasionally, lightly pointing this in before mulching the trees.—H.

ORCHIDS.

NATURAL HYBRID ORCHIDS.

EASTERN SECTION.

THE first indication of the existence of natural hybrids amongst tropical Orchids was in 1853, when Lindley correctly indicated the parentage of *Phalenopsis intermedia*. This was before any artificially-raised hybrid Orchid had flowered. Since that time Mr. Seden has proved its origin, as Lindley suggested by the intercrossing of *P. Aphrodite* (*amabilis*, as it was then wrongly called) and *P. rosea*. These seedlings flowered in 1886 and proved identical with *P. intermedia*. Other tropical hybrids have since appeared among importations of plants. In 1886 *Dendrobium crassinode Wardianum* flowered in Messrs. Veitch's nursery. Recently the well-known hybrid *D. Ainsworthi* has been recorded as having flowered amongst imported plants of *D. nobile*. *Vandas*, too, have produced their natural hybrids. In May, 1894, *Vanda Charlesworthi* flowered in Messrs. Charlesworth and Co.'s nursery at Heaton, Bradford. It is supposed to be a natural hybrid between *Vanda cœrulea* and *V. Bensoni*, and appeared among an importation of *V. cœrulea*. It would be difficult to distinguish it from that variety when the plants are not in flower. A plant recently shown at the Drill Hall by Messrs. Hugh Low and Co. I examined carefully, and failed to find the slightest trace of *Vanda Bensoni*. The habit of growth was that of *V. cœrulea*. The flowers are very similar in shape to those of a small-flowered variety of that species, the colour differing in having a peculiar tint of rosy purple suffusing the segments. In 1897 *Vanda Moorei* appeared with Mr. J. W. Moore, of Bradford. It is a well-known fact that *V. Kimballiana* and *V. cœrulea* grow together, in Upper Burmah. In *V. Moorei* the characteristics of these species are so pronounced that there is no difficulty whatever in identifying its origin. The leaves are nearly as broad again as in *V. Kimballiana*, rather fleshy, nearly flat,

and about 7 inches long. The sepals and petals are pale lilac and most like those of *V. Kimballiana* in shape, but the general characters of the flower are fairly intermediate. It is a very interesting addition. *Cypripediums* have produced natural hybrids. Some few years back Mr. Edward Low drew my attention to a good form of *C. javanico-superbiens* that was flowering among a batch of imported plants. This was interesting from the fact of its giving some idea of the habitat of *C. superbiens* (*Veitchi*), which has long been sought after, the whole of the stock of *C. superbiens* having been derived from two plants. *C. javanico-superbiens* was artificially raised by M. Bleu from the species indicated in the name. The appearance of the plant in Messrs. Low's nursery amongst an importation (I believe of *C. javanicum*) should give some idea as to where *C. superbiens* might also be found. *C. Godefroye* also has been artificially raised in two collections by the intercrossing of *C. niveum* and *C. bellatulum*. Some years ago I was struck with the intermediate characteristics that existed between *C. Godefroye leucochilum*, and suggested to one of our greatest authorities the possibility of the white ground forms being natural hybrids between *C. niveum* and *C. bellatulum*, the yellow ground forms being derived from the influence of *C. concolor* with *C. bellatulum*. This opinion was further strengthened by the fact that among the first batch of plants of *C. Godefroye leucochilum* imported there were found *C. niveum*, *C. concolor*, *C. bellatulum* and typical forms of *C. Godefroye*. The original importation was collected by inexperienced men, which seemed to me to further strengthen my contention, which I am glad to find has proved correct where artificially-raised hybrids have flowered. I have also found *C. nitens* among imported plants of *C. insignis*, proving that the original parentage given of *C. Sallieri* is correct and that it is a natural hybrid between *C. insignis* and *C. villosum*; these species must undoubtedly grow together. There are other natural hybrids which might be mentioned, but their identity has yet to be proved. *Cymbidium*s also include two supposed natural hybrids in *C. Traceyanum* and *C. eburneo-Lowianum*. A plant of the latter, exhibited at the Drill Hall some time ago, was said to be, and it bore every trace of being, an imported plant. It came from the neighbourhood of Worthing. The identity of *C. Traceyanum* has yet to be determined. I am assured by Mr. Boxall that *C. Lowianum*, *C. eburneum*, *C. grandiflorum* and *C. giganteum* all grow practically in close proximity to each other, so that there is no reason why natural hybrids should not exist among importations of these species.

H. J. C.

Warrea tricolor.—In habit and manner of flowering this plant very closely resembles a *Phaius* and its culture is very similar, the plant delighting in a sound compost of loam, peat, and Sphagnum Moss. It is not often seen, but I noticed several fine spikes of it the other day. These were about 2 feet high with many flowers, the colour of the sepals a yellowish white, with a pretty bright purple lip. It is very pretty, and the flowers last a long time in good condition, but it is probably not showy enough for present day collectors to trouble about. A moderate amount of heat is necessary, the plant being a native of Colombia. It has been occasionally imported since 1829, the date of its introduction by Messrs. Loddiges, but has never been popular or very plentiful.

Odontoglossum Wallisi.—Although the flowers of this species are not so large or showy as those of the majority in the genus, it is an

interesting and pretty plant. It is easily distinguished from any other kind by the narrow foliage, the petals standing exactly at right angles to an imaginary line drawn through the top sepal and lip, and by its distinct colouring, the brownish tint being margined with greenish yellow. The plant does well in a moderately cool house and should be given rather more root-room in accordance with its size than most other kinds. The plant takes no distinct resting season, but must be moderately watered all the year round, lessening the root and atmospheric moisture a little in the dark days. It is found growing naturally further north than most of the Venezuelan species and high up on the Sierras, where it was discovered by the collector whose name it bears in 1868.

Odontoglossum Harryanum.—It was, I believe, a constant source of regret to the late Mr. Horsman, of Colchester, that this fine *Odontoglossum*, which he was instrumental in bringing to this country, did not do better. Had he seen the fine specimens in the Trentham group of plants at Shrewsbury he would have had little cause to complain, for they were very good, one especially having a remarkably fine spike, apparently a yard or more in height, with magnificent flowers. In this form it is a splendid Orchid, but, unfortunately, newly-imported plants are often allowed to flower themselves almost to death, and they never get over the check. It is best, even in the case of the strongest plants, to remove the flowers as soon as open, and even to reduce their number to two or three when flowering for the first time in this country. Later they make strong growths, and, being established, they carry the blossoms to perfection. The plant likes a little more warmth the first year or two than most *Odontoglossum*s, and should be given fairly wide pots or pans.

AERIDES MULTIFLORUM.

THERE is a great advantage in growing these lovely Orchids, in that many of these flower at a time when there is little else in flower. In the season of gorgeous *Cattleyas* and showy *Dendrobes* one is apt to forget these grand plants, but now when most of the *Cattleyas* are over and the house is conspicuously dull, the *Dendrobiums* daily getting less like plants and more like a bundle of dried twigs and sticks, the ample foliage and glorious racemes of flower are peculiarly attractive. *A. multiflorum* is perhaps the best known of all *Aerides* with the single exception of *A. odoratum*, and though all the varieties are very pretty and useful plants, some of them are much finer in colour and form than others. Culturally, *A. multiflorum* is not usually such a success as *A. odoratum*; its habitat is probably at a greater elevation and in a less sheltered position than that of the latter, but of this I am not sure. Certain it is that while *A. odoratum* can hardly have too much heat and moisture and thrives in a shady house, *A. multiflorum* in all its forms likes a cooler and drier house, in which the growth every season is well consolidated as it is made. Plants grown in this kind of atmosphere flower very freely and regularly, but, on the other hand, if kept year in and year out in a constantly moist and shady house, the flowers will be very few indeed, and those that are produced will be poor in texture and colour. *A. multiflorum* is a fairly free-growing, but not very strong plant, and, like all such, is better treated to a moderate-sized basket or pot than a very large receptacle such as suits a plant of the habit of *Vanda suavis* or *V. tricolor*, or even *Aerides odoratum*, which can be given more material about its roots with advantage. Clean Sphagnum Moss, as usual with the distichous-leaved kinds, is better for this Orchid than any mixture, and all that need be added is a little charcoal and a few

crocks to keep the mechanical state right. In an amateur's collection near by, plants of this species when they get at all sickly are washed quite clear of all material about their roots. They are then laid out for a while to dry, and afterwards all decaying or dead roots are cut off, the stem itself being shortened if at all decayed. In more than one case I have seen a marked improvement in plants of this class brought about simply by cutting off this bad end when repotting, for anything decaying or decayed cannot but have a bad effect upon the plant itself as well as upon the compost. Careless watering after the plants have been repotted has much to answer for with regard to an unsatisfactory state at the roots, and where good Moss, green and fresh, is used, there is little need of watering in a house where the atmosphere is kept correctly moist. Dead Sphagnum Moss loses its natural power of imbibing moisture from the atmosphere, as it were, and it is just this power that has made it such a useful adjunct to successful Orchid culture. But when the Moss is healthy it will keep just moist for several weeks by being lightly damped occasionally, and in this state is just the very best rooting medium that this class of Orchid likes when young. After they have obtained a good hold the water supply will, of course, be much increased and kept up as long as growth is going on, but later on in the winter when the plants rest much less moisture is needed. For reasons above given, the plants are best suspended from the roof, but care is necessary during sharp weather that they are not injured. The flowers of *A. multiflorum* are small individually, but the spikes on good plants are remarkably fine. They are usually a pretty soft rosy tint, one of the best coloured varieties being *A. m. Godefroyanum*, or, as it is sometimes labelled, *Aerides Godefroyæ*, after a famous French orchidist whose name it bears. Of this kind I noticed a very pretty plant with several long spikes in the collection of Mr. H. Rider Haggard, Ditchingham House, Norfolk, recently. The variety *Lobbi* is also a very good one, that called *roseum* being smaller in habit and bearing shorter spikes than the type. It is a very old Orchid, having first been discovered by Dr. W. Roxburgh in Sylhet some years before the present century opened, and introduced to this country by Messrs. Loddiges in 1837. H. R.

Cattleya Mendeli.—This fine *Cattleya* is flowering on the imported bulb at Shipley Hall, and there are some very fine forms open in the way of *C. M. grandiflora*. The lip of this *Cattleya* is among the best of any in the genus, for though not so large as that of the better forms of *C. gigas*, it is very finely frilled and beautifully tinted. The Shipley plants are very fine masses, and Mr. Tallack tells me that most of those imported this year have turned out remarkably well as to variety. Some of the plants are being tried in the Belgian leaf-mould, as grown in various continental nurseries, but it is yet too early to speak as to results.

Cattleya Harrisoniæ.—This is a very pretty *Cattleya*, and I have noted it in good condition in several collections recently. Flowering fairly late in the season as it does, it is more useful than those which flower at the time the labiate kinds are at their best, while the soft rosy lilac tint of the exquisitely shaped blossoms renders it useful for various kinds of decoration when cut. *C. Harrisoniæ* blooms upon the current season's stems, and after flowering should be induced to rest for a few months. At Shipley it does well on blocks suspended from the roof, but growing in this way renders a lot of atmospheric moisture necessary. The thin compost is an advantage.

Epidendrum cuspidatum.—This species is not at all constant in its time of flowering, and I

have noted it in bloom almost every month in the year. The pretty *Brassavola* like flowers, with their white fimbriated lip and creamy yellow sepals and petals, last a fairly long time in good condition. It does well for cutting for button-holes and sprays, and is altogether a very useful plant to grow. It is of the easiest possible culture, but some growers have found it less free-flowering than most. This is chiefly on account of its being grown in too much heat and moisture, thus keeping it in a state of perpetual growth instead of allowing it to take its proper resting season. A light position in a house that suits the labiate section of *Cattleyas* is best for *E. cuspidatum*, and an endeavour should be made to ripen and well consolidate the growth each season. Immature growths seldom flower freely, and the plants so grown get into an unsatisfactory state. It is a native of the West Indies, where it covers a large tract of country, and, like all such, differs in the size of the flowers in various plants.

NOTES AND QUESTIONS.—ORCHIDS.

Cattleya aurea.—Again this superb *Cattleya* is in flower, and the sunny season has ripened the growth well. I noticed a few nice plants in flower at Shrewsbury in one of the large trade groups, and they always attract a good deal of attention. Many growers still keep this on the stage with the other *Cattleyas*, but wherever there is room the plants ought to be suspended from the roof. The receptacle for the roots need not be large, but perfect drainage must be secured. Water very freely just when the growth is resting, and afterwards in accordance with the weather.—H.

Oncidium macranthum.—There were some extremely fine spikes of this *Oncidium* in the Trentham group at Shrewsbury shown in the way I have frequently advised in these pages, *i.e.*, not tied in any way, but allowed to the fullest extent to show their natural scandent habit. The effect was remarkably good, and I was very much pleased with it. Those who tie this beautiful plant up have no idea of its fine appearance when shown this way.—H. R.

GARDEN FLORA.

PLATE 1239.

EPIPHYLLUMS.

(WITH A COLOURED PLATE OF *E. MAKOYANUM*.)

MENTION of the genus *Epiphyllum* suggests at once the charming winter-flowering *E. truncatum* and its numerous varieties. The species in the coloured plate to-day differs widely therefrom not only in the shape of the flower, but also in the season of blooming, as its showy blossoms are produced in the spring, generally in April and May. *E. Makoyanum* was, according to M. Pynaert in the *Revue Horticole*, introduced from Brazil by M. Makoy in 1888. On April 23, 1889, it was awarded a first-class certificate by the Royal Horticultural Society. There is, moreover, a very nearly allied plant introduced previously to *E. Makoyanum*, and known as *E. Russellianum Gaertneri* and *E. Gaertneri*. Under this latter name it was figured in the *Botanical Magazine*, t. 7201, where it is by Sir Joseph Hooker regarded as synonymous with *E. Makoyanum*, for he says:—

I have retained the name of *Gaertneri* for this plant as originally proposed, though only as a variety. *E. Makoyanum* was a mere name in Makoy's catalogue, and was adopted by Pynaert under the impression that it was a different species from *Gaertneri*, which, however, he alludes to when speaking of *Makoyanum*, but gives no characters for either differing from *Russellianum*.

* Drawn for THE GARDEN by H. G. Moon in Messrs. J. Veitch and Sons' nursery at Chelsea. Lithographed and printed by J. L. Goffart.

anum. According to Regel, who published it in 1884, *E. Gaertneri* was introduced by Messrs. Haage and Schmidt from the province of Minas Geraes, in Brazil.

Though the two may be regarded as synonymous from a botanical point of view, yet from a horticultural standpoint there are certain slight, but well-marked differences between them. In *E. Gaertneri* the flattened stems are broader and with a shorter distance between the joints than in the other, while the terminal joints are fringed with prominent hairs (a noticeable feature in the *Botanical Magazine* drawing), but, as may be seen on the accompanying plate, they are almost, if not quite, wanting in *E. Makoyanum*. The petals of *E. Gaertneri* are also somewhat shorter and of a rather lighter tint. As decorative plants the two are, however, on a par, and very beautiful they are, while their cultural requirements are but simple, and, given ordinary care and attention, they will flower profusely.

EPIPHYLLUM TRUNCATUM.—This, the best known and most generally cultivated species, was introduced from Brazil in 1818, and quickly became popular. Numerous varieties after a time made their appearance, many of them differing widely from each other and from the normal form. Some of the brighter-coloured flowers are particularly attractive, and a specimen in full bloom is a very showy feature. This *Epiphyllum* may be treated in different ways. In the first place it can be, and generally is, grafted as standards on to the *Pereskia*, the stem being any height from 9 inches to a yard or more. Next, given a good stout stock, a plant may be built up by inserting several grafts at intervals throughout its length. In hanging baskets, too, it is very effective, in which case grafting is not needed, the object of this mode of propagation being to keep the pendulous branches clear of the soil, so that when suspended that object is attained. A particularly fine example of a grafted specimen standing, I should say, nearly 6 feet high and laden with blossoms was very attractive last winter in the succulent house at Kew. A few good varieties of *E. truncatum* are magnificent, bright rose; salmonium, reddish salmon; coccineum, light red; purpureum, deep purple; Ruckerianum, reddish purple, shot violet; violaceum superbum, purple, light centre; bicolor, white and rose; aurantiacum, orange-red, and Princess, the latest addition to this section and not yet distributed. It received a first-class certificate last autumn, the only variety previously honoured being in 1864. In Princess the flowers are lighter than in the forms generally met with, the petals being white, suffused with purple, which colour is deeper towards the centre than at the edges, while in the throat there is a ring of purple-lake. A generation ago the blossoms of *E. truncatum* and its varieties used to be brought into Covent Garden Market in considerable numbers during the winter season and realised a fair price. At that time the pincushion-like bouquets were more popular than they are now-a-days, and the peculiar oblique-shaped blossoms were often wired and distributed at intervals around the edge. Now, however, the public taste is different and the choice of subjects so extensive, that they are little used in this way, though as specimen plants they are as effective as ever.

E. RUSSELLIANUM.—This is by some regarded as a variety of *E. truncatum*, and by others as a distinct species. It was introduced in 1839 from the Organ Mountains of Brazil, and was named in honour of the then great patron of horticulture, the Duke of Bedford, whose collector, Mr. Gardner, first sent it home. He described it as common on the mossy stems of trees, and also occasionally upon rocks, among the Organ Mountains. The flowers are rose-coloured and borne during the spring months. There are two or three varieties, but they do not show that marked divergence from the normal form which we find in *E. truncatum*.

PROPAGATION.

The Epiphyllums can be struck readily enough from cuttings put into sandy soil and given very little water till rooted, but for reasons above detailed they are usually grafted. The Pereskia, which is employed as a stock, strikes root readily, and should be grown on freely in order to obtain as stout a stem as possible. For grafting, the stock may be cut down to the height required, and, the upper portion being split, the scion, whose base has been fashioned wedge-shape, should be inserted therein and secured in position, either by passing two or three spines of the Pereskia through or by tying the whole securely with matting or grafting cotton. After grafting, the plants should be placed in a shady part of the stove, and if the weather is bright they must be lightly syringed three or four times a day. In about a month the union will be complete, and as soon as this takes place the plants had better be removed to a lighter and more airy structure. When inserting several scions on to one stock, and as it were building up a specimen, the clean incisions should be made in a downward direction in the stock at intervals of 6 inches or thereabouts. The scions being fashioned wedge-shape are inserted into the places prepared for their reception and fixed securely in position. The Epiphyllums are easily grafted, but at the same time they must be fitted together accurately. Grafting may be done at almost any time of the year except in winter, but I prefer to carry it out in the spring or early summer, usually about May.

CULTURE.

The general culture of these Epiphyllums may be soon summed up. After the flowering season is over they should have a period of rest, being kept drier at the roots and in a somewhat lower temperature. Having flowered in an intermediate house, the warm part of the greenhouse will then just meet their requirements. Potting is best done in March or April, a very suitable compost for the purpose being two-thirds good yellow loam to one-third pounded brick rubble and soft bricks, with a liberal admixture of sand. A little well-decayed leaf-mould may with advantage be added if the loam is of a heavy nature. In potting, the soil should be pressed down firmly, and great care must be taken to keep the plant well secured to a stake or stakes, as if this is not done, the weight of the branches is apt to cause them to snap off. After potting, the plants must be kept warmer, with occasional syringings, in order to encourage a free growth, while the supply of water at the roots may be increased, but care should be taken not to overdo them in this respect, as an excess of water may cause irreparable injury. Apart from the open nature of the soil, the pots employed must be thoroughly well drained. As the plants increase in size they may be kept for years without repotting, provided precautions are taken when potting them in the first place to keep the drainage open. In the case of these old-established plants they will be benefited by a little feeding in the shape of weak liquid manure during the growing period, and also just before the flowers develop. After the growth is completed the plants may be removed to a sunny greenhouse in order to ripen the wood and set their flower-buds, giving them at that period somewhat less water than when in full growth. The earliest may be taken into a little heat by the middle of September, and if a few at a time are so treated, a succession may be kept up for a considerable period. For suspended baskets, plants on their own roots are the most satisfactory, as they are better

without any clear stem. Grown in this way the flowers are seen to very great advantage, and the fact that they do not require so much water as many other subjects is greatly in their favour as basket plants, for the watering of them is not always an easy matter. I have also seen the varieties of *E. truncatum* employed for clothing a sunny wall in a warm structure, the wall being faced with network which held in position some rooting material, consisting principally of peat and Moss. Syringed freely during the growing season, the plants under such conditions both grew and flowered freely. The section of Epiphyllums that flowers during the spring months is amenable to the same mode of treatment as *E. truncatum* and its varieties, except that when necessary they should be repotted soon after their flowering season instead of early in the spring, as recommended for the others. H. P.

CORDYLINE (DRACÆNA) AUSTRALIS.

This stately, almost tropical-looking plant has been in cultivation in the milder parts of Great Britain and Ireland for a good many years, and

Cordyline in flower. From a photograph by Mr. Greenwood Pim, Dublin.

when strong and old enough frequently blooms, bearing one or more large, densely-branched panicles of small whitish flowers, followed by abundance of seed, as shown in the annexed illustration. It is nearly hardy, but a severe frost will damage the half-developed leaves, the very young ones, which are enclosed in the cone of older ones, usually escaping. It is, however, easily protected by tying all the leaves up into a bunch, the outer ones protecting all the rest. The plant from which the

photograph was taken is growing close to my house, which is covered with Wistaria, Passion Flower, &c., which form an excellent foil to the Cordyline. At Mount Usher, Co. Wicklow, where there is a large number of old Cordylines, they flower every year, some bearing four or five heads of blossom. G. P.

THE WEEK'S WORK.

KITCHEN GARDEN.

EARLY CELERY.—In the case of the earliest batches of Celery, slight earthing up will now be necessary. Where the least trace of the Celery maggot exists immediate hand-picking must be resorted to, as I know of no effectual insecticide, and if taken in time a lad can soon get through a few rows. When growth is huddled together for earthing up, the pest, if not removed previously, works sad havoc by November, and not only is the general quality inferior in consequence, but decay sets in sooner. Any extra early rows of such varieties as Sandringham White or Early Rose wanted for the dining-room in October may now have the final layer of soil applied and be banked up, and where copious rains have recently fallen, the moisture will by the process be preserved. I always set two men to each row. One can then walk backward and grasp each stick firmly with both hands, while the other brings up the soil. Some gardeners prefer tying up each plant with strips of matting. At any rate, the soil must not be allowed to find its way into the centre. Later rows will now need a little attention, suckers having in some instances grown out of the base. These must all be removed, also all weeds and rubbish, and a thorough good drenching of farmyard liquid given. When earthing up late Celery, a very wet or a very dry state should be avoided. The former encourages early decay, especially should the winter be wet or snowy, while the latter condition is productive of tough, indigestible growth. Where any spare plants were put out in drills for flavouring, a reservoir should be formed by drawing up more soil on either side with the hoe; this will prevent artificial waterings from running to waste. The same treatment should be accorded Celeriac, which, though by no means commonly grown, is a most useful vegetable, especially in hard winters.

THINNING SPINACH.—The plants resulting from the earliest August sowings of winter Spinach will now be fit for thinning. A too free hand, however, must not be used, as wireworm will sometimes attack the young seedlings between now and the final thinning stage. A distance of a foot should be left between each plant when growth is free and healthy. When sown on more exposed quarters a little less distance will suffice, as, being more hardy, the foliage is less liable to suffer from wet or frost. Even where a liberal quantity of soot and lime was dug in when the ground was being prepared, I would advise another sprinkling of the latter as soon as the first thinning is completed, mixing with it a little fish manure and using the Dutch hoe afterwards. This will give the crop a good start and a better chance of resisting grub and canker. Successional sowings must be watched, and, if necessary, cleaned as soon as the young growth peeps through the surface. This crop repays any labour

that may be bestowed on it. I have previously referred to the wisdom of sowing both the prickly and round varieties of Spinach at this season, having proved the so-called summer variety equally as hardy as the prickly, and sometimes one will do better than the other. On heavy soils slugs often attack young tender Spinach, and quickly riddle the leaves if not noticed. A sprinkling of lime and soot or wood ashes occasionally is the best preventive. Where winter Spinach is much in demand and any vacant plots of ground still exist, seed may yet be sown with a fair prospect of success, the produce, provided the winter is tolerably mild, coming in most useful at the new year. For these late sowings a sunny border is preferable. Do not draw the drills too deeply at this advanced date.

AUTUMN CAULIFLOWERS.—These will now demand attention. On hot soils this season Autumn Giant has a very blue appearance, owing to insufficient root moisture. When in this unsatisfactory condition caterpillars often attack them, and the heads turn in prematurely and are deformed and poor in quality. To prevent this give at once a good watering with liquid manure, repeating it in a week's time. This stimulant will soon alter the colour and general condition of the plants. Where the plants are growing in narrow borders that can be easily reached, a good drenching overhead with the hose or garden engine will aid in cleansing filth from the leaves and cavities, benefiting the roots likewise. When the heads are developing, care must be taken to preserve the colour, this being best done by tying up the leaves over them so as to exclude light and sun-heat. Should there be any doubt that the supply will not last out till the required date, the plants may be lifted with as much soil attached as possible and laid in by the heels behind a north wall, allowing a little space between each for a free circulation of air. Walcheren, where growing on Celery ridges, may, if the soil is required for earthing up, be laid in in the same manner. Self-protecting Autumn is unsurpassed for following on the heels of Autumn Giant. It is well protected by its folding interior leaves and comes in piecemeal, keeping in a usable condition in a cool place for some time. If care is used this valuable Broccoli may be had up to the time Backhouse's or other favourite winter varieties are fit for cutting. J. C.

OUTDOOR FRUITS.

APPLES.—The Apple crop, taking it as a whole, is not a very satisfactory one throughout the country, and I hear very bad reports from the eastern counties. Generally speaking, early varieties appear to be giving the best crops, and this being so, it behoves all who wish to make their supply cover as long a season as possible to prepare for gathering slightly in advance of the usual season. A very generally accepted but fallacious idea is that Apples keep best when allowed to hang on the trees as long as possible before gathering, but my experience is quite the reverse of this, as I have always found that most Apples, especially the early varieties, keep best when they are picked as soon as they will part from the tree with their stems intact, even if a fair amount of force has to be used in plucking them. Perhaps this may not hold good when the fruit room is not so cool as it should be, as then some amount of shrivelling will take place, but with a properly-constructed room that can be kept down to shade temperature and that is not over-ventilated, one need not fear shrivelling, and the fruits come up to perfection and will last for weeks longer than they will if allowed to really ripen on the trees. A case that will go far to prove my point here is that for some years I wanted to keep some good dishes of Warner's King for the middle of November, but always failed to do so until I adopted early picking, that is to say, picking when the fruits reached full size but were still quite green, after which I had no further trouble and always had some perfect dishes for the date mentioned,

grand in colour and without the slightest tendency to shrivel. Manks and Keswick Codlins can be well kept in the same way, and that fine useful Apple Crimson Queening, which is not nearly so frequently grown nor well known as it should be, will alone cover a season of four or five months if picked early and stored in a cool room. I have not found the colour of this or any other highly coloured variety suffer in the least from early picking. Of course I do not advocate getting off the fruits when they are palpably unfit or all at one time, but what I wish to insist on is that the general tendency is to leave the early Apples too long on the trees, whereas they might be safely housed where they will be out of reach of birds and wasps. It is particularly necessary that no unsound fruit should go to the store, as these soon decay and spread decay to others in contact with them. Methods of storing have greatly improved of late years, and it is almost needless to mention that no fruit should be placed on straw, hay, or any other dried vegetable matter, as all such things soon acquire a mustiness which is transferred to the fruits as they ripen and spoils them. The very best thing I have found for storing benches is slate, but as slate benches of sufficient thickness to bear a heavy weight are expensive, the advantages gained by the use of slate can be attained in a more economical manner by covering the ordinary lattice shelves of the fruit room with roofing slates; these will take up some of the moisture given off now by the fruits and will remain cool, slightly damp, and equable in temperature—just the conditions which suit the fruits best. If board shelves only be used in the fruit room, they should be of some sort of white wood which does not contain resin or anything that would taint the fruits. For preference they should be close-boarded, as the sharp edges of lattice-work shelves frequently bruise and spoil one's best fruits.

PEARS.—These will require still more attention to gathering than Apples, for they vary more in their seasons of ripening, so that no hard-and-fast line can be laid down with regard to them, and only the experienced cultivator will know just when it is best to pick. Some of our best Pears, such as Marie Louise, may be greatly lengthened in season by being picked in batches of a few dozen at a time, the quantities at the first pickings being regulated by the demand. Duchesse d'Angouleme and a few others which ripen up naturally during September and October should be treated in the same way, while late varieties are best left on the trees as long as they will hang, or until the nights begin to get very frosty.

PLUMS.—Wasps and bluebottle flies, the latter especially, have been particularly troublesome this year, and Plums suffer a great deal from their attacks. Where the Plums are wanted especially for cooking it is best to pick them off before they become quite ripe, as many of the cooking varieties keep well if put in single layers in a dry and cool room, provided they are not over-ripe when picked. As regards dessert kinds, these must be allowed to ripen on the trees, and in a scarce season like the present it is worth while to protect the best fruits individually by enclosing each in a separate piece of very thin muslin, which should be big enough to hang loosely round the fruit, so that it may dry quickly after a shower. Later on, as the fruits ripen, they should be picked on a dry day, and each sound fruit which can be spared for the time should be wrapped in a piece of tissue paper and put away in a drawer to keep till required. Coe's Golden Drop, Ickworth Impératrice, and Reine Claude de Bavière are a trio that can be depended upon to keep well in this way, but they must be stored in single layers and kept quite dry and cool, having an occasional look over to remove any fruits that may be decaying.

PROSPECTIVE PLANTING.—Though early yet to think about commencing the planting of outdoor tree or bush fruits, this is an excellent time to go to the nurseries and see as well as to order any stock that may be wanted, and where more than

a dozen or so of trees are to be selected there is a great deal to be gained by being early in the field in this respect. I like to see the stock growing, as a much better idea of their fruiting capacity and general quality can be gained by seeing the trees in leaf, and possibly in fruit, than can be formed later when the leaves are gone. There is also the satisfaction of being able to make one's own selection, so that there may be no mistake as to variety, &c. The long-continued drought has made ground operations almost impossible, but as soon as the soil is in fit condition it will be best to get the work in hand, double digging any ground that may be set apart for tree or bush planting. This is more satisfactory than digging pot holes, however big, for by double digging the entire plot well in advance of planting, the ground settles together and there are no hard sides—difficult for the roots to penetrate—left to the holes when dug. If there is plenty of burnt earth and wood ashes at hand, a heavy dressing of these before digging will be helpful, but if the supply is limited it will be better to reserve it for use near the roots when planting. No manure should be used except, perhaps, for bush fruits.

CORNUBIAN.

FRUIT AND VEGETABLE CROPS.

NORTHERN.

Wythenshawe, Northenden.—Apples in this garden are very few, and in the neighbourhood they are generally scarce, though some have fair crops here and there on Stirling Castle and Grenadier. Pears may be termed moderate, the frost we registered at the latter end of May and the ungenial, dry weather which extended into June being unfavourable for the setting of the bloom. Of Plums we have none, and which is general in this neighbourhood. Cherries in the open are a light crop, but on walls Morellos are better. Black and Red Currants and Raspberries are very good, and so are Strawberries. Gooseberries are mostly a light crop. Some complain of the birds as the cause, while in many cases the early blooms were caught by frost, and those which opened later gave a few berries, but only making a very light crop.

Vegetable crops are now looking better since the rain came. Early Cauliflowers on good ground have done well, while later ones had not made much headway before the acceptable rain. Peas are very good, especially where previously well supplied with manure. Other crops of vegetables are looking well, except perhaps in some cases Carrots have had an attack of fly, and Celery, having been well supplied with water, is looking very well.—JAMES DALE.

Kirklevington Hall, Yarm.—The fruit prospects here are not so satisfactory as they promised to be at the flowering season, particularly in the case of Apples, the late frosts and cold, dry weather having crippled the bloom. Apples are a light crop; Pears moderate; Plums quite a failure. Gooseberries are the lightest crop we have had in this district for many years. Strawberries, Currants (Red and Black) are a good average crop; Cherries are thin; Raspberries are an abundant crop and good.

Vegetables have done fairly well where watering has been attended to. Peas and Potatoes are turning out well.—ALEXANDER CUNNINGHAM.

Hurworth Grange, Darlington.—In the spring everything gave promise of a fruitful year, all kinds of fruit trees being laden with bloom, but late frosts and dry cutting winds have once more caused disappointment. Apples, Pears and Plums are very thin. Cherries, both dessert and cooking, are a fine crop. Peaches in case and Apricots that were protected with a good canvas sheet are both good. Gooseberries, Black, White and Red Currants are a good crop, the fruit fine, the rain coming at the right time for them. Strawberries were plentiful, but we got the dry weather when they were swelling and the wet when ripening, so that a great many rotted

before being ready to gather. Raspberries are good. Tomatoes plentiful.

Early Potatoes are small; early Cauliflowers moderate; early Peas did not fill well; midseason and later ones look better. All kinds of summer and autumn vegetable are doing pretty well.—J. SIMPSON.

Broughton Hall, Yorks.—This spring was most disastrous to Peaches, Pears, Plums, and Cherries, not so much the frosts as the continuous parching east winds. Never did the fruit trees promise better. Peaches, Plums, Pears, and Cherries were exceptionally full of fine healthy blossom, and though well protected with fish netting and canvas at night the crops of all kinds mentioned are thin. Blister on Peach trees is very bad, but, thanks to a more congenial summer, the trees are now in excellent health and vigour. Apples, Strawberries, and bush fruit are abundant, Black Currants excepted. For several years past I have never had the magnificent crops of Black Currants I used to have.

Peas and Cauliflowers are very late; midseason crops of the latter almost a failure; Peas excellent, thanks to timely mulching. Potatoes are excellent. The recent rains have improved vegetables of all kinds. Midseason and late Peas are excellent.—J. RAINBOW.

Chillingham Gardens, Belford, Northumberland.—Owing to late frosts all the early blossom on the Apricots was killed, but a few late blooms were saved. They never looked better, but 28° of frost on March 24 was too much for them and a lot of branches died as well. Strawberries have been a heavy crop, especially Royal Sovereign; Raspberries a good crop and very fine; Gooseberries a failure; Black and White Currants good, Red have often been better. Cherries are very light, also Peaches and Pears; Apples a fair crop on some trees; Plums a light crop. Wineberries are looking well, likewise Wilson's American Bramble. The Loganberry is but a light crop. Nuts are splendid.

Peas, Cauliflowers, Beet, Carrots and Cabbages are all very good. Potatoes are poor, likewise Turnips, Lettuces, French Beans and Onions, as a lot of the seed never came up owing to the cold and wet. It rained less or more for ten weeks all but three days.—R. HENDERSON.

Burnhopeside Hall, Lanchester, Durham.—We are at a disadvantage in this district compared to the more southern counties. Apricots and Peaches are very precarious unless they are well protected. Peaches and Nectarines inside are good; Apples, Pears and Plums are thin; Morello and Sweet Cherries are a fair crop; Strawberries and Raspberries are good.

Vegetables are doing well, the late rains suiting them well.—CHARLES LACEY.

Edenhall, Langwathby.—The fruit crops in these parts are, I think, a good average. Strawberries and Raspberries are very heavy and the fruit fine. Apples and Pears are a good crop, but Plums are a failure. Apricots and Peaches are good, as also are all bush fruits.

All vegetable crops look very promising.—ARTHUR SMITH.

Naworth Castle, Carlisle.—In this neighbourhood the fruit crop is below the average, Apples, Pears, and Plums being scarce. Black, Red, and White Currants have been plentiful, also Raspberries and Cherries. Strawberries have also been a heavy crop, but owing to the severe drought in June their season has been short, though on a late border Eleanor and Elton Pine are still (August 14) carrying a nice crop of fruit.

Vegetables on the whole are now doing well. The earliest sowings of the Brassica family, especially Cauliflowers, were more or less ruined by grub. Carrots in most places are almost a failure from a like cause, and early Turnips were severely checked with drought and fly. Onions are doing well, and though the maggot is again with us, nice crops will be saved, especially those raised inside and transplanted, they being quite free from grub. Early Peas did well; midseason varieties not so satisfactory, and birds have made

matters worse, even nets failing to ward off the tomtits and other small birds. Potatoes are a splendid crop all round, with up to this date no appearance of disease.—JAMES HILSON.

Harewood House, Leeds.—Apples are on the light side, but promise to be of good quality. So far the trees are clean and healthy—at least the young ones and those that were lifted and root-pruned some years ago. I find the young trees that were planted on entirely fresh ground doing best. Further experience teaches me that it is a waste of time bothering with old trees, even although they look as if they could be improved. The following varieties have borne well for the last four years and promise to ripen fruit of fair quality this year: Alfriston, Lord Derby, Warner's King, Ecklinville (this and Stirling Castle seldom if ever fail here), Winter Hawthornden, Lane's Prince Albert, Peasgood's Nonsuch, Potts' Seedling, Lord Suffield, Cellini and Northern Greening. Pears are to be a very light crop, the best being Williams' Bon Chrétien, Jargonelle, Clapp's Favourite, Louise Bonne of Jersey, Souvenir du Congrès, Brown Beurré and Pitmaston Duchess. The last, grafted on the top of a horizontal-trained tree of Beurré de Capiaumont, promises to ripen some excellent fruit, very large for this district and perfectly free from blemish or spot of any kind. Plums are light; Apricots fair; Cherries good. Peach trees have suffered from blister and the crop is very poor. Strawberries are a fair crop. Royal Sovereign is certainly the best sort grown here either for forcing or outside work; next come Keens' Seedling and President. Small fruits (except the Black Currant) are a good crop; Red Currants are a heavy crop; Gooseberries also. No caterpillars so far have made their appearance on the Gooseberry. The worst enemy here this season is the American blight on the old Apple trees.

Vegetables have done very well, Peas in particular. May Queen and William I. were sown end of February and ready to gather second week of June, which is considered early here. Prince of Wales, Duke of Edinburgh, Telephone, No Plus Ultra and others promise well. Cabbages, Cauliflowers, and Broad Beans are healthy and doing well. Potatoes (late sorts) look very well; early sorts have been very small, but of good quality. Spinach, of which there have been many complaints of not doing well this season, has been grand here. Lime has been freely applied in the gardens here and we are seldom troubled with either Onion or Carrot pests.—J. JEFFREY.

Kimbolton Castle, Kimbolton.—Apples, Pears, and Plums are a very poor crop, though there was plenty of bloom, the fruit falling off after setting. Peaches are an average crop, but Apricots are quite a failure. Gooseberries, Currants, and Raspberries were very good and fine. Strawberries are an average crop, but fruit very small owing to the frost, which cut all the earliest and finest blooms. Morello Cherries are only a fair crop; Nuts are very scarce.—J. HEWITT.

Abney Gardens, Cheadle, Cheshire.—The fruit crops here are very poor. This is about one of the worst years we have had for a long time. Strawberries certainly have been well got, but the crop is short and a lack of fine fruit. This could not be otherwise, as a large proportion of the early blooms was killed by frost, as we could see them black in the heart when the flowers were open. Raspberries are a good crop; so are Black Currants. Red Currants and Gooseberries were very much injured by sparrows taking the buds. There are no Plums, very few Cherries, scarcely any Pears, and Apples are not a general crop. Grenadier, Cellini, Lord Grosvenor, and Potts' Seedling have good crops; many of the other trees have scarcely a fruit on. Lord Suffield that here usually does well has scarcely a fruit on.

Potatoes have done well, and these generally hercabouts are looking well. Puritan I find still our first early, then Sharpe's Victor. I have had some very good early Cauliflowers, Dean's Snowball first and then Early London. I transfer them two in a pot to the open ground and leave them so, as nice moderate-sized heads are quite

right for the kitchen. Early Peas are over; they were William I. and Gradus. The former was the better with me. Later Peas, No Plus Ultra, are looking well. Onions, especially those raised under glass in January and planted out in April, are in very good condition. Brussels Sprouts for winter are also looking well.—ROBERT MACKELLAR.

Abbotswood, Furness Abbey.—The Apple crop here is a very heavy one, much above the average, but Pears are very scarce all over the district and Plums under the average. This is a bad locality for stone fruit. There is a good crop of May Duke Cherries, also Morellos. Strawberries Eleanor and President are cropping well, with finely coloured fruit. Gooseberries, Currants, &c., are heavy crops.

Vegetables are not so good owing to the cold, wet spring; some varieties of Peas are bearing a heavy crop.—I. SINGLETON.

Birdsall Gardens, York.—I consider it one of the worst fruit seasons we ever had. Apples, Pears, Plums, Cherries, and all kinds of bush fruits are under the average. Strawberries have been very good from plantations made last autumn, which says much for annual plantations of this useful fruit. Old heds have been good, but not equal to the new beds. There are exceptions in the new beds; for instance, 400 strong young plants of Laxton's Monarch have not shown a truss. My best varieties are Black Prince, Royal Sovereign, Noble, President, Sir J. Paxton, and Gunton Park. The last is one of the very best for packing and sending a long distance, and excellent in quality. Apricots on outside walls are a failure. I have a good crop in the Apricot shed. Peaches on outside walls usually carry good crops here, but this season we have none. There are some trees of Victoria Plum in this district carrying heavy crops, also large old trees of the old Hesse Pear with good crops.

Early Potatoes were damaged by the late frosts in May, and consequently are very small but good in quality. Asparagus is very good. Peas have done well. We have a good early variety in Thomas Laxton, excellent in colour and flavour. A sowing of this variety was made here on April 3, and they were in condition for gathering on July 1. Other varieties that do well here are Veitch's Early Marrow, Maincrop, Prodigy, Autocrat, British Queen, and Champion of England, still one of the best. Late Potatoes are looking well.—BAILEY WADDS.

EASTERN.

Bloxholm Hall Gardens, Lincs.—Our fruit crops here are generally very scanty this year. During the flowering season Apples, Pears, Plums, Peaches and Apricots were laden with blossom, and an excellent fruit year seemed inevitable, but late sharp frosts quickly did their destructive work, blasting our hopes of a fruitful season to a great extent. Cherries, both sweet and Morello, are an average crop and of good quality. Of Apples, Keswick Codlin, Lord Suffield, Stirling Castle, Bramley's Seedling and King of Tomkins Co. are average crops, of good quality, but these few embrace all the varieties that we have anything of a crop on at all. Pears are still worse, and I cannot name a single variety on which there is anything approaching a crop. The same remark applies to Peaches and Apricots. Of bush fruits Gooseberries were a failure, whereas Red and Black Currants were both heavy crops of fine quality. Strawberries were poor.

Early and main-crop Peas have been excellent both in quantity and quality. Early Potatoes very fair; main-crops give good promise.—W. LUMSDEN.

Shrubland Park, Ipswich.—The scarcity of bloom on fruit trees this spring, which in some instances had in consequence of the mild winter been forced on before its usual season, did not give hope of heavy fruit crops, but, all things considered it is surprising to see as much fruit as we have. We have fair crops of the following sorts of Apples: Court Pendu Plat, Cox's Orange Pip-

pin, Ribston Pippin, Warner's King, King of the Pippins, Peasgood's Nonsuch, Gloria Mundi, Ecklinville Seedling, Blenheim Orange, Manks and Keswick Codlins. Pears are under the average, but a few trees are carrying good crops, notably Doyenné du Comice, Emile d'Heyst, Pitmaston Duchess, Louise Bonne, Marie Benoist, Vicar of Winkfield, Knight's Monarch and Catillac. Damsons are a good crop, but other stone fruit is scarce. Apricots are an entire failure. Red and Black Currants, Gooseberries and Raspberries are plentiful. Strawberries were a good crop, but the fruit was small; that I attribute to the drought last season and the consequent weakening of the plants.

All vegetable crops are doing well. Peas, where good cultivation has been given, are a good crop, and as yet the later varieties are not showing the slightest trace of mildew. Early Potatoes have been good. The later varieties are doing well and rain has fallen just in time to help them forward.—G. TAYLOR.

The Gardens, Gunton Park, Norwich.—In this part of Norfolk, along the coast, Apples and Plums are a very bad crop. A few trees of Czar and Early Violet are fair; other kinds a complete failure. Late-flowering Apples, like Court Pendu Plat and Colonel Harbord, escaped the bad weather and have set a fair crop; other kinds miserably thin. Pears on walls are very fair; most of the kinds required some thinning; trees fairly healthy and clean; Pear slug not so troublesome as in former seasons. Cherries are good, especially Bigarreau Napoleon, Elton, and Black Tartarian. Morellos set well, but have turned yellow to some extent and fallen, owing to the intense drought and heat. Strawberries, Raspberries, and Gooseberries are good crops. Strawberries lasted a shorter season than usual, owing to the great heat and drought. Currants, White, Red, and Black, are under average and small on light soils. Walnuts very plentiful. The most reliable and latest Strawberries are Latest of All, Waterloo, and Lord Suffield. There is a great demand for late Strawberries here, near the coast.

Potatoes, although smaller than usual, are wonderfully good in quality. First and second earlies are ripe, or nearly ripe, and may be lifted out of harm's way, as, when the rains come, disease and second growth will be sure to follow after this extremely dry and hot period.—W. ALLAN.

Huntingdon and St. Neots.—Apples only half a crop, after a splendid promise. Pears are good on walls; on standards a failure. Peaches and Nectarines are poor; trees badly mildewed; Apricots a complete failure. Plums are poor; Victoria and Gages fairly good crop; Morello Cherries excellent; sweet Cherries do not succeed in this locality. Raspberries, Currants, and Gooseberries are heavy crops, and all clean and good; Strawberries about half a crop and rather small, owing to early blossoms being cut by frost. Filberts and Walnuts are thin, scarcely half a crop. Our crops upon the whole are much under the average.

Potatoes are good, but rather late. I still consider Ringleader the best early Kidney in cultivation, followed by Duke of York and Ideal. Cauliflowers good, but soon over, owing to dry, hot weather. Early Peas and Beans were good, but late crops a failure. Onions raised in heat and transplanted are excellent, while the spring-sown are very small and poor. Carrots excellent, also Cabbage and French Beans.

Flixton Hall, Bungay.—In this district, with the exception of most of the small fruits, the crops are very unsatisfactory. In the early part of the year the trees looked very promising, but severe frosts during the week from March 19 to 25 destroyed all the strongest blossoms, both open and in bud, on Peaches, Nectarines, and Apricots. During that week we had from 20° to 23° of frost. With so much frost, three and four thicknesses of fish netting afforded but little protection. Pears are only a light crop and Apples the same. The latter were late in coming into blossom, and I have always observed that if the

trees are in blossom and nearly in full leaf at the same time we rarely get a good crop of fruit. Cherries, both on standard and trained trees, are fairly good. Plums are partial. Gooseberries nearly all dropped off in a young state owing to continual frosts, the foliage at the time not being sufficiently forward to afford the young fruit protection. Strawberries, Raspberries, and Currants are plentiful and good.

All kinds of vegetables are looking well. Peas have been and are still abundant. Potatoes on heavy land look well and the crop promises to be very good, but on light land they are not quite so satisfactory, for, owing to the want of rain, the haulm is turning yellow and the tubers are small.—H. FISHER.

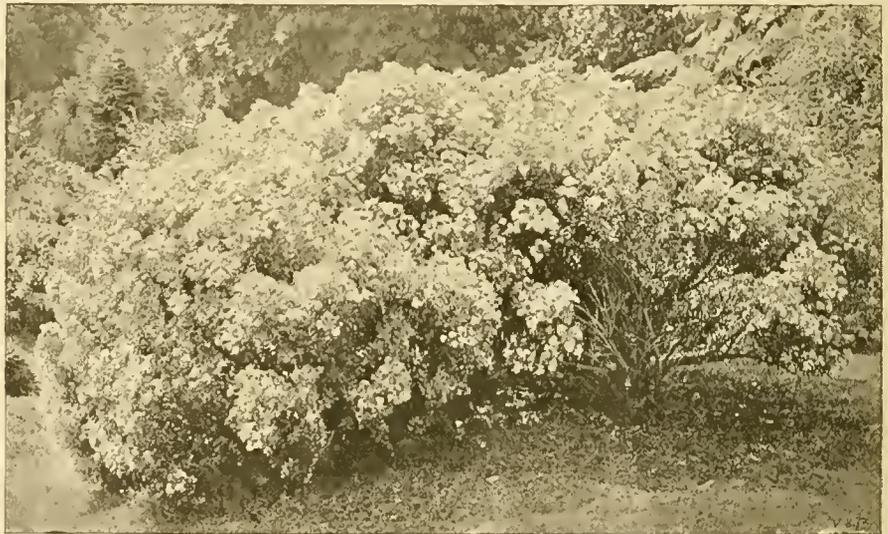

Babraham, Cambridge.—The fruit crop in this neighbourhood is not a good one this season. Apples are very uneven. The Codlins seem the most plentiful. Ribston and Cox's Orange have a crop, and King, Mère de Ménage, Newton Wonder, Peasgood's. Wealthy, Queen, Prince Albert, and a few different Pearmaines are also bearing. Plums are scarce, except on walls; Pears the same. Cherries are a very fair crop. Apricots, Peaches, and Nectarines are the thinnest crops I ever had. The severe frost on March 20 (33° at 2 feet from the ground) was

Onions are excellent this season. Most were sown in boxes and pricked out into their quarters.—J. HILL.

TREES AND SHRUBS.

OLEARIA HAASTI.

THIS bids fair to become—in some districts at least—nearly as common as the ubiquitous Privet, for it occurs in most gardens large or small, and very few evergreen shrubs hold their own so well within the smoke and dirt of London as this New Zealand Daisy Tree, which is just now producing its tiny white flowers in great profusion. The fact that it does not bloom till the month of August, when few other shrubs are in flower, is a great point in its favour. In several places along the embankment at Chelsea it is laden with blossoms. This Olearia forms a dense-growing, somewhat lumpy bush, clothed with deep green Box-like leaves. It is not nearly so graceful as some other species, but as a set-off is far hardier and more indifferent to soil and situation than any of the rest. Many only succeed in favoured

Olearia Haasti. From a photograph sent by Mr. F. Rossiter, Bath.

more than any blossom could pass through although heavily protected. Trees that were not in flower at the time are all right. Sea Eagle, Princess of Wales, Goshawk and Barrington Peaches, and Lord Napier Nectarine have suffered the most in consequence of their being earlier to bloom. Gooseberries in this garden are nearly a failure, but in some places near are good. Raspberries are a fair crop. Black and Red Currants are good. Strawberries are a very short crop. Nuts are scarce. The season has been very indifferent. Cold winds and drought with late frosts have been all against good fruit crops, without taking into consideration the drought of last year, which must mean failure on light soils for the next year's fruit.

Vegetables were late, but very good and plentiful. Peas were late. Sutton's May Queen is very early, but too tall for borders. I still rely on Chelsea Gem and Sutton's Marrowfat Seedling for the earliest crop on borders, and Earliest Marrow for the open quarter. On some damp ground I had Criterion and Duke of Albany—a better lot no one could wish for. Potatoes will be small this year. I grew on an early border Veitch's Improved Ashleaf. No one need wish for a better kind. The crop was very heavy and the tubers smooth, white, and of good flavour.

districts, such as the south of England and Ireland, and in many places need the protection of a greenhouse. *Olearia Haasti* is readily increased by cuttings from 4 inches to 6 inches long, put into pots of sandy soil, and kept in an ordinary garden frame till rooted. If taken about midsummer they will be struck by this, but the present is also a very suitable time, as they will produce roots before winter. Of course, the frame must be kept close and shaded during bright sunshine. H. P.

Rhus Cotinus.—I noticed a very finely feathered plant of this in a Nottingham garden recently, the long fluffy tendrils very bright for a town garden. It is very effective when grown singly on a lawn and allowed to spread naturally, the plant having a very distinct habit that, though it cannot be called elegant, is quite suitable in such positions. Propagation is effected by cuttings of ripened wood and by suckers, that in some soils spring up very readily. A light, open soil, a high and dry position, and not too much exposure suit it best.—H. R.

Rubus phoenicolasius.—This interesting berried plant is much in need of improvement so far as its fruits are concerned, whilst as a Bramble

it is the most ornamental of all the fruiterers, yet the fruits are small, though most profusely borne, and are much inferior to those of an ordinary Blackberry. Possibly an infusion into it of good Raspberry blood might add to the merit of the fruit appreciably. That crosses between Brambles and Raspberries have produced some fine results, as also some worthless ones, we have had evidence. Golden Queen Raspberry and The Mahdi, a very black Raspberry, are capital and make valuable additions to our stocks. Of these fruits, *Rubus laciniatus* under good culture is the most prolific and profitable of all Blackberries, and Mitchell's Selected, a very fine form of our common Blackberry, shows what can be done by patient selection. Some day, perhaps, we may secure both red and white or yellow Brambleberries.—A. D.

PARK AND WOODLAND.

WHERE TO PLANT.

LATITUDE.

LATITUDE, as we all know, affects vegetation all over the world, and it is one of the conditions that the planter has the least control over. By latitude I am here referring to the distance of any point from the equator. That the influence of latitude on vegetation is marked within certain wide limits is certain, but within say a line of 1000 miles long, or about the length of the British Islands, it is not so marked. One may travel pretty well from the Grampians to a point a good distance beyond Paris without seeing much difference in vegetation, but much depends on the configuration of the country. This is true particularly of Great Britain as regards forest trees and farm crops. It has often been said that the Scotch Fir, Spruce, and allied species are the only trees fit to plant in the north, but the assertion is far from the mark, for whereas these trees, where the local conditions are suitable, thrive just as well south as north, while the species regarded as tender, like some of our broad-leaved timber trees, do as well in the north as in the south, and in some places better. If a distinct exception can be made, it is the Oak. It certainly does not grow so fast anywhere in Scotland as it does in the midlands and south of England, and the quality of Scotch Oak is, as a rule, inferior, being more subject to ring-shake and frost cracks. According to accounts of the members of the R.S.A.S., the Oak in the south of Scotland has been found to be so badly ring-shaken as to be wholly worthless as a crop. This was on an estate near Peebles. Further north, in Aberdeenshire, I was shown fairly well-grown Oaks the trunks of which had been rent by frost. The proprietor told me that in severe winters the cracks were so wide in some trees that he could push his fingers into them easily. Such cracks close again in summer, but in some trees they bleed freely when the sap begins to move. I have often seen cracks in the Elm in Yorkshire that I could shove the blade of a knife into, but mature Oak shaken in that way is not very common.

With exceptions like these over the whole of Britain, from north to south, I should venture to say that the forester might plant with every prospect of success nearly the whole of our British forest trees regardless of latitude, provided he chooses his species according to aspect and elevation. I am of opinion that no greater mistake has been made in Scotland within the last 100 years than that of planting too many Firs, exclusive of Larch, and too few broad-leaved species—hardwoods. I had last year to report on the woods on an estate north of the Tay, and could not help thinking how much

the estate had lost in value by the planting of the wrong species, Scotch Fir and Spruce predominating everywhere, which could not at the present time be given away, and which it has always been known would never be of much value; whereas Ash, Elm, Beech, and Sycamore, it was equally well known, could be grown to perfection and to a large size in less time than the Firs, which they over-topped wherever mixed, while making also grand park and hedgerow trees. A reference to the estate books showed that nothing but the last-named species had been sold for many years, and the prices got were exceptionally high, especially for the Sycamore, which was sent (good butts) to England. These remarks apply to many spots in the north of Scotland. A few degrees of latitude is hardly felt provided there is natural shelter, and the forester may often do much by choosing his situations. Many gardeners, foresters, and especially gamekeepers, who have never crossed the Tweed have a notion that Scotland is a region of snow and ice during a large portion of the year. It would surprise them to find parts not unlike Kent as far north as Forfarshire. The Vale of Strathmore is an example. This great tract of almost level land, sheltered on the east and west and protected by the Grampians on the north, is a paradise of the farmer and gardener. The soil is also rich, and crops of all kinds are excellent. Peach Royal George on open walls I have seen well over in September, Plums dead ripe, and Apples (fine sorts) the same. Hardwood forest trees equal anything found in the most favoured parts of England. The farming is of the highest order, and the farm-steadings are probably not surpassed anywhere. The Carse o' Gowrie, Carse o' Stirling, and many other places might be mentioned equally favourable to agriculture and forestry. Even in Ross-shire and beyond the Moray Firth the climate is delightful, although the exposure is eastward, while the mildness of the west of Scotland and its islands where the cattle are pastured all the winter is proverbial. Brown, who knew just as much about the climate of Great Britain as he did about forestry, professes to speak with the greatest confidence on the suitability of the soil and climate of Great Britain to the growth of trees, and tells us things that have not a leg to stand upon. For example, all that part of the country between the river Tees and the Firth of Forth is, we are told, "fourth-rate" both in respect to soil and climate for hardwooded trees, whereas both are generally first-class. Beyond that from Edinburgh and Glasgow and further north the conditions are fifth-rate, while the greater part of the country "to the north of the central plain of Scotland" is generally unsuitable to any trees except Pine and Fir. That, we are told, is the Pine-growing region of Britain ("Forester," page 11). England has long been a Pine-growing region, especially the south, and before long it will probably have more Scots Fir in Hants, Surrey, Sussex alone than there is in all Scotland. The Germans say the Scots Fir is eminently a low country tree, preferring warm situations, and the Dutch allotment holders grow crops of it for deals in their small plots. Also on the warm, sandy lands near the Maine you may travel for miles through Scots Fir alone, and islands of Scotch logs float down the Rhine past Bingen every day. It was such teachers as Brown that led unquestioning, well-meaning Scotch proprietors to go on dibbling in Firs in the belief that nothing else would grow, and who now find their estates of much less value than they might have been. Travel over Scotland anywhere you

choose, up the eastern and down the western side, between the borders and the Caledonian Canal, and without leaving the train, it may easily be seen how far wrong we have hitherto been about the climate and trees. Some of the finest examples of Ash, Elm, Sycamore and Beech I have even seen have been in the highlands of Scotland, in the gullies and glens where nothing else would grow. There are or were some remarkable Asues at Dunkeld. At Belmont Castle, Forfarshire, the hardwood trees for their size and height are a feature, and one patch of Beech in the park called the "Straight Beeches," and much thought of for their tall, clean, cylindrical trunks, are the finest specimens I ever saw, except in the Beech forests near Louterburg. I took their height and girth last year. At Monymusk, a little beyond Aberdeen, there are also fine examples of hardwoods, and, if I remember rightly, several large Walnut trees.

ASPECT.

So much for latitude. Throughout Britain I think it may be almost ignored, and conditions of aspect and exposure only considered. These mean far more than soil. Three-fourths of the solid substance of trees come from the atmosphere through the leaves, the rest from the soil. The agents, therefore, that promote the growth of the leaves, the main timber-producing agents, must be of most consequence, and these are heat, light and moisture at the root. Supply these, provide a root-hold in a medium where the few mineral substances required from the soil exist, and they are rarely absent in the poorest soils, and all the necessary conditions of tree life are present. By heat here is meant full exposure to the sun and shelter from cold winds and currents. The late Mr. John McGregor, of Dunkeld in his evidence before the forestry committee said that the value of the Larch crop on one hill varied to the extent of £80 per acre, or thereabout, between the top and the bottom, that at the base of the hill being worth £100 and at the highest point £20. He told me the same thing himself when I was at Dunkeld. This difference was not due to soil, but to altitude and exposure. Numberless examples of this kind could be given, in some of which the difference amounted to 50 per cent. as regards bulk and value. Situation is indeed a question of the very first importance to all planters of trees, because it may far more than turn the scale between profit and loss. In some parts of Yorkshire the Wellingtonia has ceased to exist wherever the situation was exposed, but where planted low down in sheltered spots it has done well. I lately cut boards nearly 15 feet long that measured about 15 inches in the middle out of one tree that I saw planted just over thirty years ago. Grown in masses, I believe this tree will yet come to the front as a timber tree of quick growth. The Douglas Fir and all the Spruces love deep declivities facing east or west or, in the south, north, but shun exposed knolls and dry soils.

For some reason or other planters in the past have often preferred mountain-tops or high elevations on the plea of shelter, but I much doubt the utility of such schemes. For cattle shelter it would often be better to build dry stone walls. The time that such exposed plantations take just to become established is wearisome, and the Government has found that out, I believe, in their plantations near Barroole, in the Isle of Man. What a contrast these plantations afford to the forest of Glen Ellen, not far off Peel, in the Isle of Man. This was a lonely, bare glen when the proprietor conceived the idea of planting it from end to end, and now it is a forest of tall Larch, Scotch

Fir and other trees, and one of the most popular places of resort for visitors in the island. The soil is poor, lying upon the silurian formation, but the glen is a sun-trap. Everywhere in the forests of the Hartz Mountains the effects of altitude and exposure are visible, and the range is from 1000 feet to fully 3000 feet, the base of the mountain range being, I believe, about 1000 feet above the sea. Of course, at such altitudes Beech and Spruce plantations in time become trees of considerable height, through close planting and dense nursing, where they would otherwise be mere scrub, but the difference between the highest and lowest compartments is just as conspicuous as in Scotland. In planting at the highest points, 10,000 or 15,000 trees to an acre are put in in order to establish the overhead canopy quickly, and thinning is long delayed and the rotation period has to be extended proportionately.

In planting hills the tops are usually planted in preference to the lower parts, because, we suppose, the soil is believed to be better lower down and of more value for other purposes, but that only applies to the soil of the valley proper which it is not proposed to plant. The denudation of steep hills goes on from top to bottom wherever the slope is at all steep; hence the soil is much the same all over, and as far as that goes it is just as wise to plant at the base and proceed upwards, clothing the hill as planting goes on. At any rate the returns from the lower levels will be much earlier and better. This is demonstrated everywhere in parts of the country like Derbyshire and parts of Scotland where narrow glens alternate with low hills that have been planted with trees at different periods. J. SIMPSON.

ROSE GARDEN.

PEGGING DOWN ROSES.

In advocating the pegging down of Roses I am not suggesting anything novel; indeed, our forefathers adopted this method of culture on a far larger scale than is done at the present day. One need not go far to find natural exhibitions of the system. They are to be found in any hedgerow where Dog Roses abound. Perhaps a long growth has been caught by some neighbouring branch, and consequently held in a horizontal position, or the weight of the shoot has caused it to bend of its own accord. In any case the result is the same—viz., long growths smothered with delicate and fragrant blossom. Every gardener must have noticed upon a fine standard of Gloire de Dijon where the knife is almost a stranger at pruning time, how the long growths swaying in the wind are studded all over with buds and blossoms. It is entirely against the laws of Nature to prune Roses in the reckless manner now adopted. I believe in removing old worn-out wood, but the fine new growths if well ripened should be either very slightly cut back or bent down and pegged.

The illustration of some plants of Ulrich Brunner pegged down shows better than words what is possible in this style of Rose culture. It is pitiable to see the fine growths of this noble Rose rising some 5 feet or 6 feet high and to know that next spring more than half of this wood will be cut away. These growths contain some three dozen eyes, that if pegged down would yield certainly two dozen sprays of blossom; whereas with the usual mode of culture not more than half a dozen would emerge from the growth when pruned. Supposing one has two or three of such growths upon a plant,

what a grand lot of blossom may be secured by pegging them down.

The system briefly is this: In the month of March one, two, or more of those fine shoots that are found upon healthy plants of the vigorous growing kinds must have their points slightly removed. The small twiggy growths in the centre of the plant, also very old wood, should also be removed, the object being to encourage strong basal growths to succeed those now about to be pegged down. The ground should be forked over, burying the manure that has been applied in the autumn. Some strong galvanised iron pegs are then thrust into the ground so that about 1 foot of them is left above, and the long growths already alluded to bent down and attached. If there is any fear of late frosts it is advisable to delay the bending down for a time, for, naturally, as

shoots are in flower these younger growths will have reached a considerable height.

After flowering, every encouragement should be afforded the new wood, and it is a good policy to remove the flowering growths immediately they have ceased blooming, unless an autumn crop of bloom is anticipated. This would be possible from some kinds, but with others there would be little hope of a second blooming; consequently the growths are best removed. The new growths will often be crowned with bloom, and will succeed those from the pegged-down shoots, but should they appear blind then, it is a good plan to stop them early in September, an operation that ensures the well ripening of the wood. Supposing new growths do not start very early (and this sometimes is the case), then I would advise the retention of the pegged-down growths for

Rose Ulrich Brunner pegged down.

soon as the upward flow of the sap is checked, the eyes or buds upon the shoot commence to swell and eventually break out into growth, perhaps to be crippled by frost, which results in malformed and green-centred blooms. Therefore in districts where danger is feared from these late frosts do not be in a hurry to peg down the Roses. While all Roses require liberal supplies of liquid manure during the growing season (and even in winter it is beneficial), those pegged down can do with a larger amount, not only to support the quantities of breaking growths, but also to assist the new wood from the base. The very fact of bending down the long shoots compels some strong eyes at the base (that perhaps would under ordinary conditions lie dormant for some time) to start into growth, and by the time the pegged-down

use in the second year. If the plants are in a really good Rose soil, well cared for, and budded upon the Brier stock or on their own roots, there will be very few cases where the flowering shoots may not be removed after they have borne their blossoms. Roses for pegging down need a lot of room. I consider 4 feet apart none too much, and in order to fill up the apparent waste of space it is a good plan to interperse some dwarf standards of the same or different kinds. This has the effect of filling up and also relieves what might appear a rather formal mass of Roses. Again, many kinds such as Gloire de Dijon, Grace Darling, &c., are a great success if partially pegged; that is to say, one or two growths are bent down and the remainder allowed to remain in the usual manner. This is a very commendable style,

for it frees the plant of undue crowding and a much larger quantity of blossom is obtained. Many people have found the Penzance Briers splendid for pegging down, or rather for forming low hedges. By the aid of some galvanized wire and a few uprights here and there, these lovely Roscs of such delightful tints and with deliciously scented foliage may be formed into a hedge anywhere from 1 foot to 3 feet in height and as much through. When established three or four years such hedges will be telling features in the garden during the early days of June. Again, many of the old-fashioned Roses growing in borders or in front of shrubberies may be rendered much more attractive if the growths are pegged down or even layered. By thus layering them, one plant will become surrounded by a quantity of smaller plants, all of them flowering most profusely, induced by the pegging down. I have seen such beautiful old kinds as Mme. Hardy, common Moss, de Meaux, Spong, Copper Austrian, Harrisoni, Coupe d'Hebe, Rosa Mundi, Celestial, and a host of others a perfect blaze of bloom when grown on this system. Many Roses may be caused to flower in this way where other treatment has failed. Of course, one would never think of pegging down Roses of the type of Baroness Rothschild, Mrs. W. J. Grant, Etienne Levet, &c. P.

Pillar Roscs.—I can strongly recommend Mme. Alfred Carrière and Gloire Lyonnaise to "B." as good pillar Roscs which bloom freely in the autumn. From the former I have cut good blooms even in November. The blooms grow on nice long shoots, and are very valuable for cutting on that account. Mme. Alfred Carrière is a strong-growing white Rose, with a pale pink flush, and Gloire Lyonnaise white, with a lemon-coloured tinge.—B. A. THORNYCROFT.

Rose Violoniste Emile Leveque.—Many of the later additions to the rapidly increasing tribe of Hybrid Teas have peculiar and attractive yellow and orange shadings. In this case the centre of the flower is flamed with orange quite as intensely as in a very pretty, but little-known Rose, Madeleine d'Aoust. It has also the same rosy flesh colour of many of the Hybrid Teas. It is a good grower. The flowers, though not large, are freely produced. This variety, together with Mme. Eugène Boulet, appeared in the same year, and it was thought both kinds were not wanted. But further acquaintance with them has disclosed the fact of their perfect distinctness, and I look upon the two Roscs as being promising.—P.

Rose Climbing Kaiserin Augusta Victoria.—This is a great acquisition. When one considers the usefulness of the dwarf form, the full value of this vigorous sport will be apparent. It will make growths from 5 feet to 6 feet long in a season, and thus would quickly cover a wall or roof of a greenhouse. It is remarkable that we have extra vigorous sports of recent novelties like the above, whereas we had to wait years for the same occurrence with kinds such as Niphetos, Davoniensis, Perle des Jardins, and Meteor. Apart from the value of these extra vigorous sports for the greenhouse or conservatory, I welcome them for the glorious heads they make upon standards. It is well known that Climbing Niphetos is the best form of this grand Rose for outdoor culture upon a standard, and I suspect it will be the same with the Rose under notice.—P.

Rose Xavier Olibo.—This excellent Hybrid Perpetual has been very beautiful lately, no variety of this tribe save Victor Hugo being more rich in colour, which is a dark velvety crimson. Unfortunately, it is rather a poor grower and requires renewing frequently. No amount of extra trouble, however, is too great in order to have this superb Rose in perfection. Many of these poor growers are best budded upon the Brier, either seedling or cutting, and allowed to

remain where budded. I believe this is the only successful plan to adopt in order to retain the plants in a fairly vigorous condition beyond the first year. It would even be worth the extra trouble to bud a dozen or so of this fine Rose each season, for I consider it one of the best darks, and it certainly is the freest bloomer. This, one would naturally expect, knowing the Rose to be a descendant of General Jacqueminot. It was introduced by Lacharme in 1864.—P.

ROSES MOST POPULAR AT THE CRYSTAL PALACE SHOW.

THIS season has proved the futility of exhibitors depending too much upon maiden plants for their blooms, at least for the early shows of which the Crystal Palace is the chief. I believe the majority of the flowers in the champion stands were from cut-backs. Some years this is just the reverse, most of them coming from maiden or one-year-old plants. This probably accounts for the paucity of many first-rate Roscs, such as the rich crimsons of the Horace Vernet type, which are always best as maidens. Indeed, I do not remember a season when what one may term the popular Roscs were so badly shown. One could not meet with a La France worth looking at, and Marie Baumann, the queen of red show Roscs, was almost entirely absent, only about twenty-nine flowers being staged in the whole exhibition. I think every amateur exhibitor should grow a certain number of maiden plants every year, more especially of kinds only good in that form, but this year's experience will prove to him that it will not do to curtail the number of cut-backs. Taking the forty-two most popular Hybrid Perpetuals and Hybrid Teas exhibited, Mrs. John Laing heads the list again with a total of some 370 blooms. There is a big drop from this quantity to the next three favourites, namely, A. K. Williams, Caroline Testout, and Ulrich Brunner, there being only about 140 to 170 blooms of each shown. It is very gratifying to find that the last named still maintains its position, for unquestionably it is one of the best red Roscs for the garden, and it seems to be difficult to beat as an exhibition kind. According to numbers shown, the following seven varieties take precedence in the order given, from 100 to 150 specimens of each being staged: Margaret Dickson, Mrs. R. G. Sharman Crawford, Mrs. W. J. Grant, Kaiserin Augusta Victoria, Mme. Gabriel Luizet, Marquise Litta, and Her Majesty. As Great Britain is generally well represented at this National Rose show (although the northern growers were not very strong on this occasion), the above numbers sufficiently demonstrate that the kinds named are very popular all over the country. The following seven indicate somewhat the character of the season by their diminished numbers: Gustave Piganeau, 86; La France, 86; Captain Hayward, 67; Suzanne Marie Rodocanachi, 64; General Jacqueminot, 56; Charles Lefebvre, 52; François Michelin, 50. Of the remaining twenty-two varieties, from thirty to forty blooms of each of the following were staged, namely, White Lady, Dupuy Jamain, Tom Wood, Earl of Dufferin, Marchioness of Londonderry, Helen Keller, Alfred Colomb, Etienne Levet, Marchioness of Downshire, and from twenty to thirty of the under-mentioned: Marchioness of Dufferin, Mrs. Paul, Bessie Brown, Heinrich Schultheis, Marie Baumann, Prince Arthur, Lady Mary Fitzwilliam, Camille Bernardin, Horace Vernet, Countess of Oxford, Victor Hugo, Pride of Waltham, Abel Carrière, Louis van Houtte. There were some 140 other kinds exhibited among the Hybrid Perpetuals and Hybrid Teas, but in lesser numbers than twenty of each; indeed, in the case of some few of them only one specimen could be seen in the show. The Teas on this occasion were very good, although I have seen them much finer and of greater substance. I was quite prepared to find the flowers rather flimsy, but generally speaking this was not the case. From an exhibitor's point of view, the twenty-four varieties enumerated below are the most reliable. There are

two or three recent novelties that must speedily take a high place in this section, but this article is more concerned with kinds that were actually exhibited in quantity. The Bride has this year surpassed its parent in numbers shown, the respective numbers being 160 and 113. I believe it will not long retain this proud position, for, unless I am very much deceived, White Maman Cochet will rank first favourite. From 100 to 120 of each of the under-mentioned were exhibited, exclusive of any shown in bunches as garden Roscs: Maréchal Niel, Comtesse de Nadaillac, Mme. de Watteville, Mme. Hoste, Souv. de S. A. Prince, and Maman Cochet. Of such old favourites as Hon. Edith Gifford there were 97 specimens; of Innocente Pirola, 88; Mme. Cusin, 86; Cleopatra, 66; Souvenir d'un Ami, 65; Souvenir d'Elise Vardon, 61; Bridesmaid, 55; Medea, 53; Caroline Kuster, 48; Niphetos, 41; Golden Gate, 30; Ernest Metz, 30; Princess of Wales, 28; Muriel Graham, 24; and Ethel Brownlow, 21. Although it was rather late for the so-called garden Roscs, I was gratified to find such an excellent display. The style of putting up these Roscs has considerably improved during the last few years. I think all Roscs should be admitted into this class whether they are Hybrid Perpetuals or Monthlies. Any kind that is decorative and produces handsome trusses of blossom should be eligible, for I take it these classes are intended to demonstrate what kinds are most suitable for garden decoration, and surely Gloire de Margottin and the like are of that number. Taking the kinds most generally exhibited in bunches upon this occasion, W. A. Richardson comes out first with a total of fourteen, followed by Crimson Rambler with ten bunches. Eight bunches each of Rosa Mundi, l'Idéal, Ma Capucine, Reine Olga de Wurtemberg, Marquise de Salisbury, and Gustave Regis testified to their popularity, and Bardou Job, Mme. Falcot, and Mme. C. Guinoisseau were close behind with a total of seven each.

Of Macrantha and Mme. Pernet-Ducher six bunches each were staged, and five each of Polyantha grandiflora, Mme. L. Messimy, and Hebe's Lip. One would have expected to find more than four bunches of Camoens and common Moss, but it was not so. This number was also the total of each of the following: Crested Moss, Anna Marie de Montravel, Cecile Brunner, Perle d'Or, Claire Jacquier, The Garland, and Homère. It must be remembered that amateurs were restricted to not more than twelve bunches of these garden Roscs, which explains the reason why so few bunches were shown of what we look upon as some of our best garden varieties. Although the exhibits were first-rate numerically, there was certainly not half so many as there should be. I should like to see the competition as keen for these garden Roscs as it is for the trophy classes. Not more than three bunches, and in some cases only two, were seen of such lovely gems as Mme. Pierre Cochet, Blanche Moreau (Moss), Papa Gontier, Mme. Hoste, Rainbow, Souvenir de Catherine Guillot, Alister Stella Gray, Paul's Single White Gloire des Polyantha, Carmine Pillar, Marie van Houtte, Andersoni, Blanc Double de Courbet, Ma Surprise, Lucida plena, Mme. E. A. Nolte, &c. What appeared to me inexplicable was that not a single bunch was shown of Gloire de Dijon, Cramoisi Supérieur, Viscountess Folkestone, Grand Duc de Luxembourg, Perle des Rouges, Armosa, Princesse de Sagan, Princess Bonnie, and only one bunch each of G. Nabonnand, Mme. E. Resal, Mme. P. Perny, Aglaia, Beauté Inconstante, and Mme. Abel Chatenay. It cannot be said that it was too late for these, although this may account for the almost total absence of Blairi No. 2, Celestial, Austrian Copper, Austrian Yellow, and Little Gem. But there is this to be said of exhibiting: each individual brings what he has best at the time. If we had more competition then we should find more variety. As it is we must be content that these Roscs are advancing in popularity, knowing, as we do, that their culture will tend to increase rather than diminish the votaries of the queen of flowers.

SOCIETIES AND EXHIBITIONS.

DAHLIAS AT THE CRYSTAL PALACE.

THE National Dahlia Society's exhibition was held at the Crystal Palace, Sydenham, on the 1st and 2nd inst. It was announced that the entries were more numerous than usual, but the hot, dry weather must have kept some exhibitors away, as there were many vacant spaces of tables which detracted from the effect of the exhibition as a whole. It is to be regretted that the authorities of the Crystal Palace do not provide more appropriate tables for an exhibition of cut flowers. They are much too broad for Carnations, Dahlias, or Roses; they are painted of a colour which by no means harmonises with the tints of the flowers, and they are not in the least degree draped, as they should be, with baize or some such material in order to hide the yawning nakedness below them; and then there is the added fact, which cannot be gainsaid, that the very loftiness of the building dwarfs cut flowers out of all proportion and minimises their effect. These impressions were brought home to many on Friday and Saturday last. If the public is to be attracted to flower shows, there should be some attempt at effective arrangements, and that is just what was missed at Sydenham. A general survey of the exhibition showed that the larger show and fancy Dahlias fell much below their ordinary average of quality. The blooms were generally undersized, wanting in depth, and defective in form. As long as the practice of exhibiting blooms of Dahlias in this way is maintained, the old standards of quality in the flowers must be observed; at the same time the judges on this occasion were bound to take into consideration the drawbacks of the season, the prolonged drought and the heated, dry atmosphere day and night. Mr. Chas. Turner, of Slough, usually a foremost exhibitor in these classes, could not compete in any one class, and he was not the only exhibitor who found himself in this predicament. But all who could exhibit did their best, and the exhibition on the whole answered expectations.

The Cactus type of Dahlia was advanced in bloom, through the very causes which militated against the show varieties; they bloomed earlier than usual and with considerable refinement of character. At every flower show at which we have seen Dahlias exhibited this season the Cactus types have been exhibited in excellent character. D. Juarezi, the Cactus Dahlia, and its earlier varieties were tall in growth and late in flowering. The present race, greatly improved and extended in several quarters, are dwarfer in growth, much earlier in blooming, much more free of bloom than some of their ancestors, and better adapted for garden decoration. Among the newer sorts, Britannia and Magnificent are deserving of special mention. The late-flowering, tall-growing, spare-blooming type is rapidly disappearing before improved forms. The very causes which assisted to present the Cactus varieties in such good form operated also in the case of the pretty pompon varieties. They have been shown generally in a small compact shape, even, and of excellent quality, and with the Cactus varieties they were seen to great advantage at the Crystal Palace. Their bushy growth of moderate height and their remarkable floriferousness constitute them invaluable border plants, while a dozen or two varieties could be named that are perfect in form and petal and varied in colour. The single Dahlias are a declining quantity. It is their fragile character which tells so much against them. Not a few of our best varieties are of tall, ungainly growth and by no means so free of bloom as might reasonably be expected. These are defects which time can remedy, but the fleeting character of the blooms is a property that is a part of the nature of the flower. The single Cactus varieties have not been given a place in the schedule of prizes of the National Dahlia Society, but they were exhibited at Brighton by Messrs. Cheal and Sons in very winsome character.

Taking the show Dahlias in the order of the schedule, there were four collections of sixty, dis-

tinued, and all had a prize. Mr. John Walker, nurseryman, Thame, who has been exhibiting finely all the season, was placed first, Mr. M. V. Seale, nurseryman, Sevenoaks, second, and Messrs. Campbell and Son, Blantyre, N.B., third. A few of the best blooms in Mr. Walker's stand were Harrison Weir, Vice-President, Diadem, Frank Pearce, T. S. Ware, David Johnson, William Powell, one of the finest yellow selfs; Maud Fellowes, Shirley Hibberd, J. Hickling, Rosamond, Virginele, Colonist, John Walker, the best white self; Duke of Fife, Mrs. Gladstone, the best light variety and very constant; James Vick, Victor, a fine dark variety, and J. C. Vaughan. The foregoing may be taken as representing the leading varieties in all the stands. Mr. Walker was also first with forty-eight blooms. The leading blooms here were the Rev. J. Godday, R. T. Rawlings, Prince of Denmark, Dr. Keynes, a very distinct small-petalled variety; Diadem, W. Rawlings, Mrs. Gladstone, &c. Mr. Seale was again second, and Mr. S. Mortimer, Swiss Nursery, Farnham, Surrey, third. With thirty-six blooms, Mr. W. Treseder, nurseryman, Cardiff, was first, having in fine character such varieties as Pleasance, Willie Garratt, Eclipse, Mrs. Gladstone, Frank Pearce, Goldsmith, W. Powell, Duchess of Albany, J. T. West, Duchess of York, and Mrs. Morgan. Mr. George Humphries, nurseryman, Chippenham, was second, and Messrs. Keynes, Williams and Co., nurserymen, were third. With twenty-four blooms, Mr. George Humphries took the first prize, and in that for twelve blooms, Mr. J. R. Tranter, nurseryman, Henley-on-Thames, was first, and Messrs. J. Cheal and Son second. A class for twelve fancy Dahlias is still retained in the schedule of prizes. The fancy type includes all tipped as distinct from edged flowers and all striped and flaked varieties. The fancy Dahlias are shown in the preceding classes, but there is one class in which they alone can be exhibited. Mr. J. Walker was again first; his leading flowers were the Rev. J. B. M. Camm, S. Mortimer, Donovan, Matthew Campbell, Duchess of Albany, Frank Pearce, and Emin Pasha. Mr. Seale was second, and Mr. Mortimer third.

Next in the order of the schedule came the Cactus varieties, and stands of eighteen bunches, six blooms of each, made an imposing display. Mr. J. Stredwick, Silverhill, St. Leonards, had the first prize, showing generally in fine character, among them being Countess of Lonsdale, Viscountess Sherbrooke, Stella, Britannia, Mary Service, Emperor, Magnificent, Eclipse, pale sulphur-yellow, Keynes' White, Charles Woodbridge, W. T. Balding, &c. Messrs. J. Burrell and Co., nurserymen, Cambridge, were a close second. They had some highly promising new varieties in Elsie, Olive, Ibis, Whirlwind, Auburn, Imperator, also Britannia and others. Messrs. Keynes, Williams and Co. were third, also staging some excellent varieties. There were five competitors in this class. With twelve bunches Mr. S. Mortimer was first, having Mrs. J. Goddard, Magnificent, Starfish, Keynes' White, Ebony, Mary Service, Britannia and Lucius, all in good character. Mr. Seale was a good second, having distinct from the foregoing Island Queen, Charles Woodbridge and Fantasy. Mr. G. Humphries was a close third. A class for twenty-four blooms, shown on boards in the same way as the show Dahlias, brought several exhibits. Messrs. M. Campbell and Son were first and Mr. Seale second. Pompon Dahlias were shown in very fine character, small, even and very bright in colour. Mr. M. E. Seale was first with an excellent selection admirably staged, the leading varieties, Donovan, Ernest Harper, Red Indian, Capt. Boyton, Nerissa, Ganymede, Crimson Gem, Lillian Douglas, Cherub, Snowflake, Demon, Tommy Keith, Distinction, Emily Hopper, Phebe, &c. Messrs. J. Cheal and Sons were a very close second, having, in addition to the foregoing, Adrienne, Dr. Jim and Mars. Third, Messrs. Keynes, Williams and Co. With twelve bunches, Messrs. J. Burrell were first. They had Isabel, Mabel, Geo. Brinckmann, Bacchus, Eurydice, Distinction, &c. Second, Mr. J. Walker,

and third, Mr. Geo. Humphries, both with charming blossoms. Glorious bunches of single varieties were staged by Messrs. Cheal and Sons and Mr. Seale. The former gained the first prize with twenty-four bunches, having such fine varieties as Columbus, Damon, Violet Forbes, Miss Roberts, Puck, Louissette, Polly Eccles, Leslie Seale, &c. Mr. Seale was second. As 240 blossoms had to be staged in each collection, the task of exhibiting was by no means an easy one. Mr. J. Walker, though the only exhibitor, was awarded the first prize for twelve bunches, showing in good form such leading varieties as Beauty's Eye, Eclipse, Leslie Seale, Miss Roberts, Victoria, Polly Eccles, &c.

Next followed eighteen classes for the amateur members of the society. Of show Dahlias, the best twenty-four blooms came from Mr. F. W. Fellowes, Patteridge Park, Luton. This included some promising seedlings, such as Bella, lilac; Prince Ranji, dark; Lillian Mary, flesh colour, suffused with pink; Tim, Kits, &c. Mr. T. Anstiss, Brill, was second. With eighteen blooms the best came from Mr. Thos. Jones, Ruabon. Mr. R. C. West, Salisbury, was second. There were classes for twelve blooms and six blooms also. The best twelve fancy Dahlias were shown by Mr. West, and included Peacock, one of the most distinct; Dazzler, Goldsmith, Mrs. J. Downie, Duchess of Albany, Matthew Campbell, &c. Mr. F. W. Fellowes was second. Mr. R. Burgin, St. Neots, had the best six varieties. Cactus Dahlias were shown by amateurs in twelve bunches of six blooms each. Mr. R. Keeble, Twyford, was placed first with very good examples of Alfred Vasey, Stella, Lady Penzance, Fantasy, Charles Woodbridge, Mary Service, &c. Mr. James Hudson, Gunnersbury House, Acton, was second. With nine bunches, Mr. H. A. Needs, Horsell, Woking, came in first, showing in very fine character. Mr. Jas. Bryant, Salisbury, was second. Mr. E. Mawley, the treasurer of the society, was first with six bunches, and Mr. Bryant again second. In a class for six bunches, the prizes offered by Messrs. Cheal and Sons, Mr. Keeble was first and Mr. J. Hudson second. Pompon varieties were shown by amateurs in two classes. The best twelve bunches, six blooms of each, were shown by Mr. J. Hudson, and Mr. W. Peters, St. Leonards, was second, in both cases unnamed and contrary to rule. Mr. R. Burgin had the best six bunches. Mr. Hudson was first in the six bunches of single varieties, ten blooms of each, and Mr. W. Mist second, in both cases unnamed. With six varieties, six blooms of each, Mr. E. Mawley, the only exhibitor, was placed first. He had charming blooms of Victoria, Damon, Northern Star, Polly Eccles, Beauty's Eye, and Miss Roberts. Two classes, one for six show and fancy Dahlias and one for six bunches of Cactus varieties, were set apart for those who had never won a prize at a previous exhibition of the society, and there was a very good competition. It is an excellent arrangement, as it brings in new growers and exhibitors. The classes for six blooms of any one type or colour of show Dahlia are always interesting. The best dark Dahlia was Prince of Denmark, from Mr. Seale. Mr. Walker was second with the same. The best light was Mrs. Gladstone, from Mr. Walker. Mr. West was second with the same. The best yellow was William Powell, also from Mr. Walker. Messrs. Cheal and Sons were second with Mabel Stanton. The best red or crimson was Duke of Fife, from Mr. West, Mr. Mortimer coming second with Arthur Rawlings. The best white was John Walker, from Mr. Walker, shown very finely. Mr. Mortimer was second with the same. Mr. Seale had the best flower of any other colour in Duchess of York, Mr. Mortimer coming second with Sunbeam. The best tipped Dahlia was Miss Browning, from Mr. J. Walker, Mr. Mortimer taking the second prize with Peacock. The best striped was Prince Henry, also from Mr. Walker, Mr. Seale coming second with Mrs. J. Downie. The best edged flower was Miss Cannell, from Mr. Seale.

Special prizes were offered for eighteen varieties of fancy single Dahlias, the flowers to be tipped, striped, or edged. Mr. Seale was first, having excellent illustrations of Dorothy Seale, Jeanette, May Sharp, Phyllis, Miss Glasscock, Trilby, The Sirdar, Duchess of Marlborough, Gaiety Girl, Folly, &c. Messrs. Cheal and Sons were second, they having Princess Petula, Muriel, Folly, Lord Rosebery, Shamrock, Flame, Daisy, Duchess of Marlborough, &c.

Floral decorations formed of Dahlias were shown in a few classes. Mr. J. F. Hudson was first with an epergne composed of Cactus, pompon, and single varieties, with appropriate foliage. Mr. R. Edwards was second. Mr. E. Mawley had the best vase of twelve blooms, showing a Cactus variety with foliage. Mr. H. A. Needs was second, also with a Cactus. Mr. R. Edwards was first with three vases of Cactus Dahlias, and Mr. J. F. Hudson second. Mr. W. Treseder, Cardiff, had the best shower bouquet of Cactus Dahlias, a very artistically arranged one. Mr. Seale was second. Mr. Treseder was also first with a floral design, staging a harp formed of white and red Cactus Dahlias and white pompons. Mr. Seale was second with a cross of white pompons, with foliage at the base.

As many seedling Dahlias were staged, some notes of these shall be given next week. Mr. J. Green, nurseryman, Dereham, had a tastefully arranged collection of Dahlias, including a large and striking bright crimson variety named Red Rover; Zephyr, soft pinkish-rose; Green's White, a very fine new white. Messrs. H. Cannell and Sons, nurserymen, Swanley, had some 200 bunches of Cactus varieties arranged on a long table, among them some new decorative forms. Mr. T. S. Ware (Ltd.), Tottenham, had a large collection of Cactus and other Dahlias in great variety. Messrs. J. Laing and Sons, Stanstead Nurseries, Forest Hill, had two large tables filled with plants of various kinds, including Caladiums and other showy foliage subjects, hardy flowers, Dahlias, &c., and also a ground group of various hardy ornamental plants, and Messrs. J. Peed and Sons, Roupell Nurseries, Lower Norwood, Dahlias and various other flowers.

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, September 12, in the Drill Hall, James Street, Westminster, 1 to 5 p.m. At 3 o'clock a lecture on "Lessons from the great drought of 1898" will be given by Mr. E. Mawley.

NOTES OF THE WEEK.

Arundo conspicua.—Very probably this plant, if lacking the finer plumes of the better-known Pampas Grass, would prove the better kind in not a few of the colder parts of Britain where the Pampas for various reasons does not thrive. Both plants require a good deal of moisture to grow them to perfection in a season such as this, and, indeed, at ordinary times a good soaking of moisture is not lost upon them.

Verbena Ellen Willmott.—This is, perhaps, one of the finest of the modern bedding kinds that has been introduced for a long period. It deserves this appreciative mark in more than one way, for its truss of pink blossoms shows extremely well against a margin of green grass, and when bedded on the lawn, and given more freedom and less of the rigid pegging that so severely crippled these things for years, it is an extremely fine plant. We are reminded of its excellence by the free manner in which it is used at Gannonsbury House, where Mr. Hudson has it in fine condition.

Yucca filamentosa.—This still remains the best of the Yuccas if we are to take as our standard hardness, freedom of flowering, and usefulness. Its freedom of blooming is one of its marked characteristics in most gardens, and one can find few people who cannot admire its spikes of white bell-like flowers. It is not a rare plant, and is, indeed, absent from few of the best gardens, but on the other hand it is as yet unknown to many owners of small gardens, which would

gain much from the inclusion of this Yucca among the flowers they contain. As a foliage and flowering plant it has much in its favour.—S. A.

Pershore Plums.—Having some time since read in THE GARDEN a note about Pershore Plums in which the writer was anxious to know the experience of those who had planted these Plum trees out of Worcestershire, I write to say in 1896 I planted four young Pershore Plum trees in my garden near Bembridge, Isle of Wight, and both last year and again this year I have had a very good crop on these young trees. One is a bush and the others standards. This seems to show that Pershore Plum trees will fruit in other counties besides Worcestershire. The fruit is most excellent if cooked when green, but if allowed to become quite ripe loses flavour and becomes rather woolly—at least that is my experience here.—B. A. THORNYCROFT.

Lilium speciosum Melpomene.—No variety of *L. speciosum* is finer in general effect than this, the rich crimson-scarlet with which the flowers are crowned rendering the plant always conspicuous even if grown singly. Still finer than will they appear when whole beds are filled with the variety in question, for then we get an effect well-nigh unique, and with the richly-coloured flowers the massive, thick and heavy leafage is wonderfully consistent, giving the entire plant that touch of superiority that doubtless belongs to it by nature. And when these qualities blend in one kind, as in this case, the material effect is one that cannot be passed by even by the most casual observer. To the Lily grower this beautiful form has always been a great and decided attraction.

Acalypha hispida (Sanderi).—This has proved a fine decorative subject. Most frequently it has been presented at exhibitions in the erect form, without much pinching or stopping save in a few bush-like plants seen at the meetings of the Royal Horticultural Society. At Gannonsbury House, however, Mr. Hudson is trying it as a standard with a large degree of success. The plants are not of the regulation 3 feet or so given to standard Roses, but are nearer 5 feet high, some possibly a good deal more. At this increased height such things will be invaluable for indoor decoration. Pinched at first rather closely, but less so with each succeeding break, a good head has been formed, and the crimson inflorescence drooping at various heights will assist the effect materially when arranged among other plants.

Campanula pyramidalis.—Very few of the Campanulas can equal well-grown plants of the Chimney variety for its profusion of flowering. Plants of the old typical pyramidalis have been flowering for weeks in the open border with but little attention. The white variety has been better where it has come within reach of the garden hose pipe occasionally, for here the plants have been very effective in ordinary soil and with equally ordinary culture. A mixed bed, say a dozen feet across, of the blue and white forms of this Campanula with a few small or medium-sized plants of *Humea elegans* interspersed is distinctly effective. The effect of these grouped in the greenhouse is not unknown, yet there is little doubt if transferred to the open garden the same thing would create a surprise.

Kniphofia Nelsoni.—This is one of the finest of garden plants from a variety of standpoints. Many varieties, and some of the new ones among this number, are not devoid of a certain clumsiness, so short and so blunt is the inflorescence, but it is not so with Nelson's Torch Lily, which is the happy medium between short and tall, thick and thin, and very profuse. Indeed, so light in appearance is this kind, that it may be justly called an elegant plant, and the graceful foliage is equally deserving a similar mark of approval. Its bright colour too will find it many admirers, and as it flowers on into the autumn months it will be welcome in those gardens that are bedded out largely with such things as Michaelmas Daisies and Sunflowers. Anyone requiring a good free-flowering Torch Lily in large garden or small will make no mistake in selecting this

kind if good colour and freedom are points of importance.

Galtonia candicans.—The Galtonia is one of the noblest of our autumn blooming bulbous plants. When well grown its exquisite effect can hardly be equalled at the season in which it blooms. This year, probably on account of the prevailing drought, it has in many gardens been hardly so fine as in former years. Its growth has been less free and its flowers smaller than its wont so that it has not been seen to the best advantage. I have been in the habit of considering it a perfectly hardy plant, but of late years I have occasionally come across it in gardens where it is unreliable if left in the ground all winter. This is in those gardens a defect which tells against the Galtonia and prevents it from finding its way into some others. It appears that the name of *Hyacinthus candicans* is that by which it is more frequently met with than the authoritative one of *Galtonia*.—S. A.

Chelone obliqua.—There are a good many admirers of the Turtle-head among the ranks of growers of hardy flowers, yet it has an almost equal number of despisers, by which is meant those who think little of it as a garden flower. Yet it is often seen on good exhibition stands, though when it is bunched, as often shown, its distinctive characters are not so well seen as when it is growing in the garden. As much may be said of the so-called white form known as *C. obliqua alba*. It is not really white, but has a considerable addition of the crimson or purple, which is the colour of the types. The shade of the ordinary coloured form varies considerably. Some plants are brighter than others. This may either be due to the soil in which they are grown or to there being some variation from seeds. The *Chelone* is most at home and is longer-lived on a good soil than a poor, dry one.—S. ARNOTT.

Helianthus rigidus semi-plenus.—This is not a new variety of the well-known *Helianthus rigidus*, yet grown in many gardens as *Harpalum rigidum*. It is, however, not very generally known, and the other day a grower of long experience, who had it in bloom, asked the writer if he had ever seen it. Although not at present grown here, it was in my garden for several years, and was admired while it was grown, and preferred to the type. It grows a little taller and blooms rather later than the latter. The flowers are semi-double, and come in well for cutting if the stems are not left too long and the flowers are not too fully expanded to stand long in good condition. Its great fault is that of *H. rigidus* and some other perennial Sunflowers—rapid increase at the root and an inveterate tendency to monopolise too much space to the destruction of neighbouring flowers.—S. ARNOTT.

Helenium striatum.—One is not disposed to enter upon the question of the true name of this plant, which is considered by good authorities to be *H. nudiflorum*. It was introduced as *H. grandicephalum striatum*, but has also been named *H. autumnale striatum*. My motive in writing this note at present is that those who may see poorly coloured specimens this season may not be thereby led to think that these show the plant under its proper aspect. In my light soil the flowers are small on account of the long drought, but the colouring is much brighter than any I have seen of late, with the exception of one plant in another garden. I am rather sorry that this *Helenium* has been represented in some nurserymen's and other exhibits at shows by flowers in which there was so little crimson that they were only made less beautiful than those of *H. autumnale*, and were poor substitutes for the high-coloured flowers of *H. striatum* when at its best. Those here have at present the almost fiery-red colour one sees in some of the Gaillardias.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Linaria vulgaris var. Paloria.—Apart from the interest it possesses from a purely botanical standpoint, because of its being, we have been told, an attempt of an irregular flower to become a regular one, the Pelorial Toadflax is

a flower worth growing. Its singularity of form, coupled with its soft yellow colour, leads it to be observed by many. I was reminded that a note upon it might be useful by having several inquiries addressed to me at a recent show as to what flower it was. A good bunch of this Toadflax was included in a prize stand of herbaceous plants shown by an experienced competitor, and a number of people who, one would have thought, ought to have known its name did not. This leads us to think that it is rarer than we had expected, or, at least, not so generally cultivated as a plant so readily increased ought to be. Like the type, the common Toadflax, the Pelorial variety runs freely at the root and requires to be kept within bounds. It is quaint and almost grotesque in its form, but has been found useful as a cut flower as well as in the garden.—S. ARNOTT.

Notes from Baden-Baden.—From Dr. Hans Meyer, of Leipzig, the famous conqueror of Mount Kibo, I got seeds of three new *Helichrysums* which look very promising; the leaves are covered by a silky white tomentum and the flower-heads, according to specimens at hand, consist of six to twelve big blooms of a shining white or pink colour in the way of H. Manni figured in *Botanical Magazine*. Thus far they have done very well, and as they are said to stand 14° F. on the Kilimanjaro, I will try to grow a portion outside for testing their hardiness. Among flowers I must mention *Enothera formosa*, a splendid novelty, flowers freely produced and 3½ inches across, pure white; a fine plant for sunny rockwork. *Enothera Howardi* is about the same, but has sulphur-yellow, slightly smaller flowers. *Enothera Hartwegi*, having brilliant citron-yellow flowers, which are produced in large numbers, is also very attractive. *Liatris graminifolia* var. *dubia* is by far the best of the whole genus; the flower-stems rise to 6 feet, 2½ feet of which are beset with flowers of a deep bright and shining lilac.—MAX LEICHTLIN, *Baden-Baden*.

The Carton Sun Rose.—When I first visited Carton, some three or four years ago, I saw a very pretty double red *Helianthemum* called there the Carton double *Helianthemum*. This I have had the privilege of growing since, and yearly it grows in my estimation. It may exist elsewhere under another name; if so, I have not met with it. The Carton form is superior to other double red varieties, because of its long continuance in flower and of the way in which its fair-sized double blooms are displayed to view. One does not expect to find in a double Sun Rose the lightness and free-blooming properties of the single forms, which are so exquisitely beautiful on a sunny morning in early summer. The single Sun Roses are, however, as is well known, so fugacious that the flowers shed their petals in a few hours at the most. Some of the double forms have the bad habit of producing their flowers on such weak stalks that they hang down, and the bloom cannot be properly seen unless lifted with the hand. This is a fatal objection to a plant such as the *Helianthemum*, which ought to give a good display observed of all. The Carton double Sun Rose shows its flowers well up and blooms for months in succession. If it has a fault, it arises from its want of compactness, but for bold rockwork this can scarcely be considered a disadvantage.—S. ARNOTT, *Carsethorn, by Dumfriess, N. B.*

Chrysanthemums—standing the pots on grass.—In a scorching summer like the present the advantage of having a cool bottom for pot Chrysanthemums is apparent. I saw some fine plants lately at The Pines, Woking, growing in a meadow near the garden. The pots were placed upon boards in the first instance to keep the drainage perfect, and the grass has been allowed to grow among them; thus a permanent shading is provided. It is next to impossible in my case, for example, to keep the foliage perfectly green and healthy from bottom to top of the plants when the sun beats straight on to the pots in an open position on exceptionally dry soil. I do not, however, grow for show blooms, as the plants noted

are, or one might look upon them with an envious eye, so fine are they. It will indeed not be risky to predict that later on flowers will be produced so fine in development that they will reach a high position at exhibitions where they may be placed. With the pots naturally shaded watering is more easy, and where the convenience exists it would certainly be wise to use meadows or the like another year. Shading the pots with boards is a plan I have somewhere seen recommended. This seems clumsy and unsightly—something akin to placing inverted flower-pots on sticks among Dahlias to trap earwigs, a system I could never adopt.—H. S.

NOTES FROM SHIPLEY HALL.

The fine collection of Hollies in the pleasure grounds at Shipley Hall, Derby, the seat of Mr. E. M. Mundy, is undoubtedly the feature of the place. Most of the plants are very large specimens, but so perfectly grown that the lower boughs are close on the lawn, and Hollies of large size have a very fine appearance when so nicely feathered. The collection includes all the better known green and variegated kinds, and the latter when grown to such noble proportions as at Shipley are most striking and handsome, quite putting in the shade such variegated things as *Retinosporas* and other conifers. The showy *Ilex Shepherdi* is one of the best, the large, handsome deep green leaves showing up very distinctly, and when it has grown to a similar size, the beautiful *I. Mundyana* will be even better. Some of the smaller leaved kinds of the *crenata* and *myrtifolia* type were noted, and it is surprising that these compact, low-growing evergreen shrubs are not more grown. The distinct habit characteristic of each species is well shown, as the plants are all a good distance apart and not crowded, as is so frequently seen. The magnificent collection of *Anthuriums* is worth going a long way to see, for not only are the plants splendidly grown, but the varieties are exceptionally good. Most of them are of the *A. Scherzerianum* type, *A. S. Shipley Hall* variety being a magnificent form, with immense brightly coloured spathes and the plants over 6 feet across. In the same house there are some lovely plants of a form of *Nephrolepis exaltata*, the long fronds drooping from the large baskets in which they are grown to the length of a couple of yards or so. In this way it is an extremely fine Fern for large houses. Inside fruit was getting over at the time of my visit, but a large quantity of Peaches, *Madresfield Court*, *Muscot of Alexandria* and other Grapes was hanging, and I also noted some beautifully-shaped, well-finished bunches of *Gros Maroc*. Orchids are rather largely and very well grown, but naturally the amount of flower open just now is somewhat meagre. The hybrid Water Lilies are healthy and flowering freely in all the best forms, but the plants are growing in round tubs, and have not therefore the natural and pretty appearance that plants have when growing in natural water. An artificial pond is about to be made, and when this is completed and the edges planted with Irises and other plants, it should prove a delightful feature in these fine gardens. A pretty arrangement of Maiden's Wreath and a few other white flowers with small Ferns was noted in one of the corridors, and further on some fine specimens of *Cymbidium Lowianum* planted in a rockwork with Ferns were doing well. Good crops in all the departments in the kitchen garden were noticed, some grand rows of that useful Pea Autocrat being especially good. The soil is heavy and unkind, but does not appear to crack badly with the heat, though rain is badly wanted by the green crops. H. R.

Lock and ferry cottage gardens.—Prizes have this year been offered by the Thames Conservators to their lock-keepers and ferrymen for the best-kept gardens and floral displays at the lock and ferry cottages. For the purposes of the award the river is divided into five sections, with four prizes in each section. The judging duties

are carried out by a specially-appointed committee. The awards in the two upper sections have just been made known. In Section I. (above Oxford), J. Iles, Shifford Lock, takes first prize; W. Curtis, Pinkhill Lock, second; and F. Havell, Grafton Lock, third. In Section II. (Oxford to Basildon) the prize-winners are G. Yeates, Goring Lock, first; W. Butt, Cleeve Lock, second; and J. Bossom, Clifton Lock, third.

The weather in West Herts.—Another very warm week and the ninth in succession. On the 5th the shade temperature rose to 86°, which is the highest reading I have yet recorded here in September with the exception of two days in the same month last year, when the mercury rose to 88° and 90° respectively. On that day the black bulb solar radiation thermometer exceeded 134°, which is the highest reading registered by this thermometer in any previous September except that of 1890. The ground is still remarkably warm for the time of year, the temperature at 2 feet deep being about 6°, and that at 1 foot deep 7°, warmer than is seasonable. Rain fell on four days, but to the aggregate depth of but little more than a quarter of an inch. The past month proved a very exceptional one in many respects. Taken as a whole, it was the warmest August of which I have here any record (fourteen years). On eleven days the shade temperature exceeded 80°, and on two of these rose to 87°. The heat received from the sun as shown by the black bulb solar radiation thermometer was greater than in any previous August during the same fourteen years, the mean maximum reading for the whole month being 125°. The mean temperature of the soil at 2 feet deep was higher than in the warmest previous August by as much as 3°, and at 1 foot deep by nearly 4°. Rain fell on six days, or on a smaller number than in any August since 1880, and to the total depth of rather more than three-quarters of an inch, which is also the lowest fall during the same nineteen years, and about one-third of the average quantity for the month. The winds were the lightest yet experienced here in August, and for 480 hours, or twenty days, the direction was some easterly point of the compass. The atmosphere was not only calm, but also exceptionally dry. The sun shone on an average for nearly eight hours a day, or for a longer period than in any previous August.—E. M., *Berkhamsted*.

OBITUARY.

MR. ALFRED JOHNSON.

THIS well-known and widely-respected townsman of Boston, the managing director of the large firm of W. W. Johnson and Son, Ltd., seed growers and merchants of that city, died on the 3rd inst. at the age of fifty-nine years. He was a man of remarkable industry and energy, and in the course of his life had been largely instrumental in building up an extensive seed-growing industry in his native town. A few years ago, mainly for family reasons, the business was converted into a limited liability company, of which Mr. Johnson was the managing director until his death.

TRADE NOTE.

Messrs. Stevens and Co., Covent Garden.—We daily have evidence of the growing importance of the horticultural sales held in London, and we now learn that Mr. J. C. Stevens, of the old-established rooms at King Street, Covent Garden, has taken into partnership Mr. D. Pell-Smith, who has been for some years connected with Messrs. Jas. Veitch and Sons, Ltd., nurserymen, Chelsea.

Names of plants.—*X. Y. Z., Sussex.*—*Schubertia grandiflora.*—"Iris," *Bucks.*—You attach no numbers to your specimens, which gives us additional trouble in referring to them. The woolly-leaved plant is *Gnaphalium* sp. The other, send fuller specimen with buds that will expand.—*J. R. P.*—1, *Sedum Telephium Borderi*; 2, *S. spectabile*; 3, *S. quadrifidum*; 4, *Anthemis tinctoria.*—*G. S. S.*—*Tiger Lily*; *Tecoma radicans.*

ORCHIDS.

CYPRIPEDIUM PARISHI.

THIS is a very beautiful plant, though not so large as some similar habited kinds, and I have never been able to understand why such a pretty thing has not become more popular. It comes nearer the South American section of the genus than most of the Asiatic species, and at first sight the flowers remind one somewhat of a gigantic *C. caricinum*. The stout spikes attain a height of about 18 inches and bear in some cases four to six flowers. Each one is about 3 inches across and the sepals are yellowish with green veins, the petals elongated and prettily undulated, greenish at the base with purple markings, the pouch similarly coloured. In habit *C. Parishii* is very vigorous, and the deep green leaves are striking and handsome even when the plants are not in flower. Its culture, therefore, is comparatively easy provided always that ample heat and atmospheric moisture are present in the house wherein it is grown. The compost may be made up of equal parts of peat, loam and chopped Sphagnum Moss, a few large lumps of charcoal and crocks being mixed with it to ensure aëration. The liking the roots have for charcoal is seen by the way they run through and over any chance lump that may be in the compost, and this material may be freely used. As to the manner of potting, there is no need to elevate the plants, as is usual with the majority of epiphytal Orchids. This *Cypripedium*, it is true, is usually found growing on trees, but nearly always, I believe, surrounded with vegetable matter.

The roots then may be allowed free play by giving moderately large pots, and the base of the growths may be a little below the rim of the pot. It is only in the case of established plants though, for newly-imported crowns always seem to relish being above ground, so to speak, and if the long green leaves are tied up to stakes set in the pot and a little lighter material brought up to their base, there will be no fear of damping either of the young growths, the roots or the base of the leaves. Single growths of *C. Parishii* often come away well and soon make nice healthy little plants, rooting

freely into the material named above and filling their pots. This is the class of plant that takes a lot of watering, the small amount of compost left after the roots have run all through it drying up very rapidly. Moisture is necessary all the year round, especially when dry, hot weather prevails. The flowers of *C. Parishii*, like those of several other *Cypripediums*, open during a dull season for Orchids, and are all the more valued on that account. They last well in perfect condition, and though, as mentioned above, the plants require ample heat to grow them well, they will not be much harmed by a week or two in a warm room or conservatory during the time they are in flower. A rather shady position in the East India house suits it well, or in a house where *Phalenopsis* thrives on the roof, this may be grown on the stage. *C. Parishii* was first discovered by the late Rev. C. S. Parish, who found it in Moulmein in 1859, but it was not generally grown until 1868, when plants of it were imported by Messrs. Low and Co.

Lælia anceps.—By far the finest grown plants of this Orchid that I have seen for a long time I noticed this week in Mr. Rider Haggard's collection at Ditchingham House, Norfolk. The pseudo-bulbs were immense, and each new growth had its spike—a very satisfactory state. The plants are large and growing in broad, flat baskets suspended from the roof in a light span-roofed house, where they must be exposed to a good deal of sun. This is undoubtedly what this useful winter-flowering plant delights in, ample light and not too much material about its roots.—H. R.

Epidendrum falcatum.—Though not as free-flowering in many places as is desirable, this is a distinct-looking and interesting plant. It is easily known by the thick drooping foliage, which occurs rather widely apart on the creeping stems. The flowers are like a very large *Brassavola*, the plant, in fact, being sometimes labelled *B. Pescatorei*. The sepals and petals are narrow, brownish or greenish white, the lip yellow, with a long pointed centre lobe. It is a native of Mexico, and plants of it are now flowering at Ditchingham House. It should be suspended near the glass in a light, sunny house.

Ceologyna ocellata.—This pretty plant I have noted in flower during the week, earlier

than I ever remember seeing it, as the flowers do not usually open for several months. It is a pretty Orchid that merits attention from its fine erect spikes of white flowers with yellow blotches on the lip. Coming from a considerable altitude at Sikkim, it does better in a cool intermediate temperature with ample air and a shady position than in the warmest house, and may be grown in baskets or paos. The compost may consist of equal parts of peat fibre, leaf-mould, and Sphagnum Moss, and the roots should never be dried.—H.

Odontoglossum cordatum.—Though often flowering in early spring, the flowers of this plant seem more welcome now that the cool house is not so gay. The species is as variable as any, some forms being much superior to others. The plants are very free-flowering, the spikes arching and containing a large number of blossoms, the sepals and petals of which are a deep golden yellow, with blotches of chocolate; they are elongated, almost like those of a *Brassia*. The heart-shaped lip, from which the species takes its name, is white, with rose spots.

Masdevallia Chimera and *M. Backhousiana*.—These two plants are very much alike, so much so, that, distinct as they may be botanically, the ordinary observer sees little difference in them. Both are interesting and peculiar plants, the weird-looking flowers of which are produced in abundance now. Both are well in flower in Mr. Rider Haggard's collection at Ditchingham, where cool Orchids of most kinds do well. These kinds are found to do best with rather warmer treatment in winter than the majority of the genus, and should never, in fact, be in a house below 50° in winter. The plants at Ditchingham are very fine ones, in large baskets suspended from the roof.

Dendrobium chrysanthum.—I recently noted a magnificent specimen of this very pretty *Dendrobium*, the long pendent pseudo-bulbs hanging in profusion from a large basket and covered with flowers. These are a pretty tint of yellow with maroon centre and are produced all along the stems in bunches of four or five. A very fine display is thus secured, but, unfortunately, the blossoms are rather quickly over. *D. chrysanthum*, though strictly deciduous, flowers upon the young green wood, often before the leaf falls, and until this occurs the plants must not be much dried at the roots. A short resting season is then necessary, but the plant begins to grow away very soon after, often in the early part of winter, so that part of its growth has to be made during the

worst time of year. It is not wise to hurry plants then, but just to keep them gently moving and in spring, with the increased light and advancing temperature, progress will be more rapid and satisfactory. This is when a little more warmth than usual may be allowed, the plant at other times doing best in an intermediate house. The compost should be very rough and open, as the roots of this species are much larger than those of the majority of species. Fairly large receptacles are also necessary.—H.

Vanda suavis and V. tricolor.—There is a good deal of confusion existing in the nomenclature of these two fine Orchids, and on several occasions recently amateur growers have asked me what is the difference. Structurally there is little, if any, but as garden plants they are distinct enough, *V. suavis* having in almost every case a pure glistening white ground, which makes it in my opinion a far more chaste and handsome Orchid than *V. tricolor*, which is usually some tint of yellow. There are, however, intermediate forms, and some of these are prettier than others, but none can come up to the better forms of *V. suavis*, one of the most noble of all Orchids. In the Ditchingham House collection both are doing remarkably well and flowering freely, the long white roots shooting out in all directions, showing how well the treatment they get suits them. Most of these plants, Mr. Haggard tells me, have been cut down and re-rooted within the past few seasons, yet they are flowering freely, showing plainly enough that the absurd plan of leaving the plants to get untidy and leggy for fear of cutting them down is not only absurd, but quite unnecessary.—H. R.

TREES AND SHRUBS.

FLOWERING TREES AND SHRUBS IN AUGUST.

ABUTILON VEXILLARIUM against a wall has borne its arching wands studded at intervals with pendent crimson blossoms, from which the pale yellow corollas and brown stamens peep. *Aralia (Fatsia) japonica*, of which some immense specimens exist in the south-western counties, plants 8 feet or 10 feet in height and 16 feet or more in diameter being not unknown, has perfected its Ivy-like inflorescence, while tall examples of *A. spinosa* are crowned above the layers of their deeply-pinnate leaves with ivory-white plumes of blossom. In a sheltered garden *Cassia corymbosa* has expanded its golden flower-clusters, while *Catalpa bignonioides* has perfected its pyramids of bloom. During the month of August I passed through a village in East Devon in the main street of which some young trees of this *Catalpa* were in fine bloom. The Mexican Orange Flower (*Choisya ternata*) has here and there given a second crop of fragrant blossoms, and *Caryopteris mastacanthus*, which has grown into a fair-sized shrub, has been thickly set with its lavender flowers. *Ceanothus Gloire de Versailles* was in fine bloom early in the month, and in a southern exposure *Clethra arborea* has blossomed. *Cytisus arboreus* has also been in bloom, and the Holly-like *Desfontainea spinosa* has produced its scarlet and orange drooping tubular blossoms. *Escallonia macrantha* is in bloom in some places, and *E. montevidensis* is smothered in its white flower-clusters, whose sweetness is much appreciated by the insect world. On a sunny August day a large bush of this *Escallonia* presents an attractive sight, not alone on account of its floral beauty, but also by reason of the varied insect life that haunts its blossoms. Flies of many descriptions are there, while the air is murmurous with the subdued monotone of the hive and humble bees. Of the butterflies, the red admiral, its jetty wings barred with vermilion and spotted with white, is present in by far the greatest numbers, a dozen or more expanding and closing their brilliantly marked pinions on the ivory-white flower-heads at the same time being no uncommon sight. Now and again a pea-

cock butterfly displays its chestnut brown wings, each bearing in its centre the large many-hued circle from which it takes its name. Now a fritillary with orange-brown black-marbled wings sails slowly over the summit of the bush, or painted-lady or tortoiseshell, the latter's brightness tarnished by its summer-long volatile gaiety, poises lightly on the flowers, or the sober tints of meadow-brown or wood-argus meet the eye. Early in the month I noticed a *Beschorneria* bearing a red-stemmed flower-panicle some 4 feet in height. The *Habrothamnus* has been producing its deep crimson bloom-clusters throughout the month, and the Syrian Mallow, which shares with the common St. John's Wort the title Rose of Sharon, has flowered profusely. The most attractive variety of this shrub is *Hibiscus syriacus totus albus*, the flowers of which are of a snowy purity. The Sea Buckthorn (*Hippophae rhamnoides*) is adding another tint to the grey-green of its leaves as its clustering berries assume an orange hue, and *Leycesteria formosa* displays on its drooping racemes of maroon-purple bracts its whorls of white flowers. The great standard *Magnolia grandiflora* is blossoming with even more than its customary freedom, a dozen or more fragrant white chalice expanding with each succeeding day. For four months in the year this tree is never flowerless, and during the past two seasons of 1897 and 1898 its first bloom was cut in the second week of May and the last early in November, thus giving a flowering period of six months, while in 1894 on December 2, just previous to the severe weather that marked the opening months of 1895, I cut a large *Magnolia* bud which opened well indoors. The only year of the last seven that this tree did not flower satisfactorily was in 1895, when all the early buds were killed by the frost, the first flower of that year not expanding until the end of September. The tree in question is a fine specimen, sweeping the ground with its branches which have a spread of 35 feet, while in height it exceeds 20 feet, and has borne some hundreds of blossoms every year with the exception of 1895, when the number of blooms that expanded was limited to thirty-two. The Venetian Sumach (*Rhus Cotinus*) is now covered with the feathery clusters that succeed the inconspicuous flowers, the flossy plumes assuming lustrous tints of purple and metallic-brown, while the shrubby hybrid *Veronicas* are becoming purple and pink with bloom.

Torquay.

S. W. F.

FLOWER GARDEN.

ALPINE PINKS.

WE are in the habit of seeing all kinds of alpine Pinks called by all kinds of names, but it is quite true that a rock garden may display some very neat and ornamental kinds for which it is very difficult for a botanist to find a genuine name, because some of the species hybridise so readily and many of the hybrids are fertile, so that the progeny departs further from the type in every generation. Setting aside the cluster or bunch-bearing Pinks, there are hardly a dozen kinds in common cultivation which can be distinctly referred to a wild type, and can also be easily multiplied by cuttings or come generally true from seed in gardens. I am going to mention the best of these as I have grown them in Edge garden.

DIANTHUS ALPINUS.—Very good and bears seed sparingly, which comes true and flowers the first year and spreads to a large breadth the second year, after which it often dies or becomes patchy. It likes moist peat, and if the soil is well drained by nature, does as well on the flat border as the rockery.

D. GLACIALIS.—I mention this here because it is so well known to tourists as one of the flowers they see at the highest alpine elevations, but the type when cultivated does not make a good rock

plant. The leaves are too long and too dense in proportion to the flowers, and unless recently raised from seed collected wild the plant is seldom seen true in cultivation. The best of all rock Pinks, however, goes by the name in nurseries of *D. glacialis*. I cannot trace it further back than Robert Parker's Tooting nursery, from which I got it twenty-five years ago, and I believe the original plant is still alive with me. Backhouse, of York, has kept up the stock, and I believe still sells it as *D. glacialis*. It is the earliest of the rock Pinks, beginning to flower at the end of April. It is rather difficult to propagate, and though I have searched all my many plants annually I have never found a seed. In habit it is intermediate between *D. glacialis* and *D. alpinus*, perhaps a hybrid of these two, and is well worth any pains bestowed on it.

D. NEGLECTUS flowers all June. It bears dense and very acute leaves. The flowers are lighter in colour and rather larger than those of *D. alpinus*, and have the under side of the petals of a pale apricot colour. It is long-lived on the top of a rockery, growing in very little soil, but in deep, fine stone riddings, and spreads to 6 inches across, plants of that size often bearing from fifty to 100 flowers. It seeds pretty well, and seedlings are always with me true to type, though they vary in height, the best having stalks of 4 inches to 6 inches long. It is easy to cultivate if the roots can penetrate deep without encountering any stagnant moisture, but if they find their way into sodden soil the plant turns brown and dies the first winter.

D. CAESIUS is very different in habit from those already described, which do not assume a pendulous habit as this does, being never so happy as when growing in a wall or in the crack of a rock. The Cheddar Rocks, from which it takes its name, the walls of (I think it is) Magdalen College at Oxford, and several parts of the Alps have distinct varieties in size of flower and stature, and any favourite form must be propagated by cuttings, which is very easily done. Unlike *D. neglectus*, *D. caesius* hardly ever comes true from cultivated seed where other species are grown near it. It is often difficult to determine the pollen parents of its hybrids. Sometimes they seem to approach what is commonly called *D. plumarius*, having a dark eye like small single forms of the garden Pink. In others the grey of the leaves, which give its specific name, is entirely changed to dark green, and the flower is dark crimson—characters which I attribute to a cross with *D. deltoides*—but whatever their history, the crosses are often worth perpetuating.

D. ARENARIUS (of Linnæus) has a very good portrait in *Botanical Magazine*, 2038. The leaves and stalk, about 6 inches high, are small and slender for the size of the flower, which is more than an inch across, very deeply fringed, white, with an ill-defined brown eye, and very fragrant. It comes for the most part true from seed.

D. GALLICUS (of Persoon) is confused with the preceding, though quite unlike it, one of its synonyms being *arenarius*, a name it deserves by its habit of growing in pure sand. It is mentioned here because the name is far commoner than the true species, which has rather thick, solid leaves and a strong stem more than a foot high, and a fringed flower of uniform pale pink. There is an excellent portrait of it in Wooster's "Alpine Plants," tab. 40. It is mostly a maritime plant, being abundant in the warm sands on the coast near Biarritz, from which I have several times brought it home to cultivate. Though I have given it a warm situation and deep sand to grow in, it has always flowered very late, if at all, and has shown signs of tenderness, never ripening seeds.

D. DELTOIDES.—Nothing more need be said of this purely native species than that it seems contented with any situation and soil, that it is easily pulled up if its room is wanted for anything better, that it contributes its pollen to hybrids, though seldom producing them from its own seed, and that the white pink-eyed variety comes in a large proportion true from seed and is very pretty.

D. SYLVESTRIS is a good rock plant, though not long-lived. It produces seed freely and is easily raised; the leaves are long and drooping, and the stalks weak and incapable of holding up the large pale pink flowers. Though I raise it every year from seed saved in my garden, I do not know that it has ever produced a hybrid there. The flowers are not fringed, and are not unlike the type of *D. Caryophyllus*, but paler in colour.

D. CALLIZONUS, so well grown at Kew, the flower of which resembles a magnified *D. alpinus*, I have never been able to keep more than a year in spite of two or three trials.

D. FRAGRANS.—This species has a small indented flower on an upright stem 6 inches or 8 inches high. A pleasing character is its very strong fragrance of Jasmine. There is a double form of more robust habit than the type which belongs to this, though formerly distributed as *D. petraeus*. This form is very easily propagated, and is deservedly a favourite in alpine beds.

D. PETRÆUS resembles *D. fragrans* in stature and in its white indented flowers, which are rather larger. There are other botanical differences, but as the two species certainly mix with one another and with others in cultivation, those who wish for accurate definitions of them are referred to the *Botanical Magazine*, where there are portraits of both, or to the monograph of *Dianthus* in the *Journal of the Linnean Society*.

D. SUPERBUS.—This well-known and widespread species extends from near the North Cape to Spain and from the extreme west of Europe to Japan. It may be expected to vary much. The best-known type in Europe grows nearly 2 feet high, has large, much fringed flowers, recalling those of *Clarkia pulchella* in form and size, ranging in colour from pale lilac to white. The scent is strong, but hardly agreeable, and the duration of the plants seldom exceeds two or three years. It is mentioned here chiefly because it is even more prone to form hybrids than *D. cæsius*. Its hybrids become very tufty and spread into large breadths, and are much dwarfer in stature than the seed parent. They root so densely that they may generally be easily divided with a trowel, but are mostly of second-rate merit.

D. KNAPPI is cultivated by me for its unique colour—clear pale yellow—not for any merit of habit. It is said to be either identical with or a variety of the older name, *D. liburnicus*. It has small clusters of small flowers on weak stalks 15 inches high which cannot bear up the flowers. If a dozen plants are planted together the flowers cover the ground pretty thickly and make a show. It ripens seed sparingly and comes quite true.

D. MASMENÆUS, named after a mountain in Cappadocia, and one of my best rock Pinks, flowering freely from a small base, with flowers nearly the colour of *D. deltoides*, but larger. I have had the species for twenty years. It was given to me by the late Mrs. Lloyd-Wynne, of Coed Coch, who told me she found it wild either in Sicily or Palestine, the latter country only being within the range of the species. For several generations it has always come quite constant from seed, so I became convinced that it was a true species, but I could not get a name for it until I sent a good specimen to the Herbarium Boissier at Geneva, from which it was returned with the above name.

Besides these I have grown many other species of alpine Pink, but they were either deficient in merit or of uncertain identification, and my experience of seed saved in my own garden and of bought seed and plants of this tribe convinces me that the names are seldom trustworthy.

C. WOLLEY-DOD.

Edge Hall, Malpas.

Fuchsias in the flower garden.—I think it was Mr. Molyneux who last autumn had a note on the fine *Fuchsias* he had seen in the neighbourhood of Cromer growing in the open air. Hereabouts showy spreading bushes are common in villa and cottage gardens. At the present time (the

first week in September) the plants are a mass of flower, and form a most pleasing contrast to the more formal subjects by which they are surrounded. The old *Fuchsia Riccartoni* is very graceful wherever seen in rude health, and flowers so freely, that the long growths are weighed down. Some of the larger flowered varieties are just as vigorous, and as they come into full beauty just when nights and mornings are getting cooler, they remain in that condition until spoilt by early frost. By this all the year-round exposure these hardy sorts become hardier still, though in winters of more than ordinary severity a covering of some short litter or leafy material is necessary; indeed, it is best given in November as a safeguard. Some of the cottagers cover the crowns with coal ashes.—J. C.

Vallota purpurea.—"J. G.'s" note on this showy old plant is opportune. Twenty years ago it was very generally met with, but one may now inspect many greenhouses without seeing it. Its value does not altogether lie in its brilliant colour, but in the period at which it comes into flower, being, as "J. G." says, at a season when pot plants in bloom are none too plentiful. The mixture named by "J. G." cannot be improved upon, good drainage also being very necessary, as it is not advisable to disturb the plants too often. At one time it used to be well shown in collections of stove and greenhouse plants in the north of England and it always made a mark. A number of bulbs were placed in a rather large pot and surface dressings given each year that potting was not performed. The plant is much benefited during growth by liberal supplies of weak liquid manure. Ripening is an important point, the foot of a sunny wall being a good position for a time after flowering.—J. C.

CACTUS DAHLIAS.

IN spite of the drought these are making a brave show. Too much cannot be said of them as beautiful garden plants. Few plants have been so quickly improved by the introduction of new varieties as have these, and kinds which but three years or so back were thought wonderful stand no chance against the latest types. In colour, lightness in arrangement of the florets, freedom of bloom, and in the general habit of the plant's growth changes for the better may be noted. They will undoubtedly oust the stiff, formal Dahlias out of cultivation. In some shades of colour we do not yet possess perfect sorts, notably in whites and yellows, but in time these will probably come. The best white is Keynes' White. This is in every respect, except that it has a creamy shade, a very fine variety. Free-flowering and constant, it throws its blooms well out of the leaves, while the leafage is ample, and the plant not over 4 feet high, a capital height for a Dahlia. Miss Webster and Salisbury White are sorts which bear the purest white blooms of any, but neither has the form now most esteemed. The last named is especially useful where a quantity of cut bloom is required. Mrs. A. Peart is uncertain, otherwise when good this is excellent. I find the flowers come better on old plants than on those raised each year from cuttings. Lady Penzance is the only yellow kind worth growing for a fine type of bloom. Its only fault is that the stems of the flowers are short, and they are thus somewhat hidden among the leaves. By well thinning the growths, especially those which spring from under the bloom-buds, this fault may be less noticeable. Blanche Keith is a good yellow, and so is Mrs. Turner. Both have heavy-looking blooms, but the plants are striking in the garden on account of their freedom in flowering. Daffodil, which was thought highly of when first exhibited, is not with me an improvement in yellows. The habit of the plant is certainly desirable, but unless severely thinned the blooms do not come full to the centre. A Cactus Dahlia that will only produce a very limited number of perfect blossoms is hardly worth troubling about. Delicata has blooms of a lovely shade of salmon-rose. Its flowers, however, are hidden among the

leaves. A much better kind of a similar shade is Loreley, a pretty kind, rose, shaded white to the centre. The blooms are well formed, borne freely on long stems, and the plant is about 3 feet high. Its foliage is very dark green. This sort will, I fancy, become popular. Arachne is the first of a fancy type of Cactus Dahlia. The ground colour is white, each petal being more or less striped with red. The stems are long and weak, so that the blooms become pendent. This, however, does not detract from the merits of the plant as a whole. The Clown is a newer kind, having flowers with distinct markings. In this case half of each petal is a buff shade, the other part white. The habit of the plant is sturdy. When better known this sort will be much admired. Starfish is quite the best of those with scarlet blooms. Every flower comes perfect and it is very free. The habit of the plant is somewhat loose and requires more tying than many of the improved sorts, otherwise no fault can possibly be found with it.

Standard-bearer has blooms less bright and not so well finished, but with a dwarf, close habit of growth. J. E. Frewer is a scarlet-coloured variety that must not be discarded yet. Gloriosa produces blooms most rich in the shade of red, but it is heavy looking as types go now. The plant, too, is rather tall. For planting in front of shrubs, it has, however, a bold look. Night has very dark maroon flowers, almost black, and is a first rate improvement. Matchless, so long favoured as a dark kind, is quite superseded by this. One of the most free to bloom and every flower perfect in form, it is a singularly handsome bush. Ranji, now grown for the first time, is disappointing, the flowers being so rough shaped and their centres faulty. It is dark-coloured and free blooming, that is all, but unless it gives better blooms in moist weather I shall discard it. Cinderella has blooms of a purple shade, deep and rich. The form is excellent, but the plant requires to be thinned, otherwise all the flowers do not come double. Earl of Pembroke is somewhat heavy in shape of flower, but for freedom of production and general habit of the plant it is quite the best of the plum-purple hue. Charles Woodbridge is, perhaps, the handsomest of Cactus Dahlias. It has blooms of a rich crimson colour, large and perfect in shape. It is less free in flowering than many, but withal a type one would like to see in other colours. Mrs. John Goddard has dazzling light maroon blooms of the most approved formation. It is free and takes a long time to open, but each flower also lasts a considerable time even when fully out. Beatrice bears flowers of a distinct rose-pink shade. The plant must not be thinned, or its blooms come coarse. It is a tall-habited kind. Island Queen resembles it somewhat in colour. This, on the other hand, must be well thinned. If this be not done its blooms are small. The first is a desirable garden plant; the other fit only for exhibition. Bridesmaid is a capital sort, so unlike any other in its combination of colours—primrose, shaded pink. The plant is very free-flowering and the blooms long-stemmed. It must not be thinned, or the petals are too numerous to properly open. Mrs. Wilson Noble is not the least charming of Dahlias. The salmon-pink blooms have a tint quite their own, and the shape is excellent. It is dwarf and very free; so much so, that the buds should be reduced considerably. Countess of Lonsdale is a new variety of great merit. Its habit of growth the plant is first rate. The blooms are not wanting in any way, and are borne well out of the foliage. Its colour may be described as rosy salmon, very delicate and charming. Alfred Vasey has flowers of a salmon-red tint, and its spiky petals are formed in a perfect way. The plant is short and especially free flowering. A large bed of this kind alone would form a most striking object. Britannia, on account of its dwarf habit and free-blooming qualities, would make a splendid bedding Dahlia. The light buff blooms all come of capital form. Altogether it is one of the really improved types. Capstan has blossoms

of a terra-cotta-red shade of nice form. The plant is dwarf, bushy and free-flowering. This will become an esteemed kind. Mary Service is delightful in its many tints. Heliotrope and red would describe them. The blooms are of good shape and especially light, making it a desirable variety. Dwarf and free, it needs but little thinning and the blooms last well when cut. Fusilier, coral-red, is now well known as a very excellent variety. It is free, but in a year or two will probably be superseded by a sort lighter in formation of blossom. Lucius is a pretty type. The orange shade of colour is one wanted, and in all respects it is an improvement. Magnificent as yet I am not so pleased with. It may be that I have not thinned the blooms enough, for the centres are faulty. It is very free and dwarf, and if later flowers come better than the present ones the name will be thought deserving.

Harmony, Harry Stredwick, Miss A. Nightingale, Mrs. Barnes, Cycle, Mabel Keith, and Mrs. Kingsley Foster are worth growing perhaps, but are behind those kinds more fully described, which are now noted as they are in the growing state. At exhibitions many new kinds will doubtless be seen for the first time and much admired, but it is only after a trial in the garden that one can really judge of their merits. H. S.

FLOWER GARDEN NOTES.

DAFFODILS.—If existing breaks of Daffodils are to be strengthened or new plantings formed, it will soon be time to see about them. Given favourable conditions as to soil, they may be planted in almost any position except in extreme shade, but it is very little use attempting to naturalise the Daffodil in uncongenial soil, where, for instance, it is very light and sandy, unless special preparations can be made, which are naturally somewhat opposed to one's idea of *bond fide* naturalisation. Here with sand close to the surface and going to a great depth the result of planting in the turf is disappointing, but if a bit of old shrubbery is cleared away I can secure capital results by digging deeply, working in a compost consisting of one half road sidings and one half well decomposed leaf manure, and putting the bulbs well down. If an enduring display at each clump is a consideration, different varieties of the trumpet and star sections can be used.

DRY WEATHER ANNUALS.—It is interesting in a season like the present to note anything in the way of flowers that stands the prolonged drought fairly well, and that holds its foliage and continues to flower when other things have practically succumbed. From this standpoint there are few annuals better than the Sunflower known under the names of Stella, New Miniature, and one or two more that do not occur to me at present and which are not important, as they are practically the same thing. On a rather poor border and fully exposed to the sun, plants of this Sunflower have not gone so high as usual, but they are in the best of health and covered with the bright-coloured blooms, the black eye and the rich yellow of the petals forming an effective contrast. Another excellent dry-weather plant is *Cosmos bipinnatus* and its varieties, an annual with Fennel-like foliage and light graceful flowers. The latter look flimsy, but stand much longer, both on the plant and in a cut state, than their appearance would seem to indicate. A deeper and more pronounced shade of purple would be a decided acquisition. Marigolds, both tall, medium, and dwarf, as represented respectively by African, Calendulas, and French, flourish amazingly in heat and drought, only under these conditions decaying blooms have to be promptly removed in order to prolong the display. Petunias also do well, growing freely and blooming profusely, only they want a heavier and more retentive soil. Antirrhinums, of course, revel in the heat. I class them for the time being with annuals because they are treated as such; a sowing is made in slight warmth early in February, and they are

grown along quickly to secure nice sturdy plants by the beginning of May. The tall section is much the more enduring. I have been surprised to find the Marguerite type of Carnation doing so well, and am pleased to recommend them as thoroughly good dry weather plants. They were planted on a rather poor border facing due south with a wall as a background, a border that dries out both fast and deep, and yet at the present time they are looking well, not so vigorous as usual, but nice stocky plants that are throwing some very good flowers.

SUMMER BEDDING ARRANGEMENTS.—It is somewhat late in the year to write on this subject when the clearing of beds rather than the planting is under consideration, and yet in one respect it is the best time of the year for the purpose, because any alterations in the planting that may be deemed necessary for another season can be provided for by the increased propagation of those things likely to be required. The taste for mixed beds is becoming yearly more apparent, and, as in the case of other styles, is very pleasing when thoroughly well done. There is, however, a tendency to overcrowd and to push the number of species and varieties employed to an extent that is apt to make the mixture somewhat incongruous. The overcrowding is objectionable because the capabilities of individual plants are not given a chance, and what would under more favourable circumstances be a well-furnished bush is a weedy-looking plant of straggling habit, whilst the mixing together in the one bed of perennials, annuals, and bedding plants seems to me quite out of character and antagonistic to true gardening. It is also well to note that in the case of small beds too many colours should be avoided. Even with the same species, as, for instance, Verbenas, Petunias, or Phlox Drummondii, a good breadth of one shade is desirable, but when a lot of different things, as Lobelia, Echeveria, tricolor Pelargoniums, Iresine, or Coleus, are planted in a narrow strip either in lines or blocks, we get into a style approaching carpet bedding, one of the things, happily, fast dying out. There are plenty of things of dwarf habit, as Golden Harry Hieover and Manglesi Pelargoniums or dwarf Ageratum, that can be utilised for small beds, filling each with one variety and relieving the same slightly with a few plants of taller habit either in flower or foliage. E. BURRELL.

Claremont.

FLOWERING CLIMBERS IN DEVON.

It is not often that in this country such a resplendent display is afforded by *Bignonia radicans* as is so frequently to be seen on the Mediterranean shores, so that when this rare occurrence is met with it becomes all the more noteworthy. In a secluded village at the head of one of the tributaries of the river Dart the southern side of a house is covered by an old plant of this creeper. The specimen in question is said to be seventy years old, and its stem has a circumference of 18 inches near the base. It is growing in the red clayey loam of the neighbourhood and is evidently in the most vigorous health, its yearly shoots averaging 5 feet in length. In the month of August the effect produced by this plant was one of surpassing brilliance, the whole side of the house being a sheet of glowing scarlet with its abundant flower-clusters. This *Bignonia* is possibly better known under the title of *Tecoma radicans*. The Virgin's Bower (*Clematis Flammula*) is smothered in a wealth of ivory white, scented star flowers that perfume the wandering breezes with their luscious sweetness. Many cottage porches are embowered in the profuse wreathings of this plant that shrouds trellis and lattice windows with its odorous flower-trails. *Clematis Jackmani* has retained the rich purple of its blossoms well into the month, and here and there the early-flowering *C. montana* has supplemented its spring display by a sparse autumnal blossoming. *C. Vitalba*, the Old Man's Beard or Traveller's Joy, is garlanding tree and shrub with its greenish white seed-clusters,

soon to assume the smoke-grey tint that renders them so decorative when wreathing the topmost boughs of some old Portugal Laurel or Ilex. *Cobæa scandens* is bearing its bell-shaped purple blossoms, and *Eccremocarpos scaber* its racemes of orange blooms, and in the hedgerows the Honeysuckles are flowering. On a sheltered wall *Mandevilla suaveolens* has produced its fragrant white blossoms, *Lophospermum scandens* has borne its rosy flowers, and *Mina lobata*, threading the growths of other climbing plants, is showing the scarlet and gold of its bloom sprays. The Morning Glory, though a troublesome plant to eradicate when once established in borders containing subjects of less rampant growth, is a beautiful sight when relegated to a position where it may swathe a rocky spur or envelop rough poles with its twining greenery and wide-spread, snowy blossoms. The blue Passion Flower and its white variety, *Constance Elliott*, are in flower, and their earliest fruits are in some cases already commencing to colour. *Physianthus albens* has also been in blossom, and in the same garden a large plant of *Plumbago capensis* that has lived in the open against a perpendicular cliff, sheltered from the north and east, for the past three winters without experiencing any injury is bearing its pale blue flower-heads. *Solanum jasminoides* is a lovely sight, being thickly starred over the whole of its greenery with countless white bloom clusters, which, though they shed their petals until the underlying ground is white as with snowflakes, are reinforced by fresh flower sprays in such quantity, that week by week the plant becomes a picture of more perfect beauty until it reaches the zenith of its display in mid-September, provided that up to that time it haply escapes being devastated by some unseasonable gale. In hard winters the *Solanum* is usually more or less cut back by the frost, but during the past three mild seasons it has received no check, and has in consequence made unrestricted growth, a specimen on one house that reached the eaves some five years since standing out to a depth of over 6 feet from the wall. The vivid scarlet flowers of *Tropæolum speciosum* are now things of the past, but are succeeded by the purple seeds. Late-sown plants of *T. canariense* (the Canary Creeper) are still bright with their golden blossoms, and *T. tuberosum* is daily becoming more decorative with its orange and scarlet flowers, which, on their long foot-stalks are held well clear of the foliage and create a brilliant autumnal effect. A climbing variety of *T. Lobbianum* of a particularly bright scarlet, which has covered a little cottage from ground-level to eaves, is now a wonderfully striking sight, the glow of its innumerable vivid flowers being apparent from a considerable distance. Early in the month the *Wistaria* provided an unlooked-for addition to the charms of the garden by bearing an autumnal crop of perfumed flower tassels, which, though not as lavish as its spring display, was almost equally charming. S. W. F.

Torquay.

Helenium autumnale superbum.—This is one of the finest late-flowering hardy plants of recent years. Just now the fine pyramidal trusses are delightful, especially where the plants have been well watered and mulched. I have found it best to divide in spring, giving the young plants plenty of room. The immense pyramids of bloom are really marvellous. Some of those divided, which I should say are single stems, rise to a total height of 5 feet. The mass of bloom is fully 3 feet deep and 2 feet 6 inches through. Upon one I counted forty small branches, each one bearing from ten to twenty-five buds and blossoms. There could not have been less than 600 buds and blossoms upon this one stem. The colour is of the shade of yellow known as gamboge, being rather paler than *H. pumilum*. This *Helenium* would make a grand subject for a bed where something imposing is desired, and if interspersed with *Tritomas* a charming effect would be produced.—PHILOMEL.

ARENARIA AND CYPRIPEDIUM.

A VERY pretty effect is secured frequently in quite a haphazard sort of way in gardens by the association of one or two plants of distinct habit and flowering that happen to blossom at one and the same moment. It is so with the Mountain Sandwort (*Arenaria montana*) and the Mountain Lady's Slipper (*Cypripedium montanum*), as shown in the accompanying illustration. The former is, perhaps, one of the most free growing of all white spring-flowering plants, and for such there is ample room in many gardens quite regardless of their extent. As a free-flowering plant, however, the example in the picture is by no means a fair specimen of what this plant will accomplish, and it would appear in its present position rather in the light of some quick free-growing subject employed for the express purposes of furnishing the rockery stones. As a rule, in the early spring months this beautiful Sandwort is quite a sheet of pure white flowers, with usually only enough green to make an adequate foil for the mass of flowers. In the present instance the much extended growth is the outcome of the particular position occupied, and in this way serves to indicate how much a plant owes to environment and the like. By comparing the present photograph with one of the same plant in the "English Flower Garden" (edition 4, p. 296), the result will be clearly seen. One plant is grown in the open; the other is subordinate to other and stronger plants near that obviously rob it of its true character. On an open or sunny bit of rockwork this Mountain Sandwort would quickly cover a square yard by its growth, which in the ensuing spring would be a mass of snowy blossoms.

The *Cypripedium* which forms so pretty a group in the foreground is one of the prettiest of the Lady's Slipper family. The blossoms, however, as represented are exceptionally large for this kind, but as the plants have also made a fine leaf growth, it is obvious the crowns or tufts of plants must have been more than usually strong. A capital idea of the plant, however, may be gathered from the illustration, while the flowers are of an extremely delicate rosy white, veined and shaded with a deeper rosy hue. The sepals are of a brownish purple, and the yellow column is freely spotted with crimson. This pretty kind is also known as *C. occidentale*, and where the plants are strong, one to three flowers at intervals on the stem are frequent. Several of the Kew plants have produced two flowers on a stem, which may also be noted in some instances in the picture. The plant comes from the mountain regions of California, but is perfectly hardy in this country. In peat and light vegetable soil, as, for example, leaves half decayed, the plant does quite well, and, given a shady place with a fair amount of moisture, may be grown with success in British gardens. For two years in succession this pretty plant has figured freely in the hardy Slipper flowers shown by Messrs. Wallace at the Temple show, the plants having been grown in pots and generally with two flowers each. At Kew the shade is provided by a large block of rock, while the Sandwort trails over all this, as shown in the picture. For companions this Slipper flower has *Epipactis*, *Swertia*, and probably a few of the British Orchises, which in any case would be quite at home. Other plants suited for such a spot are *Claytonia sibirica*, *Omphalodes verna*, *Pratia angulata*, and the vernal and Bavarian Gentians. Many other things would be equally happy in a spot so permanently as well as uniformly cool, and good companionship is a thing to be aimed at in this style of gardening.

E. J.

CACTUS DAHLIAS AT THE CRYSTAL PALACE.

NEW varieties come an apace, and pretty well a dozen received certificates at the hands of the committee of the National Dahlia Society on the 1st inst., although some of these got such awards rather by the skin of their teeth, one especially securing the coveted honour by seven votes as against six. Such voting shows that awards of this nature should be made only by a majority of fully one third of the members present. In another case three hands were held up in favour of a variety and none against. But in most cases the voting was practically unanimous, and when this is the case it is evident that the variety as presented is a good one. But the committee's requirement that for such purposes flowers and seedlings shall be shown as grown, and without support, seems absurd, as not one in twenty have other than weak stems, and hang down in a distressingly looking despondent way. One only

Arenaria montana and *Cypripedium montanum* in the rock garden at Kew. From a photograph by G. A. Champion.

seemed to have really stout flower-stalks, and that was the most striking one of the novelties, Green's White, which is the best and purest white Cactus variety yet seen. So far as relates to the others, no one seemed to make it a requirement that the stems should be stout and the flowers erect, and for that reason showing the flowers as grown seems absurd. Amongst other novelties shown were Zephyr, colour rosy salmon, tinted with mauve, a new colour, and singularly charming; Mrs. J. J. Crewe, large pale yellow, petals much incurved; Innovation, after Arachne, but here not yet good; W. Treseder, white, flushed pink, certainly not good at present, but a pretty colour; Olive, petals thickly set and much twisted, colour coral-red, flushed lilac, a charming variety; Elsie, rather large, but a charming colour, yellow, heavily flushed with rosy mauve; Whirlwind, one of the Fantasy type, but better, the petals more dense, incurved, but many of them placed as though under the effects of strong wind, colour

reddish carmine. Ajax is another of this type, very like the preceding, but is of paler hue. A very quaint variety is Mayor Tuppenny, as also is its name. It is large, petals twisted and incurved, but still rather thinly placed, centre yellow and outer petals reddish apricot. Two Emperors were staged, one a rich crimson-scarlet, one a rosy purple. The former seemed to be the better, but which of the two was certificated no indication was given at the time these notes were taken. The varieties here mentioned comprise the best of the present season's novelties so far, but all did not receive awards. I venture to think that there are too many trade growers on the committee, for these are all more or less interested in getting certificates awarded to novelties as a matter of trade. It is hoped that some so honoured will be seen in better form later on. It is but needful to look over the fine varieties new in commerce to see how fine in form and how beautiful in colour the best are. For this reason in selecting novelties for certificates, only those showing distinct advance, especially in form, should be thus honoured. It is to be desired that at all future shows small award cards should be placed on the selected varieties by the committee as they go round, and thus assist both the Press and the public in seeking for needful information.

Of varieties in commerce, the following were shown in beautiful condition, and novelties must be good to excel them: Laverstock Beauty, reddish terra-cotta; Charles Woodbridge, rich crimson; Capstan, reddish salmon; Keynes' White, so far the best; Countess of Lonsdale, salmon, flushed mauve; Magnificent, buff; Mary Service, a lovely variety, coral-red, much flushed mauve; Island Queen, soft lilac; Countess of Gosford, scarlet; Alfred Vasey, soft rosy pink; Starfish, bright scarlet; Lucius, orange-red; Fantasy, coral-red, much incurved; Ebony and Ranji, both black-crimson and the best of that colour; Harmony, apricot; Lady Penzance, yellow, and Britannia, pale buff. Anyone having this collection of named varieties will find them very hard to beat. Looking over the other day the large collection of varieties growing at Chiswick, I could but note how very little has been yet done by raisers in the direction of getting dwarfier habits and flowers well thrown above the foliage. It seems as if a long time must elapse ere Cactus

Dahlias can be made effective for garden decoration. In that respect the pretty pompons greatly excel them. A. D.

Narcissus cyclamineus major.—As I was the first person in England to whom the Baron de Soutellinho, of Oporto, then Mr. Alfred Tait, sent the long-lost *N. cyclamineus* after its re-discovery by him, I am naturally interested in the plant. I therefore wish to know what is *N. cyclamineus major*. English bulb catalogues have for the most part ceased to offer *N. cyclamineus*, and only offer *N. c. major*, though this new bulb does not seem to have reached the Dutch growers, as Messrs. Roezen, Tubergen, Krelage, and others who favour me by sending their catalogues, make no mention of the major, though they all offer *N. cyclamineus*. I have not been regular of late in my attendance at the meetings of the *Narcissus* committee, so do not know whether any certificate has been given or registry has

been authorised for this new variety, but I have grown *N. cyclamineus* ever since I first received it, and believe that the average size of my flowers is equal to that of those now supplied by the bulb dealers. It is true that several of my seedlings have produced enormous flowers as large as those of the ordinary wild *N. pseudo-Narcissus*, and I at first thought these might be the major development now offered by the English dealers, but on further comparison of the characters I concluded that they were spontaneous hybrids with some large form of *N. pseudo-Narcissus*.—C. WOLLEY-DOD, *Edge Hall, Malpas.*

ECKFORD'S AND OTHER SWEET PEA NOVELTIES IN AMERICA.

IT is very pleasing to record that the Sweet Pea novelties of Eckford's raising which were offered in the States this year through W. A. Burpee and Co., of Philadelphia, Pa., have afforded much satisfaction. The colours of this latest set of novelties are decided and distinct. Of late years there has been a noticeable weakness in the famous English raiser's introductions so far as decision of colour was concerned. It is not disputed that they were different from others already in cultivation, but that alone will not satisfy the American critic; our horticultural standard is not ruled by association nor by sentiment. The rarity of a variety or the mere fact that it is new does not enter heavily as a factor in regulating its selling value. There must be intrinsic merit, and intrinsic merit in a florist's flower surely should be its possibility of appealing to the taste of and captivating the attention of the million rather than drawing notice from the specialist.

COUNTRESS OF CADOGAN, with standards of violet-blue and wings of deep sky-blue, gives a very pretty effect in the mass, as the two colours blend well at a very short distance. This is a qualification that does not receive enough attention in many plants. The colour impression of a single flower closely looked into will often give a very false idea to the observer, and therefore close analyses should be accepted simply for what they are. This variety has to meet here a much better, richer, and deeper blue Sweet Pea of the same type in Navy Blue (Burpee). True, it is not navy blue, but it is so named; it has a considerable amount of violet in its flowers, especially in the standards, but the distant effect is a true blue, several shades deeper than in Countess of Cadogan. I learn that some English growers of the two varieties report that the two are identical, but whatever that may be with you, they are very clearly distinct here.

LADY GRISSEL HAMILTON is assured a leading place as a flower of clear light lavender-blue or greyish blue. It is a true self, and although slightly hooded, is of a satisfactory form.

OTHELLO is a dark flower, but, as frequently happens from Mr. Eckford's descriptions, cannot be recognised. I quote from the catalogue of the introducer: "In reality the flower is a very deep tone of an intense, very intense shade of magenta-lake, the slight bluish cast being more noticeable in the wings than in standard, which by transmitted light shows up as a clear deep magenta bordering on a port wine colour. It is a glorious flower, of fine form, size and substance."

DUKE OF WESTMINSTER is intermediate between the roses and the blues. The well-rounded standard is rosy lake, heavily veined with a more intense tone of the same colour, giving almost the effect of the self. The wings are of the same character, but having a violet cast. The form of the flower is good and well expanded and fine in substance.

HON. F. BOUVERIE gives the effect of a delicate salmon-pink and is superior in its colour to the older Peach Blossom.

LADY SKELMERSDALE is a somewhat hooded flower, the standard rosy lake, with much paler wings.

MRS. DOVEDALE (Eckford) and Burpee's American novelty FASHION are two varieties which run very closely together, and one will no doubt have to go under. The general effect is in favour of Fashion for depth of colour, while the other leads in brilliancy. Both these varieties are of a rich rose tint, a faint suspicion of primrose appearing occasionally on the standard of Mrs. Dovedale, whilst a bluish cast slightly overshadows the wings and to a less degree the standard of Fashion.

SADIE BURPEE is of the purest white, perfectly clear in all parts of the flower. The form is charming, the standard being very full and broad, the wings large, expanding well, and so displaying an unusual amount of surface, giving an idea of solidity that is very remarkable. It comes in both black and white seed, and is expected to prove of extra constitution, a feature that hitherto has been lacking in the whites. I am inclined to think that this variety will at once become the standard in its colour.

In closing these notes it will be well to notice two other American novelties of merit. The first is

PINK FRIAR, a pink variation of the well-known Grey Friar; hence its name. The petals are of the faintest pink tint, a little streaked in an irregular manner with a more intense tone; altogether a very exquisite flower. Last, but by no means least, comes

GORGEOUS, which fully comes up to the high standard that one would expect from its name. The standard is pure orange-red and of dazzling brilliancy. It is of the character of Meteor, but surpasses it in all respects. The large wings are of a bright orange-crimson colour. The stems are very fine and the individual blooms well displayed. It is certainly the brightest in its class. It lights up wonderfully.

LEONARD BARRON.

TABERNÆMONTANAS AND EUPHORBIAS PLANTED OUT.

As a general rule *Tabernæmontanas* are grown in pots, and thus confined and given good attention they grow and flower fairly well. It is when planted out, however, that the best results are obtained. I recently saw some healthy productive bushes in a span-roofed house at Carrow. The plants are old and have been regularly cut back each season early in the year. This treatment they stand well, breaking away into new growth freely and blooming profusely. When I saw them they were thickly studded with flower-trusses, but they were not opening quite to Mr. Jones's (the gardener) liking. This he attributed to the house having been kept too cool. He had reduced the artificial heat as the season advanced by way of experiment, but it had taught him a lesson. An equal quantity of loam and peat, with plenty of grit to secure an open condition, was what the plants were rooting in, and that it just suited them was evident from their appearance. The roots are kept somewhat drier in winter, and particularly for a week or two previous to cutting back in January. I do not think *Tabernæmontanas* are so liable to attacks of mealy bug as *Gardenias*, although that is their chief enemy, and their fragrance is very similar to that of the *Gardenia*. Growing in the same house and occupying the opposite bed was a healthy lot of the brilliant and useful *Euphorbia jacquiniæ-flora*. The treatment accorded is exactly similar to that given to the *Tabernæmontanas*, and no one after seeing the plants at Carrow would go back to pot culture unless compelled. The long healthy growths are tied to a wire trellis, similar to the way in which Cucumbers are done, about 1 foot or 18 inches from the roof. C.

Dahlia (Cactus) Mrs. Stephenson Clarke.—This kind is at least distinct from many of its fellows, and as such should be of value on the exhibition board as well as in the garden. Like most florists' flowers, the Dahlia appears to have

reached the pinnacle of excellence so far as the florist has set his ideals, and the only hope now is for new and distinct colour breaks. This kind has a base of gold, while the tips of the florets are orange-scarlet, the two shades being more decided than in any other we remember. It should prove an attractive garden plant.

Marigold Silver King.—Compared with the better-known Legion of Honour, this Marigold is of dwarfer, more spreading habit and the colour of the blotches on the petals is even more clearly defined than in that kind. The outer tint is a pale sulphur-yellow, the blotches a brownish maroon. Grown side by side in the same border at Shipley Hall, Derby, they are abundantly distinct and make a very bright and telling edging. Another interesting plant is a variety of the common Feverfew, with bright yellow button-like flowers that show up very prettily against the deep green foliage.

BEGONIAS AND DRY WEATHER.

SOME have gone as far as to say that the Begonias would oust the Geraniums from the flower garden, but, good as the former are in their many shades of colour and ornamental foliage, they lack brilliancy and cannot be seen to advantage unless close at hand. Not only so, but unless special attention is bestowed on them they make but poor headway in a tropical summer. A drippy season is supposed to suit them best, and this is detrimental to the majority of summer bedding subjects. Much may, however, be done towards making the Begonia a success even in the hottest and driest summers by giving a suitable root-run and judiciously mulching and watering. Only a few days since I inspected several large beds in a private garden. The gardener complained of the season being unfavourable to a free growth, but I could plainly see that had the beds, which, by the way, were of a lightish, open character, been well mulched as soon as planting was completed, the plants would in all probability have been twice the size, as so much of the moisture escapes from unmulched ground, and Begonias must have plenty of moisture. Some shun mulching from a labour point of view, and are constantly wasting time by administering dribbling waterings; whereas when once mulched what water is given is retained, and half the after labour suffices. A fairly deep moisture-retaining though well-drained root-run suits Begonias best, and when the same site is used year after year a free incorporation of some entirely fresh material of the above nature should take place at least every third year. This treatment, together with a gradual and hardy system of starting the bulbs into growth in spring, is the only way of securing a regular and satisfactory growth. One amateur I know always starts his bulbs in cocoa-nut fibre, giving cool quarters, and plants with a small wig of this material attached to the roots. They seem to root freely in the fibre. He also mulches the surface with the same material, and digs the old mulch into the bed in spring. B. S. N.

Lifting *Lilium candidum*.—The notes both of "H. R." and "J. C. B." at page 155 are instructive. It used to be thought that lifting the bulbs of this old Lily, or, indeed, disturbing them in any way, was very harmful, and it must be confessed that one often sees grand clumps in cottage gardens where they have stood unmolested for years, but I think the let-alone system may be carried too far, for, as "H. R." has proved, the younger bulbs arrive at a flowering stage sooner and make better bulbs when lifted and replanted in new soil than they can possibly do if left crowded together in a semi-starved condition. I was much troubled in one garden by the disease, and never really mastered it. It seemed worse in excessively hot seasons. I quite believe with "J. C. B." that well-nourished bulbs are less liable to attacks than weakly, half-starved ones, but I have known no end of trouble taken with a view to eradicate the disease, but without avail. I once destroyed all my own stock

and procured new bulbs from a nursery, planting them in new loam, but, although growth was very vigorous, it fell a victim to disease the first summer.—J. C.

ROSE GARDEN.

SOME GOOD CHINA ROSES.

AMONG the China Roses we have had during recent years some splendid improvements in colour. The one figured above is to my mind one of the most beautiful of modern Roses. There is an indescribable charm about the flower in its wondrous tints of rich rosy pink, heavily shaded with canary-yellow and orange, also in a less degree in its pretty foliage. The buds ere they unfold have a certain resemblance to those of l'Idéal in colour, but they are not quite so large. Although single specimens either as bushes or upon standards are lovely, the Rose must be seen in groups to form any idea of its value as a first-class kind for the garden. It will grow and thrive equal to, if not better than, any of our Tea Roses. The plants should be treated well at the commencement. Where soil is not good, make it so by working in a few loads of good loam of rather a strong texture. The let-alone system of pruning should be adopted. I am no advocate for mutilating the China Roses in the way thought necessary for kinds grown for exhibition, and am glad to see a more rational treatment advocated by the leaders in the Rose world as regards pruning these China Roses.

The parent of the above-named variety is Mme. Laurette Messimy. It was obtained by M. Guillot in 1887, being the result of a cross between an old China Rose named Rival de Pestum and the Tea Rose Mme. Falcot. We have in Mme. E. Resal a distinct proof of the fact well known to hybridists that the second and third generations of a cross often produce the best results. This is no disparagement of Mme. Laurette Messimy, for it will always hold its own. When once a variety has taken hold of the public it is a difficult matter for any newcomer to oust it from its position. I think of the two kinds mentioned above the parent is the better grower.

Another fine novelty among these Roses is Queen Mab. Its buds are of the most beautiful shade of rosy apricot, suffused with orange, somewhat resembling the Tea Rose Safrano in shape, only of a more beautiful and a richer colour. Queen Mab is a first-rate grower, richly endowed with beautiful foliage of quite a ruby colour in the young state. Other good new kinds are Irene Watts, a very delicate shade of salmon-pink, another seedling of Mme. L. Messimy, and Duke of York, a most valuable variety, changing from rosy pink and white to rich crimson. The centre of the flowers, which are large for a China, is often flamed with crimson, heavily bordered with white. By artificial light this variety has a most unique appearance. A very pretty and promising kind is Aurore, one of the latest of the French novelties. The colour is crushed strawberry, and the ruby foliage is a delightful contrast. I have formed a good opinion also of Jean Bach Sisley, but should like to see a little more of it before pronouncing upon its merits.

Of the older Monthly Roses, the Common Pink is still among the best. For gorgeous colouring there is a rivalry between Cramoisi Supérieur, or Agrippina as it is sometimes called, Sanguinea, and Fabvier. I should be disposed to award the first position to the first-named, although it is not quite so free in growth as one could desire. Sanguinea or

Old Crimson is good, and rather darker than Cramoisi. Fabvier is not quite so brilliant and it is not more than semi-double, but it is, nevertheless, a free and good kind for massing. Armosa, though sometimes classed as a Bourbon, is as much a Monthly Rose as any of the above. It is a charming double variety with neat flowers of a silvery pink colour and throws up enormous trusses of bloom. It is certainly one of the best for massing, as it also is for potting up to bloom in the winter or early spring. White China Roses are not very numerous. The best of all is Ducher. Fellenberg, although usually classed with the Noisettes, is as much a Monthly Rose as any here mentioned. Its colour is bright crimson. A really first-rate variety is Mrs. Bosanquet. This old Rose is found now in almost every garden. The pale flesh blossoms have a delightful freshness about

it is bright rich crimson, in autumn almost maroon or claret colour. They are both good for pots. These two with Cramoisi Supérieur, Armosa, Common Pink, Mme. E. Resal, and Mme. L. Messimy would be a fine selection for this purpose. I cannot conclude this short article without referring to a variety (Gruss au Toplitz) lately certificated by the Royal Horticultural Society and described in the pages of THE GARDEN.

The China Roses are excellent for hedges. Often one desires sheltered recesses for choice shrubs and half-hardy plants during their infancy. Such recesses might well be formed with Monthly Roses of the more robust type.

PHILOMEL.

THE VICTOR VERDIER GROUP.

EXCEPT as regards fragrance, of which they are lamentably deficient, this race may be considered one of the most useful the rosarian has yet produced. As sturdy free bloomers they stand unrivalled. Various conjectures have been advanced as to the origin of the type, but I believe nothing is definitely known. It was introduced by M. Lacharme in 1859, and since that date a numerous progeny has sprung from it directly by seed and sports and indirectly by cross-fertilisation. It is remarkable that much of its individuality is embodied in the offspring, such as want of fragrance, nearly smooth wood and free-flowering qualities.

Those who grow for exhibition must watch carefully when the time comes for disbudding to remove the centre bud if it shows signs of being malformed, for this defect is a distinct peculiarity of the tribe. The usual practice in disbudding is to retain the centre bud and remove the two tiny outer buds, whereas in this case the reverse is required. The colour of Victor Verdier is of a very clear shade of cherry-rose and the

China Rose Mme. Eugène Resal.

them and they are also large and double. Another good kind is Archduke Charles. The flowers open a rose colour with white edges; as they expand, however, some of them gradually change to crimson, the various colours in one truss of bloom producing a striking effect. Eugène Beauharnais is also good. In giving a selection of some good China Roses two pretty kinds cannot be omitted, albeit they have more resemblance to the Polyantha group than to the Chinas. They are, however, true Monthlies if one accepts the term as applying to real perpetual Roses. These two kinds are White Pet and Red Pet. The former in flower is an exact counterpart of the rambling Rose Félicité-Perpétue. It is, however, dwarf, and yields immense trusses of bloom. Red Pet is somewhat similar save in colour. In summer

form is globular and high-centred. The buds of many of the varieties are long and handsome. The type makes a good bedding variety where the colour is admired, but as a rule these rose-coloured Roses are the least beautiful from a colour point of view. Whilst being fairly hardy, a very sharp winter leaves its damaging marks upon the wood, so that it has to be cut back very hard the following spring. I shall not attempt to name all the varieties that compose this tribe, many having long since passed out of English lists. The most important are Etienne Levet, Countess of Oxford, Mlle. Eugénie Verdier, Mme. Bois, Suzanne Marie Rodocanachi, Mlle. Marie Finger, Hippolyte Jamain and Belle Lyonnaise.

Closely related to the type either as sports from its progeny or by cross-fertilisation we have such kinds as Captain Christy, Paul Neron, Duke of Fife, Pride of Waltham, Pride of Reigate, Mar-

guerite Boudet, La Fraicheur, and probably Queen of Queens. Perhaps the best use Victor Verdier was ever put to was when the late Mr. Bennett cross-fertilised it with *Devoniensis*, and by this means gave to the world a glorious Rose in Lady Mary Fitzwilliam, which, although a wretchedly poor grower, somewhat makes amends for by seeding freely. Some of the crosses obtained from it, such as Mme. Abel Chatenay, are, to say the least, quite robust in habit; in fact, this lovely Rose is strong enough for a pillar, and, moreover, it is very sweet, a distinct departure. Other good kinds obtained through somewhat the same channels are *Souvenir du President Carnot*, *Souvenir de Mme. E. Verdier*, *Germaine Trochon*, *White Lady*, *Antoine Rivoire*, and *Alice Furon*. That these partake of the Victor Verdier character is distinctly apparent in the huge seed-pods they will yield; the latter kind I have seen almost as large as *Nonpareil Apples*. Yet another Rose to be included in this is Mrs. W. J. Grant, reputedly a cross between Mlle. Marie Finger and *La France*. Perhaps no better tribe exists for pot culture than the one under notice, their stiff, solid flowers lasting well, and the habit of growth enables them to be exhibited upon the plant to the best advantage. A number of the kinds strike freely from cuttings, their smooth, solid wood being distinctly favourable for this purpose.

PHILOMEL.

Rose Souvenir de la Malmaison.—In his recent remarks on a memorial garden, Mr. Ewbank refers to the longevity of the above Rose as proved by the one in his own possession. I have often wondered why this good old Rose was not more generally met with. Probably the desire to possess Roses of the finest symmetry has been instrumental in banishing some of the old favourites. The largest bushes I ever saw were of *Souvenir de la Malmaison*. They grew in an old Essex garden where large quantities of cut flowers were in constant demand, and these bushes yielded quite a wealth of bloom during autumn. So far as I know, there is no other variety so floriferous at that season. The colour is very beautiful when the Roses are cut in the right stage, and arranged loosely in vases they have a very chaste and elegant appearance. If I remember rightly, the bushes in question, which must have been of considerable age, were on their own roots.—J. C.

AUGUST IN SOUTH DEVON.

THE glorious summer weather that marked July prevailed unbroken, save for an occasional local thunder-shower, until the concluding days of August. On the 25th a fresh south-westerly wind and a cloudy sky gave promise of a change, but the two following days were dry and sunny. Early in the morning of the 28th heavy rain storms occurred, but from noon the remainder of the day was bright. A strong southerly wind and drenching rain ushered in the morning of the 29th, and continued with but little intermission until night-fall, but the two remaining days of the month were fair, the bright sunshine being broken only at long intervals by brief showers. The long-expected change is doubtless near at hand, but the barometer is still high and steady, and has as yet given no warning of any alteration in the atmospheric conditions. The swifths have already left for more southern climes, but the swallows and martins are later in arranging for their departure, and had not, up to the end of the month, congregated on the housetops in their usual numbers, as they generally do in the latter days of August, essaying short flights in company ere they undertake their long migratory pilgrimage. No tint of yellow is perceptible in the foliage of the trees, as was the case in 1897 before the opening days of September, and the grass, though considerably burnt up on dry hillsides, has not assumed the universal yellow-brown tint that was so apparent during the summers of 1897 and 1898. In the early days of the month the Willow Herb was still bright in a marshy spot at the foot

of a wooded hill, and the Meadow-sweets filled the surrounding air with their fragrance. A tiny orchard in the recesses of a deep coombe, whose steep sides were clothed with woods, was literally full of Meadow-sweets, and the tall mauve-pink flower-heads of Hemp Agrimony, fringing an overgrown streamlet which meandered between the gnarled and Lichen-covered trunks of the few neglected Apple trees that remained, with their serried ranks of blossom on which peacock butterflies flaunted their many-hued spots and the great Fritillaries unfolded their orange-brown, black striped wings, ever and anon displaying the silver-green reverse as they closed their pinions, while the vermilion-banded red admirals hovered aloft or poised lightly on the bloom-tips. On some high embankments by the roadside the Fennel grows in quantity and is now in flower, its aromatic odour assuming an almost pungent character in the hot afternoon sunshine. By the river-sides the berry-clusters of the Mountain Ash make vivid spots of colour, a brilliancy that the birds do not permit to remain long in evidence, since they commence their attack on the berries immediately they ripen.

Acanthus mollis has thrown up a dozen or more tall flower-wands to a height of between 6 feet and 7 feet, and *A. spinosissimus* has produced its smaller bloom-spikes. Though the deeply-cut foliage of the latter is interesting as a change, it lacks the noble grace of the great arching leaves of *A. mollis*, whose upper ones curve outward at a height of 4 feet from the ground, while the lower leaves have a spread of over 8 feet. Other handsome foliage plants particularly decorative during the month of August are the Bamboos, of which *Thamnocalamus Falconeri* can scarcely be surpassed for grace, *Gunnera scabra* and *G. manicata* with their giant leaves seen to the best advantage by the waterside, the Plantain Lilies, the blue-green foliage of *Funkia Sieboldi* being far more attractive than that of other members of the family, *Arundo conspicua* with its slender arching, plume shafts, and the giant Reed (*A. Donax*) with its pennoned lances, while of annuals, *Ricinus Gibsoni*, *Zea variegata*, and the common Hemp (*Cannabis sativa*) are valuable owing to their grace of contour. *Achillea Ptarmica* fl.-pl. The Pearl is still blossoming bravely. In the garden and in the house this little flower, though small and inconspicuous in its individual blossoms, is by no means to be despised, since its profuse flower-heads create a snowy breadth in the border from early summer until autumn, and remain fresh for many days when used for indoor decoration. The Monkshood (*Aconitum Napellus*) has borne a second crop of tall flower-spikes, and the blue African Lily (*Agapanthus umbellatus*) has afforded a delightful picture when naturalised on a gently sloping lawn and bearing on lofty stems numerous wide-spread flower-clusters above its drooping, strap-shaped foliage. The white variety of this flower is particularly charming, but, as a rule, its bloom-umbels are smaller than those of the type. A very pale blue variety, which I brought from the Cape more than ten years ago, has also been in flower. It is in warm localities like the south-west, where these subjects can be planted out, that their beauty as garden flowers can best be appreciated, but in colder districts where this method of culture is out of the question fine effects are obtainable by growing them in tubs and large pots, which may be afforded shelter during the winter and arranged on terrace walks in the summer months. *Agathaea celestis* still bears its soft blue flowers, and *Alstroemeria aurantiaca* at the commencement of the month held its orange blossoms aloft on 4-foot-high flower-stems. A dry and almost perpendicular bank is crowned with a deep fringe of *Alyssum maritimum*, the Honey Flower, as it is often called by the villagers, which was sown along the edge of the bank four years ago, and though usually treated as an annual, has assumed a perennial habit and now forms a penthouse roof a foot and more in depth over the steep verge. Seed has fallen freely at the foot of the bank, and here another thick line of *Alyssum* is in full

flower. The past three winters have proved so mild that the plants have remained uninjured from year to year, but doubtless such a visitation as was experienced in the opening months of 1895 would effectually destroy their vitality. About mid-August the form of *Amaryllis Belladonna* known as *A. blanda* commenced to flower. Its blossoms are of the palest flesh tint, and are far more gracefully formed than those of *A. Belladonna*, the petals recurring, as in the case of *Lilium Harrisii*, instead of merely sweeping outward, as in the type. *A. blanda* has green stems, generally about 2 feet in length; whereas those of *A. Belladonna* are chocolate-coloured, and the former sometimes bears as many as fourteen flowers on a scape. I brought the original bulb from the Cape some fifteen years back, and have now a dozen full-sized bulbs. I find it quite as hardy as *A. Belladonna*, and, if anything, a freer bloomer. I also have some crosses between the two varieties, which have stems of a brownish green and petals of a colour intermediate between those of the two forms, while they are less reflexed than in the case of *A. blanda*. These usually come into bloom about a week later than *A. blanda*, but rather earlier than *A. Belladonna*. The latter expanded its first blooms before the close of the month.

Anemone japonica alba Honorine Jobert is in fine flower and is in much request for indoor decoration, its white, golden-centred flowers being models of grace and simplicity. An arrangement of these and bloom sprays of *Salvia patens* form an effective colour contrast for daylight use, but as the *Salvia*'s deep blue turns to black, or almost so, under artificial light, it is inadmissible after sundown. In good soil the Japanese Anemone makes exceptionally vigorous growth, and I measured a large plant a few days since that had attained a height of almost 6 feet. The pure white *Antirrhinum*s are amongst the most valuable of annuals, since, if they are not allowed to seed, they remain in bloom for a lengthened period. Many of the plants passed through the last winter uninjured and are now large bushes. *Antirrhinum*s will flourish in a surprisingly small amount of soil, and during the summer I noticed some plants, evidently seedlings, about 18 inches in height and blooming well, growing on an outside ledge of a greenhouse wall where about an inch of soil had lodged. Arums have been flowering profusely where planted out by the waterside, and the earliest of the Starworts to come into bloom, the beautiful *Aster Amellus bessarubicus*, expanded its first blossoms at the commencement of the month. This is one of the most satisfactory of all the Michaelmas Daisies, since it bears its large mauve, golden-centred blossoms through many weeks, and does not possess the spreading habit that renders many Starworts unsuited for borders limited in breadth. *A. Novi-Belgii* Harpur-Crewe has begun to produce its white flowers, and some of the earlier Starworts are also in bloom. The Plume Poppy (*Bocconia cordata*) has afforded a fine effect in the wild garden, having attained a height of nearly 9 feet, some of its spires of inflorescence ranging in colour from ivory-white to burnt-almond colour, being almost 3 feet in length, its large, deeply-cut, blue-green leaves, with their white reverses displayed by the passing breezes, adding a pleasing note of soft colour to the picture. The tuberous *Begonia*s have been brilliant in the extreme, and old bushes of golden *Calceolaria*, growing in light soil on sloping banks, some a yard and more in diameter, have been sheets of yellow. Of the Campanulas, the Chimney Bellflower (*C. pyramidalis*) has borne its tall flower-spikes, 6 feet and more in height, studded throughout their length with white, purple, or pale blue blossoms, while *C. cespitosa*, forms of *C. carpatica* and other dwarf-growing Campanulas have been in bloom. The large-flowered *Cannas*, with their brilliant vermilion and orange blossoms, have created gorgeous effects in gardens, while the less insistent charms of *C. Ehmanni* *iridiflora*, whose large Musa-like leaves and arching spike of cerise-pink flowers offer an effective contrast to

the more erect foliage and brighter colours of the newer race, have met with equal appreciation. Marguerite Carnations are already bright in many gardens, and *Chelone barbata* has borne its tall spikes of flower along which the pendent orange-scarlet blossoms are set at intervals of a couple of inches. *C. mexicana* is very similar in habit, but bears flowers of a pink hue, both this and the former plant being now classed under the genus *Pentstemon*. *Chrysanthemum maximum* is bearing its large white stars in profusion, but the dwarfier form, known as *C. m. grandiflorum*, which is far more compact in habit and bears larger flowers, had well-nigh concluded its period of bloom before the type commenced to expand its flowers. *Clematis Davidiana* has formed a good-sized bush studded with corymbs of pale purple flowers, and the autumn *Crocus* (*Colchicum autumnale*) has revealed the faint lilac of its fragile chalice, while *Cosmos bipinnatus* has its deeply pinnate *Nigella*-like foliage thickly set with its single white and pale pink flowers in the case of specimens raised under glass and subsequently planted out, though where seed was sown in the open ground the plants, already 5 feet in height, are showing as yet no signs of flowering.

Coreopsis grandiflora is still bearing its rich golden blossoms, and late-sown seedlings of the blue Cornflower are in good form. *Crinum capense* is flowering freely in some gardens, a dozen fully-expanded bloom-scapes in one bed producing a most ornamental effect. *C. Moorei* and *C. Powellii* are also in bloom. *Crococoma aurea* was in full beauty early in the month, its golden-orange blooms being most attractive. It thrives well in sandy soil, but, unlike the *Montbretias*, spreads considerably underground, often throwing up shoots at a distance of 2 feet or more from the main clump. *Cactus Dahlias*, although perhaps at their best during the month of September, have been decorative throughout the whole of the past month. A good three dozen are: *Alfred Vasey*, reddish crimson, shaded amber; *Arachne*, white, edged crimson; *Bridesmaid*, rose, shaded primrose; *Beauty of Arundel*, crimson-lake; *Blanche Keith*, rich yellow; *Charles Woodbridge*, bright crimson, shaded purple; *Cinderella*, claret, shaded crimson and rose; *Cycle*, ruby-red; *Daffodil*, canary-yellow; *Delicata*, pink, shading to pale yellow; *Eileen Palliser*, yellow; *Ebony*, black-maroon; *E. J. Deal*, scarlet; *Francis Humphries*, bright orange; *Fusilier*, deep salmon; *Gloriosa*, crimson-scarlet; *Harmony*, reddish bronze, shaded yellow; *Harry Stredwick*, crimson-maroon; *Island Queen*, light mauve; *J. E. Frewer*, vermilion; *John H. Roach*, soft yellow; *Keynes' White*, ivory-white; *Lady Penzance*, yellow; *Magnificent*, buff; *Matchless*, dark maroon; *Mary Service*, heliotrope, shaded yellow; *Mayor Haskins*, glowing crimson; *Miss Annie Jones*, crimson-scarlet; *Mrs. A. Beck*, salmon-red; *Mrs. Francis Fell*, white; *Mrs. Peart*, white; *Mrs. Wilson Noble*, salmon-pink; *Night*, very dark maroon; *Professor Baldwin*, orange; *Starfish*, orange-scarlet, and *Tillie*, salmon-rose, shaded mauve. Here and there a few late light blue flower-spikes of *Delphiniums* are visible, and *Dianthus Napoleon III.* was still bright with its crimson blooms at the commencement of August, while a stray golden star marked the spot where earlier in the year the *Doronicums* were a blaze of yellow. The *Globe Thistle* (*Echinops Ritro*) is bearing its spiked blue flower-spheres; the *Mexican Daisy* (*Erigeron mucronatus*) is set with a profusion of its pink and white stars; *E. speciosus*, perhaps more commonly known as *Stenactis speciosa*, is still producing its mauve yellow-centred blooms; the *Sea Hollies* (*Eryngium*), with their metallic-blue flower-bracts, have been decorative throughout the month, *E. Oliverianum* being the best of those usually met with in gardens and being very generally sold for *E. amethystinum*, the true form of which plant is rarely to be met with.

The *Coral Tree* (*Erythrina crista-galli*) has thrown up its crimson flower-spires to a height of 6 feet, some of its bloom-spikes being fully 3 feet in length. When in full flower and bearing from

one to two dozen heads of blossom it presents a gorgeous sight in the garden. As a rule the plant dies down to the ground level each winter, but I am acquainted with one specimen in the county, planted against the wall of a hothouse, which has a woody stem about 5 feet in height with a circumference of 18 inches close to the ground. *Eschscholtzias* are brilliant in roadside rockeries and in cottage gardens, where great bushes, in some cases almost trees, of *Fuchsia gracilis* and *F. Riccartoni* are in profuse bloom. The *Gaillardias' crimson* and gold still brightens the garden, and at the commencement of the month the mauve *Galega officinalis* and its white variety were smothered in flower. The *Cape Hyacinth* (*Galtonia candicans*) held aloft its tall spires of ivory-white, pendent bells, and where massed in quantity presented a chaste and gracious effect. In one garden a colony of considerably over 100 bulbs was in full flower, the purity of the white bloom-spikes, ranging in height from 2 feet to almost 6 feet, enhanced by an evergreen background, while the noble form of the wide, tapering leafage gave an artistic finish to the picture. These *Galtonias* are also exceedingly useful for arranging as cut flowers in tall vases. The *Gazanias' golden glow* is still present, and *Geum coccineum* shows here and there a spot of crimson. *Gladiolus brenchleyensis* has dowered the gardens with its vivid colour, while varieties of the *G. Childs*, *G. Lemoinei* and *G. Nanceianus* sections have displayed their tall spikes of beautiful blossoms. *Godetias* have afforded a breadth of bright colouring where the individual plants have been given room to assume their rightful dimensions, a little garden on the edge of the moor being especially remarkable for the excellence attained in the culture of these attractive flowers.

Gypsophila paniculata has spread its billowy flower-lace over the verge of the pathways, and is in constant request for furnishing indoor decoration—so much so indeed, that unless plants are grown in the spare garden for the purpose of affording cut sprays, the occupants of the borders are apt to lose much of their attractiveness before their blooming period is past. In cottage gardens the great *Sunflowers* stand with their brown discs largely patronised by the banded humble bees, a specimen or two of the primrose-petalled variety being sometimes observable among the ranks of the old-fashioned golden-flowered type. Many of the perennial *Sunflowers* are also in bloom, such as varieties of *Helianthus multiflorus* and its double form, *H. latiflorus*, and *H. rigidus* Miss Mellish. The *Heliotrope* beneath the windows perfumes the surrounding air. The *Day Lilies* (*Homocallis Kwanso* and *H. aurantiaca major*) were in bloom in the opening days of August, when the *Hollyhocks* were attractive in their robust comeliness, their tall shafts of bloom thrown into high relief by whitewashed cottage walls, and now, at the close of the month, the *Hydrangeas* are at their best, and great bushes, 7 feet high and of twice that diameter, standing on either side the wooded drives are bearing a wealth of massive blossoms almost *Forget-me-not* blue in colour. The white *Everlasting Pea* (*Lathyrus latifolius albus*) has covered the trellis with its snowy blossoms, and *Lavatera trimestris* in its three colours, pink, white and red, has been most decorative. Of *Lilies*, the handsome *L. auratum*, the scarlet *Turk's-cap* (*L. chalcedonicum*), with its vivid blossoms, *L. Harris*, *L. Humboldtii*, with orange-yellow, lake-spotted flowers, *L. speciosum album* and the deep-coloured *L. s. Melpomene*, the *Swamp Lilies* (*L. superbum*, *L. pardalinum* and *L. canadense*), and the *Tiger Lilies* (*L. tigrinum splendens* and *L. t. Fortunei*) have all been in bloom, while in a garden not far distant I was shown the most vigorous specimen of *L. nepalense* that it has ever been my lot to see, which, on a stem fully 6 feet high, was bearing three fine flowers, chrome-yellow where the petals reflexed and deep purple in the interior, and emitting a most delicate fragrance. The leafage was intact and was all of a dark green colour. In the first week of the month the green-leaved *Lobelia cardinalis* was in fine flower, while

towards its close the varieties of *L. fulgens* and *L. rosea* were at their best. In deep, moist soil *L. fulgens* attains a height of 5 feet and passes through the coldest winters uninjured in the open bed. *Lychnis chalcedonica*, *L. Haageana* and *L. diurna rosea* have flowered well into the month, and by the waterside the purple *Loosestrife* (*Lythrum*) has blossomed, while the *Torch Lilies* (*Kniphofia*), with close-set, orange-scarlet spear-heads, blaze from an evergreen setting. *Mesembryanthemums* are still bright in light soil in proximity to the sea, and the crimson *Bergamot* (*Monarda didyma*), as well as its white form and the unattractive-coloured *M. hirta*, bloomed throughout the month, as did the *Montbretias*, with their orange-scarlet flower-scapes, the latter having an extremely pretty effect when seen spangling the grass of an open wood. Late plants of *Nicotiana affinis* in the twilight hours distil their fragrance far and wide, and the tall *Evening Primrose* (*Enothera Lamarckiana*) still holds its heads of wide-spread yellow blooms, and *Oxalis floribunda rosea* is yet bright with flower. *Pan-cratiun maritimum* I saw coming into bloom in a neighbouring garden the other day. In moist and partially shaded positions the *Tufted Pansies* have flowered through the entire month, and of the *Poppies*, the apricot-buff *Papaver pilosum*, the *Iceland Poppies* (*P. nudicaule*), and the *Welsh Poppies* (*Meconopsis cambrica*), though not profusely floriferous, have borne a good sprinkling of blossoms. The *Paris Daisies* have been covered with flower, and the *Ivy-leaved Pelargoniums* have been increasingly decorative. Of these, *Mme. Crousse* and *Souvenir de Charles Turner* are two of the most acceptable in colour, and in some instances may be seen trained for a distance of many feet up a cliff-face or house wall, where they create a charming effect when in full flower. During the past month I was afforded the opportunity of inspecting a collection of seedling *Ivy-leaved Pelargoniums* raised by an amateur in the neighbourhood, and amongst them saw a very perfect scarlet of good habit, producing large trusses of double blooms that should be of great value in the garden. At present the raiser holds the whole stock in his own hands. The herbaceous *Phloxes* were very ornamental in the early days of August when growing in deep, rich soil and afforded an early summer mulching of well-rotted manure, but in poor, shallow soil these subjects are sorry spectacles in a dry summer. *Phygelis capensis* has borne its tall spikes of pendent scarlet blossoms, and the *Winter Cherry* (*Physalis Alkekengi*) and its newer and larger form, *P. Franchetti*, are already showing colour in their calyces. *Plumbago capensis*, a large plant of which has lived in the open for several winters against a cliff-side sheltered from the north and east, is covered with its pale blue flower-clusters, while in the rockwork *P. Larpentæ* is bearing its blossoms of a deeper blue. *Polygonum capitatum* and *P. vacciniifolium* have been in bloom, and towards the end of the month *Pyrethrum uliginosum* expanded the first of its narrow-rayed, white star flowers. The old double white *Rocket*s were in bloom early in August, and *Rudbeckia Newmanii* and *R. purpurea* came into flower before the month was many days old. A fair sprinkling of *Tea* and *China Roses* have been available throughout the month, and the single white *Macartney Rose* has daily expanded a fresh instalment of fair blossoms. The *Salpiglossis* in its varied shot-silk hues has nobly sustained its position as one of the most decorative of our garden annuals, and the deep *Gentian-blue* of *Salvia patens*, so telling when employed in masses, has again proved so valuable as to justify the making of an exception in the case of this plant by utilising in the herbaceous border a subject that stands in need of winter removal and shelter. *S. coccinea* and *S. fulgens* are both in flower, and have passed through the last three winters unscathed. Late seedlings of *Scabiosa caucasica* are in flower, and the bloom-clusters of *Sedum Sieboldii* are gathering colour, while *Senecio pulcher* and the *Golden Rod* (*Solidago ambigua*) are in bloom, and *Statice latifolia* is bearing its branching

flower-sprays of minute lavender blossoms. In a sheltered spot *Sparmannia africana* is blooming, and late-sown Sweet Peas are still bright with flower. The *Tigridias* have made a gorgeous display with their great Orchid-like blossoms of scarlet, rose, yellow, and white, marvellously mottled at the bases of their petals, whose splendour seemed a fitting sequel to the tropical effulgence of the sunshine. *Tradescantia virginica* still produces its blooms of violet or white, and brilliant effects are created by beds of *Verbenas* and scarlet *Zinnias*. Some of the *Yuccas* have also commenced to blossom, and *Zauschneria californica* is becoming scarlet with flower.

S. W. F.

KITCHEN GARDEN.

EARLY TOMATOES.

FOR some years I relied upon cuttings struck in September for the early supplies, but at times the plants failed, as with dull weather and fogs I found the rooted cuttings wintered badly, no matter what variety was grown. Of late years I have obtained much better results by growing from seed sown now or earlier. I am not in favour of sowing too early, as a large plant is not necessary. It is somewhat late for sowing, but there is ample time if two or three seeds are put into a pot and when well above the soil the weaker seedlings removed, leaving only the strongest. This is a great saving of time, as the potting-off out of seed-pans gives a check. Provided there is ample time, I like to grow my plants in cold frames from the start. There is no harm done in starting the seed in a warm place, removing to a cold frame near the glass. When ready to be potted off into 6-inch pots, the sashes may be left off the plants at night; they will benefit by the night dews. In potting up at the start I would advise a liberal compost, as growth must be made in a short time. Bone-meal mixed with good loam and some wood ashes is an excellent compost, as this favours root-action and a short-jointed growth. After potting it is necessary to keep the plants close for a few days. Fruit is not wanted before the new year, as though a few will set at the base of the plants during October, they will not make much progress. These fruits will be acceptable the next spring, as when the plants are planted out or potted into their fruiting pots early in the new year they will swell and mature quickly. Six-inch pots will be large enough to winter the plants in, but there is no gain in crippling them, and I do not hesitate to give a small shift in October if the plants need it. The plants are removed from the cold frames at the end of October or early in November and placed on shelves near the glass, and all the ventilation given in favourable weather. Here they will be forming their trusses, and, though sturdy, they will be much superior to plants from cuttings. Early in January they are placed in their fruiting quarters. I both plant out and grow in pots. From pot plants I get the earliest fruits, but those planted out yield the heaviest crop. I have one house of each. The pits are low structures and hold two dozen plants at the front of the house. They are trained up the rafter within 9 inches of the glass. It is necessary to set the flowers early in the year. I advise a low night temperature—not more than 60°—with plenty of air in fine weather. In planting out very little soil is needed, as I top-dress after the first fruits that form in the new year begin to swell. Early kinds such as *Conqueror*, *Conference*, or a good selection of the *Old Red* set better than the large smooth-fruited kinds.

G. WYTHES.

Pea Autocrat.—Besides being one of the finest flavoured Peas in existence, this variety has the merit of flowering and bearing continuously, as pods are produced quite low down on the haulm as well as higher up. The colour when cooked is a very bright green, and, taking all its good points into consideration, I am very doubt-

ful if there is such another in cultivation. If there is, I should like to hear of it. Not only is it useful for late work, but sown in March it gives grand gatherings in July and early in August. I like it better every season, and have largely increased the quantity sown this year.

Thinning autumn-sown Onions.—Where several sowings of Tripoli Onions are made, the earliest lot of such varieties as *The Queen*, *White Lisbon* and *Leviathan*, the latter the largest of the white section, will soon be ready for partial thinning. The sooner this is performed when once the seedlings are large enough the better. Some gardeners wisely sow a row or two extra for use in the salad bowl, as then the main batch can be thinned to an inch apart at the second and final autumn thinning. If the ground is dry and hard a good soaking of water should be given the day previous, and, although by no means a common practice, I have found mulching between the rows even at this early date an excellent practice. Moisture, either from rains or artificial waterings, is thus retained, and the plants become sufficiently sturdy to withstand a sharp winter. A gross growth is undesirable, as frost soon cripples it, and on that account those who make several sowings, and if possible in different positions, reap the benefit of the extra labour incurred by preserving at least one batch. Especially is this so where the ground is rich. Give another moderate broadcast sprinkling of soot, and afterwards use the Dutch hoe to work it in beneath the surface.

—N.

Storing Onions.—If any Tripoli Onions, intended either for cooking or for seed, are still lying exposed on the open ground, let them be removed to a dry, cool store at once, as they lose much of their solidity and quality by too long exposure to wind and sun. In southern localities the earliest lots of spring-sown Onions will soon be fit for harvesting. Where the quantity is not large it is a good plan to place the bulbs in large flat hampers, which allow of their being easily removed under cover in case of rain. When allowed to remain on the plot until stored, the bulbs should be moved occasionally. My plan is first of all to throw the bulbs from one half the plot on to the other, then clean off all weeds, afterwards serving the other half in a similar manner, and finally spreading the Onions equally over the whole area. This is far better than leaving them among weeds and rubbish, which hold the dew and moisture, preventing a free circulation of sun and air among the bulbs. Any thick-necked or otherwise deformed bulbs must be stored separately to be used quickly. When stored, the best shaped bulbs, if wanted for seed, should be strung on ropes in the old-fashioned way and suspended from the roof of a cool, dry shed or out-house, a little frost being beneficial rather than otherwise.—B.

Carrots.—I regret to observe so much encouragement given to very long Carrots at vegetable shows. But the other day at the great show at the Crystal Palace the well-known Long Surrey, but, of course, under some other appellation, roots fully 18 inches to 20 inches long, because they had such long, thin, and utterly useless tails, had classes to themselves and were awarded prizes in proportion to their length apparently. I find such classes elsewhere, and think they are very undesirable. These very long Carrots are very wasteful, because so large a portion of the roots are uneatable. What good results from encouraging the growth of such things? In the same way Parsnips are more regarded for inordinate length of tail than for fleshiness of shoulder, the very best portion of the root. When we have in Carrots such superb fleshy roots as are furnished by *Nantes*, *Favourite*, *Champion*, and *Intermediate*, roots if not coarsely grown that are all soft succulent flesh, why favour long woody roots that are not one half so good? Some of what are described as *Improved Intermediate* stocks are too large. They have been grown on yearly from the largest, though doubtless handsome roots. But no large Carrots are so good for table as are smaller ones. No doubt cut up small

they do very well for flavouring soups or the stock-pot, but no gardener would send his largest roots to his employer's table. He knows that no Carrots are so much appreciated as those comparatively small and quite young. Hence the most delicious roots of all are the early Short-horns pulled small and cooked whole, also in the winter smallish roots from a July sowing of some one of the blunt-rooted or *Intermediate* varieties. There is yet much room for Carrot improvement, both as an exhibition and an edible product. We want in the stocks not so much of size, but more refinement, bright, clear, rich colour, perfect smoothness, and very soft, succulent flesh. These are points that in judging need to be emphasised.

GARDEN FLORA.

PLATE 1240.

TWO DUTCH DAFFODILS.

(WITH A COLOURED PLATE OF N. MME. DE GRAAFF AND N. APRICOT.*)

THE two Daffodils represented in the coloured plate are both very remarkable in different ways, and were originally raised from seed at Leyden, Holland, in the well-known bulb nurseries of M. de Graaff, as also was the great yellow Glory of Leyden and many other good kinds. I happened to be at Leyden in April, 1883, when the first bloom of Mme. de Graaff opened, and saw at once that it marked an epoch in the seedling history of white Daffodils, and I believe that even to-day there is nothing quite so chaste and shapely in the white-flowered section to which it belongs. Its size and the peculiar rolled-back margin of the pale sulphur trumpet are well shown in the illustration. To my mind, it is in purity and in form a point or two ahead of *Weardale Perfection*, though not quite so large as is that variety. N. Mme. de Graaff and *Glory of Leyden* were originally offered at £7 10s. the pair, i.e., one bulb of each, and most of those who bought at that price found the investment a profitable one, both being good growers and the present-day prices being remunerative. Mme. de Graaff has appeared in most of the winning stands at the *Narcissus* shows of the past ten years or so and has been certificated by the Royal Horticultural Society's *Narcissus* committee and also at Birmingham. Its exact parentage is unknown, but from its characters one may assume that it came from *N. albicans* (*Dutch moschatus*) and some one of the bicolor forms.

The second variety on the plate, *N. Apricot*, is of more recent origin, having attracted public notice only in 1898 when exhibited for the first time. It is most remarkable for the peculiar coloration of its trumpet, and it is thought may ultimately prove to be the forerunner of a new section of Daffodils having more or less red in the corona. An old white variety called *Mrs. Thompson* sometimes shows a trace of colour in this way, and even old flowers of the wild *N. moschatus* of the Pyrenees now and then die off with pale rosy trumpets. The Rev. G. H. Engleheart has raised seedlings, especially in the *Leeds* or *Incomparable* sections, which possess exquisite rosy salmon or apricot shades in their cups, but this seedling of M. de Graaff's is, so far as I know, the first seedling Daffodil in which the tendency to a suffusion of red in the trumpet is absolute certainty. In size and form *Apricot* is behind many other older kinds, but it will always be looked upon as the first real advance towards the red

* Drawn for THE GARDEN by H. G. Moon from flowers sent by M. de Graaff, Leyden, Holland. Lithographed and printed by J. L. Goffart.

trumpeted Daffodils that have often been predicted as future possibilities.

F. W. BURRIDGE.

BELLADONNA LILY AND PERUVIAN SWAMP LILY.

THE charming picture herewith gives a phase of gardening at once among the most beautiful, if the least frequently seen. It is, however, so simple in itself and so easy of imitation, that such displays, instead of being regarded as somewhat rare, should be of the most frequent occurrence in those gardens where hardy subjects find a more or less congenial home. Narrow borders, as shown in the picture, are frequent in gardens, and especially so, as in the present instance, where greenhouses are devoted to the cultivation of tropical or sub-tropical plants. In certain instances the latter, therefore, call into existence in some gardens not a few plants whose perfect hardness in times of severe frost is open to doubt. But even without the latter there is scarcely a garden worthy the name in which a suitable position for the plants indicated could not be found. The base of a wall having a south aspect will be the main thing that is required from a cultural point of view and so far as position alone is concerned. It is, however, a point in its favour when such a position may be found within the limits of the flower garden. This will save such beautiful subjects being relegated to the vicinity of the kitchen garden, a position where at flowering time they would be much less seen. The leafless character of the Belladonna Lily at flowering time may from an artistic point of view be in the nature of a drawback when it is planted entirely alone. In the present instance, however, we see a good deal in a small space. A narrow border, less than 2 feet wide, it yet contains a couple of very beautiful hardy flowering bulbous plants, each of which is exactly suited to the environment of the other. It is an excellent object-lesson on the one hand, while it also displays a *multum in parvo* style of gardening on the other. Surely it was no haphazard idea that caused so pretty and so useful a foil to the leafless stems of the taller Amaryllid to be planted in the foreground. The result is an extremely pretty one. The value of such an arrangement is enhanced by the manner in which the wall is furnished. In all this the value of these beautiful illustrations is apparent, displaying as they do in detail what is either impossible or all too inadequately expressed in words. Of the plants themselves a few remarks will suffice. The Belladonna Lily is without doubt one of the most handsome of hardy bulbs, while its freedom to flower when the bulbs have become established is almost proverbial. Once planted, this handsome subject is best when left entirely alone. This is not merely true of it for a year or two, but for a dozen years, provided the position be a good one and the bulbs thoroughly well planted in the first instance. Old plantations will, however, be greatly benefited by a mulch of decayed manure each year. This is best given immediately on the decay of the flower-stems, the object being to strengthen the ensuing growth. Select a warm, sunny position at the foot of a south wall, and clear out the

original soil for at least 2 feet deep. This is best done in a deep, wide trench, and one 18 inches wide will be ample. How much or how little preparation of the soil is needed will largely depend on the condition and quality of the original soil. What is preferred by the bulbs intended for planting is a good sandy loam to which plenty of decayed leaf-soil and some well-decomposed manure may be added. Where a sandy soil naturally exists, the addition of leaf-soil and river grit or mortar rubbish will suffice, at the same time enriching the whole. Where clay soil is the staple, it may be advisable to descend 6 inches deeper in the trench with a view of inserting ample drainage, this to be covered with rough turf and made firm. Briefly, with plenty of good sandy, holding loam and rotten cow manure, these things may be grown to perfection. In making a new border for such things, it will be found best to give an advance order for the bulbs, as it is not usual for bulb dealers to lay in large supplies unless previously ordered. Where good dry roots are obtainable, such may be planted over a somewhat extended season. The safest time, however, is with the decay of the foliage, and a special order to this effect will secure the bulbs for planting within reasonable limits. Bulbs of these things may sometimes be seen in the dry state—too dry, unfortunately—so late as December

frequently, however, the position and soil afforded are too dry for their requirements, and a decidedly moister and heavier soil would give better results. In very sandy soils these are not always a success, but in rather heavy loam or clayey loam are more successful. For forming edgings these are well suited, and the former in conjunction with the lovely Belladonna Lily makes a very delightful picture in any garden. The pretty group in the photograph was for a long time an attraction in the Royal Gardens, Kew, during the autumn of 1898. A very congenial home, judging by the results attained, has been found for these handsome late summer and autumn flowers beside the wall of the Orchid house. The profusion of spikes from some of the larger bulbs, the offsets of which have now obviously increased to flowering size, is remarkable.

E. J.

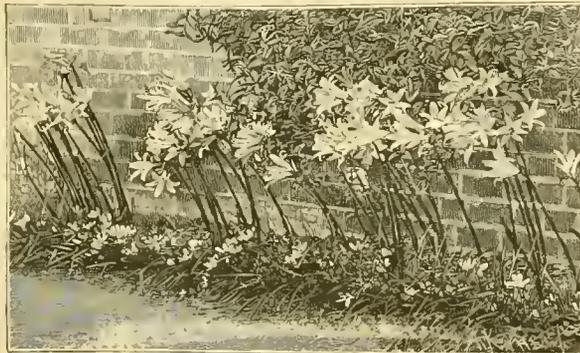

THE WEEK'S WORK.

KITCHEN GARDEN.

PLANTS IN FRAMES.—Success or otherwise in frame culture largely depends on the way in which the beds are prepared for their reception in October. When either Cauliflowers, Cabbage, or Lettuce are planted in light soil of considerable depth, lifting is invariably attended with much ball-breaking, many of the most useful fibres being destroyed, the check occasioned ending in premature hearting in or running to seed. The best way is to place a shallow frame on quite a hard bottom of coal ashes, covering this with a layer of rotten manure, and finally laying on from 6 inches to 8 inches of loamy compost, making it firm when in a semi-dry condition. From such quarters the plants if not too thickly planted will lift with good balls, a portion of the underlying manure clinging to them. The frames being ready, leave the lights off day and night to get the soil well moistened. Previous to planting make all very firm. This early preparation for frame plants is advantageous, as when they are pricked out into a newly-made loose root-run a greater check is given than when such is firm and settled by a week or two's standing.

EARLY PEA BORDERS.—It may seem full early to speak of these yet, but as in all large gardens work is always too plentiful after frost sets in, it is well to take advantage of a slack period to prepare any early borders—at least where Peas are sown in November. If these borders have not a natural fall towards the pathway, success in early Pea culture will be made more certain by adding friable soil to such quantities as will not only produce that, but secure also perfect drainage. Burnt refuse, potting-shed refuse, and the sweepings of walks are all suitable for the purpose.

WINTER CUCUMBERS.—If former directions have been carried out, plants for winter fruiting will now be fit for planting out. Providing the house has been well cleansed, no fear need be entertained of attacks from red spider—at any rate before the plants become well established. If the house is well furnished with hot-water pipes, all that will be needed is to three parts fill the bed or pit with good sound leaves, firm them well, and surmounting them with mounds composed of good fibrous loam, rather light in texture than otherwise, a free addition of fresh horse droppings, and some old mortar rubble, the latter securing a free escape of superfluous water from the roots. Do not place manure beneath the roots at this season. Small mounds will suffice to start with, as these can be easily enlarged as the plants increase in growth and emit new fibrous roots. Place a neat stick to each and water home, preserving a rather close atmosphere for a time and syringing the foliage twice daily in sunny weather, closing the house at 2 p.m. and well damping walls and pathways. Where evaporating pans exist it is a good plan to fill them with diluted

Belladonna Lily and Zephyranthes in a warm border at Kew.

and January, and because of the large size are regarded as fine. If put to the test, however, it is highly probable such bulbs, compared with the time when lifted, would be greatly diminished in weight. In the former month the established roots are breaking into leaf, and with a mild season make good headway in the early part of the year. When occasion arises, these bulbs may be transplanted from established quarters in June or early in July. Firm planting is always necessary, and equally so rather deep planting, that is, keeping the entire bulb below the surface. In seasons of great heat and drought a thorough deluging of water may be given the first week in August just before the flowering spikes break the soil. The other plant shown in the front of the picture, *Zephyranthes candida* (Peruvian Swamp Lily), otherwise known as *Amaryllis candida*, is a native of Buenos Ayres. This is an evergreen species, or nearly so, the pretty white Crocus-like blossoms appearing in plenty during the early autumn months. A closely-allied species is the *Atamasco Lily* (*Z. Atamasco*). This flowers in spring, and has somewhat channelled leaves, while *Z. candida* has decidedly flat surfaces to its leaves, the latter also very polished and smooth. Both kinds increase rapidly by offsets. Too

farmyard liquid manure, the ammonia arising from this not only assisting growth, but acting as a check to red spider. The laterals which form between the bed and the lowermost wire of the trellis must be pinched back to the second leaf.

JANUARY FRUITERS.—Seed may now be sown where house-room is at command for a successional batch of plants for fruiting during January and February. Sion House, Telegraph, and Cardiff Castle are all good sorts, and as soon as the young seedlings appear raise the pots well up to the roof-glass and in a position free from draught. Use great care in watering, as the base of the stems sometimes cankers at the time of year.

TOMATOES FOR WINTER.—Where these have been growing in frames or pits, removal to comfortable quarters must now take place. This is necessary not only to hasten on the crop, but to ward off mildew, which is apt to come on as the nights get cooler. Where 6-inch pots have become well filled with roots, a shift must now be given into the fruiting size, the most suitable being those 10 inches in diameter. Drain them well and add plenty of opening material to the soil, pot firmly and give the plants a position near to the glass. Supply atmospheric moisture by means of sprinkled floors and walls, rather than by overhead syringings, and give air liberally, avoiding front air after the end of October, as this is liable to produce mildew. Use clear water only until the crop is set, except in the case of any weakly plants, which may have a little assistance two or three times a week. Remove all side growths and train on the one-rod system. J. C.

FRUITS UNDER GLASS.

LATE GRAPES.—With me there has been a perfect plague of bluebottle flies, which together with wasps are calculated to do a great deal of damage to hanging Grapes and have to be circumvented in some manner. I do not find that the wasp destroyers sold have any effect on the flies, and I have had to go to the old-fashioned plan of hanging wide-mouthed bottles partially filled with beer and sugar among the Vines. In this way I have trapped many hundreds, but there has been no very appreciable lessening of the number that infest the houses, and we shall probably have to wait for colder weather to clear them off, the only available way of preventing them being to cover the ventilators and all openings with hexagon netting, which is effective, except in houses where the glass does not fit close at the laps. As a note of warning, I may say that at one end of a long range of vineries the outer walls are covered with Ivy, and it is in the houses at this end that we are most pestered with the flies; indeed, at the other end there are very few indeed. The great attraction which Ivy has for flies at this time of the year should prevent any being planted near the fruit houses. Some years ago I had a similar trouble in a place where the Muscat house was only separated from an Ivy hedge by a narrow walk, and during the autumn we had a great deal of trouble to save the Grapes. Covering the ventilators with netting is an evil, as it prevents the free circulation of air so necessary to prevent damping, but it is greatly to be preferred to the system of enclosing each bunch in a muslin bag, as one has the bunches directly under one's eye and anything wrong with the berries can be easily detected, while there is also the advantage of preserving the bloom on the Grapes, which bagging tends to destroy. For the present it will be necessary to try and preserve the driest possible atmosphere about the Grapes without much use of fire-heat (except in the case of any Grapes not yet ripened), and all damping down or swilling out of the houses should be entirely suspended, a dry brush through daily being sufficient to preserve tidiness. Dropped leaves should be removed daily and a few of those turning yellow may be taken off, leaving the stems to drop; a final look over, too, should be given to remove any sub-lateral growth, as any of this would be superfluous now, and would attract and hold condensed moisture where the

Vines are thick. All hanging Grapes should be carefully looked over for bad berries twice a week at least, and this is specially important where the pests alluded to above have managed to establish a footing, as one injured berry left on for a few days will spread decay to three or four others and create a disfiguring gap in the bunch.

EARLIER HOUSES.—As these are cleared of fruit they should have the ventilators thrown wide open and left open day and night, a free circulation of air being conducive to ripening the canes in a natural manner, preserving a healthy tone in the Vines. A splendid opportunity is afforded of helping the winter cleaning by heavily hosing or syringing the Vines frequently now, say once a week. Hot water, up to 120°, in which a little soft soap has been dissolved is one of the finest things that can be used, and will dislodge if not kill bugs and many other insects. Those who depend on a winter dressing alone generally get their Vines pestered with insects before they have done their season's work, and this is only natural, for the insects or their spawn find secure resting-places in various crevices long before winter comes on, and it is then difficult if not impossible to reach them. Now as they spend their time in more open quarters from which there is no difficulty in dislodging them, the chances are all in favour of destroying them entirely by removing later on an inch or so of the surface of the border on which they will have dropped. The autumn is by far the best time too to renew any borders that may require it, and where the houses are not to be used for storing Chrysanthemums, the sooner the work is taken in hand the better it will be, but I should prefer leaving it until the Chrysanthemums are over rather than to stand these on a new-made border. Cut flowers are such an important item now-a-days, that one has to sacrifice some of one's most cherished tenets in order to meet the present demands. Those who are in the fortunate position of having plenty of room for plants, without encroaching on the vineries, should commence at once the renewal of borders. The quality of soil used should govern the amount of porous material, but in no case should the latter be so limited as to prevent a quick drainage of the border after watering, as the possibility of frequent waterings during the growing season goes a long way to produce high quality fruits, and where the soil is very heavy in itself, and not well lightened, frequent waterings are impossible. In relaying the roots every endeavour should be made to render the soil about them very firm; this requires care to prevent injury to the roots themselves, but is imperative for the formation of wood of the right sort. Loose and rich borders are frequently responsible for over-grossness and softness of the wood, and such wood can never be satisfactory.

PINES.—Cooler nights and less sunshine now to be expected will necessitate a sharp look out being kept to see that both bottom and top heat are well kept up. The laxity of the summer months is often continued too long, with the result that plants get chilled and the roots inactive, a state from which it is difficult to move them. Early closing of the houses and husbanding the sun-heat will do much good, but, the nights being longer, too much dependence must not be placed on this, and it is, of course, useless as regards any action on the roots which must be kept warm by other means, either by fire-heat—by far the best method—or by fermenting material. The latter gives a good deal of trouble, and Pine-growing under such circumstances is not by any means pleasant work, for one must be always on the watch and ready to add fresh tan to the beds whenever there are indications of a lowered temperature. With young stock growing in pits that can only be worked by lifting off the lights, favourable opportunities when the weather is warm and fine must be chosen for such renewals. Continue to give manure water to plants swelling off their fruits, and clear soot water to younger stock when water is needed, but the water-pot must now be used with increased caution, as the plants will not

assimilate so much water as they have been taking during the summer; plants carrying fruits which are changing colour should now be allowed to get quite dry.

POT STRAWBERRIES.—By this time early layered plants potted up when advised should have filled or almost filled their pots with roots, and where this is the case, the crowns will be strengthened by feeding with manure water given alternately with clear soot water for the next month or five weeks. I do not advise this except in the case of well-rooted plants, for giving manure water to soil that is not well filled with roots does more harm than good by turning it sour. If the plants have grown so that they overlap each other, they should be stowed further apart at once, as crowding is bad for them, and I always set mine out at a good distance from each other directly they have got over the check of potting, so that no further moving, except to prevent rooting through, is needed until plunging time comes.

CORNUBIAN.

FRUIT AND VEGETABLE CROPS.

EASTERN.

Abney House, Bourne End.—Wall fruit very scarce; all the choice kinds, such as Apricots, Peaches, Nectarines, and Figs, quite a failure. Bush fruit in enclosed gardens is good, but in the open market gardens only half a crop, owing to the late spring frosts. Strawberries are a fair crop, but soon over owing to the excessive heat; Pears about half a crop; Cherries very plentiful; Apples a full crop.

Vegetables on the whole are very good considering the late spell of drought. Late Potatoes look very promising. Early Peas have been very fine, especially Early Giant, which is the best early Pea I have ever grown. Later varieties in some gardens are suffering from an attack of thrips.—J. G. GOODMAN.

Coldham Hall, Bury St. Edmunds.—The Apple and Pear crops in this garden are decidedly bad. I have never had so short a supply, and in a great measure I attribute this to the hot, dry autumn. Unless abundant rain falls when the trees are perfecting their growth and fruit buds, the latter are never properly developed, and I anticipated this state of things during the dry period complained of. Again, I never knew sparrows to attack fruit blossoms so persistently as during the present spring. Cherry and Pear trees were almost cleared of the buds where not netted, and this, of course, has made matters worse. The late frosts entirely spoiled the flowers on all the wall trees except one old Nectarine growing on the house. A few of the Codlin type of Apples will bear a small quantity of fruit, Hawthornden, Irish Peach, and a few more young trees have some fine promising fruit upon them, but out of some hundred or so of young, healthy trees there will not be a bushel of fruit. In some neighbouring gardens it is not quite so bad, but the crop, I fear, is a very long way below the average. Of Cherries, May Duke and Elton are the best. Strawberries have been a very fine crop and extended over a fairly long season. Every year increases my good opinion of that fine late variety Dr. Hogg, and I could now (July 20) gather dishes fit for exhibition. Latest of All is also fine, but the flavour is not nearly so good as that of Dr. Hogg. It has ripened to the points much better than usual. Royal Sovereign, Monarch, and Leader have been badly attacked by insects. Raspberries are an excellent crop; Currants distinctly good; and Gooseberries, perhaps, the finest crop of the year. I have never had such splendid berries of the large richly flavoured kinds, which are ripening fast now. Under glass, crops, on the whole, are very favourable, but a bad attack of bud-dropping in the early Peach house thinned the crop on Waterloo and one or two others. The second early varieties are just getting over and have been magnificent. Early Rivers Nectarine

amply deserves the great praise that has been bestowed upon it, and has proved itself a boon to those who require choice fruit in abundance. Grapes have been and are very good, young Vines planted last season having produced splendid crops. Melons are not doing so well as usual.

Vegetables are on the whole very good indeed. The cold spring delayed early gatherings of small crops, and, followed by a short and sharp period of drought, checked the early crops of Peas. Afterwards rain fell in plenty, and the second early and midseason crops were excellent. Late rows look very well. Potatoes have been very good up till now, but disease has necessitated lifting several kinds rather before their time. Late Potatoes were looking well, but the tropical weather of the last few weeks will probably cause the field crop to be small. There is yet time to save them if rain comes, but the sky is like brass and so is the soil, the heat being almost unbearable. Luckily, I was able to get the winter greens of various kinds planted early and they have never looked back; now they also want rain badly. Onions, Parsnips, Carrots and Beet were never better, and salads of all kinds have been abundant and good. The autumn-sown Onions have been very much better than usual this year, not a single plant having bolted out of many hundreds. No difference can be noticed in the rows that were transplanted and those that were thinned in the seed drills.—H. R. RICHARDS.

MIDLAND.

Alton Towers, Stoke-on-Trent.—The fruit crop is very satisfactory in this district. Most kinds set well, and there is every appearance of a heavy crop. Apples are very plentiful and are swelling fast. The best cropped varieties are Lord Suffield, Lord Grosvenor, Ecklinville, Bramley's Seedling, Stirling Castle, Grenadier, Ribston, and King of the Pippins. Pears are rather patchy, the best being Marie Louise, Glou Morceau, and Louise Bonne of Jersey. Small fruits are good, Strawberries exceptionally so. Royal Sovereign was excellent, carrying an enormous crop of large fruit of first-class quality. Cherries are better than they have been for some years. Some varieties of Plums are very fair on walls, while bush and orchard trees are quite a failure. Damsons vary, some trees bearing well, and others just a sprinkling or none at all. Nuts are very scarce about here.

Vegetable crops are fairly good on the whole, but early Potatoes are very late and small in this district, owing to the drought we experienced in June, and the check given them has in many instances caused the young tubers to sprout when the rain came; this is especially so in light and shallow soils.—E. GILMAN.

Bradgate Park, Leicester.—Apples, Pears, and all stone fruits are very light and below the average. Bush fruits are good. Strawberries are neither so good nor so heavy a crop as last year, but the fruit is finer and of good flavour and later.

The vegetable crops are very good, and have much improved since the recent rain.—G. H. PARRATT.

Barkby Hall, near Leicester.—Most kinds of fruit are scarce in this neighbourhood, owing to sharp frosts at the time of blossoming. We had 11° of frost, which also killed most of the young Gooseberries which were not sheltered by top fruit trees. Apples are very scarce. Trees on high ground in exposed positions have good crops in some cases, while those in low-lying places and somewhat sheltered have very light crops. Pears are almost a failure. We have a fair crop on the walls, which were all covered with three thicknesses of fish-netting, but a great number of the blooms were destroyed. Plums are also a failure on standard trees. Those on walls have a fair crop here. Apricots are very light. Those that were close to the wall were saved. Peaches are almost a failure: Cherries a good average crop. I cannot account for these escaping so well.

Gooseberries are very light in the open, but good under trees. Currants did not suffer quite so much as Gooseberries. There is a fair crop of Red, but Black Currants are very light. Raspberries are a good crop, although the first blooms were destroyed. Of Strawberries the crop was only moderate. Royal Sovereign, being early, suffered more than the later ones. Latest of All was not in flower, and the crop has been heavy and good.

Potatoes were all cut down by the frost and the tubers are small. Early Cabbages did not run to seed so much as usual and were good. Onions and Carrots are good. Peas have not done quite so well.—J. LANSDALE.

Causton Hall, Burton-on-Trent.—Fruit crops in this garden and neighbourhood, if not up to some of the best seasons, are generally good. Apples in following varieties on standard trees are a full crop: Alfriston, Blenheim Pippin, Golden Noble, Maltster, Domino, Gravenstein, Lord Suffield, Greenup's Pippin, Lane's Prince Albert, Irish Peach, Worcester Pearmain, and King of the Pippins. Bush trees, of which we have many, are indifferent. Only Potts' Seedling, Grenadier, Bismarck, Beauty of Bath, and Stirling Castle carry full crops. Pears are a failure, Beurré Diel being the only variety having anything like a crop. We have some fine bush trees which invariably carry grand crops. Plums and Damsons are a partial failure; the same applies to Peaches. The latter are clean, and have been no trouble compared with other seasons. Apricots are about half a crop. Currants, Gooseberries, Raspberries, and Strawberries are all good and abundant. Royal Sovereign, I think, is the best Strawberry sent out for years, and ranks with President for usefulness. Dr. Hogg from one-year-old plants is generally very fine here. There are few good orchards in this neighbourhood. Apples and Pears (the latter poorly represented) are carrying good crops; old trees of Blenheim are carrying by far the best crops.

The dry weather has checked all vegetable crops. Potatoes, I think, will yield fairly well. The rains in May and June were a great help, but the excessive heat has entirely dried up the moisture, and on light soils the tubers will be under-sized, but should, owing to rains coming later, be better than last year. There were many diseased tubers in early sorts. I have found none, however, in lifting a patch of Windsor Castle.—W. J. NOVELL.

Shipley Hall, Derby.—This is far from a good district for outdoor fruits, and the report from the neighbourhood must be a meagre one. In the orchards Apples are cropping very irregularly, more than half the trees being barren and only a few have a heavy crop, the individual fruits promising to be but small. On espaliers in the garden things are better; one or two early varieties, such as Lord Suffield and Warner's King, are heavily cropped and the fruits fine. Pears, on the other hand, are best on orchard trees and very scarce on wall trees, but I do not imagine that the former will come up well, though growth is free and the trees healthy, but we lie too long in the lap of winter to expect good dessert Pears in the orchard. Neither Apricots, Peaches nor Nectarines are grown outside here. Plums and Damsons are but a poor crop, the scarcity being due to spring frosts, I imagine. Cherries, too, are very poor. Currants, Black and Red, are a good crop. Gooseberries grown in the open as bushes lost many fruits through frost, but cordon-trained trees under a wire protection are heavily cropped and promise very well. Medlars are a fair crop. Raspberries are the best crop of the year, and canes which have been treated to good soakings of manure water have borne fine fruits, which the dry weather now being experienced has allowed us to gather in good condition. Strawberries on young plants have been very good, Royal Sovereign and James Veitch both very fine. On older plants the fruits have been small, but plentiful, and Vicomtesse H. de Thury has provided excellent fruits for preserving.

Filberts are very scarce, but Walnuts are really well cropped in the district. Blackberries promise remarkably well and apparently grow well here, especially the Parsley-leaved.

Potatoes are very irregular in the fields. Other vegetables are good, Peas especially so. Brassicas are now growing well, but it was the worst seed-raising season I ever knew, the ground cold, deluged with heavy rain, and not a glimpse of sunshine through May until quite the end of the month, so that things started very slowly indeed. The earliest-sown Beet and Turnips bolted badly, but later sowings are better.—J. C. TALLACK.

The Gardens, Chatsworth.—Apples are only a moderate crop; Pears and Plums scarce; Cherries an average crop; Red and White Currants an average crop; Strawberries good crop and fine fruit; Raspberries and Black Currants moderate; Gooseberries under average.

Potatoes are a good crop, and no diseased ones at present. All kinds of vegetables are growing freely.—W. CHESTER.

ORCHARD AND FRUIT GARDEN.

NOTES ON STRAWBERRIES.

THERE seems very great unanimity among growers as to the shortness of the supply of Strawberries this season. "H. R." Suffolk, complains of slugs and of another enemy that takes the seeds from the surface of the fruit. Unless by mice, I have never had seeds eaten off the fruit in the manner described, so that there must be a new enemy in the field. Mice, unless promptly trapped, will quickly spoil a quantity of Strawberries by simply eating off the seeds, this rendering the fruiting useless for any purpose. Slugs are not alike troublesome every year; in some, particularly in wet summers, they are very numerous and destructive; in dry ones they are not so much in evidence. Millipedes, of which there is one kind very partial to Strawberries, are common in any kind of weather when the fruit is ripening. I quite agree with "H. R." that the kind of mulching or the time of its application makes no difference to slug interference. I cannot quite agree with "H. R." that "the longer the ground between the rows lies open the better, as the moisture caused by the litter is an attraction to slugs." In soils of medium or light tendencies there is a difficulty in keeping the plants growing, and even with mulching applied, the drought this season was so searching, that many crops either succumbed or had a very short existence. The mulching of Strawberries in such land requires to be done for a two-fold purpose if any useful return is expected. In heavy soil the case is different. Applied early it arrests evaporation and retains moisture for a period when the plants require more to sustain them, and are often supplied with less, at any rate, from natural sources. Grass, whether long or short, is very bad as a mulch. Both rot quickly, and the latter clings to the fruit and gives much trouble in cleaning it off the berries when gathered. In fresh litter from the stables there is some manure that gets washed in by rain, and when clean affords sufficient to keep the fruit untainted. I always make an effort to get the Strawberry plantations manured early every spring, and for this reason I had not noticed that unmulched plants when in bloom suffered less from the frost than others which had straw material around them. It is quite possible that it might be so, as "H. C. P." suggests, in a dry time, for the arrested moisture would be to a certain extent stored in the straw mulch.

It has scarcely been a year when comparisons could be usefully made bearing on the merits of

new kinds. I have had Monarch and Leader growing side by side. The spring frost made the crop very light in both cases, but Monarch was so poor, that it has raised an unfavourable impression, and will only be retained in sufficient numbers for providing for future trials. Royal Sovereign does not maintain the high reputation it had everywhere. In soil which suits it there is no doubt it is a fine variety, but there is no soil that can be said to be suitable to every kind, and this is true of Royal Sovereign. With me there is both in yearling and older plants too much leafage, and in the former not sufficient protection to the flowers by reason of the length of stalk carrying the leaf beyond the flower trusses. As "H. C. P." points out, the crop was very late from the loss of the early flowers, and was rendered short from the same cause. There have been many cases where in point of size, quantity, and early or late supply the Strawberry crop has been a failure. Thanks mainly to Latest of All, the crop here has extended from June 23 to July 24, a more lengthened period than others in the neighbourhood have been favoured with. It is only by timely mulching that it has been obtained here, and without such aid I am quite sure the Strawberry crop would have been reduced in bulk and length of season very considerably curtailed. Not only did exposed soil become dry, but very hot, conditions that surface-rooting plants like Strawberries cannot endure long. As it was, great quantities of Strawberries failed to swell beyond the size of peas, and the loss to the market grower, whether it extended into scores of acres or measured only by perches, must have been considerable. My crop this season I estimate was less by two-thirds than that of last year from the same extent of ground. "H. C. P." notes the unfavourable effects of peat moss litter for mulching. I have had proof of its poisonous qualities for the land, and reports from others who have used it substantiate this. No doubt there are some soils which may benefit from its use for a time, but a continual use is sure to end badly. Unfortunately, the gardener has not always an independent opinion he can exercise in the case of manure supplied him, but is the victim of circumstances. In preparing for the planting of Strawberries it is well to bear in mind the time over which they are expected to remain without any manure placed beneath the surface to benefit the plants. Deep trenching does not benefit them much, but deep digging does, and so does a fairly good dressing of decayed manure well buried.

Wills.

W. S.

Failure of Strawberries.—I read Mr. Groom's remarks on the above subject at p. 115, and agree that the main cause of barrenness which has been so general this season is the parching ordeal the plants passed through last summer when growth should have been vigorous. Gardeners in private establishments, having only a limited area planted with Strawberries, might prevent the collapse, at least of young plants, by timely and liberal mulching. After dry springs the moisture is permitted to escape from the ground before any mulch is applied. Then frequently the so-called mulch consists of a very thin layer of straw or litter, barely sufficient to keep the fruit clean, and quite incapable of preserving moisture about the roots. I have had good results, even on light porous soils, by applying a good thick mulch of short manure from the pig-yard in January. This, when washed clean, keeps the fruit free from dirt and the root-run remains cool and moist. Comparatively few gardeners think of thoroughly soaking their Strawberry plot previous to plant-

ing in August or of mulching the plants, yet both these operations pay. I have sometimes used spent Mushroom manure for the newly-planted stock, and at others rough leaf-mould. Anything of this nature answers well, and those who neglect the above apparently trifling details must expect neither sturdy fruiting plantations the following summer nor healthy early runners. Dealing with two or more year-old beds in hot dry summers is a more difficult matter, but much may be done by plan above referred to towards preserving vitality and ensuring profitable crops of fruit.—N. N.

RELIABLE EARLY APPLES.

IN spite of an unfavourable season, the weather from the time the trees were in flower till now being very trying, there are yet large quantities of Apples in the market, and many private gardens are also well supplied with them. This satisfactory state of affairs is largely due to the fact that fruit growers are now content to plant numerous trees of a few varieties only, and those thoroughly reliable croppers, instead of, as heretofore, a few trees each of many varieties, the greater portion of which cannot be relied upon. As far as early cooking Apples are concerned, we need not expect any improvement on the varieties already available, and it is in the direction of improving on the later

has been erroneously classed as a cooking and dessert variety, but I should describe it as a good cooking Apple only. Duchess of Oldenburg or Russian Transparent might be classed as a never-failing variety—at any rate, I have never known it to fail completely. As a rule the long and somewhat slender branches are so heavily laden with large fruit as to require support to keep them off the ground. It is an early-maturing, striped Apple, somewhat soft, therefore not a good traveller, and, though often sold for eating raw, is best in a cooked state.

Manks Codlin, of which an illustration is given, we find classed as an August and September Apple, but of this excellent, reliable variety the season may be said to also include July, October, and November, so early does the fruit cook well and so well does it keep after gathering. Owing to its heavy cropping tendency, large trees are rarely seen of Manks Codlin, the majority being somewhat compact and stunted in appearance. The fruit lays on more colour, is firmer and crisper than is the case with most other Codlins, and we sometimes find it used for dessert accordingly. It is really one of the best cooking Apples we have, half-grown fruit making good pies. Keswick Codlin still proves profitable, but is not much planted now-a-days for the simple

Apple Manks Codlin.

sorts that our pomologists should go to work. Since the introduction of several comparatively new varieties, the value of Early Julien has been much overlooked by the majority of planters, yet I am credibly informed by an experienced grower, buyer, and salesman that where this old variety succeeds no other Apple pays so well. It is the first fit for use, and though classed as a cooking Apple is not to be despised for eating. Unfortunately, it is not so generally reliable as other sorts that will be named. It should be first given a trial, and if it prove a fairly reliable bearer be planted on a large scale. The most profitable trees I have yet seen of this extra early variety were horizontally or espalier-trained in a palace garden, but I know where there are both standard and bush trees that prove nearly as reliable. Gathering can commence early in August, sometimes in July. Should White Transparent prove as generally reliable as it does in the few instances which have come under my notice, a great future is before it. Both bush trees and pyramids crop very heavily, and doubtless standards will prove equally productive. The fruit is large, with a clear pale greenish yellow skin, and the first gatherings, taking the form of thinning out, may be made with advantage in July. It

reason that, good as this old favourite may be, there are other Codlins more reliable. Lord Suffield is a grand Apple where it thrives, but it is not nearly so reliable as either Lord Grosvenor or Grenadier, both of which possess better constitutions and produce very heavy crops of large Codlin-shaped fruit somewhat more ribbed than is the case with Lord Suffield. Potts' Seedling, another of these robust Codlin Apples, is equally reliable as regards bearing, and if the thinning is timely the fruit becomes larger than Lord Suffield even. From what I have seen and know of Gold Medal, this is a fine companion for Pott's Seedling, these two forming a good natural succession to Lord Grosvenor and Grenadier.

The Apple of this, and in fact most years, does not, however, belong to the Codlin section. In Stirling Castle we have the most generally reliable Apple in cultivation. This belongs more to the Hawthornden type, possessing all the good qualities of the old Hawthornden and none of its bad ones. Trees, principally on low stems, are to be seen of Stirling Castle in all directions literally breaking down with medium-sized, well-formed, clear-skinned fruit, which may be used direct from the trees or stored for a few weeks. For small gardens this

variety is invaluable. What about Ecklinville Seedling? some of my readers will ask, and in anticipation I admit that this is undoubtedly a most reliable variety, but, all things considered, it is inferior to Stirling Castle. It forms a larger tree in most positions, but it is not so heavy cropping nor is the fruit so valuable either for market or for temporary storing. In the Spitalfields Market, where immense quantities of early Apples are sold, Ecklinville, Duchess of Oldenburg and other soft, bad travelling varieties are known as Jews' Apples, owing to their being largely bought at lower rates by Jewish dealers.

W. IGGULDEN.

EARLY AND LATE GRAPES.

WOULD you kindly give me advice as to what Vines to plant in early and late vineries, each 25 feet long? There are inside and outside borders. The flavour is the first consideration.—J. R.

* * * Although "J. R." states that flavour of Grapes is to be the first consideration, I venture to think he means that only varieties of good quality are wanted. Some of the most pleasingly flavoured Grapes are most insignificant in appearance, and very few gardeners can afford to devote space to them. It is possible to have Grapes both richly and pleasantly flavoured and also of imposing appearance, such as most employers like to have on their tables. Supposing the houses are lean-to in form, eight or, at the most, nine Vines or fruiting rods are ample for each. In the earliest compartment I would plant three Muscat of Alexandria, one Muscat Hamburg, two Black Hamburg, one Madresfield Court, and one Foster's Seedling. In the late house room should be found for three Muscat of Alexandria, one Mrs. Pince's Black Muscat, one Alicante, one Lady Downe's, one Gros Colman, and either Gros Guillaume or Appley Towers. As this may appear to be a somewhat mixed or uncommon arrangement, I will give my reasons for including so many varieties and also for introducing Muscat of Alexandria into each house.

According to my experience, several varieties of Grapes are somewhat fickle. Only when the conditions are favourable do they succeed well, setting their berries, colouring satisfactorily, and ripening to perfection. For instance, in some positions Muscat Hamburg rarely fails to produce a full crop of bunches perfect as regards set and colour of berry, while the quality surpasses that of any other Muscat-flavoured Grape. Under different conditions as regards soil and climate the greatest difficulty is experienced in producing a single good bunch. Either the berries fail to set or wholesale shanking takes place and the variety is an utter failure. Much the same remarks apply to Mrs. Pince's Muscat. By some gardeners it is considered the best late Grape we have. When in good condition it is all they say of it, and I have kept it plump and good till late in May. Unfortunately, this variety also fails in many gardens, either the soil or position being once more at fault. Nor are all alike successful with Madresfield Court, another black Grape with Muscat flavour. In this instance the Vines are less fickle, and the one great drawback is the proneness of the berries to split badly during the ripening period. If this cannot be prevented failure is the result.

Other varieties which follow are more generally reliable. Foster's Seedling is not richly flavoured, but properly ripened is passably so, and does not cloy the palate. It succeeds everywhere and is one of the best stocks that can be used for shy-bearing black Grapes. All the same, it would be struck out of the list by severe critics. So also would Gros Colman, but I include it, as I happen to find it one of the best late Grapes in cultivation. If good time is allowed for ripening, colouring commencing early in August, this fine Grape is in excellent condition from November to February inclusive, far sur-

passing the best Alicante I have tested. It is particularly refreshing, invalids not tiring of it quickly, and instead of the skins being tough they are actually tender, breaking up and disappearing with the pulp. As far as quality is concerned, Gros Colman is far ahead of either Gros Maroc or Alnwick Seedling, with which it is sometimes classed. Those who have failed to grow Gros Colman satisfactorily on its own roots should give it a trial on Foster's Seedling stock before wholly condemning it. Alicante is equally variable. More often than not the berries when ripe are mere bags of sugar and water. The best I have ever tasted were cut from Vines rooting in a gravelly loam, and were ripened early. Lady Downe's may be said to be fast losing whatever popularity it ever gained. Pity it is that this should be so. With me it has always done well in strong loam, and the crop of neat, well-set, and perfectly ripened bunches never failed of appreciation any time from January to June. Before I succeeded in bringing out the good qualities of Gros Colman, Gros Guillaume was considered the best midwinter black Grape. When medium-sized to small bunches are selected these become closely furnished with well-set berries, which swell to a good size, colour perfectly, keep fairly late, and are crisp, juicy, and pleasing to the palate. Long young canes of this variety are apt to produce a limited number of sensational bunches, weighing, say, from 6 lbs. to 9 lbs. each; but worked on the Black Hamburg stock, and the laterals pruned to the second or third bud, a good choice of bunches is afforded, those responsible early removing the larger "shows" if smaller, more serviceable bunches are desired. Appley Towers is on trial, and appears to be an easily grown autumn Grape, black in colour, and of moderately good flavour. Black Hamburg never fails under ordinarily good treatment, and is the least fickle of all Grapes. Although I have only advised planting two Vines of this variety, the time may come when "J. R." will find it advisable to devote more space to it, to the exclusion of those less reliable. This can easily be done by mixing them with the others in the first instance, and then if necessary he can lay in young rods of Black Hamburg with a view to these gradually taking the place of those condemned.

Muscat of Alexandria merits a paragraph all to itself. I shall be blamed probably for allotting so much space to it in the early house, but this grand variety has no equal in white Grapes. It forces as readily as the Black Hamburg, and is not so very much later in ripening. High temperatures can be dispensed with, a good set of berries resulting on Vines in a Hamburg house if only they are grown at the warmest end and not disposed too thickly together. This variety should also have the warmest end of a late house assigned to it, and if the Vines are annually started late in February, or not later than the first week in March, the crop will ripen perfectly under conditions that also suit late black Grapes. The same may be said of the other Muscat-flavoured Grapes, but Madresfield Court ought to be grown at the outside end of a house, so as to be able to ventilate freely during the ripening period by way of preventive of cracking.

W. IGGULDEN.

The Purple Filbert.—A group of this Filbert has a very fine appearance in the shrubbery, the colour of its foliage being comparable with the Purple Beech or Prunus Pissardi. In addition the nuts produced are of excellent quality. The outer husk, which does not protrude so much as that of some other kinds, is a deep port wine colour, the shell lighter and the nut itself quite white, except the skin, which has a rosy tinge. The flavour is extremely nice, quite as good as in the best varieties of either Filberts or Cob Nuts. It does not always reproduce itself true from seed, but the majority of the seedlings show more or less colour. A better way to propagate it is by layers or by taking up an old stool

with plenty of sucker shoots and dividing it, thus securing a few roots to each divided portion, which is not always possible when getting at them without taking up the plant. Still for all purposes of a private place it is usually easy to get them, the lifting being only necessary when it is required to propagate in fairly large quantities. It is equally as strong and almost as free bearing as the common Hazel Nut and well worth a place in the fruit garden. The best time to plant is in early autumn, and it will thrive in any moderately good soil.

Loose fruit tree borders.—One of the worst cases I have seen of the ill-effects of soft tree borders was some time since in a garden in Surrey. The houses had been erected about two years, and the Peach trees chiefly planted at the same time. In every case the growth was quite outrageous, literally like Bean rods, and without the least prospect of producing fruit. I advised the gardener to lift his trees directly the leaves began to colour, to greatly solidify the soil, add plenty of mortar rubbish and wood ashes, and then replant. I do not know whether he did so, but he seemed to think fruit would come in time, of which I saw no prospect. It was easy to force a stick down 2 feet into the borders. How often do we see young Vines ruined for all permanent purposes in the same way, growers being delighted with the excessively luxuriant growth made. Market growers, by far the most successful of Grape producers, have their borders quite hard, as they also do in the case of Peach trees.—A. D.

OUTDOOR GRAPES IN EAST ANGLIA.

PROBABLY open-air Vines are more common in the eastern than any other counties, but I am sorry to find they are much neglected and seldom met with in a fruitful condition. Within a radius of a mile from where I write there are no less than half a dozen Vines on house fronts, but on only one of these is there a fair crop of fruit, and this inferior in quality. Owners of hardy Vines near towns seem, as a rule, to regard them as ornamental rather than useful, and so long as they give their walls a green appearance seem satisfied. A neighbour of mine—a builder—has a healthy, spreading Sweetwater which usually bears freely, the produce being annually made into wine. The chief hindrance to free, healthy growth and good crops is a too crowded condition of the Vines. Laterals are allowed to form too closely, stopping is neglected, with the result that a crowded mass of foliage prevents the ingress of sunlight and air, and general weakness and barrenness follow. Even when pruning and training receive due attention the roots are often in an unfavourable larder, resulting in the case of a hungry, gravelly subsoil, weak, and in a cold clayey one, rank, unripened wood.

There is no need of a large border; indeed, it is surprising in what a limited area Vines will grow and yield well for many years provided suitable top dressings, liberal mulchings and several copious waterings with liquid manure are given; and as the Grapes are generally used for wine making, the hose or garden engine may be freely used occasionally to cleanse the foliage and keep down spider without any fear of disfiguring the bunches. In planting, the best way, I think, is to take the main rod up in the middle of the wall space, carrying from this horizontal rods right and left. The laterals issuing from the main rods should be quite 2 feet apart, which will allow of the admission of a maximum amount of air and sunshine. Good results may be obtained from the ordinary close spur system of pruning, new rods being run up piecemeal when the Vine shows signs of waning, at which time also the bordering undergoes a complete renovation. Thinning the bunches is too often neglected, but attention to this matter is well repaid by the extra size and quality of the fruit. Nowhere have I seen such profitable outdoor Grapes as in Essex, where in some instances the roofs of cottages are furnished with healthy

fruitful Vines, the sale of the fruit helping materially to pay the rent of house and garden.

NORFOLK.

MYOSOTIDIUM NOBILE.

(NEW ZEALAND (?) FORGET-ME-NOT.)

PERHAPS one of the most tantalising things concerning this noble plant is the fact that it has not proved generally hardy in the British Isles or even in the more favoured portions thereof. With perfect hardiness the plant would have been an ideal subject for the rock garden, or at least that portion of it devoted to moisture-loving plants, and in company, for example, with Trilliums, Dentarias, Cypridiums would have made a striking and ornamental subject. As a plant, however, for the open garden generally a warmer clime than our own must be found. The plant has not been cultivated generally with success even in those instances where greenhouse treatment has been accorded it. Under glass the moist and cool conditions of the Odontoglossum house are well suited to it, particularly where the very cool treatment is adopted. The plant will certainly not be likely to succeed, much less attain perfection, in a dry place, for here insect pests would speedily attack it with ruinous results. I believe one of the finest cultivated batches of this plant was grown at Floore Weedon by Mr. Loder some dozen or so years

been seen, but none I have knowledge of have equalled the plants referred to. It is not difficult to raise from seeds, and the latter, being fresh, germinate somewhat freely. From the first, however, the plants should be liberally dealt with and potted without delay, wintering them either in a frame which excludes frost or a cool structure such as that devoted to Camellias. In the following spring a shift to 7-inch or 8-inch pots may be given to the largest plants, also ample drainage. A very sandy soil should be used, together with peat and loam and a little manure. With liberal treatment the largest plants should flower at eighteen months old, and anyone growing the plant will not quickly forget the giant shining leaves supported on long, deeply channelled stalks, or the leafy inflorescence that reaches to nearly or quite 2 feet high. The flowers are each about half an inch across and salver-shaped; in colour whitish at the margin and the centre rich blue, though variable. It is a true perennial in character, and with good plants to start with is worth giving a series of trials year by year by those whose gardens are situated in the most favoured parts of these islands. Failures there will be undoubtedly, and it is to be hoped some measure of success also in the end; therefore, if the whole matter is taken in hand as purely experimental by those whose time and surroundings permit, some interest-

The New Zealand Forget-me-not (*Myosotidium nobile*). From a photograph by G. Champion.

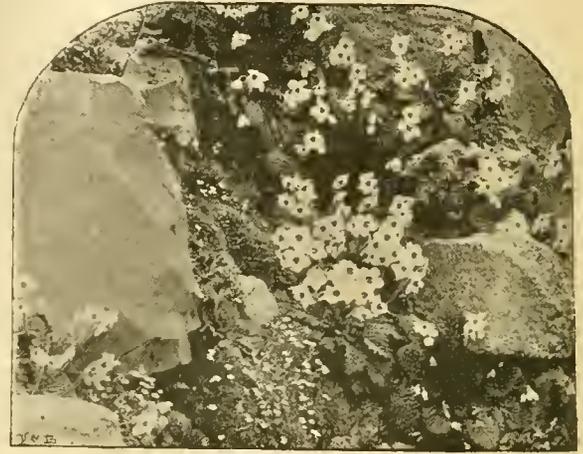

ago, a portion of which came before the Royal Horticultural Society at the time. These were excellent examples of cultural skill. Since that time occasional exhibits of the plant have

ing experiences should be forthcoming eventually. The subject, too, is unique, and for this reason merits the above suggestions being put into practice.

E. J.

RAMONDIAS.

THE Ramondias occupy a foremost place among free-flowering and easily-grown alpinines. That they are perfectly hardy in the wind-swept heights of their mountainous homes is of course beyond question, for though here the winter's frost may exceed any frost we know in lowland places, it rarely reaches the plants that lie

Ramondia pyrenaica. From a photograph sent by Mr. Gregory, Croydon.

close and snug, as well as dry and comparatively warm, below the usually deep bed of protecting snow. This is even so where the plants, as in the case of these Ramondias, grow chiefly in the chinks of the rock, often spreading out on the perpendicular face of it, for these, too, are in the long season of rest frequently covered by snow for long periods. Under these circumstances the actual cold reaching the plants is not great, while what is most important is the uniformity of the conditions that exist during the long winter season. It is quite another matter when these self-same plants are grown in British gardens, as apart from the changes that must inevitably ensue is the fact of the ever-changing character of our winters, and such as are close and warm are responsible for the death of many a beautiful alpine. Neither the close, wet, warm winter nor the dry periods of frost without snow that we sometimes experience seem capable of doing the least harm to this sturdy and hardy plant. Even the long weeks of intense frost that disfigured so much and killed outright much more three or four years since left these lovely Ramondias quite unharmed, even when the plants were growing in pots, and these were in the open with full exposure, just merely standing on a bed of ashes. During this very trying time, however, the plants, moisture-loving as they usually are, looked as though the life was dried out of them, but when the frost at length broke up no plant more quickly responded to a good watering. Passing safely through such a time, with the roots and indeed every vestige of the plant frozen through and through for weeks together, I think it may safely be stated that few more perfectly hardy evergreen alpinines exist; therefore, it is one to which amateurs may safely turn their attention. Its cultivation is of the easiest, so much so that it takes to loamy soil as readily as it does to one of a peaty nature, and with a mixture of equal parts of both made quite sandy, the plants will be quite satisfied. Indeed, some plants in large pots that have not been repotted these six years flower with greater freedom each succeeding spring, while some of the principal rosettes of leaves have

much increased in size. Of more importance than soil perhaps is the position, which should be rather shady, or even quite shaded, all day long. The plant, however, does not in the least object to partial sunshine, but care must be taken that the plants do not get too dry.

As showing the value of the *Ramondia* in the rock garden, there is a capital illustration in the Royal Gardens, Kew, a portion of this view being given in the accompanying picture. The plants at Kew are growing in a sort of secluded recess, of which the sides are nearly perpendicular, with rock stones freely interspersed, and the plants grouped in small companies. Some of the plants are placed, so to speak, on rocky shelves; others are in chinks between a couple of stones, and so on, practically furnishing one side of the bank in question. Some of the larger examples are very fine single rosettes as large as an ordinary dessert plate, and, with many smaller ones, constitute a very pretty bit of rock garden scenery when in flower.

One point should not be overlooked, viz., the apparent fondness for a stony soil, or the proximity of stones, and here the rosettes spread out their shaggy and wrinkled leaves quite prostrate. Among other peculiarities is its slow growth; this is so in all its stages, whether old plants or seedlings; indeed, I have known seedlings of five years' growth whose diameter would not exceed that of a half-penny, and if judged by this standard of progress it would take at least ten years to attain to flowering size. At the same time, when the latter stage is reached the plant flowers with unerring regularity each year, the stems being 4 inches or 5 inches high, and bearing, in strong plants, three flowers each. The group at Kew is of mixed colours, a large proportion being the violet-purple colour of the type. There is also a nice lot of white, and some variability among the coloured kinds. In the Kew collection I believe there are other kinds also, but I do not remember to have seen these in flower. Perhaps among them all no more exquisitely beautiful a plant could exist than the white form, which is a veritable gem. The large plants at Kew must be of considerable age, as they have been known to me some years and appear but little larger than when I first remember them.

After flowering, the plants produce seeds very freely, and, where it is intended to raise seedlings, I know of no better way than sowing the seeds on finely-chopped Sphagnum Moss, placed in pots and made rather firm, standing the pots in a saucer of water to supply the moisture. The pots need not be more than half filled, or rather more, and with a few pieces of charcoal at the bottom to help keep the Moss sweet. This and removing the saucer at times will do all that is needed in this direction. Another mode not generally known of increasing these things is by leaves, in the same way as *Begonias*, by laying or fixing them on a pot of moist sand. The process, however, is a slow one, as though the petiole will emit roots into the soil in three or four months, it will take another equal term before any sign of plant life appears. Naturally enough, the best results are secured from the largest leaves, but as the denuding of such will quickly spoil a plant, the system is not to be recommended in a general way. Indeed, in any case it is only worth while with the rarest kinds, as the old kind may be had in quantity and at quite a cheap rate. The longevity of the plant is remarkable, and under cultivation I do not remember seeing a plant of *Ramondia* collapse. Frequently bad packing is responsible for great losses in transit, but this is another matter.

E. J.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 12.

THIS was a very good meeting indeed. Of hardy flowers the Rose was still pre-eminent in all its glory as an autumnal subject, notably the Teas, the Hybrid Teas, and a few of the more select of the Hybrid Perpetuals. These were staged in fine condition from Waltham Cross, Cheshunt, and Oxford. Michaelmas Daisies made their appearance, but these, although present in a few of the better forms, will be more in season next month. A few other good hardy subjects were shown, as the *Colchicums* and earliest *Cyclamens*. Of Dahlias there were more exhibits than of any other flower, and of these it is pleasing to note the progress being made in the Cactus section, which is by far the most fascinating of any class. Both in variety of form and of colour, as well as in the habit of the plants, is this improvement very manifest. Several awards to the most approved of these were made, as well as to singles and pompons. Early *Chrysanthemums* (too early, in fact) made a good display. A few other good examples of stove and greenhouse decorative plants were staged, notably of *Acalypha Sanderiana*.

Orchids were not in strong force certainly, but still a few good things were in evidence, as, for instance, some finely-flowered *Dendrobium formosum giganteum*. Fruits, on the other hand, were well represented, both from under glass in the way of Melons and Grapes and from outside in that of Apples and Pears. Vegetables were chiefly confined to the splendid exhibit from Aldenham Park Gardens, finer than which no one could possibly desire, especially when the prolonged drought is taken into consideration. Fortunate are they who at such times have the benefit of a rich deep soil; the risk of failure then is greatly minimised. The lecture by Mr. Mawley will, when published, be read with great interest, as it bore upon the long drought of 1898, which has this year again been repeated.

Orchid Committee.

A first-class certificate was awarded to—

CATTLEYA LUDDMANNIANA (SPECIOSISSIMA) ALBA.—This is one of the most beautiful of the white *Cattleyas*. The sepals are upwards of 3 inches long, pure white; the petals as long as the sepals, about 2½ inches broad, of fine form and substance. The lip is broad as in the type, pure white, except the blotches of lemon-yellow on each side lobe and through the base of the throat. The plant carried a two-flowered raceme. It is a most rare and desirable variety. From Mr. W. Duckworth, Shaw Hall, Flinton, Manchester.

Awards of merit were adjudged to the following:—

CATTLEYA KIENASTIANA VAR. AURORE.—A hybrid derived from the intercrossing of *C. Ludde-manniana* and *C. Dowiana*. The sepals and petals of good form and substance, deep rose with an indication of a lighter marbling. The broad lip dark rose around the margin with a deep purple blotch in the centre of the front lobe. The disc and the whole of the throat is yellow, suffused with dark brown and lined with a brighter shade of yellow. It is a most distinct and desirable form. Two cut flowers came from Mr. Bond, gardener to Mr. C. L. N. Ingram, Elstead House, Godalming.

LÆLIO-CATTLEYA CALLISTOGLOSSA (Leon's var.).—This is one of the most beautiful forms of this hybrid we have seen. It is the result of intercrossing *Lælia purpurata* and *Cattleya Warscewiczii (gigas)*. The sepals and petals of good form and substance, of an intense rose shade of colour. The large lip is wholly of crimson-purple, which is extended through the throat, entirely suppressing the yellow eyes which are so characteristic to hybrids of this cross. There is a darker shade of colour in front of the throat. The plant came from the collection of Mr. H. S. Leon, Bletchley Park, where it was raised four years

ago by Mr. Hislop, the gardener. It is a most distinct and desirable form.

M. E. Zollinger Jumy, Villa Grötin, Zurich, sent a good form of *Vanda Sanderiana* with a raceme of eleven flowers and a pretty variety of *Cattleya O'Brieniana*. **Mrs. Temple, Groombridge,** sent a light form of *Cattleya Gaskelliana*. **Sir Trevor Lawrence** sent *Cypripedium niveum maculatum*, resembling some forms of *C. Godefroyæ*. **Col. R. W. Shipway, Grove House, Chiswick,** sent a distinct and fine form of *Cattleya Hardyana*. **Mr. C. L. N. Ingram** sent four cut flowers of the typical variety of *Lælio-Cattleya callistoglossa*. **Mr. F. Hardy, Tyntesfield, Ashton-on-Mersey,** sent *Sophro-Cattleya Hardyana (C. Aclandæ × S. grandiflora)* with two of its yellow and purple flowers. **Mr. F. W. Moore, Glasnevin,** sent *Cryptophoranthus hypodiscus*, a distinct variety of the Window Orchid, with creamy yellow and purple-tipped flowers (botanical certificate). **Messrs. F. Sander and Co.** sent a dozen beautifully grown and finely flowered plants of *Dendrobium formosum giganteum*.

Floral Committee.

First-class certificates were awarded to the following:—

RETINOSPORA OBTUSA AUREA CRIPPSI.—This is likely to be of much value in the garden. Judging by its name, it would appear to be a form of *R. obtusa*, yet it is distinct from that type, so graceful and somewhat pendent in its gracefulness as almost to merit specific distinction. So far as knowledge is obtainable, it is a selected seedling taken from a bed of the above kind some years ago. The plant not only keeps its colour in summer, but in winter also, in this respect quite surpassing the Lawson's Golden Cypress. The plant is altogether less dense than is *R. obtusa aurea* and much finer in colour. The exhibited example was splendidly coloured and very pleasing and elegant. From Messrs. Cripps and Son, Tunbridge Wells.

EUCHARIS BURFORDIENSIS.—This is a hybrid between two well-known kinds—*E. Mastersi* and *E. Sanderi*. In the result the new-comer is almost funnel-shaped in outline, minus the centre coronal-like cup of *E. grandiflora*. The present hybrid is not only a handsome addition to this group, it is a novelty of undoubted all-round merit, both for its intrinsic worth and its general freedom of flowering. From Sir Trevor Lawrence, Burford Lodge, Dorking (gardener, Mr. Bain).

The following obtained an award of merit:—

BEGONIA MRS. LEOPOLD DE ROTHSCHILD.—This is a pink-flowered sport from the well-known *Gloire de Lorraine*. The habit of the plant is more compact and the flowers larger, which gives the impression of greater freedom of flowering. The parent plant, however, is of a looser habit, hence the difference. The new-comer is a decided gain, the form of the flowers also being much improved. A charming pot plant of most useful size. From Mr. Leopold de Rothschild, Gunnersbury House (gardener, Mr. J. Hudson).

ROSA CORALLINA.—This is a Tea Rose and exhibited as a bedding kind, for which its undoubted freedom suits it exactly. The colour is very distinct, and perhaps more nearly resembles *Papa Gontier* in this single respect than all else. The outer petals may be termed a rosy-peach, the centre being of a madder-rose tint. It is, however, a variable flower, as, for example, there is a touch of salmon on the tips of some more expanded flowers. The buds are very long and tapering and almost crimson-carmine in shade. It is said to possess great vigour and freedom of flowering, and if thoroughly hardy should prove welcome in the garden where free-growing sorts are in demand. From Messrs. Wm. Paul and Son, Waltham Cross.

DAHLIA RED ROVER (Cactus).—An exceptionally large flower, possibly too large, indeed, as its presence on the show table coupled with the present award will set a fashion for over-large flowers. This is not needed. The colour is crimson-scarlet. From Mr. Green, Dereham.

DAHLIA MRS. J. J. CROWE (Cactus).—A splendid addition to the self yellow class, the shade

beautifully clear and good, the florets long and narrow, and in short a shapely and beautiful flower throughout. From Mr. J. West, Brentwood, Essex, and Messrs. Keynes, Williams and Co., Salisbury.

DAHLIA GREEN'S WHITE (Cactus).—A good and pure white of useful size, the tips gently incurved. From Mr. Green, Dereham.

DAHLIA MAYOR TUPPENY (Cactus).—A beautiful orange scarlet, with light golden centre. From Mr. J. Stredwick, St. Leonards.

DAHLIA MAJOR WESTON (Cactus).—A clear crimson-scarlet with ruby on the reverse side of the florets. From Mr. J. Stredwick.

DAHLIA UNCLE TOM (Cactus).—A very deep maroon-crimson, the centre being almost black, one of the darkest we have yet seen. From Mr. Stredwick.

DAHLIA MAURICE T. WALSH (Cactus).—In this the colour is orange and yellow, yet not sufficiently well defined or even distinct enough to merit the present award. Cactus Dahlias are greatly increasing at the present time. In our opinion the above is a poor and indistinct kind. From Mr. J. Stredwick, St. Leonards.

DAHLIA EMPEROR (Cactus).—A large flower of a rich magenta-rose, florets well incurved. From Messrs. Keynes, Williams and Co., Salisbury.

DAHLIA LOADSTONE (Cactus).—A fine orange-red, the florets having a distinct twist. From Keynes, Williams and Co., Salisbury.

DAHLIA INNOVATION (Cactus).—A rich and telling scarlet, the colour of which is enhanced by the pure white tips of the florets. From Messrs. Keynes, Williams and Co., Salisbury.

DAHLIA CHEERFULNESS (pompon).—This pretty kind is margined or tipped with scarlet-crimson, while the base is of a yellow shade. From Messrs. Keynes, Williams and Co., Salisbury.

DAHLIA EMPRESS (show).—A well-formed flower in which lilac-purple predominates in a rather uniform manner. From Mme. St. Pierre Harris, Orpington.

DAHLIA NELLIE NICHOLSON (single).—A well-formed flower of medium size, the colour white, bordered carmine-rose. From Mr. M. V. Seale, Sevenoaks.

DAHLIA EDDIE OLBEIN (single).—A distinct sort, colour rosy mauve and pink, with a clouded yellow base. From Mr. M. V. Seale, Sevenoaks.

DAHLIA VERONICA (single).—A good scarlet, freckled with orange and yellow. From Messrs. J. Cheal and Sons, Crawley.

DAHLIA DAISY (single).—Ruby-crimson in colour, lightly freckled with white. From Messrs. J. Cheal and Sons, Crawley.

DAHLIA FLAME (single).—A good and distinct flower in which orange-scarlet predominates, with a few lines and bars of similar hue. From Messrs. J. Cheal and Sons, Crawley.

There were some other good flowers, too, notably the Roses from Waltham Cross that Messrs. Wm. Paul and Son brought in such numbers and such quality. These for the most part were set in baskets, and, arranged with many buds as well, were seen to advantage. Some of the foremost kinds were Viscountess Folkestone, La France, very good; Mme. A. Chatenay, Marie van Houtte, very pleasing; Maman Cochet and the white form from it, which is equally delightful; the pretty Queen Mab, Souv. de Catherine Guillot, the ever-flowering Enchantress, the miniature Perle d'Or, Caroline Testout, Mrs. Laing, Gustave Regis, Francisca Kruger, Papa Gontier, and others, all beautiful. The new bedding kind, Corallina, was in the midst of all, and very charming was a basket of its distinctly coloured flowers and its richly coloured and very long buds. In the midst of all this flower and fragrance, well-berried shoots of the rugosa kinds appeared, the whole making a rich and telling display in mid-September. A silver-gilt Flora medal was deservedly awarded. Another exhibit of Roses came from Mr. Geo. Prince, of Oxford, and arranged in much his usual style, which is usually an attempt at decoration with Roses rather than bringing a great mass of flowers in the more primitive basket. In the large flower-

holders of the Princess pattern Mr. Prince had set up many of the choicest kinds, which with the taste displayed in arranging made a very pleasing exhibit as a whole (silver Flora medal).

Mr. T. S. Ware, Tottenham, set up a very fine display, in which several sections of the Dahlia played a leading part. Among the Cactus Dahlias were such good things as Firebrand, Magnificent, Amber (which is yellow and amber shade and a really fine flower), Beatrice, Starfish, Miss Webster (white), the fine yellow Mrs. C. Turner, Sylvia (mauve), Mrs. Peart (white), and others. There were also a large lot of pompons, very pretty and useful many of them, and an equally good lot of singles in great variety. Miscellaneous plants in the same group embraced Sunflowers in variety, very showy and helpful indeed in a group with so much intensity of colour; Eulalias, Scabiosa caucasica, Michaelmas Daisies, Heleniums, Heliopsis, Gaillardias, and such like, all assisting in making up a very fine exhibit (silver Flora medal). Mr. John Green, Norfolk Nurseries, Dereham, likewise had a splendid display, a display that at least must have given satisfaction to those who cannot endure the crowding together *en masse* of all the flowers available at the moment. In Mr. Green's exhibit there was no crowding and no attempt at it. The flowers, too, were of the finest in their respective colours, and the group as a whole was exceptionally strong in Cactus Dahlias. It was here where Red Rover was seen, a large, if not even a formidable flower. Yet it must be given its due; its largeness was not coarseness. It is one of the intended novelties of the coming year. Zephyr, which is also a coming novelty, is rose-carmine. Dr. Nansen is scarlet; Eclair, vermilion scarlet; Ranji, deepest maroon; Capstan, salmon scarlet; Wallace, pale orange and buff, quite a new combination; Britannia, salmon-buff; Dryden, deep crimson-scarlet; Green's White, and others. The majority of the flowers were thinly arranged on sloping stands, and these occurring at intervals in the background, opened recesses for inserting other kinds in smaller lots, thereby diminishing the formality of the whole to the lowest limit. The arrangement was good, and great care had been exercised in making the most of a comparatively small number of flowers (silver Flora medal).

Dahlias, too, were again well shown by Messrs. Joseph Cheal and Sons, Crawley, who had an exhibit extending nearly throughout the central table of the Drill Hall. And here, again, not only Cactus, which appear to be everywhere in the foremost rank, but pompons and many fine single kinds were admirably well shown. Indeed, this firm would appear to excel in this direction from the attention it has given to the section, and the good things also that have found publicity through their hands. A silver-gilt Flora medal was awarded this comprehensive group. A fine lot of Dahlias were also shown by Mr. J. T. West, Tower Hill, Brentwood, who had many fine boxes of the show kinds fronting a good lot of Cactus and other forms. In this lot pompons, too, were a strong feature (silver Banksian medal). Dahlias came in considerable force from Messrs. Jones and Son, Shrewsbury, though here the attempt was rather made to display bouquets and stands of the flowers as suggesting their utility in decoration rather than their value as garden flowers (silver Banksian medal). Still another lot was that from Mr. James Stredwick, Silver Hill Park, St. Leonards, whose best flowers are already given in the awards. Then in a mixed group, which was, however, largely composed of Dahlias, Messrs. J. Peed and Son, Roupell Park Nursery, West Norwood, made a big display, the Dahlias being interspersed with Bamboos and other grasses and similar plants, together with the pretty white Michaelmas Daisy Mrs. W. Peters, a rather dwarf, free-flowering plant. A group of this latter plant was also set up at the entrance by Messrs. Peed (silver Banksian medal). The Messrs. Cripps and Son, Tunbridge Wells, apart from the golden Retinospora, showed a beautiful variety of Japanese Maples, branches and twigs cut from plants grown in the open ground and

under two years old. These are seedlings raised in these nurseries and are grown in great quantity, the colours being as beautiful and varied as is possible in these plants. Messrs. W. Cutbush & Sons, Highgate, had a fine exhibit, composed entirely of *Hydrangea paniculata grandiflora*, the heads of bloom exceptionally fine and well developed, the trusses being arranged amid a groundwork of Maiden-hair Fern. A semi-circular group of early-flowering Chrysanthemums was set up by Mr. J. H. Witty, Nunhead Cemetery, the varieties consisting of Mme. Desgrange and its sports, Lady Fitzwygram, Marie Masse, Harvest Home, Mme. Jolivart, and others. There were some nicely-grown flowers here, and the plants were all in pots. At present it is a great labour to form the most perfect pudding-shape top to these groups, which are not instructive but the reverse. Maiden-hair Ferns formed the margin to this over-precise mound of flowers (silver Flora medal). Messrs. Wallace & Co., Colchester, brought up a *Lilium speciosum album* ovum, the finest of all this group; *Hemerocallis aurantiaca* major, and some pots of the Atamasco Lily (*Zephyranthes Atamasco*), the buds of which were nearly to the bursting stage.

A large group of mixed hardy things came from Messrs. Paul and Son, The Old Nurseries, Cheshunt. Here we noticed many of the most beautiful of the early Michaelmas Daisies, such as *Aster Amellus bessarabicus* varieties, *A. Lindleyana*, *A. acris*, a mass of starry flowers; *A. Novae-Angliae roseus*, very showy; *A. N.-A. pulchellus*, as well as several showy varieties of the single forms of the China Aster, *Aster sinensis*. Other good things in this very extensive group were *Clematis Davidiana*, *Senecio pulcher*, very showy in its flower-heads; *Helenium pumilum*, *Scabiosa caucasica*, *Helianthus Miss Mellish*, very fine, *H. multiflorus* pl., *Coreopsis*, *Gaillardias*, a charming basket of *Cyclamen hederifolium album*, very beautiful in the mass, some pretty tufts of Meadow Safron in several forms, *Tritoma nobilis*, *Phlox Etna*, *Heliopsis Pitcheriana*, a fine rich orange, *Helenium nudiflorum*, *Plumbago Larpentae*, *Funkia subcordata grandiflora* with its pure and fragrant flowers, *Harpallium rigidum*, *Lilium speciosum roseum*, a few charming Roses, *Clerodendron trichotomum*, the rather scarce *Asclepias tuberosa* with its clear orange-scarlet flowers, and many other things that assisted in making this a very extensive as well as comprehensive group (silver Banksian medal). The Messrs. Barr and Sons, Covent Garden, also had a group of hardy flowers mostly of the showy class, such as *Statice latifolia*, a variety of *Aster Novae-Angliae*, *Sedum spectabile*, *Helianthus giganteus*, *Lilium speciosum Krætzeri*, *Zephyranthes Atamasco*, the dainty *Leucocjum autumnale* with its bell-shaped blossoms, faintly tinted rose; *Helianthus H. G. Moon*, a variety much in the way of *H. multiflorus maximus*; *Zauschneria californica splendens*, *Phlox Coquelicot*, the Marsh Gentian (*G. Pneumonanthe*), *Rudbeckia Golden Glow*, *Senecio pulcher*, *Lonicera sempervirens*, *Aster ptarmicoides*, a small white flowered sort; *Parnassia caroliniana*, a pretty veined flower that makes an excellent study for the microscope if not very attractive to the eye, and the curious Goldlocks, *Chrysocoma* (*Aster*) *Linosyris* (bronze Flora medal). Mr. W. Wells, Earlsfield, staged a group of early-flowering Chrysanthemums, in which the majority were old and, tried kinds which appear to be standing the test of time and giving satisfaction to the public. Such well-known kinds as Harvest Home, Queen of Earlies, Marie Masse, Mrs. Pitcher, Blushing Bride, Arthur Creepy, Albert Chausson, Gustave Gruderwald, Mme. Zephyr Lionnet, Mme. Jolivart, Flora, Lady Fitzwygram, &c., were being mostly shown in bunches and naturally grown. Messrs. Hugh Low and Co. showed a curious freak in *Calla Elliottiana*, in which a leaf blade was attached to the spathe, and on the one side had imparted to it some of the golden colour of the spathe.

From Gunnersbury House Mr. Leopold de Rothschild (Mr. J. Hudson, gardener) sent a

splendid lot of *Acalypha hispida* (Sanderi), the plants teeming with the coloured inflorescences from short lateral stems. The plants had been treated as standards, *i.e.*, grown to a single stem to about 6 feet high and then stopped twice or thrice to form a head at the summit of the stem. Thus grown the plants have a most striking effect, less so in the nakedness of the Drill Hall and in the way they were placed than would happen when the plants were employed in company with tall and graceful Palms and the like. Too frequently a lack of colouring in stately rooms where decoration is carried on is very noticeable, but which is now no longer necessary, seeing this *Acalypha* can be so grown and in so short a time. From a cultural point of view the plants were excellent. It is, we believe, the first time this plant has been treated in this way (silver Banksian medal). Baskets of *Begonias* were also shown by Mr. Hudson.

Fruit Committee.

This committee attended to a fair share of exhibits of excellent quality, vegetables being grandly staged from Aldenham House and Melons and new Apples being plentiful, with other choice fruits.

Awards of merit were given to the following :—

APPLE T. A. KNIGHT.—A seedling from Cox's Orange and Peasgood's Nonsuch, a very beautiful fruit and of pleasing colour, above medium size and of first-rate flavour, deserving a higher award, but as the fruits were not ripe the committee desired to test them again at a future meeting. From Mr. Ross, Welford Park Gardens, Newbury, Berks.

APPLE VENUS PIPPIN.—A beautiful early dessert variety, medium size, yellow skin, with soft white flesh and very handsome; of conical shape, with a brisk flavour. From Mr. W. J. Godfrey, Exmouth, Devon.

APPLE BEN'S RED.—A handsome early dessert variety with bright red skin, seedling from Devonshire Quarrenden, but larger than that variety. It has firm flesh and is of remarkably fine quality; a heavy cropper.

CUCUMBER BECKETT'S ACHIEVEMENT.—A very shapely fruit, with scarcely any spines, ribbed with a beautiful deep green colour and little neck, not unlike a small Telegraph, but shorter. A valuable winter fruiter. From Mr. Beckett, Aldenham House Gardens, Elstree, Herts.

The last-named exhibitor staged a magnificent collection of vegetables, and the quality was more marked considering the bad season. They were staged for the Sherwood Cup, but unfortunately the exhibitor mistook the date. To show the value of the exhibit the committee unanimously awarded a gold medal. There was a beautiful bank of Veitch's Autumn Giant Cauliflowers; several varieties of Tomatoes, Golden Jubilee, Perfection, Polegate, and Favourite; Beans Veitch's Climbing and Ne Plus Ultra; grand Veitch's Model Carrots, Maltese Parsnips, and very fine Ailsa Craig, Cocoa-nut and The Commodore Onions; Kales, Cabbage, and Savoy in variety; Cucumbers Beckett's Achievement and Ideal, beautiful fruits; Pizetaker Turnips; Potatoes perfect in shape and colour, Windsor Castle, Satisfaction, and Goldfinger being staged; Indian Corn in the green pods, the variety being Caragua; excellent Model Leeks, and Salsafy and Scorzonera; Perfect Celery; Standard-bearer, White Gem, and Prize-taker Marrows in variety, Peas Autocrat, a fine dish, the whole well deserving the gold medal awarded.

Messrs. Wm. Paul and Son, Waltham Cross, had a fine exhibit of forty dishes of Apples and eighteen trees in pots. The latter was certainly a remarkable exhibit, the fruit being very fine, and the trees dwarf, compact specimens, laden with fruit. The collection included Beauty of Kent, Peasgood's Nonsuch, Potts' Seedling, Cellini, Prince Albert, Belle Pointoise, Mabbott's Pearmain, Lewis' Incomparable, Annie Elizabeth, and Scarlet Nonpareil, all excellent, with good dishes of Wealthy, Tyler's Kernel, Worcester Pearmain, Bismarck, Lady Henniker, Frogmore

Prolific, Washington, Peasgood's Nonsuch, and good Cox's Orange (silver-gilt Knightian medal). Messrs. Veitch, Ltd., Chelsea, sent twenty-two varieties of Tomatoes, all grown in the open, trained to stakes. These were most interesting, showing how well these plants fruit in a favourable season. They were laden, being set within 12 inches of the soil, the most notable varieties being Chemin, Ham Green, Acquisition, Golden Jubilee, Frogmore Selected, Trophy, Criterion, Perfection, Large Red, and the Peach Tomato (silver Knightian medal). Mr. W. Taylor, Tewkesbury Lodge Gardens, Forest Hill, S.E., staged a very pretty lot of fruit, some half-dozen varieties of Grapes being shown on small single stands at the back of the collection, and the bunches were well finished, the varieties being Foster's Seedling, Directeur Tisserand, Muscat of Alexandria, Gros Maroc, Alicante, and Alnwick Seedling, very fine Gladstone and Princess of Wales Peaches, Golden Drop, Primate, and Late Orange Plums, Williams' Bon Chrétien Pears, with Peasgood's Nonsuch Apples grown under glass, and several varieties of Tomatoes (silver Knightian medal). Mr. Geo. Woodward, Barham Court Gardens, Maidstone, had a notable exhibit, not large, but demonstrating what can be done by different culture to that usually adopted. It included excellent Dymond Peaches grown on a north wall; Hale's Early and Royal George from bush trees in the open, very good fruits and well coloured, the trees having borne regularly for some years; Sea Eagle Peaches from wall with coping, and splendid Rivers' Orange and Humboldt Nectarines from walls, and Beurré Mortilet and Triomphe de Vienne Pears. A silver Banksian medal was deservedly awarded. Mr. S. Mortimer, Swiss Nurseries, Farnham, had two dozen very good Melons, and one a seedling of great merit, but not ripe, the others being well known kinds noted for their rich flavour, a dozen fruits of Hero of Lockinge and Sutton's Royal Favourite being staged (silver Banksian medal). Mr. J. Coles, Highly Manor, Haywards Heath, staged a small collection of fruit, having very good Walburton Admirable and Exquisite Peaches, the last-named a beautiful yellow-fleshed variety; Pitmaston Orange and Violette Hâtive Nectarines; Pond's Seedling and Magnum Bonum Plums; good Morello Cherries, with Currants and Apples (silver Banksian medal). Mr. W. Miller, Ruxley Lodge Gardens, Esher, was awarded a cultural commendation for an excellent lot of Princess of Wales Peaches. A Melon named Taunton Hero was shown by Messrs. R. Veitch, Exeter; The Captain, by Mr. C. Ross, and from other sources, but all were passed by the committee. Apples Stamford Beauty by the Messrs. Brown, The Nurseries, Stamford; also two new seedlings by Mr. Ross, and Hunt's Early by Mr. W. Hull, Maidenhead, and Mr. E. Holden, Grosvenor Cottage, Devonport; and Mr. J. Rutter a new seedling named Lord Kitchener, Wisbech, Lincoln; new Tomato Abundance, from Messrs. Veitch, Exeter, a very heavy cropper; a new Tomato named Wonder of Italy from Mr. J. Green, The Nurseries, Dereham, Norfolk, a plum-shaped pretty fruit. Maize or Indian Corn in six varieties for use as a vegetable in a green state came from Mr. Wythes, Syon House Gardens, Brentford, from seed sown in May, and Aubergines from the society's gardens.

United Horticultural Benefit and Provident Society.—The annual dinner of the above society will take place at the Holborn Restaurant, High Holborn, W.C., on Thursday, October 5, at 6.30 p.m. Mr. W. Y. Baker has kindly consented to preside on this occasion.

The weather in West Herts.—Still another warm week and the tenth in succession; the past week was, however, the least warm of the series. On the night preceding the 11th the exposed thermometer fell to within 3° of the freezing point, making this the coldest night we have yet had

this autumn. During the last few days of cooler weather there has been a gradual, but decided fall in the ground temperatures. Nevertheless, at 1 foot deep the soil is still 3°, and at 2 feet deep 4° warmer than the September averages for these depths. Rain has fallen on five days this month, but the total measurement amounts to less than half an inch. No rain-water at all has come through either of the percolation gauges since the end of August. On the 6th and 12th the atmosphere was extremely calm, the mean rate of movement of the air at 30 feet above the ground being on each of these days less than a mile an hour, and with one exception less than in any September of which I have here any record.—E. M., *Berkhamsted*.

NOTES OF THE WEEK.

Aster Mrs. W. Peters.—Among the earlier Michaelmas Daisies this pretty white kind may certainly figure as one of the most free-flowering. It is scarcely a pure white kind, which is, perhaps, a gain rather than the reverse, as the heads of flowers would retain the amuts when in the open, and so quickly render them unsightly. As a pot plant it is a useful kind, and free-flowering and compact withal.

Zauschneria californica splendens.—Few of the late summer rock plants are more showy than this when covered with an almost endless number of orange-vermilion flowers. The plant is, perhaps, somewhat more hirsute than the type, but this in no wise detracts from its general good qualities, and when established it is among the showiest occupants of the rock garden, free-flowering and beautiful withal.

Hibiscus californicus.—We send you flowers of this from a plant that has been growing in the open ground in our nursery for three or four years without protection. It is scented like the *Magnolia grandiflora* when growing. The plant has ten shoots, each with two expanded blooms and about twenty buds to each shoot. The leaf is of a light green colour, hairy, toothed, and divided into three lobes.—KELWAY AND SONS.

Montbretia Rayon d'Or.—Among the modern varieties of this group, few, if any, have given such general satisfaction as this beautiful and well-marked kind. The flowers are considerably larger than in the majority of kinds and possess more substance, with a rich, deep tone of colour, which is also very full and well set off by the fine ring of carmine near the base internally. The growth is strong and sturdy, and the variety is one of considerable value for the garden.

Dahlia Red Rover.—This is the name of an exceptionally large Cactus kind. It is more than likely that it is too large, yet the award just made to it would appear a confirmation on the side of size. It should, however, in fairness be said that it is not a rough, if a large flower. At the same time a stand of half a dozen of its blooms would be altogether disproportionate when side by side with other good kinds. It is a self-coloured flower of a crimson-scarlet hue.

Dahlia Mrs. J. J. Crowe.—There are some good yellow Cactus Dahlias in cultivation at the present time, but there is room for this kind, which is quite distinct. Its two shades of yellow are extremely soft and pleasing, and this, coupled with the elegant, long and finely recurving florets, renders it at a glance a really beautiful as well as an artistic flower. The variety occurred in at least two stands at the Drill Hall the other day, and in each the same fine form was noticeable.

Tufted Pansy White Beauty.—Although sent out as recently as the spring of the present year, sufficient has been seen of this beautiful bedding sort to convince one of its excellent merits. The growth of the plant is somewhat unique in its dwarf and creeping-like style of covering the ground with a peculiar bright tint of green. Contrasted with this, the pure white rayless blossoms on stout erect foot-stalks stamp this variety as an ideal one for massing in beds and borders.—D. B.

Tufted Pansy Endymion.—This is a variety which was distributed two years ago, and although highly prized by some because of the large size of its blossoms and also the robust character of its growth, left much to be desired. Early in July last a batch of plants of this variety was cut back, and so satisfactory has been its progress since, that there is now a charming display of blossoms of a most refined kind. The colour is best described as soft clear yellow. The

prospect of a late display of these welcome blossoms is now very bright indeed.

Aster Shorti.—This is one of the prettiest of the early perennial Asters, and this season with me is in much better condition than has been the case for the last two years. Recent rains and cooler weather have contributed much to the plant's well-being, long graceful sprays, each carrying a large number of rather small bluish lilac blossoms, characterising the display. At the moment of writing, this variety is one of the most pleasing sorts in the collection of a goodly number of plants.—D. B. C.

Hibiscus Manihot.—The exquisitely yellow shaded blossoms of this plant render it a most desirable object in the flower garden where a good soil is at hand, so that a free growth is thereby ensured. The shade of colour comes perhaps between lemon-yellow and primrose, and the fine flowers being quite 4 inches across when open make it quite a conspicuous object at the present time. For mingling with other plants in a bed or as one of a group of foliage and flowering things this subject is worthy of note.

Tufted Pansy Florizel.—Whatever may have been said regarding the good qualities of this variety is fully deserved. Right throughout the flowering season this kind has been most consistent in the useful character of its display, and now that cooler weather and other conditions of our climate are contributing so much to its well-being the flowers are among the most interesting. The plants are flowering profusely, and the colour is a lovely shade of lilac-lavender. The stiff footstalk also ensures the blossoms being seen.—C.

Aster Novi-Belgii Parker nanus.—This variety is a distinct gain to the Michaelmas Daisies, and speaks well for the quality of the seedlings raised at Framfield by Mr. Norman Davis. It is said to be a seedling from Robert Parker, flowering considerably earlier than that variety. Unlike the parent plant, the height is not more than 2 feet, and the habit is beautifully branching, yet compact. The blossoms are large, and each one is produced on a short footstalk, and as a whole the character of the plant is unique and pleasing.—C.

Chrysanthemum Piercy's Seedling.—Although one of the oldest of the early-flowering pompon varieties, and a legacy from the late Mr. W. Piercy, this is one of the most valuable sorts for bedding. At Waterlow Park several grand masses are now to be seen in the pink of condition. The plant is bushy and dwarf and wonderfully profuse in its display, the colour of the blossoms being a striking orange-bronze, passing to yellow with age. The season of flowering is rather later this year than usual. The constitution is robust.—D. B. C.

Asters: Some sorts which have failed.—While some varieties appear to be doing very well just now, others have suffered so much by the great heat of the past summer that the prospect of anything like a satisfactory display seems to be very remote. In a favourable situation there may be nothing to complain about, but in positions which are exposed to the sun's influence the result is disappointing. Varieties looking in poor condition are *A. cordifolius elegans*, *cordifolius Diana*, *vimineus* and *ericoides*. The lower foliage of many other sorts also is quite seared, and gives the plants an unsatisfactory appearance.—D. B.

Grouping Japanese plants.—Japanese plants produce a very pretty effect when grouped together, but are very seldom seen in practice, or at least not to any appreciable extent. Quite recently we noted an arrangement in a private garden, where the pretty forms of the Japanese Maples were associated freely with some of the best of Lilies, viz., *L. speciosum Krætzleri* and the more gorgeously coloured *L. auratum*. Happily, too, the latter had not predominated in this case, and by using it in moderation, neither its splendour nor its powerful fragrance were felt to be conspicuous. Moreover, the copper and bronze tones of the Acers with the Lilies above made both a pretty and effective bed and a good garden picture.

Primula floribunda Isabellina.—This variety of *P. floribunda* is at present growing well in the conservatory at Southwick, N.B., one of the country houses of Sir M. J. McTaggart Stewart, Bart., M.P. The flowers of this are what is known as the grandiflora type of this *Primula*, and the soft yellow colour is well indicated by the variety named *Isabellina*. Mr. J. Blacklock, the head gardener, grows a few novelties every year to give the variety so welcome in a garden.—S. A.

Retinospora obtusa aurea Crippsi.—Compared with the much denser *R. obtusa aurea*, the

plant named above is graceful and elegant without the shortened branches of the old form that possess a certain restricted growth. The new plant is said to retain the golden hue throughout the year, always somewhat brighter, of course, in the early summer when growth is renewed. One of the best all-round golden conifers is the Lawson's Golden Cypress, but even this is surpassed by the plant which the floral committee honoured the other day with a first-class certificate.

The Parsley-leaved Bramble.—One is pleased to meet with this Blackberry now and again in good gardens. A few days ago I came upon a good bed of it in Terragles Gardens, Dumfries, where it is valued for its free-fruited and ripening qualities. It is in these respects much more reliable than some of the American Brambles, which were the cause of so much disappointment to many some years ago. When such sorts as *Wilson Jun.* were introduced I was much interested in them, but their behaviour in most northern gardens has not been such as to give one much confidence in them. They usually ripen too late to be of any use. Those who care to try them should give them a very sunny position.—S. ARNOTT, *Carsethorn, Dumfries, N.B.*

Chrysanthemum maximum Triumph.—There seems no end to the raising of new varieties of *Chrysanthemum maximum*. It is almost hopeless to expect to see and test the numerous seedlings now being sent out under different names. We have several pretty varieties with lacinated petals, of which *Elaine* was one of the earliest, besides several whose special worth consists in the breadth of their petals and the large size of their flowers. I saw the other day a young plant of one bearing the rather high-sounding name of *Triumph*. It looks a promising variety, its special qualities, so far as could be discovered, being the purity of its white flowers and the freedom from stiffness which characterises them. One drawback to the beauty of these *Chrysanthemums* or *Ox-eye Daisies* is due to the flies, which appear to have a special liking for them, and which in most seasons soon spot the blooms and make them unsightly.—S. ARNOTT.

Lilium speciosum album novum.—There is no white variety of *Lilium speciosum* that can equal this. The flowers are much more solid in appearance than the ordinary white form known as *L. s. Krætzleri*, and being much less reflexed, present a greater display when planted *en masse*. It is also possibly a stronger grower, the distinct foliage having a more leathery touch and the stems being very vigorous. In the bud state greater purity of tone may be observed. A well-marked feature of the plant, however, is the yellow or golden hue of the pollen masses, and even these usually are of a more vigorous turn than the dark brown form. As to its earliness to flower, it sometimes precedes those known as *Krætzleri* by a few hours, but not always; indeed, in a large group the whole of which were planted together some of the older kinds were earliest to expand. *Album novum* was finely shown by Mr. Wallace, of Colchester, on Tuesday at the Drill Hall.

Begonias at Kirkcannel, N.B.—Although hardy flowers form the special feature at Kirkcannel, Newabbey, N.B., it is not to be supposed that other things are not grown well also. For a few years *Begonias* have been taken in hand, and this year Mr. John Harper, Mrs. Maxwell-Witham's gardener, has been remarkably successful. No doubt some of the credit is due to the raisers of the fine *Begonias* grown, but only proper cultivation would give such results. Nothing has been exhibited from Kirkcannel this year, but one is safe in saying that the *Begonias* would take a high place in keen competition. The plants are remarkably vigorous, and leaves and flowers alike show that the secret of good cultivation has been found. Both single and double flowers are grown. Among the latter I noted *Conqueror*, a double salmon of great size and substance; *Avalanche*, a wonderfully beautiful flower of an exquisite white and blush; and a

lemon-coloured one named Mrs. Jenkins.—S. ARNOTT.

Tritonia imperialis in S.W. Scotland.—The manner in which the *Montbretias* thrive and increase in the south-west of Scotland has given rise to an effort to grow the magnificent *Tritonia imperialis* as an outdoor hardy flower. It is to be hoped that the attempt to establish it will be successful. This *Tritonia* is, however, as yet too expensive to run much risk with, and, so far as one can ascertain, those who have tried it in the open have deemed it prudent to give it some covering by way of protection. With this it appears probable that there are many gardens, not only in the south-west, but also along the west of Scotland in which it would be an acquisition. One of the gardens in which it is proving very satisfactory is that of Mrs. Maxwell-Witham, of Kirkcannel, Dumfries. There was a nice clump in full bloom the other day. Those who know this *Tritonia* will be able to realise how pretty the dozen or more spikes looked. The protection afforded was that of about a foot of cocoa-nut fibre placed over the soil in late autumn and removed in early spring. The *Tritonia* is showing a tendency to increase at the root. One of the young plants which was coming into bloom was about a foot from the main clump, and I suggested to Mr. Harper, the head gardener, that it would be worth while to test the plant's hardiness by leaving this one uncovered.—S. ARNOTT.

Pentstemons at Kirkcannel, N.B.—A dry season, such as this has been, is not very favourable to the full development of florists' flowers. Perhaps *Phloxes*, which naturally like a good deal of moisture, have suffered as much as any. *Pentstemons* have also been much the worse for the drought, and in many gardens, despite every care, have done badly. The fine collection at Mrs. Maxwell-Witham's was, however, in capital condition the other day when I had the pleasure of seeing it. The first spikes thrown up were quite spoiled by the dry weather and bright sun, but these were removed, and those which followed are now a grand sight indeed. The spikes are a little shorter than usual, but the individual flowers are as large as they are in ordinary seasons. It is quite a treat to see a collection such as this, which contains what one may call the *élite* of newest florists' varieties. Where there are so many of equal worth it is superfluous to single out individual flowers by name. With the *Pentstemon*, as with the *Antirrhinum* and some other flowers, the strains of seeds have been so much improved, that the time is approaching when few will care to grow named varieties. The old type of flower with its narrow tube has been superseded by the new varieties with open throat, nearly as large as a *Gloxinia* and beautifully marked. At Kirkcannel there are several large beds and in the sun they were most magnificent. They are principally from *Forbes'* and *Irvine's* strain.—S. A.

Dr. S. P. Budd died, we regret to hear, recently. He was one of the most successful private *Rose* growers in the west of England.

Names of plants.—*Randolph Symons.*—You did not number your plants, and therefore we could not indicate their names.—*L. C. Foster.*—*Lycium barbatum.*—*B.*—*Bignonia (Tecoma) radicans.*—*A. E. W.*—1, *Kerria japonica fl.-pl.*; 2, *Eleagnus sp.*; 3, *Erythrina crista-galli*; 4, *Skimmia oblata*. *Crotons* being so variable in leafage are very difficult to name with absolute certainty, but the specimens sent appear to be as below: 1, *Baronne James de Rothschild*; 2, *picturatus*; 3, *Schomburgkianus*; 4, *Chelonii*; 5, *Youngi*; 6, *Lady Zetland.*—*G. H. B.*—Your flower is *Dendrobium bigibbum*.

"The English Flower Garden."—*Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d. Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.*

ORCHARD AND FRUIT GARDEN.

THE CHERRIES.

NEXT to Strawberries, Cherries at midsummer are the popular fruit, only, as in the case of the Strawberry, those who do not possess a garden do not know what a real ripe Cherry is like. They are usually gathered before they are ripe and are fleshless and hard. I have often wondered why food inspectors are so ready to drop on the vendors of over-ripe fruit and allow the bad unripe fruit to pass. At the present time, in the provincial towns, they are hawking perfectly green and utterly sour foreign Grapes about the streets at 2d. per lb., and they have apparently a good sale. One of the best Cherries for quality and crop is Knight's Black Heart. There are a number of Black Hearts, but this is the best one. I saw it some years ago dead ripe in June under a glass screen where the ventilation was always on, and the crop was not hurried in any way, and thought I had never tasted a perfect Cherry before. The May Duke Cherry is a well known kind, but why it should be called May Duke when it is at least a second early, coming into the market in July, I cannot imagine. One fruit merchant I know secured a lot of it this season only half-ripe in July. This is a red Cherry, but rather hard unless it is fully ripe and well grown. The White Hearts are also popular, at least in private gardens, but the fine black varieties are most popular for market. On the Rhine, between Frankfort and Bingen, miles of Cherry orchards seem to consist almost wholly of the black kinds of large size, which get ripe there about the middle of June. Bigarrean Napoleon is a White Heart, and said to be one of the best, if not the best, of its kind. All the Cherries are not abundant bearers, and the shy bearers are not worth planting. The Morello Cherry comes under a different category, being fit for preserving only, but a fine fruit for that purpose. It will also grow and bear in any position on a north wall or as a standard.

The culture of the Cherry is simple. It needs lime in the soil, but there are few soils that do not contain enough for its purpose, and I have seen good crops of Cherries in soils supposed to

be almost destitute of lime. The training is simple, especially as a standard. The trees need not be allowed to get crowded with branches, but shortening of the shoots is not necessary. Left alone they become a wreath of fruiting spurs, and there is no fear of the trees getting bare in the centre. I have grown trees that covered a wall about 40 feet by 15 feet in a few years. There is no fear of the Cherry as a wall tree getting thin at the bottom like the Peach. The long wand-like shoots inwardly break regularly their whole length, and if only disbudded and cared for become fruitful their entire length. The extension system should be adopted with all varieties, and a knife should not touch the leading shoots except to maintain balance. In this way a wall 20 feet high may be covered with standards with dwarfs between in about four years, and fruit may be expected the second year.

Root-pruning is really the only kind of pruning the Cherry requires, but it does not require much of that except in heavy soils, and the work should be done at the end of summer or in early autumn so as not to interfere with the next year's crop. It is bad, too late root-pruning that does that. In the fine German Cherry orchards the soil appeared to be sandy and light, and the standard trees were models, standing widely apart with other crops between. The heads of the trees were round and symmetrical on not very tall stems and the branches rather thin, but long and well spurred, the fruit hanging thick from every branch.

J. S. W.

Melon Best of All.—I fear this good Melon, like many others, is likely to be pushed into the background, as I do not now meet with it as frequently as formerly. Probably scarlet and green-fleshed varieties are more popular than the whites, but there are those who are partial to the latter; in fact, do not mind so long as the flavour is rich. For a few years one could scarcely go into a garden where Best of All was not grown. One sometimes wishes there were fewer new Melons, as the rage for novelties has a tendency to push really meritorious older sorts on one side. Best of All is a medium sized, handsomely netted, brilliant yellow Melon, and, given good treatment, a certain cropper. It has taken many first prizes

for flavour in strong competitions, and no variety secures a readier sale.—J. N.

Canker in Melons.—Mr. Burrell's note on canker in Melons is well worth reading; indeed, I have no doubt that many who have hitherto been troubled with canker will be induced to give the system Mr. Burrell recommends a trial. No doubt the theory that Melons the roots of which have free access to fermenting material which forms the bed often become gross before the fruit is sufficiently large to check it is correct, and this is the reason of so many fruits turning yellow when the size of hen's eggs. I have known other gardeners use Seakale or Rhubarb pots for growing Melons, and although, as Mr. Burrell remarks, a good deal of attention is needed in the way of watering and feeding when the crop is swelling, this is well repaid.—N. N.

GRAFTING AND INARCHING GRAPE VINES.

HAVING had considerable experience in grafting and inarching Grape Vines, a list of experiments which have proved successful may be of service to readers of THE GARDEN. One of the first was inarching Madresfield Court on to Bowood Muscat in an early viney where ripe Grapes were expected at the end of May. This stock proved most suitable, growth being vigorous and the bunches large, heavily shouldered, and of first-rate colour and flavour. Madresfield here never cracked, though no special dryness was preserved in the atmosphere, and I am of opinion that to be proof against cracking this fine Grape should be ripe not later than July. A second early viney suits it well. I also grafted Madresfield Court on to Black Hamburgh in a late house, but always had more or less trouble with the berries bursting and decaying wherever they pressed each other. I have found Golden Queen a capital stock for Duke of Buccleuch, and I would advise those who happen to possess a Vine of the former which is not satisfactory to graft it with the Duke. With ordinary care there will be very little spotting or cracking. With me Alwick Seedling, a Grape which does not set well with everyone, seemed well suited with Trebbiano as a stock. The bunches set sufficiently thick to need a good deal of thinning, the only assistance given being a dusting over at noon with a hare's or rabbit's tail. Foster's Seedling is very suitable as a stock for Gros Colmar. This should be noted by those who have failed to colour it on its own roots. The finest berried and

coloured bunches of this noble Grape I have ever seen were on Vines inarched on Foster's. Foster's Seedling usually gives satisfaction on its own roots, but some of the largest bunches I ever grew were on a rod bottle-grafted on to Mrs. Pearson. That delicious Frontignan-flavoured white Grape Royal Vineyard, which many have been unsuccessful with, grew, fruited, and ripened most satisfactorily with me worked on Gros Maroc, setting being accomplished by drawing the dry hand down the bunches in the early part of the day in order to remove the watery globes, and dusting with a rabbit's tale at mid-day. This grafting or inarching one variety on another is often of great advantage where the vineries are small and room cannot be found for individual Vines. Sometimes I have had only a few laterals of another kind, and at others have cut the laterals clean off the parent rod to half its length, those of the grafted rod taking their place. NORFOLK.

PEARS ADOPTED BY THE CONGRÈS POMOLOGIQUE OF FRANCE.

(Continued from p. 175.)

LA CASTELINE (*syn.*, *Castelline*).—Originally obtained in 1835 by M. Florimond Castelain at Etampuis, near Tournay. The fruit is medium-sized, swollen at the base, slightly embossed in contour, the stalk of medium length, slender, curved, set rather obliquely in a narrow, deepish ribbed cavity; the eye large, open, in a wide, shallow depression; the skin rough, pale green, stippled and stained grey, rarely shaded red on the sunny side; the flesh yellowish, delicate, and pleasantly aromatic. A good fruit, maturing October—November. The tree is moderately vigorous and scarcely of average fertility. In cultivation easy to train in all forms, it only makes medium-sized trees. On the natural stock it is more vigorous, but the fruiting is too much retarded.

LA FRANCE.—Originally obtained in 1864 by M. Claude Blaichet, nurseryman, of Vienne (Isère). A fruit of medium or fair size, rounded conical, irregular, much embossed in contour. The stalk is stout, straight, in a deep, wide, and irregular cavity. The eye is medium, compressed, half open, in a narrow, deep, wrinkled and embossed cavity. The skin is green, or sometimes pale yellow, stippled grey, with smooth bronze stains at top, bronzy green on the sunny side. The flesh is white, very melting, and aromatic. A very good fruit, ripening October—November. The tree is vigorous and fertile. In cultivation this variety is suitable for all forms, especially on walls, owing to the profusion of slender branches. Graft on the Quince.

LE BRUN (*syn.*, *Burré le Brun*).—Originally obtained in 1856 by M. Gueniot, of Troyes. It first fruited in 1862. The fruit is of fair size, very long, obtuse near the stalk, lumpy in contour. The stalk is stout, short, of medium length, set straight or obliquely on the surface of the fruit. The eye is medium-sized, half closed in a normal and irregular cavity. The skin is thin, greenish yellow, stippled tawny, stained tawny at the two ends. The flesh is yellowish, firm, luscious, and distinct in flavour. A good fruit, ripening October. The tree is fertile and vigorous. In cultivation this variety is vigorous and hardy on the Quince, but forms very irregular pyramids. The fruit should be gathered before maturity.

LOUISE BONNE D'AVRANCHES (*syns.*, *Bonne Louise*, *Louise Bonne de Jersey*, *Louise Bonne de Longueval*).—Obtained about 1780 by M. de Longueval at Avranches. The fruit is medium or fairly large, long pyriform, obtuse at both ends. The stalk is stout, of medium length, generally set straight and almost flush with the fruit. The eye is medium-sized or small, with erect sepals, set in a regular, shallow and wide cavity. The skin is smooth, tender, green on the shady side, yellow, washed carmine on the sunny side, stippled grey and tawny. The flesh is white, very juicy, distinct in flavour and aromatic. A very good fruit, maturing September

to October. In cultivation this variety is easily trained, fertile on all stocks, and adapted for all forms.

LOUISE BONNE SANNIER.—Originally obtained by M. Sannier, of Rouen. It first fruited in 1868. The fruit is small or medium-sized, pyriform, swelling at the middle. The stalk is of medium strength, long, set rather obliquely. The eye is open, set in a narrow, superficial depression. The skin is delicate, yellowish green, tinged salmon-rose on the sunny side, mottled and stained a little with russet. The flesh is yellowish, melting, and juicy. The fruit ripens October to December. The tree is vigorous and fertile. In cultivation this variety grafted on the Quince is suitable for all forms. On the Pear it would be too slow in fruiting, and its branches would be too close together.

MME. BONNEFOND.—Obtained in 1848 by M. Bonnefond, of Villefranche (Rhône). The fruit is large, rather of calabash shape, the stalk stout, long, curving, set rather obliquely on the point of the fruit: the eye large, closed; the skin delicate, light yellow, tinged green; the flesh white, greenish under the skin, very juicy and delicately aromatic. It is a very good fruit, ripening from the end of November to the end of December. The tree is vigorous on the Quince and very fertile. In cultivation this variety takes naturally the pyramidal form and lends itself to all forms, even standards.

MME. GRÉGOIRE.—Originally obtained in 1860 by M. Grégoire Nelis at Jodoigne (Belgium). It first bore fruit in 1860. The fruit is of medium size, short and rather hollowed out near the stalk. The stalk is stout and fairly long, set almost straight in a fold. The eye is medium sized, closed, in a narrow shallow cavity. The skin is yellowish green, much mottled and streaked with smooth bronze, yellow and marbled and streaked tawny on the sunny side. The flesh is yellowish white, melting, very juicy, with a distinct and very delicate sharpness. It is a good or very good fruit, ripening December—January. The tree is vigorous and fertile. In cultivation this variety naturally takes the pyramidal form and is suitable for all forms.

MME. TREYVE (*syn.*, *Souvenir de Mme. Treyve*).—Originally obtained in 1848 by M. Treyve, of Trevoix (Ain). It first bore fruit in 1858. The fruit is large, regular in contour, the stalk fairly stout, short, swollen at the point of attachment, set almost straight in a slight depression. The eye is fairly large, sometimes irregular and closed, sometimes regular and open, in a wide and rather embossed cavity. The skin is smooth, polished, pale green and yellow, mottled and streaked reddish brown. The flesh is white, richly flavoured, and very agreeably aromatic. A very good fruit, ripening August—September. The tree is of normal vigour on the Quince, of great and sustained fertility. In cultivation it behaves like Williams' Bon Chrétien, is easily trained, and suitable for all forms.

MARGUERITE MARILLAT.—Originally obtained by M. Marillat, of Villeurbanne, near Lyons, in 1874. The fruit is large, sometimes very large, more or less long, rounded on the upper half, somewhat abruptly narrowing and tapering to a point at the base, which terminates in a pronounced spur. The stalk is stout, fleshy, of medium length, curved, set obliquely against the spur. The eye is small, open, in a normal and irregular cavity. The skin is smooth, straw colour, stippled tawny, mottled red on the sunny side. The flesh is yellowish white, melting, and very juicy. A very good fruit, ripening September—October. The tree is of middling vigour and fertile. In cultivation this variety is suitable for all forms of small or middling dimensions. On the Pear it is more vigorous, and almost as early to fruit as on the Quince.

MARIE BENOIST.—Originally obtained in 1853 by M. Auguste Benoist at Brissac (Maine-et-Loire). The fruit is large, broadened and rounded on the eye side, obliquely obtuse near the stalk, which is short or very short, set obliquely towards the point. The eye is medium-sized, open,

in a deep, not very broad cavity. The skin is a light green, almost entirely covered with a warm tawny red, washed red on the sunny side. The flesh is white, melting, very juicy, and aromatic. It is a good fruit, ripening December to February. The tree is moderately vigorous on the Quince, of great and sustained fertility. In cultivation this variety, without having a strong growth, makes good pyramids on the Quince.

MARIE LOUISE DELECOURT (*syns.*, *Marie Louise*, *Marie Louise de Jersey*, *Marie Louise Duquesne*, *Marie Louise Nova*, *Marie Louise Van Mons*, *Van Donkelaar*).—Originally obtained in 1809 by the Abbé Duquesne at Cuesmes, near Mons, Belgium. The fruit is medium-sized, long, swelling above the middle, narrowing at the base. The stalk is stout, set sometimes level with the fruit, sometimes in an embossed cavity. The eye is fairly large, in a normal and regular cavity. The skin is smooth, oily, light yellow and green, stippled and streaked tawny, the flesh white, melting, and very juicy. A very good fruit, ripening October to November. The tree is of normal vigour on the Quince, of great and constant fertility. In cultivation this variety is little adapted to regular forms and prefers a trellis; it behaves well as a standard on the Pear in a sheltered position.

MARIE PARENT (*syns.*, *Ferdinand de Meister*, *Surpasse Meuris*).—Originally propagated by M. Bivort, and identical with Surpasse Meuris obtained by Van Mons before 1818. It is a medium or fair-sized fruit, often irregular in contour. The stalk is slender, of medium length, set almost straight on the point or in a fleshy cavity. The eye is small, irregular, in a shallow, wide, embossed cavity. The skin is thin, golden yellow, shaded orange-red on the sunny side, and streaked and mottled tawny. The flesh is white, melting, rather gritty about the core, very juicy and aromatic. A good fruit, ripening October. The tree is vigorous on the Quince, of good and constant fertility. In cultivation this hardy species is ill adapted for regular forms.

MARTIN SEC (*syns.*, *De St. Martin*, *Martin Sec d'hiver*, *Rousslet d'hiver*).—Of very ancient and unknown origin. The fruit is small or medium, rather narrow at the base. The stalk is slender, long, set straight, or nearly so, on the point. The eye is medium, half open, set in a wide, shallow, embossed cavity. The skin is thin, golden, almost entirely tawny, more or less washed with brownish red on the sunny side. The flesh is yellow, fairly juicy, and highly aromatic. The fruit, which is good raw and very good cooked, ripens December—January, often later. The tree is of normal vigour on the Quince, of great and sustained fertility. In cultivation this variety is easily trained, and especially adapted for standards; it is of little value in dry, high soils.

MESSIRE JEAN (*syns.*, *Chaulis*, *Marion*, *Messire Jean blanc*, *Messire Jean doré*, *Messire Jean gris*, *Monsieur John*).—Of ancient and unknown origin. It is a medium sized fruit. The stalk is of normal stoutness, generally of middling length, set straight on the point or in a small crease. The eye is medium or fairly large, open, in a small cavity. The skin is rough, thick, bronzy green, changing to chamois, washed dull red on the sunny side and slightly mottled tawny. The flesh is yellowish white, crisp, juicy, richly flavoured, aromatic and agreeable. A good fruit raw or cooked, ripening November. The tree is of normal vigour on the Quince and of great and sustained fertility. In cultivation this variety is easily trained and behaves well, especially as a standard. The fruit must be watched, as it has a tendency to fall off.

NOUVELLE FULVIE.—Originally raised by M. G. Nelis, of Jodoigne, Belgium. It first fruited in 1854. The fruit is of fair size, long, pyriform and bumpy. The stalk is fairly stout, moderately long and continues the point of the fruit obliquely. The eye is medium sized, open, in a more or less deep and embossed cavity. The skin is rough, yellow, almost entirely brown, mottled and streaked tawny, stained red on the sunny side.

The flesh is white, melting, very juicy, yellowish and deliciously aromatic. A very good fruit, maturing December—February. The tree is not very vigorous either on the Quince or on the Pear. In cultivation this variety is difficult to train in regular forms. It is best to graft it and train it as an espalier.

OLIVIER DE SERRES.—Originally raised about 1847 by M. Boisbunel, of Rouen. The first fruiting took place in 1851. It is a middling or fair-sized fruit, Apple shaped. The stalk is stout, short, thick at the point of attachment, set in a deep and irregularly embossed cavity. The eye is large, irregular, in a more or less deep and irregularly marked cavity. The skin is delicate, tender, light yellow, much stippled a tawny brown, slightly stained russet. The flesh is white, delicate, very juicy, and deliciously aromatic. A very good fruit, ripening February—March. The tree is fairly vigorous on the Quince and of good and sustained fertility. In cultivation it behaves well, but requires care to keep it in a regular form.

(To be continued.)

PEACHES ON BACK WALLS.

MANY people have an idea that when planting a Peach case the trees do better on the wall than under the roof, but, as a matter of fact, it is surprising how seldom one finds good trees in such positions where the glass is unshaded. It is much better to plant in front, unless this is used for growing Tomatoes or some similar crop thinly upon. To leave the space of say 6 feet between the glass and the trees on the back wall is to court defeat, for the house gets much hotter in summer than is required, no matter how much ventilation is used. A light shade may prevent this to some extent, but I see no advantage whatever in planting on the back wall in preference to the roof. Red spider has always been a bugbear to cultivators who object to planting so that the leaves are close to the glass, but, as a matter of fact, I believe it to be worse in its attacks where the trees are on back walls. The reason, of course, is that the atmosphere is much more difficult to manage than when the trees cover the roof. The intervening space is always dry; whereas the slight shade thrown in spring and the heavier in summer keeps all moist. The only houses in which trees on the back wall are likely to do is in those where they are planted crosswise. This breaks the light from the back wall, but does not cause a heavy shade, while the sun has access to all the border more or less. This is the worst fault of houses arranged in the usual way, either span-roofed or lean-to, with trees on the roof. I am convinced that some cases at least of stone-splitting and other evils may be traced to a deficiency of light to the border. With regard to scalding, the first place it begins in properly ventilated houses is undoubtedly on the back wall. The night moisture there is not so readily dissipated as it is directly under the roof, while the sun pours in on the foliage with full force as soon as it reaches that aspect, and keeps on it for many hours. Another small point: the foliage is usually very hot when syringing is done in the afternoon, and chilled water is not always available, so a sudden check is unavoidable. Again, the water for the most part reaches the upper sides of the leaves, and it is very important that it should reach the under, where insects most congregate. This part is reached much oftener when the trees are on the roof, and this is why the foliage is usually cleaner there; in fact, all my observations of trees in both positions point the one way. H.

Grape Golden Champion.—In proof of the little demand which exists for the above Grape I may mention that a friend of mine who recently planted a Vine had a considerable difficulty in obtaining it, as so few nurserymen now propagate it. My friend used to grow it well in another garden and made up his mind to give it another trial. Could but its evil tendencies be overcome, Golden Champion would probably be

grown by everyone, as, independent of its very handsome appearance, large berries, and fine colour, it is really a good eating Grape, the flavour and texture being such as to suit most palates. When living near Birmingham many years ago I was accustomed to see it exhibited in splendid condition by a gardener living near Edgbaston. I have never since seen it so perfect in every way. When well grown and free from spot and blemish Golden Champion is indeed a noble Grape.—J. C.

Late Apples falling.—Please tell me what to do with my winter Apples. Bramley's, Rymer, &c., &c., are dropping from the trees without wind, I suppose in consequence of dryness at the root. Will they fail to keep if I pick them now? Of course windfalls soon spoil. I usually gather in October.—J. H. W. THOMAS.

* * The trouble you refer to is one that is much felt at the present moment in many gardens. If you gather late Apples now there is a great danger of their shrivelling, and if you do not gather you lose a goodly portion of the crop. Such kinds as you mention are best gathered next month. You may gather small portions of the best kinds to prevent dropping, and by so doing lighten your trees. These fruits could be used first, but they should have the coolest storage possible, and by lightening the trees the others will not drop. This is the best plan with trees heavily cropped, and you will by so doing lengthen the season and save many fruits from falling.—Ed.

Exhibition Grapes.—I read that four out of the six varieties of Grapes in the twelve-bunch class at Shrewsbury were of high-class flavour, viz., Muscat of Alexandria, Muscat Hamburg, Black Hamburg, and Mrs. Pince. When a big prize is offered exhibitors must not expect first place with Grapes of the thick-skinned, inferior-flavoured kinds, as quality, size of bunch and berry and general finish being present, is sure to lead. Muscat Hamburg if in good form always takes the eyes of the judges, as they know that, independent of its unsurpassed flavour as a black Grape, it is only in a comparatively few gardens where anything like success is achieved with it. Mrs. Pince, I should think, would hardly be in a thoroughly ripe condition the third week in August, but here, again, good judges are aware that few Grape growers are able to lay a good bloom on to this variety. What these who plant Vines with the hope of exhibiting the produce need impressing on them is that quality, at least in collections of Grapes, is of as much, if not greater, importance than bulk.—J. C.

CORRUGATED IRON FENCE FOR FRUIT TREES.

I HAVE a fence (corrugated iron) with an east aspect, 9 feet high, 35 yards long. I am anxious to know if Plums and Cherries will do on this aspect, and if so, what sorts are best, and should they be cordons or fan-trained trees?—H. D. PALMER.

* * Yes; you may grow fruit trees on the fence named. We would prefer Cherries to Plums, but in your locality we think you have a fairly holding soil, and, if Plums do well in the neighbourhood, you will find them reliable. We think you could with advantage improve the corrugated iron by painting it over with black varnish or paint, as the iron gets so hot in summer and so cold in winter, and the paint prevents injury to the trees. How do you intend to fix your trees to the fence? You cannot nail to the sheet-iron, and, of course, the trees in any form will need supports. What we advise is wooden upright strips an inch thick and 2 inches in width. These should be screwed to the fence and then wires strained to these at a distance of 15 inches apart. The wires if you wish may be closer, but much depends on the kind of trees you grow. We certainly do not advise cordons for either Plums or Cherries. We think these are the worst kind of trees for this mode of training—fer this reason, that unless young wood is laid in annually there is a poor crop of fruit, and this refers more to the

Plums than Cherries. Both fruit better when new wood can be laid in each season. Pears do well as cordons, also Apples. Plums need more room, or what is termed extension. Fan-trained Plums need much room, so that with your space you would not have room for many. For varieties we would advise Rivers' Stint, Czar, Victoria, Jefferson, and Coe's Golden Drop. There is no lack of very good Cherries, and most of them will give a good return grown thus. You could with advantage grow an upright cordon between two fan-trained trees, and the same with your Plums. This would fill every bit of wall space and also give you an idea which would be the best croppers. You may grow a cordon Pear between each set of fan-trained trees. The following are good Cherries grown in any form: Early Rivers, a fine black variety; Frogmore Bigarreau, a reddish yellow fruit; Governor Wood, a very reliable fruiter, with Napoleon Bigarreau, Black Tartarian, Late Duke, and the St. Margaret for late use. Plant early in November and not too deeply.—Ed.

EXHIBITING FRUIT.

THERE can be no doubt that well-grown fruit always commands a greater share of attention at the hands of the public than any other part of a show. It is to be regretted that in so many cases very little trouble is taken to stage it in an attractive form. Grapes are among the most badly treated of fruits in this respect, and dozens of boards in long rows with their bunches hanging quite destitute of a vestige of leaf is not the best that can be arranged. It is on a par with the boxes of Chrysanthemum blooms, especially of the incurved kinds, that so often disfigure our autumn shows. Good fruit is so much more attractive in itself than the flowers referred to, that the mode of showing it is left to go on without protest, while in the case of the Chrysanthemums, exhibitors seem to be waking up to the fact that there is a more excellent way than that so long in vogue. In the collections of fruit, again, we get usually a couple of Grape boards at the back, a Pine and Melon possibly, the former often stuck into an inverted flower-pot covered with white paper, and the other fruits stuck about on plates. Nothing is done to make the whole attractive as a rule, while in such cases as the prizes for dessert tables at Shrewsbury the vases of flowers, small plants, and other accessories make too much of themselves, so to speak, and from a visitor's point of view the fruit takes a secondary place, and the individual dishes are packed up, each Peach and Nectarine exactly upright and looking as though turned out of a mould.

There are many better ways of showing fruit than these, and it would be well if the managers of shows would offer their fruit prizes contingent on collections being shown without papered Grape boards and dishes, leaving it to the exhibitors to arrange them as they thought best. Carefully carried, the Grapes could either be laid flat on a suitable base of leaves or suspended from stands, the latter being covered with Vine foliage, and where possible some of the wood of the Vine should be used. A little more trouble would be involved, of course, but the station each exhibitor has to fill could be worked out beforehand, the size, of course, being the same in every case and distinctly mentioned in the schedule. Any fruits from which wood and leaves can easily be spared should be always shown with their own foliage, and well-coloured leaves of Vines or Virginian Creeper with trailing pieces of Bryony or Ampelopsis Veitchi suggest very pretty effects. Wood wool could be used for making an undulating surface for the various fruits to rest on, and these could be displayed something in the

way they grow, not piled up like heaps of cannon balls. Figs often look messy when shown in a heap, but laid thinly at intervals, with trails of Bryony about them and green Vine or Fig leaves underneath, they have a much fresher look. I hope exhibitors will forgive me for mentioning anything that will add to the burden of show day.
H.

CUTTING BACK NEWLY-PLANTED RASPBERRIES.

FROM experience I am convinced that the practice of cutting back newly-planted Raspberries close to the ground is a wrong one, more especially when the canes are received from a nursery in a semi-dried condition. Many old gardeners used to leave about 2 feet of last year's cane when planting, and I believe if this were always done fewer failures would be heard of. It is also necessary, and particularly after a dry autumn, to well soak all purchased stock the roots of which are at all dry, as if planted in that condition they often go from bad to worse before rain comes, and either fail to start into growth or make weak, puny canes the following season. Instead of say a 2-foot length being prejudicial to a good and vigorous start the next spring, it really encourages it, as the eyes starting into growth induce root-action. As regards summer pruning, I am at one with "G. W." (p. 176). To those opposed to it I would say, why not cut out the old canes from Raspberries as well as that from Peach trees, the latter now a general practice, as soon as the crop is gathered? Not only does the foliage of the old canes throw off rain from the roots, but also obstructs sun and air, two necessary agents in thoroughly maturing the wood for next year's work. "G. W." mentions crowding even the new canes as a great mistake. Canes so treated may produce a quantity of fruit, but the size and general quality are sure to be inferior, besides which wet plays havoc by inducing rot in the fruit, the foliage where crowded remaining wet for perhaps several days together after heavy rains. Three or four to each stool is a good number, according to the variety grown and the richness of the root-run. Raspberries to grow and produce well must have plenty of moisture, and where liberal mulching in winter or early spring is neglected, partial failure is inevitable should the season prove dry. In limited plantations where watering is practicable, nothing pays better for liberal waterings twice during the growing season with farmyard liquid.
NORFOLK.

THREE GOOD EARLY PEACHES.

"G. W. S." does not agree with "R. K.," a Russian correspondent, in his condemnation of Amsden June, neither do I think anyone will who has given it a fair trial, has forced it gently, and gathered it in the nick of time. But, if I remember rightly, "R. K." asked for the names of a few Peaches that could be thoroughly relied upon to ripen at the end of May or beginning of June, in which case it is not necessary to have recourse to the American varieties at all, as some of the largest and very best-flavoured Peaches may easily be had in a ripe condition by then. Of course, the trees will have to be started sooner than either Amsden June, Waterloo, or Alexander, but very little heat is needed in well-glazed houses during December and January, and the labour is well repaid. For ripening at the date named I would place Early York, Stirling Castle, Early Grosse Mignonne, and Bellegarde in the first rank. I know some complain about the liability of Early York to split just when on the point of ripening, but for some years I had charge of a fine old tree which annually bore immense crops, only a fruit here and there splitting. When in full flower the tree was a perfect picture with its large, delicately-coloured blooms. The fruit is of medium size, thin in the skin, and of delicious flavour. Stirling Castle is one of the most valuable Peaches ever introduced

and unsurpassed for forcing. In an old-fashioned house where the crop was expected to ripen at the end of May I used in trying, sunless seasons to experience some difficulty in securing a good set on some varieties, but with nothing more than a rap of the trellis to disperse the pollen, a capital set was certain on Stirling Castle. Its size, perhaps slightly less than Royal George, together with colour and flavour, is such as to please the most fastidious. Mr. Coleman once said to me Stirling Castle cannot be planted in the wrong place. Early Grosse Mignonne may be relied upon by "R. K." to come in at the date he names, and for all-round good quality would be hard to beat. I have never heard a fault found with this Peach, but planters must be careful to distinguish between this and the old Grosse Mignonne, which, although a splendid Peach, richer, perhaps, than its namesake, is a shy bearer and less suited for early forcing. Bellegarde is a grand forcing Peach, a regular and sure cropper, the individual fruits reaching a good size, which take on a dark, almost black-red colour, and are rich and delicious. Were I planting an early house, Bellegarde would certainly be included. No doubt Hale's Early, which failed to satisfy "R. K.," is a most useful Peach where it is at home, but there are gardens in which it has an annoying habit of casting its fruit.
J. CRAWFORD.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS—SEASONABLE NOTES.

By the end of September it is well to get the plants under glass. This refers more especially to those cultivated for large specimen flowers. If once the buds get damp after they have advanced so that the embryo florets are noticeable the blooms are liable to be damaged. In most seasons a few sorts will be inclined to show colour thus early, and even now at the beginning of the month I have seen some Chrysanthemum blooms intended for exhibition quite advanced. These early blooms I have invariably found the most difficult to open, free from damp spots, and they require considerable care when placed under glass. Later there is not much trouble—that is, if ordinary care be given. Hot sunshine in the day and cool nights have something to do with damping in the case of early flowers, for it is really not yet the season for them, but in the desire to obtain large size a long time must be allowed for development. If, then, blooms are opening now, I would stand the plants so that the flowers are as far as possible from the glass, and also well shade the latter. The doors and ventilators should be open night and day, the roots also kept moist.

In housing the bulk of Chrysanthemum plants the arrangement will be according to the convenience of each grower, and it is astonishing what positions one sees them in at times. Airy span-roofed greenhouses suit the blooms when opening best, because such houses can be kept cool and dry. Often the plants are overcrowded when put under glass. This should be avoided as much as possible. When stood close together in groups for effect the plants soon lose the lower leaves, which must have some detrimental effect on the opening blossoms. I would take away all decaying foliage at the time of housing, and examine each plant as to its freedom from disease. Mildew is usually observed at that time. If so, the parts affected may be dusted with sulphur, and if possible all structures should be fumigated when the plants are all under glass. There is sure to be aphid lurking

about, and this must be destroyed before the flowers are advanced. If left, this pest has a habit of coming in such numbers later when fire-heat is employed that it is not easy then to deal with effectually. The blooms open best with plenty of air and little fire-heat. The latter may be used to dispel moisture, but not for the purpose of forcing the flowers. If so, it is at the expense of colour as well as substance. Shade is necessary, more especially in regard to kinds with white, crimson, and bronze flowers. These appear to damp the most readily. It is in the early part of the day when the mischief is done. The sun is apt to come into contact with the florets whilst they are cool and moist through long hours of darkness; therefore make it a rule to shade Chrysanthemums coming into bloom quite early in the morning. Nothing conduces so much to well-finished blooms as encouraging top roots. This may be done by sprinkling some fertiliser on the surface of the soil during showery weather and by continuing the practice after the plants are under glass. Guard against an over supply; little and often is the safer rule. Why growers should be more liable to overfeed Chrysanthemums than other plants I do not know, but certainly a great many mistakes are made in this direction. Another error is likely to be made just at the time a wealth of fine flowers is looked for—that is, roots are lost through bad watering when under glass. A good soaking must be given when watered at all; not surface moisture only, which deceives the cultivator and causes the lower portion of the ball of earth to become dry; hence loss of valuable feeders.

Recent showers have helped early-flowering kinds, and a fair display of bloom will yet be had. Some of these early kinds make admirable subjects for lifting and placing into pots. The flowers, of course, come cleaner under cover, and the specimens may be employed for greenhouse decoration. Mme. Desgrange and G. Wermig, white and yellow, are two kinds suitable, because they suffer little by the process. Bushy-habited sorts like these produce their roots in an equally bushy way, and a nice ball of earth clings to them. This rule of bushy top growth pertains to all Chrysanthemums that lift well. I have found those of a loose-growing nature useless for the purpose. I plant out a number of all sorts for providing cuttings; some give a capital crop of bloom, too, after being lifted, whilst the majority refuse to open the flowers at all. Harvest Home, Mme. Marie Masse, Flora, Blushing Bride, and the bronze variety, besides the two kinds already named, are the most satisfactory September Chrysanthemums with me this year. Others will follow later, provided early frosts do not spoil them.
H. S.

Chrysanthemum Lady Fitzwygram.—This chaste flower seems likely to find favour as a pure white sort for market work as well as for cutting, judging by the quantity and quality of the blooms now seen in so many florists' windows. It is sturdy and of dwarf habit of growth, capable of developing some ten to a dozen capital blossoms on plants in small pots. In some establishments this season the plants were potted up into 5-inch and 6-inch pots, and afterwards plunged outdoors. These plants made rapid progress, and were quite recently lifted and placed in a cool house with abundant ventilation. For the past few weeks the display of blossoms has been very welcome. Growers of this variety make a mistake in growing it in a manner similar to that followed with Mme. C. Desgrange, and, given such treatment, the result is not so good as when the plants are disbudded to about a dozen flowers.—D. B. C

FLOWER GARDEN.

ANEMONE ALPINA.

THE alpine Windflower is without doubt one of the rarest of all the Windflower family to be seen in British gardens in anything like good established examples 2½ feet high and as much through, yet it is not a difficult plant to cultivate. The real difficulty lies in the establishing and in making good plants of the scraggy material which is from time to time furnished. The collectors of hardy alpine and such plants doubtless find a difficulty in digging up this plant with anything like an adequate amount of root fibres attached to it, and without these it is difficult to succeed in making the plant even live out the first year after having been collected. These small, unsuitable pieces, which in reality are but the crown and the root stumps attached, all the more surely perish if planted at once in the garden soil. No matter whether this is specially prepared or otherwise, the plant will seldom come through its first winter in this country alive. To attain success I know of no better way than by bedding the imported root-stocks in damp cocoa-nut fibre and coal ashes or the first named alone. In both these I have secured a far larger proportion of living plants than when the plants have been put into soil in the garden. To those desirous of establishing this handsome subject in their gardens I would suggest giving an order early in the year for a supply of a dozen or two or more according to their requirements. Not that all may be required, but with a view of establishing at least a few. When the plants arrive, take some cocoa fibre and coal ashes, equal parts, and fill a 3-inch box, inserting the tufts of plants quite firmly in rows in the boxes at a little distance apart. Do not in any way bury the crowns, but rather let them appear well above the surface. Give one good watering to thoroughly soak the whole body of material and afterwards a little once or twice a week. The plants should remain in the boxes all the first winter, placing them together and surrounding with ashes in a good open position. If a large number of plants are received it will be best to separate into two or more sizes, for the largest pieces are the most likely to perish if unaccompanied by fibrous roots. These latter, indeed, are best treated at once as root cuttings, placing them in a close, warm and shady position in the greenhouse. It will, however, be best to take away the top if this at all shows signs of decay, which will if left only follow downward to the root itself. Insert these root pieces again either in boxes or pots in the same material as above suggested. It is the medium-sized plants with a few root fibres that will be more likely to grow and succeed in our gardens, and this irrespective of soil. A very good plant of this handsome Windflower was among the good things brought to the recent Temple show. This had something like a dozen flowers upon it. The finest example I have ever seen, however, was growing in the specimen border at Hale Farm Nurseries, Tottenham, nearly twenty years ago. This must have been fully 2½ feet high and quite as much in diameter while teeming with its handsome flowers. Of course such a specimen must have been some years in the position, for the tuft alone was a giant, to say nothing of its development in full growth. As a rule, however, the most we see of this fine hardy plant is a small scrap in a 3-inch pot with a single flower or so, though occasionally plants of this and the sulphur form may be seen with two or three.

To those who can afford to wait, the raising of seedlings is a good way, perhaps the best way, to secure vigour, and if freshly gathered seeds were sent home by those visiting the mountain pastures where this plant luxuriates, much less difficulty would be found in obtaining supplies. The seeds may be sown—indeed are best sown—early in autumn quite thinly in drills in the open and in well prepared soil. Equal parts of loam and leaf soil, with a fourth of finely sifted and old manure, with plenty of grit, will do well. Select a rather sheltered place where the seed bed will not suffer extremes of dryness, and with the same object when the seedlings appear place a few boughs over the bed. Many seedlings will appear in the spring following, and these when eighteen months old should be transplanted to a permanent bed, given at least 2 feet of soil of a similar character, though rougher and it may be richer. Abundance of root moisture for the growing season must be secured to these lovely alpine to ensure in so far as is possible the great mantle of ever-melting snow that in their mountain home keeps them at all times

principal cultural details to be observed in order to ensure tall, well furnished stems and brilliant flowers. A good effect is produced by mixing them with white Honesty.—N.

Nicotiana sylvestris.—This handsome Tobacco is mentioned at p. 194 of THE GARDEN, but I think its full value has as yet hardly been ascertained by the writer of the notes referred to. In my own opinion, both for foliage and flower this recent introduction surpasses all others. It is handsome in its foliage and also one of the grandest flowering members of its race. Quite recently I saw it in splendid condition at Gunnersbury House, where Mr. Hudson has a line some 70 feet in length, the plants being in prime condition and forming quite a sheet of white flowers. The foliage is of great proportions, and the plants naturally break into several strong sheets from the ground level. This is so conspicuous and so helpful to the plant where grouping for effect is the chief aim, that I wondered whether all the stems had sprung from a solitary seed. Indeed, it occurred to me that two or possibly three small plants, having been pricked off together in one pot, had been thus transferred to the ground without mere ado. I found, however, that all the plants were solitary examples, and as such bedded out in their present places. Now there are perhaps an average half-dozen stems to each. The long tubular white flowers, which droop slightly in the daytime, but do not close, as in some other species, appear in the greatest profusion. To this testimony of its worth may be added the fact that the Gunnersbury plants are about 6 feet high. Easily grown, yet enjoying liberal treatment, it is obviously a plant that will be grown extensively in the near future.—E. J.

Anemone alpina. From a photograph sent by Miss White, Dublin.

cool at the root. It is in this respect that we fail with many of the choicest—albeit they are often the dwarfest—of the genus of alpine regions. A good plant of this alpine Windflower is given in the illustration. Internally the flower is white, and externally it is covered with a silken down of an azure-blue tone. This and the larger and more deeply cut leaves render it distinct from all else in the Windflower family. E. J.

Physalis Franchetti and *P. Alkekengi*.—Both these are very useful in their way, but *P. Franchetti*, though bearing larger flowers, is not so deep red in colour. Too frequently these winter Cherries are grown too thickly, which is one of the very worst things in connection with their culture. Crowded growth prevents the ingress of light and air; the lower portions of the stems are consequently bare of flowers, or the berries that do set either rot away through excess of moisture or fail to colour well. A good loamy soil of fair depth, plenty of room between the individual plants, restricting the number of shoots to some four, or at the most five, on each plant, liberal mulching and abundant moisture are the

below ground, so that a fairly deep border must be made for it, unless such a one exists in the natural soil. I remember seeing a number of bulbous plants of this class in Canon Ellacombe's fine garden at Bitton, near Bristol, some years ago, and I should think that the deep loamy soil of the neighbourhood there had something to do with their success, while the sheltered position was also doubtless in their favour. *C. Powellii* is equally useful as a fine greenhouse subject; in fact, the *Crinums* as a whole are sadly neglected, and if offered for sale, as they sometimes are, they seldom fetch anything like a fair price. I saw a very pretty *Crinum* recently with Mr. H. Rider Haggard, at Ditchingham Hall, Norfolk, an unnamed plant that he received from the Cape, and there are many more equally good. But these with a sheltered garden and good deep soil may get beautiful effects by their use outside.—H. R.

Varieties of *Lilium Humboldtii*.—I have in THE GARDEN several times called attention to the marked difference in the behaviour in cultivation of the varieties of *Lilium Humboldtii*, and my experience in my Lyons Valley Lily garden this season only emphasises my opinion. The conditions in my garden in the mountains seem to suit all Pacific coast Lilies, and I may say all other

Lilies that I have so far tried. This year I had three lots in parallel rows, a thousand or so of each. Soil and situation were as nearly as possible identical, and healthy bulbs of various sizes were planted. The typical *L. Humboldtii* collected in the northern and central portion of the Sierra Nevada Mountains was planted in November last. A little later *L. Bloomerianum* or *L. Humboldtii* var. *ocellatum* went into the ground, and in December a lot of *L. Humboldtii* var. *magnificum* of all sizes, from 4 inches to 10 inches in circumference, was planted. From the typical *L. Humboldtii* I had not one bloom, and I can say further that of fully 3000 planted last autumn and winter not one flowered. *L. Humboldtii* var. *ocellatum* is a dwarf variety, seldom over 2 feet high, with circles of red around the dark spots on perianth. The bulb is very small. It flowered very well; probably 40 per cent. were in bloom by July 5. Of the *L. Humboldtii* var. *magnificum* fully 90 per cent. flowered. The stalks were stout, perfectly healthy, 3 feet to 6 feet high, and as many as twenty-five flowers to the stalk. In another part of my garden there were rows containing 2000 *L. Humboldtii* type, very fine bulbs, planted in the autumn of 1897. These flowered splendidly, but did not produce any greater percentage of bloom than strong plants of var. *magnificum* planted in March last.—C. PURDY, Ukiah, California.

TUFTED PANSIES.

PROPAGATION BY CUTTINGS FOR SPRING PLANTING.

THROUGHOUT September and October propagation of the Tufted Pansy may be carried on with every prospect of success. At this season, therefore, readers should be busy making preparations for the insertion of cuttings of a desirable kind, and these are obtained on plants which were cut back a few weeks since and are now 2 inches to 3 inches in length and nicely short-jointed. Any reader who has seen the display that a few massed plants are capable of making will at once appreciate the array of colour which a larger number of plants will produce, especially if a wise choice of colours be made. Although recent summers have been exceedingly hot and dry, and the display made by the Tufted Pansies has been more difficult to retain, this fact should not discourage prospective growers. A little more than ordinary thoughtfulness in the selection of a suitable position for the Pansies is amply repaid by the display they will make. There are very few subjects, especially of a hardy character, that can compare with the Tufted Pansy, both for its long and continuous blossoming propensity as well as the charming variety in which this beautiful flower is now obtainable. The Tufted Pansy may be kept in a healthy condition, and in the autumn each plant will give numerous cuttings by which the different varieties may be perpetuated if they are planted in garden soil which has been deeply dug and well manured in the winter or early spring. If, in addition, the soil is constantly stirred by the frequent use of the Dutch hoe, and a good mulching with some light gritty material given during June, the display is pretty certain to exceed the grower's expectations. During long periods of drought an occasional watering, and this of a copious character, may be applied with advantage.

At this season the cutting bed or cold frame should be placed in a warmer position in the garden than that selected for the earlier propagation. A southern or south-western aspect is the best position for autumn propagation, as then the frames obtain whatever influence the sun may impart. In very open, cold and bleak situations the use of cold frames offers many advantages. The Pansy will root in almost any soil, so hardy is its constitution, but the rooting process is much more readily accomplished if a nice depth of light gritty material be made up for the purpose. Place in the frame, to the depth of say 6 inches, loam, leaf-soil and sand in equal proportions, thoroughly mixed, after being passed through a

sieve with a half-inch mesh. This should be carefully levelled all over and slightly firmed by placing boards over the surface, gently pressing these before removing. Some few hours before the cuttings are to be inserted, the soil in the frames should be thoroughly watered by the aid of a fine-roset can. Left thus for a few hours the soil comprising the cutting bed becomes nicely moistened and the work of propagation may then be carried out easily and expeditiously. It may be impossible for some readers to obtain the ingredients for the cutting bed as laid down above, and on this account they may be deterred from taking the Pansies in hand. By the addition of coarse road grit or sand to the ordinary garden soil, however, the cuttings will be found to root readily enough for most purposes. If in addition to the last-mentioned soil the siftings of the potting shed accumulations may be added, a satisfactory mixture may be made. Cuttings should be made about 2½ inches long, and these should be sturdy, short-jointed, and free from insect pests. Clean, healthy cuttings root very quickly during the cool weather. To make a cutting, the stem should be cut through with a sharp knife immediately below a joint, and the leaf adhering to the latter carefully trimmed off. The cutting is then ready to be inserted. These should be dibbled into holes about 2 inches apart, and nicely firmed at the base by a gentle pressure. They also should be inserted in rows about 3 inches apart, this affording ample space to lift them with balls of earth when bedding out in the spring. When commencing, first place the label at the head of the row, and repeat this as each variety is taken in hand; thus confusion of names and varieties is avoided when planting out. It is useless to insert stem cuttings. These rarely root satisfactorily, and even when they do, the plants lack the vigour which cuttings of recent growth invariably produce. Should warm weather unexpectedly prevail, the cuttings must be shaded by the use of tiffany, &c., removing this in the late afternoons. I do not advocate keeping the frames close, as it should be the aim of the grower to accord it hardy treatment. The cuttings may be sprinkled overhead occasionally to freshen them, and the soil between the rows also stirred from time to time.

D. B. CRANE.

Violet California.—Violets seem to be one of the specialties in the gardens at Terregles, Dumfries, N.B., and Mr. Mackinnon, the head gardener, grows them well. All were the picture of health, but I was particularly struck with the vigour of California, which is grown in quantity. The flowers are largely used. The plants are lifted and put into frames in October and give flowers over a long period.—S. A.

Tricolor Pelargoniums.—With a few such summers as the present it is very probable that some of the tricolor Pelargoniums would figure more prominently as bedding plants than they have done of late years, for in many instances they have acquired a brilliancy of colouring such as we seldom see. The variety Mrs. Pollock, which thirty years ago attracted so much attention as a bedding plant, still holds its own as one of the best for the purpose, being more robust in constitution than some of those with richer tints. Some of our nurserymen were not slow to take advantage of the craze for these Pelargoniums, the catalogue of a nurseryman for the year 1870 containing no less than seventy names, but the number of distinct varieties is at least doubtful, for the tendency then, as now, was to publish too long a list of names of any popular plants. While many of the richest coloured proved too delicate for bedding purposes, they became popular for exhibition, and classes for both gold- and silver-leaved tricolor Pelargoniums used for years to figure on many schedules. The plants needed very careful treatment, light, air, and sunshine being very necessary to success. To grow these Pelargoniums at their best it is necessary to be careful with the water-pot. During the winter they need a light position and a fairly dry atmo-

sphere, with rather more warmth than the other sections of Pelargoniums. A minimum of 45°, to run up another 10° or so during the day, will suit them well. Plants that are thoroughly established in comparatively small pots will pass the winter in the best condition. As pure air and a good light are very essential to the tricolor-leaved Pelargoniums, it follows that they are not seen at their best in the immediate neighbourhood of London; indeed, the difference in colour between the leaves of such plants and those grown on the open downs of Surrey, Kent, and Sussex is so pronounced, that they might be mistaken for distinct varieties.—H. P.

LILIUM SPECIOSUM.

THIS Lily has, of course, flowered earlier than usual during the present season, and while the blooms have in most cases been well developed, they quickly lost their freshness and dropped, owing to the great heat. The first variety to open with me was *album novum*, a white flower much in the way of the better-known *Kretzeri*, but with bright yellow anthers, while those of *Kretzeri* are brown. The album of the Dutch cultivators—that is, the form with mahogany-coloured bulbs and chocolate-tinted buds—has the flower sometimes slightly tinged with blush. I think this feature has been a little more pronounced than usual during the present season. Of the Japanese importations the variety *Melpomene* holds its own as the most beautiful of all the deep coloured forms, being in richness and depth of colouring much superior to any other. The rounder and more massive leaves, with their depth of colouring, are also characteristic of this variety. The form sold as *rubrum* by the Japanese, which is taller than *Melpomene* and the flowers rather larger, is also much lighter in colour. The leaves, too, are thinner in texture, and are far more liable to die off at the base than those of *Melpomene*. Huge numbers of these varieties imported direct from Japan are sold every year in this country, but those disposed of at the large auction sales cannot always be depended upon to be true to name. The bulk, as a rule, consists of the variety as sold, but with *Melpomene* there is generally a sprinkling of *rubrum*, and the reverse also holds good. A great many may be selected with almost absolute certainty by means of the bulbs, which in *Melpomene* show a much greater tendency to divide up into two or three crowns, and they are also deeper tinted than the other. Intermediate forms, however, crop up among the bulbs, and for these it is necessary to wait till growth commences. The roundish deep-coloured leaves of *Melpomene* are then very different from the long pointed ones of *rubrum*.

H. P.

Awarding certificates to new Dahlias.—I note the remarks of "A. D." (p. 217) in reference to new varieties, and I think with that writer some better method should be adopted by the National Dahlia Society than that which obtains now. In the first place it would be well if the deliberations of those persons selected to award certificates could be done without the public looking on. A looser way than that followed by a large committee of not disinterested persons standing together and voting, as was done at the Crystal Palace, could not well be imagined. Of course, trade growers have excellent chances of knowing individual varieties, but it would be possible to get three, or say five, keen amateur cultivators to do the work in a way that should benefit the general buyer of new kinds. When five certificates are awarded to the same raiser at one time it does appear that improvement is going on at a rapid rate. But at least from past experience I have found no end of disappointments in growing varieties through such having obtained that hall mark of excellence. Like your correspondent, I saw the new kinds, and did not note more than two or three distinct enough to be added to our collections. There are many others, however, who must follow

the records in gardening papers. It is they who will eventually be tired of buying so many new flowers only to find them inferior to the old. New types like Whirlwind, and distinct colours as in Zephyr, are those which want encouraging. Red Rover, too, passed as being over large, is a new variety that will not require a certificate to make it a popular garden plant.—VISITOR.

ROMNEYA COULTERI.

THERE is no more lovely flower in the July garden than this exquisite Californian Bush Poppy. The snowy petals of the large single blossoms, many of them over 6 inches in diameter, with their delicate creases, put one in

west of England and in the south of Ireland, and I have seen it in the best of health as far north as Herefordshire. Perhaps the most suitable situation that can be chosen for it is one in a deep border backed by a high wall, although it may often be seen doing well in the open border. It also forms handsome specimens when grown in tubs, but as it is most impatient of root-disturbance, great care is necessary in shifting the plants into larger receptacles. Especially is this the case with seedling plants, which often succumb to the operation of potting-on, however carefully this is carried out. For this reason it is well to sow the seeds, which often take a long while to

and often attain a stature of 9 feet or more. Plants that have occupied the same position for two or three years often throw out shoots a yard or more distant from the parent stem.

In severe winters a certain amount of protection is necessary, and it is always advisable to mulch the roots with some light and porous material, such as Pine needles, rough cocconut fibre, or, failing these, ashes. During hard frosts a temporary covering with an Archangel mat will generally afford sufficient protection to preserve the ripened shoots from serious injury, but sappy, autumnal growths from the base of the plant usually succumb to the effects of continued severe weather. Under no circumstances should the plant be closely surrounded with heavy mats, hurdles surfaced with straw or Bracken, or with other materials that have a tendency to become sodden and create a moist and stagnant atmosphere around the specimen, or the foliage will be apt to become a prey to mildew, which will eventually affect the shoots and root-stock and result in the death of the plant. During the severe weather in the early part of 1895 not a few specimens were destroyed, the loss of certain of which was undoubtedly due to the coddling system already referred to. In the summer months the Romneya is benefited by copious supplies of moisture, while occasional applications of weak liquid manure and soot water will be found to promote vigorous growth. Romneya Coulteri may be propagated by root cuttings and layers, though even by these methods its increase is far from easy, while cuttings of the shoots almost invariably refuse to strike, although they will often remain green for a lengthened period.

S. W. F.

LILIUM WALLICHIANUM.

ABOUT five years ago, so far as I can remember, I received a consignment of bulbs from a friend—Captain Grant—in Upper Burmah. Amongst the number there were several good specimens of *Lilium Wallichianum superbum* (see page 187). As it was not then convenient to grow them in a greenhouse, I put these Wallichianum bulbs in a Rhododendron bed and hoped for the best. I remember having a good deal of misgiving about the result, but I could do nothing else. Contrary to expectation, however, in a great degree these Lilies have done splendidly; they have been objects of great admiration and they have shown themselves—at all events in the Isle of Wight—to be hardy enough. I have been away from home so much during the last eighteen months, that I do not know so very much about them. My idea about them has been that there are few Lilies which are so very handsome and at the same time so easy to manage. I have also read with interest what your correspondent “W. J. H.” says about

EREMURUS ELWESI

at Alnwick. He is to be congratulated on his success, but I cannot quite follow him when he speaks of his “being a climate which is unsuitable to it.” If the climate of Alnwick is at all what I imagine it to be, there is no ground for surprise. Eremuri manifestly do well in somewhat cold and bleak places. Their headquarters in England is in the garden of Sir M. Foster near Cambridge—in his hands they are indeed a sight to see—and also they do extremely well with Mr. Carrington Ley in a cold part of Kent. A part of the world which from one point of view does not suit them is the Isle of Wight, and the reason for it is because they are excited into growth far too soon and have but a short time to rest. The only way to obviate this is by deep planting, and I can quite understand that they would like Alnwick better than Ryde. Mr. Hindmarsh seems to be on a level, so far as they are concerned, with Sir Michael Foster and Mr. Carrington Ley.

I notice Mr. Arnott's recommendation of *Leucojum autumnale*, and there is plenty of room

White Bush Poppy (*Romneya Coulteri*).

mind of the finest white crêpe and flutter at the slightest breeze, while their purity is enhanced by the superb bosses of golden stamens from which they radiate. When a large quantity of these striking blossoms is expanded at the same time, as is seen in the accompanying illustration, an effect is produced that will not soon be forgotten. Beautiful as are the flowers, they possess another attraction besides that of loveliness, since they are dowered with a subtle and delicious fragrance, which, added to their refined form and purity of tint, renders them especially acceptable for indoor decoration. The plant generally does well in the south-

germinate—ten months elapsing in one case that came under my notice before any sign of growth appeared—singly in small pots, so that as growth advances they may be shifted on with the ball of roots intact. Even in putting pot plants out into the open bed considerable care has to be exercised not to disturb the roots unnecessarily, lest the plants receive a check that they may take some time to recover, some specimens losing a great proportion of their leaves even where the ball of roots has been left undisturbed. When once thoroughly established in the open ground, however, the plants soon make rapid headway

for it; but I should like to recommend him another *Leucojum* which, in my opinion, throws his favourite into the shade—I refer to *L. roseum*, which is one of the sweetest, daintiest little plants I have ever seen. It blossoms at Ryde in July, and has a most bewitching appearance, which cannot easily be forgotten. I have only seen it once in my life, and the tender pink markings of the little bells are so very striking, it stands quite by itself. I can only express what I mean by saying that I should call *Leucojum autumnale*—very nice though it certainly is—commonplace by its side. But now comes the difficulty. *L. autumnale* is very easy indeed to manage in the Isle of Wight. *L. roseum* I find to be excessively difficult. Though a good deal of care has been lavished upon it, once, and once only, during the last fifteen or sixteen years has it blossomed in my hands—it was soon after I got it—but since then I have not been able to make anything of it, though I believe I still have it in a frame. *Leucojum roseum* stands so very high in my esteem, that I should be immensely obliged to Mr. Arnott, who seems to do many things so well, if he could put me on the right track with regard to it or help me in any way.

H. EWBANK.

CARNATIONS—AUTUMN PLANTING.

I would advocate autumn planting in preference to waiting until spring, unless the layers are potted up and protected by glass during winter. Last year I allowed many of the layers to remain on the old stools and planted in spring. They were severed and every care taken to remove them with a good ball of earth, but neither in the matter of flowering and in the ultimate strength of the grass did these bear comparison with others that were removed in October. I came across an article recently penned by an old florist wherein it is stated that one may mutilate a Carnation as one wishes up to January, but after that time the plant will resent any disturbance at the roots. There is truth in this. In the spring of the present year plants of choice *Picotees* were purchased from the north out of pots, and when they arrived I was delighted with their healthy appearance. After duly potting and nursing the same they absolutely refused to move, but instead gradually went from bad to worse until all have died. With the more hardy kinds there is nothing gained by potting, but I have not seen a locality yet where it is safe to leave the more tender ones, such as yellow ground and white ground *Picotees* and the bizarre Carnations, in the open ground all the winter without risk of spot. This is doubtless caused by damp, and the same danger is with us if we coddle the plants in frames. To have all about them dry during wet weather is what Carnations need. I am sure, however, that, whether for planting or potting, it is best to get the layers rooted early and sever them from the old stocks in autumn.

This summer has been none too favourable for layering. Mine were watered twice a day, but since the welcome showers have come rooting has taken place with great rapidity, and capital young plants are obtained before the autumn is far advanced. Nor has the maggot been noticed. This pest should be watched, for as winter comes upon us there is pretty certain to be some sort of an attack, and it rests with the cultivator whether or no much damage shall be done.

H.

NOTES AND QUESTIONS.—FLOWER.

Canna Alemana.—This new variety is a noble-looking one. It grows tall, throwing long spikes of flower upwards of 6 feet high. The flowers are unusually large for a *Canna* and are circular in form. It is richly coloured, crimson and yellow being well blended. I saw plants of this in bloom arranged here and there among Palms in a conservatory, and most effective they were. This sort should become widely known.—H.

Ranunculus Lyalli.—In regard to Mr. Arnott's note about *Ranunculus Lyalli*, if he has not succeeded with it I am afraid there is little use in some of us

inexperienced growers attempting it. Some years ago I procured a plant and gave it a sheltered and pretty dry place in the border facing south. It never seemed at home, did not flower, and next year was dead. I had not a very good plant to start with, but Mr. Chapman, at East Duddingstone Lodge, had a very good one. It flowered splendidly and seeded also, but next spring was dead too. I twice had seed from New Zealand, but, like other seeds from that country, it refused to germinate. The Lily grows in stony places in its native country, but it must either be an annual or else we have not yet found its proper treatment.—J. L., Hawick, N.B.

ORCHIDS.

LAELIA PUMILA.

This is well known to be a variable kind, but all the varieties are pretty and effective, lasting well in flower and blooming, moreover, at a useful time. Their culture has been attended with a good deal of uncertainty, many experienced growers doing little good with it, while occasionally one came across fine specimens. One of the worst mistakes in the culture of *L. pumila* was, I believe, the placing of the plants in such receptacles that they could never reach the outside of. It is useless to treat such plants as *L. pumila* as if they were *L. purpurata* or *L. elegans*. Their individual wants have to be studied and catered for, and one of the wants of *L. pumila* is a thorough and effective hold upon the home of its adoption, no matter whether this is a piece of Tree Fern stem, a pot, basket, or what not. To obtain this it is necessary in the first place that everything in the way of compost and drainage is thoroughly clean at the beginning. To place a healthy plant in semi-decayed peat is useless. Having, by means of suitably sized receptacles and good compost, given them this hold, they are all right in this respect, and will probably not need serious disturbance at the roots for several years to come.

Then the question of temperature comes in, and I believe it is a mistake to keep *L. pumila* in either a hot or a cool house all the year round. After flowering and finishing its growth it delights in a good rest without a doubt, and then, to give it a start in spring, an appreciable rise in temperature. Say, for instance, the plants during winter were kept in a compartment with the Mexican species of the same genus. As soon as the basal eyes showed signs of swelling, let them be at once removed to where the Brazilian *Cattleyas* and *Laelias* are grown. They will grow rapidly and flower freely, and may be returned to the cooler structure immediately the blossoms are past. Ample light all the year round is of the utmost importance. *L. pumila*, considering its dwarf habit, takes a good deal of water when well established and growing freely, but during the dull, wintry days the less the better if the pseudo-bulbs have been thoroughly ripened by exposure to sun and air. But on no account should shrivelling of the stems or leaves be allowed, as this weakens the plants considerably. I should always advise growers, when commencing the culture of this species, to obtain newly-imported plants if possible, selecting those that have not unduly suffered in transit, but that have green, fresh foliage upon them. The initial vigour of these is very remarkable and is kept up over a long series of years, and thus they are in most cases superior to even the healthiest of established plants. *L. pumila* seldom produces more than one flower on a spike, this in a good form being about 4 inches across, the sepals and petals rosy purple, the lip having a fine maroon or crimson-purple blotch in front and a yellow

throat. It is a native of Brazil, near Santa Caterina, where it grows at considerable altitude, and it first flowered in this country in 1838.

H. R.

Anguloa eburnea.—This is a delightful Orchid and it is not often seen so late in the season as this. I saw a plant in flower last week that was imported last year and flowering for the first time. One blossom only was produced, but this was a magnificent specimen 5 inches across and of the purest white, save for a few reddish bars in the lip which seem to enhance the purity of the sepals and petals. A cool intermediate temperature with ample moisture suits this beautiful New Grenadan kind.—H. R.

Dendrobium Dalhousianum.—This is a very fine *Dendrobium* when well grown, and produces a large number of flowers. Just recently I saw a large old specimen that was flowering for the second time this season, and though, of course, somewhat out of its time in blooming, the growth was going on all right. This is the point where many go wrong with it; they will not allow the plant to finish its growth before attempting to dry it off, as in the case of the smaller deciduous kinds.—H. R.

Pleurothallis Roezli.—Though not a showy plant as Orchids go, *P. Roezli* is an interesting and handsome species, its dusky spikes of deep red-purple flowers, which only open in part, being as showy as most in the genus. It was first discovered by the collector whose name it bears, but it is said that all the living plants he collected "perished miserably." This was about 1874, but it was quite unknown to British growers until 1885. It thrives best in a cool house, such as suits the *Masdevallias*, and should be always moist. Only a very thin surfacing of compost over good drainage is necessary.

Cypripedium grande.—This is an unmistakably fine *Cypripedium*, a hybrid raised from *C. caudatum* and *C. longifolium*, the good points of each of which it possesses. It is of the same vigorous habit and flowers as freely as the latter kind, and its blossoms are equally as beautiful as those of *C. caudatum*—a useful combination, especially when it is considered that the flowers occur over a long season and that too when Orchids are scarce. Its culture does not differ materially from that of *C. caudatum* and it is less likely to decay at the base of the leaves than it. *C. grande* was raised by Messrs. Veitch and Sons and first flowered in 1883.

Peristeria elata.—The likeness to a white dove is so striking in this pretty Orchid, that anyone seeing it for the first time is sure to be interested and attracted thereby. The beaked column aptly represents the head, and the side lobes of the lip the wings. It used to be more popular than now, and was often exhibited at shows in August and September, but now one seldom sees it shown. *P. elata* delights in ample root moisture and a somewhat substantial compost, equal parts of peat, loam fibre, and Sphagnum Moss suiting it well. During winter the roots may be kept drier, and the best time to re-pot is when the young growth is about 3 inches or 4 inches in height.

Oncidium luridum.—This is not a popular species, yet it is difficult to say why, for it is of easy culture and the long, graceful spikes of bloom last a very long time, the individual flowers being very pretty. In grouping with other Orchids, *O. luridum* should not be tied up, but the spikes allowed to hang as gracefully as possible, suspending the centre of each with a fine piece of raffia if necessary. The plant has no pseudo-bulbs, but the thick fleshy leaves doubtless serve the same purpose to some extent, and though not requiring a long season of absolute drought, the roots may with advantage be kept well on the dry side from the time the flowers are past until signs of growth reappear. For compost, a lasting make-up is best, so that it will not be necessary to disturb the roots often. Clean Sphagnum Moss, with a third of peat and

medium-sized pots will suit it. Grow it in the intermediate house, and if possible let the atmosphere be a little dry towards mid-day in late summer and autumn, this consolidating the tissues of the plant and rendering it more free-flowering. There is, perhaps, no more variable species of *Oncidium* than this, some of the forms being almost as deeply coloured as a good *O. Lanceanum*.

ODONTOGLOSSUM LONDESBOROUGHIANUM.

This is by many considered a difficult plant to cultivate, and rightly, for it is seldom seen in really good condition after the first few years in this country. When newly imported it comes away well enough and throws immense flower-spikes from bulbs that increase in size annually for a few years. But there usually comes a time when this comes to a stop, and instead of increasing in size they get smaller annually. The first signs of anything wrong, it may be, will be the ends of the roots from a new bulb refusing to enter the compost, or possibly a growth will go blind and the plant remain at a standstill for a season, only partially recovering itself by back-breaks the next season. Insects may attack it and make matters worse, and the plant soon passes out of a profitable state. The usual impression is that *O. Londesboroughianum* is quite a cool-house plant, but although I have seen it doing well there, I am sure that a temperature similar to that of the *Cattleya* house is much the best—at least for the first few years. After this it may perhaps be longer-lived than other *Odontoglossums*, but I doubt it, as the plant has a lot to do in the season to finish up the large pseudo-bulbs, push up its spikes, and often flower in the middle of winter, when the cool house is not a comfortable place for it.

I recently saw some of the best-grown and strongest plants of it that have ever come under my notice, and I was pleased to see that these were growing as I have often advised, not in a cool, shady house, but high up and close to the roof, where *Cattleyas* and evergreen *Dendrobiums* were their nearest neighbours. The plants were growing in long trellised blocks or rafts with only a small quantity of compost about them, and this naturally suited the rambling habit of the plant. The roots in many places were twisted quite round the rods, and the whole affair was taken down regularly while growing and dipped in a tank, besides being damped occasionally with tepid water. The immense spikes now pushing are ample evidence of the liking that the plant has for this treatment. The flowers of *O. Londesboroughianum* are really more like those of an *Oncidium* than an *Odontoglossum*, and are very prettily marked with brown on a yellow ground. They occur on erect spikes, those on strong plants being a yard in height. It is a native of Mexico, and first flowered with Lord Londesborough in 1876.

H. R.

Dendrobium superbiens.—Good forms of this species are not uncommon, but in addition to these there are many of a washed-out-looking tint that is far from attractive. The flowers occur on loose terminal racemes and are individually about 2 inches across, a pretty rose-purple in colour, which is much intensified on the lip. As in some other *Dendrobiums*, the colour of the flowers on newly-imported plants is often much superior to what shows in later years, and it is rather disappointing to have a fine deeply-coloured form the first year and then to have it dwindle away into mediocrity or worse. Though fairly strong in growth, it is a mistake to treat *D. superbiens* to too much compost, and baskets of small size may be used for it, suspending these at a short distance from the glass.

Galeandra Baueri.—It is late for *Galeandras*, but I noticed a small plant of this in a neighbouring collection during the week. It is a rather low-growing kind with pseudo-bulbs about 1 foot high, from the top of which the flower-spikes

issue. The flowers are pretty, the sepals and petals greenish brown, the outside of the lip white, the front expanded portion purple. Its culture is not difficult if the house wherein it is grown is kept moist, but in a dry house it is sure to be immediately overrun with red spider or thrips. Keep these insects down and a brisk, moist temperature, and there will be little difficulty in growing it well. Drain the pots well, and use a little fibrous loam in the compost. Keep the roots thoroughly moistened while growth is going on, and afterwards, when they have done flowering, remove the plants to a cooler and drier house.

Calanthe veratrifolia.—This is more often seen in old collections of stove and greenhouse plants than in *Orchid* collections proper, but years ago at the summer exhibitions no one ever thought of showing a dozen *Orchids* without including it. And though for size of flower there are many to beat it, yet it is pretty and very free-flowering, added to which it is among the most easily grown kinds in existence. It likes plenty of loam in the compost, and I have noticed some fine growths of it recently where loam, dried cow manure, and coarse silver sand formed the whole of the compost. But for my own part I should prefer loam, peat, and chopped Moss, without the sand, as the growths would be more likely to continue good in this. Ample root moisture is necessary in either case when the roots and growth are active, slackening the supply considerably in winter. The large green leaves are very apt to be attacked by scale, and this must be kept under if good results are wished for. *C. veratrifolia* produces long, vigorous flower-spikes often over a yard in length, the upper part of these covered with small flowers of the purest white. It is a native of various parts of India and Australia.

KITCHEN GARDEN.

GIANT ONIONS.

BEING rather sceptical as to the distinctions found between four of the largest Onion varieties, three of which have been recently put into commerce, I obtained seed of the respective stocks from the recognised sources, and had plants raised during the winter and planted out in a good garden in Surrey. I saw these plants in the summer, when it was too early to note differences, if any existed, but have not yet been able to see the resultant bulbs, and therefore withhold criticisms respecting them for the present. But just recently I have seen some of the varieties growing in two Hampshire gardens under the highest possible form of culture, and therefore feel at liberty to say how these new ones have presented themselves under what may be regarded as the most favourable conditions. It is one of the curiosities of Onion culture in relation to their product for exhibition that four of the most able growers, and certainly of the earliest to produce them, reside in North Hants. These are respectively Mr. Bowerman, of Hackwood Park; Mr. Kneller, of Malshanger; Mr. Pope, of Highclere Castle; and Mr. Lye, of Sydmonton. Other great growers are Mr. Wilkins, of Henstridge, Dorset; Mr. Beckett, of Aldenham House, Herts; and Mr. Fyfe, Lockinge Gardens, Berks, all of whom produce wonderful bulbs. My opportunity to note the newer as well as the older stocks was found a few days since at Highclere and Hackwood, both of which fine gardens I visited expressly to see how the Onion stocks had thriven. Certainly in all cases the bulbs are wonderfully fine this year, the deeply-worked and well-enriched soils furnished enabling the roots to go very deep, and thus obtain ample moisture and food, whilst the surface warmth has helped to develop very solid and fully ripened bulbs. Probably cleaner or firmer bulbs have rarely been seen than the present season furnishes, bull-necked ones being very rare. Everybody now knows how to grow these giant Onions, but it does seem as if the soil cannot be

too deeply worked, for the particular portions of ground set apart for their culture are annually worked to a depth of 3 feet; neither can it well be made too rich. Whatever may be one's estimate of the value of these giant bulbs, some liking them—and they have many uses—and some decrying them, at least it is now conclusively proved that until the higher order of culture was introduced we had no conception of the capacities of Onions to produce fine bulbs. But now that we see them weighing from 3 lbs. to 4 lbs., handsome as bulbs can be, or as solid and substantial as they can be, also when well ripened capital keepers—for bulbs of giant dimensions have been easily kept nine months after being ripe—we can but admit that in no other vegetable has there been made during the past twenty years such cultural strides as there has been with Onions.

Probably the largest of all the varieties now in commerce is *Ne Plus Ultra*. This as I saw it in both the gardens named is a reddish form, and most likely a selection from the famous *Ailsa Craig*. Its redness gives it distinctness, whilst selectors of the true *Ailsa Craig* have rather rejected that coloration. I fear it would be a coarse and worthless Onion in a wet season, as it ripens later than all others and seems rather softer. Indeed, I think it possesses some *Red Tripoli* blood, which is far from being a good thing to get into our Onions. A badly selected stock of *Ailsa Craig* will show this red and somewhat late form, but the best selected stocks, of which there are none in the kingdom superior to the *Hackwood* one, have nut-brown skins and much more evenness and refinement. It is assumed that *Ailsa Craig* originated in a selection from *Cranston's Excelsior*, the bulbs of which when well grown give probably the handsomest globular form produced. But the general stock of *Ailsa Craig* is larger. When first put into commerce, and for several seasons afterwards, beyond having a broadish globular form, the bulbs always displayed a bulge on one side of the base that was a feature of the variety that has, by constant selection from the handsomest, been practically eliminated now, and the variety closely resembles large bulbs of *Excelsior*. But stocks of *Ailsa Craig*, and indeed almost all varieties, except where seed be saved specially from a few select bulbs every year, exhibit so much diversity, that it is easy to select from them three or four that may be regarded as distinct. There are the *Ne Plus Ultra* reds, the true *Ailsa Craig*, the slightly smaller and paler *Excelsior*, and the flattish round *Lord Keeper*, or any other of the score of so-called varieties of this type. That fact shows how great is the need for very keen inspection by the trade of their seed stocks. That some houses do take superhuman trouble in this matter there can be no doubt, but under that or some other local name *Ailsa Craig* is sold everywhere now with results none too satisfactory. Another new Onion put into commerce with glowing description is *Aristocrat*—certainly a very foolish appellation. This, as I saw it grown under the best possible conditions at Hackwood Park and Highclere Castle, where the bulbs ripened rather early, is but a *Lord Keeper*, Banbury Cross, Exhibition, Maincrop, or indeed any other Onion of the flattish, round form, the bulbs not much exceeding 20 ozs. each, if so heavy. Some satisfactory reason should be given for putting into commerce a variety that so far has shown no distinctness. A stock of the *Wildsmith* Onion, a selection from the *White Spanish* made some years ago by Mr. Wildsmith at Heckfield, was at Highclere, as at Chiswick, far too irregular and mixed. In both the Hampshire gardens *Cranston's Excelsior* was good clean stocks. *Lord Keeper* was very good, *Cocoa-nut* rather irregular, and it is certainly an unreliable variety and not at all wanted. Mr. Pope is trying hard to set a stock of his *Tankard*, the bulbs of which have flattish bases and broad shoulders, but Onion-selecting and setting are almost a life-long labour. We see that in such old stocks as *Danver's Yellow*, *James' Keeping*, *Bedfordshire Champion*, and others grown in

many gardens, all of which give 25 per cent. of variations. However, Onions are now big enough in all conscience, and beyond size we may well ask for beauty, solidity, good keeping, finish, and, not least, consistency in them. A. D.

Potato Veitch's Maincrop.—This Potato was, I believe, first introduced to public notice last spring, as I do not remember having heard of it before. I purchased sufficient seed to plant one good long row on purpose to test its merits, and the produce has been lifted within the past few days. In the first place, when the nature of the season is taken into account the crop is a good one, the tubers being quite large enough for table use. In shape they are inclined to be flat and roundish, and have a rough or netted skin. It is a handsome Potato to look at, and, as is generally the case when a Potato has a rough exterior, the flavour is also extremely satisfactory when cooked. The flesh is whitish-yellow and floury without breaking to pieces, and such being the case, I intend growing the variety again another season. As regards its season for use, it is, as its name denotes, a main-crop sort, but the forthcoming winter will decide whether it may not also turn out to be a good late-keeping kind as well.—S. E. P.

Potato Devonian.—During the past few days I have been having a good many Potatoes lifted, and among them the new variety named Devonian, sent out by the Messrs. Veitch, of Chelsea, last spring. But a limited quantity were planted, or only sufficient to ascertain how the variety would succeed here. The result is very satisfactory both as regards crop and quality, for when a sample was cooked the tubers were found to be both tender and floury, and at the same time they do not break to pieces when dished up. Since the introduction of Syon House Prolific I have not tasted a Potato that has pleased me better, and shall accordingly reserve the whole of the stock I possess for planting next season. At present Devonian may be described as a main crop variety, but it may prove a good late keeping kind, which matter has yet to be put to the test. The tubers are medium in size, kidney shaped, with shallow eyes and the haulm is rather tall-growing. Those who have not yet grown it should make a point of doing so another season, when if the results prove as satisfactory as they are here, Devonian, will, I predict, be largely grown in future.—A. WARD.

Potato Syon House Prolific.—A very heavy crop of tubers of this most excellent Potato has been lifted here during the past week from a border facing due east. The haulm was quite green, and lifting would not have been performed for some few weeks to come had it not been found on examination that they had commenced to make fresh growth. Now, considering how dry the soil has become during the past few weeks and the fact that rain has not fallen here in sufficient quantity to moisten the ground for any distance down for a long time now, this is rather remarkable. It can, therefore, only be attributed to the soil having become so heated that the tubers were forced to make second growth without the aid of moisture beyond that contained in themselves. I think they have been caught just in time, but had they been left in the ground but a few weeks longer great numbers of young tubers would have been produced and the original crop spoilt. This would have been unfortunate, as I have grown a sufficient quantity of this sort to last for some considerable time during the winter months. Some other lato varieties have been found to be similarly affected and were at once promptly lifted.—S. E. P.

Tomato Albert Victor.—When looking round the gardens at Longford Hall, near Manchester, quite recently I was agreeably surprised to find a house nearly filled with plants of this variety of Tomato which were in splendid condition. The remainder of the space was taken up with a few plants of Lord Kitchener, which, although good, was not to be compared with the

first-named either for crop, size, or quality. Albert Victor is of dwarf habit and is exceedingly fertile, a large bunch of fruit being produced at nearly every joint. The fruits are from medium to large in size, bright glossy red in colour, and I was told that in all other respects they are equally satisfactory. The plants are growing in narrow raised borders composed principally of loam, which are built near to the front walls of the house, the house itself being a span-roofed one. They were planted about the middle of May and have now nearly filled their allotted space, and at the time of my visit were literally loaded with fruit from base to tip. It is quite the best house of Tomatoes I have seen this season, and, not having either seen or grown the variety before, on quitting the house a note was made of it with the view of testing its merits personally another season.—A. W.

Lettuce Alexandra White Cos.—At p. 196 "A. D." in his notes on hearting Lettuces refers to the above variety, and wonders whether that stock is now in existence. I believe it is. I first grew it some twenty years ago in a Worcestershire garden, my employer telling me when I took charge that it was his favourite Lettuce. I had had no previous experience with it, but was so pleased with it the first season, that for fifteen subsequent years I was never without it. I used to sow it in the Carrot frame in February, the plants succeeding autumn-planted hatches of Brown Cos and Hardy Hammersmith, and at intervals all through the summer, having even in the most tropical seasons grand heads on the ridges between the rows of Celery. It not only stood, as "A. D." says, a long time before running to seed, but, owing to its fine constitution, grew in seasons when other sorts failed. It has a splendid self-protected heart, crisp and of superb flavour. Two years ago I grew the true strain, having obtained the seed from Messrs. Veitch. Many judges are in the habit of cutting the Lettuces which come under their scrutiny at exhibitions, and this in reality is the only way of arriving exactly at their merits, few things being more deceptive. I can only say that those who exhibit Lettuces, whether gardeners or cottagers, should give Alexandra a trial.—B. S. N.

Potato Renown.—In answer to "A. D.'s" inquiry at p. 196, I beg to say that Potato Renown, to which I recently referred, was sent out by Messrs. Webb and Sons a few years ago. I had it under field culture, and thought very highly of it, not only on account of its fine round shape and general appearance, but its cooking qualities also. The soil it grew in was rather light, and in it Schoolmaster, which I consider a very fine Potato, did not seem quite at home in dry seasons. This induced me to try Renown, and I had no cause for regret. It grew and cropped well, had very few small, useless tubers, kept firm and sound till late in spring, and when cooked with care was very mealy and nutty in flavour. So many of the so-called round varieties are pebble-shaped; whereas Renown as grown by me was almost as round as a cricket ball. If grown clean in the skin it would make a grand exhibition Potato. "A. D." refers to that "at one period" generally grown Potato Woodstock Kidney. I grew it many years ago, and found well-grown samples very hard to beat on the show table and of good quality; but, if I remember rightly, it was not a very abundant yielder and rather prone to disease. Mine was a lightish soil; in deeper, moister mediums it might be more prolific. There can be no doubt that where quality is the chief consideration it would answer in the case of those possessing sufficient ground to grow many of the old and perhaps somewhat capricious varieties—the Fortyfold, for instance, though I daresay it would be difficult to obtain it true. The liability to disease was, I believe, the chief reason why gardeners turned their backs on it, but I have never eaten a better Potato than Fortyfold.—NORWICH.

Some things better omitted.—I should very much like in relation to summer exhibitions of garden produce, especially those so

plentiful in the country that they may be counted by hundreds, which are devoted to cottagers' and allotment holders' produce, the omission from schedules of classes for Rhubarb, taprooted Beets, long Carrots, and Parsnips—at least up to the end of August. Whilst waste does not of necessity occur in connection with Rhubarb, because the best stems can be easily seen, it is not so in the case of the roots named, and distressing waste often results in seeking for the best few roots to the injury of many not good enough. But Rhubarb is so much out of season in July and August, when true fruits are usually abundant, that few, if anyone, then think of using it. After the autumn rains come and new growth takes place, then nice young stems are available for cooking. I notice, however, that the old craze for huge stems is dying out, judges preferring to select those which most nearly approach to fitness for domestic uses. Long Beet is never ready for use until September, and any good stock of the Globe is for July and August far superior. The bulbs of these are easily seen, and not one need be pulled wastefully. There are no better or more desirable summer Carrots than are the Short Horn, Nantes, Champion, or Favourite types, as these are then fully grown and of the highest quality. Long Carrots are at their best in the autumn, and to pull them in the summer is sheer waste. As to Parsnips, inviting roots of these in the summer is folly. It is difficult to impress these things, however, on rural show committees.—A. D.

GARDEN FLORA.

PLATE 1241.

RHODODENDRON LITTLE BEAUTY.

(WITH A COLOURED PLATE.)*

By the crossing and intercrossing of seven different species of Rhododendron, all natives of the various islands of the Malayan Archipelago, we have now a splendid group of charming garden varieties which are particularly valuable, not only from the beauty of their blossoms, but also from the fact that they flower more or less continuously throughout the year. Of the seven species, the one that has played a part in the production of the least number of varieties is *R. malayanum*, which, however, in conjunction with the variety Monarch, has given us that charming form herein figured—Little Beauty. *R. malayanum* is a small, compact-growing shrub that was introduced by Messrs. Veitch from the island of Sumatra. The pointed leaves are each about a couple of inches long, while the tube of the flower is little more than half an inch in length and about the same across the expanded mouth. The colour is a kind of crimson-cerise. The seed-bearing parent was the variety Monarch, with orange-yellow blossoms. This resulted from crossing the blush Princess Alexandra with the orange-crimson Duchess of Edinburgh.

The variety Little Beauty has, apart from the interest attached to its pedigree, much to recommend it, as, unlike some of the older hybrids, it is of a particularly dwarf, bushy habit of growth. The flowers, which are produced in clusters of six to nine, are of a uniform glowing carmine-scarlet tint, the tube being somewhat less than an inch long, the segments of the limb spreading, with a diameter equal to the length of the tube. It received an award of merit from the floral committee of the Royal Horticultural Society, December 15, 1896, thus showing its value for winter blooming. It was, however, raised and flowered some years pre-

* Drawn for THE GARDEN by H. G. Moon in Messrs. J. Veitch and Sons' nursery at Chelsea. Lithographed and printed by J. L. Goffart.

vious to that date, as Professor G. Henslow, in his paper on "Hybrid Rhododendrons," read at a meeting of the society on May 12, 1891, refers to and describes it. Besides its value as a flowering plant, the variety Little Beauty will doubtless be made use of by the hybridist, possessing as it does the desirable features of compact habit and brilliantly-coloured blossoms freely produced. Its cultural requirements do not differ from those of the other members of this group which have been so frequently dealt with in the pages of THE GARDEN.

H. P.

THE WEEK'S WORK.

KITCHEN GARDEN.

LATE SUMMER VEGETABLES.—Where regular attention in regard to mulching, watering, and feeding has been given, late supplies of such vegetables as Marrows, French Beans, and June or July-sown Peas will now be invaluable. At any moment, however, a sudden and complete change in the weather may be looked for in some places; indeed, frost has already been recorded on several nights. Such being the case, those who would preserve Beans and Marrows in a bearing condition must be up and doing. Little frost is needed to completely paralyse the latter, yet it is surprising how much frost a thin covering of canvas will resist. Do not cover up until late in the evening, as the dews tend to recoup the foliage after hot, sunny days. Walker's Perpetual Bearer Pea deserves more general cultivation, as it is not only a good quality Pea, but resists mildew better than most varieties. In large establishments where the demand for French Beans is constant, a sowing, or even a pot-raised batch, transplanted into a cold frame or pit at the end of July will now be coming into yield, and will be sufficiently protected at night by simply drawing on the lights, covering with double garden mats by the middle of October. Care must be taken not to over-water these extra late batches, as rotting at the base of the stem, owing to a fall in the night temperature, will probably occur. Avoid administering frequent dribbles, rather allowing the soil to get fairly dry, and then give a thorough soaking with diluted farmyard liquid, choosing a fine sunny day and doing the work in the forenoon. The value of these Beans consists to a great extent in their filling up a blank which always occurs between the destruction of the latest open-air lots by frost and the supply from the first pot-grown plants indoors. The early part of November affording a none too varied assortment of choice vegetables, those who sowed a row or two of Scarlet Runners at the end of June, and, instead of treating them in the orthodox fashion as regards supports, allowed the haulm to grow to a height of 3 feet and then pinched out the leads as advised, will not only have found that so grown better all-round autumnal pickings have been obtained, parching sun and drying winds doing less damage both to root and top, but that with a minimum amount of labour protection may be given to at least one row by a simple home-made framework and canvas or mats.

FORWARDING SEAKALE.—After such a tropical season the probability is that extra early-planted beds of Seakale intended for forcing in November will, where occupying sloping south or west borders, be sufficiently advanced towards maturity as to need no aid to the same. On clay soils, however, where the ground is level and more rain has fallen, crown ripening may be hastened by thrusting a spade in on one side and severing the lowermost tap roots. Extra vigorous beds may also have a portion of the leaves reduced with a knife.

WINTER SPINACH.—Although in most places rain has recently fallen, winter Spinach sown early and in shallow soils will, I fear, have a somewhat hard time of it, and must be carefully looked after as soon as the young plants appear.

Especially is this so where the seed was sown on sites previously occupied by crops which sapped every particle of moisture out of the ground. I have practised mulching between the rows with old Mushroom manure or any similar material, this proving of great service by preserving the moisture communicated by artificial watering. This treatment will often keep the crop just merely on the move till copious autumn rains fall. I have before recommended sowing several lots in different positions, thus having several strings to the bow, as winter Spinach is in many places of such importance. Be diligent in the frequent use of soot and wood ashes, stirring them in with a Dutch hoe previous to watering. This will also aid in keeping the dreaded wireworm at bay. Nitrate of soda is also beneficial when used with discretion, as it promotes a certain amount of moisture in the soil.

PREPARING PEA PITS.—It is not wise to postpone the preparation of pits and deep frames intended for the reception of early Peas in November and December, as one is never sure what the weather may be like later on, and if the compost is got in in a semi-dry condition, a great point is gained and the seed does not rot. I have always grown Chelsea Gem and other dwarf early sorts in cold pits, and like to get them in readiness by the middle of October. I take out trenches annually and replace with new soil, first of all treading in the bottom a liberal quantity of well-decayed manure. The soil in which Pines and Tomatoes in pots have been grown is suitable, as it contains much rich food, the result of artificial feeding throughout the summer. If a little quite new loam can be added, and the compost after being duly mixed thrown in in a semi-dry condition, no rotting need be apprehended, and the Peas after sowing can be exposed to a good rain or two to ensure perfect germination. I prefer this system to merely digging the frames over and working in manure or even to going to the labour of entirely replenishing all the soil.

J. C.

OUTDOOR FRUITS.

WALL TREES.—Walls which have been covered for many years with big trees are often found to be in a very neglected state as regards pointing up, and the crevices formed by the falling away of the mortar form convenient hiding places for most insect pests that infest the trees themselves during the summer months. Pointing up such walls every few years pays for itself by the extra cleanliness gained, and the present is an excellent time to do the work, as the mortar used has time to set thoroughly before sharp frosts, which would disintegrate it and cause it to drop away, set in. To allow room for working, the branches have to be brought away from the wall and supported in some way, the best method being to fix upright stakes, to which the branches may be tied in loose bunches, or singly if time can be spared. In any case the trees should be fixed firmly enough to resist the force of high winds, which may be expected during the late autumn. Before pointing is begun some of the old mortar should be picked out from the joints in the brickwork, so that there will be room to allow for a fair quantity of new material, as it is only in this way that the facing material can be induced to stand well. The new mortar should be carefully mixed, with just enough cement in it to harden it fairly without making it too hard to allow of driving nails when required; this is a matter frequently overlooked, and nailing becomes a misery when both bricks and joints are over-hard. The removal of trees from the walls gives an excellent opportunity for thoroughly syringing Cherries, and other trees much troubled with insects, from behind; this will remove filth and insects, not easily reached when the trees are fastened back. One or other of the various insecticides should be used, and, as the leaves are now well hardened, may be used at full strength. Before the branches are again fastened back the older and more rugged portions of them should also have a good dressing of Gishurst or of what-

ever else may be used as a winter dressing, the opportunity of doing this being too good to be lost. Trees of all kinds on walls that do not require the drastic treatment recommended above for those in bad condition should have a final look over, with a view to releasing any ties or shreds that may be crippling or causing undue pressure on the shoots, as if such shoots are released now the bark will not have been much injured, and will harden nicely before frost comes, and this hardening will prevent the gumming that so often leads to badly-wounded branches.

ROOT-PRUNING.—There can be no doubt but that root-pruning is a very great help to fertility in the case of trees whose roots have got out of bounds and, possibly, into the crude and ungenial subsoil. The well-doing of trees is not regulated by the immense spread of root which some of them have, but by the number of feeding roots which can be produced in a given space where food is plentiful, and root-pruning is one of the greatest possible aids in the production of such roots. Some people are very particular to carefully lift and relay every root that can possibly be saved, but it has been proved over and over again that, provided root-pruning be done properly—*i.e.*, each root severed with a clean cut at a point close to the junction of a lesser root, and not too close home to the bole of the tree—the loss of a portion of each root is immaterial, and the work is greatly facilitated by getting rid of the trouble of relaying the uncovered portions. In this matter I make a great distinction between the trees to be simply root-pruned and those to be replanted. In the latter case I carefully try and preserve every possible bit of root, as I know that all will be required to assist in re-establishing the tree, but the case is very different where no lifting is intended, as the roots are then ready to produce feeders, and plenty of them, immediately. When root-pruning, a good broad trench should be taken out round the tree at a distance from the bole corresponding with the spread of the branches, or nearly so, and if there is a suspicion of gross growth and unfruitfulness proceeding from one or more tap-roots, the ball should be undermined and such roots severed, for if they are allowed to remain the severance of any spreading roots will be of little avail in inducing a more fruitful tendency. When refilling the trench, be careful to incorporate with the soil a plentiful supply of mortar rubbish and burnt earth or wood ashes. If some good turfy loam can be added, so much the better, but whatever may be used should be well trodden or rammed home, as firmness in fruit borders is a very desirable condition. If on examination the subsoil is found to be wet or sour, the excavation made should go to a depth of from 30 inches to 36 inches and the bottom be filled up with brick rubble several inches in depth before replacing the soil.

RASPBERRIES.—The autumn-bearing Raspberries will now be in full bearing, and may be assisted to swell up quickly by giving good soakings of liquid manure as opportunity offers. With me the advantages of cutting down all the canes of these varieties in spring has been well exemplified this year, for those so treated have come into bearing much earlier than those which have been allowed to carry a double crop, and the weight of fruit is also very much greater. I have before alluded to this and am convinced that those who give the plan a trial another year will not go back again to the old system, as one can always, or nearly always, depend on a good crop from the summer-bearing varieties, but the others are not so sure unless given this special treatment of treating the canes as annuals only. The canes of the summer bearers which have borne fruit should now be cut away entirely, as those for next year will be getting nicely hardened and will derive no further benefit from the protection and sustenance given by the older canes. All the weak canes made this year should also be cut away, saving only the strongest and best of those farthest removed from the old stools with which to make new plantations. A fortnight back I wrote of the preparation of land for prospective

fruit planting, but made no especial allusion to the Raspberry, so I may now add that ground for Raspberries should be well manured and trenched deeply; the length of time over which a bed so made will last in good bearing being ample repayment for the extra work of preparation. If this is done now, the plot will have nicely settled for planting a month hence.

STRAWBERRIES.—Since the rains with which we have been favoured, Strawberry plants have made good growth and runners have again been freely produced. The beds and pots should now have a final look over, removing all runners and hand-weeding among the crowns of the plants, after which a dry day should be chosen for running the hoe through all plots; this will kill a lot of seed-weeds if the rake follows the hoe and is plied freely among the plants. CORNUELIAN.

THE MARKET GARDEN.

FRUIT-FARMING IN SCOTLAND.

The great centres of fruit cultivation in Scotland are the Clyde valley, Perthshire, and, to an increasing extent, the neighbourhood of Aberdeen. The farm with the working of which this article is chiefly concerned is situated in Perthshire, and the observations as to the cultivation, picking, and despatch of the fruit apply more especially to that district, though the system is much the same in the other districts. Moreover, since the cultivation of Gooseberries and Currants has not hitherto thriven there—growers being discouraged partly by the length of time elapsing before the bushes become productive, and partly by a blight which has attacked them—these fruits may be dismissed with the remark that the enterprising grower who can afford to wait a while for his harvest will, if he can successfully combat the blight, reap a rich harvest, since the limited supply of both fruits, and of Currants in particular, ensures good prices being obtained.

To grow Strawberries and Raspberries profitably on anything like a large scale there are three things essential. The farm must be situated within a sufficiently short distance of a station, to admit of the fruit being easily transported to the markets; it must be near enough to a town to ensure a constant supply of labour on a large scale; and, finally, it is obvious that the land must be well adapted for the culture. It is a somewhat curious fact that our ideas as to suitable soil differ materially from those of our southern friends. Here it is thought that the best ground for growing Strawberries is a light gravelly soil—for choice, reclaimed moor or woodland—which to the Kent or Hampshire farmer would appear most unlikely to produce good crops.

RECLAIMING LAND.

The process of reclaiming moorland is, as may be supposed, a costly one. The first operation consists in what is known as trenching, that is, turning over the ground with spades to a depth of 2 feet or 3 feet, according to the character of the soil, great care being taken to avoid breaking through the crust into the subsoil proper. Trenching is usually done by piecework, at the rate of not less than 1s. per pole; and the cost per acre is therefore at least £8. The result of the trenching is to leave a most unpromising-looking surface, which to the eyes of the casual observer resembles nothing so much as a shingly beach. The next step is to try and equalise to a certain extent the balance of power between earth and stones by gathering up a few tons per acre of the latter.

Having spent as much money as he chooses on this business—and, in our opinion, the less the better, since, do what he will, at least half the soil consists of stones—the farmer proceeds to get rid of some of the superfluous weeds by planting a crop of Potatoes—one of the best patent weed-killers known. The ground is then ready for planting with

STRAWBERRIES,

which should, if possible, be done in autumn, but is often deferred till spring—the middle of March or April, according to the season. The ground must first be thoroughly manured—no small item in the farmer's expenditure, the proper amount of manure being from 30 tons to 35 tons per acre, at an estimated price of 6s. per ton. There is a very considerable degree of skill required in the apparently simple operation of planting; and, as the whole future of the plant depends upon it, the utmost care must be taken. It used to be the custom in this district to use a dibble. With this the planter made a hole in the ground, and he then proceeded to insert therein the roots of the plant wrapped closely together. This was a barbarous method of planting a Strawberry, with its spreading fibrous roots, and has been generally abandoned in favour of the orthodox method of using a trowel. It is usual to leave a space of about 10 inches between each plant, and of not less than 30 inches between the rows, and even with this interval it is heartrending to see how many berries the pickers crush into a pulp.

It might be thought that, having once planted his fruit, the farmer had only to sit down and enjoy the profits. The reality is very different. There is hardly a month in the year in which he must not be working among it. The ill weeds, which proverbially grow apace, seem to increase with lightning rapidity in a Strawberry field. In the autumn and spring large gangs of workers are employed for weeks in weeding. The weeds are collected in baskets and burnt, and you flatter yourself that never another will dare to show its head in the field. It is a fond delusion; at the first shower there spring up as if by magic Chickweed, Bindweed, Thistles, Docks, and all other abominations. And so the weeding process is repeated again and again, and unless it is constantly and efficiently carried out, good-bye to the hope of having a remunerative crop. In addition to the labour just mentioned—since this form of cultivation affords a good example of the survival of the fittest, and many plants fail to survive the inclemencies of the season—the vacancies in the rows have to be filled up, which is usually done by training the runners of the survivors over the vacant spaces.

The chief enemy which growers have to face, apart from weeds, is frost. Hardly a year passes in which the crop of the early varieties is not decimated by late frosts, and it is occasionally almost totally destroyed. In the evening a field is white with strong healthy blossoms, as if it were sprinkled with snow, and next morning a careful examination reveals that most of the blossoms have brown and shrivelled centres, which will never develop into fruit.

The varieties of Strawberries which are principally grown in this district are two: the Rifleman, a small early berry, deliciously sweet, which is said to make the best jam, and the Elton Pine. The latter is a late variety, producing much larger fruit with a slightly acid flavour. The size sometimes attained by these berries is remarkable, and it is said that six or seven selected at random have been known to weigh a pound. Other varieties, such as Garibaldi and Royal Sovereign, are also being cultivated, and it would appear from the

marked falling off in crops of late years that some new variety is badly wanted. It is an unfortunate fact, which is certainly true as regards the reclaimed moorland, that when once there has been a crop of Strawberries taken from the ground it will never bear to much advantage again. Apparently they absorb some substance out of the ground which cannot by any known process be replaced. Experiments have been tried by taking a five years' rotation of other crops off the ground and then replanting it in Strawberries, but the result has never been satisfactory. Of course, the small grower must be contented with the inferior results produced by repeated planting; or when his plot of ground has been exhausted for Strawberry cultivation, he may plant it in Raspberries. The yield per acre from the virgin soil used formerly to be most astonishing. From 2 tons to 3 tons per acre were no uncommon crop; and in those days of big prices the profit was very large in spite of the fact that the productive life of the plants is so short. But now-a-days, for some unknown reason, which cannot be wholly ascribed to the inclement seasons of the last two or three years, the yield per acre has diminished to a remarkable extent, and is very often less than a ton. It must not be assumed that all or even the greater part of the fruit grown in this district is grown on the virgin soil redeemed in the manner described above. A great deal is grown on agricultural ground which has been reclaimed at some remote period, but certainly the best results have been obtained from the new land. Whether it is worth while to go to the expense of reclaiming ground which, after bearing its one crop of fruit, is practically useless for other agricultural purposes is a question open to doubt, more especially as it is almost impossible wholly to eradicate Broom and Whins, and if left to itself the ground will in an incredibly short time lapse from civilisation into savagery.

RASPBERRIES.

Turning to the Raspberries, the lot of the grower would at first sight appear to be a far more happy one. Raspberries possess this great advantage over Strawberries, that the bushes are more or less permanent. How long they will go on bearing if properly cared for is hardly known. In gardens bushes of thirty or forty years old may be seen producing as good crops as five-year-olds, and the cultivation in fields is still too young to estimate what is their limit of profitable production. The expenses of growing them are, however, greater, and go far to reduce the margin of profit, and, moreover, they take longer to become productive. While good results are obtained in the light gravelly soil so well suited for Strawberries, Raspberries thrive better on a richer alluvial soil. It is usual to plant them after cleaning the ground with a crop of Potatoes, as in the case of Strawberries, the young plants or suckers being cut away from the old bushes in autumn. They should be planted at intervals of 3 feet in rows about 5 feet apart. This space is necessary not only to enable the pickers to move freely about without treading down and breaking the young canes, but also to admit of the passage of a horse for cleaning. When only grown in small quantities it is perhaps best to train the bushes on stakes, as in a garden; but the expense and trouble of doing this on a large scale are so great, that the large farmer usually trains them on two galvanised wires, the top one being at the height of 4 feet to 5 feet from the ground. As in the case of Strawberries, the farmer's labours have only begun when he has planted his Raspberries.

The weeding has to be carried out with the same unflinching perseverance. After the fruit has been picked, the old canes and some of the young ones are cut away, and such of the latter as are to form the bushes for next year are tied to the wires, the number left in each bush varying, according to the fancy of the grower and the strength of the plant, from five to ten. This operation, as may be easily supposed, requires judgment and skill. An error in not selecting the best canes or clumsiness in tying may ruin the whole crop. The smaller canes are simply trained upright against the wires, care being taken not to tie them so loosely as to admit of their "wagging" too much (in which case a gale of wind may do great damage by snapping them off when heavily laden with fruit), or so tightly as to interfere with the free passage of the sap. As regards the treatment of the taller canes, opinions differ. In some years they grow so luxuriantly as to attain a height of 7 feet or 8 feet, and manifestly they cannot be treated in the same fashion as their smaller brethren. Some cut off a foot or two of the canes and train them straight up the wires, and think that thus shorn they bear as well as when left their full size. Others—and theirs is probably the better course to follow—have a system of arching, or "bowing," as it is technically called; but this again is a process requiring great skill. You must humour the cane, commencing to curve it gradually from the root in such a manner that the bush resembles the shape of a fan. Too often the unfortunate canes are trained straight up for 3 feet or 4 feet, and then roughly bent and twisted horizontally along the wires, so that the stem ultimately becomes gnarled and distorted.

INSECT AND OTHER PESTS.

Every three or four years the Raspberries must be treated to a plentiful dose of manure, and an allowance of 40 tons per acre is not too much to give them. But even with the best treatment they too often disappoint expectations. It is true that, thanks to their long tap-roots, they do not feel the effects of summer droughts so much as Strawberries. Nor does the frost affect them to any appreciable extent. A far greater danger is that the young canes will flower and even fruit in autumn. The canes which do so are usually the strongest and comeliest; and if the farmer is careless enough to select them as his mainstay for next season he will have but a miserable crop. There may often be seen in a row of bushes thick with foliage and hanging with fruit a number of withered, dried-up sticks. These are the canes which have wasted their strength and energy to no good purpose in flowering the previous year.

But, apart from this danger, there are others and worse to be apprehended, for which there is practically no remedy. There are at least three insect pests which too often destroy the promise of the season. The first of these is the Raspberry moth or borer, which, when in the form of a small caterpillar, pierces the soft, juicy part at the base of the buds, and prevents the shoots from expanding. There can be no doubt that the harm done by this caterpillar is sometimes very great. It may be somewhat alleviated by forking into the ground at the roots of the bushes a mixture of soot and lime in the autumn or early winter, but the only real remedy is the somewhat drastic one proposed by the Board of Agriculture—namely, cutting down and burning the infected canes.

Another enemy which does less real mischief, though his appearance is more alarming, is the Raspberry beetle, which employs itself in eating out the heart of the berries while still in bud

and in flower. But since these beetles only attack the individual flowers and their capacity for food is not inexhaustible, the mischief done by them is less than it would appear to be, though at times they are seen in such myriads that it would seem likely they would destroy the whole crop. Spraying with paraffin appears to discourage but not to destroy very many of them, owing to the fact that they have wings, which they use with considerable agility on the approach of danger. The beetle is in appearance something like a dark and rather dissipated-looking ladybird.

Last, and worst of all, is the much-dreaded Raspberry weevil. It is a clay-coloured animal of about $3\frac{1}{2}$ lines long with dark red legs, and is said to have pitchy, twelve-jointed antennæ furnished with clubs. Its character is as bad as this somewhat formidable description of its appearance would lead one to conjecture. These weevils in the daytime live in the earth at the bottom of the bushes, whence they come out at night in immense numbers to feed. They are not content with nipping off individual berries, but bite half through the stem of a cluster of ten or twelve, so that the damage they will do in a single night must be seen to be believed. No remedial measures are of much avail. They do not come out by day, and if you hunt for them in the earth they either pretend to be dead, when they are practically indistinguishable from the surrounding soil, or burrow quickly out of sight. Some growers send out men at night to hunt them with lanterns and cloths soaked in paraffin. These they hold under the bushes and tap the wires, whereupon the weevils fall down into the cloths.

THE FRUIT MARKET.

It may be seen that the cultivation of both Strawberries and Raspberries is itself no sinecure, and that it is no easy matter to produce a good crop of either fruit. Having got his crop, however, the further question remains, how is the farmer to pick and dispose of it? His difficulties with regard to the latter point are by no means small. The small grower, with his acre or half-acre of ground, can always reckon on finding a market for the comparatively small quantity of fruit which he can supply. He can either sell it for eating, in which case it is usually sent to be sold on commission in the markets of the large towns, or he will have no difficulty in finding a sale for it with the jam-makers. But the large grower, who despatches every season from 80 tons to 100 tons of fruit, has a more difficult task. Accordingly, every year before the fruit is ripe the grower, the boiler and the ubiquitous middleman begin to haggle over terms. There is perhaps no commodity of trade which is subject to such fluctuations in price as is fruit. The last three or four years have afforded an excellent illustration of this. The price of Strawberries in these seasons has varied from £10 to £30 per ton, and that of Raspberries from £15 to the phenomenal rate of £40. At the former prices the cultivation would not pay its expenses, while at the latter the profit would be handsome. How can the grower decide what price he is to hold out for? He cannot wait, with his fruit rotting on the ground. He is perfectly sure that if he stands out for a higher figure prices will go down, and he is equally sure that if he sells at the prevailing rate they will go up; and he has excellent examples from former years illustrating the truth of both his convictions. The mere fact that his own crop is a poor one is no criterion as showing that others are equally poor; and it is the most difficult thing to obtain anything like a reliable report as to the character of the general crop, it being the interest

of growers to depreciate and of boilers to exaggerate its size. Another difficulty is to determine the quantity of fruit which he is safe in selling. He meets this as far as possible by selling a certain amount which experience shows him should be well within his margin, and disposing of the remainder as a balance. But since the amount of his balance is necessarily uncertain, the price obtained for it would be lower than that which he would get for a fixed quantity, and the temptation to sell within a very few tons of his estimated crop is strong. A shower of rain at the critical time may make all the difference between ability and inability to fulfil his contracts, and the sanguine man who trusts to luck may find himself with his contracts unfulfilled and not a berry left to supply the deficiency, while the timid man is gnashing his teeth at finding that he has a large and comparatively unremunerative balance.

FRUIT-PICKING.

As, year by year, the area under fruit cultivation increases, there is an increase in the difficulty of picking the fruit. It is absolutely essential to be within reasonable distance of a town; but even so the supply of pickers is no longer equal to the demand. A farm of seventy or eighty acres in fruit will require a constant supply of from 150 to 250 pickers; and even the latter number, in the height of the season, when the Raspberries and late Strawberries are ripe together, cannot cope with the fruit, tons of which are sometimes lost from inability to pick it. The pickers are divided into gangs of from 30 to 70, and are under charge of an overseer. The work begins at about 6 a.m., and is continued, with an interval of an hour for dinner at midday, till 4 p.m. Wages vary from about 1s. 8d. to 2s. per head, irrespective of the quantity picked. It would appear to be a far more satisfactory arrangement to pay them by the work done, at so much per basket; but in this district no one has yet been able to introduce that system. When the crop is in full swing, each picker should be able to gather something over three-quarters of a hundred-weight of late Strawberries and half a hundred-weight of Raspberries. It may easily be seen that the small grower, who is able both to weed and to pick his crop with the aid of his family and perhaps half-a-dozen hired hands, has not to meet the difficulties of the large farmer, and that his profits are proportionately larger. In picking fruit for eating, the pickers either carry baskets holding from five to seven pounds, in which the fruit is sent direct to the market, or else gather it into those small punnets containing about a pound, the appearance of which in shops is so familiar to the eye. These punnets are then packed in crates or boxes containing four or five dozen. It is only fair to the retail fruiterer to say that the mysterious law, by which the large berries invariably gravitate to the top of the basket, appears to hold good when the fruit is gathered by unsophisticated rustics, to be sent to market, almost as surely as when it has been prepared for retailing to the public.

FRUIT FOR THE JAM FACTORY.

The method of picking to send to the jam-maker is the same with both Raspberries and Strawberries. The pickers carry a large basket slung round the neck, which they partially fill with fruit and empty into pails brought round by men specially detailed for the duty. The fruit is then transferred to juice-tight kegs or barrels, and in them is sent to the jam-maker. These vary in size, but are usually constructed to hold about one hundredweight of fruit. It may come as a shock to the consumers of

bought jam to learn that the fruit out of which it is made is treated in this cavalier fashion; but it is astonishing to see how fresh and sweet a cask of good honest Scotch fruit will be on its arrival after a journey of thirty-six hours—that is, if it has been picked dry. Unfortunately, it is not always dry in Scotland, and a hundred-weight of wet fruit, after being jolted over three or four hundred miles in a goods train, is apt to present a somewhat uninviting appearance. Still, if used before fermentation sets in, it makes very nearly as good jam as the dry fruit. If only Scotch or English fruit were used by the boilers the consumer would have no reason to complain. If he were to see the quality of the foreign fruit with which too many of them doctor up their jams, he would certainly hesitate before eating. To save a few shillings, a boiler will use barrels of foreign fruit, which he picks up at a low price, and which is nothing more nor less than a seething mass of fermentation, no more fit for human food than any rotten fish condemned at Billingsgate. That some strong measure is required to meet this ever-increasing abuse is certain, in the interest not only of the home grower, whose margin of profit grows smaller year by year, but also of the consumer, who has a right to expect that his jam shall not be adulterated with this poisonous stuff. Any attempt at obtaining further legislation on the subject is met by the old parrot-cry of protection; but it is surely not demanding very much to insist that jam made either wholly or partly with foreign fruit should be marked as such. If once the public would realise the nature of the stuff which they are sometimes called upon to eat as “home-grown jam” the evil would not be tolerated for a moment. Even if the provisions of the existing Merchandise Marks Acts were more thoroughly enforced, a great deal might be done to check the evil. Much might be done by railway companies in cheapening their freights, so as to enable home-grown to compete in the market with foreign fruit; and it is only fair to them to say that in the last year or two they have shown some disposition to do this. It must be understood that this indictment is not intended to apply to all jam-makers; but it is an undoubted fact that it does apply to many, and that the quality of the foreign fruit thus used has in no wise been exaggerated in the present description.

LOSSES AND CROSSES.

The quantity of fruit which is despatched all over Scotland, to the north of England, and to Ireland in the manner described above is enormous. Given 300 pickers, picking their proper quantity, one grower will send off his 7 tons or 8 tons a day. With so great a quantity, each barrel having to be separately addressed, mistakes must sometimes occur; and, in dealing with such a perishable commodity as fruit, a misdirected barrel may be a total loss to the grower. The picking season is indeed an anxious time for him, and every day brings its cares. One boiler telegraphs to say that his works are closed for a week owing to holidays, and that he cannot take fruit during that time; another that he can only take fruit despatched by an early train; and a third that he has already more on his hands than he can boil, and that he can take no more at present. They one and all, with surprising unanimity, try to avoid taking fruit gathered on Friday or Saturday, and seem to be entirely oblivious of the fact that it will go on ripening and going to waste on both these days, and even on Sundays also, as much as on any other days in the week. As they have only a short day at their works on Saturday, the boilers expect the fruit to stand

still and await their convenience at the beginning of the week. The grower naturally does not see the reasonableness of this, and hence arise many bickerings, and much profit to the telegraph department of the revenue and occasionally also to the legal profession. At the end of a day spent in struggling to extract a reasonable amount of work from lazy pickers, in despatching numerous telegrams to obstinate boilers, and in wrestling with the intricacies of the traffic systems of railway companies, who refuse to guarantee connections, the unfortunate farmer is inclined to wish himself well out of the business. Fortunately, the season is not of long duration; six or seven weeks see the end of it, and he may then sit down for a short time and count his profits, if he has any to enjoy.

PROFITS.

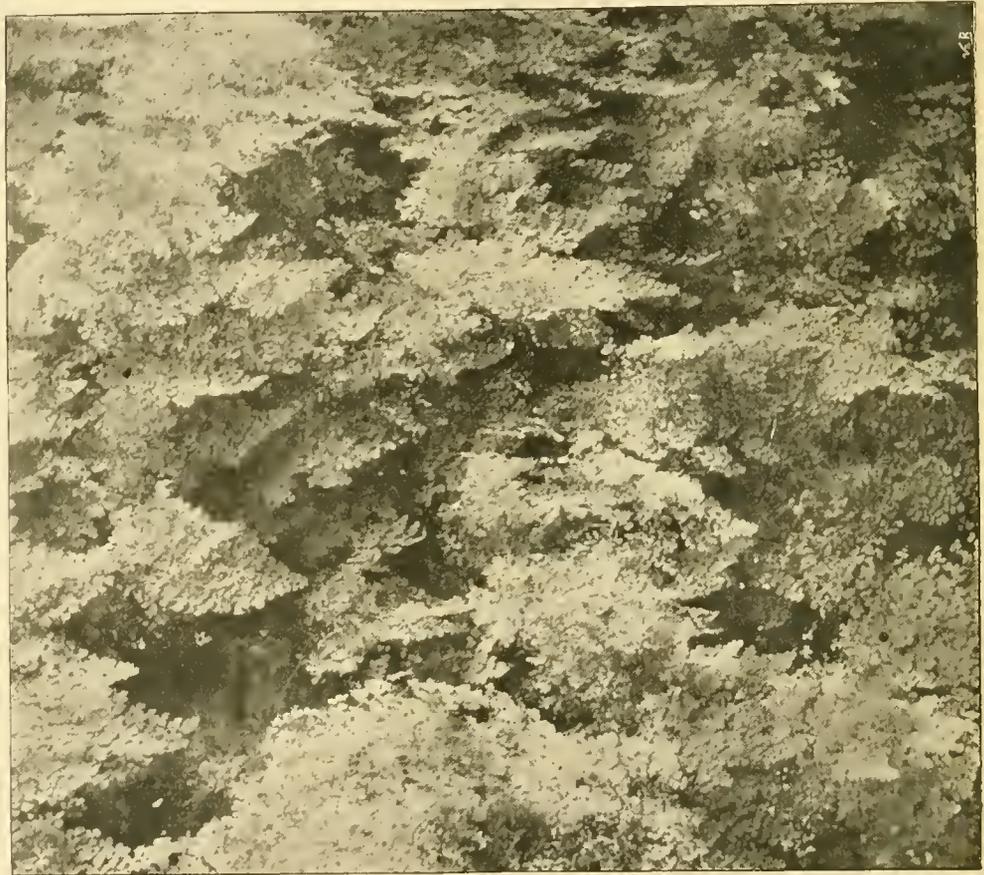

It cannot be denied that these profits in some individual years are large, and in such they

fruit farmer is not altogether a happy one. The truth of the matter is that this trade, like every other in the country, is being overdone. It is only under very favourable conditions that it can at this date be carried on profitably on a large scale. In short, fruit-farming, while it still affords an opening to a man who will count the cost before he takes it up, is no longer—if it ever was—the farmer's panacea; and the wise man will pause and reflect before following Mr. Gladstone's advice to rush into fruit growing.—*Chambers's Journal.*

FERNS.

ADIANTUMS FOR THE COOL FERNERY.

OF all the Ferns which will succeed well under cool treatment, the Maiden-hairs are the most appreciated. It is sometimes difficult to esta-

Adiantums on a wall.

amply repay the trouble and expense of cultivation. They are, however, by no means so large or so regular as they would appear to be to the casual observer, who notes that the farmer may get his ton or two of fruit per acre, and calculates that with reasonable prices he should have a gross return of £40 or £50 per acre. The expert who has made an accurate study of the trade—who estimates the expenses of planting, weeding, and picking, and who realises the constant anxieties and heart-burnings which accompany the cultivation, the losses resulting from the inclemencies of the season and the insect pests, and, lastly, the uncertainty whether anything like a fair price will be obtained for the crop—will be disposed to agree with the writer of this article that the lot of a

lish them, but once they get a good start they soon spread. In a cool house where the walls are moist, seedlings will often spring up and cover large spaces without any assistance, but, of course, it is only where the conditions are particularly favourable that a wall can be covered without any assistance. A beautiful effect may be made by covering a shaded wall with Adiantums. Some rough peat and Sphagnum Moss may be fixed by the aid of wire netting, the size of which should be regulated by the plants intended to be used. While larger plants may be used, quite small ones are the most desirable. After the wall has been properly covered and moistened, small seedlings may be pricked in at regular distances. If put in rather thicker than it is intended for them to remain, it will

allow for a few that may die off, or they may be thinned out after they have made a start. Those with the spreading rhizomes are the most suitable for the purpose, one of the best being *A. assimile*. When once this gets established the rhizomes spread freely and soon cover a large space. It is a native of Australia, and can be recommended for the above purpose and also for suspended baskets, the slender drooping fronds being of a soft pale green. Of *A. Capillus-veneris* there are some very distinct varieties, all of which do well in a cool house. The ordinary form, which is found in this country, is one of the best for walls, and where spores abound they will often cover large spaces on damp walls without any assistance. I have seen walls entirely covered, the result of self-sown spores. Of course it is only where a certain amount of atmospheric moisture is regularly maintained that they succeed well. Of the nearly allied varieties *imbricatum* is the most beautiful, having large deeply-cut pinnules, which closely resemble those of *A. Farleyense*, and it is sometimes called the hardy Farleyense. I have never raised spores of this, but it has the peculiar feature of producing small bulbils on the margins of the pinnules, and young plants may be established from these, besides which it may be readily increased by dividing the spreading rhizomes. *A. Mariesi*, also known as *A. Raperi*, is a distinct variety from Japan. The erect fronds are of a rich olive-green and the stout stipes have a peculiar bluish metallic hue. This is more suited for pots or the rockery. *A. O'Brieni*, from South Africa, closely resembles the above, but has smaller pinnules and more spreading fronds. None of the *Capillus-Veneris* varieties have any coloured tints in the young fronds, and all succeed better in a more shaded position than those with the red-tinted fronds. *A. elegans*, by some given as a variety of *colpedes* and others as a variety of *cuneatum*, is certainly harder than *cuneatum* and the best Maiden-hair for a cool house. It comes freely from spores, and grown side by side with *cuneatum* I have invariably found it to keep its fronds better and make better growth under cool treatment than *cuneatum* does. *A. rubellum* is the best of those with tinted fronds for a cool house. Grown well exposed to the light, the young fronds have a rich almost crimson tint which is retained longer than in most of the tinted *Adiantums*. A. HEMSLEY.

Fern spores.—"Another important matter," writes Mr. Hemsley at p. 186, "is in collecting spores to take them from plants that have been isolated from others which produce spores freely." That passage seems to need some explanation, as it is very well known that no cross-fertilisation, or indeed any common form of fertilisation, takes place during the formation of spores on Ferns. Practically these spores have no organs that admit of cross-fertilisation, neither are they produced by flowers, as is the case with all ordinary plants. That being so, I do not quite understand what may be Mr. Hemsley's reasons for giving the above advice, unless it is that he thinks varieties of Ferns that are free spore-producers may, if in contact with other varieties, cause those spores when the cases burst to become attached to other Fern fronds, thus when spores are sown furnishing them in a mixed state instead of quite separate and true. It is very odd, but yet instructive, to learn from botanists that the real fertilisation of Ferns takes place after the production of the prothallium, the first product of the germinated spore. These prothalliums are bisexual and produce, as it were, both male and female organs, and cross-fertilisation, which can take place only when prothalliums of diverse varieties are in contact, then may pro-

duce distinct varieties, or if there be but the one variety present, that variety only is reproduced. I should very much like to learn whether Fern raisers artificially aid cross-fertilisation, or whether they sow spores of diverse varieties in combination and leave the rest to Nature. Certainly we have myriads of beautiful Ferns in commerce the product of cross-fertilisation.—A. D.

Gymnogramma schizophylla.—There are few stove Ferns that equal this species in its best forms, for it is an extremely handsome kind, easily grown if sufficient heat is at command, and an exquisite plant for baskets. It looks well on a pedestal or some similar arrangement, its long pendent fronds like showers of green, but it is easily checked and should not on any account be kept long in a cool or draughty room. The species may be easily propagated by means of the young plants that occur at the ends of the fronds, these being pegged down into small pots and cut off the parent plant when well rooted. The small pots may be allowed to get fairly full of roots before shifting into a larger size, for this Fern is impatient of a lot of loose material about its roots. On the other hand, it is not wise to allow the little plants to get badly pot-bound, or they will not start away freely. The best compost is one a little finer than that suited to the stronger-growing Ferns, and plenty of good coarse silver sand should be mixed with it. Drain the pots or baskets well and cover the crocks with a little rough peat or bog Moss. There is a fine form of this species (*gloriosa*) which is much stronger growing than the type, with longer gracefully arching fronds. It is a garden variety, obtained probably by selection.

FRUIT AND VEGETABLE CROPS.

MIDLAND.

Gopsall Hall, Atherstone.—The fruit crops this season in this neighbourhood are below the average, with the exception of bush fruits. Apples and Pears looked at one time most promising, the show of flower being abundant, but the cold, inclement weather, coupled with the superabundance of bloom, has been the cause of a show of Apples and Pears far below the average. The only Apples we have this season are Lord Sutfield, Tower of Glamis, Cellini, and Warner's King. Pears are more disappointing, Louise Bonne of Jersey, Beurré Diel, and Winter Nelis being the exceptions. Plums are a failure. Apricots are good, also Peaches and Nectarines, although somewhat small owing to the prolonged drought; Morello Cherries moderate, also Strawberries; bush fruits average crop. Rain is badly needed for all outside trees and crops.

The effect of the drought is most apparent on many vegetables, especially Peas, Beans, Turnips, and like crops, it being impossible to keep things free from thrips owing to the dry and arid atmosphere, the rainfall being below the average of several summers past.—J. LEE.

Hopton Gardens, Wirksworth.—Red, Black, and White Currants have very heavy crops of fine clean fruit. Gooseberries are very heavy. Cherries promised well, but the fruit dropped before coming to maturity. Pears are a failure and Plums are scarce. Apples are good, there being heavy crops on Cellini, Potts' Seedling, New Northern Greening, Ecklinville, Bramley's, Newton Wonder, King of Pippins, Duchess of Oldenburg, and New Hawthornden; moderate crops on Warner's King, Alfriston, Gascoigne's Scarlet, Lord Grosvenor, Bismarck, Worcester Pearmain, Royal George, and Margil. Strawberries are good; Raspberries an excellent crop of fine fruit. Old Apple trees sawn down broke strongly, and the bolts are carrying a lot of fruit this year.—GEO. BOLAN.

Ossington, Newark.—Strawberries have been very good, especially the early varieties, the later kinds falling off from want of rain. Currants, Gooseberries, and Raspberries have

heavy crops; in fact I never saw these more plentiful. Plums are abundant in the neighbourhood. Apples and Pears are very fair, but not so early as in previous years. Apricots and Cherries are very fair.—A. WAGG.

Aston Hall, Aston-on-Trent, Derby.—The fruit in this garden is exceptionally fine this year, particularly Strawberries Royal Sovereign and Latest of All. The stone fruit is an average crop; Apples and Pears very good; Raspberries and Currants extra good.

Vegetables have turned out well as far as the season has gone.—JAMES LAW.

Worsley, Manchester.—Taken altogether, the fruit crop is not at all satisfactory. In bush fruits Currants are the only abundant crop. Gooseberries are very scarce, and Strawberries, though fairly good, were soon over. Raspberries are a good average crop. Pears are practically nil, a few fruits on early varieties being the exception. Early Apples are fair, but late ones scarce and the fruit poor; indeed, the trees seem to make no foliage. Stone fruits are a complete failure.

Vegetables are doing well generally. Summer crops of Cauliflowers, Broccoli, &c., I had a difficulty in starting during the dry, scorching time, but they are now fairly established. Peas and Beans are producing well and promise better for the future. Our humid climate seems to suit late Peas. They are seldom attacked with mildew, and usually fruit till killed by frost. Runner and French Beans revel in the heat and are making a great show of fruit. Potatoes look exceedingly well; those I am lifting are good in size and flavour and quite free from disease.—W. B. UPJOHN.

WALES.

Bodnant Gardens, Tal-y-Cafn, R.S.O.—Fruit, with the exception of Pears, is very fair in this neighbourhood. Small fruits have been fine; Currants a heavy crop; Strawberries average. Stone fruits are a fair crop; Apples average, some trees very heavily laden, chiefly cooking varieties; Pears almost a failure.—J. SAUNDERSON.

The Hendre, Monmouth.—Apples, both in orchards and upon pyramid and bush trees, are more than an average crop, and the fruit promises to be of excellent quality. The heaviest bearers upon pyramids are Cox's Orange, King of the Pippins, Sturmer Pippin, Duchess of Oldenburg, Wealthy, Worcester Pearmain, Belle Pontoise, Bismarck, Bramley's Seedling, Cellini, Dumelow's Seedling, Grenadier, New Hawthornden, Lane's Prince Albert, Lord Derby, Lord Grosvenor, Seaton House, Sandringham, Schoolmaster, The Queen, and Warner's King. The Pear crop is under average. It is best upon walls, although some pyramid trees carry good crops. The best bearers upon walls are Louise Bonne of Jersey, Durendean, Clapp's Favourite, Souvenir du Congrès, Easter Beurré, Marie Louise d'Uccle, Beurré Diel, and Prince Consort. Apricots and Peaches when in blossom were much damaged by 16° of frost, although protected by fish-netting; their crops are thin in consequence. Plums are also very thin upon walls, and the crop is below average, although some bushes of Victoria, Early Prolific, Early Transparent, and Jefferson carry good crops. Cherries are under average, but May Duke upon bushes is bearing heavy crops of fine fruit. Strawberries suffered from drought last season and did not crop so well as usual, but the quality was good. Royal Sovereign, Leader, Gunton Park, and Latest of All were the best. The last always does well upon our heavy soil. Bush fruits are abundant and fine, particularly so Gooseberries and Superlative Raspberries.—THOS. COOMBER.

Castle Gardens, Cardiff.—Apple, Pear, Plum, and Cherry trees flowered luxuriantly this year and gave every promise of an abundant crop, but Pears and Plums set badly, and the crops of these are almost a complete failure in this district. Apples, with the exception of a few varieties, set well and are a heavy crop. Many of the

trees have had to be propped up to prevent the branches breaking under the great weight of fruit. All the fruit trees in the gardens here were mulched early in the season with a good thickness of rotten manure, and on that account they have withstood the long-continued heat and drought experienced here since the beginning of June with impunity. The Apple trees in particular are now making vigorous growth, which is free from insect pests of all kinds. Last year Apple trees suffered much from the attacks of aphids in the early part of the season, and the leaves and shoots in consequence of this were much honeydewed and had to be cut off and burned. Strawberries have been plentiful and good, but of shorter duration this season than usual on account of the drought. The fruits of Royal Sovereign were large, highly flavoured, and the crop heavy. The plants now are much infested with red spider. Peaches, Apricots, Gooseberries, and all kinds of Currants are bearing good crops in this district.—A. PETTIGREW.

Penrhos, Holyhead.—Stone fruits are very scarce; Apples and Pears under average; Strawberries have been very good; Red, White, and Black Currants are heavy crops, also Gooseberries; Raspberries are under average; Plums are good generally except in very exposed positions.

Vegetables are very good in quality with the exception of Carrots, which have been infested with grubs.—T. MAISH.

Wyastone Leys, Monmouth.—Apples are a good general crop; Pears are under the average. The sorts doing best are Beurré d'Amanlis, Bergamote d'Esperen, Doyenné Boussoch, Doyenné du Comice, Josephine de Malines, and Pitmaston Duchess, all trained as espaliers or on walls. Apricots are very thin. Gooseberries, Raspberries, and Currants have all been good, especially Black Currants. Peaches are a fair average; Plums a very light crop. Strawberries have been excellent; King of the Earlies, Vicomtesse Héricart de Thury, Latest of All, and Jubilee were very good. Royal Sovereign was by far the best. Walnuts and Filberts are above the average; Quinces and Medlars average crop. Cider and perry fruit is plentiful in this neighbourhood.

All vegetable crops have done well. Early Potatoes are very good, especially Sharpe's Victor. Late varieties until lately looked extremely well, but are now suffering from want of rain, '76 in. being the total for the month of July, and '06 in. on the 3rd ult. Reading Giant is taking the place of Magnum Bonum in this locality as a general crop. Peas have been exceptionally good. Runner Beans are bearing well, considering the drought. Early Cabbages are small; Cauliflowers, Savoys, and Broccoli are much in need of rain. Fully 50 per cent. are blind.—GEORGE PHILLIPS.

Gogerddan, Aberystwith.—In this district Plums and Cherries are almost a failure; Apples and Pears are a very thin crop; Gooseberries very good; Currants, Red, White, and Black, are a good crop; Raspberries are also good; Strawberries have been a fair crop.

Vegetables of all kinds are doing well in this district, the weather being favourable for all growing crops.—JAMES VEAREY.

Powis Castle, Welshpool.—A very fair crop on the whole. Apples are an average crop, the best bearers being Lord Grosvenor, Warner's King, Stirling Castle, Ecklinville Seedling, Annie Elizabeth, Pott's Seedling, Bismarck, Peasgood's Nonsuch, Lane's Prince Albert, Bramley's Seedling, Flanders Pippin, and Gascoigne's Scarlet Seedling. Pears are an average crop, the best being Doyenné du Comice, Louise Bonne of Jersey, Brockworth Park, Bergamote Heimbouurg, Beurré Diel, Beurré Rance, Pitmaston Duchess, Beurré d'Anjou, Souvenir du Congrès, and Glou Morceau. Plums are the only crop we are short of, Victoria and Rivers' Prolific being the only two bearing a fair crop. Damsons are scarce in this district, except in sheltered places. Peaches and Nectarines are bearing the best crop

outside for the past eight years, and yet we had sharp frost at the time of blooming. Apricots are fair; Strawberries good; and all small fruit abundant. Fruit trees in general are clean and healthy, and free of insect pests.

Owing to a wet, late spring, vegetable seeds did not germinate well, several kinds having to be sown twice. Potatoes are free of disease so far, early and late varieties included. The dry, hot weather is now beginning to tell on the Peas and all surface-rooting vegetables.—J. LAMBERT.

STOVE AND GREENHOUSE.

WINTER-FLOWERING BEGONIAS.

A SELECTION of the best flowering kinds of the shrubby evergreen Begonias will, if properly managed, be of good service both for the con-

useful garden plants might be selected, we have the more or less popular hybrids, of which *B. ascotensis*, *B. Knowsleyana*, *B. Ingrami*, and *B. insignis* are familiar examples. Some of the numerous forms of *B. semperflorens* are also favoured, because of their free-flowering and ornamental characters, and in the several recently distributed kinds, of which *B. Carrièrei* is one, we have other useful plants for service in winter. Other good useful plants, such as *B. Lynchiana* (Roetzli), *B. Listeri*, and *B. socotrana*, have recently been added to the cultivated species of this genus.

The following is a selection of the best kinds for growing as flowering plants for the winter:—

B. ASCOTENSIS.—A tall-growing plant, with large terminal drooping bunches of bright red flowers. A fine autumn and winter-flowering kind.

B. CORALLINA.—A woody-stemmed species with leaves green above and purple below, and bright red flowers in long pendent racemes. This species may be grown so as to flower either in winter or summer.

B. CARRIÉRI.—This is the result of a cross between *B. semperflorens* and *B. Schmidtii*. The flowers are nearly as large as those of *B. semperflorens*, pure white, and produced in abundance. It is a compact grower and flowers freely during the greater part of winter.

B. DIGSWELLIANA.—A hybrid raised from *B. odorata* crossed with *B. fuchsoides*. It is a short, robust grower, with medium-sized leaves and pale pink flowers.

B. DIPETALA.—A thick succulent-stemmed plant with pale green white spotted leaves and axillary drooping racemes of two-petalled large pink flowers. It does not thrive if kept longer than a year. Should be raised from summer-sown seeds.

B. FUCHSIOIDES.—This may be included here, as it flowers not only in summer, but on through the autumn and winter if favourably situated. The tall handsome habit and large branching pendent panicles of bright scarlet flowers are well known.

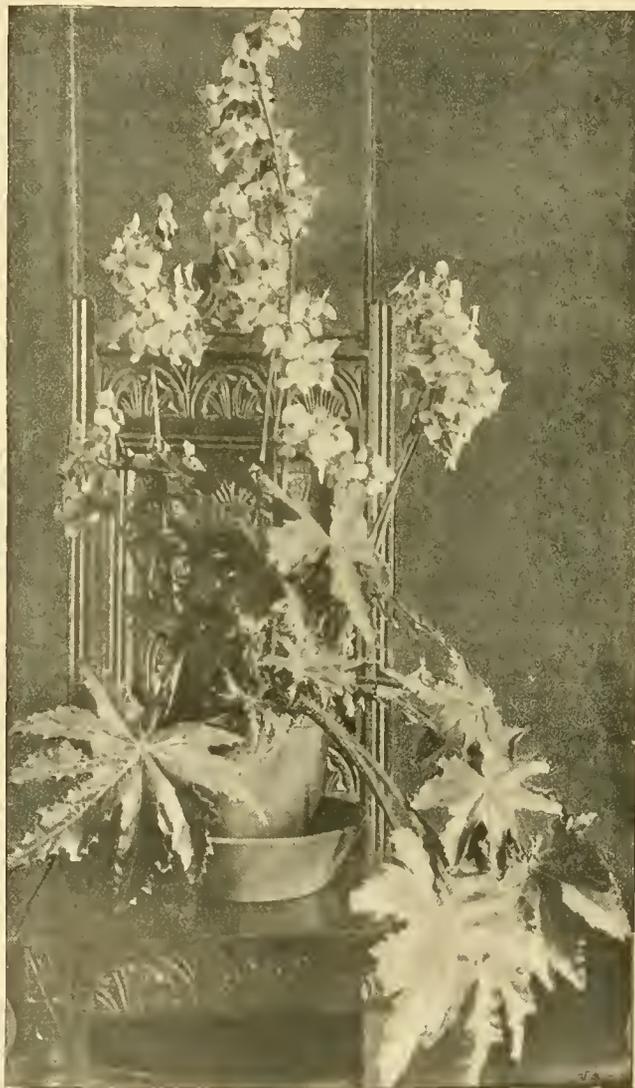

B. HERACLEIFOLIA (see cut).—A stemless species with long-stalked Heracleum-like leaves and very tall flower scapes bearing a large bunch of pale rose-coloured flowers. In early spring this plant is a handsome object.

B. INCARNATA.—A smooth red-stemmed plant, which is represented by several well-marked varieties.

They are all large-flowered, rose-coloured, handsome, and useful for winter.

B. INGRAMI is hardly distinct from *B. Digswelliana*, being of the same parentage as that kind. It is a pretty flowered plant, and blooms freely in winter.

B. LYNCHIANA.—The immense heads of bright scarlet blossoms borne in winter by this species

Begonia heracleifolia.

servatory and for cutting during the dull months of winter. Although not so brilliant in colour nor so large in size of their blossoms as the tuberous-rooted kinds, yet there is much to admire in the large drooping bunches of white, rose or scarlet flowers which are borne by the winter-blooming Begonias. In addition to the true species of shrubby habit, from which many

are of great service both when cut and when allowed to remain on the plant. It is easily grown, and should become popular.

B. LINDLEYANA.—A fleshy, hairy-stemmed species, with rather large foliage and drooping panicles of white flowers.

B. MACULATA, also known as *B. argyrostigma*, is a stout grower, with oblong green leaves marked with silvery spots. The flowers are coral-red, and are borne in large drooping panicles.

B. NATALENSIS.—A tuberous-rooted species which dies down in summer and should be started in heat in autumn. The soft green of its thin papyry foliage and the numerous cymes of large pale rose flowers which it bears in winter are attractive and useful.

B. NITIDA.—Everyone knows this useful old plant, its large shining leaves, borne on stout fleshy stems, and its terminal and axillary panicles of large, rose-coloured, sweet-scented flowers being frequently met with in conservatories during winter and spring.

B. POLYPETALA.—A singular and handsome species, which grows about a foot high, and bears hairy leaves and several terminal flowers, which are red, the whole flower having the appearance of a small single Dahlia.

B. SCHMIDTI.—A dark green-leaved plant of compact habit, bearing numerous small white flowers, which are abundantly produced all over the plant, and form a pretty contrast to the foliage.

B. SEMPERFLORENS.—This is always in flower both winter and summer. By pinching out the flower-buds in the summer handsome specimen plants may be grown, and these in winter will flower freely. The flowers of the type are white, but there are also varieties of this which bear rose-coloured or pink and white blooms.

B. SOCOTRANA.—A pretty peltate-leaved plant with bright red flowers. It is a deciduous species, going to rest in spring to start again into growth in the early autumn.

B. SUAVEOLENS is closely related to *B. nitida*, from which it differs in having smaller flowers, which are pure white and fragrant. It is also known as *B. odorata*.

B. WELTONIENSIS.—An old garden favourite raised from *B. Sutherlandi*. Its graceful bunches of pink flowers are freely borne on the numerous branches of which the plant is composed.

Those beautiful varieties of the tuberous-rooted section, embracing the varieties *B. socotrana* and the hybrids raised therefrom, as *B. John Heal*, *B. Adonis*, and *B. Winter Gem*, are all extremely useful, lasting so long in good condition. The duration of the individual flowers is also remarkable.

Sowing Persian Cyclamen seed.—I prefer the month of August—about the 15th—for sowing seed of *Cyclamen persicum*, but it is not yet too late for those who favour autumn sowing; indeed, such has been the heat that slightly later sowings will perhaps this season germinate better and more quickly. A nice shady corner in an intermediate house I find the most suitable quarters until the plants are up, by which time no harm need be anticipated from sun-heat, and the pans or pots may be raised near the roof-glass and treated to all the light available. Loam of a light fibrous nature rubbed down fine with the hands, a fifth part leaf-mould, and some silver sand form an excellent medium for early rootage. Ample drainage must be provided, as *Cyclamen* roots resent the least approach to sourness in the soil. Great care is needed in watering the seed-pans, as a soddened surface is fatal to germination; in fact, it is safer to err on the dry than on the wet side. An intermediate condition is really the one to aim at. *Cyclamen* seed is somewhat slow in starting, but if more than, say, three weeks elapse before growth is discernible, the quality and age of the seed may be questioned. I have found the young seedlings do well in the above-named position throughout the winter, as here they will grow away slowly; whereas, in an

ordinary cool greenhouse the plants remain almost stationary till the longer days arrive. Potting off has generally been done in March, or, if the plants make good headway, in February, a temperature of from 65° to 70°, accompanied by a moist atmosphere and slight shade, being given till they become established in the small pots, when a gradual hardening off is necessary until they find a home in a cool frame turned towards the north.—GROWER.

THE BREAK UP OF THE DROUGHT.

THE hot, scorching weather has at last broken up, and instead of clear skies with the heat of the sun pouring down from morn till eve we have had cloudy skies and a much cooler atmosphere. The change here took place on the 6th inst. when the sky became overcast and thunder could be heard in the distance. The storm, however, passed by, but during the night several heavy showers of rain fell, and the morning of the 7th was ushered in with a heavy fall, which continued until the day had well advanced. After this it abated, and by midday it was nothing more than a drizzle, and in the afternoon the clouds cleared away and it became quite fine, when the air was deliciously cool and formed a very marked contrast to the hot, stifling atmosphere of the past few weeks. The dry, thirsty land, the burnt pastures, and scorched lawns sucked up the rain as it fell, and it was only on the hard paths and roads that any ran to waste. The pastures and lawns had previously presented a very woe-begone appearance, and looked, as a visitor from Australia remarked, like that country does after a prolonged drought. The grass is now, I am glad to say, beginning to recover, and already looks greener than it has done for weeks. The pastures have not as yet shown much sign of recovery, and they really need another such a soaking of rain as that they had last week. The root crops have greatly benefited by the rain, and already look much greener and healthier-looking than they did. In the garden the same beneficial effect is observable among all green crops, and both Broccoli and Cauliflowers, which have been quite at a standstill for the past six weeks, have now begun to grow again. The fruit crops are also looking much the better for the change, and the fruits have swelled considerably the past few days.

It will not, perhaps, be out of place while writing on the subject to note what effect the drought has had on the vegetable and fruit crops. Brassicas in general, as has already been mentioned, were brought up by the drought soon after the great heat set in, and Cauliflowers in particular refused to grow in spite of water being plentifully supplied to the roots, and in consequence there has been a dearth of these for the past month. Having become stunted, these latter, also Broccoli and Cabbage, will take some little time before they can recover. Advantage has been taken of the moist state of the ground to get out a large quantity of Rosette Coleworts and Little Pixie Cabbage, so as to be prepared in case such a contingency as a dearth of green vegetables should arise later on through the aforesaid Cabbages and Cauliflowers being too far gone to be of any further use. Scarlet Runners which were sown on a cool and somewhat shady piece of ground have not taken so much harm, and with the advent of cooler weather and the accession of a good supply of moisture at the roots, they should go on bearing until overtaken by frost. French Beans have fared much worse than the preceding, and it has only been by dint of hard labour in keeping them supplied with water that they have been kept in a growing condition at all. The Onion crop, perhaps, ripened up rather prematurely, but the bulbs are firm. There is, however, one advantage attending this, inasmuch that it has thrown the plot at liberty much earlier than would have been the case for the planting of spring Cabbages, the first hatch of which will be got out shortly. Carrots and Parsnips do not appear to have suffered in the least from the great heat and look

remarkably well, but Beetroot, on the contrary, has been greatly distressed. It is feared the crop will be greatly affected in consequence, as the roots are but as yet in many instances very small indeed. Turnips have also had a trying time of it, and it has been owing to nothing else but the fact that I grow the summer crop of these on borders having eastern and northern aspects that I have had any fit for use. Peas have also suffered greatly, and have had to be watered assiduously to be able to obtain anything like a supply. Lettuces and Endive on a north border have done well, and, being in almost daily demand, they, as a matter of course, have had a watering every day. A large break of Seakale grown for forcing looks remarkably well, which is mainly attributable to the fact of the soil having been deeply stirred and very liberally manured. Celery had to be watered frequently, and is in consequence looking none the worse for the ordeal it has passed through. With regard to late Potato crops, these are good; but, owing to the tubers having commenced to make second growth in many cases, lifting has had to be done earlier than usual. Among hardy fruits the principal sufferers are Strawberries, particularly the older plantations, which have been badly attacked with red spider. Younger plots have been much less affected and will now quickly recover, but the older plants mentioned will have no time to lose if they do so before winter sets in. Fresh-planted beds look well. These plants were got out about the middle of August, and have since been kept watered. Heavily laden Apple trees have begun to shed some of their fruits. These are mostly early kinds, but the drought no doubt has affected them to a certain extent. Peach trees have been kept well watered and are, with one or two exceptions, in a very healthy condition. In the latter case a little red spider appeared, which made headway while the fruit was ripening, but has now been dealt with. Pears have a little spider also, but beyond this, both in their case and that of other fruits, there is nothing to record. In conclusion it may then be stated that the effects of the drought are, taking everything into consideration, not nearly so disastrous here as they were last year, and if we are only favoured with rain again, and that before long, the vegetable supply from now and onwards will be a much better one than that of the latter part of 1898. A. W.

SOCIETIES AND EXHIBITIONS.

NATIONAL DAHLIA SOCIETY.

SEPTEMBER 19 AND 20.

THE exhibition of the National Society on the above dates at the Royal Aquarium, Westminster, was excellent. Although the National Chrysanthemum Society, for reasons best known to themselves, decided to discontinue their September show, it is gratifying to know that a ready response was made to an appeal for subscriptions for a special prize fund and an exhibition held in its stead by the society mentioned above. Only eight classes were provided in the schedule of prizes, these being equally divided between nurserymen and amateurs, each affording a capital display, in which the Cactus Dahlia was to the front. A spirited competition also took place in a class for seedling Dahlias, several first-class certificates being awarded. It was to the miscellaneous display, however, that the success of the venture was largely due. Gladioli were exhibited as usual by the Cambridge firm, and the fountain at the south-east end of the building was pleasingly decorated with a variety of plants. In past years it had been contended that a Dahlia show could not be held so late as the dates of the present exhibition, but the charming display of colour in the many forms on the dates in question proved conclusively this was not correct.

NURSERYMEN.

The leading class in this section was for twenty-four blooms of show and fancy Dahlias, distinct,

and there were eight competitors. The even form, bright and varied colours were beautifully represented by the leading stand, which came from Mr. John Walker, Thame, Oxon, who had a very handsome lot of blooms. Those calling for special notice were John Hickling, a very fine yellow; Harry Keith, rosy purple; Dorothy, self; John Walker, pure white; Mrs. David Saunders, a lovely lilac; Florence Tranter, blush white, edged rosy purple; Mr. Glasscock; Goldsmith, one of the best fancy flowers, yellow, striped and edged crimson; Duke of Fife, cardinal; Frank Pearce, rose, striped crimson; Queen of the Belgians, and Eclipse, a remarkable flower of the brightest orange scarlet. Mr. Charles Turner, Royal Nurseries, Slough, was placed second with smaller, but even flowers of good form, but not so bright as those in the first-prize stand. Specially good were Wm. Rawlings, crimson-purple; John Standish, heliotrope; Earl of Ravensworth, lilac; Arthur Cockoc, reddish orange; Mr. J. Downie; Chieftain, another beautiful lilac, and Alice Emily, a buff, with yellow edge to petals. The Cactus type flowers made a grand display in the leading class for twelve varieties, in bunches of six blooms. In this division Mr. James Stredwick, Silverhill Park, St. Leonards-on-Sea, took first place. This stand was undoubtedly a very handsome one, being by far the best of the kind in the exhibition. The blossoms in each bunch were of magnificent form and beautiful in colour, and they were also very nicely set up. Several handsome seedling sorts were included in this exhibit. The varieties were: Magnificent, a beautiful rosy salmon of exquisite form; Mary Service, Mayor Weston, deep reddish plum; Mrs. Sanders, soft yellow; Eclipse, the best of the yellows; William Jowett, Uncle Tom, Mayor Tuppenny, Viscountess Sherbrooke, reddish terra-cotta, shaded apricot, and others. The second prize fell to Messrs. Keynes, Williams and Co., Salisbury, who also had a very nice lot of blooms, including several pleasing variations, and, possibly, hardly considered so valuable as those of the truest form for exhibition. All the same, they were a very handsome lot of flowers. Those worthy of special notice were Britanania, Chas. Woodbridge, Loadstone, Mrs. J. J. Crowe, clear yellow, of good form; Mrs. Carter Page, a new sort, rich reddish crimson, and Lucius, a beautiful deep orange flower. Not the least interesting section of the show was that devoted to the pompon type of the flower. These were, indeed, exceedingly pretty, well staged, and embraced a number of delightful little flowers. Judging by recent awards, it appears size is an uncertain quantity, and the exhibitor is no doubt entirely at the mercy of the individual taste of the judges. In the present instance the prizes were awarded to blooms rather smaller than usual, yet in this form their true character is undoubtedly exemplified. The first prize was awarded to Mr. M. V. Seale, the Nurseries, Sevenoaks, Kent, who had a charming display of neatly arranged bunches, twelve in number, each bunch containing ten blooms. Those worthy of notice were Sunny Day-break, pale apricot, edged rosy red; Douglas, deep maroon; Phoebe, deep golden-orange; Spitfire, very effective scarlet; Nellie Broomhead, lovely soft lilac; Hypatia, bright terra-cotta with golden centre; Nerissa, soft rose, very fine; Ganymede, amber; Ernest Harper, coral-red, and Snowflake, white. A good second was found in Mr. Chas. Turner, who also had a beautiful lot of bunches Bacchus, Mars, Capt. Boyton and Tommy Keith were each represented in grand form, and the exhibit was also charmingly arranged. There were no less than five exhibitors in this class. Singles were not so well shown as usual; the exceptional blooms of the late Mr. T. W. Girdlestone, who was unsurpassed in the way of arranging these fragile blossoms, were sadly missed. Only one exhibitor was forthcoming in the principal class for twelve varieties in bunches of ten blooms each. This came from Mr. Seale, who had a pretty lot of blossoms neatly displayed. His best varieties were the Geisha,

a pale terra-cotta and crushed strawberry beautifully blended; Beauty's Eye, lilac, crimson ring at base of petals; Phyllis, Demon, blackish-maroon; Yellow Perfection, Polly Eccles, fawn with red disc, and Leslie Seale, silvery-lilac, base of petals forming a crimson ring.

AMATEURS.

For twelve blooms show and fancy Dahlias, distinct, there were five competitors, the leading position being secured by Mr. Thos. Hobbs, Easton House, St. Mark's Road, Bristol, who had a very pretty, neat and even lot of blooms of good form and colour. Notable among them were Warrior, intense scarlet, very fine indeed; Jas. Cocker, deep purple; Mrs. Gladstone, Eldorado, Harrison Weir, primrose-yellow, and Duchess of York. Second honours were secured by Mr. F. W. Fellowes, Putteridge Grange, Luton, Beds, whose Bella (beautiful lilac), Chieftain, Warrior and Ranji were much admired. No less than eight competitors were seen in the class for nine varieties Cactus Dahlias, three blooms in each bunch. Mr. Robt. Keeble, gardener to Mr. F. W. Sharp, Waltham St. Lawrence, Twyford, Beds, was first with a very nice lot of blooms, clean, of even form, and also of rich colour, Starfish, Harry Stredwick (dark velvety maroon), J. F. Hudson, Viscountess Sherbrooke, Stella, and some beautiful examples of Mary Service. Mr. Fellowes followed with a good exhibit, Night, Mary Service, Britannia and C. Woodbridge calling for special mention. Six exhibitors made a display for six varieties of pompons, six blooms in each bunch. These again contained many charming little blossoms. Those securing first prize for Mr. J. F. Hudson, Gunnersbury House, Acton, W., were very small, but neat. This exhibit was a picture of neatness in the setting up, and the blossoms were beautifully finished. Eve, Nerissa, Orpheus, Phoebe, Douglas and E. F. Junker were those exhibited. Mr. W. C. Pagram, The Whim Gardens, Weybridge, was second with larger flowers, though lacking evenness and bright colours; Arthur West, Bacchus and Phoebe, however, were especially good. Mr. Hudson was again first among four competitors for six varieties, single, six blooms in each bunch. The staging was also good in this instance, and an even lot of flowers was represented by Donna Casilda (grand colour and form), Naomi Tighe, Phyllis and Jack Sheppard. Mr. E. Mawley, Rosebank, Berkhamsted, Herts, was second with a less even lot of flowers; Beauty's Eye, Cleopatra, Polly Eccles and Miss Roberts were in good form. A class was provided, open to all, for seedling Dahlias, and many received a first-class certificate. It was difficult in many instances to trace the name of the respective exhibitors owing to cards being misplaced; we cannot, therefore, give details respecting these.

MISCELLANEOUS.

As already stated, the miscellaneous exhibits composed by far the larger display on this occasion, and quite transformed the dreary aspect which this building usually presents. Dahlias, of course, were most largely shown, and their rich colours, combined with their varied forms, enhanced the beauty of the exhibition. A gold medal was awarded to Messrs. Dobbie and Co., Rothesay and Orpington, for a very large exhibit containing huge bunches of Cactus, decorative, and pompon Dahlias. These were set up in bunches containing no less than seventeen blooms and were very effective, although the form of the Cactus blossoms left much to be desired. A similar award was made to Messrs. John Laing and Sons, Forest Hill, S.E., for the decoration of the south-eastern fountain. This was surmounted by a fine Araucaria, Ivies, Euonymus, Golden Privet, Crataegus, Chrysanthemums, Heaths, and a great variety of other plants being arranged in a pleasing manner in suitable positions. Messrs. H. Cannell and Sons for some reason or other had their large table of some 200 bunches of Cactus and other Dahlias, and these pleasingly set off with Gypsophila paniculata and Eulalia macrantha, judged quite apart

from a lovely group of about 100 Cannas, receiving a silver-gilt medal for the former, and a silver medal for the latter. The display made by this firm was certainly one of the very best in the building, and as a whole was largely admired. A silver-gilt medal was awarded to Thos. S. Ware, Ltd., Hale Farm Nurseries, Tottenham, who made a handsome display on a large table of Cactus and pompon Dahlias. This exhibit represented most of the new varieties as well as those well known for their high merit. The pompons were very pretty, and these were disposed pleasingly at each end of the table. Mr. John Green, Norfolk Nurseries, Dereham, also staged a meritorious exhibit, arranging different varieties of Cactus Dahlias on tables in small triangular banks. This was very effective. The new Cactus Dahlia Zephyr, a cerise-pink of good form, seems destined to achieve distinction. A number of pompons were also staged (silver medal). Messrs. John Peed and Sons, of Roupell Park, Tulse Hill, S.E., set up a table of perennial Asters, their new Aster Mrs. W. Peters being represented in large numbers, also numerous other plants with Cactus Dahlias intermingled, for which a silver medal was awarded. The usual display of Gladioli from Messrs. J. Burrell and Co., Howe House Nursery, Cambridge, was forthcoming, and this is always interesting. The season has been a bad one for these plants, but notwithstanding this fact the spikes of blossoms were very handsome, and undoubtedly welcome. A few boxes of Tea Roses in bunches were also shown by this firm (silver medal). Mr. M. V. Seale, The Nurseries, Sevenoaks, secured a silver medal for a display of eleven dozen boards of Cactus, decorative, and show and fancy Dahlias in great variety. A similar award was made to Mr. J. T. West, Tower Hill, Brentwood, Essex, for a large representative table of Dahlias. The pompons here were particularly fine, and the display altogether was of a distinctly high order. Messrs. Carter, Page and Co., London Wall, E.C., also made a brilliant show, their system of staging each variety of the Dahlia in rows calling for special notice. This display was representative, and secured a silver medal. Bronze medals were awarded to the Devon Chrysanthemum Nursery, Teignmouth, for several stands of Cactus Dahlias, and to Mr. J. Williams, 4A, Oxford Road, Ealing, W., for a pretty table decoration of perennial Asters and single Cactus Dahlias. The Icthemio Guano Co., Lawes' Chemical Manure Co., Ltd., Messrs. D. Dowell and Son, Hammersmith, and Sam Deard, Harlow, made interesting exhibits, completely shutting out the north-western fountain.

NEW DAHLIAS AT THE CRYSTAL PALACE.

THERE was no lack of seedling Dahlias at the Crystal Palace on the occasion of the National Dahlia Society's exhibition. That they were composed largely of the Cactus type was to be expected, for there are now many raisers of seedlings and hundreds of new kinds are annually grown. It is necessary the standard of the Cactus Dahlia as an exhibition flower be set very high, because if a highly-refined flower like Charles Woodbridge be taken as a type, it is at once seen that high quality is necessary to reach it. To award certificates of merit to second-rate flowers is a mistake. A dozen of such awards was made at the Crystal Palace last week, and there is reason to fear there was not enough of several of these varieties submitted to enable a correct conclusion to be drawn.

The following Cactus varieties received the National Dahlia Society's certificate of merit: Mrs. Sanders, pale yellow, of a pleasing tint of colour, good Cactus shape; Mayor Weston, bright crimson, with a darker centre, a brilliant variety; Mayor Tuppenny, salmon-red, with yellow centre, a novel and distinct variety, of good Cactus character; Augustus Hare, rich orange-red, very bright; and Uncle Tom, shaded maroon, with

darker centre, fine Cactus build. All the foregoing five were raised and exhibited by Mr. J. Stredwick, Silver Hill, St. Leonards. William Treseder, the basal petals bluish, the other portions of the flower tinted delicate lilac, came from Mr. W. Treseder, Cardiff. Innovation, a very distinct and striking variety, the centre fluted petals red, with a slight tip of white, the basal petals deeply tipped with white; Emperor, ruby, flushed with purple and dark centre (it may be described as a purple Gloriosa, and is said to be of excellent habit); and Mrs. J. Crowe, delicate yellow, of good Cactus form, were shown by Messrs. Keynes, Williams and Co., Salisbury. Elsie, slight yellow ground, the petals suffused with a pleasing shade of magenta-purple, was shown by Messrs. J. Burrell and Co., Cambridge. Green's White, as shown, is decidedly the finest white Cactus yet character; and Zephyr, delicate soft rosy pink, is a charming variety. From Mr. J. Green, Norfolk Nursery, Dereham. Why the brilliant red Cactus Red Rover, a large number of finely developed blooms being staged, was passed over it is difficult to say, beyond the fact that it was considered by some too large, which is scarcely a recognised fault. The same award was made to two pretty single Dahlias—Girle, cream, with narrow side edgings of pale red, of excellent shape (from Miss E. J. Girdlestone, Sunningdale), and to Flame, pale orange, flaked and pencilled with orange-crimson, good shape (from Messrs. J. Cheal and Sons, Lowfield Nursery, Crawley).

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, September 26, in the Drill Hall, James Street, Westminster, 1 to 5 p.m. At 3 o'clock a lecture on "Instructional Fruit Stations" will be given by Mr. E. Luckhurst. — The Royal Horticultural Society's great show of British-grown fruit will take place at the Crystal Palace on Thursday, September 28, and the two following days. Entries should reach the Royal Horticultural Society's office, 117, Victoria Street, S.W., not later than September 21. On each day of the show, after 10 a.m., Fellows of the society (on producing their tickets) will be admitted to the Palace free. The first notice on p. 3 of the schedule will be strictly carried out. It runs thus: "All fruit should bear its natural 'bloom'; any polishing process disqualifies."

NOTES OF THE WEEK.

Incarvilleas in Cornwall.—Of the three *Incarvilleas* growing here, *I. variabilis* is flowering this week, and I think its blooms the best shade of the three—a very good light rose colour. The Turkestan *Incarvillea Olga* seems more robust in habit, and *Incarvillea Delavayi* has seeded well this season. All are at the foot of a south wall.—C. R.

Lobelia Carmine Gem.—This is the finest of the herbaceous section. Its distinct colouring and its free and abundant flowering are points of importance. Though never perfectly at home without ample root moisture, these plants may still be grown with much success where attention is paid them and watering done with a liberal hand. This and a partially shady spot will assist in making the plant much more a success than would be the case otherwise.

Zephyranthes Atamasco is one of the prettiest of small bulbous plants when in flower. A closely allied form is *Z. candida*, which has, perhaps, a purer white flower, slightly larger in the buds and more distinctly an autumn-blooming plant than *Z. Atamasco*. *Z. candida*, also known as the Swamp Lily, is not infrequently well grown in this country without the aid of much moisture. It is better, however, where abundance of water can be given it, and this, accompanied by shelter or shade from some adjacent building, favours the flowering of the plant.

Punica Granatum.—On the terrace at Gunnersbury House are several grand plants of the Pomegranate growing in huge tubs, or rather specially designed boxes. These plants have been flowering this year with considerable freedom, the almost solid wax-like blossoms rendering the plants conspicuous.

Their present free-flowering is the result of a series of experiments, such as pruning hard, then lighter, and again more lightly still, till finally abandoned altogether. While pruning was adopted no flowers appeared. Now with the let-alone principle a good flowering is secured, the brilliant flowers making a fine display.

Romneya Coulteri in N. Wales.—I enclose a photograph of this beautiful plant as growing in the herbaceous border here. It is over 6 feet high and has had as many as fourteen fully expanded flowers at one time. The chief point about its culture is the protection it requires during the winter, after which it throws up strong shoots in the spring and commences flowering in June, and continues to do so until September. With care a plant will last many years without being disturbed.—G. J. SQUIBBS, *Llangedwyn, N. Wales.*

Kniphofias at Biel, East Lothian.—The terrace garden at Biel, in East Lothian, has long been known as one which presents some brilliant effects as well as showing how such gardens with southern exposures lend themselves to the growth of some beautiful, but tender shrubs. Very effective in September was a long line of *Kniphofias* along the front of one of the terraces. Either from above or from the beautiful turf beneath, this long row of the scarlet heads of the Torch Lily was very showy. *K. Uvaria* appears to be a favourite in the Lothians, as it was frequently seen in quantity.—S. A.

Polygonum baldschuanicum.—A plant of this eighteen months old flowered as usual in the early summer, and now, although the leaves are mostly shrivelled owing to the drought, it is flowering again even better than before. I do not know whether this is the ordinary behaviour of the plant, but if it were, I should have expected that MM. Lemoine would have mentioned it in their description. I have not noticed the "beau rouge" fruits they speak of, though there was a quantity of what appeared to be black seeds. Some of these were sown when ripe, but they have not yet germinated.—H. S., *Derby.*

Atriplex hortensis purpureus.—In the Earl of Haddington's gardens at Tynninghame, East Lothian, there is a little garden laid out in small beds filled with old-fashioned plants and herbs. Among the others seen in the middle of September were some fine plants of the purple-leaved form of the Sea Purslane or Orache. They must have been about 5 feet high, and their appearance suggested the thought that such easily raised plants might well be more largely used in place of others which require glass protection in winter. The purple-leaved Orache was very effective and rich-looking in appearance.—S. A.

Heliopsis Pitcheriana.—In very few of the composite family do we see the rich, indeed almost intense, orange gold that renders this plant so telling. Yellow in its many and varying shades abounds, but the intense colour of this plant is not nearly so frequent even among the Sunflowers and allied things. If only for its fine, distinct and rich colouring this plant deserves a conspicuous place among the best of autumn flowers. At present, however, it is only rarely seen, but employed in groups near to the Sunflowers its merits would be quickly seen. It may be that its size is against it, for it is not so large as the usual run of the perennial Sunflowers.

Dahlia Green's White.—In the Cactus section this is a promising flower. Apart from the flower there is much that is needed to make this, or indeed any variety, an improvement on the best kinds that have preceded it. Other good white flowers have come to the front with a great flourish of trumpets, but in not a few instances are found wanting when put into general cultivation. The Cactus Dahlia to-day is so much a garden plant, that it is by no means all-sufficient that a few good flowers may be cut upon a certain day for the exhibition board. If the above can lift its flowers aloft on stout stems it will certainly prove a welcome addition to the group, and like-

wise merit the awards that have been given it of late.

Kniphofia R. C. Affourtit.—Undoubtedly this is one of the grandest of the Red hot-poker family that has yet been distributed. It is stated to be a seedling from *K. corallina*, itself a hybrid form, but whether the present plant is a chance seedling raised from *K. corallina*, or whether the result of hybridisation is not clear. This, however, is of little importance. The rich and brilliant colour, so long retained that the uppermost pips have assumed much colour before the old ones have faded, is even conspicuous among many good forms of this group. It flowers late, and is therefore a fine companion for Sunflowers, the earlier Michaelmas Daisies, and such plants.

Single Asters.—The Drill Hall on the occasion of the last meeting of the Royal Horticultural Society was enlivened by a variety of colours of the single Chinese Aster. Some of these were rather attractive, and it is more than likely would prove of considerable service from a cut-flower point of view. Despite the fact that the original has been so long uncultivated here, it would be interesting to learn in what particular this may differ from the single forms that occasionally appear among the double kinds and which are as promptly discarded. Seeing the rage for single flowers of all classes, it is significant that these Asters have been overlooked till now.

Aster acris at Whittinghame.—Among the perennial and annual plants in the beld groups in the beds at Whittinghame, the East Lothian property of the Right Hon. A. J. Balfour, M.P., is a fine form of *Aster acris*. Soil and situation do as much to modify the size and colour of Starworts as those of other flowers, so that one can hardly say with certainty whether the form was that known as *Aster acris* var. *dracunculoides* or not. It was, however, very like it. It was very effective in the middle of September, the bushes being a mass of large, deep-coloured flowers. In the beds at Whittinghame hardy perennials are largely used, but none were more worthy of remark than this Starwort.—S. A.

Origanum Tourneforti.—The tenderness of the Dittany of Crete (*Origanum Dictamnus*) has made one rather doubtful about growing a few of the other species which may be more amenable to our climate. One is led to think that we have rather neglected the distinct-looking Dittany of Amorgos (*O. Tourneforti*). This I saw a few days ago in the interesting collection of hardy plants grown at Cunningham, Fraser and Co.'s nursery at Edinburgh. It is of sub-shrubby habit and grows about a foot high. The flowers are pink and are more thickly arranged on the spike than is the case in *O. Dictamnus*. It seems to be hardy in the Comely Bank Nurseries, and as a rock garden plant is worthy of the notice of those who care for alpine of this kind.—S. ARNOTT.

Garrya elliptica in East Lothian.—At Tynninghame, the seat of the Earl of Haddington in East Lothian, there are some fine specimens of *Garrya elliptica* in the open. The truth is that this Californian shrub is much harder than some have supposed, and many who have been deterred from growing it through fear of its tenderness may safely try it either on walls or in the open. It is mostly grown as a wall shrub, but those who have seen good specimens in the open will be disposed to agree with the passage in "The English Flower Garden," which says: "If planted in a shrubbery near the path and not allowed to become crowded, its beauty can best be enjoyed." All the specimens observed at Tynninghame were fine, but one was exceptionally so with its deep green leaves and its elegant light green catkins in great numbers. Tynninghame is close to the sea, but on the east coast that does not mean much in the way of higher temperature.—S. A.

Hemerocallis aurantiaca major.—It may be welcome news to not a few who have invested in this first class perennial to know that it promises to be a good doer, if not quite so free as some other kinds in its mode of increase. The slowness of growth is, I take it, rather a gain

than otherwise, as the plant will in no sense be sufficiently prolific to become a weed for a long time to come. The rapid increase of such as *H. Kwanso*, *H. fulva*, and others is such, that constant reduction of the clumps or replanting is a necessity in light soils. The heavier soils are capable of providing more food for the plant for a longer period, and in this way the flowering does not suffer. The above plant, while possessing a good constitution, will be found quite at home in a fairly heavy soil, and perhaps not less so for the time being in lighter ones as well. Perhaps in growth this fine subject more nearly resembles *H. disticha* than any other, save, of course, the typical *H. aurantiaca*, of which so little unfortunately is known. Not in habit merely, but in the progress of its growth is it like this kind, and is therefore less abundantly tufted than all else, and quite distinct in its well-arching leaves.—E. J.

Catalpa syringæfolia fruiting. — While large examples of this handsome tree are not uncommon in this country, the instances of its fruiting abundantly are by no means plentiful, particularly so in and around London or in northern districts. Just now, however, a fine specimen of the tree in question is literally loaded with its pods of fruit in the gardens at Gunnersbury House. So numerous indeed are the pods, which hang from seven to ten in a cluster, that the tree is quite an attraction, the bunches of pods hanging over each other in remarkable profusion. The pods, the longest being 8 inches or more and not unlike those of the Vanilla, completely cover the tree for nearly one half on the sunny side, another portion inclining to east having but few pods. This, however, may have been due to an earlier flowering on this side and a subsequent frost damaging the blossom. The fruiting of the example in question is not unique in any way, though the present crop is regarded as the heaviest yet noticed. The colour of the pods is dark green, and is only varied by a slight coloration at the stalk.

Salvia splendens grandiflora.—Among the good plants that display themselves to advantage in early autumn is this modern improvement on *Salvia splendens*. The brilliant colour, the large blossoms, and the well-furnished extended spike are all points of importance in this excellent plant. By successional propagation it is possible to get a display for a very lengthened period; then with pinching and stopping far on into the season a good batch of plants can be retarded till quite late autumn for mixing with *Chrysanthemums* and other plants indoors. It should be borne in mind, however, that the cuttings must be secured when quite young; if at all hard, there is a possibility of their going early to flower without being half developed. In these circumstances, a few plants bedded out in a reserve plot and cut hard back will yield the requisite shoots, or the same plants may be kept in pots for the same purpose. It is a good plan, instead of keeping the old plants through the winter, to root a goodly batch of cuttings each autumn in a manure frame, and propagate from these again in spring. The old plants, however, make a fine array of colour in open beds, and where the latter are large, some may be retained for this purpose.

Cannas in tubs.—Replying to your inquiry re the treatment of the Cannas you noted in tubs at Mereworth, I did not disturb them last autumn, but placed the tubs in a frost-proof shed and withheld water. About the middle of February the plants were divided into pieces sufficiently small and potted into 6-inch pots, putting them on a shelf in an early Peach house, where they remained until the middle of April, removing them then to a cold pit. I planted them in the tubs the first week in May; by that date they had one strong growth from 12 inches to 18 inches, and other smaller growths pushing from the base. After planting I place the tubs against a south wall and cover with lights at night, or during rough weather until the end of May, when they are well established and ready

for placing in their summer quarters. Liquid manure is given freely as soon as the tubs are full of roots, occasionally substituting some other fertiliser. The compost used consists of fibrous loam (lumpy), spent hotbed manure, adding sifted lime rubbish and sand sufficient to keep the whole open. The two varieties grown are *Amiral Avellan* and *Joseph Bichon*. Last year I had *Duchess of York* and *Queen Charlotte* equally good, but, being of dwarf habit and green, these kinds are not nearly so effective in tubs.—J. WARREN, *Mereworth Castle Gardens, Kent*.

Lobelia Tupa.—The very distinct and uncommon *Lobelia Tupa* was well represented by a large bunch of cut flowers in the stand of Messrs. Cocker and Sons, of Aberdeen, at the Royal Caledonian Horticultural Society's show the other day. One does not often meet with it in gardens, and when seen it is generally represented by very small plants. Its comparative rarity is probably due to two causes. For one thing it has the reputation of being only half-hardy, and for another it is a remarkably difficult plant to break up without losing even a large specimen in the process. It is thus but seldom seen in such quantity as was shown by Messrs. Cocker and Sons. I made particular inquiry as to the hardiness of *L. Tupa* at Aberdeen, and was assured that it is hardy there, although the "granite city" is associated in people's minds with a somewhat unkindly climate. It does quite well in the S.W. of Scotland, like many other Chilean plants, and ought to be more generally tried, although it is said to be very poisonous. It is at times spoken of as *Lobelia Feuillei* and *Tupa Feuillei*. *L. Tupa* has flowers of reddish-scarlet and sessile, ovate-lanceolate leaves, clothed with whitish down. When established it will grow 6 feet or more high. The *Tupa* is a distinct and effective plant in its season.—S. ARNOTT.

Eucomis punctata.—There was a nice spike of *Eucomis punctata* in the table of plants sent for exhibition to the Edinburgh autumn show by Mr. John Forbes, of Hawick, N.B. It had a prominent place among the other cut flowers and attracted some notice, although those who care only for plants with bright colours could not be expected to admire it. It is, of course, an old plant, having been grown for many years as a greenhouse flower. One would not like to say that it is hardy everywhere in Great Britain, but from what I have seen of it in the south of Scotland I think it might be more largely taken advantage of in outdoor gardening, even if it had a slight covering of ashes, dry leaves, or litter during winter. I grew it here for several years, but it was lost one very dry summer from want of attention in the way of giving it a soaking with water. It has been grown in a neighbouring garden, where the soil is stiffer and where there are a few degrees more of frost, for a longer time, and is still doing well. One is confident that in moderately mild localities it might be grown with advantage. *Eucomis punctata* was introduced from the Cape of Good Hope more than 100 years ago, and appears to have been more popular a number of years ago than it has been of late. The long, channelled, oblong-lanceolate leaves are handsome, and the cylindrical scape bears a number of small green and brown flowers, which are topped by a tuft of bracts, whence is derived the name of *Eucomis*. *Eucomis punctata* appears to like a rather rich soil, where it will produce handsome spikes, which are, if not brilliant, very interesting and pretty in their way. The flowers have a peculiar sweet odour, not so pronounced as to be disagreeable, which attracts numbers of small flies to them.—S. ARNOTT, *Carsethorn, by Dunfries, N.B.*

The weather in West Herts.—Yet another warm week, and the eleventh in succession. At no time, however, did the shade temperature rise above 70°. At 2 feet deep the ground is still about 2° above the September average, but at 1 foot deep it is about 1° colder than is seasonal. Rain fell on four days, but to the total

depth of less than half an inch. The sun shone on an average for 4½ hours a day, which is a good record for the time of year. I find that the past summer (June, July, and August) was the hottest and sunniest I have recorded since I came to Berkhamsted in 1885. The total rainfall was 3 inches below the mean, but exceeded that in the same three months in 1898 by about 2 inches.—E. M., *Berkhamsted*.

Claim to produce of garden.—I made an agreement (verbal) with a builder who bought some gardens that I should have fruit and produce for finding labour and watching it, the builder to have the ground when he wanted it for building. After spending about £10 on wages, &c., he says I am not to get any more fruit, as he wants to sell the ground. Can I recover in county court for value of fruit?—A.

* * The contract between you and the builder was, that until such time as the ground was wanted for building purposes you were to expend labour, &c., upon it and were to have the produce for your reward. You may, if you choose, take all the fruit that is now on the land, whether the builder wishes to sell or whether he has sold it or not, and if he forcibly prevents you or himself removes the fruit, or if it is removed by any person claiming through him, you may sue him in the county court to recover damages for breach of the verbal contract, the existence of which can be readily proved, and which, seeing that there has been part performance, cannot well be denied.—K. C. T.

PUBLIC GARDENS.

Opening of a new park at Ilford.—On Saturday afternoon the new Central Park at Ilford was opened by the chairman of the Urban District Council, Mr. W. W. Gilson. The park, which consists of 47 acres, contains a large lake and is prettily laid out with flower-beds and shrubberies.

Hampstead Green.—The Tree and Open Spaces Committee of the Hampstead Vestry have issued a report stating that they have carefully considered a letter from Sir Henry Harben, the chairman, intimating that upon his recommendation a lady had bought for £7500 the Hampstead Green property recently put up to auction for the sole purpose of enabling the vestry to make up their minds what they will do with regard to the green or paddock in front of the houses standing on the property, and that if the offers were sufficient she would dedicate the paddock to the public in order that it might be preserved as an open space for ever. In the opinion of the committee the opportunity now afforded by the generous and public-spirited action of the lady of maintaining the present picturesque and sylvan approach to Hampstead from London should not be lost, and they recommend that the necessary steps be taken for the acquisition of the green and the dedication thereof to the public. It is expected that the owners of property immediately adjoining and facing the green will subscribe towards the purchase, and the lady referred to, who wishes to remain anonymous, has said that she will herself make a contribution to the acquisition of the green.

Names of plants.—*B. S.*—A, *Eriophorum angustifolium*; B, *Phragmites communis*.—*W. O. T.*—The Campanulas are *C. rhomboidalis* and *C. latifolia* van Houttei. Please send better specimen of the other.—*J. M. S. (Colchester)*.—1, *Polygonum amplexicaule*; 2, *Ceanothus azureus*; 3, *Clerodendron fallax*; 4, send fuller specimen, with spike of coming flowers; 5, *Stachys speciosa* probably.—*P. Bosanquet*.—Probably *Quercus Ilex* variety, but a fruiting branch is necessary to accurately determine.—*Yorkist*.—1, *Begonia*, send better specimen; 2, *Hypericum* sp., flower too shrivelled; 3, *Polygonum sphaerostachyum*.—*A. C.*—Impossible to name without flowers.

Name of fruit.—*H. Locke*.—Plum Pond's Seedling.

ROSE GARDEN.

ROSES IN SEPTEMBER.

A WALK through a nursery where Roses are largely grown will, in flowering time, give one a good idea of kinds suitable for particular purposes, as all forms of culture are adopted to suit the tastes of different customers. Here a capital chance is provided to note kinds that are yet giving a nice display of bloom. One does not expect to find huge blossoms, such as are seen earlier in the season, but as the buds are not thinned, one sees large branches laden with pretty flowers so choice in the mass. This is especially the case with Teas and Hybrid Teas, the latter class, indeed, being a comparatively new one which has already furnished some exquisite varieties, and one likely to be still further improved by raisers of new kinds. La France was probably the kind from whence this class originated, and it is itself a most profuse bloomer even as late in the year as this. Mme. Abel Chatenay, a pretty shade of salmon-pink, is excellent on both standard plants and dwarfs. Kaiseiin Augusta Victoria is a first-rate white, every flower perfect and it is very free. Grace Darling, cream and pink, seems to put on more of the latter shade late in the year. Caroline Testout, a rival to La France, the shade of colour being more rich, bears fine clusters of bloom. Papa Gontier, rosy-crimson, is delightful in the bud state, although the flower is not over-double. In a mass it is a showy kind, the habit being dwarf and free. Viscountess Folkestone, white with pink and cream tints, is also remarkably free-blooming, standards giving a fine display. Souvenir de President Carnot seems a useful addition, the flesh-white flowers borne in abundance, each bud being of capital form. Laurette Messimy is classed as a China Rose. This is especially good. The salmon-pink flowers are not of over good shape individually, but massed they give a pretty display, and it is one of the most perpetual in blooming. Whilst noting China sorts, Queen Mab, apricot, tinted rose, and Duke of York, pink and white, were two new ones which appear most promising.

Fabvier and Cramoisi Supérieur, with crimson flowers, are also a mass of colour.

Of Tea Roses proper, not the least charming is Anna Olivier. The blooms have more buff colour late than earlier in the season. It is a branching grower and most abundant bloomer. Mme. de Watteville is pretty with its Picotee-like flowers. Another very free flowerer is Mme. Cusin, of a rosy purple shade. Mme. Lambard has flowers of varied shades, but late in the year rosy red predominates. Maman Cochet, creamy pink, and its white sport give abundant proof of merits beyond those of most kinds. Francisca Kruger, buff-yellow, is conspicuous for its freedom in flowering, and the buds are very pretty. Perle des Jardins and Sunset are richly coloured buff-yellow flowers, which come of a nice shape in late autumn. This period, too, evidently suits l'Idéal; its hues of colour are varied and most striking. Few of the Roses noted compare with Souvenir de la Malmaison. It never gives blooms so perfect as when seen late in the season. On standards it is especially happy, the clusters of flesh-white blooms are so abundant. Homère, again, is an old Rose always in bloom, and in autumn comes more perfect in form. This is very attractive on huge standard heads. No list of late sorts would be complete without Bridesmaid, Catherine Mermet, Muriel Grahame, and The Bride. They are less strong in growth than those named above, but are constant in flowering. That splendid Rose Maréchal Niel bears a few blooms late in the year on standards. This seems to be the only satisfactory way of cultivating it out-of-doors.

An acre of General Jacqueminot gives one the idea of its usefulness; it is one of the few true perpetuals among the class termed Hybrid Perpetuals. This and Fisher Holmes are not surpassed for the supply of dazzling crimson Roses in September, or, for that matter, the whole season. Mrs. John Laing bears a quantity of rose-coloured blooms, but, unlike the Teas, it does not flower in clusters. Mrs. R. G. Sharman Crawford, possibly a seedling from the above, is capital now. This has been a favourite of mine, and few sorts have so many good points. Ulrich Brunner gives an

abundant supply of rosy carmine blooms. It is also among the best of growers; the foliage is handsome and not liable to mildew. Auguste Rigotard and Dupuy Jamain, two cerise-shaded flowers, are capital, and Charles Lefebvre was noted as bearing a few choice dark crimson flowers.

The Japanese Rose, varieties of rugosa, are most attractive in autumn; they produce ornamental berries in great profusion, and as the plants grow freely, huge bushes may be obtained in a very few years. Grown on tall standard stems they form splendid objects. The single flowers in summer are pretty and they are sweetly scented. Alba and rubra, Belle Poitevine (rose colour), calocarpa (rose colour also), and Mme. G. Bruant (semi-double white) are the best forms. Some Roses which we esteem highly in summer are anything but pretty in September. Her Majesty has long shoots white with mildew, and Mme. G. Luizet is a variety in the same plight. H. S.

Monthly Roses.—What a treasure these delightful Roses are in a garden, and what other plant is there that can equal them for continuance of flowering and beauty? Not long since I cut out a good deal of the old growth and tied them into shape a little on a verandah here, but though this gave them a rather tight and smart appearance they have broken away from it again now, and are as natural-looking and pretty as ever and covered with bloom. The colours are soft and pretty, and they last well as cut flowers.—H. R.

Rose Maman Cochet.—This is one of the best of Tea Roses for garden or conservatory decoration, deeper in colour than Catherine Mermet and a little less pointed, otherwise it resembles it very much. The growth is equally as vigorous as is that of the well-known kind named, and it possesses in a marked degree the same property of throwing some grand blooms in autumn. Whether it will keep on flowering under glass in the same way I have not had opportunities for proving, but I should say it would, for I have just seen plants of it with scores of fine buds in all stages of development. It is, I believe, a Rose that has come to stop.—H. R.

Rose Germaine Trochon.—This Rose is not nearly so much known as it deserves to be. It is usually described as a climbing variety, but this

term is somewhat misleading. It would never do to plant it with the object of covering the front of a lofty dwelling. Roses of the rambling nature of Rêve d'Or are best for this purpose, but let Germaine Trochon be grown as a bush or standard and its beauty is soon revealed. The first year the plant makes growths about 5 feet long. Let these be pruned back to within 2 feet of the ground, then some five or six new growths will break out, each being when about 2 feet long crowned with a fine truss of blossom. The colour of Germaine Trochon is yellow, shading to nankeen-yellow in the centre. It is a very hardy variety and has abundance of lovely glossy foliage. The flowers are large, full, and globular.—W.

Rose Duchess of Albany.—None of the La France race are more beautiful than the above variety in the autumn. The rich pink, approaching almost to red, is very marked, much more so than in the early summer. Like La France it is an abundant bloomer, but I believe the flowers are usually of better quality than those of its parent. I have found it a grand variety for pot culture either forced or grown cool. I am surprised market growers do not use it more. In strong heat the buds have a wonderfully rich colour, and its fragrance—or, at least, that of the La France tribe—is proverbial. I would advise gardeners requiring plenty of pink Roses during the early part of the London season to pot up a goodly number this autumn. Grown in cold pits the first season they should be in flower during May, and the second and subsequent seasons they, of course, could be had in bloom when required.—PHILOMEL.

Malformed Roses.—I was much interested in a plant of Homère which I met with recently growing against a gardener's cottage in almost pure gravel. This fine plant rarely produced those crippled flowers which everyone knows to be a great defect in an otherwise charming old Rose. From this I am inclined to believe that the remedy for such Roses which come badly quartered or otherwise malformed is to partially starve them. That fine Rose Maman Cochet is addicted to this splitting when grown upon very rich land. Surely it is better to have a perfect-shaped flower, if smaller, than a huge, but imperfect specimen. I think Homère a charming Rose when perfect, and in the autumn the rosy tint is especially rich. What fine standards one may see of this kind around London, which proves it to be a good town variety. Usually the soil of these suburban gardens is not very fertile, a fact that may account for this Rose flourishing so well.—W.

Rose William Allen Richardson in bush form.—Every Rose season there are complaints of the above variety producing badly coloured, almost white flowers. I have no doubt that aspect has most to do with this, but why not grow this favourite Rose as a bush? Just now some fine plants in this form are yielding richly coloured buds and flowers. Certainly they are somewhat straggling, but one does not want to see all our Rose plants of the compact form of a Baroness Rothschild. Where possible plant some W. A. Richardson in a western aspect, give them plenty of space, say 3 feet apart each way, and afford a handful of bone-meal per plant once a year, and I think there will be no trouble on the score of badly coloured flowers from such bushes. If a bed is planted, the centre plants could be trained in pillar form. Many of the vigorous Teas and Noisettes, notably Belle Lyonnaise, Bouquet d'Or, Mme. Eugène Verdier, one of the loveliest deep chamouis-yellow Roses we have, Celine Forestier, Mme. Pierre Cochet, Le Soleil, Mme. Moreau, and several others, are grand when grown in this way.—P.

Rose Mrs. R. G. Sharman Crawford.—In every respect, save its utter want of fragrance and its tendency to mildew, this Rose is a good one. It is flowering very freely this autumn, but the beauty of the plants is marred by mildew, to which they seem rather addicted. The colour of the flower is a lovely rosy pink, the outer petals

shaded with pale flesh. The form is cupped, slightly reflexed. The flowers are borne upon good stiff shoots, and may be cut with fine long stems. This Rose would be a grand kind to grow in quantity for cutting, as it comes earlier than many of the Hybrid Perpetuals, and most gardeners are aware of the value of pink Roses during May and June. For planting out under glass or for pot culture I cannot too highly recommend it. It is quite a different style of flower from its otherwise formidable rival, Mrs. John Laing, and the two could be most profitably grown in quantity for spring and early summer cutting. Mrs. Sharman Crawford makes a good head upon a standard, but if grown as a bush it should be planted in the background, for it will throw up in autumn some shoots quite 5 feet in height. It is unquestionably one of the best free-flowering Hybrid Perpetuals of recent years.—P.

NOTES AND QUESTIONS.—ROSES.

Rose Mme. C. P. Strassheim.—This variety has buds and growth not unlike those of G. Nabonnand, but the outer petals of the buds are heavily shaded with rosy pink and the inner petals a pretty buff colour. The expanded flower is large, not very double, but none the less beautiful on this account. It has an excellent bushy habit of growth, and the flowers are so very freely produced, that this Rose should be a valuable one for the flower garden.

Rose Earl of Pembroke.—I have often thought that there must be a certain amount of Tea blood in this Rose. For a Hybrid Perpetual in the autumn it is very free, and its large rich brownish crimson blossoms are most beautiful. At times the flowers are quite illumined with bright red. They are large, of globular form, and the buds fairly deep. The growth is vigorous, but not rank, and every shoot will blossom. Either as a standard, bush, or pot Rose this variety is good.

A pretty Polyantha Rose.—Just now Clothilde Soupert is flowering again very freely. It is really large for a Polyantha, but the perfect shape amply atones for this. The centre in autumn is a very pretty shade of rosy lake, the remainder of the blossom being pearly white. Doubtless many gardeners have proved its value as a good pot Rose for the conservatory. Such kinds as the above, Gloire des Polyanthas, Perle d'Or, and Perle des Rouges, potted into 5-inch or 6-inch pots would make valuable decorative plants, and they have the merit of lasting for a considerable time in flower.—P.

FLOWER GARDEN.

NYPHÆA STELLATA IN THE OPEN AIR.

HAVING seen the article in THE GARDEN for September 10 (p. 193) on *Nymphæa stellata* and other hot-house *Nymphæas*, I send you my experience with them in the open air this summer. I have tanks into which I can let a steady flow of warm water if required, but the greater part of this summer it has not been required, the sun having kept the water warm enough without any artificial means. All the *Nymphæas* I have tried at present have done remarkably well except *Nymphæa Lotus*. This grows freely, but is very shy in flowering. *Nymphæa zanzibarensis purpurea* and *Nymphæa zanzibarensis rosea* grow and bloom very freely; the flowers are large and beautifully scented. *Nymphæa elegans* is a free-flowering blue variety from New Mexico. *Nymphæa stellata*, from tropical Africa, is the most charming of all the blue-flowered *Nymphæas*, the blooms large, of a very pleasing rather light blue, of beautiful shape, very sweet-scented, and produced very freely. *Nymphæa dentata*, a hybrid night-blooming white, is a very robust grower, but not free-flowering. *Nymphæa amazonica*, from Jamaica, I think, is the very best of the white night-flowering Water Lilies, the blooms large, pure white, and freely produced. *Nymphæa*

devoniensis, a real gem, very bright crimson, flowers well and grows freely; the blooms open in the night, but keep open till mid-day. The tanks are about 2 feet deep, with 18 inches of water and 6 inches of mud. I pot the *Nymphæas*, as I have before stated in these columns, in large Orchid pans, which allow the roots to ramble out through the holes into the mud. They are put out into these open-air tanks at the end of May or first week in June, and the pans are well pushed into the mud. The plants soon start making new growth, and send up flowers freely through July and August. After that the flowers are not so freely produced, but they still keep appearing until October, when the plants are lifted and wintered in a warm pit. *Nymphæa capensis* has flowered very freely here in the ponds with the Marliac Lilies, and a beautiful addition it makes, the light blue flowers looking charming with the various shades of red, yellow, and pink of the Marliac varieties. This plant will not stand the winter, and is treated the same as the tropical *Nymphæas*. *Eichornia azurea* is a pretty plant for shallow water near the edge of ponds planted with the various coloured Water Lilies. Its mauve spikes of bloom look extremely pretty. *Eichornia crassipes* I have grown for several years, but have only seen it in bloom once. These two *Eichornias*, as Mr. Hudson remarks, will not stand the winter outdoors, but small bits of *Eichornia azurea*, planted out the first week in June, soon spread and very quickly come into flower. *Pontederia montevidensis* is taller than cordata and the flower-spikes are much larger. *Limnocharis Humboldtiana* is a charming plant, with large yellow flowers standing 2 inches to 3 inches above the surface of the water. It is very effective for shallow ponds, but I have failed to bring it safely through a hard winter.—W. J. TOWNSEND, Sandhurst Lodge.

—As is the case in a few other places this year, the above *Nymphæa* has also flowered here somewhat freely (for the first time) under similar conditions and among Marliac's hybrids excepting that the plants are lifted in November, wintered indoors and planted out in April. Dearly as I would like, I cannot look forward with confidence to this free blooming annually, as undoubtedly we owe it this year to the prolonged and intense heat and sunshine, and as such seasons are more the exception than the rule, so must an outdoor floral display of this tender and lovely *Nymphæa* also be, I fear, at any rate thus far north. Its success and regular blooming, of course, are assured where the water can be heated and in some cases covered with glass as recorded, the former of which is impracticable in most places, and the latter conditions for its growth place it entirely outside the pale of hardy plants. Treated as a hardy Water Lily in association with and under the same conditions as Marliac's and other hybrids, I much doubt if it will prove satisfactory in all seasons.—JNO. ROBERTS, *The Gardens, Tan-y-bwlch, N. Wales.*

Lobelias for stock.—Though good plants may be obtained from seed, this method of propagation is not altogether reliable, and it is advisable to rely on cuttings for the next season's supply. To do this it is a good plan to grow a few plants in pots during the summer, as these keep through the winter better than if lifted from the beds. When it is necessary to resort to the latter means some care is necessary owing to the tendency of lifted plants to damp off during the winter. It may not be generally known that a good way of obviating this evil is to select a number of plants for stock and to go over them a short time before lifting and cut off the tops. When the plants again break into growth they should be lifted and potted. Treated in this way they invariably keep through the winter without difficulty.—H.

LILIUM RUBELLUM.

MR. PETER BARR, who is staying in Japan, in a letter to Mr. Unger, head of the firm of L. Boehmer and Co., Yokohama, writes as follows concerning this Lily:—

I am very glad to know that you have secured a nice lot of that most beautiful and most refined of all Japanese Lilies, *Lilium rubellum*. When in New York in 1898 I saw THE GARDEN plate of this Lily and thought it a form of *L. Krameri*, but since seeing *L. rubellum* flowering in Japan I consider it a good species, and am sure it will be extensively cultivated when better known and its culture understood. I cannot conceive of anything more beautiful than a 5-inch pot with three plants of this lovely Lily in flower in the month of April or early in May. It is one of the earliest Lilies, flowering a month earlier than *L. Krameri*. It grows about 1 foot high. The colour of the flower is more or less that of *L. Krameri*, but the

been and how many failures I should have escaped had shippers of Lilies been generous enough to accompany with the Lily bulbs that amount of information that would have helped growers to adapt their cultivation to the wants of their newly imported friends.

Now, supposing the information I have had from the collectors and the shippers be correct, I hope in your own interest as well as in the interest of your clients you will give what assistance you can, and as I have made a special study of *L. Krameri* wild and cultivated, I will, at the risk of giving offence, state the conditions surrounding the wild and cultivated *L. Krameri*, and offer my suggestions on the successful cultivation of *L. rubellum*. When I first saw *L. rubellum* I had just returned from a southern tour. I found *L. Krameri* in a Pine forest with a thick undergrowth of brushwood, and in this thick tangle of roots this Lily grew. I had it lifted, and to my surprise found no soil adhering.

deciduous bushes where the roots in winter will keep the bulbs comparatively dry and shade the plants from the hot sunshine in April and May.

I think you should caution your clients against exposing the bulbs to a dry atmosphere. The scales are thin and soon shrivel; therefore, if they cannot be potted up or planted out at once they should be buried in dry soil or placed out of doors in a northern aspect, where the bulbs will take no injury from the weather and be kept plump.

THE MADONNA LILY.

I ENCLOSE a photo of a group of *Lilium candidum* in our garden. The bulbs were planted two years ago (old bulbs then), and have had no attention with the exception that two months ago I gave them plenty of water, as I noticed that the lower leaves were turning brown. One plant had a stem 5 feet long and $3\frac{3}{4}$ inches in circumference, with twenty large flowers.

ALWYNE SCRASE-DICKINS.

A feast of Dahlias—Any stranger or even a casual observer on getting a view into the Drill Hall recently may have readily surmised that the show was a special Dahlia exhibition rather than one of the ordinary fortnightly meetings. It certainly was no ordinary meeting from one standpoint, for the extraordinary in-gathering of Dahlias was alone a refutation of this, so great were they in numbers and so fine in quality. Nor was the quality an isolated instance; it was, indeed, general, and from a singularly varied and wide-reaching area. Those that appeared in much the strongest force were the Cactus kinds, a set that without doubt is attaining popularity by leaps and bounds. The great numbers of these with all their vivid colours render them the most striking of garden plants at their time of flowering. Some of the rose-magenta shades, or salmon with silvery edges, are extremely pretty and very attractive at first sight. An especially good flower in this line is *Zephyr*, which is described as a "high coloured rosy pink with tints of heliotrope and bluish hues." It is, however, a most attractive kind, such as would please a large number. But, perhaps, the finest of all the Cactus Dahlias at the Drill Hall meeting was the exquisite yellow kind Mrs. J. Crowe, a really beautiful and fascinating flower in which the long attenuated forets are finely incurved. The narrowness of the forets gives it an elegant and graceful bearing, and in its colour it will, provided it is a good doer, prove a useful and valuable addition to the group. It is perhaps the finest self yellow that has yet been raised.—E. J.

Tropæolum speciosum.—I think your Scottish readers over the border must be amused at the constant reference made to this beautiful plant and at the rejoicing expressed when the difficulties of cultivating it are overcome, for in Scotland there are no difficulties, and it is a perfect weed, in most places climbing up trees, covering walls and fences, and making itself at home everywhere. We in the south of England have, on the other hand, found a great difficulty in acclimatizing it—not that it is injured by frost or that the roots suffer from drought or moisture, but because we cannot get it to flower. However, it seems to me that difficulty is being overcome, for I hear from many places statements of its success, but I think that the case of a plant in my neighbour's garden (the Rev. H. W. Russell, of Hothfield Rectory) has a peculiar interest. He had planted the bulbs against a fence which faced about S.W. Here they blossomed, but last year the plants seemed to have disappeared. On looking over the fence, however, his gardener found a space of about 15 feet one mass of brilliant scarlet. It must be remembered that last winter was a very mild one and the shoots remained alive all the winter. This spring he brought some of them under the fence and against the side where it was originally planted; here it has flowered most profusely, and that is from the old shoots of last

The Madonna Lily in a Sussex garden. From a photograph sent by Miss A. Scrase-Dickins, Newells Cottage, Horsham.

height is about one-third and the leaves shorter and paler green.

On May 8 I was wandering up towards the racecourse and came upon a little nursery outside of Yokohama, and, looking over the hedge, I saw under a bush some Lilies. One of these was a stranger to me, and, desiring a closer examination, I went inside and learned it was *L. rubellum*. I was full of delight, and at once set to work to find out all about my new friend. Having just returned from a southern tour where I had seen *L. Krameri* growing wild and also cultivated, I saw the difference and superiority of *L. rubellum* for pot culture, and I may say also for outdoor culture. Collectors told me it came from the north, and as I had no chance to visit its home, I learned from yourself and other shippers that my information was correct, and on further inquiry found that the two species grew under similar conditions. This being so, I think you should make this known to your numerous clients. As one of the oldest Lily cultivators, I know how grateful I should have

The bulb was actually living amongst the roots of the brushwood with its roots in the vegetable soil, and yet the plant was healthy and in bud. A few days later I was wandering about the grounds of one of the many temples, and came upon a flower garden surrounded by a high bank covered with Azaleas and capped with trees, which threw a partial shade on the parterre. The beds were raised 1 foot above the paths, and in one of them I found *L. Krameri* in the most robust of health, stem black, and leaves of the darkest green. The soil was as poor, stony, and dry as one could possibly imagine, and I felt that herein lay the secret of the health of the Lily. I feel, therefore, no hesitation in recommending that *L. rubellum* in pots should be grown in poor, stony, sandy loam with at least 2 inches of drainage, and very judiciously watered from the time of potting. The soil must be kept moist, but never wet, and success will be sure to follow. Out of doors I would recommend a northern or eastern dry bank, and, failing this, plant under

year, and so late as the last week in August, when I was in Mr. Russell's garden, he gathered a spray covered with beautiful blossoms, which proved, I think, its complete hardiness, for although we had a mild winter, we had a few sharp frosts, and especially in the latter part of May. I think perhaps this statement may encourage some who have lost heart in trying to get it to bloom. My own roots, which were planted in a tub, grew very well, but they had only two or three flowers. I think perhaps that I made a mistake in putting too many roots in a circumscribed space, thus giving them no chance to develop themselves.—DELTA.

Cactus Dahlias at the Crystal Palace.—"A. D." puts into the note in the schedule of prizes of the National Dahlia Society affecting seedlings a good deal that does not appear in it. It simply states that blooms of "Cactus, decorative, pompon and single Dahlias must be staged with stems not less than 9 inches in length, without wire or artificial support of any kind, in order that the committee may judge of the habit of the plant and nature of the flower-stem." That is all. It is not required that the stems be stout and the flowers erect; the 9-inch stem is insisted upon with a view of throwing out those varieties which, having very short stems, hide their flowers in their foliage. Stout flower-stalks and erect will come presently. The work of improvement has so far been mainly directed to securing the best Cactus type in the flowers as well as variety in colour; the others matters—very important, I admit—will come in due course. A 9-inch stem is long enough for exhibition and decorative purposes, and it is not everyone who admires the Dahlia with erect stems; some like them a little pendent. I venture to assert, after a long experience of such matters, that the members of the Dahlia trade can be trusted to deal impartially with seedling Dahlias. They grow collections and know the varieties well, hence their value in a judicial capacity.—R. D.

Cactus Dahlia Mary Service.—The recent Dahlia exhibition at the Crystal Palace furnished renewed evidence of the excellence of this variety. It was to be seen on most of the best stands of Cactus Dahlias, and in almost every case its form and shape were such as to secure the maximum number of points allowed to a single variety. It has now been exhibited for three years and grown for two by those who keep their collections up-to-date, and we have sufficient experience of it to decide its place amongst the Cactus kinds. In my opinion it is the finest variety for exhibition that has yet been sent out. If we want to form a definite idea in our minds of what the ideal Cactus Dahlia should be like, we cannot find a better example than an exhibition bloom of Mary Service. The colour will not appeal to everybody, but that is not the point we are considering. The form of the flower is the nearest approach to perfection that we have, with the possible exception of one of this year's seedlings just certificated. Not only are the individual blooms good, but the habit of growth is such as to render it a desirable garden plant. A dense green bush is formed 4 feet in height and covered with medium-sized blooms, not with so many well-developed petals as are seen at exhibitions, it is true, but yet better than those of most varieties. Even when well thinned out to get larger flowers the plant presents a handsome appearance, for the blooms do not come below the foliage. It is one of the best garden kinds as well as the best for exhibition, and its price is now such as to put it within the reach of everybody.—J. F. H.

Leucocjum roseum.—I see in THE GARDEN of last week (p. 239) a note from my friend Mr. Ewbank asking for information as to the culture of the above plant. This, I fear, I cannot give him, except by stating my own experience with this little late summer-flowering bulb which I got from Dammann at Naples, probably about four years ago, either directly at his recommendation or from having seen it praised by him in one of his communications to this paper. As Mr. Ewbank is familiar with the conditions of my garden, he

can draw his own conclusions from the facts. I cannot now recollect whether I started with one or two bulbs, but I think it more likely to have been one, for as these things go they are, or were, rather expensive, if I rightly remember. At any rate I got a bulb, probably in 1896, planted it in common soil facing such sun as I have to show it, and had a somewhat feeble bloom late in the summer of 1897. Last year, as well as I can recollect, there was no sign of a flower, but this year it came into bloom a few days before I left home on August 18, and on my return, after nearly five weeks' absence, on the 21st inst. I find it still with a few flowers, having thrown up no less than ten flowering spikes, and that in spite of the fact that it is well-nigh smothered with a colony of seedlings of *Lithospermum tinctorium*, which, somewhat to my surprise, have sprung up on and round the spot where their "miffy" mother expired (without assigning reasons) in the early spring. *L. roseum* here at any rate seems to be absolutely evergreen, *i.e.*, I never remember to have noticed the short green, Rush-like leaves absolutely disappear even in the depth of the winter. I do not know that I quite share my friend's enthusiasm about this, at any rate regarded as a garden plant, though if one had happened to find it wild for oneself during a ramble in Southern Italy, I can well imagine becoming greatly excited about it and having a strong desire to immediately transfer it to one's garden. No doubt the habit is graceful and the flowers are pretty, though they seem to have little claim to the epithet *roseum*, but they are small, and they steal into the world at a time when, to my mind, they are not wanted, and at any rate are apt to be overlooked.—J. C. L.

CACTUS DAHLIAS.

IN THE GARDEN of September 16 are two articles on the above subject signed "H. S." and "A. D.," the latter article being entitled "Cactus Dahlias at the Crystal Palace." Having had considerable experience in growing these lovely flowers for some years past, I quite agree with the first article, and commend it to the notice of those who want to know what varieties to grow, at the same time emphasising the writer's condemnation of Daffodil and Ranji and his approval of Britannia, which, though its colour is not universally liked, is certainly one of the finest varieties in cultivation. Magnificent, however, contrary to the experience of "H. S.," has given me the greatest satisfaction. It ought to be grown in even the smallest collection of Cactus Dahlias. Excellent as is the article just referred to, the same cannot be said about the second. Intending growers who take it as a guide will be in danger of finding themselves disappointed. It contains some inaccurate statements, which appear to be due to want of experience of Cactus Dahlias in the garden, on the part of the writer. Passing over some unnecessary remarks on the requirements of the committee of the National Dahlia Society, a list of varieties is given which were well shown, and it is said that new kinds must be good to excel them. As a matter of fact, some of them have been discarded already by many growers, and some are of very bad habit. Countess of Gosford is not scarlet in colour, and it has practically disappeared from exhibition stands. Lady Penzance, as everybody knows, produces its flowers quite beneath the foliage, and sometimes with stems an inch in length. It has a lovely colour, but we may expect it to rapidly go out of cultivation now that there are better yellows. Ranji does not show much promise, and ought not to be recommended. Night is an excellent dark variety for general cultivation. Harmony, again, is no longer amongst the best varieties. It would not be difficult to make a list of eighteen varieties, of different colours, all of good habit and suitable for garden or exhibition. Why, then, should some of those named by "A. D." be included? One more point. It is impossible to draw fair conclusions from the condition of the Chiswick collection during the first fortnight of September. On

account of the drought, many varieties there were almost unrecognisable at that time, and not yet really in flower. As a matter of fact, a great deal has been done by raisers to get dwarf habit and flowers above the foliage. It is surprising that such progress has been made in so short a time. There are now good varieties that are quite dwarf enough. It is not necessary to wait a long time for Cactus Dahlias to become effective for garden decoration; the time has already arrived when they can be used with good effect, given only a judicious choice of varieties. CACTUS.

Geranium Magenta Queen.—The above is the name of a Geranium I saw last week in the flower garden at Blickling Hall. What struck me most about it was its more than ordinary loose, free character of growth and the length of stem the trusses had. The latter were of great size and depth and were borne freely. In a small garden this variety would perhaps be deemed too straggling, especially when grouped with other dwarf and more compact varieties, but in such a diversified garden as that of Blickling, where only a few Geranium beds exist, and these wide apart, Magenta Queen is certainly very effective. A fairly sustaining, though not a rich root-run is what Geraniums need if a solid, free-flowering growth is to be secured. An amateur of my acquaintance had this season a very good bed of *Vesuvius*, but he could not let well alone, and by watering them freely with liquid manure caused the plants to grow quite out of character, the said growth being almost minus flower-trusses.—J. C.

Bougainvillea glabra in Hyde Park.—Numerous examples of this in Hyde Park are now (the middle of September) profusely laden with their bright coloured bracts. The bracts are of a particularly rich tint, owing doubtless to the large amount of sunshine experienced during the growing season. Besides this *Bougainvillea*, large specimens of several other greenhouse subjects are flowering freely. Grand examples of *Plumbago capensis* laden with their charming porcelain-blue blossoms are there, while *Cassia corymbosa* is still bearing a great number of its bright golden flowers. Clusters of the reddish orange blossoms of *Browallia* (*Streptosolen*) *Jamesoni* are from their distinct tint particularly noticeable, and large *Heliotropes* and *Fuchsias* are as usual laden with bloom. Lastly, there is a bed of the Coral Tree (*Erythrina cristagalli*) the blossoms of which are nearly over, yet still enough remain to show what a grand display there was a few weeks ago.—T.

Cactus Dahlia Magnificent.—This variety, sent out last spring, is already proving itself true to its name. One of the best for exhibition, it will be still more useful in the garden. Having four plants, I can judge its character with sufficient exactness, and have decided to make a great feature of it as a border plant next year. It is the best variety for this work that I have. At last a Cactus Dahlia has been raised of such excellent habit that it can scarcely be improved upon. A group of half a dozen plants in a large border would have a most telling effect. The colour is very striking. The flowers are produced in profusion well above the foliage, and are of extra large average size. No thinning or disbudding is needed to get large blooms of this variety. Even if the flowers should in the course of two or three years be superseded by others of superior quality and a similar colour, this variety will still remain a most valuable one for ordinary garden use. Given a few more kinds of similar growth, and the Cactus Dahlia will be in no danger of a decline of popularity for years to come.—J. F. H.

NOTES AND QUESTIONS.—FLOWER.

Nymphaea Froebeli.—I have had *Nymphaea alba rosea* (Caspary) in my tank more than forty years. I always tried to obtain a finer variety of this type from seedlings, but most of the seedlings revert to *N. alba*. I had no other *Nymphaeas*, and no pollen of any other *Nymphaea* is connected with *N. Froebeli*,

which is simply an improvement on *N. alba rosea*.—OTTO FROEBEL.

Pelargonium Beauty.—Some time back I had occasion to send a note regarding the excellence of this *Pelargonium* as a pot plant, and intimated that I was also using it in the flower garden. At that time I had no doubt whatever that it would be a great success, and it has proved to be so. I had three small beds filled with it, and the brilliancy of the flowers, the freedom with which they are produced, and the dwarf, compact habit of the plants have evoked expressions of admiration from all who have seen them.—A. W.

Clematis La France—This is the clearest and most intense of the blue shades. A very conspicuous characteristic of this variety is the whitish bands down the centre of each petal on the under side and also the dark anthers. It is not so effective perhaps as *Jackmani*, but a great advance in colour. I am surprised that these *Clematises* are not more often employed by gardeners for greenhouse work. Even small specimens in 6-inch pots are very effective, especially if allowed to grow in their natural manner. I cannot say I admire the perfect balloon-shaped specimens one is accustomed to see at the Temple show.—P.

ORCHARD AND FRUIT GARDEN.

THE PITMASTON PEAR.

With the exception of the stewing kinds, this is one of the largest varieties in cultivation in this country, if not the largest, and evidence of this may be seen at many of the exhibitions of fruit held in various places each autumn. In an ordinary way, or, in other words, when the trees receive no special attention in the way of cultivation, the fruits attain a good size, but when specially treated they then assume enormous proportions, and single fruits have been known to weigh upwards of a pound and a half each. Such fruits are of course only fit for the exhibition table, they being far too large for cooking, and should therefore be grown extra large for that purpose only. It is a free-fruited variety, but if the trees are not overcropped the produce will average half a pound each in weight, and when grown for market such fruits always meet with a ready sale. It is also a hardy, vigorous grower, succeeding remarkably well either as a bush, pyramid or cordon. Low and high standards may also be planted, but on account of the fruit attaining such a large size I should advise their being planted in sheltered positions only. Bushes planted from 9 ft. to 12 ft. apart and allowed to extend would give splendid results—in fact, for market this is unquestionably the best way to grow this Pear. Although so popular, as a market variety *Pitmaston Duchess* has not yet received full recognition, but it will, in my opinion, play an important part in the future for this purpose. If the fruits are gathered just before they ripen, but while yet quite firm, and at once carefully and tastefully packed in boxes and despatched to market, their handsome appearance alone would secure them a ready sale. For the private garden it is also valuable, and may be grown either against a wall or out in the open, according to locality. That it succeeds in most districts or wherever the Pear can be grown may be gathered from the illustration, which shows it does well as far north as Scotland. Fruits taken from trees out in the open are generally more russet than those grown on walls, but they are, I think, much the highest flavoured. Wall fruits have as a rule very clear and bright-looking skins, but I always find they lack piquancy and eat somewhat flat. In flavour *Pitmaston Duchess* nearly approaches *Marie Louise* in some seasons, and in others it is inferior to it, much depending on climate. Here it is excellent, and is always exceedingly

juicy and keeps fairly well, for an autumn ripening kind. Originally sent out under the name of *Pitmaston Duchesse d'Angoulême*, it has of late years been more generally known as *Pitmaston Duchess*. It is a seedling from a cross effected between *Duchesse d'Angoulême* and *Glou Morceau*, and was raised by Mr. Williams, of *Pitmaston*, near Worcester.

Stoke Edith, Hereford.

A. WARD.

Melon Scarlet Premier.—Probably this excellent Melon is more commonly grown in the north than in the south, but wherever a really good free-setting, luscious scarlet Melon is appreciated no mistake can be made in including *Scarlet Premier*. It was raised about the same time as *Best of All*, both originating, I believe, at *Hutton Hall*. *Premier* is a very hardy Melon, sets freely, the individual fruit being of medium size, oval in shape, and heavily netted. The flesh is deep, rich, and luscious, and it will keep in a cool fruit room longer than many sorts. I know its raiser took many first prizes for flavour in the scarlet-fleshed section for some years after its introduction. As previously noted, it is

grows into a shapely tree. There is no lack of suckers to sustain old Plum orchards or form new. These suckers also form good stocks for other Plums, such as *Golden Drop* and *Jefferson*, that cannot be relied on to come true from root suckers.—D. T. F.

Open-air Figs.—The finest open-air Figs ever grown by me were grown in a border of brickbats and mortar rubbish, a paved stable-yard, and a hard, sun-baked gravel walk. With such environments the Figs will need no protection, but will make short-jointed wood. Such well-grown, closely-compacted Fig growth will stand up bravely against all ordinary climatical dangers, and be ready to furnish and finish Figs in quantity and quality far superior to the majority grown under glass. Avoid excess of food, water, and shoots, and the Figs may almost be left with a rather free head to make the most and best of the sun and air around them. I agree with "Norwich" that no two better Figs can be named for open-air culture alike for quantity and quality than the *Brown Turkey* and the *Brunswick*. Under equal conditions the latter wins easily for size, but it loses no quality in the process. Nevertheless, I prefer the

Brown Turkey for the very practical reason that most Fig-eaters can consume a *Brown Turkey Fig*, whereas a *Brunswick* may need halving, and a luscious Fig divided into two or more portions to make it more manageable is already half-spoilt.—D. T. F.

Gooseberry Whitesmith.—After all that has been written about *Gooseberries*, is there any more prolific or richer-flavoured variety than *Whitesmith*? This old *Gooseberry* may still be found in many gardens where novelties are not allowed to oust old tried friends. I know of few fruits in the hardy fruit way more delicious than a dish of full-sized, well-ripened *Whitesmith Gooseberry*. It will grow and bear abundantly in any soil in which the *Gooseberry* is at home, and small trees speedily grow into large spreading bushes. Its habit of growth is

most convenient, as being somewhat upright the fruits are more easily picked than from such as *Warrington* and some other sorts. *Whitesmith* is not usually quoted in the list of market *Gooseberries*. Why is this? Were I planting trees for profit I should certainly include *Whitesmith*, and for private use, were I confined to two varieties, my choice would be *Whitesmith* and *Warrington*.—J. C. N.

Late Gooseberries.—I find, on perusal of Mr. Iggulden's article on *Gooseberries*, that he places the old *Red Warrington* in the very first rank. I quite agree with him, and also with his assertion that it is the longest keeper. On one estate where I was employed the school children's treat took place annually in September, and they were invariably treated to a liberal supply of *Warrington Gooseberries*. There were three rows of trees behind a north wall. The wall was furnished with *Morello Cherries*, and the combined crops were protected from birds by the same trellis-work and netting. I have known in a fine dry autumn some of the fruit to hang until it assumed a blackish hue, yet it retained its rich flavour. I am quite certain that if those possessing such a

The Pitmaston Pear on a south wall at Freefield Gardens, Inch, N.B. From a photograph sent by Mr. Jas. Eddie.

singular that green and white-fleshed varieties should be so much more numerous than scarlet. Yet, fortunately, most of the latter which exist are of capital all-round quality.—C. N. N.

The Early Violet Plum.—I noticed "Norwich's" appreciative remarks on this useful variety, p. 176. He is quite right as to my reference to its usefulness, and the fact that it could be had from the nurseries of Messrs. Wood and Ingram, Huntingdon, and probably from other growers in East Anglia and the midlands. It is, however, comparatively rarely catalogued or offered for sale in trade lists. The *Violet Plum* is one of the earliest and surest croppers we have, matching *Victoria* and *Rivers' Prolific*, and equalling or excelling all other Plums in the density of its bloom. Very few Plums are of higher quality for cooking in puddings or pies, while *Early Violet* makes an excellent jam. Neither when dead ripe is it bad eating. It is also one of our hardiest and easiest-grown and most regular-bearing Plums. The *Violet Plum* is best propagated from suckers. Of course, started on this principle, every well-rooted, carefully-planted, nicely-trained sucker

site, and who sell their produce, were to prepare the ground well, so that the trees grew strongly and yielded normal sized fruit, they could—protection from birds being afforded—make such a plantation pay well, as so many people who scruple about eating, except in very limited quantities, ordinary soft autumn fruit, such as Plums, in a raw state eagerly seize upon Gooseberries if such present themselves. Mr. Iggulden's information respecting the dessert qualities of Whinham's Industry and Keepsake will be useful to many, as I know there is an impression abroad that these are fit only for cooking. Whitesmith is mentioned, and I question whether, given good culture, any white Gooseberry has a richer flavour for eating in a raw state. Mr. Iggulden also speaks of the small rough red. This is probably identical with Ironmonger, an old favourite of mine, and one which grows into immense bushes, crops heavily, and is unsurpassed for preserving.—J. CRAWFORD.

Late Strawberries.—In his lengthy and most interesting article on late Strawberries at p. 198, "J. S. W.," I am pleased to see, speaks very favourably of that old, but now seldom seen, late variety Elton Pine. I know some have characterised it as a shy cropper and acid in flavour, but my experience of it is that when properly grown it is neither the one nor the other. Well do I remember the fine beds which grew behind a north wall in an Essex garden many years ago, the fruit ripening, as noted by "J. S. W.," over a long period. The best results were obtained from two-year-old plants, for the lateness of the runners rendered it impossible to secure large plants the first season, but two-year plants were covered with the brilliant firm fruit well into September, the cool, shady aspect of course having much to do with this. I have known some gardeners, and I think the practice a good one in the case of varieties which make runners late, to plant carefully in good soil in nursery beds in autumn instead of into their final quarters. The latter may get the benefit of exposure to wind and frost by being roughly turned up during winter, the plants being put out in March. I think the advice of "J. S. W." to plant doubly thick and remove every other plant at the end of the first season well worth following, especially where the fruits are grown for sale, although it is astonishing to what dimensions some robust varieties will attain even in a single season. There can be no doubt that this late Strawberry question is an important one both to the private gardener and to the market grower, and that where practicable a north aspect and cool, moist root-run are of great moment.—B. S. N.

GRAPE FOSTER'S SEEDLING.

"H." DOES well to call attention to the good all-round merits of Foster's Seedling. It is a general favourite with gardeners and likely to remain so, but it needs to be brought before the notice of amateurs as one of the most valuable varieties for that class of cultivators. If anything, Foster's is more free fruiting than the Black Hamburgh, as a healthy Vine will usually show several bunches on each lateral. Both in cropping and setting it is a long way ahead of Buckland's Sweetwater, which, although a handsome useful summer Grape, wants careful culture, is not so well adapted for early forcing and less suitable for amateurs generally. Foster's cannot be called an aromatic Grape, but the flavour is very sweet and refreshing when thoroughly ripened, and is a Grape which can be freely partaken of by anyone. Moreover, as "H." remarks, it hangs fairly well if a suitable atmosphere be maintained so as to avoid cracking. The last evil may, I think, to a very great extent be prevented by confining the roots in a well-drained inside border, mulching the surface with old Mushroom manure when on the point of ripening so as to prevent undue evaporation and airing carefully and constantly. Under these conditions I have seen Foster's hanging plump and sound late in the season, though in time the berries assume, as "H." says, a somewhat muddy appearance. Some gardeners

will remember the somewhat amusing incident which occurred at one of the South Kensington Grape shows perhaps fifteen years ago. In the class for Foster's Seedling, Mr. Allan, of Gunton, showed three exceptionally fine bunches. The berries were much rounder than the type and so very large, that the judges took them for some other sort and an equal first prize was awarded. Some thought them to be White Tokay, although the colour and general finish bore little or no resemblance. The matter was, I believe, afterwards cleared up by Mr. Barron having some grafts and proving the variety at Chiswick. The Vine at Gunton was grafted, but on what stock I now forget. This fact, together with good culture, accounted for the abnormally large berries. Foster's Seedling is a capital stock for many sorts of Grapes; in fact, most capricious sorts seem to thrive on it. Like "H.," I do not believe in tying back leaves so as to wholly expose white Grapes with a view to colouring them perfectly. I have several times practised it, but generally regretted it, as scalding ensued. A natural thin covering of foliage is, however, essential.

J. CRAWFORD.

BUDDING PEACHES AND NECTARINES.

I WAS much interested in the remarks on this subject by Mr. Parker and "W. S.," Wilts, as some years ago, being short of Peach house accommodation, I was induced, in order to increase the number of varieties and prolong the fruiting season, to make some experiments in budding some sorts of Peaches and Nectarines on to others. Having learned that Mr. McIndoe had found the plan very useful at Hutton Hall, I wrote and asked for a few buds of various Peaches and Nectarines, also a little advice on the subject. This request was readily granted, and some measure of success attended my operations. Mr. Parker's mention of Humboldt Nectarine reminds me that I inserted several buds of this fine variety on Lord Napier in a second early house, the result being that the season of supply from that tree was extended by at least a fortnight, Humboldt ripening about that time after Lord Napier was cleared, the fruits being individually large and superbly coloured. Humboldt is, I think, deserving of more general cultivation. It is a free-growing and cropping Nectarine when carefully grown, and although, in the opinion of some, hardly so rich in flavour as its relative—Pineapple—is still one of the best of the yellow-fleshed section. I budded Princess of Wales Peach on to Violette Hative with equally good results, the difference in the time of ripening of the two varieties also being about a fortnight. It is indeed curious, as "W. S." remarks, that the union of Early Grosse Mignonne with Alexandra Noblesse should result, as in his case, in the latter ripening in advance of Grosse Mignonne. I found, as Mr. Parker says, that it is not wise to select the grossest wood of the previous year as a stock, but the medium-sized, gumming being then less liable to ensue. Examining the ties at intervals is also important, as it is astonishing how quickly the bark swells on healthy trees. I quite agree with Mr. Parker that in small Peach houses the above system of securing successional varieties is preferable to crowding in too many trees.

J. C.

Raising young Vines.—While a few still hanker after extra-strong bottom-heat-produced Vines for planting in new borders, most gardeners now prefer those which, although much smaller, are of a firm and reliable character. So much is this the case, that comparatively few nurserymen now give bottom-heat, except for starting the Vines very early in the year. After becoming established, the pots are stood on a cool ash bottom, or half plunged in unheated material, to save labour in watering. A few days since I saw a healthy lot of young Vines raised this summer standing in a cool house in order to induce gradual ripening. They were in pots about 8 inches in diameter, but these, when

turned out and examined at planting time, will be found alive and very fibrous in character. They will all live, and growth will, all other conditions being equal, be rapid and satisfactory, strong canes being forthcoming by the end of next season, though now they are little thicker than writing quills. Not so with many of the gross bottom-heat canes, which have nothing to recommend them save their size, which is, after all, only a secondary consideration. I have known many of these planted and every care bestowed, but as soon as the stored-up sap was exhausted the Vines came to a standstill until new roots were formed; these, from the shoelace character of those which were alive in the border, came very slowly, and the Vines have only been half way up the roof when others of the character described above have been going down the back wall. It is not wise to start eyes intended for the production of Vines for planting so early in the year as many do. March is soon enough; then the growth is subjected to a maximum amount of sun-heat and air from the start, and hard, well-matured, though smaller, canes result, all the fibrous roots of which are preserved for reproduction the following spring.—NORFOLK.

SCARCITY OF PLUMS.

IT IS several seasons since there was such a poor Plum crop in this neighbourhood. All varieties, however, are not alike; some are as freely fruited as could be wished, but generally speaking Plums are much below the average. The most freely fruited with me are Pond's Seedling, Grand Duke, Prince Englebert, and Diamond, the last being cordon-trained trees. Early Rivers, usually so free in setting, did not produce any fruit at all, and both Kirke's and Jefferson, which are represented by trees in different positions, are, or have been, very thin. Coe's Golden Drop, too, is very thin in crop. When this is the case it is very difficult to get many dishes free from blemish, wasps and bluebottle flies spoiling so many, despite the use of destroyers. I do not think six trees of the Green Gage produced as many fruit this year as one does in some seasons, and nets had to be used to save these few from the birds. The latter have been more persistent in their attacks on wall and other fruits this year than I have ever known them before, blackbirds in particular. These seem to have not the least energy to search for natural food once dry weather sets in and there is fruit of any kind within their reach. Despite the fact that there are extensive woods where natural food ought to be available, they migrate away to fruit gardens and orchards as soon as an effort on their part is needed to find food. Owners of gardens who preserve all and every kind of native bird have known by a lessened fruit supply what an amount of damage they are capable of doing, and nets are not always proof against them. Birds, such as thrushes, blackbirds, chaffinches, tomtits, bullfinches, jays, and house sparrows, are a terror to the gardener's life from one end of the year, to the other, and, unfortunately, they get no sympathy in very many instances from those who might lessen the difficulties in less stringent rules as to the protection of birds. I cannot see that blackbirds discriminate much between dessert and cooking Plums; any kind that happened to be ripening and was not covered with nets quickly disappeared. They were very partial to Pond's Seedling, and many fruits were spoiled before they were ripe. The rainfall here has been very slight, and the ground remains still in a very dry and hard state, notwithstanding the general rainfall which appears to have existed throughout England. Plum trees of all kinds flowered most abundantly and appeared to have set freely, but the frost and drought, each in turn, have been responsible for a small crop.

W. S.

Wills.

Gathering Apples.—"Cornubian's" remarks (page 204) on the gathering of early Apples have appeared at a very opportune time, for, with a

light crop and the bright, warm weather we have lately experienced, these are in most cases fast approaching maturity, and when fully ripe none will keep many days, but by timely storing in a cool place their season may be considerably prolonged, and the risk of damage by birds, which this season are ravenous for fruit, entirely prevented. It is doubtful whether leaving winter and spring kinds upon the trees after they have attained full size is any advantage to their long keeping, apart from the risk that is incurred by having much of the fruit shaken off by storms. Last autumn was the most favourable for the ripening of hardy fruit that we had experienced here for several years, and, thinking to improve the colour and keeping qualities of many of the late Apples by leaving them on the trees as long as possible, several varieties remained out until November. These, though carefully gathered and stored, were not in a single instance any improvement upon those gathered a month in advance, and in some cases did not keep so well. With early gathering, cool storage is the main factor, and where a cellar or earth or brick-paved room is not available, the use of slates, as mentioned by "Cornubian," will be found of great assistance, and much superior to the wooden shelves or racks so generally used for fruit.—JAMES DAY, *Galloway House, Gurliestown, N.B.*

LATE STRAWBERRIES ON NORTH BORDERS.

THE spell of tropical weather experienced during the last two seasons just when Strawberries were colouring, and which had the effect of rushing late and so-called late varieties in on the heels of the ordinary season sorts, where all alike were grown on exposed quarters, ought to impress gardeners who require fruit for the table over as long a season as possible with the necessity of returning to the once more common practice of planting for late supplies on north borders. At one show this season in East Anglia I saw Royal Sovereign, Gunton Park, Waterloo, and the so-called Latest of All exhibited, and as Strawberries now-a-days are not judged by size only, it is needless to say that the later sorts, though very fine, stood no chance with mid-season sorts of The Queen type. Lengthening the season of supply by say ten days or a fortnight is a great accomplishment, yet is quite practicable by growing the right sorts and giving the aspect named. Of course, with these late kinds one has to some extent sacrifice flavour, although several sorts, including Loxford Hall Seedling, have size, colour, and flavour combined. With a few there is some difficulty in securing strong runners soon enough for the plants to gain sufficient size for free-fruiting the first summer, but Loxford Hall, Waterloo, and Elton Pine are always at their best the second season, and the first-named in cool, shady quarters escapes the ravages of red spider, to which it is rather prone in warm soils and sunny positions.

Loxford Hall wants growing, but it pays for any extra trouble, though from the seldomness with which it is named in reports of fruit crops it has never been generally grown. The fruit is very firm and travels well. Waterloo, according to my experience, does not like full exposure to hot sun. I first discovered this when living in South Notts. I had two rows of plants, one being partly shaded by an adjoining bed of Asparagus. Some fruits on the fully exposed plants seemed to be too much hurried, did not swell to the normal size, nor was the colour so good as that of those on the shaded row. Helena Gloede used to be more generally grown than now, and is not to be despised either for size, appearance, or flavour. Eleanor or Oxonian is a favourite with a good

many, and quite deserving of culture where room can be spared for a number of late sorts. The grower of late Strawberries should have as many strings to his bow as space permits, this being the only way of making sure of a supply of fruit even in inclement seasons. One thing in their favour is their chance of escaping late frosts, which often cripple the bloom-trusses of midseason sorts in open positions. Strawberries on north borders have sometimes an indifferent larder provided, but this for such an important crop is certainly not good policy. Latest of All is a good flavoured Strawberry and not so late, I think, as some of the above-mentioned varieties. NORWICH.

LOOSE VINE BORDERS.

I QUITE agree, as will most Grape growers, with the opinion expressed by "C. N." (p. 175) on loose *versus* solid Vine borders. The roots of Vines have a great tendency to ramble away freely from the stem, and loose soil certainly favours this, and particularly when the soil is rich. The quill-like roots which are the outcome of vigorous Vine growth extend considerably in one season when favoured with an open compost in which to ramify. Firmness of soil—and it does not matter much how this is brought about, whether it is by the garden roller, a heavy rammer, or simply trodden with the feet—checks to some extent the movement of these strong roots and encourages those of a fibrous nature. Not only is this so, but, as pointed out by "C. N.," the growth of the Vine is much more solid, and consequently more easily ripened and more fruitful. The force of Vine roots in penetrating hard substances is considerable, a 9-inch or even 14-inch wall in some instances not proving a resenting barrier to their progress when they are bent on getting outdoors. New borders made with freshly-cut turf need a deal of firming to allow of the decomposition of the grass and the settling down of the soil through this decay. Of course nothing is so convincing as actual comparison, but not every gardener gets the opportunity of carrying out such experiments as those mentioned on p. 175. The lesson is a useful one to those who may be in doubt, and should readily dispel any faltering that may arise between the advantages of firm over loose borders. A friend of mine a few years ago was most successful with Vines in narrow and shallow borders, and he not only insisted upon the firmness of the soil by treading, but by the use of brick, which, by the way, is an excellent rammer for small surfaces. Finer Hamburgs or Madresfield Court I have never seen, either in bunch, berry or colour, than were grown for a few years in these narrow yet solid borders. During the hottest part of the summer water was given daily, yet a cracked berry was rarely seen. W. S.

Birds and the Apple and Pear crops.—Not content with the damage they have inflicted during the past few weeks on fruit crops, such as Strawberries, Cherries, and bush fruits in general, the birds are now attacking the early Apples and Pears. Blackbirds and thrushes are the principal culprits in the former case, and tomtits in the latter. I had a complaint several days ago from a person who grows a good many of the early kinds of cooking Apples, that the birds before mentioned were ruining all the best of his fruits, and that shooting seemed to have but little effect as a deterrent, as they recommenced their depredations as soon as ever matters became quiet again. I find on looking round that they have attacked the fruits of Ecklinville Seedling and Red Beitingheimer, on some trees in a rather quiet part of the garden here. The fruits are quite hollowed out and, of course, quite useless, and, what is more annoying, it is the largest and best of the fruits that they have spoilt. The tomtits have also begun to peck holes in the sides of fruits of the William's and Pitmaston Duchess Pears, and unless they can be prevented from

doing further mischief, they will soon ruin the whole of the early Pears. Bush trees can be netted over, but when it comes to standards, the only thing is to wait for the marauders and shoot a few of them, and hang them up among the branches. I never remember birds to have been so troublesome in any previous season as they have been in this one, and it is astonishing the number that have found their way under the nets to get at the Gooseberries and other fruits. What is really wanted is a severe winter to thin down their numbers, for the increase during the past few seasons has been enormous, the losses during the previous four winters, in consequence of mild weather prevailing more or less throughout, having been almost nil.—S. E. P.

PEAR CLAPP'S FAVOURITE.

HAVING had occasion last autumn to lift and transfer a cordon-trained tree of this variety from one part of the garden to another, I have kept the same under rather close observance all through the season, with the intention of ascertaining the amount of harm, if any, the tree sustained from the lifting. The lifting was performed with all due care, and the soil being so dry last autumn, a thorough watering was given at the time of planting. In the spring the tree blossomed well, and in due course set a good crop of fruit, which I quite expected would drop when the time came for them to swell off. Contrary to expectation, very few, if any, did so, and the result has been an excellent crop of large, well-developed, clear-skinned fruits. The only effect the lifting had was to hasten the maturation of the fruits, they being almost ready for use at the time of writing. I can attribute this early ripening to nothing else but the fact of the roots having been disturbed, as the tree faces just the same point of the compass that it did when in its former position; consequently it does not occupy a warmer site than it formerly did. As a rule Clapp's Favourite generally ripens after Williams' Bon Chrétien, and such will be the case this year with regard to the crop on a tall bush tree in the open garden. It is a large, excellent Pear, of American origin, and although it keeps but a short time, it is most useful for augmenting the dessert during September. In appearance it is more handsome than either Williams' Bon Chrétien or Souvenir du Congrès, as the side of the fruit exposed to the sun becomes beautifully coloured with a deep crimson flush, while the remainder assumes a golden yellow tint. The flesh is white, tender, juicy, and sugary, with a highly perfumed or rose-water flavour, but is not quite equal in this respect to the two varieties already quoted, which have a musky aroma. It is a Pear that will succeed equally as well on the Quince as on the Pear stock, and the Quince is to be preferred for cordon and small bush trees, as it makes rather strong growth on the Pear stock. For forming a wide-spreading bush tree, the Pear is undoubtedly the best stock to employ, and although it is quite possible that lifting may have to be performed the second season after planting, matters right themselves afterwards, as the lifting at once throws the trees into a bearing condition, and future trouble is thus averted. A. W.

Apple Peasgood's Nonsuch.—I think that in certain localities various kinds of Apples and Pears have their on and off seasons, and where one kind is good one year it is not so the next. In no case have I seen such fine specimens of this Apple either for colour or size as I did last year, and I am rather doubtful if there will be as good a display of it anywhere this season. It is early to speak as yet, of course, but one can usually tell by now what they are going to do. The few fruits I have of it here are very poor compared to their last year's form, but I have never seen it so good anywhere in the eastern counties as it is grown in the west. At Shrewsbury it was in very poor form, but this, of course, is early, and perhaps by the time of the big show at the Crystal Palace there will be better specimens forthcoming. To

get the best results this fine kind should be grown on a wall, where with care the fruits colour up grandly, but, of course, they are very attractive to birds in such positions and should be early protected.—H. R.

Burnt refuse for Apples.—Whenever I have any of this material to spare I make it a rule to place it about the stations of Apples growing on the grass, and it is easy to see by the improvement in the colour of the foliage on the trees how far it has been used. In many cases I have noticed when it has been applied to the roots of old trees that the fruit has been less liable to crack and spot, thus showing that there is virtue in it for the fruit as well as the growth. After the potash and other constituents have been washed out of this material there still remains the roughness of the ash, which is a great help mechanically to the roots of all trees, in a heavy, close soil more especially. It is one of the best of many ways in which this useful material may be used.—H. R.

Firm soil for Vines.—I am in thorough accordance with "C. N." on this point, and I have frequently advised readers of THE GARDEN to firm the compost well when renewing old or making new borders. Indeed, I am afraid "C. N." skipped a bit of my note, for in it I said: "In borders of this kind the roots are soon running all through them, and being trodden and rammed very firmly when putting together, they will be of the best class for fruit production and the formation of sturdy, short-jointed wood." Still, this point cannot be too widely known, and "C. N.'s" instructive note may meet the eye of some who are not convinced of this important point, in which case it will not have been written in vain.—H. R.

Plum Denniston's Superb.—This Plum fully deserves all that "J. C." has to say in its favour on p. 174. It is not so largely cultivated as it should be for private use, and owners of orchards, whether they be farmers, amateur gardeners, or cottagers, would do well to grow it for home consumption, as it bears splendidly grown as a standard. For the kitchen it ranks almost, if not equal, with Green Gage. It is also a first-rate dessert Plum, and when allowed to hang until they commence to shrivel the fruits are then, as "J. C." truly remarks, very delicious for eating. Where space is restricted and standards would therefore not be admissible, very successful results may be obtained by growing this variety as a bush. It is then often necessary to lift at the end of the second year after planting to check strong growth, but once this is accomplished the trees bear freely enough afterwards if attention is bestowed on summer pinching. It is supposed to be a Plum of American origin; it has a hardy, vigorous constitution, and both grows and bears very freely in the majority of seasons.—A. W.

Strawberry St. Joseph.—At Highclere Castle Mr. Pope layers this variety in the summer into 3-inch pots, giving the plants a firm loam, then taking them away and standing on a cool ash floor, where they become well rooted, and at once throw up small trusses of bloom. As the flowers soon set well, the plants are taken into a cool house and stood on a shelf near the glass, where they fruit freely. It is by having a sufficient batch very possible to have a succession of fruiters for six weeks, and dishes of fruit thus obtained are most valuable during the shooting season. The plants after they have done fruiting can be planted outdoors to give stock to produce both fruit and runners the following season. The fruits have none of the roughness of the alpine, and if they do not possess the somewhat imaginary flavour of that section are larger, smoother, and much more pleasant eating. Of course, the outdoor plants fruit very well, and if mulched with long litter the fruits are clean. But in wet autumns or where insects are troublesome it is a great gain to have the plants in pots in the way described. Most certainly it is a novelty to find a variety that fruits so well and so precociously from summer runners as St. Joseph does. It is a

variety every gardener should have, and amateurs who like Strawberries will find that it is very easily grown.—A. D.

FLAVOUR IN STRAWBERRIES.

MR. ENGLEHEART'S paper relative to flavour in Strawberries is well worthy of the careful consideration of raisers. Size and travelling qualities are very much pushing flavour out of court. Still I do not consider size and flavour as necessarily antagonistic. I have grown British Queen of 3 ozs., and, without a doubt, that Strawberry stands on the tip-top apex of the present pyramid of perfection in flavour. It certainly is a curiously eccentric kind. For about five years it did admirably with me where I now live, then it took a sudden dislike to me, and I have never since been able to secure even a decent crop. I am surprised that Mr. Engleheart made no mention of Laxton's Latest of All, very nearly equal to British Queen in flavour, very large, and producing very heavy crops. Its two drawbacks are the white (sometimes green) tips, which it inherits from one of its parents, and it fails to last. It is one of those Strawberries which are improved by an annual treatment. If good runners can be got into their quarters by the first week in July they will always give a splendid crop the following season. After that (with me at all events) the plants dwindle and gaps are frequent. I wonder whether many of your readers recollect the old Carolina, a very pale coloured round Strawberry with an exceedingly high and most peculiar flavour—a flavour perfectly distinct from that of any other Strawberry of the period. It was always a wonder to me that this failed to save it from extinction. I was as much pleased as surprised to find this peculiar flavour resuscitated in the new French Strawberry Louis Gantier. This variety is (as far as this part of Ireland is concerned) perfectly worthless as an autumn bearer on its runners, but along with its fine flavour it bears perfectly astounding crops of (I must confess) ugly dirty white fruit. It never will be a market Strawberry, but a few lines should be grown in private gardens. Marshal McMahon is another very highly flavoured Strawberry. I have not got Mr. Engleheart's letter before me, but I think he fails to take any notice of it. Here again we have a resurrection. I am old enough to remember the old Myatt's Pine, probably the very best flavoured Strawberry that ever existed, but possessing a constitution of such extreme weakness that it soon disappeared. I recognise in M. McMahon a very decided trace of my lamented and long-lost friend. I should be glad if any of your readers could tell me whether Myatt's Pine was even its remote ancestor. One more neglected favourite I mention in conclusion, Myatt's Eleanor. I cultivated it successfully forty years ago, but have never been able to do so where I now reside. It was (and I suppose still is where it succeeds) a very late variety. I have often had it, and had it good, on September 1. I know no very late variety with so good a flavour, though I daresay the new St. Joseph may in a fairly good climate (which I have not) have an excellent though entirely different taste.

Co. Caran.

D. K.

NOTES AND QUESTIONS.—FRUIT.

Apple Washington.—There was a very fine dish of this handsome Apple on Mr. McIndoe's second prize fruit table at Shrewsbury, and though, of course, it is not yet in season these fruits were very handsome. I did not hear what position they had been grown in, but, judging by their appearance, they had been taken from indoor trees.—H.

Melon Gunton Scarlet.—At p. 115 "J. C." writes respecting the above variety. I have had several opportunities of noting its merits. With me Gunton Orange proved an excellent Melon, not large by any means, but always reliable as regards flavour, and this is the best test of a Melon. With Mr. Allan's new Melon growers will have little to find fault. I admire it for its size. It is quite right

a Melon should never be sent to table a second time after being cut, and to follow out this advice large fruits are not needed. In the Gunton varieties the fruits are just the size liked for private gardens, and the flavour is excellent and the fruits handsome.—G. W.

Pear Doyenne d'Alençon.—I was pleased to notice in the list of Pears adopted by the Congrès Pomologique of France the name of Doyenné d'Alençon. Only in one garden have I seen this variety, and that was at Hillside, Newark. The late Mr. Newton obtained it from a friend near Paris and fruited it as a horizontal cordon. A small tree bore a nice lot of fruit, which came into use in February and March. The garden at Hillside is very exposed and the soil a stiff clay loam. A good many late Pears require a warm climate and wall space to secure thorough maturity, so that a late variety which is at home in a midland or northern locality, and especially in cold, strong soils, is indeed valuable.—NORWICH.

GARDEN FLORA.

PLATE 1242.

THE NEW GIANT VIOLETS.

(WITH A COLOURED PLATE.*)

A VAST change has taken place during the last half dozen years in the modest Violet, and if this popular flower continues to improve in the near future as rapidly as it has done in the past, then its size and stateliness will become more apparent than its traditional, but fast disappearing, modesty. Few will be disposed to complain of the increased size provided the giant Violets do not come short in other respects, such as fragrance and free flowering. The addition of 3 inches or 4 inches to the length of stem and the expansion of every petal by more than half have added immensely to the value of Violets for cutting. Some maintain that the fragrance of California and Princess of Wales is not so pronounced as in the older varieties, and others think that the increased size is a drawback, but the latter especially is only a sentimental objection, for the majority acclaim the strides which the flower has made, and look for greater wonders in the future.

CALIFORNIA was about the first giant Violet to make its appearance, and in spite of a little incredulity at the outset was largely bought, and in many cases successfully grown. Having a rank habit of growth, in many cases it soon became crowded and tangled, and disappointment resulted; but where it has been judiciously cultivated it has generally produced abundance of immense blooms. It possesses the true violet colour and has a most graceful pose. It has been my best outdoor variety for three years.

PRINCESS OF WALES, which made its appearance about the same time as California, easily leads the way so far as size is concerned, but its colour is not so good, and it is more suitable for frame culture, as it is rather less hardy. It does well in pots and is a grand flower. The leaves are large and leathery. It is easily propagated, and lifts well in September for frame culture. I have frequently gathered blooms measuring close on 2 inches in width from plants in the open ground.

PRINCESS BEATRICE is rather smaller than the two first-named varieties, but the colour, which has more mauve in it, and the perfect shape of every bloom make it a very desirable addition. In

PRIMAVERA and ITALIA we have two continental varieties which rather resemble California, but they bloom over a somewhat longer season.

LA FRANCE is decidedly darker in colour than Princess of Wales, which is an advantage. It

* Drawn for THE GARDEN by H. G. Moon in Messrs. House's Coombe nurseries, Westbury-on-Trym. Lithographed and printed by J. L. Goffart.

PLANTAE
RANUNCULUS

has been claimed for this Violet that it is the largest up to date, and I think the claim will probably be upheld, and that it will also prove most prolific. The French varieties,

LUXONNE, L'INÉPUISABLE, and EXPLORATEUR DYBOWSKY, have not yet been sufficiently tested in this country to form a definite opinion as to their general utility, but they are robust in habit and have successfully resisted the red spider during the past exceptionally trying summer.

Apropos of the red spider, many Violet growers must be sadly disheartened by the ravages which it has already made, and a cheap and effectual insecticide which can be relied upon to dispose of it will be welcome.

Whilst the culture of Violets is not so difficult as many would suggest, they certainly call for care and patience right through their career from the cutting-bed to the rubbish-heap. Briefly, I root the cuttings in September either in frames or sheltered borders. If they make much growth before winter, I lift and line them out in nursery beds, taking care to plant sufficiently deep. A slight protection from the frosty winds of February and March is advisable, although in many localities nothing in this way will be required. Plant out from 12 inches to 15 inches apart in April or early in May and use cow manure as a dressing, especially in light soils. The trying months are July and August, and it is then that Violets will give out unless they can derive substantial assistance from beneath, and that in spite of overhead watering. The shade afforded by large fruit trees has been very beneficial, and some such position should be secured for planting in where quantities of Violets are indispensable. This is especially desirable where the clumps will be removed into frames in September.

Much has been written about the culture of Violets under glass, but one point calls for attention, viz., the necessity for plenty of light and air even during a severe winter. A little frost will not injure Violets half so much as the unreasonable nursing and coddling which they often get in frames. I am sure that this remark especially applies to the rank-growing giant Violets. Much water is also injurious. Pick off the decayed leaves and keep the soil fresh and sweet. When the plants have done flowering they may as well be thrown away, as it is presumed that plenty of cuttings will have been rooted from the runners which the plants have supplied during the previous August and September.

JAMES C. HOUSE.

Peat-moss litter as manure.—Various opinions have been offered from time to time as to the bad and good effects of this material as manure. Of late years there has been a growing tendency to use it in stables instead of straw, and consequently gardeners in many establishments have found themselves in the awkward position of having to use peat-moss litter manure or nothing. Compared to good straw litter manure, I do not consider it worthy of the name, and have come to this conclusion after using it on a somewhat retentive soil. In itself the manurial properties contained are very small. After lying in the ground for a whole season I have seen it turned up in exactly the same condition as when dug in. I can also substantiate the statements made by several correspondents on the ill effects of peat-moss when used as a mulch for Strawberries. It may answer fairly well if the weather happens to be dry during the fruiting period, but let it come wet, and wholesale rotting is almost sure to be the result. There may be some instances where peat-moss is apparently beneficial, but I fail to see how bog peat, in which nothing grows naturally to any perfection, can eventually prove to be of lasting benefit.—H. H.

THE WEEK'S WORK.

KITCHEN GARDEN.

PRICKING OUT CABBAGES.—After the required number of spring Cabbage plants has been planted on the various quarters from the second sowing, the more weakly that remain over may well be pricked out closely on very firm ground not over-rich. This is the safest plan, as one is never certain what the winter will be. If mild and much bolting occurs in the main plantations, the latter are often the more valuable of the two, and if severe weather should be the order of the day, the nursery plants can easily be protected with litter, Bracken or some such material; and should they survive, their constitutions are better than of those wintered in frames or pits and the plants go away better when transplanted in March or April. If not required, the labour is not much, and it is gratifying to know one is on the safe side. Cauliflowers may be treated similarly, so that dry leaves or evergreen branches may be used for protection. I have had such varieties as Snowball and Erfurt, also Early London, stand through a moderate winter planted at the foot of south and west walls like Lettuce. In districts where early Cabbages occupy hot, dry sites the present is a trying time for first early spring Cabbages, as the amount of rain that has fallen has made some, but not sufficient impression on the root-run. Where flagging has been excessive, owing to an arid atmosphere or violent winds, evening sprinklings overhead by means of rosed watering-pots are beneficial, enabling the plants to assert themselves by morning. The same remarks apply to Endive. Batches of the latter, owing to lifting time approaching, must, where growth is not vigorous enough, be assisted with liquid manure.

MUSHROOM HOUSE.—In a former calendar I gave instructions concerning the preparation of an early bed, which will by this time have been spawned and soiled over. Hitherto, the temperature has been sufficiently high without the aid of artificial heat, but with colder nights a gentle warmth in the pipes may be allowed, 55° being a suitable figure to aim at. Later on, when it is discovered that the spawn is actively operating, a fall to 50° or 52° will be advisable, as suiting secondary and main-crop beds best. In the event of the heat of the earliest bed falling lower than is desirable, give a liberal covering of dry litter. I prefer oat-straw, as this lies loosely on the bed and does not become mouldy like hay. Provided the material is fairly moist, do not apply water to the surface until the young Mushrooms appear. For making successional beds, manure from corned horses should be collected every morning, for, as a rule, by the time sufficient has been collected and gently sweated it is time to make up another bed. Much carelessness is often displayed in the preparation of the droppings. Some allow them to be thrown into and remain in a heap for days together in order to save time, but the practice is a bad one, as by such violent sweating when the material is in a moist condition much of the ammonia required for producing and sustaining the crop is lost in evaporation, neither do such beds last so long. Throwing it into a ridge and turning it every morning is by far the best plan. The long straw should be removed as the material is collected, the short being left in to assist in keeping it open and thus encourage a free working of the spawn. Saturating the walls and floors of Mushroom houses every morning with water is not good practice, as it creates a close, steamy atmosphere, which soon turns the tiny Mushrooms black and prevents them swelling. The best way is to slightly syringe the paths and walls each morning, and no more. Insert the spawn when the heat of the bed has fallen to 90°. Some spawn nearer 80°, but sometimes the disturbance of the surface and opening and shutting of doors cause a sudden drop of 5° or even 10°.

PICKLING CABBAGES.—Most gardeners like to secure large, heavy specimens of red Cabbages, but these extra large heads are not at all times the most profitable. Not infrequently when the

plants are raised say with the earliest lot of ordinary spring cooking Cabbage they grow vigorously if the winter is mild, and the succeeding spring favourable, monstrous Cabbages are formed by early autumn, and as they are not usually required for pickling until well into November, bursting and decay take place. Of course they can be pulled up and suspended by the stem in a cool, dry outhouse. I have grown excellent solid heads from plants raised in a frame in spring. At any rate, too early autumn sowing is not advisable.

GENERAL WORK.—After a very dry summer we often get a succession of heavy rains in autumn; therefore the sooner a good-sized heap of soil is got in readiness for use in forcing early batches of pot and box-grown French Beans the better. It can then be stored away in some convenient corner where it will not become too dry, and can be covered with boards or thatched to protect from drenching rains. A good friable loam, with a small percentage of horse droppings or a little artificial manure, should be added to the soil. Those who force in shallow wooden boxes—a system which has much to recommend it, especially in mild winters—should take advantage of wet days for the repairing of the same, or making new ones if required. Everything will then be in readiness for a start in October. Those who are venturing on Bean forcing for the first time and are unacquainted with the best varieties will find Osborne's, Sutton's Dwarf Forcing, and Syon House reliable. J. C.

FRUITS UNDER GLASS.

FIGS.—No other fruit tree grown is so prolific as the Fig, and there seems to be practically no limit to its continuous cropping while growing conditions can be maintained. It is advisable now to prevent any further development of fruit or growth on trees intended to be forced early next year. Late or third-crop fruits are never so fine as the earlier ones, and they may well be sacrificed with a view to building up the trees for next year. With me the wood is apparently ripening up well and little fire-heat is being used; free ventilation night and day and a drier condition of the soil will do all that is necessary in order to finish up the growth in a satisfactory way. Where bug has established itself, the leaves, as they turn yellow, should be picked off by hand and carried away to the fire heap instead of being allowed to drop on to the borders. If the stems are left to drop of themselves no harm will be done by taking away the leafy portion, and at the same time removing all fruit that has formed. If replanting is contemplated, no time could be better than the present, and in the case of trees that have been making gross and unfruitful wood, I would suggest, as the very best possible remedy, that the borders be opened up, removing the rich soil and substituting a very much poorer rooting medium, but one that contains lime and broken brick in large quantities, giving plenty of drainage and ramming the soil as firmly as possible. The Fig is not a delicate tree, and it does not object to an amount of root-disturbance that one would not like to employ with many other trees, so no fear need be felt that the loss of a few roots will do the trees any harm, and in many cases it would be a great benefit to cut them away freely and to curtail the borders considerably at the same time, so that the new roots shall be confined to a very limited space and fully occupy that space before any additions to the border are made. By proceeding in this way the trees will be induced to make wood of the right sort for fruiting, and the fear of the first crop turning yellow and dropping when half grown will disappear.

PEACHES.—Early-forced trees will now have cast most of their leaves and may be pruned at once, first of all loosening them from the trellis and getting rid of all old ties. Whatever system of pruning may be used, the operator should bear in mind that the general tendency is to leave far too much wood in the trees. Probably this may arise generally from an anxiety to secure a good set, but there is always far more need to fear bud-dropping from trees that have been

thickly trained than there is with those which have been allowed ample room for the full development of their leaves. Personally I adopt the extension system of pruning and training and cut away all spurs that form, retaining only as much new wood as will clothe the trellis at about 5 inches apart. These shoots I rarely shorten, except, perhaps, a few of those which have encroached beyond their limits, and which must be curtailed owing to want of room to extend them. In shortening such shoots it is necessary to be able to recognise the wood-buds and to prune always to one of these, as, unless there is a wood-bud at the end of the shoot, it will die back. The old axiom that the centre bud of three on the same cluster is sure to be a wood-bud is a mistake, and holds good only in some cases, as many Peach trees carry young shoots with very few wood-buds, and bunches of three flower-buds are by no means rare on these; consequently the man entrusted with pruning should be able to recognise wood-buds at a glance. This is not difficult, as they are quite different in shape from the flower-buds, being long, thin, and pointed instead of being plump and round. Where the trees have had due attention paid to them in the matter of disbudding during the growing season pruning is an easy matter, as there will be but little to cut away except the wood that has borne fruit, leaving to replace it the young shoot that has been retained at the base of each piece of fruiting wood. If more than sufficient wood to furnish the tree has been laid in, it is advisable, for the sake of retaining the trees in good shape, to cut away the new shoots that have been laid in on the under-sides of the older wood and retain those laid in on the upper sides. When pruning is finished, the roof, glass, wood-work, and walls should be syringed and washed down with hot water and soft soap, using considerable force in syringing, so that the water may be forced into the crevices and drive out insects that may already have secreted themselves. Whitewash the walls with hot lime, and then turn attention to the trees, which should have the older wood thoroughly gone over with a solution of Gishurst compound, applied in accordance with the directions, and well worked into all cracked bark and other crevices. The young wood may be gone over with a weaker solution, but it is very susceptible to injury from strong insecticides of a solvent nature, and as the smoother bark on this wood offers no hiding-places, there is not the necessity to be so particular with it. The next process should be to remove the top 2 inches of soil from the borders, not forgetting those portions situated under the pipes and other places not easy of access, for these places are apt to be passed over unless their clearance is insisted upon, and neglect of these odd corners means undoing all one's good work by leaving a stock of insect life behind. It may be objected to this stripping the face of the borders that it exposes and injures fibrous roots near the surface, but the injury caused is more than counter-balanced by the good done in replacing the soil removed with fresh material. It is not yet too late to plant trees in an early house; indeed, those grown and prepared out of doors will now be in the best condition for planting, and if they are carefully dealt with they will carry a moderate crop the first year.

MELONS—From now onward it is not advisable to use the syringe on the plants in whatever stage they may be. Atmospheric moisture must be kept up in houses carrying fruits still in the swelling stages, but this may be done by keeping the evaporating pans filled with manure water and by frequent damping down of walls and other surfaces; this will be sufficient to keep down spider. Over-ventilation should be carefully guarded against and fire-heat kept on night and day, so that the temperature shall be kept fairly high and steady with only the usual fall at night. A few hours of a low temperature will probably spoil the crop. Whatever water may be needed by the plants should be given in the morning, and the soil near the collars should be kept dry

without fail, for at this late date canker may be readily set up by wetting the stems, and it is not so easily checked now as it may be in the summer. To assist the fire-heat and to prevent cold winds from blowing in on to the plants through the laps of the glass, the pits or houses should be covered with frigi domo or mats, the former for preference if it can be put on in a dry condition each night. CORNUBIAN.

KITCHEN GARDEN.

SOILS FOR POTATOES.

MANY who grow Potatoes never trouble about any special preparation of the soil for them, and it is not at all unusual to grow them on a dirty fallow where the necessary hoeing and cleaning will kill some troublesome weed or another that has established itself. This is, of course, wrong, and is at the bottom of a lot of our Potato troubles. Time after time during the present season I have received samples of Potatoes from growers in different localities with the request that I should tell them what was wrong with them. In nine cases out of ten poverty and unsuitability of soil have been evidently the cause, for the tubers have been exceedingly small for the kinds sent—so small in some cases as to be quite unrecognisable—and bear that stunted look that shows plainly the want of suitable plant food in the soil. Fresh farmyard manure planted with the sets cannot really be of great service to the crop, and owing to the soil having lain close and inert all the season there are injurious acids formed that damage the tender skin of the growing tuber. Nature trying to remedy this fault, the flesh of the Potato grows out at that point, making either a very ugly-shaped or a scabby tuber.

One of the greatest aids to successful culture of Potatoes is preparing the land as far as possible in autumn. Whatever crop they follow should be off the ground by September, and as soon as the ground is sufficiently softened on heavy lands or directly the crop is cleared from lighter ones, let it be as deeply ploughed as possible or well dug as the case may be. If farmyard manure is to be used, it should be spread thinly and regularly before digging, and the soil left as rough as possible. But there are other materials that may often be got that are more suitable for Potatoes, and a heap of well-prepared compost applied either now or in spring is a valuable aid. The cleanings of ponds and ditches, odds and ends of soil, verge clippings, and coal ashes with a good sprinkling of lime when it is being turned, are only a few of the materials that a careful gardener may gather on most estates, these helping out the often very short allowance of manure and suiting this important crop exactly. About burnt earth and charred garden refuse it is hardly necessary to say much. This material is so well known as a valuable aid to Potato culture that little of it is likely to be wasted. This may, however, be kept dry and off the land until the final preparations for planting are in progress, as it is quick-acting in a chemical way when rains follow planting, and is also useful for placing along the drills and furrows, the tubers always turning out very clean afterwards. But even the fact of exposing the land to frost and rains in winter is a great help. It purifies and cleanses it, besides making it work very much better in spring, and it is always a sign of very bad management when you see a farmer ploughing old land, or a cottager or gardener digging it and planting at the same time. The effect of such dilatory work is worse in a dry season

than a wet one, especially on heavy lands where the ground turns up lumpy and dries hard, and one has to wait for rain before hoeing or moulding up can be done. The Potato is a long-suffering plant, and takes care of itself in a most remarkable manner against very long odds, but no one who will give it proper cultivation on practical lines is likely to lose by the experiment. H. R.

Lettuce White Chavigny.—Many notes have appeared recently on Lettuces, but I have seen no mention made of this Cabbage variety. Doubtless most growers will agree that any kind that will give good tender heads in a season like this should be known. I consider this the very best for a summer kind for coming in in hot, dry weather. I have grown it the last three seasons and prefer it to any other kind. My plan is to sow it on Celery ridges through the early part of the summer, allowing the plants to remain where sown. In this position they receive good supplies of water and manure water occasionally. When treated thus it grows wonderfully quick and is very tender. I grew Continuity many years ago when first put on the market, and although praised by some growers, I consider it poor beside this kind. I am convinced Chavigny will remain as long before running to seed; added to this, it is devoid of that dark colour which is against Continuity.—DORSET.

A good insecticide.—In a recent issue of THE GARDEN "A. D." refers to my using a solution for spraying Peas affected with thrips, and also to my showing the haulm and Peas at the Drill Hall, stating he knows nothing of it, but suggesting it should be tried at Chiswick. I consider this a capital idea and hope it will be carried out. I used this insecticide (the name is Improved Spimo, not Spioæ, as written in THE GARDEN) on three long rows of Peas with the best results. Had I not used Improved Spimo I should have lost all my late Peas early in July from thrips. One evening I resolved to try this, having just obtained a gallon. Accordingly I had these rows, which were Ne Plus Ultra, Chelsonian and Walker's Perpetual, sprayed over with a weak solution, just warm. Although the tops and young leaves were curled in and eaten badly, in four or five days it was clear it had a good effect. A second application was given. This arrested the pest, and green leaves with elongation of shoots were visible. I then resolved to water and mulch the roots, with the result stated by "A. D." at page 196. Undoubtedly this is a splendid insecticide. Another advantage is that that being cheap it is within the reach of all.—J. CROOK, *Forde Abbey*.

The vagaries of Kales.—I shall be glad if anyone who, like myself, has experienced the difficulty, or rather the impossibility, of doing any good with some of the types of Kales will offer a suggestion as to the probable cause of failure. I grew Asparagus Kale successfully for several seasons until it went off in the mysterious manner chronicled last year in THE GARDEN pages, and as this was repeated for three years it was expunged from the list. This year the opportunity offered of trying many varieties of Kales, and two forms of Asparagus with Labrador were included. Two rows of each, half a dozen in all, were planted in the centre of the plot, and at the present time (September 16) there is not a plant left of the two hundred that were put out. On either side of them the dwarf curled types, both green and purple, Reid's Hearting, Scotch Kale, Cottager's and many different forms of garnishing Kale, are in the best of health, have completely covered the ground, and will make some splendid stuff. So far as the root is concerned, there is absolutely nothing the matter with the Kales that have collapsed. It is simply an above-ground question, as the foliage in the best of health to day droops to-morrow, then withers and finally dries up, the last being accompanied by the rotting of the stem. I have entered somewhat fully into the particulars of the disease with the view

to ascertain if other growers are in a similar plight, also to solicit notes from any contributors who may possibly have found the cause of the disease and, it may be, a remedy for the same. Failing to obtain the latter, I shall avoid all Kales of this type and rely solely on the green and purple curled and Cottager's.—E. BURELL.

POTATOES IN THE SOUTH.

ANYONE who has travelled from the southern to the northern counties will have noticed the different aspects that exist owing largely to the amount of rainfall. The season everywhere has been dry and south of the Thames excessively so, and this no doubt has been the cause of the early harvesting of most crops. For weeks past it would have been almost impossible to find a green field in Kent, and before August was out the majority of the corn was safely harvested. Potatoes, too, have come along at the same rapid rate, and in many gardens the lifting of the main crop was effected during the opening days of September. The same may be said of Onions, and with me the crop has been harvested several weeks ago. From observations made in different localities all of which have suffered severely from drought, I am of a stronger opinion than heretofore that Potatoes do not necessarily suffer to any great extent in a dry season, supposing, of course, that they have been subjected to fair and reasonable cultivation.

The early varieties were perhaps a little disappointing, not on account of the quantity so much as the smallness of the tubers, and this I attribute to the rapidity with which the tops ripened. In digging Potatoes this season we have had a good illustration of the value of autumn or winter manuring for this crop in preference to applying it in the spring, as in cases where the latter was done the manure, except being more hard and dry, came out much the same as when put in. Neither have I been able to see much difference in the results obtained from farmyard manure and artificials, as in the case of a piece of ground treated with kainit and superphosphate the crop was as heavy as where farmyard manure was used, and the application in both instances was made some time prior to planting.

In referring to varieties one approaches a wide subject, for their name is legion, and everyone knows how widely they vary according to locality. In spite of this, however, there are so many varieties of Potatoes in cultivation, and more are annually being added, that one would naturally expect that classification of Potatoes would be in a state of perfect chaos. But such is not the case, and it appears to be explained from the fact that out of the great number of varieties of Potatoes on the market only a very few possess really good all-round qualities, and, by the law of the survival of the fittest, these are well known and widely grown in most localities, while a great many sorts of inferior quality are only grown long enough to prove them, and then they sink into obscurity. Amongst early Potatoes, Improved Ashleaf, Sharpe's Victor, Early Puritan, and Harbinger, the sorts on which I depend and all well known, came out well except for the smallness of tuber, to which I have already referred. With stronger-growing main-crop sorts it does not need the eye of an expert to tell to a little from the appearance of the haulm how the crop is going to turn out, and though a good deal is urged against vigorous-growing Potatoes, it is quite impossible to get good tubers without healthy tops, and my heaviest crops have this season been lifted from rows where the haulm was the most vigorous. Over and over again I have had opportunities for observing patches of Potatoes where here and there could be seen a plant ripening off before the rest, and almost without exception these roots gave the lightest crop of tubers. Second growth is very prevalent this year, and in all cases where the haulm retains an exceptionally healthy appearance it is advisable to lift the crop, and it is almost certain that second growth will be found as the cause of it.

Disease showed itself a little both on the early and late crops, but with one or two exceptions no trace of it was found when lifting the tubers.

Taken all round, the yield of main-crop sorts has been as good as need be, and I append a few remarks on some of the varieties lifted. For the second successive season I have grown Snowball, and I am more than satisfied with it. Though one of the most robust kinds I had, the crop turned out to be a very heavy one, and the tubers, which are of an even, white, round character, are of excellent flavour. I do not hesitate to recommend Snowball as a high-class variety for main crop. Though strictly speaking a second early sort, I should like to say a word in favour of Pride of Tenbridge, a comparatively new variety, and one that will be sure to work its way to the front. Grown side by side with the popular Snowdrop, I am so favourably impressed with it as to give it preference to the latter sort. From several years' experience I am doubtful whether any better white round Potato exists than Universal. This variety, which has already been favourably mentioned in these columns, is somewhat rough in the skin, perfectly round, free from deep eyes, and of very superior flavour. Since growing it I have never come across a diseased tuber, and even late in the spring it boils with that white, floury appearance which characterises a good Potato. The much-vaunted Up-to-date has toned down somewhat this season, the tubers not being nearly so large as heretofore. The crop is fairly heavy, and though from my soil the flavour is fairly good, I have tasted tubers from other mediums of a very watery character, and have come to the conclusion that the quality of Up-to-date is best when grown in a fairly dry aspect. I have a good word to say for Crawley Prizetaker, which has a wide reputation as a white pebble-shaped variety. The first consideration in choosing a Potato is quality. Unfortunately, this is by no means a general rule, nor will it be, I am afraid, so long as there are sorts which have only appearance to recommend them, and in view of the fact that at present there is no other mode in vogue of judging Potatoes at shows except by appearance.

G. H. H.

Beets.—It is interesting to find how good Beets are this season in spite of the drought. It will be a good thing if scarcity in other directions should lead to a greater consumption of these roots than has hitherto been the case, for we have none more wholesome or nutritious. But I have specially noted that the Turnip-rooted variety has done on very dry soils even better than has the tap-rooted varieties. That has been specially my own experience in a trial of a dozen varieties, where the Crimson Globe, the best stock of the Turnip-rooted forms in cultivation, has made capital bulbs of rich colour and delicious quality. But there is ample time for tap-rooted Beets in dry soils to grow yet. As to the best out of the eleven others, I find it very difficult to say where all are so good. None of the varieties selected are coarse, all being apparently equally good for garden culture.—A. D.

Leeks.—It is needful to see Leeks grow strongly, as the various vegetable exhibitors do to enable distinctions to be determined. These are less seen in the stems when exhibited, as all being blanched white as high as possible, the chief distinction is found in length and comparative narrowness of stem or in shortness and thickness of stem. Still, these conditions will often result from diverse methods of culture with the same variety. But, as seen recently in two gardens, marked differences of top were noted in Prize-taker, Sutton's Selected, and Dobbie's Exhibition. The first has broad flag-like leaves closely set on the ground. With such, stems may be stout, but cannot be very long. The second has tall glaucous foliage, quite distinct, and in the best forms set with remarkable precision. Some of the plants have habits that lead to the impression they will have long blanched stems. The last has similar erect leafage, but it is quite

green. It is so far satisfactory to find that so much distinctness really exists in these varieties.—A. D.

Climbing Beans.—How well these Beans repay generous culture is evidenced in good gardens. At Hackwood Park, Highclere Castle, Forde Abbey, and other gardens recently visited I found what seemed to be remarkable rows of the best scarlet and white runners, but scarlet chiefly, of great height and luxuriance and fruiting abundantly. At Hackwood the growths were 12 feet in height, carrying splendid crops. Such varieties as Ne Plus Ultra, Best of All, Hill's Prize, and others of the new long-podded section are wonderful croppers, and it is folly for anyone to assume that these are less productive than are the old stocks of runners. Really they are far more prolific. It is doubtful whether, allowing 5 feet space across a garden quarter for a tall row of runners, any other crop could give such profitable products as one of these rows does. But, apart from variety, which is of some importance, this fine product is a question of culture. Trenches are opened 2 feet wide, and the ground broken up and liberally manured fully 30 inches deep. The seeds are also planted thinly, from 9 inches to 12 inches apart, and the result is seen later in remarkable growth and productiveness, the crop being at the end of the season measured by many bushels. Shopkeepers, unfortunately, never get such Beans as are thus produced. The average town runner Bean this season has been hard, dry, stringy, seedy, and a tasteless product. No matter what the vegetable, this season deep cultivation and liberal manuring have been abundantly rewarded.—A. D.

PEAS AND DROUGHT.

THOSE who have had an ample supply of green Peas during the whole of the summer must be regarded as fortunate. In the south of England I never had a more trying season. Although the dry days were fewer than was the case in Jubilee year, the drought was more serious. The continuous easterly winds, accompanied by the fierce heat, quickly dissipated any land moisture there might be within 1 foot of the surface. For years I have trusted to a variety that does not appear to be much known out of the county of Devon—one named Goldfinder. It is best described as an improved Ne Plus Ultra, or perhaps it would be more fitting to say an enlarged form of that sterling variety. Goldfinder will grow and crop heavily early and late, and I never yet saw it attacked by mildew. It has one fault, perhaps, although I do not regard it as such—viz., it grows 8 feet high in some seasons. I prefer tall-growing Peas, as better crops are obtained than from dwarf sorts, and what I regard as the main point about Peas—flavour—is not lacking in many tall-growing sorts, certainly not in Goldfinder. Eight large green Peas are found in nearly every pod, sometimes more. The pods, too, are numerous, which is a very important item. A larger share of success is obtained if thin sowing is practised. How can we expect Pea haulm to grow strong and keep clear of any fungus, like mildew, if sufficient space for development of stem and leaf is not afforded? This is a far too common error. Too many persons when sowing Peas seem to be afraid they will not get rid of the seed fast enough.

The plan of digging a trench and filling it with manure for the roots to grow in I strongly object to. Peas growing in such a preparation more easily succumb to drought if they are not regularly and copiously watered. In such a preparation the roots all too soon ramble to the extent of trench, and the wall-like sides of the trench too often act as a root deterrent. When the land is deeply trenched and sufficiently manured in the autumn, well broken up and

pulverised in the spring, choosing dry weather if the soil be at all heavy and retentive of moisture, a thorough and correct preparation is then obtained. All that is afterwards necessary then is to draw out a wide drill and sow the seed thinly, earth up the plants when 4 inches of growth have been made, and mulch 1 foot wide on either side of the row with half-rotted farmyard manure. It is useless to wait until the bulk of the moisture has evaporated from the soil before applying a mulching of some description. Seldom indeed does early mulching do harm. I never yet heard of Peas being too wet at the roots in the month of June, July, or August. Some persons blame too much wet for mildew attacks, but I think the reverse is more often the cause.

E. MOLYNEUX.

Vegetable Marrows.—I must confess surprise that your correspondent "H." (p. 196) should fail to understand why Vegetable Marrows are thought so much of at cottagers' shows. I think there can be only one explanation, and that is the extreme usefulness of the vegetable from a cottager's point of view. My experience of the average cottager is that he does not grow any particular crop because its cultivation happens to be interesting, but rather for the food supply of his household, and with no other vegetable does he get a better return for so small an outlay. The dry season of 1899 has been an illustration of it. Many cottagers have not been able to gather enough Peas to pay for the sticks, and Beans of all sorts have not come up to the mark, and yet in the rubbish corner of the garden the Marrow plant has grown apace, and is still providing a supply for the table. Nor does the supply end when frost closes the career of the plants, for most cottagers are in the habit of storing a few of the best Marrows for use in the winter when other vegetables are scarce, and though they are not then so good, they are by no means to be discarded.—G. H. H.

STOVE AND GREENHOUSE.

PORTLANDIA GRANDIFLORA.

THIS, of which I send a photograph, is a very beautiful rubiaceaceous shrub from the West Indies. It is, I believe, rare in collections of stove plants, and is said to be difficult to flower. The plant in question, however, had three flowers on it last April, and in July, when it was photographed, thirteen blooms were fully out. The flowers are sweet-scented, creamy white, and very beautiful with their waved or almost crinkled edges. It is in a 9-inch pot, and was placed in the open in full sunshine for three weeks in August, 1898. It was afterwards kept rather dry during the autumn, and was fed with artificial manure occasionally in the spring and early summer. It has been grown in a moderately warm stove and rather crowded up with other stove plants. Like most other Rubiaceæ, it is easily grown from cuttings.

Sispara, West Hill.

R. H. B.

Crinum roseum.—This is a noble plant when well grown into a large specimen, and when it flowers it is sure to attract a lot of attention. A plant now in bloom has upwards of a dozen of its large spikes, each with a magnificent flower-umbel open, and the effect is very good. It is one of the easiest of all plants to grow, all that is necessary being a greenhouse temperature with ample light and plenty of water at the roots.—H.

Begonia Gloire de Lorraine.—At Shipley Hall, Derby, there is a fine stock of this useful winter-flowering Begonia, a splendid plant for decoration of all kinds, lasting well for many

months and standing better than most things in a cool or dry sitting- or living-room. Of course, such treatment as the latter is not to its taste, for to do it well it must have a moist though not overheated house, where thrips, its worst insect enemy, is kept at bay. Many people have given this plant a bad name by starving it and getting it into flower in summer instead of getting a good growth into it and pinching off any flower-buds that form before October. It is a capital subject for keeping up a display after the bulk of the Chrysanthemums are past.

Plumbago capensis.—This is certainly one of the most beautiful of greenhouse climbers, and there is nothing to beat it in its colour. The long shoots produced in spring are at this time of year wreathed with blossoms, and, good as it is in a small structure, it is simply unique among all climbers for a large structure where it can be allowed to take its own way entirely and hang in long festoons or ramble about at will over pillars or supports of the roof. Then its true beauty is seen. The culture is very simple, all that is necessary being to see that free drainage is

Portlandia grandiflora. From a photograph sent by Col. Beddome, Sispara, West Hill, Putney.

secured and a not over-rich border given." When grown in pots it looks much prettier if allowed freedom than when tied in to circular or other trellises. A shoot pushing out here and there loosely and naturally is a great offence to the eye of some gardeners, but the plants are really much prettier so, and if lightly cut in every year, no more training or pruning of any kind is needed. The compost for pots should be rather rich when the plants are strong and healthy, and feeding from the surface will also be necessary when the pots are full of roots. Syringe the growth regularly to keep red spider in check.

Aristolochia gigas.—Where there is room to train a plant of this singular and very large-flowering plant it ought to be grown as a curiosity, for most employers like to have something of the kind to show to visitors. The blossoms are of immense size, the colour varying a good deal, and from the shape of these when opening they have been called the Goose Flower, not inaptly, as the

tube is bent and not unlike the neck of this bird. This class of plant requires a fairly large house or a long length of rafter, as it seldom flowers freely in a young state. The compost may be good, but not over-rich, as too rapid growth will be at the expense of flowering, the blossoms dropping from the leaf axils when small. For beauty it cannot compare with *A. elegans*, a very richly-marked and free-flowering kind with smaller flowers. I have had a yard or more of roof covered with this latter kind quite a mass of the deeply-tinted and prettily marbled flowers, but the larger kind named above flowers less freely, though more continuously. I saw a nice plant of it flowering freely at Shipley Hall, Derby, a few weeks ago, where it was growing in a corridor-like house in an intermediate temperature.—H. R.

Witsenia corymbosa.—This South African Irid, once popular, but now very rarely seen, is at the present time in full flower, and pretty it is, the blue blossoms being distinct from those of any other occupants of the greenhouse. It forms an erect stem of a firm, woody texture, while the sword-shaped leaves arranged in a fan-like manner are collected at the ends of the branches. Of the pretty blue flowers a succession is kept up for some time. The reasons that cause the merits of this *Witsenia* to be overlooked now-a-days are doubtless its slow growth, somewhat exacting cultural requirements, and the difficulty attending its propagation, for cuttings do not readily strike root. They succeed best taken off with a portion of the woody stem, inserted into well-drained pots of very sandy peat, and covered with a bell-glass till rooted. They require very little artificial heat at first, though after a time a slight additional warmth will assist their rooting. The soil best suited for this *Witsenia* in all stages of growth is a good fibrous peat with a liberal admixture of sand. The pots prepared for the reception of the plants must be well drained, and the general treatment should be much the same as that given to Cape Heaths.—T.

EUCHARIS AMAZONICA.

I CONSIDER the flowers of this plant to be the most chaste and beautiful of all species that I am acquainted with, but it is so often used by florists and others in ways that are quite unsuited to it that it has come to be looked upon as a rather common white flower, useful, of course, but much in the same way that Narcissi and other popular flowers are used, *i.e.*, for filling up, and such things as Lily of the Valley, Roman Hyacinths and others are placed or wired over it. This, our florists say, gives a light effect, but it shows very bad taste on the part of any floral decorator to use such a lovely flower as the *Eucharis* for a groundwork, as it were, and make other flowers spring out of it in an unnatural way.

The *Eucharis* is essentially a restful flower; it is a pity to cut it at all if it can possibly be avoided, for it never looks so well as against the deep green of its own beautiful foliage, the contour of each pure white blossom shown up by this and the light and graceful pose on the spikes not being excelled by anything in the whole range of flowering plants. But, unfortunately, many growers never see *Eucharis amazonica* as it should be; they have come to know it as a stove plant, and a stove plant it must be with them to the end of the chapter; so, instead of the stout, erect spikes, the deep green, stiff, leathery foliage, we have a weakened and debilitated plant that flowers three or four times a year instead of once naturally, and the blossoms, unable to hold up their pretty heads, droop in a half-ashamed kind of manner about the pale green flower-spikes.

Owing to its great beauty, a taste for the flower has grown up, and market men, to supply this demand, keep their plants over bottom-heat, driving them for all they are worth the whole year round and pick hundreds of the flowers daily. It is well to do so, for they will not last on the plants, and soon wilt and die in any case. They are quite different from the massive, thick petalled flowers that one may see in a cool,

pleasantly moist house where Eucharises really thrive. Here you have not to look for the spikes under the leaves; they push up well above them, and if a plant happens to be needed for room decoration you can take one, and it will be fresh and good in a week or ten days' time, not hanging out over the side of the pot directly it is taken from the enervating heat and moisture.

Why, then, should private growers who cater for a cultural taste imitate the men in the market who have to turn out everything at express speed—cut flowers on the first day of the week for the second day's market, and turn a delightful pursuit into a manufacture of flowers? These latter have to do it, because the day of the old nurseryman who hated to part with his finest plants is gone. But this kind of thing is not necessary in a private garden, and here we ought to see plants grown in the first place for their own intrinsic worth, *i.e.*, their beauty. This with the plant in question is not the case when it is subjected to forcing conditions. The foliage is the true guide to the health of almost any plant, and especially so of that of the Eucharis. Grow a stout, well-leaved plant, and flowers will follow as a matter of course—not every month in the year, but once a year, and then in quantity. The cultural details as to root and atmospheric treatment are of the very simplest, and only sufficient shade to prevent injury to the foliage is required.

H. R.

Repotting Cyclamen.—The young plants of Cyclamen should by now be ready for their flowering pots, and unless they are fit by the middle or end of September they are not likely to do very great things in the way of flowering. My plants are now being repotted from 4-inch or 3-inch to 6-inch and 7-inch pots, according to their strength, and these they will soon fill with roots, making large plants with foliage well over the sides of the pots by the turn of the year, when the flowers are much esteemed. The compost for Cyclamen is in a way a secondary matter, as a good deal of feeding has to be done from the surface after the plants are well established. But choose the best loam at command and use it in a very rough, open condition, adding thereto sharp silver sand, some well-dried cow manure, and plenty of burnt refuse. This last is one of the finest additions to all composts for bulbous plants. The soil should not be rammed with a potting stick, but firmed as tightly as possible with the thumbs. Leave the surface loose, and stand the plants in a fairly light, but cool house, where they are shaded from bright sunshine. Light syringings overhead may be given as long as the weather remains bright.—S.

Statice profusa.—This is one of the fine old plants formerly included in every collection of any note, but which seems in danger of going out of cultivation to a great extent. It is still a favourite plant with those who grow large specimens for exhibition, but it is so useful for conservatory and greenhouse decoration that it is worth a place in all gardens. The flowers are very lasting and also freely produced, so that from early spring to quite late in autumn the plants are usually full of bloom. The culture of *S. profusa* has been much neglected owing to the idea that it is a dirty plant as regards insects. This it certainly is not if the proper atmospheric conditions are kept up, *viz.*, plenty of air on all possible occasions and a cool, fairly moist temperature with almost constant exposure to sunlight. Fibrous loam, with a good sprinkling of coarse silver sand and well-dried cow manure suit the plant well, and at no time should the roots be overwatered. They take a fair supply when the plants are large and the pots full of roots, and also a little liquid manure when the flower-spikes are throwing up. That made from clear soot water is best, and its application is followed by increased colour both in leaves and blossoms.—C. H.

Winter-flowering plants.—Things required for early winter-flowering that were planted outside in the beginning of the summer and include

such things as late Chrysanthemums of the *L. Canning* type, *Salvias*, *Eupatoriums*, *Bouvardias*, *Solanums*, *Callas*, and last, but by no means least, *Violets*, will want looking round early this month to give one of the cuttings in with the spade preparatory to lifting. With the exception of the *Violets*, all these are planted in shallow trenches somewhat in the way prepared for Peas and runner Beans, and, as a rule, shift for themselves with the aid of a good mulching. This season, however, two or three soakings of water have been necessary to keep them on the move. *Solanums* have berried splendidly, and together with the *Eupatoriums* and *Salvias*, make attractive groups for cool houses. I mean those structures where very little fire-heat is used and the glass on cold nights is apt to drop to 40° and under. The mention of temperatures reminds me to note that we had the first frost this morning, September 11; the thermometer stood at 31°. *Perennetya mucronata* and its varieties, representing so many different shades, is a better berried plant than the *Solanum*, but there are comparatively few places where the flowers will set and the berries develop satisfactorily, and an annual purchase of plants is rather an expensive business. *Violets* for autumn lifting have done well, the plants being large and bristling with buds, but much time and labour were necessary to bring them up to this form. I always plant rooted runners on a north-west border that has been well prepared for their reception, mulching at planting-time with short manure which, as a rule, brings them through satisfactorily. Extra attention was, however, necessary this season, growth being slow and red spider getting a firm hold of the plants, so the ordinary mulch was removed and one of fresh horse droppings substituted, followed by a thorough soaking. This had the effect of checking the attack of the spider. The plants have grown away well and are now nearly clean, but I shall dip them as usual before planting in the pits.—E. BURRELL.

ALLAMANDAS.

I WAS reminded of the beauty and usefulness of these free-growing stove plants recently by seeing a healthy, free-flowered specimen growing in a pot, the numerous growths being trained to a trellis about a foot distant from the roof glass. When well managed, *Allamandas* will give a succession of their beautiful yellow flowers for several months, the latter being very useful for floral decoration in various ways. The plants when once established require plenty of pot room, being exceedingly free rooting, and good drainage must be afforded, as when in vigorous growth liberal supplies of water will be needful. Good fibrous yellow loam and peat in equal parts, a little leaf-mould and sufficient silver sand to ensure an open condition will grow *Allamandas* to perfection. Supposing a young healthy plant to be bought in, it should be pruned hard back before the buds start in spring, and given a liberal shift either previous to or after new growth commences. The position given must be a light one, and by rights no shade whatever should be given, as *Allamandas* delight in full sunshine. If the plants are wanted to cover a considerable space, planting out in limited-sized beds or pits well drained is preferable, and long growths should be allowed; but under pot culture the best way, I think, is to practise pinching the growths once or twice in the growing season, by which means a dense, bushy character is ensured, and the trellis or stakes, as the case may be, are the sooner and more effectually furnished, also freer flowering. Few insect pests trouble *Allamandas* if ordinary care is given, though mealy bug will prove very troublesome if it comes into contact with the plants. The plants enjoy abundance of heat and moisture, for which reason the syringe must be freely used when the house is closed early on fine, sunny afternoons. Farmyard manure water or that made from steeping a bag of sheep or deer manure in a tub of water, given at every alternate watering, the colour of

pale ale is the best stimulant, and soon makes a mark both on foliage and size and colour of the blooms. In October drying off must be commenced, this being a very gradual process, until in winter little or no water is given. *Allamanda cathartica* is a fine variety for clothing pillars or rafters, its brilliant coloured blooms being most effective for months in succession. *Hendersonia* is perhaps the most desirable variety from an exhibitor's point of view, its gorgeous flowers, which are of a deep rich orange shade, being produced in great profusion for at least seven or eight months of the year. Its habit of growth is more branching and short-jointed than in most other sorts and soon covers a trellis. That grand old variety *grandiflora*, though smaller in its individual blooms, is still unrivalled for its hardy, free-flowering character and the exceptionally clear pale yellow of its flowers. It can be grown without the aid of a trellis, and may be kept very dwarf and bushy by training it to a few sticks when young. For exhibition purposes it is invaluable. Amateurs possessing a stove should plant an *Allamanda* at one end and train the growths along under the roof. This need not necessarily exclude sufficient light and sun from the ordinary occupants of the house. One of the best plants grown in this way is in Mr. Branton's garden at Winthorpe, near Newark.

J. CRAWFORD.

Schubertia grandiflora.—When looking through the plant houses at Carrow House, Norwich, a few weeks ago I was much struck with the above-named plant growing in one of the stoves. It is of climbing growth, the foliage resembling the large-leaved *Dipladenias*, the flowers, which are produced in clusters of some five or six, being tubular-shaped and white in colour. The scent is rather powerful, though by no means pleasant, and the flowers last some time in good condition. It was growing in a limited-sized bed of loam and peat, and trained to wires some 15 inches or 18 inches from the roof-glass. I learned from Mr. Jones, the gardener, that he annually pruned it hard back, say, in January, and with heat and moisture new growths were quickly made. I had never seen the plant before, although it may be more common than I am aware of.—C.

Chironia ixifera.—This is a pretty greenhouse plant now in flower, and being so dissimilar from the other occupants of that structure, it is sure to attract attention. The *Chironias*, of which there are about half a dozen species in cultivation, are all natives of South Africa. They belong to the order *Gentianaceae*, and, like many of their allies, careful treatment is necessary to success. Of one species a coloured plate was given in vol. xlv. of THE GARDEN. This is the procumbent-habited *C. peduncularis*, whose rosy purple blossoms are freely borne. *C. ixifera* is, on the other hand, of an upright style of growth, the branches, which are rather sparingly furnished with narrow, glaucous leaves something like those of a *Dianthus*, being terminated by few-flowered panicles of lilac-rose blossoms about an inch across. The yellow anthers are very noticeable. This *Chironia* succeeds in a compost consisting of two-thirds good fibrous peat to one-third of loam and a liberal admixture of rough silver sand. A light, airy greenhouse suits it well, and care must be taken not to overwater during the winter months, while at the same time drought is equally injurious to it.—H. P.

Medinilla magnifica.—This fine old plant is not so often seen as it deserves. It is very ornamental when out of bloom, its broadly ovate, rich shining dark green foliage having a fine effect. The flowers, borne in large terminal pendulous racemes, are rosy pink in colour and remain a long time in perfection. A plant which came into bloom the last week in April was taken into the house a few days later and remained there till the first week in June. When brought out it showed little or no effects from its long stay indoors. The plant in question measured 4 feet through, carried eighty-two

spikes of bloom, and was grown in a 13-inch pot. Its culture is very simple, requiring ordinary stove treatment while growing with plenty of moisture. After its growth is made up, the temperature of an intermediate house and less moisture will suit it admirably. Equal parts of peat and fibrous loam, with a little leaf-mould or Mushroom manure and about one-sixth part of silver sand, with a good sprinkling of charcoal added, will make a suitable compost. Cuttings will strike readily in the propagating pit, and with liberal treatment will soon make good plants.—T. S.

TREES AND SHRUBS.

THE WISTARIAS.

EACH recurring spring increased attention is directed to the beauty of the common *Wistaria sinensis*, which is certainly one of the finest hardy climbers that we have in this country. It is equally charming whether trained to a wall, clothing an arbour, pergola, or arch (as the white variety is shown doing in the accompanying illustration), while allowed to ramble over a neighbouring tree it has a very beautiful effect when in full bloom. Again, within the last few years it has been put to an entirely different use, as it is now often forced into bloom and employed for greenhouse decoration in that stage. When so treated, although the massive clusters of flowers are paler in tint than those which expand naturally in the open ground, they are still very distinct from anything else so employed, and form a decidedly attractive feature. It is, however, as a hardy climber that this *Wistaria* commends itself to everyone, and there is a steady and continuous demand for it in nurseries. The roots are few in number, stout, and of a deep descending nature, with scarcely any fibres, and, in common with most plants of this character, it does not transplant readily, and is therefore in some nurseries kept in pots. While this admits of easier removal, the cramped roots do not take so good a hold of the soil as those which have grown untrammelled. I have seen plants lifted from the ground many of which have stood till quite late in the season before they made any signs of growth, even though they were well supplied with water, and some of their number were already in full foliage. Yet, strange to say, as the summer wore on nearly all these dormant plants pushed out rapidly and grew away freely till the end of the season. The following year there was no difference in any of them.

Besides the ordinary form there are several other kinds of *Wistaria* in cultivation. The varieties of *W. sinensis* include

W. S. ALBA, with pure white blossoms. This is very beautiful, but the flowers are, as a rule, neither so freely borne nor in quite such massive clusters as in the common kind. The double blossoms of *fore-pleno* rarely expand in a satisfactory manner, though occasionally good examples may be met with, but even at their best they cannot be compared with those of the type. In the variety *macrobotrys* they are longer and thinner than in any of the others, while the variegated-leaved form is simply rubbish.

A second species, and one perfectly distinct from *W. sinensis*, is

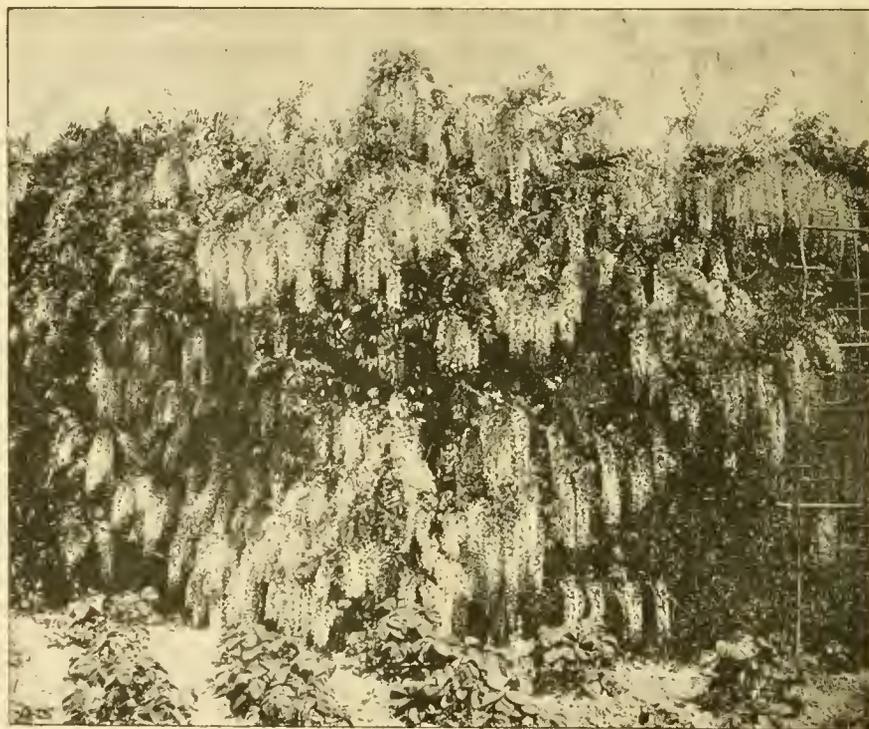

W. MULTIJUGA, which, previous to its flowering in this country, was considered superior even to *W. sinensis*. This was owing to the fact that the descriptions of *W. multijuga* gave the length of its drooping racemes as 2 feet to 3 feet, which turned out to be correct, but at the same time they were not nearly so showy as had been expected. This is owing to the fact that the blos-

soms are smaller and of a lighter tint, but above all to there being a much greater space between them, so that the aggregate of flowers is really little, if any, more than that of *W. sinensis*. Besides these features *W. multijuga* differs from its better-known relative in being less vigorous in growth, with smaller and more numerous leaflets and in flowering somewhat later. There is a variety of *W. multijuga* known as *alba*, but in many cases the blossoms have a lilac tinge, and are not so pure as in the corresponding variety of *W. sinensis*.

W. FRUTICOSA from North America is not nearly so vigorous as either of the preceding, though it is of climbing habit. The racemes of bluish purple blossoms are small compared with those of the others and are not disposed in the same gracefully drooping manner, being partially erect. From the circumstance that it is the only member of the genus from the western continent and the fact that it flowers in June after all the others are past, this *Wistaria* is well worth a

the *Bumalda* section be treated in this way, but the majority of the shrubby *Spiræas* can be increased to a greater or lesser extent by division.—T.

Tecoma radicans.—This plant is now very beautiful with its terminal bunches of bright flowers, and when a plant is sufficiently aged and established, there are few climbers that can fill its place at this time of year. It often fails to flower freely in a young state, but when well established and not cut about too much it will be a beautiful sight for many weeks in autumn. The very tidy gardener who likes to bring everything into line and detests a loose branch will not do much with *T. radicans*. I saw one of this class recently cutting it back, and as the shoots were then about a foot long, it is very unlikely that they will flower this season. He had been trimming up the rest of the shrubs and evergreens, and possibly thought the *Tecoma* needed it. The plant must be left alone to a certain extent; if it is always being hacked at it cannot flower.

White *Wistaria* at The Larches, East Grinstead. From a photograph sent by Miss E. C. Brown.

place in gardens. The variety *magnifica* is in all respects superior to the type.

Spiræa Anthony Waterer.—The excessively hot summer has, in many places at least, considerably affected this *Spiræa* by taking out the colour of the blossoms, so that in some instances they appeared to be but a pale form of *S. Bumalda* instead of the beautiful rich tint we are accustomed to see. With the return of cooler weather the blossoms have already acquired more of their normal tint than was to be seen when they expanded under the influence of such brilliant sunshine. The drought, too, has in many cases affected it, for *Spiræas* as a class are only seen to advantage in moderately moist soil, hence they suffer considerably during seasons of exceptional drought. *Spiræa Anthony Waterer* is now freely distributed, for it is a plant that can be increased without difficulty, and if planted rather deep it can be split up almost as readily as a herbaceous subject. This must of course be done during the dormant season. Not only can the members of

Besides, its beauty really consists in its loose habit, and the bright scarlet corymbs of blossom need the set-off given by the ample foliage. Though requiring a fair staple to start and grow it, *T. radicans* is perhaps more free-flowering in rather a dry soil. A sunny position where the growth gets well ripened is also essential.—H. R.

The Mountain Ash.—The beautiful berries of the above tree appear to be scarce this season, owing probably to the unfavourable weather when the trees were starting into growth in spring. It ought to be more freely planted in pleasure grounds and public gardens, as, independent of its great beauty in autumn, its general character is very ornamental. The worst of it is, in extra dry seasons, when other food is scarce, blackbirds and thrushes soon strip the trees of their berries. There is a belief among country folk that a rich display of *Mountain Ash* berries is a sure token of a hard winter. Personally I do not attach any weight to the idea, as generally by November every berry is gone. The colour of the berries on some trees is much darker than in others. This

may, of course, be due to soil and position.—
J. C.

CORNISH COTTAGE GARDENS.

In the first week of August I journeyed by road from Devonport to Penzance, passing through Liskeard, Lostwithiel, St. Austell, Truro, and Helston *en route*. The road, a decidedly hilly one, was in many places charmingly picturesque, skirting here heavily wooded valleys, here running water, but the chief interest to the flower-lover was not so much the attractive scenery as the numerous little cottage gardens that in the villages passed through flanked the road. The proprietors evidently vied with one another in keeping their tiny plots well tended, for almost all of them gave evidence of scrupulous care, and scarcely in one of them was a withered leaf or faded flower-truss to be detected. As the evening of an exceptionally hot day approached the gardens showed signs of movement as their master spirits sauntered about within the confined spaces busily engaged in picking off pods from the group of Sweet Peas, securing the tall Hollyhock spire by another tie to the sustaining stake, or deluging the narrow borders with frequent cans of water, the latter proceeding proving a work of supererogation, since the tropical heat of the day culminated after nightfall in a thunderstorm and a copious downpour, which rendered the earth moist for at least a couple of days. It was interesting to note the diversity of plants employed in the decoration of these gardens. In some villages one flower was common to almost every garden, though the remainder of the plants varied according to the whims of the respective tenants. Thus in one village every cottage had a white Everlasting Pea in its garden, while in another a particularly brilliant Phlox that had a great resemblance to Etna, if, indeed, it was not that striking variety, appeared to be the favourite plant. Sometimes along the whole length of the street garden after garden showed a family likeness, the same flowers employed and the arrangement very similar, until a note of contrast would be struck by a plot evidently belonging to a man who refused to be bound by the accepted custom and determined to strike out a line for himself. These exceptions to the general rule appeared to be, if anything, even more assiduously cared for than those of the usual type—though the latter showed no symptoms of neglect—as if the proprietor, having introduced an innovation, was determined to demonstrate its superiority to the existing order of things. Almost every cottage that boasted of a porch—and it was a very small minority that did not—possessed some flowering climber that wreathed it at some period of the year with blossom; here the Virgin's Bower (*Clematis Flammula*) was thickly starred with ivory-white perfumed flowers, here a Jasmine twined, or blossoming Myrtles formed a canopy. The blue Passion Flower and its white variety Constance Elliott were evidently favourites, and over not a few walls the white flower-clusters of *Solanum jasminoides* hung a snowy veil. Honey-suckles were also largely represented, especially the golden-leaved variety, the latter particularly decorative in the autumnal days, while an unrecognisable plant of shrubby growth that had been trained over the porch of one cottage was so smothered by the widespread white blossoms of the Morning Glory, that its identity was indistinguishable. Here and there the orange-scarlet flower-racemes of *Mina lobata* or the vivid brilliance of a climbing form of *Tropæolum Lobbianum* struck a high note of colour. Other plants not strictly climbers had been utilised for training over walls and porches. Myrtles have already been mentioned in this category, and the Lemon-scented Verbena (*Aloysia citriodora*), Escallonia macrantha, *Pyrus japonica*, *Cratægus Pyracantha*, *Cotoneaster microphylla*, and many other subjects were to be seen similarly treated, and in one instance two high bushes of *Salvia coccinea* flanked the porch and testified to the prevailing mildness of the climate. Ivy-leaved Pelargoniums in many

cases provided most attractive displays, the variety chiefly patronised being the salmon-pink Mme. Crousse, though occasionally the rose-cerise of *Souvenir de Charles Turner* was apparent. In some instances these Pelargoniums had been trained up the walls to a height of 6 feet or more, having probably been planted in the late spring of 1895, but a lengthened period of severe weather, such as was experienced during the opening months of that year, would doubtless kill the plants or so far cripple them as to render their display valueless the following summer.

Large bushes of Fuchsias, not only of *F. gracilis* and *F. Riccartoni*, but of forms with crimson perianth and white corolla and white perianth with purple corolla, were common. Large plants of *Calceolaria* that had probably been in position for some years were golden with bloom, and in some instances apparently fully 3 feet in diameter. Dahlias were grown in many of the gardens, but the Cactus varieties were in a decided minority, the old show Dahlias and pompons evidently still retaining the precedence. The tall Hollyhocks had seen their best days, but the upper blossoms of the lofty spikes still glowed against the white-washed walls. Out of the numerous plants that I saw there were none that did not possess double flowers. Phloxes were bright in many gardens, but except in a few villages decided colours were in a minority, and washed-out purples, magentas and pinks preponderated. Japanese Anemones were commencing their display, the white variety outnumbering the coloured forms by ten to one. *Statiche latifolia* was in flower in not a few gardens, but I did not notice a single plant of the still more delicate *Gypsophila paniculata*. *Gladiolus brenchleyensis* was to be found in most of the gardens, and *Montbretias* were in full flower in a few, while in one half a dozen plants of the new large-flowered *Cannas* were in bloom. Perennial Sunflowers and Golden Rod were entering on their season of effulgent brightness, and the great annual Sunflowers hung their heavy golden-rayed brown discs over many a cottage paling. Other annuals, such as Phlox Drummondii, Asters, Godetias and Balsams, afforded bright spectacles, and at Newlyn a mantle of *Mesembryanthemum edule* hung from a wall abutting on the harbour, exactly above the stem of a hauled-up fishing lugger. In the window of one cottage that I passed I noticed three plants of *Campanula isophylla alba* that were pictures of successful culture, being veritable cascades of bloom-covered trails. S. W. F.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 26.

TAKING into consideration the fact that the fruit show at the Crystal Palace is also held during this week, the number of exhibits on Tuesday last was remarkable for extent and variety. Had the average amount of fruit been staged it would have been a very full meeting. Amongst cut flowers the Dahlia was pre-eminent, notably so of the Cactus section; of these, a few more distinct acquisitions will be noted upon a perusal of the following report. Early Chrysanthemums, of course, were to be seen, but as yet these are not so much needed as they will be in October. Fine-foliaged plants, composed chiefly of Crotons, were a fine feature, demonstrating their value in this particular line. A good example of decorative grouping was also presented. Those who are in the habit of packing their groups would do well to take a lesson from the one in question, in which every plant told to the best possible advantage. Orchids were fairly plentiful and of first-class quality, notably the hybrids of the *Lælio-Cattleya* families, *L.-C. Nysa* being specially fine. Beautiful forms of *Cattleya Hardyana* were also staged from other sources. Only one collection of vegetables was staged for the Sherwood cup, and the exhibitor of the same is to be highly con-

gratulated upon his efforts and upon the superior quality of his produce. A few Apples were staged, one collection from Scotland being very good indeed for the northern part of the country.

Orchid Committee.

Awards of merit were adjudged to the following:—

CATLEYA WEEDONENSIS.—A hybrid derived from the intercrossing of *C. Mendeli* and *C. granulosa* var. *Schofieldiana*. It belongs to the section of hybrids to which the natural hybrid *Cattleya Czar* is allied. The sepals are greenish white, flushed with rose; the petals of good form and substance, deep rose, suffused with a bronzy tint. The lip is rich crimson-purple on the front lobe, mottled and margined with rose; the side lobes white, becoming yellow at the base, with a tracing of brown on the disc. A cut raceme of three flowers came from the collection of Mr. T. W. Thornton, Brockhall, Weedon.

ODONTOGLOSSUM CRISPUM BASANO.—In this the sepals are white, with only the faintest trace of colour. The petals are pure white, beautifully crisped on the margin; the lip white, with a large yellow disc. There is one large blotch of chocolate-brown in the centre, with a few smaller ones at the sides. The plant, which carried a raceme of eleven flowers, came from Mr. W. Cobb, Dulcote, Tunbridge Wells.

Messrs. J. Veitch and Sons, Ltd., were awarded a silver Flora medal for a large and interesting group, which included many meritorious varieties of both hybrids and species, considering the dull period of the year. Among the hybrids were some good forms of *Lælio-Cattleya Nysa*, one of the most beautiful of the *L. crispa* hybrids. It is superior in the better forms, but in the ordinary varieties it would be difficult to distinguish it from varieties of *L.-C. exoniensis*. The sepals and petals are deep lilac; the front lobe of the lip crimson, margined and fringed with rose; the side lobes yellow, becoming suffused with deep brown at the base. *L.-C. callistoglossa* was included in various forms. *L.-C. Fortuna* has delicately tinted rose flowers with a rich crimson-purple blotch in the centre of the front lobe. *Cattleya Chloe* is one of the most distinct and best coloured of the *C. Bowringiana* section of hybrids. The sepals and petals are a deep mauve-crimson, flat, as in *C. bicolor*, the lip also partaking of the characters of that species. The long front lobe is intense crimson-purple, veined with a darker shade of the colour, the small side lobes delicate rose with some purple at the base. The species included good forms of *Cattleya labiata*, *C. aurea*, *C. granulosa*, *C. Patrocini*, and good varieties of *C. Loddigesi*. *Dendrobium* included *D. formosum* and *D. superbiens*. *Zygotepalum maxillare* and *Oncidium* of the *O. phymatochilum* section were well represented. The scarce *Houlletia Brocklehurstiana*, with five of its two shades of brown and black spotted flowers, was most attractive. *Odontoglossums* were represented by a superior variety of *O. grande*. *Cypripediums* included good specimens, well flowered, of *C. Spicerianum*, *C. Charlesworthi*, *C. ænanthum superbum*, *C. Milo* and *C. Charles Canham*. A plant of *Angræcum articulatum*, with its pure white flowers, was also well represented. Messrs. Hugh Low and Co., Bush Hill, Enfield, were awarded a silver Banksian medal for a nice group. In the back row were two good varieties of *Vanda cœrulea*, also some well-flowered plants in good variety of *Oncidium Marshallianum*. The rare *O. incurvum album* and *O. ornithorhynchum album* were also represented. *Cattleyas* included good varieties of *C. velutina*, *C. Loddigesi*, *C. Gaskelliana alba* and *C. Eldorado Wallisi*. The hybrids included *C. Minucia*. Several forms of the natural hybrid *Lælio-Cattleya elegans* were also included, as were *L.-C. exoniensis* and good varieties of *Odontoglossum grande*.

Mr. C. H. Fielding, Southgate House, Southgate, sent a nice group, consisting of numerous varieties of *Dendrobium Phalenopsis* and *D. formosum*. The *Cattleyas* included a nice form of

C. Loddigesi, several C. Gaskelliana, and numerous *Cypripedium* of both species and hybrids. A silver Banksian medal was awarded. Mr. T. B. Haywood, Woodhatch, Reigate, sent a distinct and pretty form of *Cypripedium Fowlerianum*, possessing the intermediate characters of the parents. Mr. R. I. Measures sent *Cypripedium Lachme*, the petals being particularly fine. Mr. W. M. Appleton, Weston-super-Mare, sent *Cypripedium enfieldiense* and C. Julia (*Lawrenceanum* × *Exul*), the flowers intermediate in character, the spottings of C. *Exul* being particularly prominent in the upper sepal. Mr. H. Little, Twickenham, showed the lovely *Laelia-Cattleya elegans* var. *Littleana* and *Cypripedium Sanderianum*. The Rev. F. Paynter, Stoke Hill, Guildford, sent a yellow variety of *Odontoglossum grande* and a hybrid *Cattleya* of the L.C. *elegans* section. Mr. H. T. Pitt showed the lovely *Cattleya Hardyana* (Pitt's variety), one of the best forms we have seen. The lip was upwards of 3 inches across. Major Joicey sent a dark form of *Dendrobium taurinum*, and Mr. W. Cobb had a bright and pretty form of *Cattleya Hardyana* with a three-flowered raceme.

Floral Committee.

The following received an award of merit:—

DAHLIA MME. THEODORA HENSON (Cactus).—A distinct shade of scarlet, the pointed florets somewhat narrow and slightly incurving. From Mr. T. S. Ware, Tottenham.

DAHLIA AUGUSTUS HARE (Cactus).—In the earlier stages the predominant shade is crimson-scarlet and very showy, but a little later a decided flame-coloured scarlet replaces it and imparts quite a novel feature to the flower. In the latter stage it is one of the most distinct Dahlias of the year. From Mr. James Stredwick, Silver Hill Park, St. Leonards.

CARYOPTERIS MASTACANTHUS.—This will be welcomed for two reasons, viz., its colour and its late flowering. The habit of the plant is rather meagre, and the nearly erect stems are well clothed with dark green leaves that assume a whitish tone beneath. The flowers, which are of a distinct lilac-blue tone and produced in alternate axillary clusters, are borne on pedicels about 1 inch long. These appearing in considerable profusion render the plant very attractive at this season, when flowering shrubs of this colour particularly are far from common. Cut sprays were contributed by Messrs. Barr and Sons, Covent Garden, and a basket of small plants came from Messrs. James Veitch and Sons, Ltd., Chelsea.

There was a considerable falling off in the numbers of the groups as compared with the preceding meeting, though enough remained to constitute a very good effect for the season of the year. One of the chief groups was that from Mr. H. B. May, Dyson's Lane, Edmonton, which was mainly of small and useful-sized *Crotons*, some sixty varieties of these plants being staged. The whole of the plants were in small pots and finely coloured. In the narrow-leaved section we noted *The Countess*, *Superbus*, *Doucetti*, a rather densely-leaved kind and well coloured; *Ruberimus*, very rich in colour, an extremely showy kind under artificial light; *Imperialis aureus*, one of the narrowest-leaved varieties in this group; *Mrs. Dorman*, and *Aigburthiensis* as among the more distinct and beautiful. Among the broad-leaved kinds were such well-known forms as *Morti*, *Reedi*, *Alexander III.*, *Comte de Germiny*, *Thomsoni*, rich golden leaves excepting the tips, which are variegated with green; *Baron Frank Selliere*, yellow and dark green; and *Newnani*, of a rich reddish colour for the most part. A few small *Palms*, *Eulalias*, *Ferns*, *Isolepis*, and *Lygodiums* were interspersed here and there through the group (silver-gilt Banksian). A very pretty and well-grown group of *Statice* in variety (seedlings probably) was staged by Messrs. Hugh Low and Co., Enfield. The plants were compact, less than 15 inches high, in 5 inch pots, and very attractive on account of their free-flowering. A pretty *Kentia*, *K. Veitchi*, with dark and almost mottled stems, was also noted in

this group. Mr. S. Mortimer, Farnham, again set up a brilliant lot of Dahlias, each kind good in itself. It would be well if this idea were more strictly adhered to, not in respect to exhibitors of Dahlias exactly, but in other groups where the notion obviously exists of bringing all, good, bad and indifferent. The outcome of this is an overwhelming mass of things, the very bulkiness of which tends not only to mar the effect of the best kinds, but in reality to obscure them from view. Mr. Mortimer's flowers were fresh and distinct. A few of Mr. Mortimer's best among Cactus Dahlias were *Starfish*, *Exquisite*, *Harmony*, *Gloriosa*, *Keynes' White*, *Mary Service*, *Magnificent*, *Alfred Vasey*, *Ebony* (a very dark flower), and *Harry Stredwick*, perhaps the darkest of all the race. These were disposed in good sensible bunches and the colours well mixed also. Apart from these, some ten or more boards of show and fancy kinds were staged, the flowers very good and well finished (silver Flora medal). Mr. Sander, St. Albans, sent a few plants of *Dracæna Godseffiana*, *D. Sanderi*, some medium-sized plants of *Acalypha hispida*, and the graceful *Linospadiæ Petrickiana*. Messrs. James Veitch and Sons, Chelsea, had groups arranged in baskets of the pretty *Caryopteris mastacanthus*, *Hydrangea Hortensia Mariesi* with pale blue flowers of large size, and a pretty red-leaved shrub, *Nandina domestica*, which should be useful for its colour effect so early in the season. Messrs. J. Hill and Sons, Lower Edmonton, had an exceptional group of the varying forms of *Asplenium Nidus*, many of the plants being of large size and well grown. The plants were arranged in a setting of *Maidea-hair Ferns* in variety, above which the broad shining fronds of the *Aspleniums* were very telling. Plants were also shown of the variegated *Ficus*, *F. radicans variegata* (silver Flora medal). Mr. James Stredwick, Silverhill Park, St. Leonards, had some good kinds of the Cactus Dahlia, such as *Mrs. Sanders*, yellow; *Mayor Weston*, *Magnificent*, *William Jowett*, scarlet; *Mayor Tuppeny*, orange and yellow; *Autumn Queen*, *Uncle Tom*, and *Chas. Woodbridge*, a finely coloured crimson (bronze Banksian medal). Mr. T. S. Ware, Tottenham, arranged an extensive bank—too dense, as we think—of single, pompon, and Cactus Dahlias, together with some few good and distinct *Michaelmas Daisies*, summer-flowering *Chrysanthemums* in variety, *Pyrethrum uliginosum*, a few *Torch Lilies*, grasses, *Bamboos*, and such like plants, for which a silver Banksian medal was awarded. Messrs. Barr and Sons, Covent Garden and Long Ditton, brought an interesting gathering of hardy things in season. Some of the early *Michaelmas Daisies*, as *A. Amellus*, of which *Riverslea* and *Framfield* are good and noticeable, as well as distinct kinds; *Aster acris*, *A. levis acretus*, with dark shining stems; *A. Lindleyanus*, &c. Very good, too, was the white *Everlasting Pea* and the distinctly coloured *Verbena venosa*, the latter much too little grown. Among *Torch Lilies*, *Kniphofia Leichtlini*, *K. L. distachya*, *K. Triumph*, a bold yellow-looking spike, were prominent. *Senecio pulcher* was very good, and *Convolvulus mauritanicus* pretty in the pale mauve flowers. *Helenium nudiflorum*, *Sedum Ewersi*, and a set of summer-flowering *Chrysanthemums* were also included in this lot. A variegated grass, *Glyceria spectabilis variegata*, which is, perhaps, too short in its growth to prove very telling in the garden, and a pair of *Zauschnerias*, *Z. californica splendens* and *Z. mexicana*, were also contributed by the same firm. Mr. W. J. Godfrey, Exmouth, sent a late-flowering border *Carnation*, *Mrs. George Foster*. It is a yellow flowering kind, a pod-buster, unfortunately, though of good size. From the same source came the yellow sport of *Chrysanthemum Lady Fitzwygram*. The colour of the flowers is so very pale that it could easily be taken for a poor white under artificial light. Mr. W. Wells, Earlswood, Redhill, had a few early-flowering *Chrysanthemums*, mostly, however, of the Japanese kinds. Perhaps the best of his lot were the yellow-flowered *Mme. Liger Ligneau*, which is good in

colour, early in flower, and dwarf in habit; *Jules Mary*, crimson; *Market White*, *Jeanne Villermot*, a chestnut-red sort; *Mytchet White*, *Mme. Marie Masse*, and the so-called crimson *Mme. M. Masse*, which is certainly anything but crimson in point of colour. It is certainly related to the popular kind mentioned, and may best be described as a chestnut-bronze. A variety named *Victor* is said to be a sport from *Mrs. Hawkins*. It is, however, no sport as this term is understood; it is but a reversion to the original white kind *Mme. C. Desgrange*, from which it in no wise differs. Some wretchedly small flowers of this last were shown by way of comparison. A small plant of *Retinospora pisifera aurea Rogersi* came from Mr. W. H. Rogers, Bassett, Southampton, but beyond being of a golden hue and in its present form bearing some semblance to the well-known *Golden Lawson's Cypress*, no definite opinion could be formed, as the example was too small and quite undeveloped for a *Retinospora*. This much should be stated plainly, because frequently the committees before whom such things are placed are charged with favouritism by those sending things from a distance. In the present instance quite two years' growth and development are necessary before any definite opinion can be formed of such a plant. A group of fine-foliaged plants with *Ferns* and similar things came from the gardens of Sir Henry Tate, Bart., Park Hill, Streatham Common (gardener, Mr. Howe). The plants employed were of the usual order of such groups—*Palms*, *Dracænas*, *Crotons*, and such things in unlimited numbers being arranged amid *Ferns*, the variegated *Eulalias*, and other plants. Some excellent examples of *Bamboos* occupied the extreme corners of the group at the back, while in the immediate front a pair of *Aralia elegantissima* were placed. A silver-gilt Banksian medal was awarded. The *Dowager Lady Freake*, Fulwell Park, Twickenham (Mr. A. H. Rickwood, gardener), sent a good variety of *Cannas*, mostly, however, of the green-leaved kinds. The collection included many of the best kinds now in commerce—shades of crimson, scarlet, yellow, and this last with scarlet spots predominating.

Fruit Committee.

This committee had its fair share of exhibits and most of them of excellent quality. The collection of vegetables staged for the Sherwood cup was a notable exhibit, and the Apples from Galloway were excellent.

Awards of merit were given to the following:—

PEAR TRIOMPHE DE VIENNE.—A large, handsome early fruit with rich flavour. It is a heavy cropper, strong grower, and forms a good bush or pyramid tree. From Mr. G. Woodward, Barham Court Gardens, Maidstone.

POTATO THE SIRDAR.—This, one of the varieties tried in the society's gardens, is a midseason or late variety. It is of excellent quality and a good cropper. From Messrs. Hurst and Son, Houndsditch.

POTATO ELLINGTON.—This varies, but is usually pebble-shaped, with rather deep eyes. It is a first-rate cooker and cropper and a late variety. From Mr. Ellington.

Mr. E. Beckett, Aldenham House Gardens, Elstree, was the only competitor for the Sherwood cup. The conditions for the same were that it must be competed for on two occasions, and on each Mr. Beckett has been the only exhibitor. On this occasion forty dishes were set up, these obtaining 160 points, salads being the weakest. Onions *Ailsa Craig* and *Cocoa-nut* were excellent, as also were *Model* and *Intermediate Carrots*. *Cucumber Beckett's Ideal* was good. *Autumn Giant Cauliflower*, four varieties of *dwarf Beans* and *runners*, the same number of *Vegetable Marrows*, a good dish of *Autocrat Peas*, *Red Globe* and *Prize-taker Turnips*, *Celeries White Gem*, *Standard-bearer* and *Prize-taker*, *Kales* in variety, *Goldfinder*, *Windsor Castle* and *Satisfaction Potatoes*, *Leeks*, *Brussels Sprouts*, *Parsnips*, *Salsify*, *Scorzoneria*, *Celeriac*, *Capsicums*, *Tomatoes* and *Beetroot* were also included. From

Mr. W. Day, Galloway House Gardens, Garliestown, N.B., came a very good lot of Apples, notable for their grand colour, considering their having been grown in the north. Thirty-six varieties were staged. The fruit lacked the size of that of our home counties. The best kinds were Lane's Prince Albert, Peasgood's Nonsuch, Tower of Glamis, Loddington, Blenheim Orange, Galloway Pippin, Jas. Grieve, and Lady Kinloch, a late cooking variety raised by the exhibitor. In the dessert varieties, such kinds as Adams' Pearmain, Worcester Pearmain, Jacob's Seedling, and Duchess of Oldenburg were excellent, the exhibit well meriting the silver Knightian medal awarded. A new black Grape was much admired by many on account of its fine oval berries, beautiful colour, and finish and shape of bunches. This was called Diamond Jubilee, and was sent by the Messrs. Buchanan, Forth Nurseries, Kippen, N.B. A new seedling Grape was sent by the Messrs. Pearson, Chilwell Nurseries, Notts. It is a cross between Bowood Muscat and Gros Colman, and has oval amber berries with a brisk, refreshing flavour. The fruit sent had been grown on a pot vine, and the committee desired it to be sent again from permanent vines. Mr. Ross's new Apple T. A. Knight was again brought up from Chiswick, but not in sufficient quantity for an award, and the committee desired the raiser to send fruits to the next meeting. This is one of the best seedling Apples we have seen, the parents being Cox's Orange and Peasgood's Nonsuch. Seedling Apples came from Messrs. R. Hartland and Son, The Nurseries, Cork. One named Stone Peach was not considered of any value, but Hartland's Pearmain will doubtless be sent again. Mr. A. Bacon, Romford, sent seedling Apples Wheatsheaf Russet and Bacon's Seedling, but both lacked quality. Mr. W. Green, of Wisbech, sent Apple Emmet's Early. This was stated to be the same Apple as the committee recently gave an award to under the name of Early Victoria. Melon Gunton Scarlet was sent by Mr. Allan, Gunton Park, Norwich, but was too ripe. Mr. Doe, the Gardens, Knowsley, Prescott, sent a green-fleshed Melon Countess of Derby, and a scarlet-fleshed netted fruit called Salmon Queen came from Mr. Bewick, Walton-on-Thames. The Rev. Darnley Smith, Ashburton, Devon, sent his new fruit protectors with fruit that had been protected, and some otherwise. There was increased size in the protected fruits. Mr. C. Curtis, Penang, Straits Settlements, sent fruits of Mangosteen, but not in good condition.

National Chrysanthemum Society.—A meeting of the executive committee was held at Carr's Restaurant, Strand, W.C., on Monday evening last, Mr. P. Waterer occupying the chair. The chairman announced that the new medals had been ordered, and he felt the members would unanimously approve of what the finance committee had done in the matter. Mr. A. E. Stubbs made a practical suggestion with reference to the question of running excursion trains into London for the purpose of inducing country members and their friends to attend the shows of the society. A sub-committee was appointed to consider the matter. The chairman announced that Messrs. Green and Nephew, of Queen Victoria Street, E.C., had the vases in course of preparation which they were lending the society for the purpose of exhibiting the sixty specimen Japanese blooms on the occasion of the show in November next, this being the new and special feature of the present season. The vases would be 16 inches in height, and not 18 inches, as stated in the schedule. The secretary announced that in future, exhibits submitted to the floral committee would be numbered, an arrangement which was readily assented to by the committee. Mention was also made that the new rule regarding certificates would come into operation at the meetings of the floral committee this year. In future the support of three-fourths of the committee present would be necessary to obtain a certificate, and if there were not more

than ten members present the voting must be unanimous. An invitation was given to members to visit the Lyons Chrysanthemum show on Friday, November 3. It was intimated that already several members had promised to attend, and it was hoped more would join the party. Communications regarding this matter should be addressed to Mr. C. Harman-Payne, the hon. foreign corresponding secretary. Eight new members and one Fellow were elected.

NOTES OF THE WEEK.

Convolvulus mauritanicus.—The flowers of this pretty trailing plant are always admired. It may perhaps be described as between a French grey and a very delicate pale sky-blue, a soft tint that renders the flowers almost transparent. The plant is free-flowering, and given freedom will maintain a profusion for many weeks in succession.

Dahlia Mrs. Sanders (Cactus).—Among the self yellow kinds this is a pre-eminently good one—one that is likely to find favour when distributed to the public, provided always that in habit of growth it is as desirable as the flowers would make it appear. So much depends upon habit of growth in these plants, that one is loth to praise any variety from flowers alone.

Kniphofia Triumph.—In point of colour this kind is not unlike some others of this fast-increasing family, the colour being yellow, with tones of amber and light apricot. It is, however, in its freedom of flowering that its value lies, as each stem has two, and sometimes three, smaller spikes attached to the side. These will not only afford a later supply of bloom, but on account of their much smaller size will be useful in a cut state.

Senecio pulcher is one of the finest border plants of early autumn. To see it at its best and to retain it in perfection so as to secure a good display of blossom each year, one must adhere strictly to a system of propagation that may prove too much for many amateurs, who have to content themselves with plants less exacting in their requirements. All the same, the beauty of a fine group of this Groundsel is not soon forgotten.

Chrysanthemum Mme. Liger Ligneau—For those that mere size will satisfy, this variety may be mentioned as among the largest of the early-flowering kinds yet introduced. But if early and large, it scarcely comes into the category of the so-called summer-flowering Chrysanthemums, and possesses but little of the freedom and abundance that characterise so many of the beautiful kinds now in commerce. It is, however, of excellent colour and of good size. The habit is also quite dwarf.

Fruiting of the Indian Bean.—The Indian Bean (*Catalpa bignonioides*) is producing fruit in great abundance at The Dignaries, Blackheath, or rather Westcombe Park. The pods, which greatly resemble those of the runner Bean, average nearly 11 inches in length and are of a bronzy brown colour above, light green beneath. Probably the unusually warm summer has had to do with the abundant flowering of the *Catalpa* all over Southern England at least.—A. D. WEBSTER.

Cyclamen hederifolium.—The pretty Ivy-leaved Cyclamen is making a pretty picture in the garden at the present time. That these pretty early autumn flowers thrive with so little care and prefer dryness to moisture is a matter that should be known to all who prefer to grow hardy things in every possible position. Beneath the shade of trees or small shrubs these plants are quite content, and not merely give a pretty display of blossoms in their season, but furnish the ground with handsome foliage during winter. Once established they give but little trouble.

The Aquarium Dahlia show.—Unable to visit this show on the first day, I went upon the second early in the afternoon, and was greatly pained as well as disappointed to note how wretchedly faded and withered were the majority of the Cactus blooms, no matter how set up. It must have been very disappointing and annoying to visitors to the show on the second day to see such a general collapse. The chief object in holding the show was to enable seedlings to be exhibited for certificates. The poor array of new ones and the few certificates granted lead to the inference that the primary object of the show

resulted in failure, and it may well be questioned whether it is worth repeating.—A. DEAN.

Chrysanthemum Lady Fitzwygram (yellow variety).—A basket of plants of this kind was among the exhibits at the Drill Hall this week. It is evidently a sport from the original and quite distinct, but of too pale and washy a tone to be of much service. Like the white kind, this could only be of use after severe disbudding, and as a garden plant, and a border plant in particular, this should prove a disqualification. *Lady Fitzwygram* produces the flowers at so many levels one above the other and in such quantity, that unless disbudding is early resorted to the flowers are small and insignificant.

Montbretia crocosmiæflora.—There are many plants such as this which, with roots in a deep bed of soil, flourish in the great heat of such a year as this. In a season which is the reverse the flowering is usually less fine and the foliage does not retain its freshness in a similar degree. To see a group of this plant at its best the corms should either be established or have been planted in early autumn so that they have taken well to the soil. Too frequently the planting of these things is deferred till quite late in spring, and then with no allowance for diminished vitality. Then if a hot, dry season ensues the plant has but a poor chance to show its value.

Phygelius capensis.—This seasonable flowering perennial is among those things to which attention is frequently directed. It is a good and distinct as also a serviceable autumn-flowering plant, sufficiently hardy, too, for our climate, though bearing a suspicious name. In winters of extreme severity it may be lost outright, and more especially if the plants are old, but in a cold northern district with clay soil I have grown this plant quite satisfactorily. Indeed, though badly cut down, so far as any vestige of life was apparent above ground, the more deeply-covered roots have sent forth shoots again in spring. The reddish scarlet flowers are now attractive, and in good soil the plant will attain from 2 feet to 2½ feet high.

Caryopteris mastacanthus.—This recently introduced shrub promises to be valuable in gardens. It is hardy, it is late flowering, and of a good blue colour. Such things among shrubs late in the year—September and October, for example—are not numerous. A nice lot of this in good flower was shown at the recent meeting in the Drill Hall. A nice plant was noted recently in the gardens at Gunnersbury House, where in early September it had begun flowering. It is not a particularly bushy plant if left alone, yet a good bush could be formed by the early and judicious use of the knife. Indeed, if pruned in the early part of the year to within a few inches or a foot of the ground a greater number of shoots would push forth. Even the small plants alluded to above had many breaks at the base from the quite hard wood.

Ranunculus Lyalli.—I feel indebted to "J. L.," Hawick, for writing regarding this New Zealand plant, with which so many have failed. I had the pleasure of seeing the plant at Easter Duddingston Lodge while it was in seed, but until now I was unaware that it had died after seeding. My experience with most seeds from New Zealand is much like that of your correspondent: they germinate badly. The seeds of *R. Lyalli* failed to grow with me. One fears that we have not yet discovered the secret of growing this *Ranunculus*, but there is so much variety of soil and climate in the United Kingdom, that someone may succeed where others have failed. The establishment of so fine a plant is worth a good deal of trouble, and I think some of the many enthusiastic growers in Ireland have a better opportunity of growing it than we in the sister isle.—S. ARNOTT, *Carsithorn, by Dumfries, N.B.*

Romneya Coulteri in Scotland.—I have observed several notices of the hardness of this beautiful plant. I have had it growing outside against the house here for two and a half years or

thereby. The aspect is south, but it is fully exposed to S.E. and S.W. winds, and has only had a rough protection of loose Heather in the winter. The last two winters have not been severe—that is, the minimum temperature has been moderately high and frosts have been of short duration. The plant flowers freely, and now, after the recent rains, still shows a great many buds. Earwigs are a very great trouble and very fond of the flowers, boring into the unopened buds and destroying them. It well repays any little trouble there may be needed, giving winter protection. Here it does not ripen seed. I have tried layering to propagate it, but failed, the branches withering in spring.—Wm. Low, *Monifieth, N.B.*

Aster Thomsoni.—This distinct and pretty Starwort does not appear to be grown so freely as its merits would warrant. One finds that some have a prejudice against Asters which come as early into bloom as this. Probably this may account for the infrequency with which one sees it in gardens, even in those with large collections of hardy flowers. My first acquaintance with it was made in the gardens of Edge Hall several years ago. Recently I came across the plant, as I have known it for some time, together with a dwarf variety of a different tint of colouring. This was at Kirkconnel, in Kirkcudbrightshire. The dwarf form was, I thought, even prettier than the other. It would be not more than a foot high, and rather bluer in colour than what I had seen and grown before. *Aster Thomsoni* (not *Thompsoni*) comes into flower early in July in good seasons, and lasts in bloom for some time. It comes from the Himalayas.—S. A.

Iris Susiana at Tynninghame, N.B.—One meets with, and hears of, so many disappointments with *Iris Susiana*, not in Scotland only, but throughout the kingdom, that it is a pleasure to come across it doing well and giving satisfaction. Thus it was with pleasure that I noted a nice little clump in the beautiful gardens of the Earl of Haddington at Tynninghame, Haddingtonshire. The *Iris* was at rest, but an examination showed hard, firm bulbs, such as are almost sure to bloom in anything like a favourable season. *Iris Susiana* has been at Tynninghame for several years, and Mr. Brotherston informed me that it flowers regularly. The position is one which suits it well. It is grown at the foot of a sunny wall, where it can receive a good roasting in summer—conditions under which this *Iris* is usually fairly successful—although with us in the west, where we have, as a rule, more moisture in summer, these do not always bring success. These Cushion Irises are so attractive in their own way, that those who have even a chance of succeeding with them should not fail to make the attempt.—S. ARNOTT.

Phlox Le Mahdi.—The raiser of this *Phlox* might well have given it a name which would have been more acceptable to flower growers than he has done. While not caring for its name, one cannot, however, but admit that it is a distinct step in the advance towards attaining a really blue *Phlox*. Until the coming of *Le Mahdi*, the nearest approach to a blue among the tall *Phloxes* was in the flowers of one named *Iris*, which, unless I am mistaken, originated in the same continental nursery as the subject of this note. *Iris* was well shown among other hardy flowers at the recent autumn show of the Royal Caledonian Horticultural Society in Edinburgh. The later production, in the form of a young plant, appeared in the stand of Mr. John Forbes, of Hawick, at the same show, so that one could compare them properly. This was only from a colour point of view, as a small plant such as that of *Le Mahdi* could not be expected to yield either such fine spikes or so large pips. The colour is, however, much deeper and rather bluer than that of *Iris*. As a garden flower it will not be prized for its brilliancy, although it may be appreciated for its rare colour among the *Phloxes*.—S. A.

Leucojum roseum.—I regret to say that I have been no more successful with *Leucojum roseum* than the Rev. Mr. Ewbank, so that I fear

that I am unable to give him any assistance in the way of suggestions for its cultivation. Personally, I should feel greatly obliged to anyone who has succeeded with this pretty little *Snowflake* and can give us any hints as to how it should be treated in this climate. If Mr. Ewbank, with all his experience and perseverance, has been unable to get it to bloom at Ryde, I fear there is but little prospect of many of us being fortunate enough to induce it to flower. Perhaps some reader of THE GARDEN in Devon or Cornwall may have succeeded where we have failed, and will kindly favour us with his treatment. While we are on the subject, one may also ask if anyone can enlighten us as to our chances of growing *L. trichophyllum* in the open. This has been tried here twice in different positions, but on each occasion the bulbs have died. The evil seems to be that growth is made too early and that the tender leaves are killed, to the destruction of the bulbs. This is a common cause of loss here, especially in the case of purchased bulbs which have been ripened off early in a warmer climate than ours. This initial difficulty overcome, there is not much fear of losing *Leucojum autumnale*, which is so pretty that it should be grown by all who care for delicate beauty in flowers even if they are lucky enough to bloom the charming *L. roseum*.—S. ARNOTT, *Carsehorn, by Dumfries, N.B.*

Statice penduliflora?—Under the name of *Statice pendulifolia* there is rather a nice *Statice* in the nursery of Messrs. Cunningham, Fraser and Co., Comely Bank, Edinburgh. The name, so far as one can discover, has no authority to support it. There is nothing in the habit of the leaves to make the name in the slightest degree appropriate; but, as Mr. A. MacSelf, who has charge of the department, says, the name of *penduliflora* would be in agreement with the drooping tendency of the flowers. Many of the Sea Lavenders are, however, difficult to identify, and it is doubtful if anyone would undertake to refer this variety to any particular species. This *Statice* grows to about 3 feet or so in height and has small, but pretty, blue flowers in graceful panicles. As already mentioned, these are of a drooping habit, which, although not very pronounced, gives the plant a character of its own. Autumnal-blooming flowers of the style of the Sea Lavenders are too little seen in our gardens, and one feels justified in thinking that their worth ought to be more fully recognised, by their being more grown. In addition to the charm they give by their gracefulness to the flower border, they may also be prized for their value as dried flowers for house decoration in winter. They dry quite readily, and form a nice change from the equally graceful *Gypsophila paniculata*, another invaluable thing for ornamenting the house in winter. The plant which has given rise to these remarks seemed to be the only one in the nursery, and I was unable to ascertain its origin.—S. A.

Anemone alpina.—The article by "E. J." in THE GARDEN of September 23 deserves a careful perusal from all who grow, or have tried to grow, the beautiful *A. alpina* and its variety *sulphurea*. This note is written, not for the purpose of differing from the treatment advocated, but, if possible, to induce some to observe the advice given regarding abundance of root moisture. I can well recollect in my early days of growing alpine how I lost plants of these *Windflowers* from planting them in places which were too dry. In this garden I find them do best at the base of rockwork, where they can have a proper supply of water with, at the same time, abundance of drainage.—S. ARNOTT, *Carsehorn.*

—I was much interested in reading "E. J.'s" article on *Anemone alpina*. He does not say a word too much in praise of this beautiful *Windflower*. I have now some well-established plants of it raised from seed which I gathered in Switzerland. I have counted twenty-five blooms on one plant, and the plants flower abundantly every year. I would recommend it being raised from seed, which, if sown as soon as it is ripe, should

germinate the following spring or summer. It is very impatient of any disturbance of the roots. The sulphur variety is quite as well worth growing as the white, and is raised in like manner from seed. It is of a very pure and fine shade of yellow, and quite as free-flowering as the white. The two together make a charming group. There is another *Anemone* the seed of which I also gathered in Switzerland, though I do not know if it can rightly be called alpine; it is, I believe, called *narcissiflora*. It is not so striking a plant as either the white or sulphur, but it is very pretty and well worth growing.—H. H., *Daljarrock, Ayrshire.*

The weather in West Herts.—The past week was the first unseasonably cold one since the middle of June, and yet, after all, the mean temperature was only a few degrees lower than is seasonable. As the present month has advanced the weather has been getting gradually cooler, so that the ground at 1 foot deep is now rather colder than is usual at this time of year, but it is still somewhat warmer than the average at 2 feet deep. Some rain has fallen nearly every day during the week, but the total measurement amounted to less than half an inch. A selected plant of wild Ivy came first into blossom on the 23rd inst., or ten days earlier than last year.—E. M., *Berkhamsted.*

The Celery fly.—I am sending by this post a box containing Celery stalks and a bottle of insects, and should be very pleased if you could tell me what the insect is. You will see how it attacks the Celery—entering the leaf-stalk at the bottom, and working its way up. I have never seen it before, and should like to know what it is. Nearly every plant is attacked by it.—H. R. LOVER.

* * The box containing Celery stalks and leaves duly reached me, but there was no bottle in it, so that I am sorry not to be able to name the insects it contained. The leaves were badly attacked by the Celery fly (*Tephritis onopordinis*). Cut off all the diseased leaves and burn them, and when the crop is off burn everything that remains of it and bury the surface-earth as deep as you can, for the chrysalides are formed in the earth, and when the flies leave them they will not be able to make their way to the surface through several inches of soil. If you will send another sample of the insect working in the stems I shall be pleased to name it for you.—G. S. S.

Names of fruit.—*Randell*.—1, *Hawtbornden*; 2, *Warner's King*; 3, *Cellini*; 4, *Queen*.

Names of plants.—*A. T. Bowles*.—*Antennaria margaritacea*.—*North*.—1, *Escallonia macrantha*; 2, white Everlasting Pea (*Lathyrus latifolius albus*); 3, *Lobelia cardinalis*.—*J. C. L.*—*Cassia floribunda*.—*M. Attenborough*.—The White Willow or some of its varieties, which you can obtain at any of the leading tree nurseries.—*A. F. Pike*.—*Dane's Blood* (*Samolus Ebulus*).—*Hibernia*.—*Not M.* (*tripetal.*). We think it is *Magnolia acuminata*.—*F. V. H.*—1, *Populus alba candicans*; 2, the Hungarian Lime probably, but should like to see better specimen.—*F. Randolph-Symmons* (*Colchester*).—1, *Salvia Rozei*.—*Ginger*.—We have no knowledge of the use of a disinfectant for garden use.

BOOKS RECEIVED.

"Cultivated Roses." Illustrated by T. W. Sanders. W. H. and L. Collingridge, Aldersgate St., E.C.
"The Strawberry Manual." Laxton, Bedford.
Hulatt and Richardson, Bedford.
"Vegetables for Exhibition and Home Supplies." By E. Beckett. Simpkin, Marshall, Hamilton, Kent and Co.
"Botany for Beginners." By Ernest Evans. Macmillan and Co., Ltd.

"The English Flower Garden."—Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d.
Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c.

PARK AND WOODLAND.

THE DOUGLAS FIR.

THOUGH this is undoubtedly a fine tree, it is a much over-rated species for general planting. It makes phenomenal growth in some parts—north and south—and in others it refuses to grow and becomes a poor, stunted specimen. I do not think soil has much to do with it, but climate evidently has. The Stanley Wood of the Douglas Fir in Perthshire is a fine example of the tree's adaptability to plantation culture, the trees having grown fast and evenly and kept in fine health, but the soil is of poor quality, apparently rather wet and cold. At Dunkeld and Murthly Castle it grows equally well on a different soil, that is certainly very dry, being naturally well drained. The fact that the Larch and Douglas Fir succeed together speaks for itself, because the Larch will not thrive in a soil that is not well drained. In Norfolk, not far from East Lynn, on a dry, pebbly soil, I have seen the Douglas Fir growing beautifully, and in the New Forest there are long lines of it in splendid health. In many parts of East Yorkshire and Lincolnshire, however, the tree does not succeed, and it has been tried time after time by those who desired to get up a covert quickly. The chill east winds of spring do not seem to suit it, and where these prevail (as they do in some parts from March till June) in conjunction with a dry soil and a short rainfall, I would not advise the tree to be planted. Both the Silver and common Spruce behave very like the Douglas Fir under the same conditions. *Abies mollis* and *Abies Nordmanniana* are the only two Spruces I know of that succeed fairly well where the others will not grow. Another fault of the Douglas Fir is that it is very apt to lose its leader by the wind. In Scotland this has been found to be a serious drawback to its value as a timber tree. Nevertheless, wherever the tree will grow it is well worth planting, as probably no other Fir at present known can approach it for laying on bulk in a short time. The trees in the Stanley Wood were too thinly planted at the first, and made an enormous branch growth, producing huge knots up the trunk that detracted from

the value of the tree; but since then they have grown fast in height, being now perhaps from 60 feet to 70 feet high, though still young, with trunks of good plank diameter, and having established a complete overhead canopy, the lower branches are being regularly shed, and the bulging knots spoken of have been grown over and quite disappeared. The trunks are straight, clean and cylindrical and of the shape they ought to be where timber is the object.

As to the quality of the timber, it must be remembered that the Douglas Fir is a Spruce and the timber is soft—at least, in this country—in trees of timber size. Grown for timber, the tree would be fit for the saw-mill in from thirty-five to fifty years. Poles of pit-prop dimensions would be produced long before that, but I am speaking of trees that would produce good planks and deals from 9 inches to 12 inches or 15 inches wide. These are the sizes that consumers prefer, and those who grow the tree for timber would probably find fifty years the longest rotation period desirable. The timber of the Douglas Fir, though like that of the Spruce, is of better quality, and the heart wood of young trees has a red tint and a weight and texture that are absent in the Spruce. Wind-fallen young trees that I have seen cut up for posts were quite red inside with a broad band of white sap-wood. Age would no doubt make much difference to the quality of the wood, but in trees grown in this country the annual rings are very broad—as much as an inch in some cases. This denotes inferior quality in a Fir. Sections of trees grown in the natural habitat of the tree in Western America present a very different appearance, the annual rings being very narrow indeed and regular and the wood hard and heavy. Examples are shown in the Edinburgh Museum.

J. S. W.

BEECHES IN NEW ZEALAND.

I WAS much interested in Mr. Bean's article on "The Beeches" in your issue of April 22 last, but was surprised that no mention was made therein of any of our New Zealand Beeches. We have seven recognised species, all of which are called Birches by the colonists, the small leaves, which certainly have a greater resemblance to

those of a Birch than a Beech, having given rise to the misnomer. All over the colony where these trees are found the name Birch has been adopted, but there the unanimity of the settlers as regards nomenclature ceases, for in different parts of the colony the popular specific names are jumbled in an extraordinary fashion. For example, the Black Birch of one district is the White of another, the Red Birch is elsewhere the Black, and so on. I expressed my surprise that none were mentioned in the article, as a Tasmanian species was, and it is probable that our Beeches are harder than the Tasmanian representative. The majority, if not all, of them are harder than our Cabbage Tree (*Cordyline australis*), our common Flax (*Phormium tenax*), or our Toe-toe (*Arundo conspicua*), all of which I learn from your pages can be grown in parts of Great Britain and Ireland. In Devonshire, Cornwall, and the south and west of Ireland our Beeches ought to be perfectly hardy, and probably in other localities also. Here some species grow in exposed situations and in parts of the country where the frosts are severe at an altitude of considerably over 1000 feet above sea-level. The three species best known are *Fagus Menziesii*, which has a small leaf with serrated edges; *F. Solandri*, which has also a small leaf without any serrations; and *F. fusca*, which has a much larger serrated leaf, but though its leaf is twice the size of that of the others, it is only about an inch in length. The foliage of the two first is dark and sombre, and grows in dense masses on horizontal branches. The trees possess a striking and distinct individuality, and resemble some of the horizontal-growing Cupresses in general appearance more than any other tree I can think of. *F. fusca* is of a more open habit and is the tallest growing of the three; its foliage is lighter in colour, though at times its leaves are of a brownish hue. It grows in groves and forests by itself, requiring a deeper soil and more sheltered situation than the others. Such forests are totally different from the ordinary New Zealand bush, as there is little or no undergrowth, except thousands of seedlings, 99 per cent. of which must die before they attain even to the dignity of saplings. There are also few Ferns, and as the canopy is not so dense, it is therefore much lighter than in the ordinary bush. All three are evergreens, but *F. fusca* has a pleasing habit of putting on some autumn tints in the spring; some of the old leaves turn to varying shades of red and yellow at the time when the

young leaves are beginning to display their fresh, bright green. Owing to the small size of the leaves, the effect is only visible at a short distance, but it is a very charming and unique one. The trees are not greatly prized for timber, but the timber yielded by *F. fusca*, which is the best, is a nice clean-grained, reddish wood, suitable for indoor purposes, as it does not stand the weather. They are fairly rapid growers, about the same, probably, as their British cousin. All our timber trees are of very slow growth. I feel sure that these trees would, as I have said, prove hardy in the south of England, though in some parts they might require protection in winter till they had attained some size and vigour, and as they are handsome trees they would prove an ornament to any arboratum.

A. BATHGATE.

Dunedin, N. Z.

P.S.—More than one Mistletoe grows on our Beeches. One is very free-flowering, with a crimson-scarlet blossom, which is very effective. I once saw a mountain-side covered with Beech forest ablaze with the Mistletoe. It was a glorious sight. I have tried to introduce it on the trees in my garden, but without success. I read with much interest your various notes on the cultivation of the English Mistletoe, and shall try again if I can get the seeds, but as the plant does not grow in my neighbourhood this is difficult. I once got a few seeds of the English Mistletoe from a friend and tried them on my Apple trees, but the experiment was a failure. After reading your notes I am fired with a desire to try again, but am at a loss how to obtain the seeds, as apparently seedsmen do not deal in them. Perhaps some of your readers would be kind enough to send me a few seeds by post, and I should be happy to send some New Zealand seeds in exchange.

ORCHARD AND FRUIT GARDEN.

EXHIBITING FRUIT.

MANY will agree with "H." in the high estimate he places on fruit exhibits and his objection to the methods in some respects of staging Grapes. There is no doubt that many bunches of Grapes when exhibited would be much more attractive with the addition of some kind of trailing foliage such as the several Virginian Creepers afford, those having small foliage in particular. Vine foliage cut with stems soon withers, and, instead of adding, rather detracts from the appearance of Grapes. Placed under fruit on dishes this is not so apparent. It will, however, be a long time ere the sloping boards will be dispensed with for Grapes, because they not only form a convenient mode of carriage, but save a deal of time in staging on the morning of the show, which to a large exhibitor is most important. Sloping boards neatly covered with white or pink paper, and these draped with some suitable foliage, make good Grapes attractive. Poor quality is represented at every show in some classes and stands, and this will presumably ever remain so, and, no matter what treatment such Grapes receive in staging, they can never be made attractive. It has often struck me that if societies possessed a standard for the regulation of the size of Grape boards, the same as is done with Chrysanthemums, a much more uniform effect would be the result. The first-prize table at Shrewsbury, judged from a photographic illustration, was vastly superior to what is usually seen, but compensation in prize money accounts for much at shows. Some fruit growers are very averse to the use of any accessories in collections of fruit or Grapes. One first-class Grape grower of my acquaintance I heard commenting on the wisdom of allowing a proportion of points for decoration in the great Grape class at Shrews-

bury. He considered there were men who were good growers who would be behind on the score of points simply because they were not experts in the art of decorating. Such arguments are sure to be advanced by some, but they do not always carry weight. For this reason I very much fear "H.'s" suggestion for collections of fruit without papered boards or dishes, leaving it to exhibitors to arrange as best they can without, would not find favour among societies, exhibitors, or the public, because no uniform result would be arrived at. I take it that "H." suggests that fruit be shown on the same lines as vegetables, which are arranged on the stages, having a groundwork of Parsley or green Moss. I do not think the use of wood-wool could be made so attractive for the purpose as "H." seems to think. I certainly do not see the objection to plates being used, as they always have been, but I do think collections may be made much more attractive than they often are by trails of suitable foliage placed about among the plates, largely concealing them from view.

I am afraid "H." is not an exhibitor of fruit collections, or the advocacy of such changes in the staging would not be so prominent; the additional labour involved by such a course would be more in practice than appears superficially. In compiling schedules, too, there is often great laxity, and to clearly define the requirements set forth would, I am sure, be beyond the capacity of a good many. Schedules already are too brief in descriptive matter, and not a little confusion exists in consequence, and there are, I fear, many cases where the scope of "H.'s" views would be impossible. If an exhibitor simply contented himself with showing a collection of fruit, he would then have the time to stage, but more often than otherwise collections form only one of several classes demanding a share of time and attention. There always has been a variety of opinions bearing on the display of exhibition fruit, but "H." certainly deserves some credit in advancing what seems to be quite an original conception. Certainly it opens up a subject that is deserving of some recognition, and I hope others may be induced to give their views. The management of flower shows is often greatly at fault. Exhibitors arrive with their produce, only to find that no provision has been made for them or any calculation made as to how much space is required, notwithstanding that they have forwarded some days previous the necessary information as to the number of classes in which they are to exhibit.

W. S.

The Koslov Morello Cherry, says the *Canadian Horticulturist*, seems to be remarkably hardy. Prof. Macoun in his recent report says that in 1895-6, when Cherry trees at Ottawa were killed out generally, this variety was an exception. It was sent out by the Ontario Fruit Growers' Association in 1890, twenty-four trees having been received from Jaroslav Neimetz, Winnitza, Podolia, Russia. Only five of these have failed; the rest have borne fruit for several years.

Peaches on back walls.—When it is attempted to grow Peaches on the back wall of a vinery, failure commonly results. But I have seen almost myriads of cases where Peaches have been grown well on the back walls of Peach houses when the front trees have been trained to low, rounded trellises. That seems to be by far the most satisfactory way of utilising lean-to houses, for, whilst the front trees get ample light and air, the back trees also get plenty. Only a few days since in a Peach house of this nature in South Haunts I saw the front trees on a trellis, at its highest part not exceeding 5 feet, and the

back wall trees with leaves close to the ground. As to excessive heat, that is hardly to be feared. Ample ventilation can invariably correct trouble from that source.—A. D.

Cutting back Raspberries.—"Norfolk" has raised a matter of great interest to all Raspberry growers, yet it is one on which there ought not to be two opinions. Most certainly myriads of failures have befallen amateurs and some others who, in planting their young suckers, have omitted to cut the hard woody stems back in the spring. The practice of cutting back the newly-planted suckers or canes to within 9 inches of the ground is an old one, and seems to be fully justified by long established practice and experience. When it is stated that leaving at least 2 feet-lengths of old cane, the growth which follows from its buds in the spring helps to promote root action, there is no doubt that a truism is expressed. But then, does not such root action tend to retard rather than help the production of root or sucker stolons? For it is chiefly through the agency of root suckers or stolons that new canes are produced. When we newly plant an ordinary fruit tree we know that anything which causes strong wood growth, causes also strong root growth. But in the case of Raspberries, fruits that in their habits of growth and increase differ from nearly all others, the root growth referred to by "Norfolk" may be of service to the old canes, but none at all to the new ones. These so soon as their points appear above ground practically proceed at once to cause roots to form at their own bases. For these reasons I think the old practice of cutting down newly-planted canes to cause new canes or suckers to form is the best.—A. D.

LIFTING AND REPLANTING APRICOT TREES.

IN the case of Peach and Apricot trees, and, indeed, all hardy fruits, provided the tree is not too old, excellent results may be secured by carefully lifting and relaying the roots, thus infusing new life into them. Unless the recent long-looked-for rains should have the effect of starting a secondary growth, lifting Apricot trees will be practically early this autumn. I do not advise too long delay—not even until a too yellow condition of the foliage has taken place—as often then, instead of the leaves remaining on for say a fortnight after lifting and inducing an immediate and free formation of new fibrous rootlets, they fall, and the tree does not become, as is most necessary, semi-established previous to winter setting in. Therefore I advise taking the work in hand as soon as an actual change from green to yellow is perceptible, then with care, also regular syringings until the last leaf falls, re-establishing is pretty certain by the middle of November. It is surprising what an all-round change is effected in old Apricot trees by lifting the roots up nearer the surface and replacing the old, inert compost with sweet, open loam and mortar rubble, omitting all manures, except, perhaps, a small percentage of bone-meal. Fruit tree planting on wall borders should be carried out more than it is on the piecemeal border system, as in the case of Vines, and what a saving it is where both labour and material are scarce. Where only an addition of new compost can be afforded, a certain width of the border should be marked out, a trench taken out at one end, and new soil consisting of loam, lime rubble, burnt refuse, or wood ashes, and where maiden loam is at a premium a percentage of ordinary kitchen garden soil, hitherto unimproved by fruit tree roots, thrown in and well mixed as the turning over proceeds. The soil from the Apricot border can then take the place of that brought from vegetable quarters. In such cases the lifted tree should, in the interval between lifting and planting, be laid in by the roots in some sheltered corner and kept moist overhead by the syringe. Exactly the same remarks as regards compost are applicable to young nursery or home-grown trees. The difficulty with

very shallow borders is in keeping them sufficiently moist, but I believe if these could be kept watered in dry seasons and mulched into the bargain and impoverishing vegetables kept at a distance, surface-roots, which are the most valuable, would be more numerous, trees would sooner recover from the checks often produced by inclement springs, short jointed, hard, well-ripened wood would result, and the dreaded paralysis, which ruins so many fine trees now-a-days, reduced to a minimum. J. CRAWFORD.

Strawberry Leader in frames.—I had not a particularly good opinion of this Strawberry for forcing at first, but I saw it in good order during the present spring, and now some of the same plants that have been kept well watered since are throwing some useful fruit in frames. Some may say that Strawberries are not wanted at this end of the year, but every good gardener likes to get as much variety into his dessert as possible, and a dish of good Strawberries now is sure to please. Sir J. Paxton is also a good variety for the purpose.—H. R.

Apple Emperor Alexander.—This fine cooking Apple is one of the best for planting in proximity to the house and pleasure grounds, where, owing to the graceful habit of the tree and the prettily coloured fruit, it is always attractive. Although it looks well and is even of fair quality for eating, its very soft character will always militate a little against its coming into general market use. Yet I have sold it at a good price in the west of England, but only in limited quantities. The tree is a hardy and vigorous one, and as noted of pretty semi-pendulous habit when a few years established.—H.

Strawberry Stevens' Wonder.—This variety has probably more enemies than friends, for, early as it is, the fruits are rarely handsome. But at Hackwood Park it is a capital doer, and is largely grown for first early work; indeed, only this variety and Royal Sovereign are grown for early forcing. Mr. Bowerman likes it greatly, for with him it fruits capitally. I saw the respective plants a few days since. Royal Sovereign wore a meagre look, and seemed to need considerable time to enable crowns to be formed. Stevens' Wonder, layered at the same time, showed on every plant a fine head of leafage and stout crowns. No plants I have seen anywhere looked so well. It was easy to perceive that it is at Hackwood a first-rate forcer.—A.

Boxing Strawberries.—Not at all a novel, but still now a somewhat unusual, plan in the forcing of Strawberry plants is that adopted at Greenham Lodge, Newbury, by Mr. Dalby, who layers all his runners for forcing into boxes of stout inch wood 5 feet long, 8½ inches wide, and 5½ inches deep inside. He has some fifty of these boxes all filled with Royal Sovereign, and each one contains sixteen strong-rooted layers. These plants were generally stronger than others in pots, not having suffered so much from the heat and drought. Practically they need less attention, as one watering will usually serve a box for three days. They are stood on shelves in a low span-roofed house, being brought in in batches, and the plants give heavy crops. No plants in pots for forcing are there grown.—D.

Three good Apples.—I saw just recently at Forde Abbey, Chard, bush trees of Domino and Stone's Pippin carrying for their size truly wonderful crops of fine clear fruits that were perfect pictures, and well merited illustrating. Domino is a hardier early Apple than Lord Suffield and is a free cropper. The fruits are clear, semi-conical, and carry a profuse bloom. Stone's Pippin is well known, and in this case the crop was a grand one. The third Apple was the still better-known Lane's Prince Albert. This I saw in several gardens fruiting freely, but nowhere so markedly as at Hackwood Park, where on a couple of espaliers 4 feet high and about 10 feet long there was the other day a splendid crop of superb samples. What a fortune should this grand Apple furnish were it generally

grown in bulk in this espalier form, for it adapts itself to such training admirably.—A. D.

A CURIOUS GRAFT.

THREE years ago a M. Dardar, of Brouvaux, near Metz, brought to notice a Medlar more than 100 years old, grafted on a Hawthorn. Directly below the graft the stock (White Thorn) gave birth to a branch (which we will call No. 1), intermediate in form between the Hawthorn and the Medlar (*Mespilus germanica*), yet approaching more nearly to the latter than to the Hawthorn. This branch differs from the grafted part of the tree, that is to say the true Medlar, in being thorny, and, in lieu of single flowers, these are borne in corymbs of as many as twelve. The fruit (Medlars) are small and generally very much flattened. Side by side with this branch and springing from the same point of insertion, another has developed of completely different form (No. 2), the young leaves of which are lobed, velvety, and shaped like those of the White Thorn; the full-grown leaves, on the contrary, are little or not at all lobed, are long in shape, and, in fine, bear a certain resemblance to those of the Medlar. The young shoots are downy, the flowers in corymbs almost similar to those of the White Thorn, but somewhat larger, and the calyx pubescent. Two years ago these flowers were roseate in colour, sometimes also the rose-coloured petals alternated with white petals. This year there have been only white blooms, though it is true I only saw them at their decline, which may explain the apparent change of colour. The fruits of No. 2 are long, brown, smaller and quite different from the true Medlar. The same tree has also produced, likewise below the graft, another very remarkable branch (No. 3). The base of this branch is none other than the White Thorn, but the extremity is transformed into a branch which, if not exactly similar to No. 2, bears a very close resemblance to it. This third form, unfortunately, now only exists on the mother stem in a withered state. Possibly I cut this branch a little too short in taking branches to graft. Fortunately, however, the grafts have taken very well, so that I am enabled to study this form. This year I made two new discoveries not hitherto observed. Form No. 1 has given birth to a young branch, which is the true single-flowered Medlar. On the same branch a forked twig at a slight distance from its point of insertion has produced on one side an inflorescence of White Thorn and on the other a corymb of eight Medlar flowers.

What ought one to conclude from this extraordinary disjunction? In my opinion all these changes are without doubt due to the influence of the graft (the Medlar) on the stock (the White Thorn). The intervening forms which have sprung from it, and of which we possess vigorous two-year-old plants fixed by the graft, logically can only be called hybrids. But if this description ought to be applied to them it will be necessary in botanical treatises to rectify the definition of the term and to distinguish between the different sorts of hybrids, viz. (1) those obtained by sowing, and (2) those got by grafting.—ED. JOUIN, in *Le Jardin*.

Plum Kirke's Black.—This is a Plum that has given very excellent results this season, and for the matter of that it generally does, as it is but seldom that it fails to bear. This season, however, when the Plum crop is not so satisfactory generally as it might be this fact is worth recording, as it shows that the variety under notice possesses a good constitution, and is to a very great extent capable of resisting the effects of the great diversity of weather usually experienced at the season when Plums are in blossom. It is also a variety that does exceedingly well on a wall either having a northern or north-western aspect. Bush trees also bear well, and I have seen it stated that it is quite as prolific when grown as a standard. Under good culture the fruits grow to a large size on wall trees, and when

fully ripe and covered, as they usually are, with a very dense bloom they are then strikingly handsome, and form a fine dish for the dessert. The fruits when partaken of are invariably found to be quite as good as they look, the flesh proving to be both tender and juicy and very richly flavoured.—A. W.

Apple Devonshire Quarrenden.—On the trees this has a very pretty appearance, and it is one of the most useful of early Apples on a suitable soil. Unlike many other kinds it colours well even in cold and heavy soils, while in sheltered places it comes very early. In a Huntingdon garden recently I noticed a fine tree well loaded, the only one in the garden, in fact, that was bearing a crop. At another place in the midlands its showy fruit stood out conspicuously from all others, and it is a pity it is not much more grown. To help with the dessert at this time of year it is excellent, though the flavour is not, of course, up to the standard of later kinds. Many people like the soft rather sweet flesh of these early kinds, and to such this variety will appeal. It is strictly hardy and free-bearing, does well on any stock or under any form of training, but best of all on bush and free pyramid trees. In the west of England it is a very favourite kind, and in Gloucester, Somerset and Devon may be met with in almost every cottage garden, many of the cottagers making a good percentage of their rents out of their "Quarantines."—H. R.

NOTES OF THE WEEK.

Dahlia Island Queen is perhaps among the most beautiful of this fine race. It is a *Cactus* kind, with flowers of an exceptional shade of delicate mauve. The kinds in this particular line of colour are by no means numerous, so that this stands out quite prominent among the best of these flowers.

Helianthus orgyalis.—Perhaps the most striking feature of this plant is not the great size of the flower-heads, but the reverse, for it is indeed one of the smallest in this respect. The elegant and graceful habit and the well-recurved linear leaves are items that make its presence in the garden as welcome as it is distinct and beautiful.

Kniphofia Nelsoni.—Can any reader of THE GARDEN say if there are early and late-flowering forms of this fine plant? A year or two since I planted a nicely established example of it, but it appears destined to be a late-flowering variety of this beautiful Torch Lily. Not that lateness would be any drawback, but many spikes appear too late to admit of full development.—E. J.

Gerbera Jamesoni.—At the last Drill Hall meeting the Messrs. Wallace, Colchester, had flowers of this fine plant. The brilliant colour of the ray florets and the large size of the flower-heads make this a really handsome subject. The flowers are borne on single stems, and, when sufficiently plentiful, should make a most telling subject in decoration, and under artificial light in particular.

Early frost.—On the morning of the 29th ult. quite a sharp frost was experienced in this district (West Middlesex), Vegetable Marrows and the more tender things suffering here and there. Late in the afternoon of the previous day some rain fell, this leaving vegetation generally quite wet and easily affected by frost. To this is due the fact that some fully expanded flowers of *Chrysanthemums* were quite spoiled.

Apple Lady Kinloch.—A slight error appears in last week's GARDEN in referring to Apple Lady Kinloch sent from here to the Drill Hall meeting on Tuesday. It is there stated that this variety originated here, instead of which the raiser was Mr. John Brunton, Gilmerton, East Lothian, who placed the stock in charge of Messrs. D. B. Laird and Sons, Edinburgh, for distribution. This firm sent a plant here for trial a few years ago, and the fruit shown was grown upon that plant.—JAMES DAY, *Gilroway House, Gartiestown, N.B.*

Early or summer-flowering Chrysanthemums.—These showy and useful subjects were greatly in need of the rain, but which, however, has come too late for the earliest bloom. Only the other day some plants of these in variety were drooping just as badly.

as though exposed to the great heat of summer, demonstrating how exceedingly dry they were at the root. Indeed, even now where the plants have not been watered the soil is dust-dry an inch from the surface. In the meantime, however, the plants are refreshed and should give a nice display if the weather remains favourable.

Statice Bondwelli.—Yellow or shades approaching this are very rare in this genus, so that the present plant is unique, having flowers of a good brimstone-yellow shade that with age become somewhat paler. The plant is an annual, and the distinctly forked inflorescence is very striking. The main branches of the inflorescence are slightly angled, the branchlets merging from a simple attenuated stem to an acutely triangular form, the blossoms appearing in considerable profusion at the tips. *S. sinensis* is said to have yellow flowers. The above, however, on the testimony of Messrs. Wallace, Colchester, forms a free-flowering bush, very pretty by reason of its distinct colour.

Aster Amellus.—A word of warning may not be altogether out of place respecting this and the variations obtainable when raising plants from seed. As a matter of fact, scarcely any two of these are alike, and it needs a note of warning to prevent quite a host of these with their minor variations being saddled with distinctive names. It is always advisable to raise seedlings of such things, though up to the present time very few that we have seen have surpassed the original in point of colour or freedom. One of the finest is named *Riverslea*. Already, however, there are spurious forms in the market with this name attached. This is unfortunate, as the colour of the true plant is so distinct, while in habit it is but a counterpart of the type.

Physalis Franchetti.—It is, of course, as an autumn plant that this is valuable, when the abundance of its richly coloured calyces renders it one of the most striking plants in the garden. The plant is in every way superior to the older species, *P. Alkekengi*; indeed, in leafage alone it is a gain upon the old sort. With good treatment and early planting some very decided effects may be secured. Not that this should be construed to imply tenderness on the part of the plant; rather is it perennial and one of a somewhat persistent type. At the same time, the inclination of its roots to travel may sometimes leave a gap where no such gap was intended, and by transplanting each year this may be avoided. Just now the plant is very fine, and if dwarfer than we have before seen it, there is no lack of brilliant colour.

Aster F. W. Burbidge.—If I recollect aright, I sent to THE GARDEN a short note about this *Michaëmas Daisy* in the autumn of 1898. My only plant has now attained larger proportions, so that I can now more fully understand its worth. The high opinion I formed of it before has not been lessened, but rather increased, by longer acquaintance and by the finer appearance presented by the larger plant. It is of sturdy habit, has strong stems, and grows in this light soil about 5 feet high. The individual blooms are large and of a fine colour. I see them described as being of a fine soft heliotrope, and it is not easy to suggest an alternative description more suitable. There is about the flowers in certain conditions of the atmosphere a warm rosy tint which is quite attractive. *Aster F. W. Burbidge* comes into bloom with me early in September, and will, to all appearance, last well through October. —S. ARNOTT.

Statice minuta.—While one cannot claim for this tiny Sea Lavender that it possesses either the elegance or the usefulness for cutting of its taller congeners, it has some features which will commend it to at least a few. Its principal claim upon our notice is, however, one which many will not recognise as such. It consists in its miniature size, a grievous defect to those who like showy flowers, but a high recommendation to those who delight in the smaller gems of the alpine garden. There has, to all appearance, been some confusion in the names of these very dwarf *Statice*s, but there does not seem much reason to

doubt the name of the little plant now in my garden under the name of *Statice minuta*. It grows only some 4 inches or 5 inches in height, has small leaves almost spoon-shaped, and stiff spikes of flowers of almost a lavender colour. Small and unassuming as is this *Statice*, room should be found for it in the rock garden.—S. A.

Phlox Berenice.—The favour generally accorded to white flowers is shared by white *Phloxes*. In these there has been a considerable advance of late years. This has largely consisted in the size of the individual flowers and in the greater purity and substance they show. It seems only a short time since *Panama* attracted the notice of admirers of these fine autumn flowers. It, however, is not easy to obtain in good form. Fine as the individual pips may be, the spike is usually poor in comparison with that of some of the older whites. In the one named *Sylphide* we have, however, a considerable improvement. It is beautiful from almost every point of view with its white flowers, its wax-like texture, and its good spike. In *Berenice*, which was shown at Edinburgh show by Mr. Forbes, of Hawick, we have what promises to be another acquisition. Unless I am mistaken, it also is from the same continental source which has of late years given us so many beautiful florist's flowers. Among the newer *Phloxes* there are still some which fall short of the best of the older varieties in the form of their spikes, but one can observe an improvement in this respect also.—S. A.

Carduncellus pinnatus.—This pretty little alpine plant is giving a second crop of bloom at present. One says crop with some reserve, as the flowers are, perhaps, not so freely produced as to justify the term, which carries with it the idea of a number of blooms. It does not seem at best a plant which will at any time give many flowers, yet it is one which is uncommon enough and pretty enough to be a favourite. It has been growing on a rather dry rockery here for fully three years, but I have an idea that it would flower more freely if in a place where it would have more moisture at the root. One of the beauties of *Carduncellus pinnatus* consists in its exceedingly neat habit, which makes it of high value among the dwarfest of the rock garden plants. It forms a nice tuft of pinnate leaves, each about 3 inches long and of a rather deep green colour. From the centre of each tuft is produced one solitary, almost stemless, flower. This is rather like a small flower of *Centaurea montana*, but with the florets differently arranged. The flowers of this *Carduncellus* are of a light purplish blue. The only information accessible regarding the native home of this plant is the somewhat unsatisfactory statement that it comes from the East.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Tropæolum speciosum.—This brilliant creeper is not so easy to establish in some Scottish gardens, and your correspondent "Delta" will find that a good many readers north of the Tweed can appreciate the difficulties experienced in establishing it in the south. I know of gardens in which it has been tried many times, with the invariable result that it has failed to flourish even when a season's growth had given hope that it had established itself. I have in view a garden where it has been planted several times. More than once it has attained several feet in height, but failed to come up the following year. One season it was over 7 feet high, yet the following year not a vestige of it was visible. In moist districts it is much easier to establish than in those where the rainfall is less, but it is altogether a plant difficult to fairly establish, and one, too, which has a great dislike to disturbance. I can remember a house which was for many years the admiration of all passers-by on account of the way it was covered with the brilliantly coloured wreaths of flower of this *Tropæolum*. The house changed tenants, the one who left removing, as far as possible, every bit of *T. speciosum*. The new tenant obtained a number of roots in the same neighbourhood, where it

grows luxuriantly. Some years have elapsed, yet the *Tropæolum* has never fairly got hold, and is still weakly and far from being as fine as before. Anyone who has felt the difficulty of establishing the plant can thoroughly sympathise with the spirit of rejoicing of which your esteemed correspondent "Delta" speaks.—S. ARNOTT.

Fuchsias in S.W. Scotland.—Although the climate of Cornwall is very different from that in this corner of Scotland, and, indeed, almost all the west coast, many might profit by the pleasant notes on "Cornish Gardens" in THE GARDEN of September 30. I know of gardens where the *Myrtle* lives and flowers against a wall, and such places as *Poltalloch* and *Inverewe* could give us many lessons. What one would, however, like to draw from the note by "S. W. F." is a hint of the desirability of more attention being paid to the *Fuchsias*. With us there are good bushes of *Fuchsias* which have no protection in winter, but escape unscathed, save the loss of their leaves and tender twigs, in all but the most severe winters. Even in such record seasons as the winter of 1894-95 these were only killed to the ground and started again from the base. For some years I have had under observation in a cottage flower border facing south a *Fuchsia* with white perianth and purple corolla. It is not a vigorous grower and never attains more than about 3½ feet high. It is perfectly hardy in the garden in question, which, although facing the south and close to the sea, is yet pretty much exposed. I do not know the variety, but it is not too much to assume, I think, that others of similar colour might succeed as well. In my own garden for the last two winters I have grown without any protection one of M. Lemoine's hybrids of *F. myrtifolia*. I saw a few of these at Newry, where they are hardy, and afterwards obtained as an experiment the one called *Bouquet*. It is a dwarf-growing little *Fuchsia*, such as growers of alpinists would appreciate, and one with which I have been much pleased. I have not given it any covering.—S. ARNOTT.

Ranunculus Lyalli at home.—As Mr. Arnott truly says, "the establishment of so fine a plant as *Ranunculus Lyalli* is worth a good deal of trouble," and as reliable information concerning it seems of the vaguest description, it may be of interest to him and other growers ambitious of succeeding with it in the Old Country to relate my personal observation of it in its own native wilds. There it flowers during the months of December and early January. I saw great groups of it growing on the top of Arthur's Pass, on the way to the entrance of the far-famed Otira Gorge, on the West Coast Road, Middle Island, New Zealand. At such an altitude all vegetation was naturally sparse, especially when compared with the luxuriant growth of the bush running riot lower down. The *Mountain Lily* was a conspicuous object in the nooks and depressions on the otherwise somewhat level ground on either side of the coach road on the summit of the Pass. The plants grew in the open, their large leaves overtopping the coarse grass and smaller herbage that surrounded their roots. It also appeared to grow in somewhat marshy situations, though, as the rainfall on the West Coast Road is proverbial for its persistence at all times of the year, this conclusion may have been perhaps too hasty. From his own long personal experience, our driver told us at this elevation the cold during the winter months was intense, though he could give us no approximate idea of the average temperature at that season. The ground on which the *Ranunculus Lyalli* grew was not remarkably stony, though rocks lay scattered about the locality much as they do on any ordinary moorland. I am almost sure this *Ranunculus* is not an annual, as I was shown some fine plants of it growing in the little garden of a Scotchwoman, hostess at one of the rest-houses at which we put up for the night. There I was informed the *Shepherd's Lily*, or *Mountain Lily* (as the colonials call it), thrived as well in the valley below as in its native haunts on the heights above.—E. W.

GUNNERSBURY HOUSE.

In the pretty and well-kept gardens that surround Gunnersbury House a particular phase of gardening is in favour, and the most casual observer will not be long in deciding for himself after having once seen them what the chief aim and desire of the owner, Mr. Leopold de Rothschild, are. Indeed, it is obvious on every hand. The very naturalness of everything as opposed to the stiff and the formal fully demonstrates that the one desire has been not garish beds of this or that at every turn, but the careful avoidance of these, and in place thereof groups of this or that. This is perhaps most apparent in the vicinity of the pond. The meeting of grass, Sedge, Rush and water is all so much a bit of Nature, that one

view. To this end Mr. Hudson, the gardener, has devoted considerable space this season to the more showy

HARDY BORDER PLANTS,

and right well has he succeeded in making a display of these things. That this much has been accomplished in what has undoubtedly been one of the worst seasons for freshly-planted subjects only tends to show the care that has been bestowed on this fine border and its occupants. The border is of semi-circular outline, and is 5 yards wide and 70 yards long, figures that show that a great number of plants of varying sizes would be needful to fill it to advantage. It was quite early in September when I had an opportunity of seeing this border. The plants are not arranged to form

sort of surprise when in full view from the front. The idea is good, not merely for the reason just stated, but because a partial shade-loving plant may be introduced and used to advantage. In just this way a lovely group of *Lobelia Carmine Gem* was obscured from view till one faced the plant, which, however, was no solitary one, but a fine mass in splendid flower. No finer addition has been made to the hardy *Lobelias* during recent years, and as a good early autumn perennial it has much to recommend it. Some of the finest tall-growing perennials were to be seen in this border. Among them *Helianthus orgyalis*, *H. Miss Mellish*, the several forms of *H. multiflorus*, and among them the true *H. multiflorus major*, which is not often seen, being generally confused with *H. m.*

maximus, from which it is distinct. The kind mentioned is nearly 2 feet taller than the ordinary *H. multiflorus*, which in full flower only a short distance away afforded a good contrast. *Pyrethrum uliginosum*, *Helenium autumnale superbum*, *H. nudiflorum*, the taller *Michaelmas Daisies*, such as *Robert Parker*, the *Novæ Angliæ* forms, *W. Bowman*, and others, were all in fine masses. A splendid mass, too, of *Rudbeckia Golden Glow* was teeming with flowers. Here, however, in spite of fine vigour and excellent colour, the plant had rather weakly foot-stalks. All the same, the effect was very good amid so much that was quite erect. Other striking objects not perennial in character were pillars of *Convolvulus major*, the silvery *Polygonum tomentosum*, which provides a fine leaf effect not merely in its boldness, but equally in the colour. *P. orientale* is also a fine tall subject. Among things of more medium height the most noticeable were masses of Japanese

The lake at Gunnersbury House. From a photograph by Geo. Champion.

is struck by the very likeness and similarity. How very different this pond would appear with its wealth of lovely Lilies had it been formally treated and given over to the mason. Another very charming as well as secluded spot leads from the terrace, and may be styled a Rose garden, for Roses largely abound, and then at one end of this almost everything employed is fragrant to a certain extent. Beds of *Heliotrope* and *Humeas*, with others of *Bouvardias*, make this sheltered and secluded spot a most pleasant and enjoyable one. It is more particularly during the late summer and autumn that this garden is at its best, for the family are then in residence. Hence no trouble is considered too great to attain the object in

one sloping bank of blossoms for reasons of effect; indeed, had the height of each plant been strictly observed, the whole border would have simply resolved itself into a series of half circular lines, with the tallest things behind and the shorter ones in front. Happily, this was avoided with the best results. The arrangement, therefore, while adhering to a strict method, is something after this sort. A group, say, of some tall-growing plant, *e.g.*, any of the perennial Sunflowers, while fully occupying the background would here and there extend as a sort of promontory to the front, and thus form a panel or recess for a much shorter group of things that was not visible in the distance, and therefore created a

Anemones in white and coloured kinds and the fine *Heliopsis Pitcheriana* with golden orange flower-heads. This is a fine subject for August and September flowering, yet it is rarely that justice is done to it. Whether this is due to its smaller flower-heads or not is a question; still it is so distinct in the Sunflower family, that it should be grown well and liberally where effect is desired at this season. *Boltonia asteroides*, groups of *Cannas*, *Aster laevis formosissimus*, and a very fine late Torch Lily, *Kniphofia R. C. Affourtit*, a seedling from *K. corallina*, were also effective. One or two good *Phloxes* only were used, as the majority of these are too early flowering to suit the case. Those employed are *Jeanne d'Arc*, white;

Coquelicot, cerise; and Miss Pemberton, a large-flowered carmine variety. Another year, however, these will be tried on another plan with a view if possible to retard their blooming. Again in masses occurred the Montbretias, *Rudbeckia Newmanii*, the pretty Goldilock (*Aster (Chrysocoma) Linosyris*), the purple Clary, *Salvia Horminum*, *Physalis Franchetti*, *Chrysanthemum frutescens*, *Kniphofia Nelsonii*, *Aster Thomsonii*, *A. ericoides*, *A. cordifolius*, *A. Mrs. W. Peters*, *A. Amellus* and its vars., *Gaillardia Vivian Gray*, a soft yellow kind, which also possesses a disc of the same uniform colour, a few Balsams and a margin of dwarf Snapdragons completing the more important things at the moment. Several feet of a grass verge occupy the foreground, and the effect is not lost upon the border. At the back is a veritable fence of *Cactus Dahlias*, that not only forms a most perfect floral screen, but here and there as seen through this border of flowers is helpful by reason of the fine array of colour. Sheaves of bloom are taken from this flower fence. This border is no doubt one of the most satisfactory and still one of the least formal we have seen. That it serves the purpose for which it was intended there is no doubt; it does more than this, for it proves how much may be accomplished in a single year by the judicious blending together of the best the season provides.

PLANTS FOR THE TERRACE.

Leaving the border, the main terrace intercepts the lawn and the gardens beyond. On the terrace specimen Pomegranates (*Punica Granatum*) have this year given a rich display of flowers of almost solid wax-like substance, the brilliant colour alone forming a considerable attraction. The handsome bushes of the sweet-scented *Verbena* and the splendid bushes of *Myrtles*, both of which have been raised from cuttings by Mr. Hudson, also flower very freely, and promise to carry it on for weeks to come. Then close by is that probably unique collection of fragrant *Pelargoniums*, many growing quite naturally in large pots and others trained in huge fan-shaped outline to afford a special screen in a town garden in London. No garish bedding breaks the lawn here, but on either hand fine trees provide a welcome shade, and beds of bulbous-flowering and other plants abound. It is here, too, that one notes in such abundance the several forms of the *Lilies* of the *L. speciosum* group, not over-massed to form a vulgar array of colour, but grouped, some with *Bamboos*, others with the varied kinds of *Japanese Maples* that display a pretty effect with many diverse tints; others, too, with the ever-welcome *La France Rose* flowering freely together, in which case the white *L. s. Kretzeri* was the chosen companion, while in another this same variety with *L. auratum* mingled with *Acers* in very pretty fashion. Another large *Lily* group was composed of the Cape-grown *L. Harrisii*, which was flowering finely in a bed of *Veronica* as a foreground to larger shrubs and things behind. Nor can one pass over a notable specimen of the well-known *Catalpa*, on which hung in the greatest profusion its clusters of long Bean-like fruiting pods, pods that almost compare with the more tropical *Vanilla* in form than aught else. It was here, too, that the pretty masses of *Cyclamen hederifolium* made so charming a picture, and though not long planted, and therefore not fully established, promise a still better display in the future.

THE HYBRID WATER LILIES

are important; indeed, of recent years much interest has been taken in these things at Gun-

nersbury House; and to remember that all the beauty this water garden represents is so little removed from London should go not a little way to encourage others who have water at hand to try and produce similar results. It is not a huge or costly lake that is required to grow these plants, for quite a large number may be grown in a small space, and their exquisite flowers are indeed no little gain to any garden. Nor is it only the water and the Water Lilies at Gunnersbury that make the whole thing so purely natural, for the very approaches and the margin of the pond or lake afford a well-marked lesson. Of the Lilies themselves a few words must suffice, for they are now a large and interesting throng and number at least some three dozen kinds; indeed, all that are good and procurable. For the summer and autumn months these things provide a touch of colour that has long been needed in the garden, and now the want is supplied the desire for more will grow apace. Water without water plants not infrequently becomes a neglected area, and sometimes an unsightly one too, but with a few good plants introduced follows the desire of watchfulness and care to do them justice. As may be gathered from the accompanying pictures, the water space at Gunnersbury is considerable, and many of the plants are now of fine proportions. This, indeed, is the most encouraging part, seeing the short time that has elapsed since their introduction. Now it is easy to count a score or more of buds from a single plant—a plant, by the way, that four or five years ago would have been easily put into the waistcoat pocket. A few of the more important of these *Nymphaeas* are *N. Marliacea alba*, *N. M. carnea*, and *N. M. Chromatella*, while the higher coloured kinds may be mentioned, as *N. M. flammea*, *N. ignea*, and *N. sanguinea*. In the odorata group, the lovely *N. o. exquissima*, *N. o. rosea*, and *N. o. sulphurea grandiflora* are fine. Other good things are *N. Laydekeri fulgens*, *N. L. rosea*, &c., while such as *N. Ellisiana*, *N. gloriosa*, and *N. lucida* are plants alone of very decisive hues. A pretty miniature kind, *N. pygmaea Helvola*, is among the daintiest of all this tribe. Here they flourish one and all with that vigour and freedom that were for long regarded only as the inheritance of the well-known white Water Lily, *Nymphaea alba*. It will be in keeping here, before leaving this group, to mention the lovely *Nymphaea stellata*, which is also a feature here. This, too, is well shown in the picture, but it is not grown in the lake with other kinds, but in a tank adjacent to one of the greenhouses, where a return pipe passing through just suffices to warm the water in the early days of the year and through winter. All the summer long this lovely plant sends up its splendid flowers well out of the water on long petioles that render it most welcome in decoration. The tank is, perhaps, 6 feet or 8 feet long and about 5 feet wide, and here scores of blossoms appear in the wildest profusion, often as many as twenty being taken at a single cutting. Through the winter months a spare frame covers the tank, and thus with very little trouble this fine blue Water Lily yields almost unceasingly of its flowers. It is assuredly a kind which no garden should be without even for the colour it affords, if nothing more. On the opposite side of the lake from the mansion is

THE BAMBOO GARDEN,

though *Bamboos* really encircle another side also. In the Bamboo garden, which is a series of beds of these things, a great number are being tried, and though established and growing well, as indicated by many freshly formed

shoots, the plants are yet lacking their true character, and for the moment may be thus briefly disposed of. There are, however, one or two notable exceptions—*Phyllostachys nigra*, for example, which here is not only one of the hardiest and most free-growing, but also one of the most elegant in plumage. Already has this fine example endured 24° of frost, and the plant still grows apace, each year's growth being stronger than before. But even now the finest growth must be nearly 10 feet high, and, though not erect, is of the most graceful bearing. There is also a gigantic example of *Bambusa Metake*, which grows in close proximity to the water's edge. *Arundo Donax macrophylla* (syn., *A. D. glaucescens*), recently certificated at the Drill Hall, is here also, and quite distinct from the old kind. No mention of these gardens would, perhaps, be complete without a reference to the

FRUIT DEPARTMENT UNDER GLASS.

How well Mr. Hudson excels in this particular is well known, and visitors to recent Temple shows will not have forgotten the fine and varied displays that have been made on these occasions. And what is true of the earliest forcing kinds is equally so of the latest that can be obtained, and the best of Plums and Pears for late dessert are grown here in very considerable quantity. Of the former, *Golden Esperen*, *Golden and Late Transparent*, *Ickworth Impératrice*, *Coe's Golden Drop*, *Grand Duke*, *Late Rivers*, &c., form the bulk, the trees, all of which are in pots, bearing good crops. In a private garden such as this so large a number of pet trees is no inconsiderable item, and as the entire batch is repotted each year the care for the trees is constant. The early trees were in the open and dripping with their usual evening bath. Figs, too, are a feature here, some four houses alone being utilised by these. *Negro Largo*, *Nebian*, and *Bourjasotte Grise* are those grown, the last taking the palm for flavour. It is in one of these Fig houses in the full light suspended near the glass that Mr. Hudson succeeds so well with *Dendrobium formosum giganteum*. Some of the plants are now in their fifth year as cultivated examples, and each succeeding year the pseudo-bulbs are stronger. The plants, indeed, are in the finest condition and progress everywhere apparent. Some hundreds of flower-buds and blossoms alone demonstrate not merely the worth of the kind, but how well the treatment suits the plants. For late supplies, a fine house of *Melons* was planted on July 4, and in eight weeks from that date some of the earliest were approaching ripeness. There are nearly forty plants in the house, the scarlet-fleshed varieties only being cultivated. The house itself is a span-roofed structure, lofty and wide, the vines and foliage extending several feet beyond the fruits, an item which doubtless conduces to flavour as opposed to the more restricted practice that sometimes obtains. The vineries also had their complement of the fruit, the good crops that were apparent bearing evidence of good culture, while the perfect freedom from spider, in spite of hot weather, was alone remarkable. Peaches, Nectarines, and Strawberries, a large number of which are alpine, are grown here in quantity. Still one more department, and this

THE MUSHROOM HOUSE,

or rather cellar, for it is indeed an old wine cellar which is thus converted into such excellent use. The beds are in the arched recesses and have a surface of about 100 feet. In all there are nine of these compartments, and from early in autumn one bed is made and spanned

each fortnight. The spawning takes place when the thermometer is at 85° with a downward tendency. The beds are about 1 foot thick of the materials used, the earliest being only recently spawned, with others in course of preparation. The accompanying photograph will better convey an idea of the success achieved than any description. The cellar is very convenient for the intake of the needful materials, and being lighted by electricity may be regarded as well up to date in these matters. What strikes the visitor most forcibly perhaps is the uniform condition of the inside temperature; indeed, this alone is sufficient to ensure success in the culture of this much-esteemed edible, and failures seldom occur.

The foregoing are the most important departments in this compact and well-kept garden, yet the variety is so great that many important things are of necessity passed over altogether or only lightly touched upon. But in all, one impression remains, that the good and beautiful are the things chosen to adorn this garden and give it as much a touch of Nature as is possible with situation and environment. E. J.

FRUIT AND VEGETABLE CROPS.

SCOTLAND.

Balcarres Gardens, Fife.—The fruit crops in this district are very good, but ten days late. Apples, Plums and Cherries were abundant, but Pears, Peaches and Apricots are scarce. Small fruits are extra good. Strawberries have been plentiful, but small. Raspberries are very good. All fruit trees are vigorous and free from aphids. Vegetables are very late.—E. TATE.

Brechin Castle, Forfar.—The season has been very much against early crops. There was little growth during April, and indeed it was only in the beginning of June that we began to have genial weather. Onions were very late in starting, but are now making good progress. They are healthy and have not been troubled with the maggot. Carrots also look well, as they generally do here on specially prepared ground. Peas did well. Potatoes, like everything else, are late, but have a good appearance. Early varieties are coming in, but the quality is not so good as it generally is, owing to the wet weather. As yet I have seen no appearance of disease.—W. McDOWALL.

Eastwood Park, Renfrew.—In spite of the cold, wet spring and late frosts, all small fruits in this neighbourhood, with the exception of Gooseberries, are a fair average crop of good quality. Strawberries, though very much below last year, have on the whole given very satisfactory results. Vicomtesse Héricart de Thury and Elton Pine are the kinds which have done best here. In some gardens Royal Sovereign has done well. Apples are very much below the average. The trees were late in coming into blossom and escaped the late frosts, but the spell of hot, dry weather we had when they were in flower, which brought so many insect pests along with it, is, I think, accountable for the comparative failure of this crop.

Up till the present time vegetables in this neighbourhood have been very scarce. Autumn-planted Cabbages looked promising up till the beginning of February, but the severe check they received at that time made 80 per cent. bolt. Early-planted Cauliflowers went off badly with maggot. Young Turnip plants could not get into their rough leaf, owing to attacks of the Turnip fly. Late Brassicas of all kinds were difficult to get up to the planting stage; seedlings pricked into nursery beds when ready for planting were found to be so badly infested with maggot as to be almost useless. Early Peas have been almost a failure, Chelsea Gem being the only kind that has given satisfaction. Midseason sowings are little better, old reliable kinds being

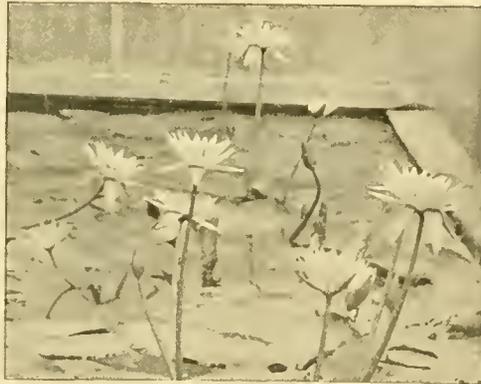

almost worthless; later sowings are more promising.—W. HUTCHINSON.

Callendar Park Gardens, Falkirk.—Fruit crops in general are very thin, owing to the late frost we had here. With the exception of Pears and Raspberries, all other fruits are below the average.

The vegetable crops are fully a month later this year, but everything is promising well for good returns. Early Potatoes have been very poor owing to the heavy rain in the early season. Garden pests are very plentiful on everything.—THOMAS BOYD.

Taymouth Castle.—Fruit prospects in this district are fairly good. Bush fruit is plentiful and of good quality except Black Currants, which are only moderate in crop, and I hear complaints of Gooseberries being poor in places. Strawberries were a grand crop. Raspberries were good. Apples are an average crop and trees clean. Plums are scarce, except Victoria. Early Pears are fairly good, but later ones nearly all dropped. Cherries are good, Morello and Kentish especially so. Insect pests on fruit trees have given less trouble than usual this year.

Vegetables of all kinds are very late. Potatoes are good, at least the early ones; late ones promise well. Peas were very good. Cauliflower was late in coming into use. The earliest Turnips were good, but the successional sowings have been more or less failures owing to the fly, which attacked them badly during the dry spell at the end of May to the middle of June. Farmers in

Nymphaea stellata in the open air at Gunnersbury House.

this district had to sow afresh in many cases, so badly were they eaten.—WM. WRIGHT.

Haddo House, Aberdeen.—The fruit crops in general are poor. Apples, Pears, Plums, and Cherries had a most abundant blossom, but set badly and are a very poor crop, except a few Apple trees on walls and some Victoria Plums. Two or three May Duke Cherries have a fair crop; Morellos are almost a complete failure. Small fruits are also below the average. Strawberries, except on young plants, are poor. Gooseberries are a fair crop, also Red Currants. Black Currants are not half a crop. Raspberries are abundant.

Vegetable crops are fairly good, though late. The dry, hard weather in the end of May and greater part of June was very trying to any crops newly sown or planted, but since the rain came they are doing well and give promise of a full crop. Potatoes especially are vigorous and healthy. Early sorts are a fair crop and of good quality.—J. FORREST.

Dunrobin Gardens, Sutherland.—Apples, Pears, and Plums are the worst crop we have had for many years. During May we had a good deal of rain, with cold winds and occasional frosty nights, followed in the early part of June with about a fortnight of burning sun and drought. The crops of the above fruits are almost *nil* on

most of the trees. The only exception appears to be the old Keswick Coddlin, which has a fair sprinkling on some trees. Small fruits, fortunately, are mostly a fair average, Gooseberries under, and Strawberries rather over average. Cherries are a thinner crop than usual.

Vegetables of all kinds are good, but somewhat later than usual. Potatoes particularly are ten days to a fortnight later. The drought of the early part of June has been succeeded by a wet time. Out of the twenty-eight days from June 18 to July 15 rain has fallen more or less on twenty days, amounting to 3.69 inches. Comparatively little damage has been done by Onion or Carrot grub.—D. MELVILLE.

Cullen House, Cullen.—The wood of Peach trees was badly ripened last year, therefore the blossom was scarce. Apricots were much the same, and, owing to the continuous cold and frost during the flowering season, the crop is practically *nil*. The cold, cutting winds much affected the growth of the trees, and the foliage was very much blistered. Strange to remark, Figs grown here on the open wall do well. Plum blossom looked remarkably promising, but the continuous bad weather has affected the setting of the crop and made it thin. Plums on standards, owing to their flowering much later, have set a fairly good crop. All the better varieties of Pears on the walls were rather short of blossom, and have therefore a thin crop. Standards show a good crop. Apples looked remarkably well earlier in the season, showing an extra display of blossom, but owing to the continued dryness they dropped a quantity of their fruit. Small fruits on the average give evidence of a good crop throughout. Strawberries have been good, especially Royal Sovereign, which maintains its good name.

Vegetable crops in general were good, except Peas, which have gone much to straw with the wet weather. The earlier varieties of Potatoes, such as Sharpe's Victor, which were planted before the bad weather in March, made a very good start, but owing to the late frosts got badly damaged. Later varieties and field crops in general look remarkably well, the spell of dry weather during the early stages being favourable to their growth. Those of the early varieties which are now being used are under average size, the season being quite three weeks behind.—J. F. SMITH.

Eglinton Castle, Irvine.—All small fruits are a good crop, but two to three weeks late. Old plantations of Strawberries (three and four years) are very poor, but young plants are bearing a good crop. Apples, Pears, Plums, and Cherries are a thin crop and very disappointing after a splendid show of blossom. The continued cold weather in May and early June caused them to drop after they were set.—W. PRIEST.

Clifton Park, Kelso.—After passing through one of the most trying springs which we have experienced for years the prospects of a good fruit crop were very small. On May 6, 7, and 8 we had 9°, 10°, and 6° of frost; again, on the morning of May 26 we had 4° of frost. The consequence is, Plums, Pears, and Cherries suffered severely, the crop being a poor one. Apricots are an average crop, although damaged to some extent by frost in spite of protection. Peaches are a failure on the open walls; Apples are a good crop. They being late in expanding their blossoms escaped the late frosts. Currants are a heavy crop; Gooseberries about an average. Raspberries are a heavy crop, the rains which we have had lately proving most beneficial to them and all fruits. Strawberries are neither so large in berry nor in quantity as last year owing to the prolonged drought we had in June.

Vegetable crops almost without exception are late; the weather we experienced in spring was so wet and cold, that vegetation was almost at a standstill. On March 24 we had the lowest reading of the thermometer for the season, viz., 34° of frost, or 2° below zero. Fortunately, there were 3 inches of snow lying on the ground, or the result must have been much more serious than it was. Early Cauliflowers were later in maturing

than usual, but that was amply made up in the quality. Methven's Extra Early Forcing and Early London wintered in a cold frame have given us a supply which leaves nothing to be desired in quality and quantity. Early Peas have been a very heavy crop, and successions are promising to be equally so. Root crops, although a long time in making much headway, came away with a rush after warm weather set in. Early Turnips have run to seed badly. All winter crops, such as Brussels Sprouts, Savoys, Borecole, Broccoli, Leeks, and Celery, give promise of giving abundant supplies. Brussels Sprouts at time of planting gave a lot of extra labour in the way of watering and made very little growth till rain came. Since then they have grown away splendidly.—J. MACGREGOR.

Calder Abbey, Calder Bridge.—There is a scarcity of all kinds of stone fruit, especially Plums and Damsons. Apples are only a moderate crop, also Gooseberries, especially on young trees; the older trees are carrying a very good crop. Black Currants are a heavy crop, as also are Red and White, and the fruit is quite as large as in former years. Raspberries are also a heavy crop, and the same may be said of Strawberries, especially Royal Sovereign. I attribute the scarcity of stone fruit to the wind and rain which we experienced just as the fruit should have set, the show of blossom being quite up to the average.

Peas have been poor, as the dry weather was very much against them, but they are doing better now. Beans of all kinds were very good, as also are Beetroot, Carrots, Parsnips, Cabbage, Cauliflowers (early), Leeks, Potatoes, and Onions, although the last are very much troubled with grub.—H. SANDWICH, JUN.

Barrogill Castle, Mey, Thurso, N.B.—Owing to the late spring the crops in the garden are not so forward as last year at the same time. There is a very heavy crop of Gooseberries and Currants. Strawberries are scarcer, grub having been hard on them in May. This, I believe, is the most northerly garden on the mainland, and much exposed to the north and north-easterly gales. Apples are not so plentiful as last year, owing to easterly winds and a heavy hail shower when the trees were in blossom.

The vegetables are looking very well.—G. HEGGIE.

Glamie Castle.—The fruit crops in this neighbourhood are under the average this year, except Strawberries and Gooseberries, which are a heavy crop and of good quality. Raspberries promise to be a fair crop; Currants and Cherries are light. Pears are a poor crop, and Plums are almost *nil* both on wall trees and standards. Apples are only a casual crop. Some young trees are bearing good crops of fine fruit, but the bulk of the older trees has very little fruit on them.

Vegetables are all very good crops except the Cabbage tribe, which have suffered very much from the grub. Potatoes in gardens are looking very well; early ones are of fine quality. Field Potatoes are very late and not looking well.—THOS. WILSON.

Terregles, Dumfries.—The fruit and vegetable crops in the south-west of Scotland are on the whole of a very fluctuating nature this season. I hear from many reliable sources that they are much under the average, while in some cases reports speak favourably of the yield of some kinds of hardy and half-hardy fruits and vegetables. The weather is always a guiding element in the cultivation of all kinds of garden crops, and in this immediate neighbourhood it has been from a weather point of view one of the worst seasons we have passed through for many years. The winter was mild, with a very heavy rainfall, while all through the spring months the atmosphere was dull and damp, with a continuation of excessively low temperatures and an unusual lack of sunshine, which retarded the early growth of fruit trees, vegetables and crops generally. Without having any real genial spring weather, summer burst on us all at once, and the sudden rise of

temperature and the scorching sunshine experienced in the early part of June were very trying to all kinds of plants, both under glass and out of doors. In this district Apples and Pears are very much under the average, and the same must also be said of stone fruits, such as Peaches, Apricots, Nectarines, Cherries and Plums. Bush fruits, such as Gooseberries, Currants, &c., are an average crop and the quality good, while Strawberries and Raspberries are giving a very good return, and if the weather now continues dry, good gatherings of fruit will be got from them for some weeks to come.

Early Potatoes, although ten days later than usual, are lifting well and the quality is excellent. Field crops look well everywhere, and up to date no sign of disease has made its appearance. Vegetables under good cultivation are, generally speaking, looking fairly well at this date, although we had to wait eight, ten and in some cases twelve days longer for Peas, Cabbages, Cauliflowers, Carrots and Turnips. The weather, however, is now favourable to their growth, and little difficulty will now be experienced in keeping up a good supply.—JOHN MACKINNON.

Carron House, Stirlingshire.—Here the Apple crops never were better. I seldom have a failure of a single tree, a selection having been made some seventeen years ago of sorts which do well in the locality. They are kept well above the surface of the low-lying ground, which cannot be properly drained. The roots are rendered independent of wet and unwholesome subsoil by reason of their being kept up by a good layer of lime rubbish, and encouraged by frequent surface dressings. Fruit-bud formation then becomes certain and the buds well matured. Among the best and certain croppers are Stirling Castle, Seaton House, Lord Suffield, Golden Spire, Lord Grosvenor, Large American, Potts' Seedling, Wellington, Sandringham, Northern Greening, King of Pippins, and Worcester Pearmain (this last does as well here as I ever had it in the south of England). Small fruits made a great show, but the severe frost at the end of May reduced them severely. Morello Cherries on eastern aspects were a good crop. Plums on standard trees were a heavy crop, but only confined to the Victoria. On high walls the crop of Plums promised to be abundant, but they thinned themselves very severely. Pears as cordons trained on high walls are a good crop. Beurré de Capiaumont, Louise Bonne of Jersey, Jersey Gratioli, Van Mens Leon Leclerc, and Easter Beurré are the best, but are small compared with those of last year. On western aspects the Pear crop is thin.

Vegetables on the whole have done fairly well on our heavy soil. In the early part of the season there were fears that many failures would occur. Such untoward weather as we had during April and May is rarely experienced. Potatoes and some other crops seemed almost to collapse, but during the warm summer weather they quickly recuperated. The Potato crop generally is good and the quality is very fair, especially the kidney varieties. Veitch's Ashleaf is still one of the best. Sharpe's Victor (yellow variety) is the favourite for earliest supplies. Snowdrop, Syon House Prolific, Austin's No. 1, and Dobbie's Main-crop Russet are much in favour for field culture. Regents and Abundance are largely grown; they are considered good disease-resisting sorts. All the Brassicas have suffered severely from caterpillars. Peas suffered much from drought. Onions were long in starting into growth, and the size of bulbs is generally less than in former years. They are very free from maggot. Veitch's Maincrop is by far the best. Ailsa Craig is of good size and of fine form. The finest Peas were Chelsea Gem, Gradus, Dickson's Favourite, Dr. McLean, Autocrat, Duke of Albany, and Ne Plus Ultra. I never saw the ground so dry as at present, it being like dust to a depth of 1½ feet.—M. TEMPLE.

Galloway House, Garliestown.—Small fruits in this part were good average crops, Currants of sorts and Raspberries being especially

heavy, while Gooseberries and Strawberries though slightly below the average of former years in weight of crop, gained some compensation from the excellent weather that prevailed at the time the fruit was ripening, which enabled nearly all to arrive at maturity free from waste. Apples are not a full crop, but are now turning out much better than was anticipated a few weeks ago, as the recent heat and moisture have swelled the fruit very quickly, and although less in bulk, very good samples of sound and handsome fruit will shortly be ready for storing. A few varieties have good even crops, of which the best are Loddington, Warner's King, Lane's Prince Albert, Alfriston, Keswick Codlin, Yorkshire Beauty, Galloway Pippin, Lord Suffield, and Manks Codlin; dessert sorts, King of the Pippins, Thorle Pippin, Beauty of Bath, James Grieve, Worcester Pearmain, Cox's Orange Pippin, and Mr. Gladstone. Apricots are fair crops; Moorpark, Large Early, and The Royal are the best. Pears are very scarce, and both in quantity and quality of the fruit are much inferior to any crop for many years past; Pitnaston Duchess, Williams' Bon Chrétien, Beurré Bosc, Ne Plus Meuris, Fertility, and Beurré de Capiaumont are the most promising. Plums are generally a thin crop, though some varieties are very satisfactory in this way, and the fruit will be large and well coloured, which, thanks to the absence of wasps and, so far, excess of rain, can remain upon the trees until fully ripe. Early Rivers, Czar, Pond's Seedling, Victoria, Magnum Bonum, Goliath, and Belle de Septembre are bearing fair crops, while of dessert varieties, Kirke's, Lawson's Golden Gage, Jefferson, Denniston's Superb, and the Green Gage are the best. Damsons for the second year in succession are almost fruitless. Dessert Cherries were a very light crop; Morellos are below the average, but an excellent sample, being large and well coloured. Peaches, Nectarines, and Figs are very scarce, and some of the trees fruitless.

The drought has not been so severely felt here as in many places; consequently vegetables are very plentiful, and late Peas, runner and dwarf Beans and Marrows have grown to an unusual extent and are cropping very freely. Potatoes on well-manured and deeply-worked land are heavy crops and of excellent quality, but on shallow soils the dry weather has checked the growth and the yield will not be a heavy one. Field crops are mostly free from disease, and are now showing signs of ripening off very rapidly.—JAMES DAY.

Tynninghame, East Lothian.—Apricots are a very light crop; Plums average. Some kinds of Apples and of Pears are good; others very thin. Peaches have never been worse with curl, while the crop of fruit is not a heavy one; Figs about an average. All kinds of fruit trees with the exception of Peaches have vigorous, healthy foliage, and the fruit large for the time of year and promising to be finely coloured. Of small fruits all are a good crop, but in some gardens there are no Gooseberries, and Strawberries are also somewhat erratic as to cropping.

Vegetables are looking well and growing luxuriantly. Cauliflowers are the one exception, and these are poor.—R. P. BROTHERSTON.

The Hersel, Coldstream.—There was an abundant blossom, but this was succeeded by a spell of dull, cold, wet weather, and again by a long drought; hence the disappointing results.

Vegetables, though somewhat later than in normal seasons, have been good so far. Peas have been abundant. Potatoes look well, not having been injured by frost, as they often are here.—JOHN CAIRNS.

Judging at the Crystal Palace show.—The judging was very erratic in many cases at the great fruit show, but perhaps the worst instance was that in the class for Beurré Diel Pear. The excellent dish shown by Mr. Wythes should have been first without a doubt, and the winner of the first place would, I should say, be one of the first

to acknowledge its superiority. I do not know who the judges were. I am simply stating my opinion of their methods. The Syon House fruit was equally or very nearly as large, much cleaner, and, I consider, far better in every way than that on the winning dish.—H. R.

STOVE AND GREENHOUSE.

BOUVDIAS.

THESE are among the most serviceable plants we have either for cut bloom or as pot plants for the conservatory. By growing on successive batches of plants, or stopping them at different times, they may be had in flower from now onwards well through the winter. With the exception of *B. Humboldtii*, which does not flower well when stopped late, the more they are stopped the better the results will be, and those required for late blooming should be selected from those that were propagated early in the year, and if they have been left to make fairly long growths, or even if they have begun to show flowers, may be stopped back now and allowed to make a new start. They do not require much heat, but should have all the light possible, and although air should be given, a cold draught or dry atmosphere should be avoided. The syringe may be used freely until they begin to open their flowers. It is most essential to keep the plants free from insects. A very small brown thrips is often very troublesome, and if once it gets established there is little hope of getting good blooms. Frequent fumigation is the only remedy. If plants are clean and healthy to start with, clear soot water used for syringing will go a great way towards keeping all insect life off; it is also beneficial as a liquid manure, especially when used with cow manure. The period of flowering may be considerably prolonged by the judicious use of manures, but whatever manure is used, it should not be over-done, and when liquid is used it should always be allowed to stand until it has settled down, so that it can be used in a clear state.

I have often heard complaints that *Bouvardia* bloom does not last well after it is cut, and in the summer-time no doubt this is the case, but after the weather gets cooler it will last very well if the plants are grown in a cool house. I believe it not infrequently occurs that the bloom is not cut until it is nearly exhausted. If cut when the first two or three blooms on each truss are open and put into water at once, I have found it will last fully a week. Although all the *Bouvardias* are worth growing, I should particularly recommend the following as the best for winter: *Vreelandii*, white; *President Cleveland*, scarlet; *Mrs. R. Green*, flesh-pink; *Priony Beauty*, a rather deeper shade of pink; *Alfred Neuner*, double white; and *President Garfield*, double pink. As a pot plant *Candidissima* may be recommended, but it does not keep up a succession of bloom like *Vreelandii*.
A. HEMSLEY.

Abutilons planted out.—Many gardeners grow a good batch of *Abutilons* in pots from cuttings every year, and most serviceable they are, but they are not utilised as often as they might be for clothing pillars and hiding unsightly walls in conservatories. If plants with one or more leading stems are trained up walls, they will, if cut back annually, break into dense heads and hang gracefully down, forming objects of considerable beauty and proving useful for cutting. They need a loamy compost of average richness, well drained and porous, and will stand frequent and liberal applications of liquid manure while making their growth.—J. C.

Euphorbias planted out.—On page 218 "C." speaks of planting out *Euphorbia jacquiniæflora* in preference to growing it in pots, and I should like to supplement his remarks on the subject. Some years ago I planted this *Euphorbia* in a narrow bed, training the shoots up wires, and by

no other method have I been able to produce finer racemes of flowers. Space, however, for this kind of thing is often at a premium, and where such is the case the next best plan is to plunge the pots in the soil of a disused Melon or Cucumber bed and train the shoots up the wires. Necessity caused me to try this plan in the first place, and it gave great satisfaction. As soon as the Cucumbers were done they were removed from the wires, and the soil in the bed, instead of being taken out, was broken up and loosened. In this the *Euphorbia* pots were plunged, and before long the roots found their way through the holes at the bottom of the pots. The soil kept the plants moist at the root, and a brilliant display of bloom was the result.—H. H.

Begonia carminata.—This is a very distinct and useful variety for autumn and winter flowering, the pendulous clusters of bright coral-red bloom being shown off well by the bright green foliage, which is of good substance. It is said to be the result of a cross between *B. coccinea* and *B. Dregei*, the latter being the seed parent, but it certainly partakes more of the character and habit of *coccinea*. Before the advent of the tuberous varieties *coccinea* was a general favourite, and I have seen it grown on into quite large specimens. One great fault, however, was that the bloom dropped as soon as exposed to a change of temperature. This also applies to the male flowers of *carminata*, but the female flowers hold on well. A peculiar feature is the large seed vessels with broad wings, the whole being of the same bright coral-red. Here we have a change from the popular *Gloire de Lorraine*, female flowers being rarely seen, while in *carminata* it is almost as rare to see many male flowers open, as they invariably drop off before they are properly expanded.—H.

Freesias.—So far the bulbs I have seen are not so good as those of last year, being smaller and not so heavy. The largest bulbs are not always best, of course, but they should be heavy according to their size, or they will fail to produce fine flowers. As soon as they are received they should be potted in light, fairly rich compost and go into a plant protector or a sheltered position outside and be covered with cocoa-nut fibre or ashes. A thin layer only is necessary, as if too much is put on there is a danger that the young growths will draw and fall about when taken out. If examined regularly there is no fear of this, of course, and in this case the additional thickness serves to keep the soil in the pots more regularly moist without watering from the surface, which is a mistake. Quite cool treatment from first to last suits *Freesias* best. In a warm house the foliage draws and often gets covered with insects, while the flower-spikes are never so stout and strong. A strand of raffia may be passed round four neat stakes placed in the pots for the purpose, this keeping the plants together and giving them a smarter appearance. When in flower their delightful fragrance makes them favourites for cutting and for house decoration.—H.

Fittonias.—Easily grown and bearing very handsome foliage, *Fittonias* ought to be far more thought of. There are so many ways in which they are useful and ornamental, that one would naturally expect to see them in every collection of plants; but this is far from being the case; indeed, they are not nearly so much grown as formerly. Distinct species are few, but there are many varieties of the two or three species that are grown, and all these may be easily propagated by cuttings placed over a brisk bottom-heat at any time of year. Where there are large pots or tubs in which Palms, Tree Ferns or anything of this class is grown, a few cuttings of *Fittonia* and *Panicum* dibbled in give a pretty surface and hide the bare pot. Fine specimens may be made up by striking a number of young plants in $2\frac{1}{2}$ inch pots and filling pans with these, using the largest and strongest in the centre. Give water rather sparingly until they are rooting again, when increase the supply. Plants slightly pot-bound colour better than do others that have more root-room, and the necessary feeding may be

done by means of chemical or other manures from the surface. *Fittonia gigantea* and *F. Verschaffeltii* are the best known species, each having several varieties.

Begonia Mrs. Leopold de Rothschild.—Pot plants, particularly if free-flowering and of a useful size, are just now among the most valued of subjects, whether for home decoration or for market. It is in this light, therefore, that the above will prove welcome, for it is not merely the embodiment of much that is useful and beautiful, it is also an attractive plant. The new-comer appears to have originated with Mr. Jas. Hudson at Gunnersbury House, having sported apparently from the well-known *B. Gloire de Lorraine*, which kind in some respects it much resembles. Indeed, in habit or rather in leafage it is the counterpart of this latter, while in general aspect it is a closer growing plant, and therefore would appear denser in its flowering. In short, as a pot plant it is a perfect model, the neat little bushes crowded with flowers from base to summit. Nor is this all, since the clear pink shade of the flowers gives it a final touch that cannot fail to carry weight, and therefore render it one of the most popular of all these plants. In its own way it is one of the finest novelties that has appeared this year, which is saying a good deal, and it is a novelty come to stay, which cannot be said of all novelties. Possessed of the same constitution and growth, it will be able to be increased in quantity and rapidly, so that there will be no interval of years before the plant is within the reach of all.—E. J.

New Heliotropes.—During the present year three new varieties of *Heliotropes* were presented in good form to the floral committee of the Royal Horticultural Society for certificate. The plants were in small pots, in good flower, and well grown, and came from the gardens at Gunnersbury House, where, after some three years' trial, Mr. Hudson considered them superior to existing kinds for the purpose indicated. Ultimately it was desired that plants of each be sent to Chiswick for trial. Under the circumstances, however, and seeing the lengthy, not to say absolutely impartial, trial given the plants by Mr. Hudson himself, whose only motive in the matter was to test the merit or otherwise of these against older sorts as bedding plants, Mr. Hudson decided not to send the plants to Chiswick as suggested. Having seen these kinds during the present week in the Gunnersbury House gardens, we can support Mr. Hudson in his view as to their superior qualities, and as good free-flowering and decidedly profuse blooming kinds, both in pots and in the open air, they deserve to be very widely known. Their names are: *Picciola*, an exceptionally good dark, and probably the finest of the set; *Mme. Fillay*, pale lilac, large-headed truss, and very vigorous, and *Chameleon*, light blue. Beds of each of these have been for a long time a feature at Gunnersbury House, and the varieties are destined to have a popularity there at least.

Ceropegia Woodii.—Last year I noted the beauty of this when grown in a suspended basket at Kew, and now after further experience I regard it as one of the best of little-known basket plants. Most of the *Ceropegias* are climbers, but this is in a natural state of a procumbent habit of growth, the thin wiry stems travelling for some distance along the ground and rooting from many of the joints. Small, globose, tuber-like masses are also produced at intervals along the stems, even when the plant is in a hanging position. As a basket plant the very slender dark-coloured shoots will droop directly downwards for 3 feet or 4 feet, and are clothed with small, orbicular-shaped leaves of a thick fleshy nature. These leaves are from one-half to three-quarters of an inch in diameter. Their colouring is of a very uncommon stamp, for while the surface is green, it is generally so much marbled with silvery white on the upper side as to be almost entirely of that hue. In this respect, however, a great variety exists even on the leaves of a single plant. The underside of the leaf is tinged with red. Compared with the showy blossoms of some *Jeropegias*, the flowers of this

are small, but they are produced so freely and extend over such a long time that they certainly merit notice. The entire flower is little, if at all, over 1 inch long, the tubular portion being pink and the upper part brownish purple. Cuttings striko root readily if put in at any season of the year. Besides its value as a basket plant, this *Ceropegia* may with advantage be employed for other purposes. For rockwork under glass, particularly if it is kept at a stove or intermediate house temperature, the long slender shoots with their greyish leaves have, when creeping here and there, a very pretty effect, while they will also clothe a portion of a Tree Fern stem if kept moist. Lastly if the plant is secured to a stick 2 feet high and the side shoots are all allowed to assume their natural drooping character, it is decidedly attractive.—H. P.

ORCHIDS.

WATERING ORCHIDS.

By now many of the pseudo-bulbous section of Orchids will have finished their bulbs, and others of various kinds will have reached the end of their growing season. The weather, too, will be cooler and the nights longer, so that a general reduction in the water supply both in the atmosphere and at the roots may be made. The plants in the various houses differ, however, considerably in their wants in this respect, and a knowledge of varieties and observation of individual specimens are necessary to success. A plant, for instance, growing in a pot a size too small for it will need watering at the roots more frequently than one properly suited. The easiest of Orchids to manage in this respect are, of course, such things as *Thunias* and deciduous *Dendrobiums*, which, having finished growing and lost their foliage, may be kept absolutely dry for several weeks. Any later plants not quite finished will need a little until the leaves have dropped, but nothing like regular moistening is needed even here.

Many *Cattleyas* have finished growing, and those which flower upon the new growth, such as *C. Gaskelliana*, *C. gigas*, and *C. aurea*, will have done blooming. These all need much drier treatment now, not sufficiently so to cause shrivelling, but less water than they have been taking during the growing season. With these, more than with most Orchids, it is necessary to watch individual plants, as some will have unfinished growths that require a little sustenance if the older bulbs are not to be weakened. Autumn-flowering kinds, as *C. labiata*, late-growing plants of *Lælia purpurata*, *L. elegans*, and *L. grandis tenebrosa*, again all need encouragement more or less, as well as any plants of the *C. gigas* and *C. Dowiana* section that may have started to grow out of season. Among the distichous-leaved kinds, the *Angræcums* and *Phalenopsis* require more water than *Saccolabiums*, *Aerides*, and most of the *Vandas*, but here again there are individual kinds liking special treatment. The almost deciduous *Phalenopsis Lowi*, for instance, takes wonderfully little moisture later on, though it is as yet too early to dry the roots, while the large winter-flowering *Angræcum eburneum* requires a full supply all the year round, according to circumstances of weather and position. But from now onward far less water in all houses devoted to Orchids will be necessary.

Cypripedium Sedeni.—There are few easier grown Orchids than this and none more free-flowering, the plant being in bloom for months together, and where a number are grown even longer. The flower-spikes occasionally produce young growths that may be taken off and rooted,

these soon making plants. *C. Sedeni* is a strong grower, doing well in an intermediate temperature and a fairly shady house. The roots are very strong and persistent, so a substantial compost must be provided and an ample water supply given all the year round.

Cypripedium amandum.—This is one of the oldest, but still a very useful and pretty hybrid, a cross between *C. insigne* and *C. venustum*. The influence of the former is perhaps the most apparent in habit and the colour of the blossoms, but that of *C. venustum* may also be seen in the dark markings on the leaves and the venation on the lip. It will be noticed that *C. amandum* in a young state has more of the black marking on the foliage than when the plants get older. The intermediate, or even the cool house suits it, for it is as easy to grow as the old *C. insigne*.

Oncidium Harrisoniæ.—This pretty little *Oncidium* has always been a favourite with me, its slender spikes of pretty yellow blossoms and the singular grey-green of the foliage giving it a very distinct appearance either in or out of bloom. It only grows a few inches high, and the flowers are easily distinguished from those of any other kind by the rather large crest. It thrives well in an intermediate house and should not be too heavily watered at any season, especially during dull periods in winter. Small pans or pots are most suitable, and the usual mixture of peat and Moss for compost.

Oncidium undulatum.—This is one of the finest of the *Oncidiums* with scendent-flowered scapes, and very pretty when in bloom, especially when arranged with suitable greenery. The plant itself is very vigorous, finishing up immense pseudo-bulbs when the spikes are not allowed to remain on too long, and rooting freely and vigorously through a more than ordinarily rough, open compost. The peat should be good, and plenty of rough lumps of charcoal may be mixed with it. When the roots, as they sometimes do, push over the surface of the compost, cover them with a little Moss if there are slugs or other insects about. The plants may be kept in the cool house the whole year round, and should never be dried at the roots.

Barkeria elegans.—It is strange to note how some plants vary in the way they take to altered conditions. Many cultivators have failed utterly with the *Barkerias* as a whole, and, notwithstanding all the trouble they take with them, get puny, weak growths and poor flower-spikes. It is usually understood that the plants like very little in the way of compost and a cool temperature, but I recently saw some very fine plants of the species named above growing in a *Cattleya* house with quite as much compost in their pots as one would use for a strong-growing *Epidendrum*. Yet the plants were pictures of health and strength, each stem having a fine flower-spike forming, and such a state is, I think, worth noting. *B. elegans* is certainly one of the prettiest of the *Barkerias* and worthy of general cultivation.—H.

Trichocentrum albo-purpureum.—Though not appealing to lovers of large showy blossoms, this pretty species is sufficiently attractive to be worth a place in any collection, however choice. The flowers have a white and purple lip, with tawny brown sepals and petals. Like many another dwarf growing Orchid, it has obtained a bad name as a garden plant simply by being wrongly treated. It will not thrive in a large pot and compost suitable for a strong-growing *Oncidium*, but given a small pan or a lightly dressed block of Tree Fern stem it will usually be satisfactory. For temperature a cool intermediate house is best, and the plants should be suspended in a good light. Water should be sparingly provided all the year round, a moist atmosphere suiting it best while growing. *T. albo-purpureum* is a native of the Rio Negro district in Brazil, and is one of the best in the genus. It first flowered in this country in 1866.

Saccolabium giganteum.—The flower-spikes of this plant are already beginning to

show, and it is important that the plants be kept well up to the light in order to properly harden the leaves. The latter will then be less likely to fall prematurely should the winter prove very cold and wet. Its habit of flowering in mid-winter is greatly against *S. giganteum* remaining in a healthy condition under cultivation, for at the time when the plant is least able to it is called upon to bear this strain. The stronger and riper the plants can now be made, then the better the flowers will be and the less likely are they to suffer from this and kindred ailments. *S. giganteum* thrives best in a strong moist heat with ample sunlight, and while liking less water at the roots when growth is quiet, must not be too much dried. A dry winter atmosphere must be avoided, except in so far as is necessary to conserve the flowers.

Oncidium pubes.—Flowers of a good form of this *Oncidium* come from a midland correspondent. It is a good deal like *O. sarcodes* in growth, so like as to be often mistaken for that species. Both are natives of the Organ Mountains in Brazil, and though *O. pubes* is inferior to *O. sarcodes* in size of flower, it is equally bright and telling and as free-blooming. The spikes on strong plants attain to a height of nearly 2 feet, are much-branched and many-flowered, the individual blossoms yellow with pretty red-brown markings. It is said in some works on gardening that *O. pubes* bears but a single leaf on the pseudo-bulb, but well-grown plants have more often two. It is very distinct in every other way from *O. sarcodes*, and though often imported together from the Organ Mountains, the difference is readily apparent when the plants flower. *O. pubes* does well in rather small pans or baskets suspended from the roof of an intermediate house, where the growth gets well consolidated by the light and air. In a very hot, moist house it grows freely enough, but does not flower regularly. Equal parts of peat and *Sphagnum* Moss suit it well. It is a widely-distributed plant naturally, and was introduced from Rio de Janeiro in 1824 by the Horticultural Society.

GARDEN FLORA.

PLATE 1243.

ANEMONE BLANDA AND VARIETIES.

(WITH A COLOURED PLATE OF A. B. CYPRIANA.*)

ANEMONE BLANDA, the blue winter Grecian Windflower that appears with the *Crocus*, *Primrose*, and other such things, is among the most justly prized of the early hardy flowering plants. It matters not whether the flowers are of the fine blue of the typical kind with its rather long and stellate ray florets giving it so much of its grace and elegance, or of the varying tints that merge from this into the nearly white kinds. It is such things as these that produce—or, in truth, create—verdant carpets where no such verdant carpets appeared before, presently to be embellished in their beautiful shades of colour that fill almost everyone with delight.

The plant represented in the coloured plate is but one of them, though it is but fair to admit a decided and well-marked form of the plant that is now so well known in gardens. It will be noticed that the petals of the variety *Cypriana* are shorter and more rounded, resembling more closely the Apennine Windflower, while fewer, if longer, petals are more usually identified with *A. blanda* itself. These minor differences, however, are of the least possible value to gardeners, and better serve to interest the botanical student than anyone else. Viewed from the standpoint of a garden

* Drawn for THE GARDEN by H. G. Moon in the gardens at Belvoir Castle, Grantham. Lithographed and printed by J. L. Goffart.

ANILIN DE FLANDA (Y. POLA) 18

plant, *Anemone blanda* in any form is excellent, inasmuch as the plant is mostly at home in the ordinary soils that occur, and produces a wealth of blossoms in the earliest spring such as is not equalled by any other garden plant at the time. The plant that can and will do so much and give so much of its beauty to adorn the earth not only merits all praise, it deserves the widest possible culture. Beyond doubt there is a growing desire for such good and distinct flowering subjects for the open garden—subjects, moreover, that are as happy in good clay as they are in the lighter and less holding soils. Of the plant now figured when shown in the early part of the present season before the floral committee of the Royal Horticultural Society every member appeared in favour. The example thus honoured came from the historic Belvoir Castle gardens, where for possibly some thirty years the beautiful *Anemone blanda* has been grown. Indeed, the plant was a special feature for years with the late Mr. Wm. Ingram, and the way it was increased and extended by means of seeds afforded a solid, if unadmitted, lesson in gardening to many who saw the fine display of its flowers in the Belvoir gardens in early spring. That Mr. Ingram's successor has embraced the same view may be gathered from the beautiful subject in the plate to-day. This when shown at the Drill Hall was a mass of pure white on the inner surface of the petals, while externally they were gleaming with a shade between violet-blue and porcelain. The combination of blue and white thus imparted invested the plant with an almost indescribable charm. A little breeze will quickly reveal to the onlooker what is here briefly described, but the beauty of the scene will not quickly be lost to view. Happily, the Greek Windflower is not fastidious, and those who have in the past been delighted with it as one of the gems of early hardy-flowering plants will not be long in adding this variety. As to the

CULTURE

of this section of the Windflower family there is but little to add. A good free open soil will grow them well. In strong loam I have grown the finest examples, some patches occurring in woodland places where the staple soil was strong clay doing splendidly. It is but right here to add, however, that the twiggy roots of tree and shrub afforded a welcome kind of environment for such things in winter, so much so that all idea of a waterlogged condition of the soil was never thought of. In open spots in the shrubbery there is a delightful home for this plant, and in any other of the places named, so long as a good free-rooting medium is at hand, the culture of these things gives little trouble. The places where they refuse to thrive or to grow at all are in the minority, and the fault usually a local one, and generally that of very poor or badly drained soil. The best method—i.e., the quickest and most valuable by reason of the variety afforded—of increasing these plants is obviously by seeds, which are usually borne abundantly. The seeds are best sown in the open in shallow drills or broadcast, though for reasons of weeding and the like the drills are best. The soil of the seed-bed should have been previously well prepared, as the seedlings must at least remain for eighteen months before being transplanted or even ready for this. The season of transplanting can always be measured by the progress of the seedlings themselves, and, provided the seedling bed is in good ground and room is at hand, no loss will be sustained by allowing the young plants to remain another year. Assuming that

the seeds are sown after the flowering this year, the first blooms would appear in the year 1901, yet by no means is it likely all the seedlings will be of flowering size in the time stated. Still, much may be done to accomplish this by hoeing, watering, and other small attentions in the same direction, none of which can possibly be lost on so good a plant. A good way would be, if a large sowing has been made, to lift the plants with the first signs of decaying foliage and select those of flowering size, i.e., those having flowered the first time. All such may be given permanent places in the garden, while the remainder may be replanted for a later period. In all its forms it is so good a plant as to be worthy of every care, and those who grow it well are usually well repaid for their labour. E. J.

THE WEEK'S WORK.

OUTDOOR FRUITS.

THE ORCHARD.—As a rule the orchard connected with a private garden is greatly neglected, the trees being allowed to grow almost at will and the fruit produced is small and spotted, only the best of it being of any service either in the kitchen or as dessert. It requires some amount of courage and entails much labour to bring such trees into something like form and induce them to bear fruit of good quality, and the gardener who intends to do this should commence operations as soon as the fruit is gathered and push on with the work whenever the opportunity offers, first of all tackling the thickest and most unpromising trees. The thinning of such trees, or rather the marking of branches which would be better taken off, must not be left to the ordinary garden labourer, who has generally the most hazy notions of what is required, and would prefer to cut off all the bottom branches and leave those on the top of the tree, because he may have noticed that the latter have borne the best of the fruit, and also, possibly, because it is easier to cut away from below. To thin a tree judiciously requires judgment, for in some cases a branch may have to be removed entirely right away from the main stem, and in others it is only necessary to remove some of the strongest side growths made from the main branches. Again, only a practised hand can mark a big and neglected tree at sight, and it will be found much the better way to be on the spot most of the time while the actual branch-thinning is going on, as one can then see the result of taking away each branch as it comes and act on such result when dealing with the next branch. After having gone through the tree in this way until it appears to be thin enough as to its frame, each branch left should be gone over, removing entirely some of the gnarled old fruiting spurs and reducing others. The entire removal of some will cause a fresh break of spur-growth from the branch, and these in the course of two or three years will take the place of the older ones which were only shortened at first, but which can then be cut out in their turn without sacrificing a crop. In treating old trees in this way, many of them will become rejuvenated and will go on for many years longer, producing finer fruits than they have ever borne since they began, imperceptibly at first, to thicken up and to shut out light and air from a goodly portion of their crops.

AMERICAN BLIGHT.—The season appears to have suited this pest, for I have seen more this year than I ever saw before, and this in many parts of the country, all districts being alike infested. There can be no doubt that this is the result of neglect in a sense, or rather in a want of persistence in application of remedies, for there are many insecticides, among them some home-made ones that I have recommended in my calendar notes, that will kill any of this blight that they touch, and yet we see the woolly flecks all over the trees.

Nurserymen are greatly to blame in spreading the blight, for many of them send out young trees apparently clean in their winter garb, but which show in the growing season that they are badly infested. Surely this is a suicidal practice, which will bring its own reward in the end, and one is sorry to find that the practice is not confined to the small nurseries, but obtains among some of those with a big reputation, who ought to avoid selling such stock, as the work of cleaning is not nearly so troublesome with young stock as it is with older trees. There is some excuse for a little neglect in a private garden where, perhaps, help is limited and many other things have to be attended to, but in the nurseries to which we look to replenish our stock the neglect is reprehensible.

PEACHES.—In some soils and situations Peach trees have a tendency to make gross growth, and if this tendency is not counteracted in some way the trees never crop freely and generally become blistered. Before adopting any other means of reducing this grossness I would suggest lifting the trees and providing for them a mixture similar to that recommended for Peaches under glass. If the case is not a bad one, it will be sufficient to take out a trench at a suitable distance round the tree, gradually working up the latter until the ball left is not a large one. This is necessary so that one can find and sever any roots that may have struck downwards, as such roots as these are the greatest possible sinners in producing soft, gross, and unfruitful wood. Fortunately, Peach trees are not much given to the production of these vertical roots; still, they do so occasionally, and where there is a suspicion that this is the case they should be searched for. Some of the roots exposed in opening out the trees may also be shortened back and then covered in with the new soil, which should be firmly rammed in.

BUSH FRUITS.—Proceed with the planting of all kinds of bush fruits whenever the ground is in a fit condition for being trodden upon, but do not continue the work in wet weather if the soil is inclined to be heavy, as it then must be returned to the roots in a pasty condition and becomes impenetrable to the finer root fibres. Watering in after planting is finished is quite another thing, as the whole body is then rendered of one consistency, and the rootlets find no difficulty in penetrating the soil provided it has not been trodden upon after watering. When planting Gooseberries and Red or White Currants examine the stems and remove all adventitious buds that would be likely to form sucker growths below the soil line, as these growths are more or less robbers, and in any case they are not necessary. With Black Currants, on the other hand, such sucker growths or buds may well be left on, as the shoots they produce are likely to be very fruitful ones, the Black Currant liking always a plentiful supply of young wood, room for which should be made by cutting away much of the older growth. In choosing positions for the various bush trees, it should not be forgotten that both the Gooseberry and the Black Currant like a cool soil, and if one position is inclined to be wetter than another, it should be devoted to the Black Currant. The espalier form of training suits the Gooseberry and the Red Currant well, and very useful dividing lines to the various plots may, with the aid of a few strained wires, be formed with them.

FILBERTS.—Any of the bushes which have become at all too thick should be thinned out now, allowing plenty of room between the main leads. The spurring in of shoots may be left till winter or spring if it is inconvenient to carry it out now, and some growers leave all pruning until after the catkins have shed their pollen with a view to having as much pollen as possible for fertilising. One thing ought, however, to be done as soon as possible, and that is the removal of the sucker growths which nut bushes so persistently form, as these rob the nuts and cause them to be small and poor. When clearing off suckers remove also coarse grasses round the bole, and mulch heavily with good rotten manure. CORNUBIAN.

KITCHEN GARDEN.

GLOBE ARTICHOKE.—When giving instructions about sowing this vegetable in spring I suggested that the seedlings should be put out on some spare piece of ground and proved previous to making up the permanent rows, as so many out of a batch generally are worthless or very inferior. Those worth retaining may now be planted in good deeply-worked ground—that is, where the latter is fairly warm and well drained. On heavy, retentive soils it will be wisest to defer planting till spring, giving the plants a liberal mulch of short littery material in November. Those whose stock needs renewing and who are able to secure a sufficient number of fairly stout side offsets should now sever them from the parent stools and pot them up into, say, 6-inch pots, giving them the shelter of a cool pit or frame, and plunging the pots in coal ashes or old leaf-mould. A rough covering can then be thrown over them should very severe weather occur. These will become established by March, and if then planted out will give finer, though, of course, later, heads than old weakly stools. In some few gardens mulching old plants in winter has been abandoned, gardeners having an idea that it does more harm than good, but the fact is it is the rotten manurial mulch which does harm in snowy or wet, rainy winters, as severe frost coming when the material is in a soddened state destroys the crowns. If due care, however, is exercised and the right kind of loose litter or even dry Bracken packed round each shoot, this in the event of a snowy or wet November and December being removed and a fresh lot placed round, no damage need be apprehended. Where Artichokes are valued as late in the season as procurable, those whose plants have thrown up autumn heads may ensure their safety from injury by driving in a few rough stakes and protecting at night with old mats or canvas. Where plants are at all weakly liquid manure may still be given, but on stiff soils no more moisture than that which falls from the clouds should reach the roots.

CAULIFLOWERS.—It is now time—at least in gardens situated in midland and northern localities—that the first batch of such Cauliflowers as Early London, Erfurt, and Walcheren were placed in the handlights. Where these are still used a great advantage is gained, as no root-disturbance, and consequent check to growth, occurs through lifting in spring, and protection from frost is as easily effected as when the plants occupy frames or pits. Presuming the ground was well trodden and the lights placed in position, as advised a short time ago, the soil should now be in a nice firm condition for receiving the plants. Where the seedlings were pricked out into nursery beds they may now be carefully lifted with a trowel, and should feel the effects of removal but little. If rain has not fallen recently, give the soil a nice moistening with a fine rose two days previous to planting, and choose a calm, dull day for the operation. Avoid the too common practice of lifting and laying out too many plants at a time; rather repeat the journey and lay out say as many as will fill a dozen hand-lights, otherwise the delicate fibrous roots are apt to suffer. If the lights are full-sized, I like to place five plants in each light, one at each corner and one in the centre. This is a good number, as they can then be reduced to three in spring, and allowance is thereby made for destruction by grub or bolting. Plant firmly and sufficiently deep to prevent the plants swaying to and fro by late autumn winds, as these ruin many a lot of plants in exposed gardens. Planting completed, give a gentle watering to settle the soil round the roots, and if the weather is open and nights warm, leave the tops of the lights off for the present. Should, however, frost or very rough weather set in, they will be better left on, arranging them crossways so as to admit a little air. If the plants have to be drawn from the seed beds, avoid the largest, choosing rather the medium-sized ones with perfect centres. The next thing requiring attention is the protection of a sufficient number of plants in pits or frames for transplant-

ing for successional supplies in June. Where later sowings are not coming on take care to select the smallest plants for this purpose. The smaller the better, provided they have perfect centres and are free from the disease known as blacklegs. The shelter of the frame front frequently induces Cauliflowers, Cabbages, and Lettuces to become too large by March or April, especially should the winter be mild and open. Both amongst hand-light stock and plants in frames a sharp look out will be needed for the troublesome underground grubs which cut the plants asunder just beneath the surface. Should the weather set in wet and slugs make their appearance, dust fortnightly with a mixture of lime and wood ashes or not too fresh soot. I have also used a mixture of wood ashes and flowers of sulphur for dusting between plants in pits and frames during trying winters and springs, having proved it to be an effectual absorbent and saving the plants from wholesale decay. But no measures of this kind will avail unless coupled therewith is careful and systematic ventilating. I cannot too strongly advocate the system of taking every care of surplus plants either from main or secondary sowings, pricking these out rather closely together in sheltered nooks and corners where protection can be given in severe weather. Of course, there is a certain amount of risk attending this, but the labour of pricking out is small, and often after mild or medium winters such often do better than those which have been taken care of in the orthodox fashion. When beds have failed from any cause and other sowings have had to be resorted to, I have sometimes, in consequence of the seedlings being late and weak, covered them with a spare light resting on four flower-pots. This makes a vast difference to them in cold, stormy weather.

J. C.

FERNES.

SPECIMEN FERNS.

It is now rarely one sees the immense overgrown specimens which were met with at one time at most exhibitions, and though in a way interesting, I think fresh, healthy, younger specimens are far more useful and certainly more elegant. There are exceptions, of course. Some of the Tree Ferns, for instance, may be grown on for ages and retain a symmetrical and noble appearance, but with the exception of those which form an erect stem, young plants make finer fronds and are not so dense and irregular in outline. Most Ferns are pretty in quite a small state, but there are some which cannot develop to their full beauty unless grown on freely until they attain to fair-sized specimens. The following are a few which are well worthy of a place in any collection, and when well treated make fine specimens. Of the numerous varieties of *Adiantums* which may be grown on until they attain to large specimens,

ADIANTUM TETRAPHYLLUM ACUMINATUM may be commended. When confined to a 5-inch pot this makes a well-furnished plant about a foot high, but potted on in a good porous compost and grown on in the stove it makes a much taller plant. The young fronds have a peculiar soft mauve tint, changing with age to a rich deep green. From Central America.

A. CARDIOCHLENUM also makes a tall and elegant specimen. The fronds are of a soft pale green, and, when much exposed, almost straw colour, with a pretty tint in the young fronds. Although the above is the most popular name, *A. polyphyllum* is adopted in Hooker's "Species Filicum." From Peru. Both of the above should be grown in the stove, and succeed best when well exposed to the light.

A. TRAPEZIFORME is well known, but may be mentioned, as it will make a larger specimen than any of the genus. This also comes from Tropical

America, but does fairly well in an intermediate temperature. All of the above have spreading rhizomes, and when propagated by division an extra strong single crown will make a much finer specimen than where a number of weak crowns are grown together. They may be grown in large pans or pots, but when the latter are used a good depth of drainage should be given. Of those with smaller pinnules,

A. ETHIOPICUM ALATUM is the tallest, attaining from 3 feet to 4 feet in height. It will succeed well in an intermediate temperature or may be grown in the stove, and if given plenty of pot room it grows rapidly.

A. WILLIAMSII may also be included. This does well in a greenhouse temperature.

DAVALLIA EPIPHYLLA is a native of Java and the Malayan peninsula. It is a distinct and beautiful species. The thick rhizomes spread freely and have a tendency to grow upwards. The large drooping fronds are finely cut and of a thick leathery texture. It may be recommended as one of the finest of the genus, especially for growing on into large specimens. Although usually classed with the stove Ferns, it does well in an intermediate temperature, and the fronds being of great substance it should prove most useful for decoration. In potting, the plants should be kept well up in the centre and plenty of drainage used. As it requires a good deal of surface room, pans are preferable to pots, particularly for the larger specimens.

D. SOLIDA is another fine species from the same locality. The rhizomes run out longer and keep on the surface. The fertile fronds somewhat resemble those of the above, but the barren ones have broad pinnules of a deep green with a bright surface. Grown in a suspended basket the rhizomes will run down a great length. This and *D. ornata* are sometimes confused; the latter is only a variety, but sufficiently distinct to retain the name. I have not seen this produce such finely cut fertile fronds.

MICROLEPIA PLATYPHYLLA.—Though now included with the *Davallias*, this is very distinct in habit of growth and general appearance. It has soft, fleshy underground rhizomes. The fronds grow nearly erect and are of a pale glaucous green with broad-lobed pinnules. The spore cases are not quite marginal, as in the true *Davallias*. When grown on freely it makes a fine specimen, the fronds attaining to fully 4 feet in height. It succeeds well in a loamy compost with good drainage. It may be increased by division, but seedlings make much better and more compact plants. Even as a small plant in a 6-inch pot it is very pretty, but the fronds in young plants are too soft to be of much service for cutting.

MICROLEPIA HIRTA CRISTATA.—Although this may be recommended for growing on into large specimens, it is apt to get too coarse when treated liberally, but when grown in loam and confined to moderate-sized pots the fronds are of a beautiful soft pale green. It is inclined to get dense, and it is only when grown on from a single crown that it makes the beautiful arching, tasselled fronds. I do not remember to have seen fertile fronds of this, but have not paid particular attention to this point. Being so readily increased by division, it is hardly worth troubling to raise seedlings.

DIDYMOCHLENA TRUNCATULA.—Though not a very serviceable Fern for decoration this makes a very handsome plant. Potted in a rich porous compost and grown in the stove it makes rapid growth, and the large spreading fronds have a bronzy tint when young, changing with age to a bright olive-green. In older specimens the fronds will attain to from 4 feet to 6 feet in length. It is, perhaps, seen at its best in a young state before it has lost the earlier fronds which clothe the base. Spores germinate freely, and in quite a small state it is very pretty. It is of easy culture, except that with a change of temperature or when allowed to get too dry at the roots the pinnules fall off. The above is the name usually given, but *lunulata* is perhaps more correct. It

is a native of Tropical America, and is also found in Madagascar, the Fiji and Malayan Islands.

CIBOTIUM SCHIEDEL.—This makes one of the most effective specimens. The long, gracefully arching fronds, which are finely cut, are of a soft pale green above and of a peculiar glaucous hue beneath. The crown and lower portion of the frond-stalks are densely clothed with long hairs of a pale brown with a silvery shading. It is only from spores that this can be obtained, and I have rarely seen a large batch of seedlings. It appears that it is only when spores are collected from plants in their native habitats that they can be depended upon to germinate. Once seedlings are established they make rapid progress, but it is not until the plants have attained to a good size that they are very attractive. It is a native of Mexico and Guatemala, and is now included with the genus *Dicksonia*. Although it forms a trunk, it must be very slow in doing so, for plants I have known for years, though the crowns are very conspicuous, do not rise much above the ground.

LITOBROCHIA VESPERTILIONIS.—Some time ago I saw a nice batch of this useful Fern at Messrs. Hill and Son's nursery, Lower Edmonton. It may be grown on into large specimens, and the peculiar soft green with the pale under surface makes it a desirable variety for contrast with those of deeper shades. Although from the tropical regions, it succeeds well in an intermediate temperature. As the rhizomes spread and require more surface room than depth, larger specimens should be grown in pans. This Fern is given as synonymous with *L. incisa*, but this, which I had from Kew a few years ago, is very distinct from the variety grown by Messrs. Hill and Son, and of which I have dried specimens collected nearly thirty years ago. This Fern may be propagated by division, yet seedlings are preferable, as they make more compact and better furnished plants. A. H.

Dicksonia antarctica.—Though one of the oldest and best known of the Tree Ferns, it is surprising how little attention is given to this species. In the majority of cases the plants are simply left alone to grow a little every year and die back about as much, so instead of a handsome well-feathered head there is a whorl of leaves fresh and green, another in some stage or other of decay. The plan of establishing small bits of other Ferns on the stems of this class is very apt to be overdone, and many plants have been killed by this means. A few bits of *Davallia* or some similar creeping Fern may do no harm if not allowed to run too far and choke the small roots of the *Dicksonia*, which are numerous on the stem, but to clothe the latter entirely is a great mistake. The roots of *Dicksonia antarctica* must of necessity be kept in pots of more or less limited size, unless, of course, it is planted permanently in a winter garden or conservatory. This being so, feeding is absolutely necessary, soot-water used in connection with one of the better class of artificial fertilizers being a capital medium for the purpose.

Adiantum elegans.—In many respects this plant resembles the well-known *A. cuneatum*, but it is hardier and much freer in growth, yet standing equally well when cut. It will not, of course, come absolutely true from spores, but a number of the young plants will usually be all right, and not long since I saw a batch raised in which very few of the seedlings showed any deviation from the type. A very short life is before many of the thousands of young Ferns that are annually sent out from our market nurseries, but this should stand as well as any of them, and, of course, the fault lies not with the Ferns, but with the treatment to which they are subjected. As a matter of fact, most of them are seedlings, and these make far better plants than divided old specimens if not allowed to get pot-bound before being repotted. Small shifts are best for them, and if it is desired to push them as fast as possible, *A. elegans* may be given a much richer compost than is usually thought necessary

for Maiden-hair Ferns. Nitrate of soda and soot are capital stimulants for Ferns and Palms, putting colour into the leaves and making them very vigorous.—H.

FERN SPORES.

REPLYING to "A. D.'s" inquiry (p. 247) in reference to my remarks on collecting Fern spores (p. 186), it would, perhaps, have been as well to have given my reason for recommending that spores should be collected from plants which have been isolated as far as possible from others which produce spores freely. I had no idea that anyone would suppose that this advice was to avoid cross-fertilisation, especially one who might be expected to be better informed on these matters. It is quite evident that "A. D." has not had much experience in the raising of Ferns, otherwise he would know of the dangers of taking spores of those slow to germinate from plants which have come into contact with what may be termed Fern weeds. With the greatest care it is well known to those who have had any experience that some weeds will occur, and it not infrequently happens that some of the choicer sorts are completely choked by these Fern weeds. I have previously given the names of some of the most troublesome, but may mention those which have given me most trouble. They are: *Nephrodium molle*, *Polypodium trichodes* (syn., *P. tenericaule*), also known as *Phegopteris trichodes*, *Gymnogramma Pearcei*, and *G. chrysophylla*. Now, if the above varieties with matured fronds are in the same house from which spores of *Asplenium*, *Platynerium*, *Cheilanthes*, or others with woolly fronds are gathered, it will be a great chance if anything but the above weeds are obtained. I could give further instances, but the above will be sufficient to illustrate what was meant by recommending that spores should be collected from plants which have been isolated from those which spore freely.

Now with regard to cross-fertilisation, "A. D." writes: "Certainly we have myriads of beautiful Ferns in commerce the products of cross-fertilisation." "A. D.," like many others, would like to know how this cross-fertilisation is accomplished. I must confess to being unable to throw much light on the matter. I very much doubt if there is any certainty about the numerous varieties we have being the result of cross-fertilisation, but would rather regard most of them as the result of natural variations of the same species.

Of the numerous varieties which have originated under my personal observation, all have been the result of chance seedlings. Many of our tasselled and crested varieties have been much improved by careful selection, and some have originated from a chance sport in one frond. *Nephrolepis pluma Bausei*, for instance, came from a few pinnæ taken from *N. pluma*, and other instances might be given where a small portion of a single frond has given a distinct variety. I am aware that it is recorded that certain well-defined varieties are the results of crosses between distinct species, yet during the thirty years that I have been intimately associated with Ferns and their culture, though I have made many experiments, I have never been able to be positive as to the results of sowing mixed spores or how to account for what appear to be Fern hybrids. Although it may be an open question, I very much doubt if anyone has been able to effect positive cross-fertilisation in Ferns.—A. HEMSLEY.

—The sentence in Mr. Hemsley's article on sowing Fern spores (p. 186) that "A. D." (p. 247) seeks to be enlightened on is quite plain to any

one who has had practical experience of raising Ferns from spores, as in many instances, at least, if the spores are taken from a plant standing in a mixed collection, in all probability some of its neighbours will have already ripened their spores, and from their minute size and lightness they are often distributed around for some distance. Thus a frond gathered from a plant standing in the midst of different kinds will frequently have the spores of many varieties deposited upon it, and in this way, if the spores are sown, a mixed crop often results therefrom. Some of the *Gymnogrammas* and several forms of *Pteris* are very apt to make their appearance in many pots, whatever may have been sown therein. Another caution to be observed to which Mr. Hemsley also directs notice is, when sowing spores to keep the pots as much isolated as possible. A good way of doing this is, if the prepared pots are at one end of the propagating house to carry out the actual sowing at the other end, fetching just the required number each time. If these cautions are observed and care is taken to wipe the hands after each sowing, the risk of mixture will be considerably minimised.—H. P.

FLOWER GARDEN.

GUNNERA SCABRA.

WHILE most people believe that this striking plant, as also the still larger *G. manicata*, should always be planted near to a pond or streamlet, where the roots indeed may actually be in touch with the moisture, it may be well to state that the preference of the species is not absolute in this respect. I do not say that the plant will attain to the same dimensions away from the water as it will when in touch with it, but it will make an exceedingly fine plant in a soil quite light and sandy, and one, moreover, heavily drained, with sand and gravel below. The finest single example I have ever seen thus treated was growing in the late Mr. Robert Parker's nursery at Tooting many years ago, where, quite removed and quite unaided by any permanent root-moisture, the plant attained to quite huge proportions in an open, sunny position in the nursery. The example must have had a spread of leaves of about 18 feet across, while the foot-stalk of the more erect leaf-blades would be perhaps between 5 feet and 6 feet. Of the size of the leaf-blades I have no information, though, judging by the size of the petioles and the spread of the plant, these would be of good size also. I am fully aware that much finer examples have been grown with moisture, and particularly of *G. manicata*. The point, however, that I have in view in penning this note is that any plant that will attain 12 feet across in a dry position such as that described is worthy of being more frequently tried in similar places, for in fine-foliaged plants at least we have nothing that will compare with these noble *Gunneras*. Because of the frequency of the statement that these *Gunneras* must have water, many who have it not refrain from attempting to grow them. At the same time, this constant root moisture is not always accompanied with success, and I have known instances where the plants quite refused to grow. In two of these, however, the soil beneath them has been a strong clay, quite adhesive and almost impervious to moisture. This, of course, may have been opposed to the well-being of the plants, and stagnation following, the result would be failure, and that quickly. Perhaps one of the items that tended to the success of the Tooting plant was the manner in which the majority of things took root in the fine sandy loam of which the nursery was largely composed. That being so, it only required a liberal dressing of manure to ensure a free growth, and with the plant established in such a soil, success was but a question of time. It would be interesting, moreover, to know the success attending the planting of the above *Gunnera* in moist places in England, and of others in drier places, if such exist. Of two plants that some years ago were in my own

charge, one was growing in the rock garden in full moisture, the other in a shady dell, with little moisture, where a heavy clay soil abounded. But neither the one nor the other made anything like the progress of the Tooting plant, and one at least was in what is usually regarded as an ideal spot for such things. I have more than once seen other plants that would form parallel instances; indeed, two such have occurred to me this year.

That such a fine plant is worth some care to make it a success all will agree, and I think that really handsome examples may be grown in light loamy soil with plenty of leaf-mould and some well-decomposed manure in quite open beds, as at Tooting. Planted in spring when frost had gone and well tended in the first year, so that the roots may get possession of the soil, the rest would only be a question of time and age. Of the age of the Tooting plant I have no information, but I believe I am correct in saying that it was never watered, even in hot, dry summers. Of this much I am certain, as the plant for some time was under my charge, and its size gradually increased each year. In some parts of Ireland the giant of all, *G. manicata*, appears to flourish grandly with moisture, assisted also by a naturally favoured climate. But I doubt if the equal of some of these famous examples could be met with even in similar positions in England. Is it, after all, not so much a question of water or moisture for a plant whose natural inclination is admittedly that way as it is of a more or less congenial climate, which cannot fail to be an influence for good in such a case? The instances of noble examples of this plant in England are rare; therefore one is constrained to look beyond the question of water in the production of fine examples in other and more favoured districts.

E. H. JENKINS.

National Dahlia Society—second exhibition.—On p. 269 of *THE GARDEN* Mr. A. Dean writes: "The poor array of new ones (*i.e.*, seedlings) and the few certificates granted lead to the inference that the primary object of the show resulted in failure, and it may well be questioned whether it is worth repeating." A few figures will suffice to prove the contrary, that as to its primary object—the awarding of certificates to new varieties that were not in fit condition on September 1—the show of September 19 was quite successful. There were staged for the consideration of the committee seventy-two seedlings, of which thirty-two were Cactus, twenty-one singles, fourteen show or fancy and five pompons. First-class certificates were awarded to four Cactus, two single, two show or fancy varieties and one pompon. Is not a total of seventy-two seedlings and nine certificates sufficient at such an exhibition?—J. F. HUDSON, *Hon. Sec.*

Victoria Asters.—I have never had these fine showy annuals so good as they are this season, and as I have also noted them especially good in almost every garden I have visited this year, I think we may take it that the seeds sent from the Continent last autumn were better than usual. Those who are in the habit of sowing their own seed know that if only the outer florets ripen the seed properly, those of the German or Quilled Aster are never so good as when the

whole flower ripens off, and those who wish to keep a strain true should sow early and finish the flowers in pots in the greenhouse. No plant pays for good culture so well as these Asters, and a good large flowering strain shows up better in beds and borders than small semi-double ones. A soil of medium texture enriched with well-decayed manure and well tilled is the best for them. The seed should be sown in March, and as soon as ready the seedlings should be pricked out 3 inches apart both ways into a frame or shallow boxes. Plant out finally at the end of May in large clumps of one colour, say eight or nine plants. This looks far better in the herbaceous or any other border than when they are planted in straight lines.—H.

POMPON DAHLIAS AT CHISWICK.

At the present time there is an extensive collection of pompon and Cactus Dahlias in the gardens of the Royal Horticultural Society at Chiswick.

kinds are decidedly good. Secondly, most of the colours can be found in varieties of first-rate quality, both as regards habit of growth and free-flowering, and the blooms are of good form and of small, or at any rate medium size. The day has gone past when any great improvement can be looked for in pompons. Changes will now be slow and gradual. Growers should go in for the small-flowered kinds and throw away freely from their collections all those with large or coarse blooms. If this were done everywhere, surely no words would be required to recommend or defend the pompons. The small pompons are essentially pretty, easy to grow, and useful either for the garden or as cut flowers. For cutting, their double character gives them lasting properties superior to the single or Cactus kinds.

The following varieties are well worth attention, and are arranged here in about the same order as we come across them at Chiswick: Nancy, good dwarf garden habit, is of a telling colour that many ladies would like—orange and

Mushrooms in an old wine cellar at Gunnersbury House. (See p. 275.)

The pompons are flowering freely, so that from an examination of the varieties to be found there it is easy to make a selection of what would probably be the best dozen or the best two dozen to grow if a small collection of them is desired. On the whole it can be said that the varieties sent from different nurseries are coming true to their character as we know them elsewhere, and seeing so many growing together it is easy to make comparisons. Most of the varieties that are in general cultivation, or that deserve to be generally cultivated, can be seen, those only excepted that have only just been sent out, and are therefore as yet too new to be considered as having passed beyond the trial stage.

Looking at the collection as a whole, two things are impressed upon us with respect to the pompons. Firstly, leaving out blue, which we do not expect in Dahlias, it is not easy to imagine a desirable colour which is not already represented, nor any combination of colours, for the fancy

red; Captain Boyton, one of the best dark kinds, colour maroon, shaded crimson, good form. Tommy Keith is very dwarf, flowers uniformly good, colour dark red, tipped white, fine variety both for exhibition and the garden; Ruy Blas is very distinct, crimson and purple, tipped white, weak centre, opens much too rapidly; Zoe, good in habit, is a well-formed fancy flower, very delicate combination of white and pale yellow, petals white, edged with yellow. Cecil, red, tipped with white, is a small, neat flower; Mars, one of the best scarlets, has medium-sized flowers, with good centre; Douglas, perhaps the best dark variety, is of splendid shape, dark maroon, shaded crimson; Phoebe is one of the best both for the garden and for exhibition, colour deep orange. Whisper, of very dwarf habit, has clear yellow flowers, edged with reddish bronze, excellent for all purposes; Arthur West, a dark crimson, is apt to come too large; Bacchus shares with Mars the distinction of being the best scarlet (it is of splen-

did form, but rather large); White Aster and George Brinckmann are the best white varieties (a new white with small, neat flowers is needed). Grace forms a dwarf bush covered with blooms, colour cerise; Nerissa is one of the very best yet raised, flowers small and of a novel soft rose colour; Fashion, an old variety, but one of the most effective colours in the garden, has intense orange blooms; E. Hopper is probably the best yellow, the flowers of perfect shape. Red Indian, deep rich red, is of fine shape (a very attractive flower); Florence Woodland, yellow, tipped bright red, is of good form, but a little large; Jessica, small, neat flower, good form, is amber, edged with red. Lilian is primrose, edged with peach, growth very sturdy; Ganymede, amber and fawn, shaded with pale lilac, is of excellent habit, shape of flower almost perfect; Orpheus is one of the best yellows.

For a collection of a dozen varieties, the following should be selected, on account of their small and perfect flowers: Ganymede, Jessica, Red Indian, Emily Hopper or Orpheus, Nerissa, Whisper, Phebe, Douglas or Captain Boyton, Cecil, Zoe, Tommy Keith, and White Aster.

J. F. H.

FLOWER GARDEN NOTES.

HARDY PLANT BORDERS.—It has been rather a curious experience this year on borders devoted to hardy plants, and writing at this date (September 19) one is able to give results throughout the year, and a hint as to work the outcome of that experience that will be necessary at no distant date. The past year has been notable for its prolonged drought. The earlier flowers, of which Pyrethrums, Dornicums, and Polyanthuses may be cited as examples, were good, but short-lived. If opportunity had offered to give them liberal supplies of water it would have been different, but this was not possible, and so the display was brilliant, but decidedly ephemeral. The borders were well done last autumn and a heavy dressing of cow manure worked in, a system of culture that in connection with a light soil would have given capital results. Unfortunately, however, the rainfall in the autumn of 1898 and the winter of 1898-99 was much below the average; it did not penetrate far enough to saturate the cow manure, except in those cases where this was worked in at a distance to benefit surface-rooting plants. Lower than this the manure turns up at the present time just about as it was placed into the trenches. Certainly it has helped all plants a little, but nothing like it would have done had the rainfall been up to the average. Of the dwarfier plants, possibly the Antirrhinums, Linarias, and Campanulas have given the best results, the display having been very good and well sustained. To these, however, must be added Gaillardias, that gave a splendid lot of bloom early in summer, and are now again well in flower with the aid of a surface mulching and a thorough soaking of water. Other things that will often throw a second lot of bloom, given similar treatment, have failed to do so this summer. The varieties of Coreopsis are capital dry summer plants, and have done remarkably well. A regrettable failure has to be recorded in the case of herbaceous Lobelias, and it is the more unfortunate because their brilliant foliage and handsome flowers are almost unique in hardy plants, and render them so acceptable for mixing with other things. They were late in breaking and nothing like so strong as one likes to see them. Growth was slow and poor, much of it gradually dwindling away, and not one plant out of ten was ever at its best. In the case of most of the things named where growth has not been satisfactory and that are not at present in a thoroughly healthy state, I shall make a clean sweep of them, preferring to start another season with healthy young plants obtained by seed, cuttings or division, and, so far as the two latter modes of propagation are concerned, the cuttings or offsets will certainly not be taken from miffy old plants. The two most reliable tall autumnal flowers—Starworts and Sunflowers—

have done remarkably well. They are flowering splendidly, apparently quite indifferent to drought, and plenty of bloom will be forthcoming until frost comes of sufficient severity to make an end of them. I have Sunflowers in many varieties, both double and single; the best single forms are most in request for cutting, although doubles, like multiflorus plenus and Soleil d'Or, are very fine for this purpose. Occasional clumps of very tall-growing sorts, as latifolius, remain in the borders, but I shall clear them out: they are more suitable for the wild garden. Writing of Sunflowers reminds me to suggest the advisability of more simple names. To the ordinary observer they are all Sunflowers, and when inquiries are made as to the particular name of a favourite, it would be well if one were able to give it as simply as possible. For instance, a lady was asking the other day the name of a certain variety. "I know it is a Sunflower or Helianthus," was the remark, "but should like its name." I was obliged to say that it was classed as a Helonium, and that the full name was *H. grandicephalum striatum*. Why all this for a simple hardy flower? There is an idea that, so far as Starworts and Sunflowers are concerned—and, indeed, many other hardy flowers—once planted they may be left for an indefinite time and will do well for a number of years. This may be so on some soils, but not here. Two seasons, or at the most three, are quite enough for them. I should say they are at their best the second season, and that after this they begin to deteriorate.

In the matter of autumn flowers do we make quite as much use of hardy Fuchsias as their merits deserve? I am led to the suggestion by a border just now about at its best mainly devoted to Fuchsias and Starworts. It is about 9 feet wide, with a wall and a big Wistaria as a background. The clumps of Fuchsias were planted some towards the back and others about 3 feet from the edge, blocks of Starworts being filled in afterwards in different heights to complete the arrangement. It has a very telling effect just at present, the contrast being clear and well defined, and yet soft and pleasing. Besides the pleasing display, it is a border from which cut bloom in great abundance can be obtained for tall vases.

Claremont.

E. BURRELL.

NOTES FROM A SWISS NURSERY.

THINKING that a visit to M. Froebel's nursery would well repay me the additional journey necessary to reach Zurich from the central parts of the Alps, I managed to include it in my homeward journey. M. Froebel is keenly interested in all matters horticultural, and almost everything in his nursery bears unmistakably the mark of quality—the best varieties everywhere. The first thing one sees on entering the gate is a fairly large tank filled with some of the best varieties of M. Latour-Marliac's hybrid Water Lilies flowering freely and growing vigorously. I have not seen them doing so well in a nursery before. They are planted here for effect, but are also found to be most useful for cutting, finding a ready sale. There was a really fine display of cut blooms of the red varieties to be seen in the window of M. Froebel's shop in the main street of Zurich—the Bahnhofstrasse. English florists might well follow this example and use Water Lilies more. The new varieties are free-flowering, and the colours, white, pale yellow, pink, and red, can be mixed very well with one another. The different kinds flourishing in the tank are now well known and have often been described in THE GARDEN, so they need not be referred to in much detail now. *N. Laydekeri rosea* was very fine, and *N. fulva* appeared to produce flowers in accordance with the description of it in the lists of Latour-Marliac—ground colour yellow, flushed with rose or pink, a combination which I cannot admire as seen on the petals of *N. fulva*. As the blooms of this variety do not seem to come true in this country, one wonders whether the difference can be accounted for by climatic influences. In one corner of the tank was to be seen a plant

of *N. Froebeli*, the only hardy red variety that has been raised in Europe outside of the establishment of Temple-sur-Lot. The flowers were of medium size and dark carmine in colour. The petals are narrower than in several of the French varieties, more numerous and more refined in shape; in point of colour there is not much difference. The flowers resemble those of the odorata section rather than the Marliacea section of M. Latour-Marliac's varieties. It is a seedling from the Norwegian Water Lily, *N. alba var. rosea*. There being no pond here, the tub system of growing and propagating the Nymphaeas is adopted and is quite successful. *N. stellata* and its varieties are to be seen growing in tubs in the open air without any protection or warm water being provided, and they have been cultivated in this way at Zurich for years past. A large number of *N. s. sanzibarensis* seedlings were in flower planted out in an ordinary brick-built pit that had been rendered water-tight and filled up with the necessary soil. If it be considered desirable to shelter them a little, all that is required is to replace the light in its usual position. Nelumbiums have been grown in this way, but M. Froebel has not succeeded in flowering them out of doors. *Eichornia* (*Pontederia*) *crassipes* and *Eichornia corulea* were in flower in the tank before mentioned. Both varieties require protection in the winter, but are well worth the attention then required when they can be induced to flower like this in the open air. The former bears large spikes of pale blue flowers, conical in shape, each bloom more than 1 inch in depth and breadth. The shade of colour is peculiarly attractive—much more so than that of most blue flowers. The plant itself, floating freely as it does on the surface of the water without taking any hold of the soil, is of unusual interest to those who see it for the first time. The latter variety, commonly called the Water Hyacinth, possesses similar spikes, but of a much darker and less fascinating colour. *Pontederia cordata* was also in flower and is quite hardy. It will grow in any English pond, but is very insignificant when compared with the tender varieties. That pretty yellow-flowered aquatic, *Limncharis Humboldti*, was blossoming in the same tank with considerably greater freedom than it does in this country. I also noticed *Trapa natans* and *Trapa verbonensis*, two water plants that deserve more attention than they have hitherto received. These particular varieties are hardy, and their handsome foliage and great distinctness at once engage the attention. The leaves, produced in pretty rosette-like clusters, are of a brownish chestnut hue, marbled like the leaves of some of the hybrid Water Lilies. Small hard berries or nuts are produced; hence *T. natans* is called the Jesuit's Nut, or Water Chestnut. It is found distributed over Southern Europe and parts of Asia and Africa. *T. verbonensis* is a variety that is found in Lago Maggiore, in North Italy.

One of the most striking novelties that I saw was a double pink *Rosa rugosa* called Conrad Ferdinand Meyer. The blooms are large, quite double, and well formed, not unlike those of La France. This is a great addition to the rugosa class of Roses. Another new Rose that promises well is called *Eglanteria remontant*; it is a variety of the Austrian Brier, but the petals are coloured with pink on the yellow ground of *R. lutea*. Its value is increased by the fact that it flowers twice in the year. I should call it *R. lutea bicolor*. Johanna Sebus is a new Hybrid Tea Rose that is highly thought of here. The stock which is used is *Rosa laxa* (Siberia), which appears to be quite free from the fault of producing suckers. Amongst the

HARDY HERBACEOUS PLANTS

I noted a particularly fine and healthy-looking stock of *Rudbeckia purpurea* and *Gentiana asclepiadea*, a very useful dark blue variety. Other autumn-flowering hardy plants with blue flowers are *Amasonia angustifolia* and *Veronica noveboracensis*, coming at a time when blue is welcome. *Lilium Henryi* was making a grand display; the individual heads of flowers would form

an addition to any garden. A fine lot of bulbs of the rare double white Autumn Crocus (*Colchicum autumnale album plenum*) was being planted out and would make a fine display soon. The Hellebores were making vigorous growth, and *Incarvillea Delavayi* had been in flower. Mention should be made of *Arenaria Rosani*, a variety which forms very dense dark green clusters, and is most useful for covering up dry places or for a rock garden.

Some old Pomegranates in tubs were just coming into flower, and gave promise of making a fine display. When about to flower water is very freely given, and they are fed as well. There is a large stock of well-grown young standard trees, with heads about 18 inches through, in the open ground. The shrubby stove plant, *Medinilla Curtisi*, introduced about fifteen years ago, is strongly recommended by M. Froebel as preferable to *M. magnifica*. It is almost always in flower and is dwarf in growth. I noted, too, that rarely-seen but handsome winter-flowering plant, *Euphorbia jacquiniiflora* (syn., *E. fulgens*).

There is not much space left to devote to the Orchids, though there is an interesting collection. *Vanda cœrulea* is well represented both in quantity and quality. The plants are strong and healthy, growing in a sunny position, where they get plenty of air. Beside them *V. Kimballiana* flourishes. This variety, M. Froebel thinks, is usually grown in too much heat. I also saw some good plants of *Vanda Sanderiana*, some being in flower, and one a very fine variety. The Mexican Orchids, *Lælia anceps*, *L. superbiana*, *L. furfuracea*, &c., seemed to thoroughly enjoy the treatment given to them. They were growing with much shade and plenty of air, and could be left entirely in the open air, if desired, during the night by taking off the lights and shading. The result is great freedom in flowering. I noticed *Epidendrum radicans* growing practically in the open air along with *Clianthus Dampieri*. For cool Orchids the summer is the most difficult time at Zurich. It is not easy to keep them cool enough. *Oncidium ornithorrhynchum* was good, also the *Masdevallias*. *Miltonia vexillaria* is allowed an abundant supply of air, and *M. Phalaenopsis* was true to its character of being always in flower. *M. v. Lehmanni* is a fine variety, pinker than the type, and quite distinct. *Zygopetalum celeste* and *Z. Lehmanni* must be mentioned as two Orchids that are well grown by M. Froebel. VISITOR.

Agapanthus umbellatus in the open.—Blue-flowering plants are so few in the garden in the early autumn that this plant, which each year blooms with unerring regularity, is always welcome. And what is true of the ordinary form is equally so of the larger flowered varieties, one of the best of these being *A. n. maximus*. There are other forms, however, known as *major* and *giganteus*. The variety *giganteus* has flowering stems each fully 3½ feet high, often more when the plants are given good treatment and not merely watered occasionally. The great heads of blossom often contain something approaching 200 buds. Too often, however, the plant receives but the merest support for its great mass of fleshy roots and huge tuft of leaves. Being somewhat tender, the plants have to be housed during winter or protected from frost. This is no reason for confining all the stock in large pots or tubs, the former of which are sure to burst by the very pressure from the roots of the plant. A portion of the stock should be planted out in deep soil each year, and in a suitable spot a fine effect would be secured. The white form, which is more deciduous, is also more hardy, and with good covering may be left out during the winter. This is certainly a gain to the outside garden, though, all things considered, the blue-flowered kind is, perhaps, the finer garden plant for general purposes.

LILIUM NEILGHERRENSE.

I HAVE found on my return home that the Lily which has done so exceptionally well in my garden this summer is not *L. Wallichianum superbum*, as I imagined it to be, but *L. neilgherrense*, which is more remarkable still, as it is generally supposed to require greenhouse culture, and is, indeed, given in this way in the interesting catalogue which has been lately issued by Messrs. Wallace, of Colchester. Of course, the Isle of Wight has great advantages to offer, but I cannot help thinking that some of these Burmese Lilies have special qualifications of their own which are not sufficiently recognised—e.g., Mr. Wallace

neilgherrense still at their best and still giving a delightful reminder of the summer that is so fast slipping away from us? I cut some of these blossoms and sent them to London a day or two ago. The last Lily of summer is as valuable in its way as the last Rose of summer, and where you can meet with a Lily towards the end of September it is a much more uncommon event than if twenty Roses had put in an appearance.

I feel sure that if the season had been of an average description this year and more rain had fallen, my Burmese Lilies would have been better even than they are. I wondered when I came back to my garden the other day and saw the arid

Water Lilies at Gunnersbury House. (See p. 275.)

asserts with regard to *L. Wallichianum superbum* that it "takes front rank," and he gives as his reason for saying so that "it is easily cultivated, hardy, and very prolific." What more could be said about a Lily than that? It would be difficult to say as much of *L. auratum*, and as for a handsome appearance, these Lilies from Burmah will hold their own against the productions of Japan, North America, or elsewhere. Owing to absence from home during the greater part of the year I have missed the flowering season of some of the best of my Lilies; but what could be more satisfactory towards quite the end of September than to find the extremely beautiful blossoms of *L.*

waste which it looked to be that any plant or bulb could exist in it at all. H. EWANK.

St. John's, Ryde.

NOTES AND QUESTIONS.—FLOWER.

Tufted Pansy Mrs. A. H. Beadles.—This new Pansy has been flowering well during the present season. During the great heat when there was an absence of rain the plants blossomed profusely, and at the present time the display they are making is very pleasing indeed. The flowers are large and somewhat circular, pure white, and faintly rayed.

The growth is dwarf and vigorous and the constitution robust.—C. A. H.

Gentiana asclepiadea deserves to be much more generally grown in gardens as a late summer and autumn herbaceous plant. It will grow in almost any position or soil, though moisture suits it best, as may be seen at the present time by a visit to the Kew rock garden, where this variety is displaying itself to great advantage and in considerable quantity. In height it varies between 1 foot and 2 feet according to its position. Its continuous blooming renders it valuable, the flowers succeeding one another in pairs up the stem over a considerable period. It is a good variety to plant in shrubby borders or to naturalise in wild gardens, or even in woods in large quantities. There is a white variety as well as the blue one.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY'S FRUIT SHOW.

CRYSTAL PALACE, SEPTEMBER 28, 29, 30.

THERE was again a really grand display of fruit of British growth, variable in quality as compared with previous exhibitions in some instances, it is true. In Grapes there was a perceptible falling off in several classes, notably in the smaller collections of varieties and in the Muscat class. Some growers have had their Grapes, so to speak, rushed on owing to the hot weather; hence in many cases, no doubt, they were past their best. The one Grape above others to hold its own was Mrs. Pince's Black Muscat. Another class well filled was that for Alicante, whilst in the any other white class Dr. Hogg was staged in first-class condition. The quality of the fruit in the mixed competitive classes for collections was quite equal to other shows. In the class for nine varieties there was but little difference between first, second, and third. The competition was not so keen in the large class for outdoor fruits as last year, it being practically useless to think of competing with success against the more favoured of the Kentish growers. Where there were five exhibits last year there were only two this time. The competition was not any too keen in the divisional classes, *i.e.*, those for various parts of the country. These, above all others, ought to be filled, affording as they do some data to form more correct opinions as regards the several districts. The market classes were well represented, showing a decided improvement upon last year both in quality of fruit and in the methods of packing for market. This section of the schedule is an excellent one, and deserves well of fruit growers for market supplies. The nurserymen's classes, *i.e.*, those who grow trees, &c., for sale, were also well filled, occupying, as they did, a large amount of table space. With the exception of the grand Pears from Jersey, the Pears in these classes were not up to the average, but the Apples were fully so. Various methods were adopted for displaying the fruit, and a very fine display was made, reflecting great credit upon the trade who supported the show. The classes open to private growers only from all parts of the country brought together some of the finest produce in the show. Both the Apples and the Pears in these classes from Kent and the most favoured of other counties were grand examples of culture; finer fruits of the best-known kinds than those exhibited could scarcely be desired. Outdoor Peaches, Nectarines and Plums were scarcely so numerous as last year, but here again the quality was of the best, far better in some respects than many would have expected after the very trying weather and drought. Orchard-house fruits were very fine indeed from the well-known sources. Apples, Pears and Plums as trees in pots were fine examples of culture, and so were the picked fruits. Growers of orchard-house fruit should keep strictly to dessert kinds. There cannot be any possible good in growing a few of the largest of cooking Apples in pots just for a show and nothing more. Peasgood's Nonsuch Apple, it should be noted, when so grown becomes a des-

sert fruit; not so many others, as *Gloria Mundi*, &c. The show on the past occasion was rather confined in space, owing no doubt to the exhibition of crafts in the other transept; this, however, was quite unavoidable, and in no way reflected upon the executive of the Royal Horticultural Society.

The schedule as at present drawn up requires some modification in the Apple classes. For instance, small, highly coloured fruits of *Blenheim Orange* and *Gascoigne's Scarlet* are asked for; thus small-sized fruit ruled in these classes, but in some others the opposite was the case. These Apples should, in our opinion, have two classes provided for each variety, so that large fruits could be staged in the one if not in the other.

DIVISION I.—FRUITS GROWN UNDER GLASS OR OTHERWISE.

For a collection of nine dishes of ripe dessert fruit, *Lady Henry Somerset*, *Eastnor Castle*, *Ledbury* (gardener, Mr. Mullins), was placed first in a close competition. The Muscats here were a strong dish, the colour and finish excellent; *Gros Maroc*, the other Grape, had size and colour to recommend it; *Albert Victor Nectarines* were extra fine, but *Lord Palmerston Peaches* were a weaker dish; *Pitmaston Duchesse Pears* made an imposing dish, being also well ripened; *Barrington Peaches* were extra fine, so also were the *Ribston Pippin Apples*; a well-coloured *Melon* finished up this exhibit. *Sir Joseph Pease*, *Hutton Hall*, *Guishorough* (gardener, Mr. McIndoe) was well up for the second place. The Grapes here were not so good, but the *Queen Pine* made up for that deficiency; other first-class dishes were *Sea Eagle Peaches*, extra good; *Souvenir du Congrès Pears*, a strong dish; *Prince of Wales Peaches*, large and highly coloured; these, with *Bryanston Gage* and *Reine Claude de Bavay Plums*, made up a capital exhibit. *The Earl of Harrington*, *Elvaston Castle*, *Derby* (gardener, Mr. Goodacre), was placed third; the Grapes here were first-class, having quality in both dishes (Muscats and Mrs. Pince's Black). Other excellent dishes were *Brown Turkey Figs* and *Coe's Golden Drop Plums*. For a collection of six dishes of ripe fruit, *Colonel Walpole*, *Heckfield Place*, *Winchfield* (gardener, Mr. Maxim), showed well and deservedly won the first place. Muscats here had the deep amber tint so desirable, *Coopey's Black* (alias *Gros Maroc*) being the other choice; these also were fine. *Nectarine Peaches* were extra fine also; *Lady Sudeley Apples* were also attractive. *Mr. Biddulph*, *Ledbury* (gardener, Mr. Dawes), was placed second, his best exhibit being extra fine *Gros Maroc Grapes*, probably the best shown, with excellent Muscats, *Ribston Pippin Apples*, and *Williams' Bon Chrétien Pears*.

In the large class for the best six varieties of Grapes, where the first prize embraces a silver challenge cup of the value of twenty-five guineas, with the stipulation that it is to be won three years in succession (a stupid and unreasonable condition), *Mr. Goodacre* was a comparatively easy first. The varieties were *Gros Maroc*, well finished, but this is no difficulty even for an amateur to accomplish; *Alnwick Seedling*, also in fine condition; Muscats, extra fine, with large berries; huge bunches of *Barbarossa*, well coloured; Mrs. Pince's Black, extra fine in berry and bunch, with Alicante to complete the number. *Mr. Bayer*, *Tewkesbury Lodge*, *Forest Hill* (gardener, Mr. Taylor) showed up bravely for second place, and were all the conditions equal he would have pressed his antagonist hard. The best dishes here were *Gros Colman*, well finished; Mrs. Pince, which lacked colour, bunches, however, fine; Alicante, a strong lot; Muscats, excellent; and *Madresfield Court*, extra good in colour and fine in berry, with *Gros Maroc* to complete the exhibit. Only one exhibitor appears to have entered for the three varieties, but as regards finish it was all the same a very strong lot in every respect. The varieties were Muscat, long, tapering bunches, highly coloured, *Gros Maroc*, and Alicante. These were staged by Mr. Dawes. The single dish classes were, on the whole,

disappointing and do not call for any lengthened comment. Some fine dishes, it is true, were staged, but in these instances the best far outdistanced the others. For *Black Hamburgs*, Mr. Fleming, *Chilworth Manor*, *Romsey* (gardener, Mr. Mitchell), was easily first with well-coloured bunches with medium berries; second, *Sir George Russell*, *Swallowfield Park*, *Reading* (gardener, Mr. Cole). For *Madresfield Court* Mr. Mitchell repeated his success, staging grand bunches quite in the old style, Mr. Taylor coming in second. For Mrs. Pince Mr. Mitchell again won, and that quite easily, with superb examples in every respect, Mr. Taylor again following. *Mr. Goodacre* was the only exhibitor of *Muscat Hamburg*, showing medium bunches. Alicante was a strong class, *Lord Suffield*, *Gunton Park*, *Norwich* (gardener, Mr. Allan), being placed first with perfect bunches. Mr. Cole followed, also staging fine produce. Mr. Mitchell won for *Lady Downe's* again, and once more staged a strong lot, large bunches, highly coloured; Mr. Taylor once more having to be content with second place. Mr. Allan staged *Gros Maroc* in the class for any other black of first-rate finish and fine in berry, being followed by Mrs. Tulk, *Cowley House*, *Chertsey* (gardener, Mr. Sadler), with the same variety. *Muscat of Alexandria* was a case of "first" and the rest nowhere. Mr. Lucas, *Warnham Court*, *Horsham* (gardener, Mr. Duncan) staged very fine bunches, well coloured, and deservedly won. For Mrs. Pearson the judging requires some explanation, the first prize being awarded to the largest bunches, it is true, but these were not well coloured or so fully ripe as is desirable; in fact, it is doubtful if they would thoroughly finish. The first prize went to Mr. Baker, *Ottershaw Park*, *Chertsey* (gardener, Mr. Osman); second, Mrs. Wingfield, *Amphill, Beds* (gardener, Mr. Empson), who had the highest coloured, the largest berried and the best ripened examples. In the class for any other white, that excellent Grape, Dr. Hogg, was shown in the best possible condition, and when so staged it is at this season of the year a rival to the Muscat; these were put up by Mr. Osman; the second prize went to *Foster's Seedling*, from Mr. Cole.

Mr. Maxim was first for Peaches, with grand samples of the *Nectarine Peach* highly coloured, and Mr. Mitchell second with *Sea Eagle* of large size. For *Nectarines*, Mr. F. W. Thomas, *Mannock*, *Polegate*, *Sussex*, was first with *Spenser*, and *Sir M. Samuel*, *Mote Park*, *Maidstone* (gardener, Mr. Bacon), second with *Victoria*. With *Plums* in three varieties, *Mr. Leopold de Rothschild*, *Gunnersbury House*, *Acton* (gardener, Mr. J. Hudson), was first with highly finished fruit, quite characteristic of orchard house culture in pots. The varieties were *Transparent Gage*, *Golden Transparent Gage*, and the rosy coloured sport from *Coe's Golden Drop*. Mr. McIndoe was second, his varieties being *Reine Claude de Bavay*, *Bryanston Gage*, and *Late Transparent*, all fine fruits.

HARDY FRUIT—GARDENERS AND AMATEURS.

For the collection of hardy fruit, thirty-six dishes, Mr. R. Potter, *The Gardens*, *St. Clere*, *Kemsing*, *Sevenoaks*, this year, as last, took the premier award. The council for some reason had this year reduced the number of varieties to thirty-six instead of fifty. We do not see the necessity, as last year there were six excellent collections and only two this. Pears and Apples were the principal dishes, and with so great a number of classes for these fruits we think more variety could be shown. The second place was taken by Mr. T. Dawes, *Biddulph Grange*, *Ledbury*. For twenty-four (dishes of orchard house grown fruit, Grapes excluded, the fruit differed but little from that grown in the open. There was only one competitor, Mr. R. Potter. We fail to see the need of this class when such grand produce from the open as was staged in other parts of the building was to be seen. Far better give a few third prizes in the excellent single dish classes.

DIVISION II.—NURSERYMEN ONLY.

In the following four classes many hundreds of dishes were staged, these occupying the three

centre tables in the building. We certainly think these exhibits could with advantage have been curtailed. The premier position, gaining the gold medal, was obtained by Messrs. G. Bunyard and Co., who staged no less than 300 varieties of fruit, mostly Apples and Pears. It is impossible to enumerate anything like this number or comment upon such a splendid exhibit. The centre was raised with highly-coloured fruits in sections, mostly dessert varieties. Grapes growing on the Vines were arranged with Smilax and Ferns. Also included were Medlars, Black Currants, Bullaces and Plums. The Messrs. Veitch, Ltd., Royal Exotic Nurseries, Chelsea, came next with twenty-five large baskets of Apples and 130 varieties in dishes and 100 varieties of Pears. A nice basket of the new St. Joseph Strawberry with fruit on the plant with the new Gunton Orange Melon were shown, but these fruits were not grown in the open, as stipulated by the schedule. In this lot were some very choice dessert Apples, as American Mother, Bijou, Rouge Précoce, and Cox's Orange. The cooking Apples in many cases were excellent, though lacking the colour of the Kent fruits. A silver-gilt Knightian medal was awarded. Messrs. Laing and Sons, Forest Hill, staged in this class, but they had not adhered strictly to the schedule, and had introduced pot trees and Vines in pots. At the time of making our report no award was given. Mr. H. Berwick, Sidmouth, Devon, was the other exhibitor in this large class, and a really commendable exhibit it was, Ferns, Palms, and Lilies being used freely as decoration for centres and corners. This exhibit well deserved the silver-gilt Banksian medal awarded, as the colour of the fruit was astonishing. The next class brought out seven competitors, each having about 180 feet of space, and several very excellent collections were staged. Mr. J. B. Colwill, The Nurseries, Sidmouth, having splendidly coloured fruit (silver-gilt Banksian). Messrs. Paul and Son, Cheshunt, staged a good collection of Apples and some Pears, the whole well arranged and representing the best varieties (silver Knightian medal). Messrs. Cheal and Sons, Lowfield Nurseries, Crawley, had a beautiful lot of fruit, Apples mostly, including some excellent dessert kinds, and well merited the silver medal awarded. Mr. J. Watkins, Pomona Farm Nurseries, Hereford, staged in this class and well deserved the silver Knightian medal awarded for the collection, which was noteworthy for the fine colour and finish of the fruit. Here were some of the finest Medlars in the building, the variety being the Dutch Monstrous. Messrs. Peed and Son, Roupell Park Nurseries, S.E., staged 100 dishes of Apples of good quality, and were awarded a silver Knightian medal. Messrs. R. Smith and Co., Worcester, staged fewer dishes than the others, but none the less interesting. The Jersey Agricultural and Horticultural Society had a large collection of fruit, mostly Apples and Pears. The centre was formed of dot plants of huge Cabbage stems some 11 feet high, and not at all ornamental in a collection of fruit, as the fading leaves had an untidy appearance. Here were the largest Pears in the show, including Durondeau, Chaumontel, with some excellent dishes of Apples. One, Pride of England, is a nice looking fruit. There was also a collection of Melons grown in the open. This was an interesting exhibit (silver-gilt Knightian medal). Mr. G. Meunt, Canterbury, showed in this class some good fruits, mostly Apples and Pears, with Plums Baskets of well coloured Apples formed the centre of the exhibit, the varieties being well-known cooking kinds (bronze Banksian medal). In Class 23 there were six competitors, who showed some excellent produce. The leading position was gained by Mr. J. Basham, Fair oak Nurseries, Newport, Monmouth. One hundred dishes of distinct varieties were staged, well meriting the silver-gilt Banksian medal awarded. Messrs. Spooner and Sons, Hounslow, also staged 100 dishes of fruit. These lacked the size of the Kent fruit, but, considering how near they are the metropolis, they

were most deserving of the award given—a bronze Knightian medal. Messrs. Pewtress Bros., Tillington, Hereford, staged an excellent collection of Apples and Pears, receiving a silver Banksian medal. Messrs. Brown, Stamford, set up some excellent fruits nicely arranged, having fine Barnack Beauty and some seedling Apples, a good lot of September Beauty, and some good Pears (silver Banksian medal). The Messrs. Rivers, Sawbridgeworth, in addition to their fine collection of fruit in Class 24, staged in this class, and had some very beautiful fruit, well meriting the silver Knightian medal awarded. Mr. W. Taylor, Hampton, had a stand of his new Grape Reine Olga from open-air Vines. The berries were well coloured (bronze Knightian). Mr. R. C. Notcutt, Woodbridge, Ipswich, had a smaller collection of fruit. Good here was the Pear given an award last March, Winter Orange (bronze Knightian medal). For orchard house fruit and trees there were two competitors—the Messrs. Bunyard and Rivers, the former securing the gold medal, having more fruits and in greater variety. The centre of the stand was trees fruiting in pots. The dishes here were a strong feature, especially the Apples. Walburton Admirable, Sea Eagle, and Nectarine Peaches were good. Messrs. Rivers had more pot trees, and received the Hogg medal. Plums in pots were a strong feature.

DIVISION III.—MARKET GROWERS.

For white Grapes, not less than 12 lbs. in a baby basket, there were three entries, Mr. W. Iggulden taking the premier award with good Muscats, Mr. W. Green, Harold Court, Essex, being second. Far greater interest was shown in Class 27, for any variety of Grape in any other package. Here the competitors changed places, Mr. Green being a good first, having a handled basket crossed over with twigs, the variety being Gros Colman. Mr. Iggulden, Frome, was second with the same kind of basket. For cooking Apples, four varieties, 42 lbs. in a basket or box, Messrs. W. Poupart and Son, Twickenham, were first, sieves being employed, each fruit packed in paper; Mr. Basham being second, using boxes and wood-wool. For 20 lbs. dessert Apples, Messrs. Poupart were first with the same kind of packing. Mr. A. Wyatt was second with fruit in boxes. For cooking Apples, any one variety, Mr. G. Tebbutt, Isleworth, was first with good Lady Henniker in sieves, the fruit packed in paper, Mr. A. Wyatt being second. For 20 lbs. of dessert Apples, one variety, Messrs. Poupart were first with Cox's Orange in half sieves, each layer of fruit having paper with wood wool lining the basket, Mr. O. Marchant being second with Worcester Pearmain. For an improved form of packing for market, Mr. Basham was first, the packing wood wool, the fruit in three layers. Mr. Basham was the only exhibitor of 42 lbs. of Apples to show an improved system of packing. This was similar to the last class, hampers or flats being used. Messrs. Poupart were first for Pears: Mr. Wyatt second, with no packing between the fruits. For one variety of Pears Mr. Wyatt was first with fruit in boxes packed in wood wool. For twelve varieties of Apples and six of Pears, each to be laid on the table without dishes or baskets—and this certainly does not need repeating, as side by side with the single dishes the varieties staged bore no comparison—Messrs. Poupart were first. For Plums (cooking), 28 lbs. in boxes or baskets, Messrs. Poupart were first, and Mr. Tebbutt second. For twenty-four Peaches packed in a suitable box, Mr. J. Gore, Polegate, was first with Sea Eagle in long boxes, paper and wood wool being placed round each fruit. For 12 lbs. of Tomatoes packed in a box or basket, Mr. J. Gore was first, using a cross-handled basket, with paper between each layer of fruit.

DIVISION IV.—FRUITS GROWN IN OPEN AIR—(GARDENERS AND AMATEURS ONLY.)

Mr. McKenzie, Linton Park Gardens, Maidstone, won the premier award for twenty-four dishes of sixteen cooking and eight dessert

Apples. We have seen larger fruits in a few cases, but not better in quality. Mr. Parker, Goodwood Gardens, Chichester, was second, he having splendid Grenadier and the best dish of Lady Henniker in the show. In the class for twelve kinds, Mr. A. Maxim, Heckfield Gardens, Winchfield, was first, Mr. G. Mullins, Eastnor Castle Gardens, being second. Only four competed in the class for nine dishes. Much the same varieties were staged, Mr. Dawes being a good first, Mr. W. Jones, Wallington Bridge, Carshalton, being second. Five staged in the class for six dishes of cooking Apples; first, Mr. Hurnard, Gurney's Manor, Norfolk, Mr. R. M. Whiting, Credenhill, Hereford, being second. For three dishes of cooking Apples, Mr. G. Fennell was first, having excellent Castle Major and Lord Derby. There was a great falling off in the class for six dishes dessert Apples, only two lots being staged, Mr. King having a grand lot of Ribston, Allington, and King of the Pippins, with Blenheim, Cox's Orange, and Worcester Pearmain, Mr. H. Cook, Knowle Gardens, Sidmouth, being second. For three dishes of dessert Apples no less than fifteen competed, Mr. G. Sage, the Gardens, Bayham Abbey, Lamberhurst, being first with highly-coloured fruits of Washington, Cox's Orange, and Ribston. For dessert Pears, twelve dishes, Mr. R. Potter was placed first, but afterwards the award was withheld. Mr. A. Bacon, Mote Park Gardens, Maidstone, was second. For six dishes Mr. Sage was first. For three dishes, Mr. R. Edwards, Beechy Lees, Sevenoaks, was first. For cooking Pears, Mr. Humphreys was first with Catillac, Triomphe de Jodoigne, and Uvedale's St. Germain. For a single dish Mr. Potter was first with Bellissime d'hiver. Peaches grown in the open brought forth a good array of fruits. Mr. J. Sparks, Upper Grove House Gardens, Putney, was first with good Sea Eagle, Princess of Wales, and Late Admirable, Mr. S. Osborn, East Sheen Lodge Gardens, being second. For a single dish, Mr. G. Wythes, Syon House Gardens, Brentford, had the best dish, the variety being Sea Eagle, of beautiful colour and the fruits large, Mr. Slade, Poltimore Park Gardens, Devon, being second with Princess of Wales. There were eleven competitors in this class. For one dish of Nectarines, Mr. Sparks was first with Victoria. For Plums, four dishes, Mr. Folkes was first with good Jefferson, Washington, Reine Claude de Bavay, and Cloth of Gold. Only three lots were staged. For one dish, not Gages, any variety, Mr. T. Spencer, Goodrich Park Gardens, Ross, Hereford, was first with a good dish of Golden Drop, Mr. Wright, Walcot Hall Gardens, Stamford, being second with the same variety. For Gages, Mr. J. Duncan, Warnham Court Gardens, Hershham, was first, Mr. Rich, Ross, being second. Mr. McIndoe was first for cooking Plums, four dishes, having grand Archduke, Grand Duke, Magnum Bonum, and Pond's Seedling, Mr. H. Felkes second out of three entries. For one dish, Mr. E. Coleman, North Frith, was first with excellent Pond's Seedling, Mr. Hurnard second. For Damsons, Plums, or Bullaces only two staged, Mr. Clinch, Sittingbourne, being first, Mr. Fennell second.

DIVISION V.—COUNTY CLASSES.

The prizes offered to growers in separate counties and groups of counties were competed for with considerable spirit. Kent was represented by four collections in each class. In both cases the judges must have had considerable difficulty in making their awards. Mr. G. H. Dean, of Whitehall, Sittingbourne (gardener, Mr. W. T. Stowers), was first with an even and good collection. His best cooking kinds were Lane's Prince Albert, of which he had an excellent dish, and Peasgood's Nonsuch. In the dessert varieties he was weaker. For second place, Mr. G. H. Sage, gardener to the Marquis Camden, put up a very nice collection, and his Cox's Orange Pippin in the dessert kinds was very fine. Peasgood's Nonsuch was shapely, but not particularly large. The last-named exhibitor was given first

place for Pears, and his fruit was excellent. The best dish was undoubtedly a splendid one of Gansel's Bergamot, a useful Pear not often staged in such fine condition. Mr. R. Edwards, gardener to Mr. G. H. Field, Bæchy Lees, Sevenoaks, had a very fine even lot for second place. Doyenné du Comice and Marie Louise were especially well shown. The next batch of southern counties covers a lot of good fruit-growing country, including as it does Surrey, Sussex, Hants, Dorset, Somerset, Devon, and Cornwall, and although we missed one or two well-known exhibitors from this neighbourhood, there was still a very strong competition, six collections of Apples and four of Pears being shown. The Duchess of Cleveland, Battle Abbey, Sussex (gardener, Mr. W. Camm), was placed first for Apples, a good clean-looking collection. The second prize lot was put up by Mr. King, gardener to Mr. Jeremiah Colman, Gattin Park, Reigate. First place for Pears was well won by Mr. W. Mancey, gardener to Mr. A. Benson, Upper Gattin Park, Merstham, who had very fine Durondeau, Marguerite Marillat, and Souvenir du Congrès. The second prize collection from Mr. J. Colman, of Reigate, was rather irregular, but contained very fine Doyenné Boussoch and Souvenir du Congrès. Wilts, Gloucester, Oxford, Bucks, Beds, Herts, and Middlesex were the next batch of counties, and here in the Apple class Mr. W. Strugnell, gardener to Colonel Vivian, Rood Ashton, Trowbridge, was successful. Mr. Lonergan, Cressingham Park, Reading, came next, his gardener (Mr. Chamberlain) having an excellent lot of fruit, including finely-coloured Alexander and Cox's Pippin. For Pears, Mr. W. A. Cook, gardener to Major Heneage, Compton Bassett, was first, Mr. Chamberlain being an extremely close second. In the Essex, Suffolk, Norfolk, Cambridge, Hunts, and Rutland districts there were three collections of Apples and the same number of Pears shown. Here again there was very little to separate the first and second prize collections of Apples. Mr. H. Hurnard, of Gurney's Manor, Higham, Norfolk, was first, and he was followed by Mr. Andrews, gardener to the Hon. W. Lowther, Campsey Ash, Wickham Marke, who had superb cooking fruits, but his dessert kinds were rather small. Mr. W. Allan, gardener to Lord Suffield, Gunton Park, had a splendid collection of Pears for first place. All the dishes here were good. Mr. Andrews, of Campsey Ash Gardens, followed closely, his best dishes being Durondeau and Doyenné du Comice. The counties of Lincoln, Northampton, Warwick, Leicester, Notts, Derby, Stafford, Shropshire, and Cheshire were not particularly well represented, nor was the fruit of a particularly high order of merit. Mr. A. Wright, gardener to Mr. J. W. Dearden, Walcot Hall, Stamford, and Mr. W. H. Divers, gardener to the Duke of Rutland, Belvoir Castle, Grantham, took first and second prizes respectively both for Pears and Apples. As to Pears, Mr. Divers certainly had the finest lot as far as quality was concerned, but the judges marked his Beurré Clairgeau "not a dessert Pear." It is not a first-rate kind by any means, but it figures in many lists of dessert kinds, and it was doubtless due to this variety that the Belvoir fruit was placed second. Louise Bonne in this collection was also extremely good. Hereford, Worcester, Monmouth, Glamorgan, Carmarthen, and Pembroke furnished undoubtedly the finest coloured fruit in the show, but the unsightly marks made by netting individual fruits were too much in evidence. Mrs. Blashett, Bridge Soblers, Hereford, took first prize for Apples. Here Peasgood's Nonsuch was superb but for the netting marks mentioned above, and there were rather small, but finely coloured fruits of Adams' Pearmain. The second prize fell to Mr. R. M. Whiting, Credenhill, Hereford. Pears were also well shown. For Pears, Mr. G. Hadfield, Moorarton, Ross (gardener, Mr. John Rick), was first. Mr. Spence, gardener to Mr. H. C. Moffat, Godrich Court, Ross, took second place, his best fruits being Doyenné du Comice, a superb dish, and Durondeau, a little out of character for this very

distinct kind. The next division included all the Welsh counties except those mentioned above, and only three collections were put up from here, two of Apples and one of Pears. Mr. R. D. Hughes (gardener, Mr. Jones) was placed first, his only good dish being one of Ribston. The second prize lot was very coarse, and was composed either of windfalls or they were wretchedly packed, for almost every fruit was badly bruised. Pears were even worse, and here the judges rightly refused to make an award. It was a disgraceful exhibit, certainly not worthy of Wales. One collection came from the northern counties, Mr. J. Garside, of Larbreck, being awarded first in the Apple class for a fairly good lot. From Scotland there were but three entries, two for Apples and one for Pears, but the quality was distinctly good. Mr. J. Day, gardener to the Earl of Galloway, Carlisle, N.B., had a nice even collection of clean, well-coloured fruit in the Apple class. Mr. J. McKinnon, gardener to Mr. W. Miller, Roundwood, Crief, took second place. In the collection of Pears that Mr. Day put up for first prize were characteristic examples of Doyenné Boussoch, Marie Louise d'Uccle, Souvenir du Congrès, Gratioli of Jersey, and Mme. Treve.

DIVISION VI.—DESSERT APPLES.

In this division popular and useful kinds were very much to the fore, and we noted with satisfaction that there were, for instance, three dozen dishes of Ribston, thirty-three of Cox's Orange and over twenty of Blenheim Orange Pippins. Not so satisfactory by any means was the judging, and complaints from exhibitors were plentiful and amply justified. In one class—that for Cox's Orange Pippin—a superb dish from Reigate won, and rightly. In that for Blenheims splendidly grown fruit was passed and the prizes awarded to much smaller specimens. Either Blenheim Orange ought to be left out of the dessert class or else the best fruit should win. As it stands, exhibitors do not know what to show—small dessert-sized fruits or fruits characteristic of the variety, viz., large, symmetrical and of good colour, for both were passed over in this case for medium-sized and not too well grown specimens. Of Adams' Pearmain four nice dishes were shown, none of them coming up to last season's form, but still good. The first prize went to Mr. H. H. Williams, of Truro (gardener, Mr. Cornelius), for rather rough but large fruit, the Duchess of Cleveland, Battle Abbey (gardener, Mr. Camm), being second with much better finished, but smaller fruit. Allen's Everlasting is evidently not thought much of. It was poor last year, it was worse this, only one dish from Mr. F. W. Buxton, of Sawbridge-worth, being shown. Allington Pippin is a fine-looking Apple, and here the judges had apparently made up their minds that colour should carry the day, the first prize in a strong competition going to Mr. C. Ross, gardener to Capt. Carstairs, Welford Park, Newbury, Mr. Whiting, of Credenhill, Hereford, being a close second. The same exhibitor just wrested the first prize from Mr. H. H. Hurnard, of Gurney's Manor, Norfolk, for Baumann's Red Reinette. Among the losers in this class was a dish of beautifully finished, fine fruit that showed marks of netting very plainly. As there were a number of prizes withheld, it seemed a pity that the judges did not, if they had the power, give extra prizes in the Blenheim Pippin class, for, as mentioned, there was a very strong competition. The first prize went to Mr. F. M. Lonergan, of Cressingham Park, Reading (gardener, Mr. Chamberlain); second, Mr. A. E. d'Avigdor Goldsmid (gardener, Mr. Earl). Four medium dishes of Brownlee's Russet were staged, Mr. Coleman, gardener to Mr. T. L. Boyd, North Field, Tonbridge, putting up the best dish, Mr. Sage, gardener to the Marquis Camden, being second. Mr. R. M. Whiting, of Hereford, and Mr. F. W. Buxton, Sawbridge-worth (gardener, Mr. Gedden), had first and second places respectively for Claygate Pearmain. Three dishes of Cackle Pippin were shown, Mr. A. F. Carter, Newfields, Billingham, and Mr. Kidley, gardener to Mr. W. A. Sanford, of

Nynehead Court, Somerset, taking the prizes in order given. For Court Pendu Plat, the first prize went to Mr. H. Lintott, gardener to Mr. Walpole Greenwell, of Morden Park, Surrey. Seldom has such a splendid dish of Cox's Orange Pippin been shown as that which Mr. King, gardener at Gattin Park, Reigate, put up in this class and which won first place. Each fruit was a model, superbly finished and of extra size. Mr. Slade, gardener to Lord Poltimore, Poltimore Park, Exeter, was second. Duke of Devonshire was represented by six dishes, Mr. J. Rick, Hereford, and the Marquis of Camden taking first and second out of a poor lot. Mr. Whiting was first and Mr. Spencer second for Egremont Russet. Fearn's Pippin was a good class, twelve dishes, mostly good, being shown. Mr. G. H. Dean (gardener, Mr. Stowers) had a very finely finished dish for first place, and he was followed by Mr. S. W. Cornwallis, Linton Park, Maidstone (gardener, Mr. McKenzie). Gascoigne's Scarlet was asked for in the schedule as "small, lightly-coloured fruits," and this well describes the first prize lot put up by Mr. T. Clinch, Denaway, Key Street, Sittingbourne. A fine dish of Gravenstein from Battle Abbey and a poor one from Mr. J. T. Charlesworth were placed first and second, a very fine, well-finished one from Mr. Maxim, gardener to Col. Walpole, Heckfield Place, Hampshire, being quite overlooked. Two dishes only of James Grieve were shown; the first by Mr. J. Day, of Galloway House Gardens, Galilee-town, N.B., the second by Mr. A. E. d'Avigdor Goldsmid (gardener, Mr. C. Earl). In the class for King of the Pippins gain many cultivators must have been struck with the way the judging was done. The first prize went to Linton Park, Maidstone, the second was won by Mr. Stowers, gardener at Whitehall, Sittingbourne. King of Tomkies County was not largely shown, the best, a very fine dish, coming from Heckfield Place, Hants. Mabbot's Pearmain was not particularly good, the first prize lot coming from Somerhill, Tonbridge. Mr. F. S. W. Cornwallis had the best Mannington Pearmain, fine, well coloured fruit. In the class for American Mother the smaller fruit took first prize, these coming from Mr. Whiting, of Credenhill, Hereford. They looked very good, but were not so well grown as the second prize dish from Surgeon-General Planck. Mr. King, of Gattin Park, Reigate, had a very fine dish of Ribston Pippin. Half-a-dozen dishes of Rosemary Russet were shown, good characteristic fruit from Battle Abbey taking first place. A good dish of Ross Nonpareil won first place for Mr. F. S. W. Cornwallis. Mr. Hudson, gardener to Messrs. Rothschild, Gunnersbury, showed the only dish of Scarlet Nonpareil, and was awarded first prize. Sturmer Pippin was shown by six exhibitors, but all were poor, the first and second prizes going to Welford Park and Reading. Three dishes of Wealthy were shown, Mr. R. Whiting being decidedly first. That the showy Worcester Pearmain retains its popularity was shown by the fact that eighteen dishes, mostly of excellent appearance, were staged, and here again Mr. King, of Gattin Park, was successful, his fruit being very regular and most beautifully coloured. Mr. Duncan, gardener to Mr. C. J. Lucas, Warnham Court, Horsham, ran him hard and obtained a good second. In the class for any other variety, Thomas Andrew Knight, the new seedling Apple, said to be a cross between Peasgood's Nonsuch and Cox's Orange Pippin, won easily; it was shown by Mr. Ross, gardener to Captain Carstairs, who raised it. Mr. Wythe, gardener to the Duke of Northumberland, Syon House, Brentford, was awarded second place for a nice dish of Golden Russet.

COOKING APPLES.

The cooking Apples in single dishes made a good display, some kinds in particular being very fine. With Alfriston, Mr. T. Spencer, gardener to Mr. H. C. Moffat, was first out of seven entries; Mr. J. Allen, gardener to Mr. G. Hanbury Field, second. Mr. Chamberlain, gardener to Mr. F. M. Lonergan, Reading, and Mr. R. Whiting won with Beauty of Kent. There were only three

entries for Belle de Pontoise, Mr. McKenzie easily winning first prize. Messrs. Sweet and Stower took the prizes for Bismarck. Bramley's Seedling brought fifteen entries, some of the dishes being unusually fine, Mr. H. Cook, Sidmouth, Mr. Ross, Welford, and Mr. W. Humphreys securing the prizes offered by the Messrs. Merryweather. Mr. Slade, gardener to Lord Poltimore, took first with Cellini in a class, though numerically strong, yet weak in quality. Cox's Pomona was better, but not equal to some we have seen. Mr. Stowers had the best, and Mr. King, gardener to Mr. J. Coleman, Reigate, was second out of eleven entries. Fifteen competed for Dumelow's Seedling, Messrs. Camm and King winning the prizes. The season was over for Ecklinville, and the fruits not very fine for the sort, Mr. Stowers having the best. Mr. McKenzie staged some fine Emperor Alexander for the first prize, and also Golden Noble, Golden Spire, and Grenadier, the two latter being small entries. The best New Hawthornden came from Mr. Herbert, gardener to Mr. J. F. Charlesworth, Redhill, and Mr. Ross, Welford Park. Lane's Prince Albert made a capital class of eleven entries, Mr. Stowers winning, as he also did with Lord Derby out of nine dishes, Mr. Herrin, gardener to Mr. J. B. Fortescue, Dropmore, following. Neither Lord Grosvenor nor Lord Suffield was good, the date of the show being too late for them. Mère de Ménage brought out six entries, the winning dishes, staged by Messrs. Ross and McKenzie, being exceptionally fine. The best Newton Wonder from the northern counties came from Mr. H. Turner, of Norfolk, and Mr. Divers, Belvoir Castle; and in the southern counties, Mr. Cook, of Sidmouth, and Mr. Potter, gardener to Sir Mark Collett, were the winners. Much the best Peasgood's came from the Kentish growers, Messrs. McKenzie and Stowers, of Maidstone and Sittingbourne, and remarkably fine fruits they were. Mr. McKenzie showed the best Potts' Seedling, and Mr. Ross the best Royal Jubilee. Mr. McKenzie again led with Sandringham, and Mr. Sage, gardener to the Marquis Camden, had the best Spencer's Favourite. Messrs. Whiting, of Hereford, and C. Ross staged the finest out of ten dishes of Stirling Castle. The Linton Park and Welford gardens contributed the best Stone's. The Queen was represented by nine handsome dishes, Mr. Stowers, of Sittingbourne, and Mr. Maxim gaining the prizes. Tower of Glamis, shown by Messrs. Hagon, Liphook, and McKenzie, were very good. Waltham Abbey produced only a small entry, but Warner's King numbered ten dishes of very fine fruits, one dish in particular being brighter coloured than any we have previously seen, Mr. J. Harris, Croydon, and Mr. W. H. Davis, Newent, having the best. A fine dish of Tyler's Kernel won for Mr. J. Dawes, gardener to Mr. Biddulph, Ledbury, the first prize for any other variety, Mr. Ross staging Harvey's Wiltshire Defiance for second.

DESSERT PEARS.

Generally speaking the classes for dessert Pears were well filled, there being but four classes not represented. Mr. J. Friend, gardener to the Hon. P. C. Glyn, Rook's Nest, Godstone, was first for Beurré Bosc. There were only three lots of Beurré d'Anjou, Mr. Chamberlain having the best and Mr. Sage the next best. Of Beurré Diel there were some very fine dishes, Mr. W. Allan, of Gunton, winning with what was generally considered an inferior dish to that staged by Mr. Wythes for second. Mr. Sage was first with Beurré Fouquieray, Mr. Hudson second. Messrs. J. Allen and Stowers had the best out of four good dishes of Beurré Hardy. Beurré Superfin was not numerous, but very good, Mr. A. H. Rickwood, gardener to the Dowager Lady Freake, Twickenham, and Mr. Allan, of Gunton, gaining the awards made. Mr. Herbert, Redhill, showed the best Comte de Lamy, and Mr. W. Allan the next best out of five dishes. Mr. Hudson, Gunnersbury, showed Conference in fine form, as did Mr. Chamberlain and Mr. Ross in the class for Conseiller. Eight competed with Doyenné du Comice, Mr. W. H. Bacon, gardener

to Sir Marcus Samuel, Mote Park, Maidstone, and Mr. W. Harrison, gardener to Col. Archer Houlton, Bishop's Stortford, having the best out of several good dishes. The only dish of Duchesse de Bordeaux came from Mr. E. Coleman, gardener to Mr. T. L. Boyd, Tonbridge. Mr. Bacon won with Durondeau, Mr. Spencer, Goodrich Court, Ross, being second. There were but two lots each of Easter Beurré and Emile d'Heyst, Mr. W. Jones and Mr. W. Allan, of Gunton, winning first prizes. Four competed in the class for Fondante d'Automne, Mr. W. H. Godden, gardener to Mr. F. W. Buxton, and Mr. W. Allen, gardener to Lord Brassey, Normanhurst, Sussex, taking the two prizes offered. Glon Morceau was not well shown, but Josephine de Malines was in very good form, Mr. Jones and Mr. Ross staging the best out of six entries. Mr. Wythes contributed a very bright dish of Louise Bonne of Jersey, as did Mr. Cook, Compton Bassett, Wilts, for second out of eleven entries. Mr. W. H. Godden showed the best dish of Marie Benoist, and Mr. W. Allen and Mr. Moore some fine Marie Louise. Three very handsome dishes of Marguerite Marillat were shown, the best by Mr. F. W. Thomas, Polegate, and Mr. Slade, gardener to Lord Poltimore, Exeter. Mr. Thomas staged the best Nouvelle Fulvie; Mr. Wythes was second. Only two competed with Olivier de Serres, but seventeen staged Pitmaston Duchess, mostly of large size, Mr. C. Morgan, gardener to Mr. S. J. Du Croz, Oaklawn, Weybridge, and Mr. J. Webb, gardener to Mr. H. Padwick, Manor House, Horsham, gaining the prizes. Sackle, the best of all Pears, was well staged by Messrs. Ross and Sparks. Souvenir du Congrès was enormous and of beautiful colour, Mr. C. Herrin and Mr. Thomas having the best. There were six dishes of Thomson's staged, the best by Mr. Allen and Mr. Hudson. Winter Nelis had also six entries, Messrs. Chamberlain and Webb scoring. There were seventeen lots staged in the any other variety class, Mr. Allen contributing fine Williams' Bon Chrétien, and Mr. Stowers Duchesse d'Angoulême almost equally good.

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, October 10, in the Drill Hall, James Street, Westminster, 1 to 5 p.m. At 3 o'clock a lecture on "The Injurious Scale Insects of the British Isles" will be given by Mr. R. Newstead, F.S.

National Dahlia Society.—At the exhibition held on September 19 at the Royal Aquarium, Westminster, first-class certificates were awarded to the following new varieties: *George Hobbs* (Show), a dark, well-formed flower; colour crimson-maroon. From Mr. T. Hobbs. *Empress* (Fancy), ground colour purplish rose, striped with purplish crimson. From Mr. St. Pierre G. Harris. *Mme. Medora Henson* (Cactus), good form, very narrow petals, centre too heavy; crimson, shaded purple. From Mr. T. S. Ware. *Maurice S. Walsh* (Cactus), a good pale yellow variety. From Mr. J. Stredwick. *Mrs. Carter Page* (Cactus), a large flower, long petals, good form, crimson-scarlet. From Mr. J. T. West and Messrs. Keynes, Williams and Co. *Sylph* (Cactus), very fine orange-coloured variety of medium size, with incurved petals. From Messrs. J. Burrell and Co. *Nara* (Pompon), neat yellow flower, of medium size. From Mr. Chas. Turner. *Hilda* (Single), fancy variety; white, flushed with pale flesh colour and bordered with yellow, very beautiful. From Miss Girdlestone. *Claribel* (Single), pale yellow, tipped with rose. From Mr. E. Mawley. *Eddie Obelin* (Single), golden salmon colour, very pretty and well-formed flower. From Mr. F. W. Seale.

The weather in West Herts.—With one exception the days and nights were all cold during the past week. On the night preceding the 28th ult. the thermometer exposed on the lawn indicated 3° of frost, and on the following night 5° of frost. Both at 1 foot and 2 feet deep the ground

is now about 2° colder than is seasonable. Rain fell on every day during the week, and to the total depth of nearly 2½ inches. On the 1st the fall was a very heavy one, amounting to 1½ inches, making this the wettest day here since July 18, 1895. The heaviest downpour took place between 3 p.m. and 4 p.m., when at one time the rate of fall for three minutes amounted to 2 inches an hour. The second of the above-mentioned frosts blackened the upper half of my Dahlias and ruined their prospects of flowering for the rest of the season. September proved warm, and especially was this the case at the beginning of the month. Rain fell on nineteen days to the aggregate depth of 2½ inches, which is half an inch below the September average. Nearly half of the above total fell during the last two days of the month. With the exception of the same month in 1895 and 1898, this was the most sunny of the last fourteen Septembers. With September ended the summer half of the rainfall year, and during these six months 12 inches of rain fell, or 2 inches short of the average for the same period in the last forty-three years.—E. M., *Berkhamsted*.

OBITUARY.

DR. ALEXANDER WALLACE.

DR. ALEXANDER WALLACE, M.A. Oxon., M.D., and M.R.C.P., who had distinguished himself in the study of botany and entomology, died on Sunday, Oct. 1, at his residence in St. John's Terrace, Colchester, aged seventy. He received his professional training at St. Bartholomew's Hospital and at Oxford, when he took the M.B. and A.M. degree in 1858, having been elected a member of the Royal College of Physicians, London, the preceding year, and in 1861 proceeded to the M.D. degree. He was for a time physician to the Metropolitan Free Hospital and the St. Pancras and Northern Dispensary, and he was a member of the Entomological Society of London, acting physician to the Essex and Colchester Hospital, and a member of some of the learned societies. In addition to many contributions on professional subjects to the St. Bartholomew Hospital Reports and to the professional journals, Dr. Wallace was author of "Notes on Lilies and their Culture," which had passed through two editions; "Ailanthiculture, or the Prospect of a New English Industry," and of "On the Oak-feeding Silkworm from Japan," prize essays of the Entomological Society of London in 1865-6.—*Times*.

Death of Mr. Jas. Martin.—We regret to announce the sudden death, early on Wednesday morning, of Mr. Jas. Martin, the well-known hybridist, who was for over forty years the faithful servant of Messrs. Sutton and Sons, of Reading. His death was entirely unexpected, he having retired to rest in his usual health on Tuesday night.

Fruit "appropriation."—At the recent fruit show at the Crystal Palace some work in this line was done. The writer was a loser in more than one instance of selected fruit. It is, of course, impossible for an exhibitor to remove all his single dishes at once; meanwhile someone else does so without his consent. A few detectives would have been of service on the last occasion along the outside tables, where the fruit could readily be removed back out of sight in a short time.—A LOSER.

Names of fruit.—*Webb and Brand*.—Fearn's Pippin.—*Anon.*—1, Ribston; 2, Winter Hawthornden; 3, Cox's Orange Pippin; 4, Ribston; 5 and 6, Blenheim. We cannot name more than six varieties in any one week.—*J. R. P.*—1, Apple looks like small Blenheim.

Names of plants.—*J. R. P.*—2, Geranium; send better specimen with fresh flowers; 3, *Spiraea prunifolia*; 4, *Spiraea japonica* alba; 5, *Adiantum concinnum* latum.—*W. W. Flemming*.—1, *Colchicum speciosum*; 2, *C. Szovitzianum*.

CHRYSANTHEMUMS.

AUSTRALIAN SEEDLINGS.

ONE of the chief aids to keeping a certain class of flower popular is the introduction of novelties. In regard to Chrysanthemums this has certainly been the case, and one who has watched each changing phase cannot record anything which appears more remarkable than the rapid rise of varieties sent from Australia. The raisers there seem to know the requirements of cultivators here, and many of those varieties have such merits as to leave little to be desired. The majority, perhaps, incline to the form of incurving Japanese, but for handsome appearance, bright shades of colour, and sturdy habit with healthy leafage they are among the best. The first lot sent over included *Pride of Madford*, *Australia*, and *Oceana*, now well known as splendid exhibition sorts. The lasting powers of the last-named, too, are most marked. Master H. Tucker, a dark crimson bloom fine in every way, followed with a sort called *Beauty of Adelaide*. This has not succeeded. Then came a host of new kinds, some of which are now in pretty general cultivation; others are not. *Nelly Pockett*, creamy white, is a lovely flower. Not extra large, but big enough, it gives a gracefully-formed bloom from every bud, and is as pretty as a bush as when severely disbudded for show. A short grower that keeps the foliage well, it is excellent for small pots from late-struck cuttings. Another white more pure in colour but less good for large blooms is *Mrs. C. Bown*. This variety makes a splendid bush plant. It blooms somewhat late; therefore valuable on that account, and for the supply of cut flowers it is first-rate. *John Pockett*, a rich, very dark shade of terra-cotta and gold reverse, is a noble variety. This has fine foliage, and is equally choice either for exhibition blooms or for the growth of a quantity on a plant. *Fair Maid of Adelaide* is a white-flowered variety of exceptionally dwarf and free habit. *Euterpe* produces blooms of a pleasing rose-pink shade, and I look upon it as a promising variety. So, too, is *J. R. Upton*, which has a very sturdy habit, the yellow blooms reminding one of those of Australian

Gold, but richer in colour. *Mabel Kerslake* and *Pride of Stokell*, which are one and the same, came through a sporting branch of *Pride of Madford*. The blooms, instead of being of a purple shade, as in the type, are bright crimson with gold reverse; the back shade of florets of the parent is lilac. Curiously, the growth of the new variety is less strong. In Chrysanthemums obtained from sports the growth is always similar. The above instance points to the contrary, and this is not an isolated one. Observation convinces me that the colours of the blooms have a considerable effect upon the comparative strength of growth. *Miss Mary Underhay*, yellow, is not unlike *Oceana*. Its habit, however, is tall, and the blooms lack the great substance of those of the variety named. *Miss Vera May Fraser* is an excellent sort, the flowers of an amber-yellow shade, of large size and shapely form, the florets drooping with just a curl at their tips. It is dwarf in growth. The *Convention* is another sort with amber-tinted blooms, a colour so much esteemed. The flowers are of rare substance; it is dwarf and most promising. *Mr. T. Carrington* is thought by some to be too much like *Australia*, but as the last grows to a height of 9 feet and the new kind less than 5 feet, it is an improvement. To my thinking, it gives better flowers as well. The habit of the variety *Mrs. Ernest Carter* is excellent, and its light yellow flowers well formed and lasting. Taking into account the number of white sorts we have, *Mrs. H. B. Higgins* may not be required. It bears gigantic flowers, however, and will be valued for exhibition. *Purple Emperor*, as its name suggests, gives blooms of a decided purple hue. There is nothing in Chrysanthemums like it. The flowers are of medium size and the plant of medium height. *Tucker's Perfection* is rather a tall grower. This will probably be discarded on that account. *Chatsworth*, a first-rate kind, white, with rosy stripes, is distinct, the shape of the blooms exceedingly graceful and the growth satisfactory. *Lord Ludlow* is noted for the depth of its blooms. The colour, golden amber, and its good habit of growth make it a sort of considerable merit. *Walleroo*, of a purple shade, is likely to be a good exhibition sort. *G. H. Kerslake*, pearly white, bears fine flowers;

the habit dwarf and branching. This, with *Mrs. Bissett*, *Wonderful*, and one or two others, are on trial for the first time this season.

There are later consignments of Australian seedlings in this country which should be watched with interest, as I look in the direction named as an important source in the way of further improvement in respect to Chrysanthemums. H. S.

Chrysanthemum Emily Silsbury.—No variety under glass equals this in beauty at the present time. It is one of the few really early sorts which produce their terminal buds in September. The spare growth and small foliage look as though they cannot perfect such large handsome blooms as are obtained. But it is a sort that should be grown in quantity. The flowers are white, with petals of a thick leathery texture. They recurve one above the other in a dense mass. Even if not freely disbudded the blooms come perfectly double. This, with stiff wiry stems to each bloom, makes it a valuable kind to grow for cutting. In the race for novelty exceptionally good varieties often get put aside. I think this is one, and would recommend its more general cultivation.—S.

Chrysanthemum growing round Norwich.—The number of acres devoted to the culture of Chrysanthemums in the neighbourhood of Norwich is astonishing. One would scarcely think it possible all the bloom could be disposed of. In one nursery I visited recently there were, I suppose, at least 50,000 plants growing in the open, and I was quite surprised to find the plants in such robust health and so full of bloom after the great drought. The two shades—yellow and white—of *Mme. Desgrange* occupied several acres and were in full beauty. They are at their best fully early, however, and the fact that other summer and autumn flowers—Asters, for instance—are yet in good condition and plentiful renders the sale of Chrysanthemums extremely slow. These will all be cut and conveyed to market before frost cuts them down, but the thousands of later varieties will be lifted and planted closely in a rough-and-ready manner in Cucumber and Tomato houses.—C.

NOTES AND QUESTIONS.

Chrysanthemum Mme. Liger Ligneau.—This is an excellent addition to the early-flowering

kinds. It blossoms very well in the open, but I fancy it will be more valuable as a pot plant, because of its being somewhat tender. The habit is especially dwarf and bushy; colour of the blooms a clear shade of yellow.—H.

Chrysanthemum Francoie Vuillermet.—This useful early-flowering sort is very little known, and yet it may be classed as an ideal plant for the open border. The habit of the plant is dwarf and branching, rarely exceeding 2 feet in height, and under ordinary treatment developing an immense number of rather small rosy lilac blooms. This is now in fine form.—D. B. C.

Chrysanthemum Queen of the Earlies.—This early-flowering Chrysanthemum deserves extended cultivation. We have somehow got into the way of confining the selection of early white sorts to such well-known kinds as Mme. C. Desgrange and Lady Fitzwygram, while the superiority of the variety under notice is most marked. The flowers are large, with long and fairly broad florets of good substance. The habit is fairly dwarf and the constitution robust, while it also flowers freely.—C.

Chrysanthemum Mme. Carnot.—Complaints reach me again this year that this variety, also its sports G. J. Warren and Mrs. W. Mease, are troublesome in the matter of the buds—that is, they swell to about the size of Peas and then turn black and perish. The cause is difficult to determine. It seems to me wise to give these kinds little feeding. The flower-stalks are gross, and it would be well to stand the plants in a shady place to get the buds over the stage when they are likely to be affected.—H. S.

Chrysanthemum Harvest Home.—When this sort was introduced a few years since it was hailed with delight by those interested in possessing a range of colour in the early-flowering varieties. Its reddish crimson colour, although tipped golden yellow, makes it a distinct flower in the early section. Unfortunately, it is rather spare in its growth. At the trial of early sorts in the Chiswick Gardens this variety received the distinction of ***. For the past fortnight the plants have been flowering freely, and promise to do so for some time. Market growers are now taking up this sort.—C. A. H.

Chrysanthemum Mrs. A. H. Hall.—This flower is now in splendid condition, and has caused some surprise because of its being a seedling from the well-known Japanese Edith Tabor. A batch of plants, which were topped in the middle of April and second crown buds retained, is just now at its best, the height not more than 3 feet at the most. The earliest blossoms are almost yellow in the centre, passing off to a bronzy crimson at the ends of the petals. The florets are broad, slightly curled and twisted, and of good substance. Later flowers promise to be of a much richer colour.—C. A. H.

Chrysanthemum Mychett White.—It is gratifying to find this chaste flower is coming very nicely this season. This is more noticeable where the stock has been carefully nursed and stimulants to a great extent avoided. As a white Chrysanthemum for outdoor culture it is one of the best, the more natural conditions of growth evidently suiting the plant admirably. In the first and second seasons of its introduction the stock plants were worked far too hard, and as a consequence the constitution was impaired. A recent visit to Ryecroft Nursery served to illustrate the usefulness of this sort in the open border, while indoor plants in 5-inch pots were each carrying a lot of pretty little blossoms.—C. A. H.

—The above variety is first-rate as regards flowers, but the habit of growth is not so satisfactory. It is not easy to propagate, the plants during the winter being very tender and the cuttings few. Then it has a way of sending out one strong shoot instead of many; consequently it is not easy to obtain a bushy plant. This tells seriously against it as an outdoor kind. I think the sort should be cultivated in pots, and these small ones. It flowers most profusely on the few growths that are made, and under glass the blooms are first-rate, but as an outdoor white it will never surpass such well-tried favourites as Mme. C. Desgrange and Lady Fitzwygram.—H.

Leaf-down a cause of hay fever and cold.—Some persons, notably those subject to hay fever, are well aware that they have only to betake themselves in the evening to the shelter of trees to immediately contract a sore throat or a

cold in the head. Many people are unable in the evenings to sit under trees without catching cold, and sometimes fever. The evening air, it has been said, is fatal to people of a certain temperament. To put it more plainly, the atmosphere after sunset is laden with moisture, and is the vehicle of certain organic matters which irritate the respiratory passages. Many people are not influenced by this state of the atmosphere; others, on the contrary, are very susceptible to it. A Mr. Hilliger, a German residing at Barcelona, lately took note of these effects in so far as they concerned himself. For some years, at the commencement of spring he and his family suffered from an epidemic of coughs without being able to define the cause. On his placing some of the expectorated matter under the microscope, it revealed to him certain strange star-shaped bodies, which he found also present in the dust on his window. He noticed the similarity between these bodies and the fine down which covers the young leaves of the Plane tree. This dust, then, was the cause of the inflammation of the bronchial tubes of the Hilliger family. The discovery of Mr. Hilliger has very ancient authority in support of it, as the same had been noted by Dioscorides and Gallien. Those eminent persons laid it down in the most formal manner that the down of the Plane leaf engenders hoarseness and cough and is even dangerous to the eyes and ears. What is true about the Plane is true of other species. It is well to know it, as it offers a very simple explanation of some mysterious maladies.—*La Semaine Horticole.*

BOOKS.

THE BIRDS OF BERWICKSHIRE.*

THIS is one of the best books of the kind we have seen. It is full of charming illustrations, and the paper, printing and binding are excellent. There are several full-page etchings by W. B. Hole, R.S.A., W. D. McKay, R.S.A., and Mr. John Blair, as well as numerous fine vignettes by the last-named artist, whilst beautiful pen-and-ink drawings of the nests of many of the birds, taken from Nature by the late Mrs. Muirhead, are given as tail-pieces to the chapters.

In the introduction to his valuable work the author describes the natural features of Berwickshire, with the Lammermuir Hills on the north, its bold, precipitous coast, its fertile, undulating, wooded plain known as the Merse. It must be a true paradise of the bird lover, with its well-wooded slopes and its wild and rocky coast. In the olden days the Merse, now a fertile and well-drained plain, contained many shallow lochs and impenetrable bogs, the haunt of aquatic birds, from the teal to the wild swan, where "the hollow boom of the bittern, or 'bull of the bog,' was heard resounding through the marshes, mingled with the weird cries of innumerable water-fowl of various kinds." Birds of prey abounded.

The white-tailed eagle soared in the sky, the peregrine, the merlin, and the sparrow-hawk swept the hills and the plains, whilst the buzzard and the hen-harrier hunted the fields and marshes. The hoarse cry of the raven was ever present, and the chattering of the magpie and the jay was constantly heard in the wooded valleys.

Since the commencement of the last century the improvements in the management of the land, the planting and draining that have been going on under energetic proprietors and industrious tenants have caused many of these birds to forsake their ancient haunts. Where the bird of prey formerly abounded is now the

"The Birds of Berwickshire." By Geo. Muirhead, F.R.S.E., &c. In two vols. Edinburgh: David Douglas.

haunt of the blackbird and the mavis, the wood pigeon and the stock dove. In autumn and spring immense flocks of wild geese still revisit their favourite resorts in the higher ground, and the

wild whistling notes of the curlew and the golden plover, as well as the screams of the lapwing, are heard in the summer all over the moors, for here they have their nests and rear their young. The snipe frequents the bogs, where it drums in spring and has its home among the Rushes. At the same season the song of the ring ouzel cheers the weary shepherd, whilst the wheatear and the whinchat flit chirping from stone to stone. The skylark rises from the dewy grass to salute the morn, the timid titling peeps in the Heather, and in the neighbouring vale the voice of the wandering cuckoo falls upon the ear. When the hill-sides are glowing with the golden bloom of the Whin, the linnet builds her bower in the prickly fortress, the twite nestles in the Heath, and the fragrant Larches, here and there fringing the sides of the rocky streams, afford shelter to the willow wren, which gladdens the solitary angler with its song.

On the bold and precipitous coast

the rock dove rears its young in safety amid the spray of waves which never rest. On yonder point, where the shelving reefs are being rapidly covered by the advancing tide, we see a small group of herons patiently waiting for their finny prey, and on a dark crag a little further from the beach the swarthy cormorant sits in undisturbed repose. Flocks of mallard float in security on the surface of the heaving waters, the golden eye dives at intervals beneath the surf, whilst the eider displays its parti coloured plumage to his sober-suited mate.

The above quotations are taken from the author's introduction. Each bird of Berwickshire has a chapter devoted to its history and its appearance and habits. The book is in two volumes, the first containing the smaller birds and the second the larger, birds of prey and game birds. We cannot speak too highly of the way Mr. Muirhead has performed his task. It must have been a labour of love indeed to have carried it out so well and spared no expense or pains to make each chapter full of interest as well as information, and every single vignette an artistic achievement of its kind. These handsome white volumes will be a delightful addition to the library of the sportsman as well as the mere Nature lover.

Botanical books, as we see in "Proserpina," have often very hard words, even for the scholar, but bird men, to give them an English name, seem to have even less heart than the botanist, as we may see opening such a book as Backhouse's list of birds, which begins with a mechanico-technical description of a rarity like the robin. What can be thought of a critic who objected to any further information being given about the birds of Berwickshire than the length of their tails and the like? In writing the accounts of the birds in this book Mr. Muirhead has tried to give them as much human and local interest as possible, so as to make his remarks readable by people who are not dry-as-dust ornithologists. If we wish to see what these men think or know about birds, read their writings in some of the leading ornithological periodicals. Their whole ideas of these most lovely and interesting creatures are that the "tarsi are $2\frac{1}{8}$ of an inch long and the fourth toe $\frac{1}{8}$ ths of an inch long." Their descriptions are so tiresome, that they are quite unreadable to the human being whose first thought of a thrush is not the length of some of its lesser parts. It is a shallow pretence of science these trivial measurements of certain parts, as many

other questions about even our common birds would interest all, such as the habits of life, migration, distribution, relationship, variation, nests, and nesting-places. But we are treated in just the same way by the botanists, and even some of the foresters choke us off with the dry and small bones of the subject.

The late Mrs. Muirhead was the constant companion of her husband in his study of the birds of their county and made many drawings from Nature, taking the greatest pains to draw and study all the surroundings of each nest. The result is a very artistic and precious book in every way.

Murray's "Handbook to Wilts and Dorset."—A carefully-revised edition of this has just made its appearance. Wilts and Dorset, two of the most naturally favoured of English counties, have an added interest in being the theatre of most, if not all, of Thomas Hardy's romances. There is a revised account of Salisbury and Stonehenge, of which much has been heard of late, and the maps and plans are unusually numerous. Mr. Murray's guides are too well known to need fresh commendation. We suppose no intending tourist ever contemplates any other. The maps are very clear and good, and the book in all ways worthy of the counties it describes.

KITCHEN GARDEN.

LONG-ROOTED TURNIPS.

LONG-ROOTED Turnips are valuable, more especially in dry seasons. Any vegetable that roots deeply has a better chance, as it obtains more moisture. In continental countries the long-rooted Turnips are greater favourites than with us. I noticed in the Paris markets very few of the round roots, but great quantities of the long-rooted varieties. The flavour, too, was excellent. This is a strong point, as Turnips, or their substitute, Kohl Rabi, are used daily. I must admit they are cooked well and are a valuable addition to the meat courses, as they are placed round the dish, cut into different shapes, and are more relished than if served mashed or boiled as in this country. The Jersey Navet, or French Forcing, as it is more commonly called in this country, is an oblong root, and is certainly one of the best forcing roots I have grown. It will often be found that a root that forces well is good in dry weather. The Jersey Navet is noted for its good drought-resisting qualities, and is of very good flavour. This is a favourite in the market for earliest supplies, as it turns in quickly in the spring. It may be said that it is not necessary to grow more than one or two kinds of the long-rooted varieties. I certainly advise growing at least three of them in addition to the Jersey or French Forcing. Another very fine-flavoured Turnip, Marteau à collet rouge, is noted for its superior quality, and is largely grown for summer and autumn supplies for the Paris markets. The root is coloured a portion of the way down and is less tapering than the Jersey variety, with a thick end. A variety called De Freneuse is not so good as regards shape of root, but it has a longer tap root and will stand more drought than the more shapely roots. Navet à forcer demi-long blanc is doubtless a type of the Jersey Navet, and one will suffice. An excellent white variety, Long blanc à collet vert, only differs from the red in colour. A popular variety in Paris is Navet long des vertus Marteau, a name which I fear would not be popular in this country on account of its length. This variety is small at the top and thick at the bottom, almost inclined to be oval, with a long tap-root. There are others less known, but the

kinds named appear to be the most popular, and are certainly worth notice in this country. As of late years we have had hot, dry seasons, it is worth a little extra trouble to obtain those kinds that are more reliable. My note refers to those I have grown. The roots noted above are equally good for winter, as they keep well when stored. I have kept them in the open, but to do this I would advise sowing early in August in cold soils. G. WYTHES.

Cardoon Blanc d'Ivoire.—I recently saw a very superior form of Cardoon to that which we grow in this country. The variety I refer to is much grown for the Paris market under the name of Blanc d'Ivoire, and is a dwarfier variety than the Large Spanish and the De Tours varieties. The variety in question is a good garden Cardoon on account of its solid stalks and peculiar build. The stalks, too, are of a much purer white. In this country we have a poor choice of Cardioons. This vegetable needs careful selection, as it soon deteriorates if left to chance. No matter what kind is grown the best culture must be given to get good stalks, and lack of moisture in dry weather is fatal to succulent growth.—G. WYTHES.

Lifting Potatoes.—Lifting Potatoes that have grown to their full size is frequently postponed, especially if the weather holds dry; consequently many are caught napping, a wet time occurs, and second growth follows or disease is set going, which develops after the tubers are lifted and stored. In East Anglia early lifting is, as a rule, punctually attended to, even if gardeners have to abandon the routine work for a time, as in that part autumn rains, when once they set in, are often heavy and continuous. My contention is that disease may exist in its embryo state and yet not develop to any appreciable degree unless encouraged by some excessive change either in the condition of the soil or atmosphere.—B. N.

Tomato Eclipse.—On visiting a market grower's establishment last week I found that one favourite Tomato was Eclipse. I had not heard of it before, but was assured that for freedom of cropping, shapely fruit, good colour and general quality it was very hard to beat. I think it has been grown there for some years, so it cannot be a new sort. The other sorts grown are Up-to-date and the old Hathaway's Excelsior. The latter, the grower informed me, always secured a ready sale on account of its medium size and shapely appearance. In another grower's houses I found Up-to-date and Challenger, both heavily cropped, with fine, medium-sized, shapely fruit, Ham Green and other varieties having been abandoned. This last grower until recently grew the useful, though perhaps a little small in size, Trentham Fillbasket, which for flavour is still hard to beat.—N.

Brussels Sprouts.—Such an important winter green crop as this is worthy of the best of care from first to last, and the plants should never be allowed to suffer from want of room. The earliest plants for gathering from in September are usually raised under glass, but here I make my earliest sowings outside in March, drawing flat, shallow drills and covering with finely prepared soil. These are drawn and pricked out as soon as large enough, and as early as possible they are put out in rows 3 feet apart and 30 inches apart in the rows. The consequence of this ample room even for the dwarfier kinds is that the plant from first to last is sturdy, and sprout-production begins just above the soil. The quarters for this crop can hardly be too rich, provided the soil is firm, a piece of ground dug and well manured the previous autumn being the best preparation for it.

Autumn Onions.—The autumn-sown Onions are looking very well and are now forward enough to be thinned considerably. It is not a good plan to sow very thinly where there is likely to be a large demand for plants, as in some seasons the seeds are not so good as in others, and birds are very fond of picking them out just as they are

coming through the soil. They should be thinned early so that those left have the advantage of plenty of light and air, which hardens them and makes them more likely to stand the winter. Some gardeners still pull their spring salading Onions from the same rows as their plants for spring, but this is not by any means good practice, for in the first place the rows have to be left much thicker than is desirable and the varieties sown for spring transplanting are not usually the best for salads. The small silver-skinned kinds are the best for salad, The Queen, for instance, being an excellent one. This may be sown several times during the year, and any that are not required for salad are sure to be useful in the kitchen. I have usually found the White Spanish and similar kinds run worse in spring than the Tripoli and Giant Rocca types.—C. H.

PEAS FOR MARKET.

Will you give me the names of two early Peas suitable for market, to be grown without sticks, also the names of two others that would come in say middle of July to the end of September; these will be grown with sticks?—JOHN CLOUGH.

* * Among market growers Eclipse is the most popular early variety for field culture, and large quantities of it are grown. It is hardy, reliable, and early. Ameer, a newer variety, forms a close succession, and when better known will also be largely sown. The seed, being blue round, may also be sown early, or as early in February as the state of the ground permits; whereas if wrinkled seed is sown thus early it is liable to decay wholesale. The haulm under favourable circumstances attains a length of 3 feet, and produces a heavy crop of large, deep green pods, well filled with extra fine peas. Salesmen have no difficulty in getting top prices for good samples of Ameer. No doubt extra heavy cropping is a strong point in favour of midseason and late Peas, but it is possible to attach too much importance to this. Much the best prices are realised for Peas which present the most attractive appearance, both as regards the size of pods—if well filled—and the colour. If the pods are long, thin, and closely packed with peas the buyers get the best of the bargain, as this class of vegetables is usually sold wholesale by measure—not weight. In Hallamshire Hero "J. C." will find a perfect market Pea, and one of the best to gather in July. It is of medium height, a heavy cropper, the pods being of good size, dark green in colour, and well filled. For August I know of no variety to surpass Autocrat. This variety possesses a good constitution, resisting mildew surprisingly well; crops heavily, the pods being moderately large, deep green in colour, and well filled, while the quality is excellent. All the above succeed well without stakes.—W. I.

Market Cucumbers.—Many of the fine exhibition Cucumbers are ignored by growers whose chief consideration is pounds, shillings, and pence. Private gardeners also who dispose of their surplus produce should acquaint themselves with the most profitable constant cropping varieties. Strange to say, most of the latter section are comparatively short, though of fine shape and good deep colour. A Cucumber of medium length always sells best, as many do not care to bring a fruit on to the table a second time after being cut. For a number of years Telegraph was the foremost market Cucumber, and some grow it now, although its somewhat pale colour is against it, and it often develops an objectionably long neck. A variety named the Rochford is very extensively grown, especially near the metropolis, and it certainly is a prodigious cropper, and over a long season, too. I have seen healthy, fruitful plants growing in wonderfully small mounds of soil, plenty of root moisture and a non-arid atmosphere being supplied. Cardiff Castle is gradually gaining popularity as a market Cucumber, and is grown by some for winter supplies, its free-bearing, hardy character at the latter season increasing its value. Lockie's Perfection is an-

other grand Cucumber for profit, as, besides being very free, its fine shape and general appearance soon take the eye. Verdant Green, a variety raised by Mr. McIndoe at Hutton, is rather shorter than Lockie's perhaps, but the darkest in colour of any I know. It scarcely ever develops any neck, being even throughout.—B. S. N.

NOTES OF THE WEEK.

Chrysanthemum Jules Mary.—Among early or semi-early sorts this is one of considerable promise, the flowers of a good shade of rich crimson. The variety would also appear somewhat more hardy than some, for not a few of the darker sorts have felt the recent frosts keenly, while this has escaped. It is also very dwarf in habit.

Chrysanthemum Mrs. Burrell.—This is the pretty sulphur-yellow kind belonging to the Mme. Desgrange section, but it has never had a popularity like the old kind, for the colour at night is too much that of a dirty white, and, indeed, cannot be distinguished from such. In the open it is less effective than the ordinary yellow form, so much so that the variety in a year or two may be forgotten.

Colchicum autumnale album pl.—This is one of those ever-prized hardy bulbous things that promises to be a long time before it is plentiful owing to its slow rate of increase. As an early autumn flower it has a value of its own, and good clusters of it are among the finest things to be seen in border, rock garden, or grass at this season. Its leafless character especially fits it for grass planting, though it may prove to be less speedy of increase here than in good border soil.

Aster N.-B. Robert Parker nanus.—Certainly any Michaelmas Daisy with half a dozen names to its credit is not lacking description when applied as above, but a new name might be chosen for it. The variety is so good, so dwarf and free, and so generally useful, that there is room for it. The pale or light blue flowers are large and plentifully produced, and the whole plant is less than 18 inches high. For borders or for groups this will prove a most welcome kind.

Caryopteris mastacanthus.—This pretty flowering shrub, which has been recently referred to in THE GARDEN, is at Kew employed in No. 4 greenhouse, where a group of plants is profusely laden with the pretty lavender-blue flowers. These blossoms are disposed in whorls on the upper parts of the shoots, the long protruding stamens, of a somewhat deeper tint than the rest of the flower, being very noticeable. This Caryopteris is well worthy of increased attention for flowering under glass, as it supplies a tint quite distinct from the *Salvias*, *Cannas*, *Chrysanthemums*, *Bouvardias*, &c., which are at this time in bloom.—H. P.

Gentiana asclepiadea.—At p. 287 this plant is the subject of an appreciative note which all hardy plant admirers will admit it well deserves. I quite agree with what is there said of its moisture-loving propensity, but I am not at one with the writer in suggesting it as a good plant for shrubby borders, which are of such a variable quantity that knowledge of any particular border is requisite before recommending plants for it. That this Gentian may be established in the wild garden and well grown in the usual hardy plant border is quite true, but in the shrubby border little moisture, to say nothing of other things, exists for so graceful a flowering plant as this.—J.

Tacsonia Van Volxemi fruiting.—I shall be much obliged if you can inform me whether the fruit of *Tacsonia Van Volxemi* is edible. An old plant occupying a border in a house where the temperature at times falls to 48° F. is still flowering profusely, and has perfected fruit. The fruits are at present of a pale green, 3 inches to 4 inches long and 1 inch to 1½ inches in diameter. On a sunny border in the open *Mirabilis jalapa* has been smothered with its richly scented flowers and has also ripened quantities of seed.—H. COMER RENSCHAW, *Stretford*.

* * We have never heard of the fruit of the variety you mention being eaten.—ED.

Tufted Pansy Florizel.—This is proving one of the most satisfactory of the Tufted Pansies

that I have tried here. On light, dry soil, such as that here, comparatively few of these plants will give a long continuance of bloom. Florizel is proving one of the most valuable in this respect, and even now (October 9) old plants are flowering. There are some of more tufted habit at this season, but one can forgive any defect for the sake of its free-flowering all through the season and for its fine blooms. I see these are called "rosy blush," but one fears this is hardly near enough the colour to please those who are particular about colour descriptions. It is easier, however, to criticise than to offer an alternative. Florizel is one of the best of Dr. Stuart's rayless Tufted Pansies.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Tropæolum speciosum in Oxfordshire.—I think that perhaps those of your readers who are interested in the difficulty of inducing the *Tropæolum speciosum* to grow in England may care to hear how I have succeeded in Oxfordshire with it. For many years I have planted it with every care and in every possible situation and aspect, but in vain. Two years ago I was told by a friend to put the roots in autumn into pans or pots filled with ordinary mould with sand mixed, to place the pots in an absolutely dark cellar, where no light can penetrate, to leave them there unwatered till end of March, then plant them against a wall or hedge looking north, and where the long shoots can climb over into the sunny south side of said wall or hedge. All those I have so treated have done splendidly. In winter I cover the roots lightly with Bracken. *Tropæolum tuberosum* also succeeds well under the same treatment.—MARY HERMIONE DAWKINS, *Wilcote, Charlbury*.

Phlox coccinea.—It seems rather singular that some flowers retain their position long after others of more recent introduction have fallen out of cultivation in gardens where only the best of everything are grown. In some cases this is due to their superior form, habit, or colour. There are many instances of this, and talking over the subject with an experienced and enthusiastic florist has reminded me that *Phlox coccinea* is one of such flowers. I cannot at present discover when it was raised or by whom. It has, however, been in cultivation for a good many years. Since it was first grown many bright-coloured varieties have been raised, but there are none of exactly the same shade and of equal effect. Some are of similar shade but defective in other respects; others with larger flowers are of inferior habit. Anyone looking through a good collection of *Phloxes* can hardly fail to be impressed by the appearance of this old variety. Its good habit, fine spike, and bright colour with healthy growth mark it as a variety of great merit. Its glowing colour is not that of the grand *Phlox Coquelicot*, nor is it that of *Etna*, but more of a glowing crimson.—S. A.

Cæsalpinia (Poinciana) Gilliesi.—It is very seldom that one sees this Chilian shrub flowering in the open air near London, but just now a specimen trained to the front of the museum overlooking the lake at Kew is in bloom. The general aspect of the plant reminds one of a rather attenuated *Acacia lophantha*, while the flowers, which are borne in a crowded terminal raceme, are yellow with prominent red stamens, which give to a head of bloom a fluffy appearance. Apart from the interest attached to it from the fact that we very rarely see it in bloom, this *Cæsalpinia* is decidedly ornamental when in that stage. In the more favoured districts of the country it will, of course, succeed better, and was last year noted in THE GARDEN as being in flower with Mr. Ewbank at Ryde. It was, however, there referred to under the generic name of *Poinciana*, in which genus it was formerly included. The *Cæsalpinias* and their near allies the *Poincianas* include among their number some very attractive flowering shrubs, which are, however, rarely met with. The best known and at the same time the hardest is *Cæsalpinia japonica*, a rambling shrub with prickly stems and spikes of canary-tinted blossoms, which are lit up by a cluster of bright red stamens in the centre.

This is fairly hardy in the open ground in the neighbourhood of London, and formed the subject of a coloured plate in vol. xl. of THE GARDEN.

Plumbago Larpentæ.—If, as one gathers, the proper name of this is *Ceratostigma plumbaginoides*, one must plead guilty of a strong disinclination to adopt that name in preference to the one at the head of this note, which is easier to pronounce, easier to spell, and easier to remember. It is, one knows, only in accordance with good practice to give the prior name the preference, but, after all, the real use of a name is that we may identify a plant. This flower is better known as *Plumbago Larpentæ* than as *Ceratostigma plumbaginoides*, and one need not hesitate to speak of it by the former appellation. Now (October 9) it is yet in bloom, and a look at its pretty blue flowers open in the sun of a late autumn day induces one to think that a note in its favour once more may lead to some other flower-lover adding it to her or his garden. Such a plant as *Plumbago Larpentæ* is worth cultivating if we can succeed in growing it. It is of neat, low-growing habit, and comes, moreover, at a time when a rock garden needs all the brightness one can give it. Its blue colour is also welcome. Its failing is a somewhat serious one, and it would be unfair not to state it fully. It lies in the fact that the plant comes so late into bloom that in cold places it is practically useless. It flowers with me annually, but it is grown on the top of what is probably my driest rockery, where it gets all the sun of summer, and is so dry that one is surprised that it is not injured by a continued spell of drought. It never suffers from this, and is among the plants which give hardly any trouble.—S. A.

Tropæolum tuberosum.—The other day I had sent me from Kerr Brothers, of Dumfries, some flowers of *Tropæolum tuberosum*. This was a pleasant surprise, as this plant seldom flowers with most of those who have tried it in our district in S.W. Scotland. This is unfortunate, as even those who are so successful with *T. speciosum* would appreciate highly the scarlet and yellow flowers of *T. tuberosum*. It is at all times a troublesome plant to induce to flower in the open, and they are fortunate who are happy enough to bloom it annually. It is fairly hardy in some gardens, but its disinclination to bloom is, of course, against its being largely tried either as a hardy or a half-hardy plant. This defect is one which is not confined to this district; nor is it one which has not given trouble ever since its introduction in 1827. It appears to have attracted a good deal of notice about the year 1837, as one observes from several communications in the "Floricultural Cabinet" for 1840. At that time great difficulty was experienced in flowering it, and this was the cause of the articles appearing in the "Floricultural Cabinet." Several growers detailed their practice. This was not uniform, but the most promising recipe appears to be that of adding lime rubbish to the soil, and in addition planting the *Tropæolum* against a wall. One correspondent added lime and Moss. This, he said, gave good results. The difficulty with us is that our summers are of too short duration, and that the plant is cut down by frost before it can come into bloom. To treat a plant such as this as a half-hardy one is not particularly desirable, and one would like to grow it altogether in the open. As a half-hardy flower it requires to be planted out after having made some growth under glass. While this note is somewhat despondent, it is written with a remote hope that someone may be able to throw some light upon the question of how to grow it. I have not taken it in hand myself for the reason that I have seen it tried unsuccessfully in gardens in which it is more likely to flower than in mine. Should no one be able to help us, the ventilation of the question will at least have the negative, but useful purpose of preventing some from wasting money, time, and space upon a beautiful creeper unsuited for the hardy flower garden.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

THE WILFUL DISFIGUREMENT OF FOREST TREES.

RECENTLY certain magazines and illustrated journals in the great chase after subjects for "copy" have dealt with the clipped gardens of England, and some of the most stupefying works in this way ever done have been chosen for illustration. Of English counties, Derbyshire is the most distinguished in this way. The Dutch, who painted like Nature and built like sane men, left their plantations to the shears, though they always cut to lines or some kind of plan, judging from their old engraved books. But British clipping has no relation to any plan, and in this they exceed in extravagance the Dutch, Austrian, and French, who at least clip their trees to bring them within bounds in garden, street, or by a canal. This peculiarly British mode of clipping single trees has done much harm, not merely in large private gardens, but even our public gardens. The late Mr. McNab, of the Edinburgh Garden, excellent planter though he was, had an idea that he kept his conifers "in shape" by clipping; nor is there a suburban district round London in which in our own day the gardener

on a distinct statement he generally falls into error. For instance, we are told that Elvaston, in Derbyshire, is not remarkable for natural beauty, and that the grounds there are so flat, that landscape gardeners, in despair of any other planting, are compelled to have recourse to topiary work; that

Even that man of fame, "Capability" Brown, seems to have shrunk from the work of laying out the grounds, for he bluntly wrote to the fourth Earl of Harrington, who invited him to undertake the task, that "it was all well, and he would let well alone." Whereupon the Earl demanded the reason for so strange a retort, and Brown replied, "Because the place is so flat," &c.

Instead of there being any truth in the assertion that we cannot make level ground beautiful by planting in natural ways, level ground has a great deal in it that is favourable to right and artistic ways of planting. That is to say, with flat ground we may more easily secure breadth, simplicity, and dignity; get dividing lines in the easiest way; richer soil and nobler, finer and more stately growth and essential shelter. Many of the most beautiful gardens in Europe are on perfectly level ground

Lawn with trees in natural form. (Cassiobury).

does not run amuck with his shears to get the trees, as he calls it, "into shape." A false idea runs through all growers of the Pine tribe that the trees, the most frequent victims of this practice, should be kept in a pyramidal shape, the truth being that all the Pine trees in the world in their state of highest beauty lose their lower branches and show the beauty of their stem forms when growing in a natural way. The conical Pine is the seedling Pine. With a few exceptions, it is the way of these trees to shed their lower branches as other trees shed their leaves. By isolating conifers in our gardens and pleasure grounds we do indeed often lose this effect, as most Pines grow naturally in great colonies and groups, and protect and to some extent prune each other. Even in countries where the Pines often stand alone, as in the foot-hills of California, we have often seen them with a hundred feet or more of clear stem.

The writing about this subject is usually of that see-saw sort, praise and blame alternately, the writer avoiding any clear statement of his views, in accord with the artistic drivel of the day which leaves nothing clear, or if he ventures

—for instance, Laxenberg in Vienna, the English Garden at Munich, not to speak of many in our own river valleys and counties like Lincolnshire. What should be said of planting in all the lowland countries of Northern Europe if this assertion were true, to say nothing of the absurdity of assuming that the only way out of the difficulty is the stupid disfigurement of trees? We shall not imitate the example of these writers in leaving the matter in a fog of doubt, but state some reasons against wasting precious labour to rob trees of their natural charms. The old poets and satirists who laughed at it did not go into the reasons against clipping big trees, which are serious.

(1) LOSS OF FORM.—Tree form is so wonderful and beautiful, that the marvel is we should have to allude to its loss at all. But people may get so accustomed to surround themselves with ugly objects in their gardens, that they often miss what in nearly every parish in England one has only to walk a hundred yards or so to come face to face with, that is, lessons in tree form and beauty. Some protest against the cropping and docking of animals' ears and tails, but when the

worst in that way is done, the dog or the horse remains in his full beauty of form in all essential parts; but if we cut a noble tree which in natural conditions is beautiful in all its parts, we reduce it at once to a shapeless absurdity—that of a bolster standing erect being the usual result.

(2) LIGHT AND SHADE.—A great loss is that of light and shade—very important elements of tree beauty. These are entirely neutralised by shaving trees to a level surface, whether the trees take the form of a line or we clip them singly, as in the British phase of tree clipping we are now discussing. If we see old examples of the natural Yew, a forest tree and the commonest victim of the shears among evergreen forest trees, and look at them in almost any light, we may soon see how much we lose in destroying, with all our wasted wills, light and shade, as the play of these enhances the force and beauty of all the rest.

(3) COLOUR.—In gardens we are so much concerned with flower colour, that we often fail to consider the more delicate colours in Nature, and such fine tone as we see in a grove of old Yews bronzed by the winter, or Ilex with the beautiful silver of the leaf, or a grove of naturally grown, glossy, rich coral-bearing Hollies. Even the smallest things they clip, such as Juniper, have in a natural way much beauty of colour if left alone. The clipping of the Cherry Laurel into banks, as we see it at Mentmore, Cliveden, and, unhappily, a thousand other places in England, mars a tree naturally good in colour, and even the beauty of the large leaves is destroyed by the merciless shears. All the above-named trees, each a favourite subject for clipping, are many times more beautiful in colour than ever they are in the shorn state, the loss of the stem colour alone being a great one, as we may see by the "Pilgrim's Way," or anywhere where old Yews show their finely coloured stems.

(4) MOVEMENT AND SOUND.—In the movement of trees stirred by the wind and the gentle sighing of their branches we have some of the most welcome aspects of tree life. In the case of groups of Ilex, as at Ham House, and masses of it, as at St. Ann's, the effect of the motion of the branches is to many a very beautiful one. This movement is also of great beauty in groves of old Yew trees, and is seen in every Cedar and Pine that pillar the hills. The voice of the wind in these trees is one of the most grateful sounds in Nature, and has often inspired the poet.

(5) DEATH AND DISEASE OF THE TREES.—The constant mutilation leads to this not infrequently, as may be seen constantly at Versailles. In the Derbyshire examples recently so much illustrated the stems of dead Pines are shown in the pictures. It is simply an end one might expect from the annual mutilation of a forest tree, as the Yew certainly is, as we see it among the Cedars on the mountains of North Africa, as well as in our own country and Western Europe. Other trees of the same great Pine order are yet more impatient of the shears than the Yew, and the dignity of some of them, like the Cedar, allows of its escape. However one distorts the Yew, we know that it is in Nature sometimes as fine as a Cedar.

(6) ANNUAL COST AND CARE.—Few begrudge outlay if it gives a good result; but merely to use the labour of many men with shears is to miserably waste both time and money when there is so much of the country yet to be planted with beautiful trees.

A statement which wearies us by its reiteration as well as its absurdity is that if we concede the right to clip grass, then also we are justified

in clipping trees. The answer is that grass is mown for our own comfort and convenience. There is a distinct and good reason for it, and by it we disfigure nothing. Moreover, short grass is not an artificial thing, as there are hundreds of natural lawns in the mountain ranges of Europe; and in mowing our lawns we are merely doing for our pleasure what exists to a vastly larger extent in many upland and hill countries.

The shopman, if we make a mild protest against the ugliest of his wares, tells us it is "a matter of taste," and, unhappily, many in all ranks have the same idea as to any artistic question—an idea that obscures all issues. But if we look into almost any artistic subject we find it is false as well as foolish. The difference between a portrait of Rembrandt in the noble series lately shown in London and the first Academy daub in pigments is a question not of taste, but of very awful fact; between an Elizabethan or Tudor house and one of the "carpenter's gothic" of our day; the sculptures of the Parthenon and the statues that adorn our squares; between the churches of Bourges or Lincoln and the first we meet in tin or plaster. But, vast as are the differences of these things, between none of them is there so great and hideous a difference in fact as between the divinely given natural form of the northern evergreen trees, whether those of the lawn slopes of Jura, the hills of the Pacific coast of America, or the rocks of Scotland, and the ridiculous and shapeless results of the wilful distortion of forest trees by man.—*Field*.

—Some time back you gave some instances of the practice of barbarously pruning forest trees in pleasure grounds, but I fear it is not sufficiently known to what an extent the practice has been carried and advocated by men calling themselves experts in the art of forestry. The Blue Book Report on Forestry, 1887, containing the proceedings of the committee and minutes of evidence has, perhaps, not been much read, but it contains some tit-bits from such "experts" that are well worth perusing, as showing what extravagant and fantastic methods of culture men calling themselves landscape gardeners and practical foresters have pursued on well-known estates where they were allowed a free hand by the proprietors. A witness, who was regarded as one of the most important summoned before the Committee on Forestry, stated that he had had about fifty years' practical experience in forestry; that he had had charge of some of the most extensive woods in England belonging to noblemen, with head foresters under him and about 100 men; that he had been professionally consulted as to the planting and management of woods all over Great Britain; that he had given his attention to the instruction of the persons who had the management and charge of woodlands; and the system he taught was as follows: First, he nursed the trees in plots in a nursery till they were about 5 feet high and seven or eight years of age (at which stage most respectable nurserymen burn their stock as unfit to be offered for planting); second, he then planted them out in the wood not less than 4 yards apart, or as wide as the ultimate crop was to stand; third, he trimmed the side shoots of the trees in by pinching every two or three years, "so as to get a mass of leaves all up the stem," till the trees were something like columnar Cypresses, we presume, and this pinching he practised on Firs like the Scotch Fir and others. I am exaggerating nothing. The non-practical mind even will realise that all this business meant enormous initial expense in plants and

planting, a thin crop of timber in the end even if all went well, and an army of men with telescope ladders periodically to go over the wood and perform the pinching, operations which if done would involve expense sufficient to swamp the whole business. I have often wondered what the woods managed in the above way were now like and what their owners thought of them. The "system," as its author called it, took no cognisance of such factors as density, overhead canopy, soil protection, thinning, or winds which were sure to overturn his tall plants every season until they would be growing at every possible angle and producing deformed trunks that no one would ever buy as timber. The examiners of this witness were Sir Edmund Lechmere, Sir Richard Temple, Mr. Munro Ferguson, Mr. Rankin, Mr. Acland and others, some of whom appeared tickled by the pinching process, and inquired of the witness if he really thought it would be more profitable to employ a large amount of capital in such an enormous amount of manual labour "than to leave the trees alone," and the answer was "Yes, most decidedly." About 300 trees to the acre, no intermediate fellings, realisation deferred to the far end, the trees for planting, seven or eight years old, to cost perhaps from £10 to £40 per 1000, and all to be trimmed like Azaleas or pyramid Pears. It puzzles one to guess how such notions on the subject of forestry could have originated. They could have no foundation in practical forestry, but might be derived from the plot culture of shrubs in a nursery. There is no worse practice than that of planting forest trees above 9 inches, or at most 18 inches high, and as young as possible. The most disastrous results have invariably followed the planting of trees 4 feet or 5 feet high and proportionately old, to say nothing of their cost. No nurseryman can prepare such trees for safe removal except by frequent transplanting. The expense is great and the buyer pays for it and gains nothing.—*J. SIMPSON, in Field*.

FRUIT AND VEGETABLE CROPS.

IRELAND.

Straffan House, Co. Kildare.—The fruit crop here is the worst for seventeen years, nearly all kinds being much under average, especially Apples, Pears, and Plums. Bess Pool is the only Apple with full crop. Continued east winds all through May were the cause of failure here. Apricots were splendid—the best I have ever seen. Bush fruits were good; Red Currants were the least good. Strawberries were an average crop, but suffered from rain, 4 inches having fallen in the first twenty days of July.

Vegetable crops on the whole have been good, and among Peas there are none better than Exonian, Veitch's Criterion, and Ne Plus Ultra. There is no better all-round Tomato than Hathaway's Excelsior, of which Hackwood Park and Ham Green are selections. Golden Jubilee is a splendid kind for dessert, and is preferred by some to Gage Plums.—*FREDK. BEDFORD*.

Fota, Cork.—Like most other parts of the British Isles we were visited with very cold, stormy weather when the fruit trees were in blossom, with the result that in many gardens not a Gooseberry set, and some other kinds of fruit were almost as bad. Apples are an average crop, the following a full crop: Lady Sudeley, Worcester Pearmain, Cox's Orange Pippin, Tom Putt, Blenheim Orange, Loddington, The Queen, Lady Henniker, King of the Pippins, Warner's King, Domino, Mère de Ménage, Hambleton Deux Ans, Bullinora Pippin, Grenadier, Annie Elizabeth, Bramley's, and Small's Admirable. Pears a light crop of poor quality. Beurré

Hardy, Gratioli, Louise Bonne of Jersey, and Doyenné du Comice are the best. Plums are a good crop, Victoria, Potts' Seedling, Monarch, Coe's Golden Drop, Kirke's, Prince of Wales, Jefferson, and Prince Englebert having very heavy crops. Peaches good crop, well-coloured fruit. The Strawberry crop is average; season short in consequence of heat and drought. Gooseberries abundant here, in places a failure. Other small fruits an average crop.

Vegetables in early season were very good; later, in consequence of want of water, crops poor and tough. Potatoes are of good quality; Ashleaf still the best early garden Potato for quality. Windsor Castle and Up-to date are good.—*W. O.*

Westport House Gardens, Co. Mayo.—Apples are a good crop in some cases; this applies to standard and bush trees as well as walls and espaliers. Pears are greatly under average; some trees have heavy crops. Cherries are poor; 17° of frost destroyed nearly all the fruit. Plums and all small fruits are good. There was a good crop of Strawberries here, except Guntan Park. Young plants of V. H. de Thury gave a splendid crop. There was a heavy crop of Gooseberries. Black, Red, and White Currants and Raspberries are good.

Vegetables on the whole very fair, except mid-season and late Peas, which are almost a failure.—*JAS. MACKENZIE*.

Headfort Gardens, Kells.—We had a nice show of blossom and expected a good fruit year, but frost, cold rains, and hail prevented the fruit setting. Strawberries were plentiful but small. Bush fruit very good.

Vegetables are very good. The second lot of Peas did not fill well on account of three weeks' hot weather. Potatoes are very good, especially Ashleaf Kidney.—*JAMES HOUNSLOW*.

Powerscourt, Wicklow.—Apples are carrying good crops. Pears are somewhat thin, Beurré d'Amanlis, B. Clairgeau, B. Rance, B. Diel, and Louise Bonne of Jersey being our best. Cherries are bearing an average crop, the old May Duke the heaviest; Morellos are very abundant and good. Plums, such as Rivers' Prolific, Victoria and Mitchelson's, have good crops; on walls, Kirke's, Denniston's Superb, and Victoria are a full crop; Apricot, Magnum, Washington, and Green Gage are not half a crop; other kinds almost *nil*. Apricots are average crop; on some of the trees the fruit is very rusty. Raspberries are a very good crop, fruit large, Superlative being the best variety in my opinion. Strawberries are very good, Royal Sovereign the best. All other small fruits are abundant and of good size.

With the exception of Beans (Broad) and Peas the vegetables are not equal to average years, especially on light land. All suffered more or less from the excessive heat and drought in the first fortnight of June.—*DAVID CROMBIE*.

Carton Gardens, Maynooth, Co. Kildare.—Apples are much below the average; Apricots very good; Cherries (sweet and Morello) a heavy crop; Plums light; Filberts and Walnuts plentiful; Strawberries, Gooseberries, Raspberries, Red and Black Currants a heavy crop and good.

The season has been good for vegetables; all kinds are plentiful and good.—*A. BLACK*.

The Gardens, Bessborough, Co. Kilkenny.—Generally speaking, this is a very good year in these gardens. Strawberries were an excellent crop, but out of a number of sorts two proved much the best, viz., Royal Sovereign and Latest of All. The former from an early border, planted July 28, 1898, was fit for use the first week in June. Latest of All in this garden is a grand variety, immense cropper, fine fruit, and of good flavour. Viscountess also proved one of the best varieties both for flavour and cropping. All Currants were very good, Gooseberries, Raspberries, and Morello Cherries also being very good. Pears are (as far as my experience goes here) a very uncertain crop. The trees are covered with bloom, which is usually destroyed by late spring frosts, only the trees on walls escaping. Apricots were

very good, the trees setting an immense quantity of fruit. The trees seem to do very well indeed, not dying back, as in some localities. Of Apples, there are heavy crops on the majority of trees; Plums, the best crop for three years; Figs, a nice crop also.—J. G. WESTON.

SUPPLEMENTARY.

Monmouth.—We have had but a poor season in Monmouthshire for either fruit, vegetables, or flowers. An early frost in May did much injury to one of the finest fruit prospects I have ever seen. This was followed by four months of continuous drought. I had an excellent Strawberry crop, though not of long duration. I mulched, as I generally do, heavily with old Mushroom manure, and was amply rewarded, especially with Royal Sovereign, Latest of All, Keans' Seedling, and British Queen. Raspberries, Currants, and Gooseberries are poor crops; wall fruit, Peaches, Nectarines, Plums, and Cherries utter failures. Figs, with the exception of Brown Turkey, are very poor, and even Brown Turkey not by any

growth above ground, but the tubers have been small. The soil here being little better than sand, it has been a very trying time. Every kind of fruit here requires to be netted this year owing to blackbirds, which eat even green Nectarines and Tomatoes as they begin to turn colour.—A. EAST.

Hackwood Park.—Apples are thin; a few having a full crop are Lord Suffield, Warner's King, Keswick and Potts' Seedling. Pears are much under the average. Some sorts of Plums have a full crop, Victoria, Rivers' Prolific, The Czar, and Monarch being the best. Peaches are scarce, and the trees badly blistered in the spring. Nectarine Early Rivers had a splendid crop; Apricots have failed; Strawberries were poor and fruit very small. All kinds of small fruit and Filberts are a full crop.—J. BOWERMAN.

Euholmes, Patrington, Hull.—Bush fruit has been good, also Strawberries, Royal Sovereign having been the best. The Apple crop is very peculiar, some trees being laden, while others have no fruit on them. Pears and Plums are a

Walnuts are very good in places. Strawberries promised a heavy crop, but took mildew just before the ripening period and partially failed.

Vegetables have done well, Peas being very good.—ALBERT PARRY.

Grimston Park, Tadcaster, Yorkshire.—We had a very dull, cold, ungenial spell of weather during the blossoming time of fruit trees, hence the crops are not abundant in any case. Frosts, too, were very frequent. In my opinion the non-setting of the abundant blossom was more due to the paralyzing effect of the wet, unless weather than to the frosts. At any rate, we have had good crops of hardy fruits hereabouts when the frosts have been more keen than they were this year. Apricots are a good half crop, fruit fine in size and trees generally healthy. Branch-dying has been very rare up to date. If ripe wood is an absolute necessity for good crops of the delicious fruit there should be such next year, as we have seldom had a more profitable time for this process to be properly carried out. This remark applies to all well established hardy fruit trees. Our soil is a stiff, loamy one, about 3 feet in depth, overlying the magnesian limestone, hence if well soaked by rain in the early summer we do not feel the effects of continued drought as those situated on lighter soils. Apples are a partial crop, but promise to be a fairly good sample. Lord Suffield, Warner's King, Cockpit, Hawthornden, Worcester Pearmain, Yellow Ingestre, Winter Pearmain, Cockle Pippin, Lord Burghley, and Kerry Pippin have the best crops. Keswick Codlin, a very excellent early Apple for this part, is not doing well this year. Singular to say, blackbirds are eating up the early Apples. We had to pick our Lord Suffield and Ecklinville before they were quite ripe on this account. Plums, too, they have attacked, as also Tomatoes on walls. I have had to net the vineries also, or they would have soon destroyed the Grapes. Plums are not a good crop; Victoria and Early Rivers are the only varieties with anything like a crop on them. Dessert Cherries do not bear well. I had a very good crop of Morellos. Pears are very partial, Doyenné d'Été, Citron des Carmes, and that old fine-flavoured early Pear Ambrosia had all fair crops. I have a sprinkling of fruit on Doyenné du Comice, Marie Louise, Louise Bonne of Jersey, Thompson's, Ne Plus Meuris and Beurré Rance. Peaches and Nectarines are almost a complete failure on walls. Hale's Early is the only Peach that had anything like a crop. Currants, Red, Black and White, had good crops in each case; while not free from the Black Currant mite, it has not injured our crops up to now. Raspberries were a good crop. Another year's experience with Superlative bears me out in confirming my last year's note of it, viz., it is the best Raspberry I know of for this part. It throws up suckers somewhat scantily. Has anyone tried raising it from seed? Strawberries were a good crop, but, owing to the dry weather, soon over Noble is the earliest to ripen, but its flavour is not very good. Veitch's Perfection is a good variety. Royal Sovereign I like and grow. It is a grand Strawberry, but on some soils is very liable to mildew. For preserving, an old Yorkshire-raised Strawberry, viz., Newton Seedling, is bad to beat. Jubilee and Waterloo are very good late varieties. Walnuts are a good crop; Mulberries not so good as usual.—H. J. CLAYTON.

Madresfield Court Gardens, Malvern.—The fruit crops on the whole are peculiar, many trees being heavily laden, whilst similar kinds growing only a short distance away are quite barren. The trees flowered equally well, and the only conclusion I can arrive at is, the probability of waves of cold air of an unequal degree at certain critical periods. The intense drought of a second season has told heavily upon the size of the fruit as well as upon the shortness of the season for individual kinds. On the other hand, all fruits have possessed the fullest flavour. It has been a matter of no small difficulty to supply the roots with moisture, whilst the extreme dryness of the atmosphere has favoured insect attacks. There is evidence that growth will be well ripened, and

Old Yew hedges, Holme Lacy. From a photograph by Miss K. Pilkington.

means a large crop, yet the fruit was and is fine and of good flavour.

Vegetables nearly all failed. Asparagus, thanks to a heavy dressing of seaweed, was early, lasted well, and produced as fine a crop as could be desired. Tomatoes were not a success either indoors or out; they suffered, and are suffering, from blight and mildew, which I do not understand, as they had their usual treatment, which I have found generally successful.—G.WENT.

Brockhampton Court, Ross, Herefordshire.—Apples are very good; Pears very scarce; Plums a light crop with the exception of Victoria and Pershore; Peaches and Nectarines are good; Damsons fair; Raspberries and Red and Black Currants were very good, but Gooseberries were scarce; Strawberries were good, but very soon over owing to the intense heat and want of rain.

Vegetables have been fair. Peas have not done well, the blooms shrivelling up before they were expanded. Cauliflowers raised in pots in early spring were very good, but nearly all the others have gone blind. Potatoes made enormous

failure or nearly so. Peaches outside are a failure. This is owing to the very severe frosts in March when our trees were in full bloom. The frosts not only destroyed the fruit, but nearly killed the trees. Here in favourable seasons we can grow very fine Peaches outside.

Vegetables have not had a good chance, as the early part of the season was very unfavourable—first wet and cold, then a long dry time. Slugs and snails have been rampant this season, especially the latter. Potatoes, I think, will be very good.—J. WORTLEY.

Cut Hedge, Halstead.—Apples in this district are an uneven crop, some trees being heavily laden while others a few yards from them have none. Those bearing the best with me are Wadhurst Pippin, Claygate Pearmain, Betty Geeson, and Hawthornden. Pears all round are a light crop. Plums were very thin. The best here was Belgian Purple. Damsons are very poor; Cherries an average crop; Gooseberries and Red Currants very good; Peaches and Nectarines a failure; Apricots an average crop; Nuts scarce.

the assurance that, where tree roots have been fairly supplied with moisture, good, healthy flower-buds are in course of development for the next season. Apples have cropped best on garden trees where there is a better larder, and doubtless this will be repeated next year, for where shallow cultivation is practised, exhaustion follows, not that the roots necessarily go down deeper, but by heavy mulchings added, capillary attraction is set up and moisture at the root is conserved. Bush trees and cordons are loaded with high-class fruit, but old trees on turf are very indifferent. Pears are on a par with Apples. Apricots and Plums are half a crop, but of high quality and fine size. Cherries are very heavy crops. Peaches and Nectarines are splendid crops on south walls, somewhat smaller than usual, probably owing to a cold May and the tropical forcing weather ever since. Bellegarde on the Pershore Plum stock has proved satisfactory. Strawberries were very light and soon over, old plants nearly barren, chiefly owing to a lack of moisture at the roots last autumn. Young plants in deeply trenched and well-manured ground did well. I always grow Royal Sovereign as a biennial, taking one crop only. Gooseberries and bush fruits were fairly good, but not heavy crops.

One of the worst seasons I ever remember for vegetables, owing to the intense and protracted drought. Peas almost an impossible crop, owing to the extreme dryness in the atmosphere. Spinach and Turnips have given much trouble. Potatoes are much under-sized, but of good flavour.—W. CRUMP.

The Gardens, Tan-y-bwlch, N. Wales.—Of Apples the Codlins and Barnack Beauty are a full crop, the latter variety carrying a very heavy one. With these exceptions the crop is a failure, for I believe we have no more Apples in number than we have trees. Pretty well the same applies to Pears, and Plums are a failure. These crops have been scanty for the past two seasons notwithstanding a grand bloom each year. Sixteen degrees of frost and a heavy snowfall proved too much for Apricot bloom, although protected with netting; half a dozen fruit have been about our total. Gooseberries were a heavy crop and fine clean berries. Currants (Black, White, and Red) very fair. Raspberries were excellent in every way, clean and free from maggot; in fact, the cleanest lot I have had for the past twenty years. Japanese Wineberries also carry a very heavy crop; these come useful late. Strawberries were a variable crop, some kinds badly burnt up when the berries were half grown. The earlier kinds fared better than later sorts and were of a fair size, clean, and of excellent quality, but main-crop and late varieties were not so good, for I had no means of adequately watering them, and plants and fruit were quickly parched up. I think the most satisfactory main-crop kind this season was McMahon, which swelled up a heavy crop under very unfavourable conditions.

A wet, late spring followed by a dry summer is not exactly the conditions under which vegetables will thrive in this district, but, on the whole, they have turned out better than was anticipated. The first four or five sowings of Peas, despite all precautions, were destroyed by pheasants. Later sowings became crippled and almost barren owing to heavy and repeated attacks of thrips, while mildew was rampant, so that the supply was considerably curtailed until the late main croppers turned in. These have done much the best, for they have grown and cropped well. Gladiator has succumbed to mildew without bearing a dish. Chelsonian, Alderman, Veitch's Perfection, and Autocrat have been the best; Omega followed. Climbing and dwarf Beans as well as Butter Beans were good; runners set badly. Potatoes were a fair crop of even tubers, some slightly diseased. As only yellow-fleshed Potatoes are favoured here, Myatt's forms the bulk of the crop, for no variety I am acquainted with surpasses it for genuine Potato flavour. Spring Cabbages were late. Spring Broccoli, on the other hand, were very good,

plentiful supplies being afforded up to the middle of June. Early Cauliflowers also turned out well, but later ones, owing to want of moisture, are small and grubby. Onions are not large, but solid and free from maggot. Turnips, although quickly grown, cut up streaky and spotty, more so than usual, I think, while Carrots are not quite so badly infected as is usually the case on this land. Beet is clean and not too large. Asparagus has been late and weakly. Salading has necessitated much labour in watering to supply the demand and keep up high quality. Early planted Brussels Sprouts are looking well, but I cannot say so much for later and other winter crops, and, to add to the mischief, we were visited with a plague of caterpillars which, despite our efforts to destroy them, demolished every leaf of the Cabbage and Turnip tribe. They were in such numbers that they riddled a quarter of young plants in a few hours.—JOHN ROBERTS.

Addington Park, Croydon.—The fruit crops here are not half the average, although there was plenty of bloom. The late spring frosts no doubt prevented the free setting of the fruit. The bloom of all kinds here was papery and weak and did not look matured, owing, I have no doubt, to the dry weather we had last year. Gooseberries were abundant, but they did not ripen at all satisfactorily. The same may be said of Strawberries. Raspberries, however, were better than I have had for a number of years. Apples, Pears, Plums, Peaches, &c., are a partial crop, owing, no doubt, to the late spring frosts. For the last forty-five years I have observed the seasons, and I have no recollection of such a bad year as this.

The vegetable crops have been poor.—W. WHALLEY.

FLOWER GARDEN.

M. LATOUR-MARLIAC'S HARDY HYBRID WATER LILIES IN IRELAND.

As I have during the fine summer now coming to a close had the pleasure of blooming successfully, in a tank specially built for their cultivation in my vegetable garden, nearly all the finest varieties of these most beautiful and free-blooming plants for which the gardening world is indebted to the distinguished French hybridist whose name heads these notes, I hope that some account of my method of cultivation and of the varieties cultivated may be of some interest to those readers who may feel inclined to follow my example. The dimensions of my tank are 21 feet long by 9 feet broad by 3 feet deep. At the bottom I placed 16 inches of black slimy mud, mostly composed of decayed leaves fallen from trees surrounding the pond whence it was taken, with two rows of well-decomposed cow manure between the rows of plants. The tubers arrived from France by parcel post on May 6, and took about a month to establish themselves in their new quarters before they began to grow. Their development was surprisingly rapid. Early in July they commenced to bloom, and have produced an abundant crop of beautiful flowers during July, August, and nearly the whole of September.

The varieties planted were gloriosa, Ellisiana, Andreana, Robinsoni, lucida, Aurora, Marliacea flammea, Seignoureti, sulphurea grandiflora, Marliacea rosea, Laydekeri rosea, tuberosa Richardsoni, pygmæa alba, and pygmæa Helvola. Nearly all good judges of the respective merits of these hybrids are agreed that for brilliancy of colour the variety named ignea deserves the first place, but its flowers are, unfortunately, relatively small. This fine variety I have not yet seen. Next comes Ellisiana, and third gloriosa, but as

the flowers of this grand variety are nearly equal in size to those of the two first-named put together and are of a fine deep carmine with bright yellow anthers, many to whom size is of prime importance would place this first of all. It is also, fortunately, an extremely free and continuous bloomer. Andreana and Robinsoni are almost identical both as to colour and form of flower, the only recognisable difference being that the flowers of Andreana are rather larger than those of Robinsoni, but no one having one need plant the other, especially where it is desirable to have as many distinct sorts as possible in a limited space. Lucida has by far the handsomest foliage of any of them, and is of an extremely vigorous habit of growth. Its leaves are of immense size, handsomely mottled with deep maroon blotches, and borne on stout leaf-stalks of from 4 feet to 5 feet in length. The flowers are also of good size, with paler outside petals and clear deep rose-coloured inner ones, with yellow anthers. Aurora is also a pretty variety somewhat resembling the last-named, but with deeper coloured interior petals and smaller-sized flowers. It is of not nearly so vigorous a habit of growth or such handsome foliage. Marliacea flammea is, I think, rather inaptly named, as the colour of its flowers has nothing to do with flames, being of a deep vinous-purple. It is, however, a very distinct and handsome variety. Seignoureti, though it may have appeared distinct and good in its day when first sent out, is now no longer worth including in any collection of really choice varieties, as it may be described as a poor and pale form of lucida, which far surpasses it in every way in beauty. Sulphurea grandiflora is, unfortunately, rather a shy bloomer, but its very large and handsome flowers of a pale lemon colour, most of which are about 8 inches in diameter, stand well up out of the water, and open nearly flat in the full sun, making it indispensable for all first-class collections. The beautiful Marliacea rosea is so well known, having been sent out several years ago, that it needs no special description; but its large and delicately-tinted flowers have been as much admired as any in my tank. The beautiful Laydekeri rosea, which opens the palest shade of shell-pink, deepening as the flowers age till they end of a clear deep rose colour, is also extremely free-blooming and should be in every collection. Richardsoni is a perfectly cup-shaped flower of an exquisitely pure white, of medium size, and acts as a good contrast to the higher coloured varieties. It is, I believe, of American origin. Pygmæa alba is a most beautiful small flower of pure white colour, and p. Helvola has pretty creamy blossoms of an even smaller size, and may be described as a little gem amongst Water Lilies.

From America are promised for next season's bloom some wonderfully beautiful novelties, one of which is said to be of the brilliant colour of ignea, with the splendid size of gloriosa added. If this comes up to its raiser's description it should throw all other varieties into the shade, and prove indeed a grand acquisition to our water gardens.

W. E. GUMBLETON.

Belyrove, Queenstown, Ireland.

Helianthemum amabile fl.-pl.—This is, I believe, to be the name of the variety alluded to in a recent number of THE GARDEN under the name of the Carton Sun Rose. It has been in Mr. G. F. Wilson's Wisley garden for some years without a name, and I have now a stock of it obtained from a plant that Mr. Wilson gave me. It is a really good thing, its merits being conspicuous in a hot, dry season like the one we have just passed through. Planted on a dry bank or on rockwork in the full sun it gives a nice bit of

colour and continues to flower all through the summer. Where the soil is very poor and gets much parched in summer this *Helianthemum* is quite at home, but does not extend very fast under such conditions. It assumes a shrubby, compact form, flowers more freely, and is altogether much more effective than where a richer soil induces a ranker growth. Plants that have run away a little too much to growth may be restricted and made to take on a more compact habit by means of hard cutting back in early spring.—J. CORNHILL.

Hemerocallis aurantiaca major.—This is certainly a grand *Hemerocallis* and well merits all that has been recently said in its favour in THE GARDEN, but at the same time—in some places at least—it does not flower with that freedom which one would wish. As stated on p. 251, it is certainly a good deer; still, many examples have come under my notice, both last year and this, which, though full of promise, failed to flower. The plants referred to were in different localities and under various conditions. Many bloomed in a satisfactory manner, but still the percentage of unflowered ones was considerable, and this I find is a very general complaint. It is such a grand plant when in bloom, that any hint how to render its flowering more certain would be welcomed by many.—T.

Sweet Sultans for market.—There are various shades of colour in the Sweet Sultan, but the yellow, to my mind, is by far the best; indeed, few things look better when carefully and not too thickly arranged in glasses. Recently I saw some long beds in a market garden near Norwich, and the assertion sometimes made by writers that these plants need lime in good proportion in the soil was borne out by the fact that close by the garden in question are large lime pits, the soil around no doubt being more or less impregnated with lime. At any rate, the plants had thrown a wealth of flowers and the various beds seemed even throughout. I have heard it stated that the seed should be sown out of doors, as the plants do not care for being transplanted. This may be true in some gardens. Those in question had evidently been transplanted, but not very early in the season, as the position was rather an exposed one. I think early sowing under glass is a mistake; better wait till April and then sow in a frame, keeping the young plants dwarf and stocky by admitting plenty of fresh air and thinning them freely as soon as handling is practicable. If left crowded, a weak, leggy condition follows, and the plants, more than many things, are slow in establishing themselves when transplanted. If the soil does not contain lime, a free incorporation of old lime rubble should be made. Adding animal manure is a dangerous practice.—C. N.

Tender Nymphæas in the open air.—I was pleased to read Mr. Burbidge's note in THE GARDEN, August 19, regarding *Nymphæa stellata* flowering in a lake at Carton, Kildare. This is the first time I have noticed such an account, and I hope many other growers may be stimulated to do likewise. There are several varieties that will respond to such treatment, notably *N. zanzibarensis azurea*, *N. z. rosea*, *N. cœrulea*, *N. pulcherrima*, also *N. gracilis*. The best method to adopt prior to planting out is to start the tubers indoors. Plant the tubers in 4 inch pots, using a rich loamy soil. Place the pots in shallow water, about 6 inches of water over the pots, and the temperature of the water should be kept about 75°. They should be in a light, airy position, no shade at any time. In about four weeks' time the plants will require repotting into 6-inch pots, using similar soil as before, but the plants will require more room for leaf development and a few inches more depth of water. Where a tank cannot be called into service, wash-tubs or half barrels may be utilised, and to allow depth of water over the crowns of the plants use pans instead of pots. In four weeks' time from repotting the plants will be in fine condition to plant out. This in most instances should be June 1, and the plants if grown as directed will

be in bloom before this time. No better place can be conceived than a Melon pit for starting and growing tender *Nymphæas*. A section can be walled off, say two or three sashes, and made water-tight by a plastering of cement. A depth of 20 inches can be given, the young plants brought near the surface by using inverted pots to stand them on, and during the month of May plenty of air can be given and all the sunshine available, which will harden them off preparatory to planting out. A single plant may be placed in a tub or box containing about 10 cubic feet of soil and allowed to occupy a single sash, and when well established the sashes may be entirely removed during warm weather and replaced later when cool weather sets in if at all desirable to prolong the season.—W. TRICKER, *Riverton, N.J., U.S.A.*

CALIFORNIA BULBS FOR FORCING.

A CLASS of flowers, which for its ease of cultivation and brilliancy of colouring is but little known to eastern horticulturists, is the various sorts of Californian bulbs, *Brodieas*, *Calocherti*, *Camassias*, *Erythroniums*, *Fritillarias*, and *Lilies*.

BRODIEAS are in shape and appearance like *Crocus*, bearing grassy radical leaves, one or several slender stalks terminating in open umbels, or a dense umbellate head. The smallest bulb is a reliable bloomer, doing well in almost any soil and under any conditions; can be forced, or is perfectly hardy outdoors in the United States and Europe. The handsomest species are in point of colouring and size: *Brodiea peduncularis*, pure white, immense umbels of flowers; *B. ixioides splendens*, colour delicate yellow; *B. californica*, largest of all *Brodieas*, rosy lilac; *B. stellaris*, star-like clumps of a brilliant waxy purple; *B. coccinea*, glowing crimson; and *B. volubilis*, or Californian twining *Hyacinth*, stalks of a climbing or twining habit with beautiful rosy wax-like flowers. Splendid for forcing in pans or for cut flowers are

CALOCHERTI.—The flowers resemble in form the *Tulip*, while the colouring and marking are marvellous. The best are *Calochortus splendens atroviolaceus*, a brilliant purple; *Calochorti* of Eldorado strain, in colours rose to red, creamy white, gold blotched, are marked with a showy eye, yellow to brown, beautifully dotted and lined; *C. venustus citrinus*, lemon-yellow with black eye; *C. clavatus*, orange; *C. macrocarpus*, lavender, banded with green; *C. nitidus*, lilac, with deep purple blotch in centre of each petal; *C. Vesta*, white, suffused lilac to rose and purple, centre red, back of petal purple; and *C. Gunnisoni*, pure white flowers barred with green.

CAMASSIAS are splendidly adapted for forcing. The flowers are borne in racemes; leaves long and glossy, like those of a *Hyacinth*; stem stout, 1 foot to 3 feet high. Among the best are *Camassia esculenta*, 1 foot high, deep blue; *C. Cusicki*, leaves 1 foot in length, flowers produced in great racemes, 2 feet to 3 feet high, pale sky-blue; *C. Leichtlini alba*, a pure white form; *C. Leichtlini*, tall, splendid purple.

DOG'S-TOOTH VIOLETS are noted for their large, Lily-like flowers and beautifully mottled foliage. They are easily forced. *E. grandiflorum* has large, bright yellow flowers; *E. revolutum*, large white flowers, tinted lilac; *E. r. Johnsoni*, flowers dark rose, orange centre; *E. giganteum*, cream; *E. citrinum* opens a pale straw colour, turning to pure white, with lemon centre; *E. Hartwegi*, delicate yellow; and *E. Hendersoni*, pale purple, with dark purple centre. Of

FRITILLARIAS, with their graceful, Lily-like flowers, the Pacific coast has many sorts. The finest: *F. recurva*, brilliant scarlet; *F. pudica*, clear, bright yellow; and *F. pluriflora*, crimson. Among the showy spotted or Leopard

LILIES are *L. Humboldti*, clear orange, spotted maroon; *L. Bloomerianum*, tigered; *L. columbianum*, orange-yellow; *L. Bolanderi*, deep red; *L. pardalinum*, orange-red, scarlet tipped, thickly spotted maroon. *L. Parryi* is one of the finest *Lilies* in the world; flowers long, trumpet-

shaped, clear lemon-yellow, and very fragrant. *L. Washingtonianum* grows from 4 feet to 7 feet in height, with many pure white, trumpet-shaped flowers of great fragrance.—H. H. BERGER, in *Florists' Exchange*.

EUCOMIS PUNCTATA IN THE OPEN.

THE note by Mr. Arnott (p. 252) calling attention to this plant should induce other lovers of outdoor flowers to attempt its cultivation in borders, for variety is none too common late in September, its flowering season, as we are then confined almost wholly to the order of composite plants for what there is left to attract attention. The *Eucomis* is generally looked upon as a greenhouse plant, but is far more effective when grown outside, where there is room for its roots to ramble and for its wide-spreading leaves to develop to their fullest. The fact that it has lived and grown well in one of the borders here in Derbyshire for several years should be sufficient proof that it is hardy, except perhaps in the severest winters, for it has had no protection as far as I can learn, and it had none last winter. A clump growing on a raised border has now fourteen well-developed spikes, some being 3 feet high, on the least of which there are over 100 flowers. There is nothing very showy about the flowers as seen from a distance, but they well repay closer acquaintance. They are star-shaped and of great substance, having the appearance of being moulded in wax; the ground colour is greenish white and the dome-like centres are deep rosy purple, a colour with which the petals themselves become suffused as the flowers become older. The flower-stems are as stout as those of *Galtonia candicans* and thickly spotted with purple. In a cut state and under artificial light the flowers are charming, as the petals lose their green tinge and the centres look more rosy. The individual flowers then bear a striking likeness to those of *Hoya bella*, except that they are larger and six-petaled; they also emit a delicate and sweet perfume. As regards the position in which to plant the *Eucomis*, it appears alike at home in sunshine and in shade. It is growing in both here and equally well in either, but I may add that the shade is not that from overhanging trees, but from a low span-roofed house on the north side of which the bulbs are planted. Probably it would be unsafe to plant in ground below the surrounding level, and I should certainly choose a raised position for it.

J. C. TALLACK.

Cactus Dahlia Magnificent.—Various notes have recently appeared respecting this new variety. At first, owing no doubt to the dry weather, I was not pleased with it, but since rain and cooler weather have come, my opinion of its merits is considerably changed. It is now flowering beautifully; so free, and every bloom perfect. It is dwarf in habit and the stems are long. It requires but little disbudding; therefore one may get a mass of colour. The apricot tint is much admired, and plants of it are striking even among other good kinds.—H. S.

Anemone alpina.—I refer again to this beautiful *Windflower* by reason of the remarks of Mr. Arnott and "H. H." Daljarrock, Ayrshire, at p. 270. It is interesting to learn that one's experience is confirmed in these matters, and there is no doubt the plant is worth a good deal to make it a success. I am of opinion, too, that readers of THE GARDEN would thank "H. H." were he able to tell them something of the time that has been taken in building up the fine example he speaks of. In my original notes I touched but very lightly on the sulphur-flowered form of this plant, believing it to be generally understood that in their cultivation the two were as one. All the same, I quite agree with what has been advanced in respect to it, and the colour in particular. Nor is there the least doubt that seeds of these things afford the best facilities for securing a stock. The remainder is one of waiting and watching. A little more stress may,

perhaps, be laid on the fact that open-ground sowing is far better for such seeds than aught else, for the labour in watching and the like is not merely reduced to a minimum, but the seedlings, when these appear, are in safer keeping altogether. Those who would still like to try the stumps of these things, which as imported are known as plants, may like to know that the present is the season for securing them; secondly, that to plant these fibreless pieces in the soil is to court failure from the very starting point; and thirdly, to plant them in cocoa-nut fibre and ashes or the first named alone is to afford them the only possible chance of making fibrous roots, without which all are useless.—E. J.

SEPTEMBER CLIMBERS IN DEVON.

In a sheltered nook *Berberidopsis corallina* has borne its bright vermilion berries, and in the same garden a plant of *Bougainvillea speciosa* against a southern wall has produced flowers in the open. In the early days of the month the Virgin's Bower (*Clematis Flammula*) was a cloud of perfumed ivory-white blossoms, and the yellow-flowered *C. graveolens* and *C. songarica*—the blooms of *C. graveolens*, though of the same colour as those of *C. songarica*, being less than half their size—were in full flower. Now the blooms are for the most part succeeded by the feathery seed-vessels which in these species form quite as attractive pictures as those of the Traveller's Joy (*C. Vitalba*), that in the late autumn veils our southern hedgerows and woodlands with its smoke-grey feathery trails. Here and there the deep purple of *C. Jackmani* was to be discerned at the commencement of September, while varieties of the *C. lanuginosa* section have in many cases borne their widespread mauve or white stars throughout the month, one plant covering a porch not far from where I write being at this time (October 4) crowded with perfect blossoms, each from 5 inches to 6 inches in diameter. *Convolvulus mauritanicus*, though perhaps rather a trailing than climbing plant, may be mentioned as being in bloom during September, and *Muhlenbeckia complexa*, albeit a non-flowerer for all practical purposes, since its blossoms are inconspicuous, is most decorative when draping high wall, cliff, or tree trunk with its verdant cascade. *Lapagerias*, both white and pink, have blossomed well on a north wall in the open, and will continue to produce flower for some weeks should frost not intervene; indeed, I have seen fresh *Lapageria* blooms on the open wall in South Devon as late as mid-December during a mild winter. The blue Passion Flower is now extremely effective, though not by reason of its flowers, which have by this time for the most part faded. The oval fruits have now assumed their bright orange tint, and hanging thickly amid the dark green foliage present delightful effects. Some houses have their walls covered from ground-level to eaves with this Passion Flower, and the hundreds of bright globes strung on the dark background give the idea of an illumination. One of the sights of the month has been a fine plant of *Plumbago capensis* growing against a perpendicular cliff, sheltered from the north and east, in the public gardens at Torquay. This specimen must be 10 feet or 12 feet in height and almost as much in spread, and has produced a lavish display of pale blue flower-clusters. It is to be hoped that the plant in question, which has already passed three winters in the open unscathed, may remain uninjured for many more years and increase in size and attractiveness. *Solanum jasminoides* has become even whiter with bloom in September than was the case in August, when it appeared to have arrived at its culminating point of beauty, and in the closing days of the past month presented a lovely picture with its innumerable white flower-sprays hanging from the eaves downward, a very cataract of blossom. *Jasminum revolutum* is producing its bright yellow flowers, and on *Stauntonia latifolia* the long, rounded seed-pods are assuming a purple tint, while *Physianthus albens* bears its great irregularly-shaped, corrugated seed-vessels

as large as cricket balls on its straggling growths. Of *Tropæolums*, *T. speciosum* (the Flame Nasturtium) is for the most part displaying its purple seeds, but in certain instances is still in flower, this being the case in a garden I lately visited, where the branches of a Yew were still scarlet with this *Tropæolum's* vivid flower-trails. *T. tuberosum* is, however, at the present time more generally decorative than *T. speciosum*, its large orange and scarlet blossoms standing well out from the thickly growing background of leafage and presenting a brilliant autumnal picture. The climbing form of *T. Lobbianum* still retains its attractiveness and mantles walls with a veil of rich scarlet, while the gold of the Canary Creeper (*T. canariensis*) is still bright where seed has been sown in the open during the summer. Many of the Vines are becoming exceptionally beautiful, this being especially the case with *Vitis Coignetia*, whose reddening leaves, when the level rays of the setting sun shine through them, assume a wonderful richness of colouring. The foliage of the Grape Vines shrouding a pergola is becoming of a pale yellow-green hue, and the thickly-set bunches of fruit that hang from the canopy are being rapidly rifled by the birds as soon as they exhibit a sign of colouring. *V. humulifolia* is a pretty and distinct Vine, especially charming when bearing its turquoise-hued fruit. The Virginian Creepers have been later than usual in changing colour, *Vitis inconstans* on cliffs and walls not having as yet attained the perfection of its autumnal brilliance.

S. W. F.

Dianthus Heddwigi for button-holes.

—On several occasions I have potted up a few of the healthiest-looking plants of this *Dianthus*, and kept them going gently in a cool house or frame for a supply of button-holes through the early winter months. They are usually much liked for the purpose, especially if care is taken to lift only those with good coloured blossoms. The chief requirements are a cool and airy atmosphere in the house and not too much moisture either in the air or at the roots. The soil is a secondary matter, any light kind answering well.—H. R.

Lobelia Carmine Gem.—In the Gunnersbury House Gardens I saw recently the brilliant new *Lobelia Carmine Gem* in fine form. It seems to me to be an acquisition, as it was flowering more freely than any other of the section that I have seen this year. It has the branching habit of Firefly, and this habit, produced in such a dry and hot season, speaks volumes in its praise. It was not all due to the plants having received plenty of water, as I saw many plants of *L. Queen Victoria* in a swamp by the lake-side at Kew the same day, and these were not nearly so well flowered. The colour is one that requires to be used with judgment in the garden, as it would kill any other shade of red, and there are not many things with which it would blend. Probably it would look best grouped by itself in a green setting, but it is certainly a plant that should find a position in every garden, as its brilliance late in the season could not fail to please.—J. C. TALLACK.

Heliotropes in the flower garden.—Well-grown *Heliotropes* have a charm about them that is not associated with many other flowers. The wonder is they are not more frequently used in the flower garden. They look well in a mass with an edging of some other plant, but they seem to possess a bolder aspect when employed as dot plants in a groundwork of some other dwarf plant. For this purpose they need to be strong. The old Miss Nightingale was once a great favourite, and for massing still is, but some of the larger flowered kinds are finer for the purpose. Swanley Giant forms immense heads of fragrant flowers. Pot-grown plants trained into columnar shape are very striking plunged in beds among other flowers or on the turf. The finest *Heliotropes* for colour and size of their heads I remember having seen were at Gunnersbury House. These were planted among the small fibrous-rooted *Begonia Princess Beatrice*, a

variety that makes an excellent carpet. These at Gunnersbury were distinct in colour, and do as well in pots as outdoors.—S.

NOTES AND QUESTIONS.—FLOWER.

Cactus Dahlia Eileen Palliser.—This yellow sort is most attractive. It is of a deep rich tint, and the most remarkable thing in the flower is its fine full centre. This makes it valuable, because most of the yellows in commerce are wanting in that respect.—H.

Limncharis Humboldti not flowering.—I have grown this for the last two years in a tub in my greenhouse, but am much disappointed in getting no flowers from it, although it has produced abundance of leaves of large size. Can you suggest any reason for the want of flowers? I have been successful in flowering *Eichornia crassipes* in a pan in the same greenhouse in which a *Stephanotis* and a *Hoya carnosa* bloom freely.—C. J. F.

Selecting Cactus Dahlias.—When visiting Dahlia shows in the autumn, how often does one see persons jotting down the names of varieties which happen to take their fancy. It is well known that many would-be Dahlia growers visit shows for the purpose of selecting varieties for their own gardens in preference to making an examination of the growing plants in the nursery. It may happen that the flower showing up most conspicuously on the stand is never seen on the plant, owing to its short stalk and habit of hiding itself in the foliage. The moral then is obvious. Do not be led away with the appearance of Cactus Dahlias at shows, but see them growing before giving an order.—H. H.

GARDEN FLORA.

PLATE 1244.

PRUNUS PSEUDO-CERASUS (SINGLE VAR.).

(WITH A COLOURED PLATE.*)

THE accompanying plate represents one of the several single forms of the Japanese Cherry that have been imported from Japan during the last few years. This Cherry—the accepted name for which is now *Prunus pseudo-Cerasus*—is well known in our gardens and nurseries in its double forms, which are grown under various names, such as *Cerasus Watereri*, *C. Sieboldi*, *C. Lannesiana*, *C. Caproniana fl.-pl.*, &c. These double-flowered forms vary in the size of the blossoms and in the depth of the rosy tints that suffuse the petals. Of their value as spring-flowering trees it is scarcely necessary to say anything at this date. Although eighty years have passed since the first plants were introduced, it would be difficult even now to name a more beautiful or desirable flowering tree. Perfectly hardy, easily accommodated, and never failing at the flowering time, the species combines in itself almost all the qualities that one asks for in an ornamental tree.

Of the new single-flowered varieties not much can yet be said. The charming spray, however, depicted on the plate shows that although so different from the big double blooms to which we are accustomed, the flowers possess all their charm and delicacy of colour, and if they are not so large they have an even daintier gracefulness. More than twenty varieties of *Prunus pseudo-Cerasus* are grown by the Japanese. About half of these they grow in pots for exportation, and they can now be obtained from nurserymen in this country. The flowers (which in these new varieties are double as well as single) range in colour from almost white to rosy pink. One variety the Japanese call *Ukon* is remarkable for the yellowish green colour that tinges the petals. The name *Prunus*

* Drawn for THE GARDEN by H. G. Moon in Messrs. Sander's nursery at St. Albans. Lithographed and printed by J. L. Goffart.

pendula which appears on the plate has been given, perhaps, to this Cherry because of its perfectly pendulous flowers. This name belongs, however, to a quite different tree—a Cherry from Japan, known in nurseries as *Cerasus pendula rosea*.
W. J. B.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

EARLY VINES.—Vines intended to be started in November should be pruned as soon as they are ready—that is, when the leaves have fallen. With me the leaves are being carried later than usual, but I look on this as a good rather than a bad

and that the bud points in the right direction. Where young rods are being run up to replace the older ones, all spurs on the old rods likely to produce shoots that would crowd growth on the younger rods next year should be sawn close off to the main stem, leaving, of course, those towards the top of the house until the full length of rafter is furnished by new rods, when the old should be cut out entirely. By a judicious use of this method on Vines that have become old, but whose roots are in good condition, the house may be refurnished with young rods without any perceptible loss of crop. Cleaning should follow close on pruning. Little, if any, bark should be removed except that which peels off, without using any force. Every portion of the house should be subjected to the scrubbing brush, soft soap and hot water treatment, which I have recommended for other houses in earlier notes, and, as a supplementary precaution in houses where mealy bug

BOTTLING GRAPES.—Where houses are leaky, or where plants have to come into the vinerias at this time of the year it is a relief to get rid of the Grapes. To keep the latter in good condition for some months is a very simple matter provided one has a thoroughly dry room. The two essentials are dryness and coolness, and I find that the colder the store room is kept short of freezing the better the Grapes will keep. I have kept them all through the winter with no artificial heat, and I believe that those who have failed or partly failed to keep Grapes sound and plump after bottling them have done so through coddling them with fire-heat and over ventilation. The best Grape room I ever had was a loft, the windows of which were shut tightly and darkened all the time it was occupied with Grapes. There were no ventilators provided, and the only means of heating or drying used were a few gas-burners, which were seldom lighted. Pure spring water was used for filling the bottles, and this did not need changing during the whole period through which the Grapes were kept, neither was it often necessary to add any water, as the cool and somewhat close conditions which prevailed in the room brought evaporation to its lowest point. Another thing which I proved to be unnecessary was charring the freshly cut ends of the stems, the bunches being cut with sufficient length of wood to go fairly well down into the water, and in the case of bunches which were growing too near the bunch to allow of sufficient wood below the bunch to reach the water, the other end was left long and the stem reversed. Before cutting the Grapes the room was subjected to a good drying-out process for a day or two, and the bottles were filled and put into position, after which it was only necessary to choose a bright dry day for cutting, divesting the wood of all leaves and leaf-stems; take the bunches direct to the room, and prevent spilling any water about when inserting the stems in the bottles. Each stem should reach the water and be pushed down 1 inch or 2 inches into it, as there will be some amount of absorption at first.

ORCHARD HOUSE.—As the various orchard house fruits are gathered the trees should be put outside in a nice open position, where they will not be subjected to drip from trees or overhanging buildings. Any that appear to require potting should be attended to, using the best loam it is possible to get, for these trees have much work to do with a very limited root-run, so that it is necessary to see that they have a good larder. Others may require attention in the way of drainage, for, in spite of the best care when potting, the drainage material is liable to get out of place, or clogged now and then, and this does much harm, as one cannot feed such trees when they require it so freely as one could wish to do. Renewing the

drainage is a matter that requires much care, and should only be put in the hands of a man with a good eye, for it is not easy to so adjust the new material that the tree will go back into its pot to the exact depth to which it had been; and, again, it should go into exactly the same position, for pots are sure to vary a little in shape, and a ball of soil filled with roots cannot be made to adapt itself to any other position than the one it has already occupied, and to alter this in any way is to store up future trouble. What little pruning has been necessary for pot trees will probably be done before now; if not, there should be no further delay in dealing with all kinds of stone fruits, especially Cherries, which are so susceptible to injury from the use of the knife, for by doing the pruning in late summer or during the autumn much of the danger of gumming is averted and the cut surfaces heal over more readily.

CORNUBIAN.

Example of terrace garden with trees in true form (Sandside, Thurso, N.B.). From a photograph by Miss K. Pilkington. (See p. 295.)

sign, especially as the foliage now left on is not that of the sub-laterals, but the main leaves of the laterals themselves, and these assist the buds greatly up to the time they drop. The wood is in fine hard condition, so that the buds can hardly fail to break well when the Vines are started. When pruning one always likes to cut back to a fairly plump bud, but I am not sure that harm has not been done at times by the advice to prune to the "best" bud, the "best" being sometimes interpreted to mean the largest bud within reasonable distance of the spur, and in this way not only have the spurs been lengthened inordinately and become ugly, but loose bunches instead of compact ones have resulted. There are some varieties which require to be grown on long spurs, but these are mostly late Grapes and not those chosen for forcing, therefore, of the latter it may be said that the closer back they are cut the better, provided a good leaf has ripened off at the same joint that has produced the chosen bud,

has appeared, it would be wise to rub petroleum into crevices in wood and brick-work. Then the Vines should be scrubbed over with a solution of some insecticide powerful enough to kill insect life, but not so strong as to injure the wood or buds. Mixtures of dressing thickened up with clay or some other dirty substance I never tolerate, for I look upon them as a filthy and useless nuisance, disfiguring to any plants which one may have to grow under the Vines during the spring time when the syringe is being used. After being scrubbed, the Vines should be suspended so that the ends of the rods are lower than the middle portion, and quite young rods may be tied to the trellis with their tips at the lowest elevation, as this will induce regularity in the breaking of the buds. Before reckoning the work complete, a little of the surface of the border should be carefully removed to get rid of any insects or eggs that may have fallen, and this should be replaced by some new soil.

KITCHEN GARDEN.

LIFTING EARLY BEETROOT.—Early-sown breadths of long varieties, also Turnip-rooted Beet, may now be taken up, sorted, and removed to the root shed. The best way is to size them, placing the coarsest by themselves for immediate use. The shapely, medium-sized roots are most appreciated for the salad bowl. Care must be taken when lifting not to injure the tap-root, and when removing the superfluous soil a knife should not be used, or the skin may be broken, and bleeding and consequent discoloration when cooked follow. Some gardeners cut the tops off close to the crown, but I think this wrong, as the knife is apt to go too deeply. The same thing sometimes happens when the tops are screwed off. Leave a fair length of leaf-stalk and store in moist soil or sand, putting a good thickness of the latter between each layer of roots. If any choice strain is needed for seed next year, the best plan is to select the required number of medium-sized, symmetrical roots and preserve them in a clamp by themselves. Cover with a good thickness of dry Bracken and afterwards with soil, sinking a Seakale pot at the top of the clamp as a means of ventilation in mild weather. During frost or snow the mouth of the pot must be stopped up. Where shed room of the right kind is scarce, every other row of roots may be lifted, and the others earthed up at the end of the month to protect from frost. Beet will stand a good few degrees of frost and take no harm if covered with Bracken or litter.

JERUSALEM ARTICHOKE.—These are considered better when the ground has been frozen; consequently lifting the main crop is postponed till November or December. Still, where they are now in demand a limited quantity may be lifted and covered with soil in a perfectly cool position in the open. All the small tubers should be reserved for seed in the spring. The Chinese Artichoke (*Stachys tuberosa*) is a favourite with many, and when properly cooked and served with sauce makes an agreeable change in the dining-room. The first or second week in November is a good date for lifting them, although they are quite hardy, and might, except for the inconvenience in lifting caused by frost, be left in the ground all the winter.

LIFTING HORN CARROTS.—Although Carrots are not easily injured by frost, it is far the best to lift the various sorts as they mature, so that the ground may be turned up as soon as possible and subjected to the beneficial influences of frost and wind. Moreover, digging roots during very severe weather is a very unpleasant, as it is also an unprofitable, operation. Where ample shedding exists it is a capital plan to let the Carrots lie loosely for a few days so that they may dry somewhat, and they can be sorted and finally stored on wet days. Carrots keep capitally in the open air covered with sand, ashes or leaf-mould; indeed, this is probably the very best position for late breadths which are to supply the kitchen during the spring months. The lifting must at present be confined to the Horn section, such sorts as Long Red Surrey, Altringham and some of the improved strains of Intermediate, which are about as long again as the original James's, being best left in the ground some time longer. Spring shrivelling is one of the evils resulting from too early lifting. Late-sown Carrots for autumn and early winter, whether grown in pits, frames or the open garden, must be kept quite free from weeds and rubbish, so that they may enjoy what sun there is and a free circulation of air.

WINTER TURNIPS.—Breadths of Chirk Castle or Orange Jelly sown for a supply during winter will now be of a considerable size, and may be encouraged by one or more moderate applications of guano or fish manure. Later batches having bulbs no larger than Walnuts will be much benefited by frequent stirrings with the Dutch hoe, as, provided the winter is mild, Chirk Castle will continue to swell till the new year, a portion of the sowing also supplying tender tops later on. Any full-grown bulbs of Golden Ball should be lifted and stored beneath ashes behind a north wall, as if left in the ground longer, splitting

and decay may in the event of excessive rains work destruction.

SALSIFY AND SCORZONERA.—It is too early yet to lift these, as healthy rows on good ground will increase in size and improve generally for some time to come. I am afraid many early sown lots will, owing to the tropical heat and drought, have run to seed. This should teach gardeners the folly of sowing this vegetable too early. Another good soaking of farmyard liquid may be given, as thin, wiry roots possess very little quality. The Russian is an improvement on the original strain.

ROUTINE WORK.—In many districts copious rains have fallen, these having induced fresh colonies of weeds amongst late-planted crops. After a few dry, windy days the hoe should again be put through and the weeds raked off. If left on the ground at this time of year they only grow again. Remove from the quarter all exhausted Pea, Bean, and Marrow haulm, and in gardens minus Box edging where salt is still used for killing weeds, give another and final sprinkling.

J. C.

ORCHARD AND FRUIT GARDEN.

LATE STRAWBERRIES.

In reading over the able article on the above subject in THE GARDEN for September 9 the following sentences rather surprised me, viz., "I cannot too much impress upon cultivators the importance of securing a crop the first year. It is seldom one sees that in gardens, but it is just as easy to have the crop as not. Layer the Strawberry runners in July on a ridge of good soil laid between the rows," &c. With me the Strawberry is a very important crop, and the garden soil a very light loam on gravel. I have for years gathered the finest dessert fruit from plants planted early in August of the previous year. I also know many other gardeners who do the same; indeed, the practice is by no means so very uncommon as your correspondent "J. S. W." would lead us to suppose. At one time, when living in Roxburghshire, in Scotland, I used to pinch off all the flower-stems the first year, and by so doing secured immense crops of large fruit the second and third years. James Veitch Strawberry treated in this way produced the largest and finest fruits I have ever seen, yet the same variety only succeeds moderately here, soil and climatic conditions being so diverse. Under this method of culture I used to have a grand supply of excellent fruit for dessert.

My method for years past has been as follows: Early in July I have the required number of 4-inch pots prepared by placing a piece of turf in the bottom without any crocks, then filled with good loam to which a little leaf-mould is added. The pots are then taken on a hand-barrow to the Strawberry quarter and placed between the rows of plants. The runners are pegged into the pots with Bracken twigs, which suit very well and are easily made and quickly used. As soon as the runners are rooting into the pots they are severed from the parent plants, the pots removed to a convenient place (each variety stood separately), which makes watering easier and more quickly performed. All the ground for Strawberries is trenched during the winter from 2 feet to 3 feet deep, heavily manured and generally cropped with early Peas. When the Pea crop is cleared off, a heavy coating of well-decomposed farmyard manure is dug in, the ground then made firm by rolling or by treading, the rows then marked out and drills drawn with a draw-hoe. The plants are laid out along the drills, each pot being dipped in a bucket of water before being turned

out. This, I find, prevents any plant being set out with the ball dry. This season, owing to extra pressure of work at the time, I had a number of runners layered in soil placed between the rows, carefully attended to with water afterwards, lifted when rooted, and carefully planted in a break where another thousand plants were planted out of pots, the difference between the plants being most remarkable. The pot plants started away freely and have not required half the attention in watering the others have. The whole break was planted in the second week of August, and even now (September 12) one can see at a glance the benefit of layering into pots. Some may think it a heavy undertaking to layer Strawberry runners into pots, yet it is not so. The pots I use are those the bedding plants are turned out of. Sometimes the pots are washed before being used for the Strawberry runners, but as often not; indeed, I have never noticed any difference so far as washing the pots is concerned. After many years' practice I am confident it pays well in the long run to layer into pots, and is after all a saving of labour compared with the layering into soil.

In the same article referred to the writer, in treating of mulching, recommends short grass from the lawn mower. I have tried most, if not all, of the different materials recommended from time to time for mulching newly-planted Strawberries, and have long since come to the conclusion that nothing equals old hotbed materials. For mulching to keep the fruit clean, nothing I have ever tried equals clean Wheat straw, being easily and quickly applied after the fruit is set. It has a clean appearance, and even if battered down with heavy rains expands again with sunshine. When cleared off after the fruit is gathered it does well for littering. My motto in Strawberry culture may be summed up very shortly. Select an open site; trench in autumn or winter 2 feet or 3 feet deep; manure heavily with farmyard manure. Before planting the Strawberry plants, give a good dressing of decomposed manure; dig it deeply in; make the ground firm after digging; water the plants well after planting; mulch with old hotbed material if weather continues dry; water repeatedly, and the following season the result will be a fine crop of splendid fruit.

As to varieties, I have tried many, both new and old, and find after several years' experience that it is quite impossible to have Strawberries anything like so late in the south as in the north, or even in the midlands. My best late sort taken all round here is President. Keens' Seedling planted in August last year ripened its fruit this year in the second week in July; so much for lateness. Elton Pine got so eaten up with red spider on our light soil that I have discarded it altogether, although in Sussex on a cooler subsoil it succeeded admirably. Alpines I do not grow, as Strawberries are not wanted after August. My forced Strawberries are wanted about the middle of March, and the supply is kept up until the outdoor crops are ripe. I rather think Strawberries in September are more of a novelty than anything else in this part at least, there being so many other fruits fit for dessert at that time. DAVID KEMP.

Stoke Park Gardens, Slough.

Apple Tyler's Kernel.—The present season appears to have suited this Apple, as the fruits individually have grown to a very large size and have coloured splendidly. Although by no means a new sort, it is not so well known out of its native county of Hereford as it deserves to be. It is a first-rate Apple in every respect as regards size, colour, and quality. It is also an

excellent market variety, as it is not only a good bearer, but is also a healthy and vigorous grower, and soon forms a good tree. Tyler's Kernel received a first-class certificate from the Royal Horticultural Society in 1833, but it has been grown in Herefordshire orchards for many years.—A. W.

Apple King of the Pippins.—Good as this Apple is and prized for dessert, a good deal has been said and written against it by those who happen not to have succeeded with it. Some consider it an uncertain Apple as a standard on the Crab, but I have seen many fine old trees so grown, with lofty, wide-spreading heads, bearing annually heavy crops of the finest fruit. My belief is that King of the Pippins should not be planted in low-lying positions or in cold, retentive soils. By far the best trees I have seen have been in light, well-drained soils. In the former it is likely to canker and die off. I lately saw a grand tree in a villa garden in the rudest possible health and carrying a good crop of full-sized, clean fruit. Such fruit in a season like the present is sure to be appreciated, and would if sold fetch a good price. I prefer the upright-growing variety, which bears very conical, highly-coloured fruit.—C. N. N.

Young Strawberry plants.—Those gardeners who this year planted their young Strawberry plants on solid ground, either between rows of spring-sown Onions, the latter being 2 feet apart or on plots prepared some months beforehand and well trodden or rolled several times, will now be reaping the benefit. Such a medium retains the moisture much better and encourages the formation of a colony of fibrous roots. Those who neglected to mulch round the young plants, especially on shallow, warm soils, will find that, owing to excessive evaporation, growth is less vigorous than usual. Plants treated as above, and watered say twice with farmyard liquid, or even given a sprinkling of some quick-acting artificial manure before the mulch is laid on and then watered home, stand an infinitely better chance of developing robust foliage and prominent crowns than those put out into loose, dry ground and allowed to take care of themselves.—J. C.

PEARS ADOPTED BY THE CONGRÈS POMOLOGIQUE OF FRANCE.

(Concluded from p. 235.)

ORPHELIN D'ENGHIEN (*syns.*, *Beurré d'Arenberg*, *Beurré Deschamps*, *Beurré des Orphelins*, *Colmar Deschamps*, *d'Arenberg parfait*, *Duc d'Arenberg*).—Originally raised about 1820 by the Abbé Deschamps, director of the Orphan Hospital at Enghien, Belgium. The fruit is of medium size, pyriform, with a very bumpy surface. The stalk is short, stout, fleshy, set sideways, level with the fruit or in a small cavity. The eye is small, irregular, almost closed in a normal and regular cavity. The skin is rough, yellow, stippled and streaked russet almost all over. The flesh is whitish, very delicate, and melting. A very good fruit, ripening November—January. The tree is of medium vigour on the Quince, of good and sustained fertility. In cultivation this variety, easily trained, is not hardy, and does best as an espalier. It makes better growth on the Pear.

PASSE COLMAR (*syns.*, *Ananas d'hiver*, *Cellite*, *Fondante de Paris*, *Passe Colmar doré*, *Passe Colmar gris*, *Passe Colmar tardif*, *Passe Colmar vincux*).—Obtained originally by the Abbé Hardenpont at Mons. It first fruited in 1758. The fruit is medium or fair-sized, turbinate, more or less long and more or less regular. The stalk is of medium strength and length, set obliquely on the point. The eye is medium-sized, open, set in a superficial depression. The skin is thin, yellow, stippled grey, washed carmine on the sunny side. The flesh is white, very delicate, and highly aromatic. A very good fruit, ripening December—January. The tree is of normal vigour on the Quince and of great and sustained fertility, but with sometimes long interruptions.

In cultivation this variety is suitable for regular forms, especially those attached to trellises, upon which its fruit, which is very liable to fall, hangs better.

PASSE CRASSANE.—Originally obtained by M. Boisbunel, of Rouen. It first fruited in 1855. It is a medium or fair-sized fruit, in form Bergamot. The stalk is fairly thick, of medium length, set straight in a small cavity. The eye is medium-sized, open, in a wide, shallow and regular cavity, the skin rough, pale dull green, streaked and stained red-brown, changing to light yellow on the sunny side. The flesh is very white, delicate, and agreeable. A very good fruit, ripening January to March. The tree is of continuous vigour on the Quince, of good and sustained fertility. In cultivation this variety is easily trained and demands no particular care.

PRÉCOCE DE TRÉVOUX.—Originally obtained by M. Treyve at Trévoux (Ain). It first fruited in 1862. The fruit is of medium size, oftenest in Bon Chrétien shape, widely truncated at the stalk, which is of medium length and thickness, set rather obliquely in a little russet-covered fold. The eye is small, closed, with erect sepals generally projecting from a slight wrinkled rose-stained depression. The skin is delicate and tender, bright yellow, very finely stippled green, washed rose-carmine on the sunny side. The flesh is white, delicate, juicy, and agreeably aromatic. A good or very good fruit, ripening the beginning of August. The tree is very vigorous and fertile. In cultivation this variety is suitable for all forms of a certain extent. On the Quince it comes early into bearing.

PRÉMIÈRES D'ECULLY.—Originally obtained in 1847 by M. G. Luizet, senior, of Ecully-sur-Lyon. It first fruited in 1855. The fruit is fair-sized, truncated and embossed at the stalk. The stalk is stout, swollen at the point of attachment, of medium length, curved, set rather obliquely in a wide, superficial cavity. The eye is medium, half-closed or open, in a somewhat deep wrinkled and embossed cavity. The skin is smooth, light yellow, slightly shaded rose on the sunny side, finely stippled greenish grey. The flesh is white, very juicy, and with a very agreeable musky flavour. A very good fruit, ripening September to October. The tree is vigorous on the Quince, of great and sustained fertility. In cultivation this variety is easily trained, and lends itself to all forms. On an espalier the fruit is of excellent quality.

PRESIDENT DROUARD.—Originated among some seedlings found near Pont de Cé (Maine-et-Loire) by M. Olivier, gardener at Angers. The fruit is fair-sized, the stalk short, rather bent, set rather obliquely in an irregular embossed cavity. The eye is small and open, in a deep and regular cavity. The skin is nearly smooth, slightly unctuous, a uniform yellow, finely stippled tawny. The flesh is white, delicate, and agreeably aromatic. A very good fruit, ripening January. The tree is vigorous and fertile. In cultivation this variety lends itself to all forms on the Quince.

PRESIDENT MAS.—Originally obtained by M. Boisbunel, of Rouen. It first fruited in 1865. The fruit is large, conical, the stalk short, of medium stoutness, set rather obliquely in a small, rather embossed cavity. The eye is medium-sized, open, in a deeply embossed cavity. The skin is rather rough, yellowish green, much stippled russet, streaked and stained tawny about the eye. The flesh is white and very agreeably aromatic. A very good fruit, ripening November—January. The tree is vigous and fertile. In cultivation this variety requires to be grafted on the Quince. Its vigour and neatness make it suitable for all forms.

PROFESSEUR HORTOLÉS.—Originally obtained by M. F. Morel, of Lyons. It first fruited in 1864. The fruit is fair-sized, taking generally the Beurré d'Amanlis form, sometimes calabash form. The stalk is stout, short, set obliquely in a small embossed cavity. The skin is smooth, delicate greenish yellow, heightened with rose, and streaked red-brown on the sunny side,

stippled grey all over. The flesh is white, delicate, and delicately aromatic. A very good fruit, ripening September—October. The tree is very vigorous and very fertile. In cultivation this variety, sufficiently vigorous on the Quince, lends itself to all forms. The finely coloured and pretty-to-look-at fruit finds a quick sale in markets.

ROUSSELET D'AOUT (*syn.*, *Gros Rousselet d'Aout*).—Originally obtained by Van Mons at Brussels and propagated by M. Millot at Nancy. The fruit is medium-sized, pyriform. The stalk is long, stout, curved, set at the point of the fruit. The eye is large, open, set flush with the fruit or in a slight depression. The skin is smooth, light yellow and green, stippled grey-green, shaded rose on the sunny side. The flesh is white, melting and agreeably aromatic. A good fruit, ripening in August. The tree is vigorous on the Quince, of good, but inconstant fertility. In cultivation this healthy, vigorous variety is well adapted for regular forms. It behaves well as a standard on the natural stock.

ROUSSELET DE REMIS (*syns.*, *Perdreau musqué*, *Petit Rousselet*, *Rousselet musqué*).—Of ancient unknown origin. The fruit is small, the stalk thin, of medium length, curved, set nearly straight at the point. The eye is large, open, regular, set flush with the fruit. The skin is smooth, pale yellow, tinged reddish brown on the sunny side and stippled grey all over. The flesh is yellowish white, richly and agreeably musky. The fruit is good raw and very good cooked. The tree is of normal vigour on the Quince and on the natural stock of very great and sustained fertility. In cultivation this variety is rather delicate, and only does well on dry, high soils. It is best grafted on the Pear and trained as a standard.

ROYALE D'HIVER (*syns.*, *Duchesse de Montebello*, *Pera Casentina*, *Pera Passana*, *Spina de Carpi*).—Of ancient and uncertain origin. The fruit is large, the stalk long, slender, but thickened at the two ends, set obliquely in an irregular embossed cavity. The eye is medium-sized, regular, open, in a wide, irregular depression; the skin citron-yellow, washed orange-red on the sunny side, stippled and mottled tawny; the flesh yellowish and well flavoured. A good fruit, ripening November—January. The tree is vigorous on the Quince and on the natural stock, and requires age to fruit well. In cultivation this variety is easily trained and behaves well as a standard in the southern climates, but requires an espalier and a good exposure in cold soils.

ROYALE VENDÉE.—Originally obtained in 1860 by M. Eug. des Nonhes in his Cacauidière property in the commune of Ponzange (Vendée). The fruit is medium-sized, blunted near the stalk. The stalk is fairly short, generally thick and fleshy, set obliquely against a small mound. The eye is large, open, regular, almost projecting. The skin is rough, dull yellowish green, slightly mottled, and streaked grey and light tawny. The flesh is yellowish, melting, very juicy, and delicately aromatic. A very good fruit, ripening January—March. The tree is moderately vigorous even on the natural stock and of great fertility. In cultivation this variety is suitable for all stocks. Pyramids are generally very good the third year.

SAINT GERMAIN D'HIVER (*syns.*, *De l'Artheloire*, *Inconnue la Fare*, *Saint Germain*, *Saint Germain doré*).—A chance seedling, found on the borders of La Fare, at Saint Germain d'Arce, near the little town of Lude (Sarthe). The fruit is medium or fair-sized, long, pyriform, often irregular in contour. The stalk is of medium length and thickness, set rather obliquely on the blunted point of the fruit. The eye is medium-sized, half closed, almost projecting. The skin is rough and thick, greenish yellow, stippled red, slightly golden on the sunny side. The flesh is white, delicate, and distinctly aromatic. A very good fruit, ripening November—March. The tree is vigorous on the Quince, of very great and sustained fertility. In cultivation this variety forms excellent pyramids, but is delicate. As an espalier it does well.

SAINT GERMAIN PANACHÉ.—This variety is distinguished from the type by its mottled yellow and green branches, as also by the fruits, which are fair-sized and light yellow, being marked with little longitudinal bands.

SAINT GERMAIN GRIS (*syn.*, *Saint Germain brun*).—Originally found about 1804 by M. Prévost in the old monastery garden of Saint Ouen, Rouen. A medium-sized fruit, the stalk thickish, curved, set rather obliquely in an oblique depression. The eye is medium-sized, open, and but slightly depressed. The skin is wrinkled, grey-green, stippled and streaked brown; the flesh yellow, juicy, and distinct in aroma. A very good fruit, maturing November—January. The tree is moderately vigorous on the Quince. In cultivation this variety should preferably be grafted on the natural stock.

N.B.—Many pomologists are of opinion that Saint Germain gris is only a variety of Saint Germain d'hiver and Saint Germain panaché.

SAINT MICHEL ARCHANGE.—Of uncertain origin. It is believed to have been raised in the neighbourhood of Nantes at the middle of the last century. The fruit is medium-sized or fairly large, pyriform. The stalk is thick, sometimes rather short, set on the point or in a slight cavity. The eye is small, almost closed, in a wide and embossed cavity. The skin is delicate, green, stippled tawny, washed and streaked orange-red on the sunny side. The flesh is yellow, delicate, and very juicy. A very good fruit, ripening September—October. The tree is of normal vigour on the Quince, of great and sustained fertility. In cultivation this easily trained variety does well as a pyramid.

SAINT NICOLAS (*syns.*, *Beurré Saint Nicolas*, *Duchesse d'Orléans*).—Originally found by M. Maurier at the Garenne de Saint Nicolas at Angers, and propagated by M. Flon in that town. It first fruited in 1839. The fruit is medium-sized, the stalk thick, swollen, and fleshy at the two ends, of medium length, set obliquely at the point of the fruit. The eye is medium-sized, half closed, placed almost flush with the fruit or in a wide depression. The skin is fine, bright yellow, streaked light tawny, with orange tones on the sunny side. The flesh is yellowish white, very delicate, melting, and deliciously aromatic. A very good fruit, ripening October. The tree is of normal vigour on the Quince, but of inconstant fertility. In cultivation this variety does best in a well-drained, generous soil, and is best grafted on the Pear.

SECKEL (*syns.*, *New York Red Cheek*, *Seckle Pear*, *Shakespeare*).—Originally found, about 1760, on the banks of the Delaware River, in a forest of Philadelphia. The fruit is small or turbinate, round-headed, the stalk short, set in a scarcely perceptible cavity. The eye is small, regular, open, set flush with the fruit. The skin is thin, rather rough, dark yellow, covered with golden rust, washed largely dull red on the sunny side. The flesh is white, delicate, half-melting, and highly aromatic. A very good fruit, ripening September to October. The tree is insufficiently vigorous on the Quince, of precocious, very great and sustained fertility. In cultivation this variety should be grafted on the Pear. It is especially adapted for standards.

SENATEUR VAISSE.—Originally obtained by M. Lagrange at Oullins, near Lyons. It first fruited in 1861. The fruit is medium-sized, conical, as wide as high. The stalk is thick and fleshy, of normal length, seldom short, set in a small embossed cavity; the eye small, irregular, in a deep, wide and embossed cavity; the skin fine, bright yellow, stippled and streaked tawny, mottled red on the sunny side. The flesh is yellowish, very juicy, and delicately aromatic. A good fruit, ripening August to September. The tree is of medium vigour on the Quince, of good vigour on the natural stock, of great and sustained fertility. In cultivation this variety behaves well in all forms.

SEIGNEUR (*syns.*, *Belle Lucrative*, *Bergamote Ficée*, *Beurré Lucratif*, *Fondante d'Automne*, *Fondante de Maubeuge*, *Gresillier*, *Seigneur Es-*

peren).—Originally obtained by Major Esperen, of Malines. It first fruited in 1827. The fruit is medium or of fair size, the stalk short, fleshy, often ringed, set almost straight in a small crease. The eye is small, open, in a wide depression. The skin is rough, light yellow, mottled and streaked tawny, with a warmer tone on the sunny side. The flesh is white, delicate, very juicy, and deliciously aromatic. A very good fruit, ripening September to October. The tree is of normal vigour on the Quince, of early and constant fertility. In cultivation this variety succeeds on all stocks and lends itself to all forms. The fruit should be gathered at intervals.

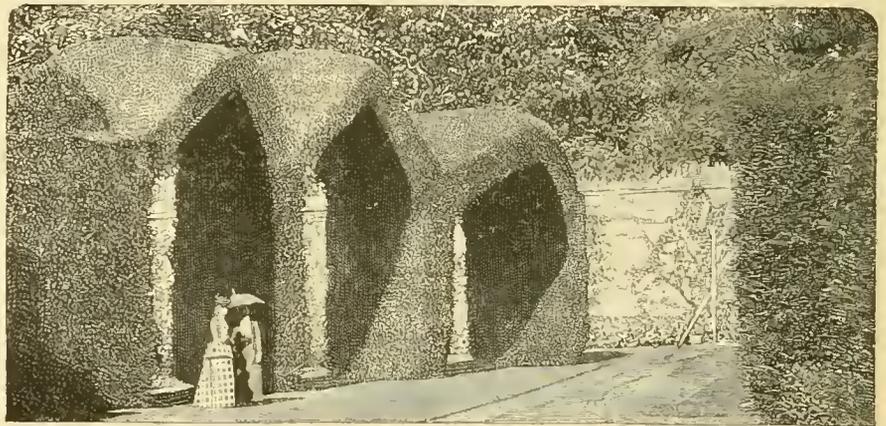

SEUR GREGOIRE.—Originally raised by M. Gregoire-Nelis, of Jodoigne (Belgium). It first fruited in 1858. The fruit is large, Bon Chrétien in form. The stalk is of medium stoutness and length, set in a deep and embossed depression. The eye is large, open, in a deep, bumpy depression. The skin is wrinkled, thick, yellow, streaked and stained reddish grey, and shaded dull red on the sunny side. The flesh is white, melting, and agreeably aromatic. A very good fruit, ripening November—January. The tree is of normal vigour on the Quince and fertile. This variety does best in a light, warm soil.

SOLDAT LABOUREUR (*syn.*, *Beurré de Blumenbach*).—Originally obtained by Major Esperen, of Malines. It first fruited in 1820. The fruit is of fair size, ovoid pyriform, or turbinate. The stalk is of medium length or short, sometimes woody,

and stout, sometimes more slender and of medium length, set most frequently in a small embossed cavity. The eye is large, open, set in a deep, shallow cavity. The skin is thin, golden, stained light tawny near the stalk, tinged with rose on the sunny side. The flesh is white, melting, and slightly musky. A good fruit, ripening August to September. The tree is of normal vigour on the Quince and fertile. In cultivation this easily trained variety does well on all stocks and succeeds in all forms.

SUCRÉE DE MONTLUÇON (*syns.*, *Sucrée verte*, *Sucrin vert*).—Originally found about 1812 in a hedge of the Montluçon College garden by M. Rocher, the gardener. The fruit is of fair size, generally turbinate, and as wide as high. The stalk is slender, of medium length, set rather obliquely in an embossed cavity. The eye is large, regular, half-open, in a shallow, generally regular cavity. The skin is grass-yellow, stippled brown, and of a warmer tone on the sunny side. The flesh is white, delicate, and pleasantly aromatic. A good fruit, ripening September to October. The tree is vigorous on the Quince, of good and sustained fertility. In cultivation this variety succeeds in all positions and soils, and adapts itself to regular forms.

SUZETTE DE BAVAY.—Originally obtained by Major Esperen, of Malines. It first fruited in 1843. The fruit is small or medium-sized, round, conical, more or less short. The stalk is short, woody, straight, in an embossed cavity. The eye

Clipped arches of Yew. (See p. 295.)

sometimes stout and fleshy, set straight in a shallow depression. The eye is large, half closed in a narrow and shallow cavity; the skin smooth, bright yellow, mottled and streaked with russet. The flesh is yellowish, very juicy, and aromatic. A very good fruit, ripening October—December. The tree is of normal vigour on the Quince, of precocious and sustained fertility. In cultivation this easily-trained variety does best as an espalier or in a sheltered position, as the fruits are apt to fall.

SOUVENIR DE BREUIL PÈRE.—Raised by M. Dubreuil when professor at the Jardin des Plantes, Rouen, and sent out by M. Nicolle, of Rouen, about 1856. It is a medium or fair-sized fruit, round, conical, more wide than high. The stalk is slender and short, set in a fairly deep, wrinkled cavity. The eye is small, open, regular, in a narrow and medium deep cavity. The skin is very fine, yellow, stained and streaked with light red. The flesh is white, melting, juicy, and pleasantly aromatic. A very good fruit, ripening November—January. The tree is of middling vigour on the Quince and of medium fertility. In cultivation this variety requires some care to adapt it to regular forms. It does well as an espalier.

SOUVENIR DU CONGRÈS.—This, originally obtained by M. Morel, of Lyon-Vaise, first fruited in 1863. It is a large or very large fruit, pyriform and embossed. The stalk is sometimes short

is medium, closed, irregular, almost prominent; the skin smooth, light green, changing to citron-yellow, streaked brown, slightly orange on the sunny side. The flesh is white, melting, and delicately aromatic. A good fruit, ripening January to April. The tree is of continuous vigour on the Quince, of precocious, very great and constant fertility. In cultivation this variety is easily trained and lends itself to all forms. The pyramidal form is the best for it.

THOMPSON'S (*syns.*, *Van Mons*, *Uesembeek*).—Originally obtained by Van Mons at Dijon before 1820. The fruit is of fair size, obtuse or turbinate. The stalk is short, of medium stoutness, set obliquely in an embossed cavity. The eye is of fair size, open in a superficial depression; the skin light yellow, streaked with grey, mottled and stained with russet. The flesh is white, melting, with a slight aroma of rose. A good or very good fruit, ripening October—November. The tree is of very continuous vigour on the Quince, of good and sustained fertility. In cultivation this variety is easily trained, and forms generally satisfactory pyramids.

TRIOMPHE DE JODOIGNE.—Originally obtained in 1830 by M. Bouvier, burgomaster of Jodoigne. It first fruited in 1843. The fruit is large, in form Bon Chrétien. The stalk is of medium strength and length, set rather obliquely on the fruit. The eye is medium-sized, open, often irregular, in a shallow, broad cavity. The skin

is smooth, light green, changing to citron, washed and stippled dull red on the sunny side. The flesh is white, pleasantly aromatic, and subject to decay at the core. A good fruit, ripening November—December. The tree is vigorous on the Quince, of great and sustained fertility. In cultivation this variety requires care to maintain it in regular forms. It adapts itself well to the espalier form.

TRIOMPHÉ DE VIENNE.—A chance seedling found by M. Cl. Blanchet at Vienne (Isère). The fruit is large, slightly angular, resembling Bon Chrétien in the thickness of its form. The stalk is of normal length and stoutness, set straight in a small wrinkled cavity. The eye is medium, open, in a deep cavity surrounded by bosses. The skin is bright yellow, mottled and finely streaked with russet, tinged rose on the sunny side. The flesh is white, melting, very juicy, and delicately aromatic. A very good fruit, ripening end of August and September. The tree is vigorous and fertile. In cultivation this variety is easily trained and lends itself to all forms.

VAN MONS—LÉON LECLERC.—Originally obtained by M. Léon Leclerc, of Laval, and dedicated to Van Mons. It first fruited in 1828. The fruit is large, cylindrical. The stalk is of medium length and stoutness, set sideways and flush with the fruit. The eye is small, open, regular, in a wide, shallow depression. The skin is grass-yellow, much mottled, and streaked russet. The flesh is greenish, very melting, and delicately aromatic. A very good fruit, ripening October—November. The tree, insufficiently vigorous on the Quince, is fertile. In cultivation this variety is delicate, and requires to be grown as an espalier. It grows more freely on the Pear.

VICE-PRESIDENT DECOYE.—Obtained in 1871 by M. Arsène Sannier at Rouen. A medium or undersized fruit, sometimes turbinate, more frequently barrel-shaped, swelling in the middle, and narrowing equally to the two ends. The stalk is sometimes short, stout, and swollen at the point of attachment, set obliquely at the point. The eye is medium, sometimes open, sometimes closed, in a shallow depression; the skin yellow, mottled and streaked tawny. The flesh is white, slightly gritty, very juicy, and agreeably aromatic. A good or very good fruit, ripening in October. This variety is suitable for all medium forms on the Quince; on the Pear it is slow to fruit.

VIRGOULEUSE (syns., Bufaleuf, Chambrette de Glace, De Laborie, Paradis d'hiver Virgoulée, Virgoullette).—Originally discovered at the village of Virgoulée, near Limoges, about 1650. The fruit is medium-sized, ovoid; the stalk medium, long and stout, rather fleshy near the base, set flush with the fruit; the eye small, open or half closed in a wide wrinkled depression. The skin is smooth, unctuous, tender green, finely stippled and slightly streaked russet; the flesh white and distinctly aromatic. A very good fruit, ripening November—February. The tree is vigorous on the Quince and on the Pear, of very great and sustained fertility. In cultivation this variety does especially well on the Quince, and is grown as an espalier to have sound and abundant fruit.

ZEPHIRIN GREGOIRE.—Originally obtained about 1831 by M. Gregoire-Néllis, of Jodoigne, Belgium, this Pear first fruited in 1843. A small or scarcely average sized fruit, round, conical or turbinate, much embossed. The stalk is of medium length, fleshy near the fruit, which it continues; the eye medium, often irregular, set in a shallow, irregularly embossed cavity; the skin light citron, finely stippled green, stained reddish brown, and tinged red on the sunny side. The flesh is white, melting, and very pleasantly aromatic. A very good fruit, ripening December—February. The tree is delicate on the Quince, of good and sustained fertility. In cultivation this variety is easily trained and ought to be grafted on the Pear for large forms.

BARONNE LEROY.—Originally obtained by M. Th. Boisbunel, of Rouen, in 1870 from a sowing made in 1859. It is a medium sized fruit, hol-

lowed somewhat at the base and rather angular at the top. The stalk is of medium length and stoutness, sometimes long, set straight in a fold. The eye is medium sized, almost closed or half open, in a deep and regular cavity. The skin is yellow, almost wholly tinged with dull red, stippled and slightly streaked russet, and somewhat rough. The flesh is white, luscious and aromatic. A very good fruit, ripening October—November, the tree vigorous and fertile. In cultivation this variety on the Quince forms pretty pyramids.

BERGAMOTE HÉRAULT.—Obtained by M. A. Héraul at Angers from a sowing in 1860. It first fruited in 1870. The fruit is large, irregularly and obtusely hollowed at the base, somewhat angular and embossed. The tawny-coloured stalk is short and stout and very fleshy, set straight in a hollow. The eye is small, closed or half-closed in a narrow depression, more or less deep and wrinkled. The skin is citron-yellow, stippled and streaked russet, especially round the eye and stalk. The flesh is white, somewhat gritty at the centre and delicately aromatic. A very good fruit, ripening December—January. In cultivation this variety grafted on the Quince is suitable for all forms.

BERGAMOTE SANNIER.—Originally obtained in 1870 by M. Arsène Sannier, of Rouen, and brought out in 1874. The fruit is generally average sized, depressed at the ends, and narrowing from the middle to the base. The stalk is short, stout, fleshy, rather inclined in a wide, shallow cavity. The eye is small, half-open, in a wide, very deep cavity. The skin is smooth, dull green, stippled russet on the shaded side, olive-green and glossy on the sunny side. The flesh is white, gritty, otherwise delicate and with a peculiar and agreeable aroma. A very good fruit, ripening January to March; the tree vigorous and very fertile. In cultivation it requires no particular care.

BEURRÉ AMANDE.—Originally obtained in 1870 by M. Arsène Sannier, of Rouen, from a sowing in 1861; brought out in 1874. The fruit is of fair size, of Bon Chrétien form, sometimes turbinate and variable in height, generally angular; the stalk of middling length, stout, and rather fleshy, set sometimes straight, sometimes obliquely in a crease. The eye is small, closed or half-closed, in a narrow, embossed and generally shallow cavity. The skin is citron-yellow, slightly stippled red, more or less stained russet. The flesh is white, gritty at the core. A good fruit, ripening October. In cultivation the tree grows vigorously on the Pear, but is long in fruiting on the Quince. It answers in all forms.

CHARLES COGNÉE.—Originally obtained by M. Charles Cognée, of Troyes, and brought out in 1879. It is of middling size. The stalk is short, of medium strength, set straight, or nearly so, in a deep and much embossed cavity. The eye is open or closed, in a regular and deep cavity. The skin is unctuous, citron-yellow, golden in the sun, and streaked tawny. The flesh is white, somewhat gritty at the core, delicate, melting, mildly and pleasantly flavoured with almond. A good fruit, ripening February to March. The tree is of medium vigour on the Quince and very fertile. In cultivation this variety is fairly vigorous on the Pear. It generally does well as an espalier.

CHARLES ERNEST.—Originally obtained by M. Ernest Baltet, and brought out in 1879 by Baltet frères, of Troyes. A large fruit, somewhat angular. The stalk is short, stout, and curved, set nearly straight on the point or in a crease. The eye is medium, open, with erect sepals, set in a wide, wrinkled, and ribbed cavity. The skin is citron-yellow, often slightly tinted rose on the sunny side, very finely stippled grey on the light side, stippled green on the shaded side. The flesh is white, melting, and aromatic. A fairly good fruit, ripening November—December. The tree is vigorous. It is an easily trained variety, lending itself to all forms, and is at home in all positions.

FONDANTE FOUGÈRE.—Obtained by M. Fougère at St. Priest (Isère) in 1878 from a sowing made in 1871, brought out in 1887. It is of fair size,

irregular in contour, and rather bumpy. The stalk is of medium length, stout, generally swelling at the two extremities, especially the point of attachment, set straight or nearly straight in an embossed hollow. The eye is half closed in a shallow and regular cavity. The skin is pale yellow, much and finely stippled red with some tawny streakings, tinged and stippled rose-carmine on the sunny side. The flesh is white, somewhat gritty near the core, delicate, and agreeably aromatic. A very good fruit, ripening January to March. The tree is of middling vigour, hardy and fertile. This variety is vigorous in nurseries, but less so planted out in the garden. It requires grafting on the Pear. It fruits early.

FAVORITE JOANON.—Obtained in 1883 by M. Joanon at Saint Cyr au Mont d'Or, and sent out in 1889. The fruit is of fair size, narrowing to a blunt point and rather angular. The stalk is stout, somewhat swollen at the two ends, set obliquely on the point. The eye is medium-sized, closed, or half closed in a regular, wide cavity of medium depth. The skin is smooth, yellow, stippled grey, turning to rose, stained a light russet near the stalk. The flesh is white, melting, very juicy, and pleasantly aromatic. A very good fruit, ripening end of August and commencement of September. The tree is of normal vigour, hardy, and fertile. On the Quince this variety is suitable for all regular forms.

GIRAM.—A chance seedling found in a hedge on the Giram estate, near Nagaro (Gers), propagated by Dr. Doat and M. Bazillac. The fruit is small, sometimes rather turbinate, rounded at top, and narrowly obtuse at base. The stalk is long, stout, set almost straight upon the fruit. The eye is medium, open, with erect sepals on the rounded and rather russet summit of the fruit. The skin is rather glossy, apple-green, stippled dull grey, often rose-bronze, and sometimes red on the sunny side. The flesh is very delicate, tender and melting, and pleasantly aromatic. A very good fruit, not liable to turn off, ripening during the first fortnight in August. The tree is fairly vigorous, hardy, and fertile. This early variety is suitable for exposed situations.

JANSEMINE (syns., Canette de Boncouge, Jeanette, Merville-Bouche de Bordeaux).—Of ancient unknown origin, the fruit under the average in size or small, and as wide as high. The stalk is stout, set sometimes obliquely in a wide, shallow cavity, sometimes nearly straight in a slightly marked fold. The eye is large, open, in a wide cavity of variable depth. The skin is grass-green, stippled greyish red, shaded light maroon on the sunny side; flesh white, gritty at the core, rather crisp, and pleasantly aromatic. A fairly good fruit, ripening the middle of July and beginning of August. The tree is of normal vigour and of very great fertility. It is best as an orchard tree. The variety is much valued in the Bordeaux country owing to its great fertility and earliness.

MME. CHAUDY.—Obtained by M. Chaudy at Chaponost (Rhône) from a sowing made in 1861 or 1862, and sent out in 1882. A large fruit, sometimes taking Bon Chrétien shape. The stalk is stout, fleshy, short or medium, set nearly straight in a crease more or less deep. The eye is small, closed or half-closed, in a regular and shallow cavity; the skin slightly rough, pale yellow, stippled grey, red on the sunny side, streaked and stained light russet, especially at the two ends. The flesh is fairly white, gritty at the core. A very good fruit, ripening November. The tree is of normal vigour on the Pear, weak on the Quince. It is fertile and bears early. This variety is suitable for small forms.

NOTAIRE SEPIN.—Originally obtained by M. Rollet at Villefranche (Rhône) about 1860. It is a large Pear, varying in form and size, sometimes Bon Chrétien shape. The stalk is stout, swelling generally near the fruit, set somewhat obliquely or straight in a crease or a more or less marked cavity. The eye is small, closed or half closed, in a medium and wrinkled cavity. The skin is slightly rough, yellow, stippled red, mottled and

streaked russet. The flesh is white, gritty at the core, very juicy, and aromatic. It is very variable in quality, and ripens in January to April. The tree is vigorous and fertile. This tree is suitable for all forms on the Quince, but grows too freely on the Pear to fruit early.

Peach Princess of Wales.—As I have in the past frequently complained of the want of quality in this strikingly handsome Peach, I think it only right to say that this season it has been much better. There is less of the woolly fleshed fruit this year than usual, and it has been much liked in the dining-room. My experience of it leads me to think that it requires a good position and should not be allowed to bear too heavily. The fruit should not be allowed to hang until dead

STOVE AND GREENHOUSE.

AZALEAS.

AZALEAS, with fair treatment and reasonable attention to their well-being, never fail to do well and to outlive the greater portion of other hard-wooded kinds grown in pots; in fact, Azaleas are amongst the longest lived of the various tribes of greenhouse plants. In proof of this I may instance several large collections that are in the hands of some of the market growers near London, many of the specimens in which are known to be fifty years old. They consist mostly of the old white *indica alba* and *Fielder's White*, which is only slightly different

year. As soon as all the flowers are cut, the plants are started into growth in heat and kept there until the buds are as big and plump as large Apple pips, after which, to prevent their blooming before the flowers are wanted, the houses are either thrown open or the plants are moved to the open air. But when the latter course is followed with plants that are forced to come in early, and which are afterwards kept for six months under glass with fire-heat until the weather comes hot, it has a widely different effect to that which follows when plants that do not bloom until the end of the winter or in spring are put out either as soon as they are well out of bloom or whilst the young wood and leaves are both soft, and

Azalea Mrs. Turner; flowers pink, with white margin.

ripe, but be pulled when just a little force has to be used, or the flavour will be spoiled.—H. R.

Apple Beauty of Bath.—Anyone thinking of planting Apples to come in early in the season may with advantage add this to his list, for it is of good quality for an early kind. Being very firm, it will doubtless bear travelling better than *Duchess of Oldenburg*, *Lady Sudeley*, and others of that ilk, while its appearance is all in its favour for market work. The tree is a vigorous, healthy grower, and apparently does well under various forms of training. In a heavy, cold soil it thrives well and the fruit puts on a good colour, which is more than can be said of many kinds.

from the original sort. The plants in question are as full of vigour as it is possible for them ever to have been. They make shoots from 8 inches to 15 inches in length annually, only a small percentage of which fail to flower. The whole of the flowers are cut with from 4 inches to 6 inches of wood attached. The plants are models of skilful cultivation; many of them run from 7 feet in height to 9 feet or 10 feet in diameter, though they are subjected to hard forcing, every year coming into bloom at the beginning of November and onward up to the commencement of the following

the ripening process has not commenced. Yet this is the way that in nine cases out of ten Azaleas are treated. The outcome of this barbarous exposure of plants that have flowered at the end of winter or in spring, when, to do justice to them, all the time that intervenes between their going out of bloom and the close of summer they should be in a genial growing temperature under glass, is that Azaleas are, as a rule, the most unhappy-looking things to be seen in most gardens. One of the results of thus turning out the plants directly the danger from frost is over or soon after is that they

never attain the size they should, although the annual growth is not sufficient to admit of much in the way of cutting, unless the flowers are taken off with a scrap of wood that makes them all but useless.

Another source of weakness that Azaleas, in common with most other hard-wooded plants, suffer from is want of sufficient nutriment. In the case of pot plants of the numerous kinds that bear partial shaking out and repotting annually, the old material which has become exhausted is to a great extent got rid of and its place supplied by new. With Azaleas and other things of a like description, the nature of which is such that they will not submit to be treated in this way, the roots remain for years in the same soil, and unless something is done to make up for what the roots extract from it, the whole becomes so poor that the plants cannot do more than exist in it. This especially is what takes place with old specimens that, after being put into pots as large as it is convenient to give them, shortly become dependent on what they receive in the shape of manure in some form. That old Azaleas can be kept for any length of time full of strength and vigour I have proved with specimens that have remained undisturbed in the same soil for ten years, and at the end of that time they made as much wood as when they were young. It may be well here to say that peat of even the best quality is not rich enough to enable Azaleas to make the growth they should do. The assistance that is required in this way to either get young Azaleas on quickly or to keep up the vigour of old plants is much more than seems to be generally supposed. When ordinary manure-water is used for old specimens it should be given once a week during the time the plants are making their growth, and up to the time the wood is approaching a hard, mature condition and the buds are prominent. After this stage has been reached it is doubtful if manure in any shape does not do more harm than good. GROWER.

Schubertia grandiflora.—This plant, noted by "C." on p. 265, has now been in cultivation ten or a dozen years and was more popular eight years ago than now. I think one reason why it lost favour was the rather unpleasant scent of the flower which "C." mentions, and again the brownish tinge about the blossoms and the rambling habit are against it. But many have given up its culture because of its liability to insect pests, and especially mealy bug a way of begging the question that ought to commend itself to few gardeners, for if a plant has sufficient beauty to make it worth growing it is certainly worth keeping clean. I was always rather attracted by it. I like the wild and free manner of its growth and flowering, and if started clean in a moist atmosphere, I had no more trouble in keeping it clean than I had with the rough-leaved *Dipladenias* of the *amabilis* section. Still, it is some years now since I saw it in anything like good condition, though it is often to be seen in the form of a half-starved plant in many stove collections. Possibly "C." will be better acquainted with *Physianthus* (*Schubertia*) *graveolens*, and *S. grandiflora* is a very near relative. It should be allowed to have its head in a sunny, hot and moist house and be well fed at the roots when in active growth.—H. R.

—This stove climber, alluded to on p. 265, has been grown extensively for the last ten years or thereabouts. At one time it was spoken of as a formidable rival to the *Stephanotis*, but the unpleasant smell of the blossoms and the still more disagreeable odour of the leaves if they are rubbed have tended to curtail its popularity. It both grows and flowers freely, while cuttings of the young shoots taken in the spring, put into pots of sandy soil, and kept close and shaded soon root.

It is a native of Brazil and was introduced in 1835, but was apparently lost, or nearly so, till 1886, when Mr. Bartholomew, Park House, Reading, received seeds of it from a friend in the Argentine Republic. The plants obtained therefrom flowered freely, and a first-class certificate was awarded it by the Royal Horticultural Society on September 13, 1887. Though usually spoken of as *Schubertia grandiflora*, it is often met with under the name of *S. graveolens*, while our botanical authorities include it in the genus *Physianthus*, with the specific name of *P. graveolens*. The nearly hardy *P. albens* is related to this, the flowers being much in the same way, but not so large.—T.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

THE meeting on Tuesday last was a very instructive and interesting one, illustrative of the season in more ways than one. The most notable, as it was also the most extensive, exhibit was that of the Michaelmas Daisies from Trent Park, Barnet, which were thoroughly representative of this fine class of autumnal flowers. The staging, too, was in good taste, reflecting as it did on the whole the greatest credit upon Mr. Lees. Of autumn tints there were several examples to be seen in the cut specimens from Coombe Wood, also of berry-bearing subjects. In both instances these were composed of either rare or seldom seen plants. Fruit, too, was well represented, a splendid collection coming from Barham Court and another from Hayes Place. Potatoes, too, were contributed, beautiful samples to the eye, with shapely tubers and clear skins (too clear, in fact, for the liking of many). A capital lot of early *Chrysanthemums* was likewise on view from Earlswood; the majority of these staged in masses, with buds and foliage as grown, being far and away more attractive than formally set up flowers; a few large blooms, too, were included, but these did not comply with the regulations of the floral committee, being supported with wires around the base of the florets. A good group of decorative plants came from Edmonton, and a capital selection of London shrubs from Tulse Hill, with *Nerines* and other seasonable things from Highgate and cut flowers (hardy) from Thames Ditton. Orchids were not present in any quantity, owing no doubt to the state of the weather. The lecture on insect pests should be looked for in the next issue of the Journal, it being a subject full of interest and instruction to gardeners.

Orchid Committee.

Awards of merit were adjudged to the following:—

CATLEYA DOWIANA AUREA (Little's variety).—This is a beautiful form, showing more of the characteristics of the Costa Rica forms of *C. Dowiana* than most of the varieties of the so-called *C. aurea*. The sepals, of fine form and substance, are deep yellow; the petals heavily fringed on the margin, deep yellow, with a few purple streaks at the base. The lip is rich crimson-purple around the margin, suffused and veined with deep orange-yellow, the whole of the centre suffused with a distinct bronzy purple. A cut flower came from the collection of Mr. H. Little, The Barons, Twickenham.

ODONTOGLOSSUM CRISPUM DAPHNE.—In this, though somewhat starry in shape, the sepals are white, with a distinct blotch of violet-purple almost wholly covering the centre. The petals are white, with two or three purple spots; the lip white in front and around the fringed margin, the whole of the centre covered with a bright blotch of brown. This distinct and pretty form has many of the characteristics of *O. Wilckeanum*, and may ultimately have to be classed as a variety of that hybrid. From Mr. W. Thompson, Stone, Stafford.

ODONTOGLOSSUM GRANDE PITTEANUM.—This is the yellow variety of *O. grande*, in which the brown markings of the typical form are replaced

by deep yellow. The sepals are greenish yellow, barred with deeper yellow markings, the top half of the petals pale yellow, the base deep yellow. The broad lip is pure white, with some bands of yellow at the base. The plant carried a three-flowered raceme. From Mr. H. T. Pitt, Rosslyn, Stamford Hill, N.

Messrs. J. Veitch and Sons sent two small plants of *Cattleya Minerva*, each bearing a three-flowered raceme. The colours of *C. Loddigesii*, one of the parents, are most pronounced in the offspring, while the shape is more like that of *C. Bowringiana*, the other parent. Messrs. H. Low and Co., Bush Hill, Enfield, sent *Cattleya Mantini*, *C. Gaskelliana alba*, a fine form of *Lælia pumila*, an exceptionally dark variety of *Cymbidium Traceyanum* with a raceme of eight flowers, and the rare *Cypripedium Olivia* with its two parents, *C. niveum* and *C. tonsum*. Messrs. F. Sander and Co. sent six finely flowered plants of *Stenoglottis longifolia* and a plant of *Bulbophyllum grandiflorum* with three flowers and buds. Mr. J. Bradshaw, Southgate, was awarded a silver Banksian medal for a choice, but small group, in which was a fine plant and variety of *Cattleya Maroni*, the sepals and petals rich bronzy yellow, the lip yellow, suffused with purple and veined with a darker shade of purple. The side lobes are of a distinct shade of rose on a yellow ground, the base deep orange with some brown markings. *C. Mantini* had two racemes of seven flowers each. In this the sepals and petals are deep rose, of good form and substance, the lip rich crimson-purple in front, suffused and veined with yellow on the disc, the side lobes rosy purple with some indistinct yellow lines at the base. Some good forms of *C. labiata*, *Odontoglossum crispum*, and a plant carrying a three-flowered raceme of unusually large flowers of *Cycnoches chlorochilon* were also included. Mr. W. Thompson sent *Odontoglossum crispum Queen Empress*, a beautiful variety, white, with a deep rose suffusion. The plant carried a ten-flowered raceme. *O. c. Katæ* is a starry form, white, covered with numerous purple spots. Mr. H. Little sent a spike cut from the certificated plant of *Cattleya Mantini nobilior*. This is superior in every respect to the forms generally distributed under this name. The sepals and petals are larger and of an intense crimson, the lip deep crimson-purple, the disc in the centre deep orange on a brownish ground, the golden lines also most prominent. The side lobes are of the same colour as the sepals and petals, with a few whitish lines at the base. There were seven flowers on the raceme exhibited. A pretty form of *Cattleya granulosa* var. *Schofieldiana* was sent from the same collection. Mr. H. T. Pitt sent the distinct *Bulbophyllum grandiflorum*, in which the large dorsal sepal is green, suffused with brown, and spotted with white. The lower sepals are green, slightly suffused with brown, each about 3 inches in length. The pretty *Saccolabium Calceolum*, the flowers yellow, thickly covered with miniature bright reddish brown spots, came from the same collection. Mr. De B. Crawshay sent a pretty form of *Cattleya Hardyana*, the segments being unusually light. *Lælia pumila Lionel Crawshay* is an exceptionally large-flowered variety of the typical form. Mr. F. Hardy, Tyntesfield, Ashton-on-Mersey, sent a dark form of *Lælia Euterpe* and *Sophrone-Cattleya Hardyana*, in which the sepals and petals are scarlet as in the *Sophrone* parent, the lip also scarlet, shading to yellow through the throat.

Floral Committee.

The following received the award of merit:—

ASTER NOVI-BELGII ROBERT PARKER NANUS.—Very few indeed are there who do not know the Michaelmas Daisy Robert Parker, and the point of difference here is the exceeding dwarfness, the plant being about 18 inches high. The value is not wholly in this, for quite half of this is flowering material, for as seen it is much superior in this respect to the old form, and the colour being of the palest blue, is very pleasing and effective. From Mr. F. A. Bevan, Trent Park, Barnet (gardener, Mr. W. H. Lees).

ASTER AMELLUS DISTINCTION—This is a very good name for the most distinct break in the Amellus group we have yet seen. The typical kind is a free-seeder and the seedlings vary greatly, though a large number are not of much value. This one, however, is distinct, the light mauve blue flowers very pleasing, and the ray florets being quite flat, the variety is seen to advantage. There is a warmth of tone in this not usually seen. From Mr. F. A. Bevan.

There was a considerable falling off at this meeting compared with some previous ones, yet much useful material was in evidence. One of the most interesting was a group of flowering and fruiting shrubs, shown doubtless with a view to demonstrate the autumn character of these things, which is of course most important. Some of the more effective of this interesting group, which came from the Messrs. Veitch and Sons, Chelsea, were *Oxydendron (Andromeda) arboreum*, the foliage a brilliant red, and with the bunches of fruit very pretty in effect; *Caryamicrocarpa*, of golden hue; *Rhus glabra laciniata*, *Cratægus Pyracantha Lelandi*, rich with scarlet berries; *Acer japonicum microphyllum*, *A. j. laciniatum*, *Euonymus europæus fructu-albo*, very distinct; *Koeleruteria japonica*, *Styrax japonica*, full of small almost Acorn-like flowers; one or two forms of *Cornus*, *Clerodendron trichotomum*, *Ampelopsis tricuspidata*, very pretty, and a charming lot of fruiting sprays of the best hybrid Sweet Briars. These last alone would form a pretty colony at this season by reason of their richly coloured fruits. The same firm also had a semi-circular group of Chrysanthemums, of which Mme. Gustave Henry, white, very broad and with finely quilled florets; Louise, pure white Japanese incurved; Little Nell, white, but a singularly flat, uninteresting kind; Emily Silsbury, pure white; Eastman Bell, crimson and gold; Mons. A. de Lucvievier, golden orange, being some of the best. The group was surrounded by Ferns and backed with a few Palms. A set of the hybrid Rhododendrons between javanic and jasminoides was also shown. A silver Flora medal was awarded. Of more than passing interest was a group of Roses from Messrs. Paul and Son, Old Nurseries, Cheshunt. Here the chief interest centred in the fruiting sprays of various kinds that were set up in goodly numbers. Of these may be mentioned *Rosa pulverulenta*, *R. macrophylla*, with distinctly long and very spiny fruits; the true old York and Lancaster, *R. alba*, a very glossy fruit, usually borne in threes; *R. caroliniana* quite distinct in its red stems and small fruits; *R. pomifera*, rich crimson-maroon-coloured fruits; *R. lucida*, *R. l. Vicid*, the former having foliage of a dark coppery bronze and the latter of a red hue; *R. pimpinellifolia*, very dark crimson fruits amid miniature leaves; and *R. blanda*, of a light coral-red hue. From these it will be seen how greatly varied these things are, and if grouped thinly with this in view the plants would prove very pleasing and relieve much of the more sombre tints of the garden at such a season as the present. Some very pretty and acceptable blooms in the same group were Maman Cochet, G. Nabonnand, very lovely for so late a date; Paul Neyron, Mrs. Grant, the pretty China Mme. G. Resal, La France, White Maman Cochet, Ma Capucine, &c. (silver Flora medal). Messrs. Hugh Low and Co. had a small group of *Statices* in flower, and Messrs. Sander and Co., St. Albans, had a batch of *Dracæna Sanderiana* var. *viridis*, a green leaved form of that well-known and useful kind. A large group of flowering and fine-foliaged plants was set up by Messrs. Wm. Cuthush and Sons, Highgate, such things as *Erica gracilis*, *E. caffra* (white), *Aralia Veitchii*, *A. gracillima*, and *A. elegantissima* being shown in groups. *Skimmias* in fruit and the small *Tabaite Orange* were also noted in considerable quantity. In the centre, *Nerine Fothergilli* major was very brilliant. A good deep rose Carnation (Malmaison var.) was named Lady Ulric, but the blooms are very small as shown (silver Banksian medal). Mr. H. B. May, Lower Edmonton, had a very pretty mixed group, in which *Salvias* and

Bouvardias played an important part. The *Salvia* was *S. splendens grandiflora*, and very brilliant were some medium sized plants. The *Bouvardias* included such excellent kinds as *candidissima*, *alba odorata*, *Vulcan* (scarlet), and *Vreelandi*, all in compact and neat examples. Variegated *Ophiopogons* in flower, variegated *Hydrangeas*, and *Eulalias* disposed here and there were very helpful, while *Asparagus Sprengeri* and *A. plumosus* var., with small Palms, gave a background. As a groundwork to the whole some very choice and well-grown Ferns were employed (silver Banksian medal). A fine lot of early Chrysanthemums was that from Mr. W. Wells, Earlswood, Redhill, the flowers cut in long sensible sprays with abundance of buds affording every possible opportunity of arriving at the full worth of these things; otherwise it was a collection of kinds with no material effort at effective grouping, but rather aiming at the proper disposal of the various colours. One of the finest undoubtedly is *Jules Mary*, a capital crimson. Chas. Joly, deep rose-pink; Mme. Zephyr Lionnet, bronze orange; A. Beeret, chestnut-red, with gold reverse; Market White, Mme. E. Lefort, a golden-bronze of the larger pompon class; M. G. Meunier, red-amaranth; Nellie Brown, De la Guille, apricot, very free and beautiful; Edmund Duval, white; Coral Queen, and a variety of pompon kinds were also included. Mrs. Hawkins Improved is as shown a good coloured, free-growing sort. The variety possesses the growth and general freedom of Mr. G. Wermig, and is practically an improved form of this rather than of Mrs. Hawkins (silver-gilt Banksian). Messrs. Peed and Sons, Roupell Park, Norwood, had a group of evergreen and variegated shrubs intermingled with Ivies and such things. The various Ivies, both tree and climbing varieties, were numerous, and of these such as *Regneriana*, *maculata major*, *Cavendishi*, and *Silver Queen* were prominent. These with *Hollies* in variety, *Aucubas*, *Laurels*, *Osmanthus*, *Cotoneasters*, *Veronicas*, and such like made up the remainder of a group of very useful winter town plants (silver Banksian medal). Messrs. Barr and Sons, Covent Garden, had one of their usually varied exhibits of hardy things, in which *Michaelmas Daisies* were prominent. These, however, were so numerous represented that a few only must suffice. Of leavis kinds, *Areturus* and *Calliope* are good; of *Novæ-Angliæ*, *J. F. Raynor* is a fine red, though scarcely surpassing the old *N.-A. ruber* for effect. The pretty and frail *turbinellus*, several kinds of *cordifolius*, and *Novi-Belgii densus* were also shown. *Caryopteris mastacanthus*, in pots that revealed its worth, is a desirable plant. *Anemone japonica rubra*, *Phyalis Franchetti*, *Kniphofia Pfitzeri*, *K. corallina*, *K. hybrida nana remontant*, a bright coloured and compact growing plant, were also included. *Linaria alpina*, *Anthemis Aizoon*, *Crocus speciosus*, and the pretty red and white *Cyclamen hederifolium* vars. were also noted. Mr. W. J. Empson showed an early flowering Chrysanthemum named Mrs. Empson. It is a pretty kind and dwarf. *Michaelmas Daisies* from Miss E. Armitage, Rudor, Ross, Herefordshire, were in several kinds, but hardly in condition to determine their true worth. A very pale blue and another of rich deep violet-blue appeared showy, but require to be grown in comparison with good kinds. *Gypsophila paniculata elegans* is also much in the same way, but comes too late in the season for its merits to be seen. A very extensive arrangement of *Michaelmas Daisies* came from Mr. F. A. Bevan, Trent Park, New Barnet (Mr. W. H. Lees, gardener). The group extended more than half way down one side of the hall and contained many of the leading sorts. One or two are noted already in the awards, while *Maiden's Blush*, 3½ feet, rose-purple, a warm tone of colour; *Beatrice*, 4 feet, white, in good panicles; *N.-B. Harpur Crewe*, white; *Versicolor Themis*, 5 feet; *N.-B. densus*, 2½ feet, good blue; *N.-A. ruber*; *Newry Seedling*, very pale blue; *leavis Chapmani*; *ericoides*, the latter very beautiful; *Robert Parker*, 5 feet; several forms of *Amellus*;

Snowflake, very tall; *St. Brigid*, a good white, and *sibiricus*, only 1 foot high, were also shown. *A. sibiricus* may best be described as a dwarf and very late acris. Curiously enough, while much attention is apparently being devoted to the *Amellus* varieties, of which several were in this group, the true *A. bessarabicus* is now rarely seen even in large and would be representative collections of these things. It is, however, well worth growing, but too often is confused with and seedlings of *Amellus* supplied for it. A silver-gilt Flora medal was awarded this fine group.

Fruit Committee.

A first-class certificate was given to—

APPLE T. A. KNIGHT, which had previously received an award of merit. By consent of the committee the name was allowed to be changed to *Charles Ross*. From Mr. C. Ross, Welford Park, Newbury.

An award of merit was given to—

PEAR MARGUERITE MARILLAT.—This is not unlike *Duchesse d'Angoulême* in form. The flesh is soft and sweet, with much of the average character of *Pitmaston*. From Mr. Woodward, gardener to Mr. Roger Leigh, Barham Court, Maidstone.

A basket of eight handsome oval and rich yellow Melons came from Mr. Beswick, Walton-on-Thames. These were the result of crossing *Sutton's Scarlet* with a seedling. The fruits gave scarlet flesh, but with rather hard rind; flavour was fair, but generally the fruits were unripe. Asked to be seen again. Mr. H. Glover, Orwell Lodge, Wigan, sent as new an Apple that closely resembled a small *Beauty of Kent*. Mr. Hussey, Walton-on-Thames, sent an Apple that was like *Early Julien*, but of less excellence. Mr. Owen Thomas, gardener to Her Majesty, sent from the Royal Gardens, Frogmore, a quantity of fruits of *Tomato Epicure* and plants showing fruiting properties. The fruits are smallish, round, handsome and very richly coloured, but when tasted did not give satisfaction. In form the variety bears some resemblance to *Abundance*. Mr. Empson, gardener to the Honourable Mrs. Wingfield, Ampt-hill, Bedfordshire, sent *Melon Beauty of Ampt-hill*, with white flesh, but devoid of flavour. Mr. G. Wythes, Syon House Gardens, had two seedling Melons, rather small, but handsome. One named the *Duchess* had very pale scarlet flesh, the other white flesh, and named *Syon Queen*. Messrs. Laing and Sons, Forest Hill, sent *Apple Dyke's Seedling*, but it had no merit; also a medium-sized very white-skinned *Pear*, *Seneca*, the flesh of which was entirely devoid of flavour. Mr. Woodward sent *Pears* enclosed in the new cloister or celluloid protectors, but they did not meet with any special approval; generally muslin bags are preferable. Mr. Balderson, Hemel Hempstead, showed branches of *Superlative Raspberry* from summer growths fruiting freely. It was remarked that this autumn fruiting was common on this variety. Mr. C. Blich, gardener to Mr. Martin R. Smith, Hayes, Kent, sent a collection of thirty-six dishes of fruit. In this there were superb *Pitmaston*, *Uvedale's St. Germaio*, *President Brouard*, *Doyenné du Comice*, *Marguerite Marillat*, *Durondeau*, *Souvenir du Congrès*, and very handsome *Beurré Hardy*, *Marie Louise*, *Beurré Superfin*, *Fondante d'Automne*, and *Doyenné Boussoch*. A silver-gilt Banksian medal was awarded. Mr. Woodward staged a grand collection of Apples and Pears, having some sixty dishes of the former and fifty of the latter. Not a few of the samples, whilst superb in size, showed the effects of the hailstorm which did so much injury to the fruit at Barham Court some weeks since. Of Apples, very fine were *Warner's King*, *Peasgood's Nonsuch*, *Mère de Ménage*, *Lady Henniker*, *Stone's Pippin*, *New Hawthornden*, *Tyler's Kernel*, *Cox's Orange*, *Scarlet Nonpareil*, *Calville Rouge*, *Cornish Aromatic*, *St. Edmunds Pippin*, *Ribston*, and *Washington*. Fine Pears were *Doyenné du Comice*, *Pitmaston*, *Doyenné de Merode*, *Durondeau*, *Fondante d'Automne*, *Gansel's Bergamot*,

Passe Crassane, and Emile d'Heyst. A silver-gilt Knightian medal was awarded. Mr. W. H. Lees, gardener to Mr. F. A. Bevan, New Barnet, staged a fine collection of fifty dishes of Apples and twenty of Pears. These were dressed with coloured foliage with nice effect. Finest of the Apples were Peasgood's Nonsuch, Bramley's, Warner's King, Newton Wonder, Round Winter Nonsuch, Grange's Winter Pearmain, and Cellini Pippin, whilst there were of eating varieties, good Ribston, Cox's, King, and other Pippins, Lord Burleigh, Rosemary Russet, and Fearn's Pippin. Good Pears were Doyenné du Comice, Bauré Diel, Beurré Hardy, Doyenné Boussoch, Durondeau, and Marie Louise. A silver Knightian medal was granted to this collection. Mr. J. Key Allen, Bitterne Park, Southampton, showed ten dishes of Apples, Warner's King being very fine. A bronze medal was awarded. Mr. R. W. Green, of Wisbech, had a collection of Potatoes in fifty dishes, all very clean, handsome samples. Very good were Up-to-date, Maincrop, Ring-leader, Snowdrop, Satisfaction, Reading Russet, and Beauty of Hebron (silver Knightian medal).

NATIONAL CHRYSANTHEMUM SOCIETY.

OCTOBER 10, 11, 12.

THE exhibition opened on Tuesday last at the Royal Aquarium, Westminster, was one of the best of the kind held in October. Twenty-three classes were provided for Chrysanthemums, and in the majority of cases the competition was good and the exhibits of a high order of merit. The competitive classes were supplemented by numerous displays not for competition, these latter embracing a variety of subjects, Chrysanthemums, of course, predominating. The vegetables, for prizes offered by the Banbury firm, made an exhibition in themselves. The attendance appeared to be much larger than usual.

OPEN CLASSES.

A class attracting more than ordinary interest was for a group of Chrysanthemums and fine-foliaged plants, arranged for effect in a space of 72 superficial feet. This brought out three competitors, the coveted position being secured by Mr. J. Spink, Summit Road Nursery, Walthamstow. The Chrysanthemums were represented by blooms of very high quality and in varieties of recent introduction. Each plant was on a single stem, developing one bloom only. Although arranged rather formally, this was somewhat relieved by the use of plants of Eulalia, &c., which would have looked better had they not been quite so prominent. Plants of Souvenir de Mme. F. Rosette, R. Hooper Pearson, and Mme. Couvat du Terrail were noticeable. A handsome exhibit from Mr. W. Howe, gardener to Sir Henry Tate, Bart., Park Hill, Streatham Common, S.W., secured second place. In this case, however, the display of fine foliaged plants was considerably larger than usual, the Chrysanthemums being represented by fewer plants. The free use of graceful Bamboos, Dracenas, Crotons, Ferns, &c., made a noble group. There were no competitors in the class for four plants, bush grown, and this is to be regretted, as there are so many excellent semi-early sorts specially adapted to this method of culture. Perhaps the prizes are not liberal enough to tempt growers. The class for twenty-four blooms of Japanese Chrysanthemums, not less than eighteen varieties and not more than two blooms of a variety, brought a very meritorious display considering the past season. Unfortunately, the best display was disqualified, the exhibitor staging only sixteen varieties. This was a very fine lot, and Mr. Gleeson is to be sympathised with that the error was not discovered earlier. First prize was consequently awarded to Mr. J. Brooks, gardener to Mr. W. J. Newman, Totteridge Park, Totteridge, Herts. This exhibit contained among others good flowers of Pride of Madford, a useful purple-amaranth at this season; Mme. M. Ricoud, a pleasing lilac rose; Soleil d'Octobre, the best of the early yellows; Mrs. G. W. Palmer, Oceana,

Mrs. J. Lewis, a splendid October white; Emily Silsbury, and Mlle. Louise Brossillon, a flower of great promise. Second honours fell to Mr. J. Fulford, gardener to Mr. F. D. Lambert, J.P., Moor Hall, Cookham, whose stand contained smaller and less even blooms, Mrs. J. Lewis, Lady Phillips, and Dorothy Seward representing the best flowers in this instance. In the class for twelve blooms Japanese, distinct, Mr. M. Gleeson, gardener to Mr. A. Von André, The Warren House Gardens, Stanmore, N.W., stood out distinctly from all others with flowers of splendid quality, M. Chenon de Leche, Mutual Friend, Henry Weeks, J. Brooks, and Australie being equal to those usually exhibited a month later. Mr. J. Brooks, with smaller blooms, but in a pleasing variety of colour, secured second place, Pride of Madford, Werther, Soleil d'Octobre, and Mrs. Barks, the buff-yellow sport from Edith Tabor, being his best flowers. For six blooms Japanese, distinct, the judges placed Mr. W. Meredith, gardener to Mr. George Wilder, Stansted Park, Emsworth, Surrey, first, his blooms being large, refined, fresh, and clean, Mrs. D. Dewar, a chaste white flower, and Mme. Philippe Rivoire, a good white, being the best. To all appearance a much better lot of blooms secured second honours for Mr. C. Payne, gardener to Mr. C. J. Whittington, Elmhurst, Bickley Park, Kent, who had an exceptionally fine lot of flowers. Mrs. Coombes, a lovely soft pink, was very fine, also Mme. Gustave Henry, General Paigue, bronzy yellow, and Mlle. L. Ricoud. Only two competitors were forthcoming in the class for six incurved blooms, first prize being awarded to Mr. R. Jones, gardener to Mr. C. A. Smith-Rylands, Barford Hill, Warwick. These were fairly good, though some were distinctly rough. Second prize went to Mr. Thomas Robinson, gardener to Mrs. Lawrence, Elksfield House, Hollingbourne, Kent. The class for six blooms Japanese, one variety only, made a welcome variation. In this case Mr. R. Gladwell, gardener to Mr. S. Smith, Wernden Hall, South Norwood, S.E., was placed first with large and handsome blooms of Australie, second position being secured by Mr. W. Paton, gardener to Mrs. Harmsworth, Poynter's Hall, Totteridge, Herts, this exhibitor staging large and even blooms of the true October-flowering Mme. Gustave Henry. Mr. T. L. Turk, gardener to Mr. T. Boney, Southwood House, Southwood Lane, Highgate, N., in a class for twelve bunches pompons, not less than six varieties and not more than two blooms of any one sort, was first with an excellent lot of flowers, Vésuve, Osiris, Mlle. Elise Jordan, White St. Crouts, Alice Butcher, and Miss Davis being very fine. There was only one competitor in the class for two vases of Chrysanthemums, each containing twelve blooms, with the addition of appropriate foliage. Mr. J. Brooks was awarded first prize for neatly arranged blooms of high quality pleasingly associated with Ferns, Asparagus, and autumn-tinted foliage. The vase of pompons from Mr. Turk was distinctly ahead of the others, the flowers lightly and prettily arranged. Second prize was awarded to Mr. S. Foster, gardener to Mr. R. Nevison, Tenterden Hall, Hendon, whose prettily arranged vases of Piercy's Seedling (bronze) and grass were somewhat unique. For six bunches pompons, Mr. A. Taylor, 5, Vernon Terrace, East Finchley, N., was second. A new class introduced this season was for twelve bunches early-flowering Chrysanthemums, in not less than six varieties, from plants grown in the open air and not disbudded. These were set up in vases, and in most cases large, handsome bunches were exhibited. The first prize was awarded to Mr. W. Paton, who had G. Wermig, Mme. C. Desgrange, Mme. Marie Masse, Ivy Stark, Mrs. J. R. Pitcher, Francois Vuillemet, Blanche Colomb, and Harvest Home. The second prize lot from Mr. Eric F. Such, nurseryman, Maidenhead, embraced many very pleasing colours. For three stands or epergnes there were four competitors. Miss Cole, The Vineyard, Feltham, Middlesex, made a charming display with three epergnes, using orange, yellow,

and crimson flowers in association with Croton leaves, Ferns, Asparagus, and autumn-tinted foliage, and was awarded first prize. Second honours fell to Mrs. W. Green, Jun., Harold Wood, Essex, who had rather large epergnes arranged with yellow Japanese and pompon Chrysanthemums and suitable foliage. The base of the epergnes was, however, somewhat formal and cumbersome. It is a pity that the class is not clearly defined, and the executive should see that either stands or epergnes—one or the other—should be asked for, as this has proved misleading. Six competitors entered the lists for a single vase of Chrysanthemums suitable for table-decoration, the vase not to exceed 18 inches in height. Miss Easterbrook, The Briars, Fawkham, Kent, was an easy first, arranging twelve large, handsome Japanese blooms very happily with foliage of an appropriate kind. Milano, Mrs. G. W. Palmer, and Lady Byron were the three varieties used. Second prize was won by Mr. E. H. Chitty, gardener to Mr. S. Hardy, Cholmeley Lodge, Highgate. A special prize offered by Messrs. R. & G. Cuthbert, New Southgate, for three vases of the new Mrs. Wingfield, early Chrysanthemum, brought out only one competitor, this being Mr. W. Howe, who staged very handsome blooms of this variety.

AMATEUR CLASSES.

These were in most cases poorly contested. For twelve blooms Japanese, distinct, Mr. R. Gladwell was placed first out of three competitors with a nice fresh and even lot of blooms well staged. Simplicity, Phœbus, Werther, Susie, Australie, and Louise were his best flowers. Mr. W. Perrin, gardener to Mr. C. W. Richardson, Fairgreen House, Sawbridgeworth, Herts, was second, Mutual Friend and Australie being staged in excellent condition. In the class for six Japanese blooms, distinct, Mr. Gladwell had neat and even flowers throughout. Mr. Perrin was again second with a nice lot of flowers. In Division B, which is confined to *bona fide* amateurs, the competition was very poor. First prize was secured by Mr. W. G. Prudden Clark, York Road, Hitchin, Herts, with a fairly good stand, in which more colour was badly needed, he having too many very light varieties. Mr. Martin Silsbury, Providence, Shanklin, Isle of Wight, was second of the two competitors for twelve Japanese blooms, not less than six varieties, the whole of the blooms being somewhat rough and of poor quality.

VEGETABLES.

For prizes offered for vegetables by Mr. Henry Deverill, Banbury, Onions as usual played an important part, and although very fine, we think they were not so good as last season. For six Aristocrat Onions, Mr. W. Masterton, gardener to the Earl of Camperdown, Weston House, Shipston-on-Stour, was placed first with fairly even specimens, second prize falling to Mr. William Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury. Of six competitors for the twelve largest Ailsa Craig or Cocoa-nut Onions, Mr. J. Bowerman, gardener to Mr. C. H. Hoare, Hackwood Park, Basingstoke, was first, having large, clean bulbs, scaling in the aggregate no less than 31½ lbs. Second prize was won by Mr. F. L. Clatworthy, gardener to Mrs. Bradshaw, Lifton Park, Devonshire, with good, though slightly smaller and less even specimens, totalling 29½ lbs. For six Ailsa Craig or Cocoa-nut Onions Mr. J. Bowerman was again first with specimens of mixed quality, weighing in the aggregate 14½ lbs. The only other competitor was awarded a fourth prize. For twelve specimens of either Anglo-Spanish, The Lord Keeper, Royal Jubilee, or Rousham Park Hero, Mr. W. Maybury, Brooke House Gardens, Ash, Dover, was first with rough and uneven bulbs, and there was a bad fourth. Mr. Bowerman again secured leading honours for six Oxonian Leeks. These were large, handsome, though rather irregular specimens, beautifully blanched. Mr. R. Lye, gardener to Mrs. Kingsmill, Sydmonth Court, Newbury, was second with smaller, but very neat and even specimens.

For twelve Intermediate Carrots Mr. J. Masterton was first with exceptionally good roots, large, clean, and highly coloured. Second prize was awarded to Mr. Pope with smaller and less even specimens of good colour. The Beets were not so good as usual, although a nice lot secured first prize for Mr. R. Lye. Mr. Pope was placed second with useful roots. Mr. Edwin Beckett, gardener to Lord Aldenham, Aldenham House, Elstree, had a grand lot of Celery in the class for six sticks Aylesbury Prize Red; Mr. Bowerman was second with much smaller heads. Mr. Beckett was again to the fore with twelve specimens Hollow-crowned Parsnip, which for quality and finish were unsurpassed. Mr. Pope was second with good specimens, though much shorter. For twelve Glenhurst Favourite Tomatoes Mr. Beckett again led with a beautifully even lot of good colour, followed by Mr. Bowerman with much smaller fruit. For eight distinct kinds of vegetables there was a keen competition. In this class Mr. Beckett was again invincible, staging Autumn Giant Cauliflower, Parsnips, Scarlet Intermediate Carrots, Onions, Leeks, Tomatoes, Celery and Satisfaction Potatoes. Mr. Lye also showed well, being placed second. There was also a collection of vegetables open to amateurs and cottagers, first prize being secured by Mr. R. J. Horton, Tysoe, Kineton, Warwickshire, who set up a neat collection, followed by a smaller lot from Messrs. E. and H. Wells, Tysoe, Kineton, Warwickshire. For twelve Pedigree Onions there was a spirited competition, Mr. Thos. A. Beckett, Havering Park, Romford, Essex, being placed first with very neat, globular and well-ripened specimens.

MISCELLANEOUS EXHIBITS.

As usual, these contributed largely to the display made on this occasion. Mr. H. J. Jones, Rycroft Nursery, Hither Green, Lewisham, S.E., had a fine group arranged right across the centre of the building and backed by graceful Bamboos. The central group was confined to Chrysanthemums, yellow and bronze colours predominating, and at either end smaller groups, one of richly coloured Crotons and the other of Dracenas, gave a finish to the whole. Considerable taste was displayed in the disposal of the plants (gold medal). A similar award was made to Messrs. John Laing & Sons, Forest Hill, S.E., who had a superb display of 150 dishes of Apples, Pears and Nuts. Worcester Pearmain, Tom Putt, Lady Sudeley, Lane's Prince Albert, Cox's Orange Pippin, Adams' Pearmain and Peasgood's Nonsuch were a few of the good things to be seen. Messrs. S. Spooner & Sons, Hounslow Nurseries, Middlesex, also had a large table of Apples of fine quality and of a most representative character, for which a silver-gilt medal was awarded. Messrs. William Cutbush & Sons, Highgate and Barnet Nurseries, made a magnificent display of Apples, embracing all the best varieties. This exhibit was noted for its quality and the high colour of many of the individual dishes of fruit. Autumnal foliage considerably enhanced the richness of the display, for which a silver-gilt medal was awarded. A similar award was made to Mr. W. J. Godfrey, Exmouth, Devon, for a large table of Chrysanthemums, Carnations and perennial Asters. The exhibition Chrysanthemums were largely in evidence, embracing such sorts as Reginald Godfrey, Mrs. Coombes, R. Hooper Pearson, Oceana, Autumn Glory, and a new decorative sort, Ettie Mitchell, a pretty orange-bronze flower on a beautifully dwarf habit of growth. A silver-gilt medal was also awarded to Mr. S. Mortimer, Knowledge, Farnham, for a superb display of Cactus and show and fancy Dahlias. This was a remarkable exhibit so late in the season. The blooms were typical in form, while the colour in most cases was wonderfully rich. To Messrs. Dobbie and Co., Orpington and Rothesay, a similar award was made for a large table of hardy border Chrysanthemums, embracing all the new and popular sorts. The varied character of the early-flowering sorts, together with their profuse display, was noted here. This exhibit also contained a pretty lot of

blossoms of the single Cactus Dahlias. Messrs. H. Cannell and Sons, Swanley, Kent, were again to the fore with a bright and attractive group of Cannas. These were admirably arranged with a fine background of Palms, &c., and a pretty edging of Ferns (silver-gilt medal). Messrs. Thos. S. Ware, Ltd., Tottenham, secured a silver medal for a grand display of Cactus Dahlias. A similar award was made to Mr. W. J. Prowett, gardener to Mr. Arthur Pearson, Fronsam Place, Farnham, Surrey, for a beautiful display of Apples, Pears, and other fruits. This was a highly meritorious exhibit. A small silver medal was awarded to Mr. Henry Deverill, Banbury, for a grand bank of early Chrysanthemums, perennial Asters, &c. Aster Amellus Riverslea and A. A. Stella were much in evidence. Mr. E. Such, Maidenhead, had a similar group of cut flowers prettily set up (silver medal). A bronze medal was awarded to Miss Easterbrook, Fawkhams, Kent, for a superbly arranged hand-basket of Michaelmas Daisies. Mr. T. Williams, Ealing, was highly commended for his rustic table decorations, using in this instance Michaelmas Daisies and early-flowering Chrysanthemums.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE thirteenth annual dinner of this flourishing society was held on Thursday evening, the 5th inst., at the Holborn Restaurant, Mr. W. Y. Baker, of the Thames Bank Iron Company, presiding. A goodly number of friends and members sat down, and a very enjoyable evening was spent. Among those present we noticed Messrs. J. H. Veitch, G. Bunyard, W. Icton, H. B. May, P. Kay, G. Ingram, J. Hudson, and others.

After the usual loyal toasts had been duly honoured, the chairman, in proposing "Success to the United Horticultural Benefit and Provident Society," called attention to the many benefits the members enjoyed, one being that the society was a savings' bank as well as a benefit society. He found on referring to the books that the number of members was 890, and of that number only three were now in the receipt of sick pay. Mr. Baker urged the claims of the convalescent fund, which was started some years ago in order to allow members who have been ill to go away for a change. To such the sum of 10s. weekly is allowed for three weeks in addition to their sick pay. We think that this fund might be more taken advantage of. Mr. Baker coupled with the toast the name of Mr. J. Hudson, the treasurer, who in the course of his remarks stated that the handsome sum of £15,000 was now invested. The annual dinner, he said, was held in order to popularise the society, and he hoped that in a year or two the members would number 1000. He also on behalf of the society thanked the Press for the interest they had taken in the society. In referring to the honorary members he said that 96 per cent. of the receipts came from the members, the remaining 4 per cent. coming from honorary members.

Mr. Thomas Winter proposed "The Honorary Members," and made a special appeal for funds to the convalescent fund. Mr. Bunyard, in responding to this toast, thought that the list of honorary members should be doubled, and suggested that nurserymen should call attention to the society in their catalogues. "The Craft" was proposed by Mr. R. Dean in an excellent speech, this being responded to by Mr. Wright, of the Royal Horticultural Society's Gardens, Chiswick, who said that at the present time there was a great want of good fruit growers, he having failed to find men in no less than thirty cases. Mr. Icton, in a few well-chosen words, proposed "The Chairman." The following contributions were received during the evening: W. Y. Baker, £15 15s.; W. Icton, £2 2s.; B. Maller and Sons, £1 1s.; N. N. Sherwood, £5 5s.; P. Kay, £3 3s.; J. Veitch and Sons, £3 3s.; Thames Bank Iron Co. (employés) £1 1s.; J. Laing and Sons, £2 2s.; W. Marshall, £1 1s.; A. Watkins, £1 1s.; Messrs. Dickson, Chester, £2 2s.; R. Dean, 10s. 6d.; S. T. Wright, 10s.;

T. N. Cox, £1 1s.; G. Monro, £1 1s.; J. George, 10s. 6d.; Willingham Bros., Pine-apple Nurseries, £1 1s., making a total of £42 10s.

The musical arrangements were under the direction of Mr. Herbert Schartau, and the tables were decorated with flower and fruit kindly sent by Messrs. Cannell and Sons, H. B. May, W. Thomson and Sons, Clovenfords, J. Veitch and Sons and others.

OBITUARY.

MR. JOHN WOOD.

ON September 24, Mr. John Wood, of Kirkstall, Leeds, died after an illness of a few hours, aged fifty-seven years. To all readers of THE GARDEN his "Notes on Hardy Plants" were well known, and others than the writer would probably confess to a habit of first looking for this column. These communications not only introduced to amateurs new species suited to their collections of alpine plants, but gave valuable cultural information. He had nearly reached middle life before he took up the culture of hardy plants, which he carried on with much success. Mr. Wood's advice and influence will be missed in many gardens that will still retain the memorials of his past work.

R. R.

Chrysanthemums in the parks.—We are asked to state that the annual show of Chrysanthemums at Southwark Park is now open, and that the houses at the Council's other parks will be ready for opening on the following dates: Finsbury Park, October 12; Victoria Park and Waterlow Park, October 14; and Battersea Park, October 25.

Pruning the Horse Chestnut.—With great interest I read the article on the Horse Chestnut by "J. S." in THE GARDEN of July 8, but he does not say anything about pruning old specimens. Here, with the same climate as the north of England, there are thousands of beautiful old Chestnuts round the town, but rather too thickly planted. To prevent them getting bad, many gardeners advise cutting them back. Others are of quite a different opinion, as they say the young shoots would then get frozen and the trees would never again be effective.—GUSTAVUS POL, Head Gardener, Botanic Gardens, Cracow, Austria.

Lapageria rosea and L. alba.—I planted one red and one white Lapageria in a conservatory last year, same aspect, the wall looking north. The red variety is doing well and flowering abundantly, but the white one has only produced six flowers and does not flourish. I am told that it has a habit of dying away. Can anything be done to prevent this?—SHERBORNE.

*** Possibly there may be something wrong with the drainage as regards the white variety. We have grown both forms in exactly the same position and under identical conditions, and found that on the whole the white variety was always the more vigorous and flowered more freely than the red one. It may have been a weaker plant at the start.—ED.

BOOKS RECEIVED.

"The Student's Flora of New Zealand." By T. Kirk, F.L.S. Eyre and Spottiswoode, Fleet Street, E.C.

"Annual Report of the Department of Parks." Boston. 1898.

Names of fruit.—H. Parker.—Quite impossible to name from such a poor specimen.—Richmond. —Pears: Dark, Beurri Clairgeau; green, Louise Bonne of Jersey; Apple Lord Suffield.

Names of plants.—Mrs. Blackwell.—The Poison Ivy (Rhus Toxicodendron).—Alice Wilson.—1, please send better specimen; 2, *Leycesteria formosa*; 3, looks like an Ash, but should like to see better specimen.—Whatcombe.—*Thymelæa ligustrina* (S. Europe).—S. H.—*Rhamnus Frangula* (the Alder Buckthorn).—A. K. Gale.—1, *Euonymus latifolius* (the Broad-leaved Spindle Tree); 2, *Crategeus coccinea*.—Subscriber.—*Torreya californica* (the so-called Californian Nutmeg). It is a rather uncommon plant in gardens. The fruit is of no value that we know of, but it is not injurious.—*Glaucus*.—A, *Fuchsia Riccartoni*; B, *Fuchsia gracilis*.

ORCHARD AND FRUIT GARDEN.

SEAWEED FOR FRUIT BORDERS.

SEAWEED for various garden crops is seldom used so freely as it might be, especially by those whose gardens are situated near to the coast. Many, no doubt, in the midlands would be only too pleased to lay in a store for Asparagus and Seakale plantations, but the distance entails too much outlay for seaweed to be used generally for such purposes, while others who can obtain large quantities for the mere cost of carting appear to ignore its value. What I wish to point out, however, is that seaweed can be put to other and very valuable purposes besides that mentioned above, viz., as a mulch for fruit trees. Those who have not tried seaweed in their orchards and fruit gardens would be surprised at the beneficial effect it has on the trees, especially Apples and Pears, when, of course, it is used with care and moderation. This is particularly the case during dry seasons such as the past three. My first impression—and it was not a slight one—was gained at Bembridge, Isle of Wight, last August on land recently reclaimed from the sea. The site no doubt is well known to many of the readers of THE GARDEN, but perhaps it is only a few who have visited that portion in the occupation of Mr. C. Orchard, who has converted it into a fruit, flower, and vegetable garden. The great depth of sandy soil is undoubtedly to a great extent composed of thoroughly decayed seaweed and sand, and the way all vegetation appears to thrive in it is marvellous, more noticeable perhaps to such as myself, whose crops the last two summers were collapsing from the want of moisture in spite of the mulchings of stable litter freely applied. It occurred to me then that for light soils and for use during a very dry season seaweed would undoubtedly prove more valuable as a mulch than any other material generally used for the purpose. Apart from any manurial properties it contains, it is, like salt, moisture-holding as

well as feeding, the value and importance of which should not be ignored by those whose fruit trees are growing in too porous soils and where the rainfall is light. I certainly never saw more healthy trees or better samples of Apples, though, of course, the climate and situation are also very favourable for their production. I should not be in favour of burying fresh seaweed near to the roots of established trees, or incorporating it with the soil in forming a new orchard or fruit garden, but frequent mulchings of the surface ground piecemeal are, I am sure, a safe means of stimulating growth and sustaining the trees under the trying influence of a long drought. By this means it would gradually find its way into the lower ground and undoubtedly improve its staple.

These views were further strengthened when recently visiting the gardens at Arundel Castle. In these gardens the outdoor culture both of Peaches and Nectarines is gone in for largely, the grand walls and mild climate proving very favourable to their well-doing. Some of the borders are on rather sharp slopes, causing rain to run off freely and the work of watering thoroughly somewhat difficult. For many years Mr. Burbury resorted to heavy mulchings of stable litter, not only round the trees themselves, but also all over the borders, which are usually cropped with something dwarf, such as French Beans, &c. The effect of this was that it not only formed a harbour for sparrows and other birds, but, what was worse, woodlice, earwigs, weevils, and beetles found it a safe lurking place by day, while they made the softening fruit of Peaches and Nectarines on the walls their feeding ground at night. Many fine fruits were therefore entirely spoilt before they were ripe, and had to be used in the kitchen. No finer fruit could possibly be seen than on these walls this autumn, large, bright, and without a speck, and, what is more, each fruit ripened perfectly without any damage by the pests named above. The reason for this very satisfactory result is not far to

seek, a happy thought occurring to Mr. Burbury to use seaweed in the place of stable manure for mulching. Further comment on this point is perhaps needless unless it be to urge others to follow his example, as I certainly intend doing myself in future. So far I have proved that the use of seaweed is valuable in the cultivation of the different trees named above; that being so, could it not also be employed with equal good results with Vines? Many Vine borders have to be formed with soil far too light in composition to suit the requirements of the occupants, in which case an occasional dressing of seaweed might be used with advantage, proving better than repeated mulchings of stable manure. There are other borders which, owing to the too free use of manure, have become sick of such dressings, causing the soil to become sour or uncongenial to proper root-action. A change then is certainly advisable in such cases, and I know of nothing more calculated to restore it to a sweet, healthy condition again than applying a dressing of lime with a mulching afterwards of seaweed. Seaweed, however, varies considerably, some being far too coarse and heavy for the different purposes mentioned above, unless it has first had sufficient time for partial decomposition. Preference is given to that of a finer and lighter character, which when collected generally contains a fair amount of sand, making it more suitable in every way for use in the garden, let it be for Asparagus beds, fruit borders, or even as a plunging material for pot plants during the summer months.

RICHARD PARKER.

Goodwood.

Apple Tyler's Kernel.—This handsome Apple is not sufficiently known. It keeps well, I believe, until quite late in the season, is of very fine form and good colour, added to which its shape prevents waste. My tree of it has not yet fruited, but I have seen it in neighbouring collections, and this induced me to plant it. The fruit is bright red on the side next the sun, and it has a shining appearance that should render it a valuable kind. About its flavour for eating I

cannot say, but it is a very free-bearer and a good cooking Apple.—H.

Plum Pond's Seedling.—As a kitchen Plum this fine variety is hard to beat, but I do not think it is so well grown as formerly. There were a few dishes of it at the Palace, notably one in Mr. McClode's collection that was characteristic and good, but the majority were very poor for the variety. Possibly the lateness of the date was to blame in some cases, but I have had it in the south in first-rate condition at the end of September. The constantly growing plague of birds is all against good late fruit.—H.

Pear Marie Louise.—This popular Pear more than any other I know gives fruit of good quality under poor conditions of culture. Quite recently I saw some really fine specimens growing on an old and neglected tree that one would imagine would not produce a good fruit. But this is no excuse for neglecting it, for though it may be long-suffering, there can be no comparison between these and fruit from really well cultivated trees. On the other hand, I have known many cases where Marie Louise with the best of care refused to thrive well, and this on soils where other Pears did so. The roots must be kept near the surface if possible and frequently mulched.—GROWER.

Peach Sea Eagle.—I am inclined to place Sea Eagle at the top of the list for cropping, quality and usefulness among the late varieties of Peaches. I rarely miss having good fruits of the above variety and of the best quality. I am aware in colder districts my high opinion of this Peach may not be shared by many, as fruits differ so much in various soils and localities. My soil being thin and light on gravel is, of course, much warmer than heavy land. I do not think that Sea Eagle can be classed as a bad grower, as I have it on a north wall and it makes a free growth if the wood is kept thin. It also bears well, and the fruits are not much later than on a warmer aspect. Its free cropping should make it a great favourite in all gardens where late Peaches are required.—G. W. S.

Strawberry Fillbasket.—Fillbasket with me promises well, being robust and bearing freely, and, what is better, the fruit is of excellent quality. It is a first-class variety to follow Royal Sovereign, and, like it, it sets quite as freely and appears to be at home in most soils. Its parents are Royal Sovereign and Latest of All. It has the cropping qualities of Royal Sovereign with the Pine-like flavour of Latest of All. Fillbasket, though not so free a grower as some, is very prolific, and will give large quantities of fruit from a small area. In soils where Strawberries are not always a success I do not think anyone need fear planting Fillbasket. It does not become quickly infested with insect pests, having thick leathery foliage. I have not yet grown it in pots, but should think it will be valuable for forcing for late spring supplies.—G. W.

Apple Bismarck.—This Apple has now been a sufficiently long time in our gardens to prove it, and there can be no doubt as to its popularity. I have seen it doing well in diverse soils and situations. It certainly is a valuable introduction, not only for its size, colour and shape, but its free cropping qualities, as young trees bear so freely. Few varieties grown in bush form are so handsome. This year Bismarck is one of my best croppers, though the trees are young, the soil thin and the season a most unfavourable one, owing to the drought. The trees of this variety need less pruning than some kinds, as doubtless their free-cropping prevents a gross growth. This is a great gain in small gardens, as this variety can be grown close to walks. It fruits freely in any form, bush or standard, and answers admirably grown as a cordon.—G.

Cherry Late Duke.—Few fruits are more in demand than late Cherries, and the Duke section furnishes some of the best dessert fruits. Late Duke is one of the best late kinds I have grown, and though it is less sweet than some kinds if it is gathered early, it is rich and good if allowed to

hang well into August. I have gathered fruits in September. The fruits are valuable on account of their size and beautiful black colour. Of course as regards season, a great deal depends upon the aspect the trees are grown in. In the north this variety succeeds grandly on a west wall, and I have recently planted it on a high north wall. Grown thus, should the Morellos fail, it will be valuable for bottling gathered late in July. This variety if allowed to hang does not shrivel so soon as most of the dessert kinds, and it takes on a much darker colour as it ripens. It bears and grows freely.—G. W.

An effective cure for oidium in Vines.—We learn from the *Revue Horticole* that to M. Uchet, a Vine grower of Chapareillau (Ièdre), belongs the credit of an important discovery, namely, the cure of oidium in Vines by substituting carburate of calcium for the sulphur treatment, which he has found ineffectual after repeated applications. The carburate was reduced to a fine powder and then sprayed upon a Vine trellis 220 yards in length after this had been well syringed with pure water. The immediate effect of the carburate on the water was the formation of acetylene gas, the effervescence from which rid the Vine of the oidium in a single operation. Neither burn nor check to growth was found to result, and eight days afterwards, convinced of the efficacy of his discovery, M. Uchet applied it to his other Vines with great success.—*La Semaine Horticole*.

AN EPISODE.

It was in the troublous and anxious times of the Royal Horticultural Society that Mr. John Lee—that good and amiable English gentleman whom we have not so long lost, but regret—was sitting as chairman of the fruit committee. Included amongst them was the writer of this paper. It is a long time ago, but I well remember it as about the beginning of the hankering after the marvellous. It gained for me an ill-will which has stuck, and it came about in this way: At a meeting at South Kensington I gave the only adverse vote to a display of large fruit, even for those days. In my opinion the fruit was too large—vulgar, if you will—to be encouraged by the Royal Horticultural Society as a paragon for dessert upon an *élite* table for quality. Mr. William Earley, who I am glad to find is still in the land of the living, sat next to me at the committee table and expressed himself very strongly against my judgment. I suppose I must have kicked too often in this way, for I found no place upon the committee at the next election of members. Nevertheless, it did not prevent me keeping in evidence against the big things overruling when entered for prizes at South Kensington or elsewhere even to this year of grace 1899. You may therefore surmise how glad I was to read the end of your critical paragraph on p. 287, issue of the 7th inst. I will add, not merely for Apples, but for all other produce entered for prize-money at exhibitions. You are, too, in good company. I did not make a note of the date, but in an after-dinner speech made by the Rev. Mr. Wilks at a horticultural club dinner not very long since, he strongly commented against this preponderating influence of size. I have, too, more recently seen the subject cropping up in the pages of THE GARDEN, and I hope it will continue to go on to assist in forcing a wedge into this big-block-produce—'e'en to the splittin' o't—to allow prizes to be given on one side for medium-sized quality for the majority, and on the other for bulk for the mere minority. I consider Apples and Potatoes to come under the same category of importance in regard to our national food, the latter taking a place only next to wheat. A few years ago when I was assorting a batch of seedlings, our

squire, Major Thoys, happened to call to consult with me about some parish business. He expressed his astonishment at the size of one variety—tubers as large as a child's head and handsome withal. He remarked: "I suppose those are for seed." "No, Major," I answered, "they are to be boiled for the pigs: exterminated, as being delusive, non-sustaining watery matter." I do not intend to produce from my present or future—I have some valuable experiments now under weigh—hybridising work larger Potatoes than I have already put into commerce. The huge kinds so popular at present I consider are positively doing harm in regard to our food. In flowers, size with beauty for exhibition may be praiseworthy and can do no harm, but there is no high art, or at least public benefit, in creating by crossing large to produce larger, and by consequence inferior sustenance by merely considering a quick filling of the measure, or in appearance, to satisfy a grasping for prize-money. Agricultural shows have gained a march upon us by the extinguishing of those mountainous cattle with which they erst used to astonish the natives. However, if the monstrous must continue for horticulture, let quality and quantity contend in their separate spheres.

Sulhamstead.

ROBT. FENN.

Pear Clapp's Favourite.—This is an excellent early Pear when taken at the right time, and I was surprised to see how sparsely it was represented at the Crystal Palace fruit show. Only a few dishes of it were noted in the county classes, where it should certainly have carried more weight than varieties wanting another two months before they will be fit to eat or over-ripe samples of very early kinds. It should be left on the trees until almost fit for use, but when the samples are fairly well coloured birds soon find them out and they must be gathered. Then, of course, they need a little longer time in the fruit room.—H.

Damsons and Bullaces.—Although many of the varieties of Damsons growing in a half-wild state about the hedges in different parts of the country are very inferior, yet their value to cottagers and others in a year of scarcity is unquestioned. To-day I saw two trees growing side by side—one the common white Bullace, and the other a very poor kind of Damson—and both were laden with fruit which is very useful now and right up to the end of October. The Bullace especially is improved by being exposed to a few sharp frosts. There is no doubt that these common fruits would be greatly improved if given a little attention and planted in good soil. Even as they are they are profitable, and they may with advantage be planted in hedge-rows and on waste land, which is plentiful on most estates.—H.

Open-air Figs in Wales.—One of the places that have come under my notice where outdoor Figs flourish is Tredegar Park in Monmouthshire. In the gardens there there are old walls, against which Figs have been growing probably ever since the walls were erected, and rarely do they fail to carry heavy crops of fruit. One side of the gardener's house is clothed with a spreading Fig tree, whose only rooting medium is the soil under a hard gravelled yard. In my opinion the success of Fig culture, so far as pruning is concerned, depends on persistent summer pinching, nipping back the young growths when they have made a few leaves, and again as fresh shoots form. By following this practice, long sappy shoots with leaves and buds thinly dispersed are prevented.—H. H.

Currants on north walls.—Just before planting begins, a reminder as to the usefulness of Currants on north walls may not be out of place. I prefer cordons—double or single—as grown thus the trees, if kept closely spurred in, are both ornamental and useful, and grown in

this way space is more quickly filled. It is surprising how quickly the trees grow if such kinds as Reine Victoria, Raby Castle, La Versailles, and the white variety of the last-named with the White Dutch Cut-leaved are planted. It is important to keep the trees clear of insect pests just as the fruit is colouring, green and black fly being troublesome. Syringing with soapy water, or, what is better, quassa about twice will clear the pest. There is no difficulty in protecting the trees grown thus. The fruit will keep sound for months after that on the bushes is over.—S. H. B.

The Logan Berry for preserving.—In many gardens there has been a short crop of Strawberries—at least, in the southern parts of the country. Owing to various causes, both the Strawberry and Raspberry crops were much under the average. The new Logan Berry has borne exceedingly well. Not yet being well known, I am induced to send you a note as regards its good qualities for preserving. It is less sweet than the Raspberry or Strawberry, which is an advantage and will be appreciated. The fruits are borne in clusters, darker in colour than the Raspberry, and somewhat sharp when nearly ripe, but if allowed to hang and become black they are sweet and useful for dessert. I think their value is greater for preserving, as they may be gathered less ripe and are of a delicious flavour. I find the Logan Berry fruits grandly grown on an east or north wall and treated much like the Raspberry. The plant is a strong grower, soon fruits after planting, and is not at all particular as to soil or position.—G. WYTHES.

EXHIBITING FRUIT.

I AM obliged to "W. S." (page 272) for his practical and kindly critique of my note on this subject, but am sorry he considers it impracticable to make our fruit exhibitions a little more tasteful. "W. S." says he is afraid I am not a fruit exhibitor, but in this he has not guessed correctly. Not only have I been successful with fruit collections during the present season, but in one case was placed first in a strong local competition with a collection arranged something in the manner set forth in my note, though through lack of space I had not full scope to carry it out well. In another case the schedule asked for six varieties of fruit in a basket. Now most people will, I think, agree with me that half a dozen kinds crowded into a basket are about the most unsightly class of any, and though I had perforce to follow the schedule, I cast about for some way of making the basket attractive. I chose a large plant hamper about 4 feet across and very shallow. The rim was covered first with moss and all the centre filled up with the same material. All the fruit was carried as usual—the Grapes on boards, and Peaches, Nectarines and others packed in shallow boxes. The Grapes were taken off the boards and tied at the top of the basket to the rim, the moss being kept high there in order to show the full length of the bunches. A couple of Melons filled the centre of the basket and the rest of the fruit was disposed around these upon the moss. Sprigs of Bryony and trailing pieces of Ampelopsis finished off the arrangement. Everything was prepared at home, and the staging took perhaps half an hour, so the waste (?) of time is not extravagant by any means. As to the schedule difficulty, this should be very slight. Arranging for effect half a dozen or a dozen distinct varieties of fruit upon a space of so many square feet is not difficult to understand, yet it would be amply sufficient, for naturally the judges would, in case of a close competition, give points to quality of each dish represented and the arrangement as a whole. No "uniform result," as "W. S." puts it, is needed. We have far too much uniformity in shows, and if any exhibitor by an original departure gets ahead of his fellows, all the better for him. They will copy his methods next season without a doubt, and only the disappointed exhibitors will find any fault. Take for instance the grand groups of flowering plants that were put up at the show "W. S."

mentions. Originality in conception has led by degrees from the flat sloping banks of flowers of former days to the graceful and effective displays we now see. That there is not the same scope in fruit showing goes without saying, but there is ample room for improvement. As to the unpreparedness of show officials, that is another story, but one that badly needs correcting. Many a time have I had good fruit and other produce shifted from pillar to post by committee men and others totally ignorant of the trouble involved in its production, or the great risk of injury when it is pulled about. I am glad to see "W. S." calling attention to it, for it is a great evil, especially at local shows.

H.

Peach Violette Hative.—Again this grand Peach has finished a remarkably heavy crop of fine, good quality fruit. The flavour is sweet and good, the growth of the tree free enough for all purposes, and it is undoubtedly one of the most, if not the most, generally useful in cultivation. Always grow Violette Hative Peach was the advice of a famous fruit grower when I left him some years ago, and I have never regretted doing so.—H. R.

Apple Hawthornden.—This is a useful kind well known and much grown in many parts, but in others it is seldom seen. The large juicy fruits are excellent for cooking, and many people like them for eating, while they keep much better than the Codlin types that ripen at the same time. It is one of the best kinds for restricted culture on walls or espaliers, its growth not being over-luxuriant, but its fruits much better on bush trees where the small fruit-spurs can form along the young growth. It is also one of the prettiest kinds when in flower, and is worth planting for this alone in shrubberies.—H. R.

Strawberry Latest of All.—I was somewhat surprised to find a writer who has been some time out of gardening decrying Latest of All Strawberry as a late variety. Few other Strawberry growers will share in that *ex parte* opinion. I will aver that ninety gardeners out of every hundred who have grown it will say that Latest of All is one of the most valuable late varieties in cultivation. But no doubt it has, like all other varieties, its tastes for soils, and it does best on a retentive loam or clay. It may not be a British Queen in flavour, although much like it in appearance, but at least it will give a peck of fruit to every fruit given by the Queen, and later. Elton Pine is a good late variety where it does well, but that it does not do well everywhere is evidenced by the fact that it is now seldom grown.—A. D.

Shapely Apples.—Although there were a number of instances to the contrary, I thought that as a general rule the Apples at the Crystal Palace this year were not so large, but much more shapely than last year; more characteristic of the individual kinds. The value of the rule as to polishing the fruit was apparent, some of the dishes looking as though they had only just been gathered from the trees, the bloom being perfect. One or two of the nurserymen's collections were polished, but these presumably do not come under the society's rules. But as a whole there was much improvement. There were several dishes of Peasgood's Nonsuch and Bramley's Seedling last year that were very heavy, but the deep eyes and prominent ribs, which are certainly not characteristic of good Peasgood's at any rate, detracted greatly from their value, and the more regularly shaped specimens of this season are far better.—C. H. S.

Strawberry St. Joseph.—This new variety promises well for autumn supplies, and the flavour is really good when the plants have a good root-run and are well supplied with moisture. It fruits more freely if given a holding soil. As the runners that give the later crop are made whilst the plants are fruiting, it is essential to give them liberal culture. The fruits are not large, but they are produced freely, so that what is lost in size is made up in quantity, and they are well coloured, the flesh being bright red and sweet.

This new Strawberry is a welcome addition to our list, as it can be relied upon for autumn fruiting. There is another mode of culture to get late fruits, and doubtless this will become popular—that is, potting up late-formed runners into small pots. These placed in cold frames near the glass will give fruit in October, and as they take up so little space they may be stood on shelves later on if needed for any special purpose, and will force freely if well rooted before placing in heat. It is surprising what quantities of fruit small plants will furnish.—G. W. S.

DESSERT APPLES AT THE CRYSTAL PALACE.

GENERALLY I am in entire sympathy with the criticisms in your recent report on the single dish dessert Apple classes at the Crystal Palace, especially in relation to the scanty number of prizes offered in classes for varieties that are popular, widely grown, and of the very best description. But I fear there has been in the arrangement of the schedule a certain description of reasoning as thus: These fine varieties, Blenheim, Ribston, King, Cox's, Sturmer, and a few other Pippins are universally in cultivation, and the object should be the leading to a demand for other varieties that are newer and may be but little in cultivation, thus leading to trade. On no other basis is it possible to assume that varieties, as presented at the Palace comparatively worthless, could have had the same encouragement pecuniarily offered them, only one or two dishes, and those poor, being shown, whilst of the old popular varieties twenty dishes or more were shown, many of the samples really first-rate. I fear, so far as another show is concerned, suggestions made may have little weight as against trade requirements, but I should like to see at least six prizes offered in all those classes that in all years bring many dishes. Then, in relation to the awards made in the Blenheim Pippin class, when I pointed out that certain very beautiful medium-sized samples had been passed over—samples that exactly represented the average size and character of this fine Apple—I was met with the reply that the conditions of the schedule had been strictly adhered to. That was so, and therefore no fault lies with the judges, but with the improper conditions imposed upon them, and which they too rigidly interpreted. Really it was odd to find that, no such conditions being imposed on but one other variety, even Cox's, Ribston, Gravenstein, King of Tomkins County, and some others had larger fruits selected for the prizes than were those of so relatively large an Apple as Blenheim Pippin. Clearly, if any variety is placed in the dessert list, fruits that are the handsomest, most even, and most representative of the variety should be allowed to win. Admittedly, Blenheim Pippin may be a large-fruited variety generally, but does it for one moment compare in size amongst Apples with Pitmaston amongst Pears? Yet with this huge Pear no limitation is imposed on size of fruits shown. The fruits shown were all large, and, as your report says of Souvenir du Congrès, the fruits awarded prizes were of enormous size. I am not for one instant assuming that size is a merit in dessert fruits or that quality and size go together, but a large Blenheim Pippin is always a good eating as is a small one. But consistency should prevail in all the dessert classes. A. D.

NOTES AND QUESTIONS.—FRUIT.

Pear Triomphe de Vienne.—I note an award of merit has been given to Pear Triomphe de Vienne. Is it usual to give this award to an old Pear? I have

grown it since 1884, and then it was not a new Pear. Can you give me the names of Apples which bloom late. They escape the frost, and, what to me is of more consequence, the buds are not so frequently destroyed by birds.—GEORGE MAY, *Reading*.

Pear Pitmaston.—A. Ward, in giving a description of this Pear in a recent number of THE GARDEN, mentions that if not overcropped the fruit will average half a pound in weight. I picked from one tree on a south wall on October 6 eighty-four fruits, which averaged a trifle over 1½ lbs., and from another tree I gathered twenty fruits, which weighed 36 lbs.; the largest of these weighed 2 lbs. 2 ozs., and the smallest 1 lb. 10 ozs. In 1896 I gathered some which turned the scale at 3 lbs. During the long spell of drought I gave the trees frequent waterings, which no doubt helped the fruit to get to such perfection. I find that for an October Pear there are few that will equal it for dessert.—C. M., *Guernsey*.

— This well-known Pear is of much better quality in some seasons than others, and though rather later this year, it is as a rule good. Although many Pears are better gathered early, Pitmaston, according to my experience, is better left on the trees as long as consistent with safety. A few of the earliest and best placed may require gathering before the bulk of the crop, but most of those that drop are eaten by maggots and not worth considering. By the middle or end of October it will usually be ripe, and if properly developed is richly flavoured and melting.—H.

ORCHIDS.

CATLEYA LABIATA AUTUMNALIS.

THOUGH for size of the individual blooms this grand old species cannot compare with *C. gigas*, or for gorgeous colouring with *C. aurea* or *C. Hardyana*, there is no other *Cattleya* that can compare with it for general utility and freedom of flowering at a dull season. It was a fortunate thing for Orchid lovers when the re-discovery of *C. labiata* and the immense number of plants subsequently imported brought it within reach of all cultivators, whether their means were large or the reverse, and there is hardly a collection, large or small, where it is not represented. This of itself is sufficient recommendation for it, as, no matter how much a plant may be pushed by importers or nurserymen, unless it has sterling qualities it will not find its way as *C. labiata* has. A plant to do so must not only be free-flowering and useful, but it must also be fairly easily grown, and I should think that those writers who a few years back were prophesying the quick disappearance of it from our collections, owing to poor constitution, will by now have ceased croaking. Poor constitution, indeed! It needed a fairly good one, I should imagine, to remain for seventy years or so in cultivation with only a very few plants of it imported, and those at very long intervals.

As a matter of fact, *C. labiata* has taken its place as a popular kind, just as *C. Mossiae*, *C. Trianae*, and others have done, and it is equal to the best of them. Enter a nicely warmed house on a raw November day where 200 or so of this plant are in flower and gauge its usefulness from your impressions. In such a house a great variety in the colours of the flowers will be found. The species has, in fact, given several tints that so far have not appeared in any other *Cattleya*, as witness the charming *C. l. R. J. Measures*, the little colouring in the lip of this charming albino being quite unique. The usual tint is a rosy mauve on the sepals and petals with a deeper coloured blotch on the lip. The flowering bulbs have usually a double sheath instead of the single one of *C. Trianae*.

C. labiata autumnalis is an easily grown kind, partly because it keeps well to its proper annual routine of growth, flowering, and rest. In the *Cattleya* house there is usually a fairly regular temperature kept, this rising gradually in spring and falling

again in autumn, no very great amount of fire-heat being maintained at any time, though the house often runs up fairly high by sun-heat in summer. This suits *C. labiata* exactly, as it is usually rooting freely in spring and summer, and the cooler treatment while the plants are in flower helps to preserve the blossoms. Repotting may take place, if seen to be necessary, immediately the flowers are past, as often at this time there are young roots pushing from the base of the pseudo-bulbs, but it is best to wait until February or March if possible, and in this connection the plants should be studied individually where possible. When newly imported, the plants are often, of course, of very awkward shape, and the more these can be pulled into shape at first the better. It is wrong to bury any of the leads, and if too high out of the compost, they do not obtain the same support as do those lower down where the roots can reach it easily. Many are of a straggling habit, too—indeed, the species varies most of any I know in habit—and these require large flat baskets or pans in preference to deep pots for obvious reasons. Sometimes the pulling about a plant gets in shaping it leads to its breaking back from bare places, and a well-furnished specimen results without much trouble. No compost should be given at first, but the plants potted up in clean pots should be covered with a thin layer of compost. Some will do so almost directly; others will go on growing for a long time before doing so, but it is best to wait until the roots are starting before placing in the compost.

Cypripedium Charlesworthi.—There is a brightness about this pretty species that is lacking in many that are more rare and valuable, and though it has not, perhaps, quite come up to expectations as a popular kind or as a parent in hybridising, it is a very pretty species none the less and well worth a place in all collections. The usual treatment accorded to the genus suits it well; indeed, its easy culture is one of its chief recommendations.

Epidendrum Wallisi.—Flowers of this very useful species come from a correspondent for a name, these being of a fairly good form. Few *Epidendrums* keep up a longer succession of flower than this, the large racemes occurring from most of the uppermost joints of the leafy stems. It is best grown in an intermediate house, where there is ample room for the long shoots. The compost may be of the usual character and the pots fairly large. It is a native of New Grenada.

Masdevallia Davisi.—Orange-flowered *Masdevallias* are not very common, and the beautiful rich tint seen on this fine species is therefore all the more admired. Though it has been in cultivation over twenty years it has never become very common, but should sufficient plants of it be forthcoming, there is no doubt it would be an extremely popular plant. Its culture does not differ materially from that of *M. Harryana* and others of the showy-flowered section, it liking a cool, moist, and shady house.

Resting Thunias.—Instead of placing the old plants of *Thunias* about in draughty, cold places in winter, it would be a good deal better to turn them quite out of their pots, shake the compost all away from the roots, and tie them up in bunches, suspending them from the roof in any out-of-the-way corner in a warm house. They require absolutely no attention from the time the leaves fall until the new growths start at the base of the stems, and are better out of the way where they take up less room. It is dangerous to ripen them off too quickly, the plants always flowering more freely the next season when the leaves are allowed to come off slowly and natur-

ally. The plants have flowered well and are now quite leafless, having stood out of doors for a month with no water but what fell in the form of rain, and the stems are very plump and hard.

Feeding Calanthe Veitchi.—Those who are in the habit of feeding this Orchid as the spikes rise must be careful after this date not to do too much to it, for the roots are already beginning to lose their hold on the compost, and it is only reasonable to suppose that the plant has by now stored most of the nutriment it requires in its pseudo-bulbs. I doubt very much if feeding ever does any real good after the leaves have attained their full size, for a decided check to root-action occurs then, and unless the roots are active they cannot certainly assimilate anything in the way of manure. Clear water then only ought to be used, and only sufficient of this to keep the bulbs plump and hard, while as soon as the leaves fall even this may almost entirely be withheld.

Miltonia Clowesi.—A good form of this species comes with other Orchids from a Somersetshire correspondent. It is a useful autumn-flowering species, each bloom about 3 inches across, the sepals and petals chestnut-brown, with markings of orange-yellow, the lip violet and white in a very pretty combination. *M. Clowesi* likes an intermediate temperature with plenty of atmospheric and root moisture while growing, not too much in the way of compost, and a flat basket or raft. It should be kept a little on the dry side in winter, but nothing like a shrivelled condition of the pseudo bulbs must be allowed. It is a native of the Organ Mountains in Brazil, and first flowered in this country in 1839.

Cattleya bicolor.—This pretty and interesting species is in flower now in many collections, and I noted a fine specimen in full bloom during the week. It is an upright-growing plant with flower spikes springing from between the upper pair of leaves, each one bearing a number of flowers. The sepals and petals are of a greenish brown or olive tint, the side lobes of the lip do not unfold the column as is usual in the genus, and the front lobe is of a very pretty crimson-purple tint, sometimes with a margin of white, as in *C. b. Measuresiana*, sometimes with green. It thrives in the *Cattleya* house in fairly large pots or pans filled with a rough, open description of compost consisting of peat-fibre and Sphagnum Moss, with plenty of large rough lumps of charcoal and crocks. It should be gently excited in spring and grown as strongly as possible until it flowers, after which it rests, and may be kept a little on the dry side during the winter.—H.

Dendrobium nobile is, I think, most useful and one of the easiest of cultivation, for where a number of plants are grown a succession of bloom may be kept up for six months out of the twelve. The flowers may be used in a cut state either without or with the pseudo-bulbs, in the latter case with little or no injury to the plants if strong. Plants while in flower may be utilised for conservatory or room decoration with good effect, and will continue in full beauty for a period of six or seven weeks. They can be cultivated on blocks of Tree Fern, in baskets, pans, or pots. The var. *nobile Wallichianum* succeeds equally as well as the ordinary *nobile*, but produces longer and stronger pseudo-bulbs, with finer flowers of more substance, the nodes not being so liable to turn to growths as in the ordinary variety on being placed into heat after the resting period. I have some plants from three to four years old taken from offsets and made up in the baskets, pots, or blocks they flowered in. A single specimen growing in a basket 16 inches square (made of Oak strips) carried over 1000 expanded blooms, while several plants carried over 800, one being in a 10-inch pot. The plants have been kept in a cool *Camellia* house since last September until the early part of the following May, when they were placed into a warmer temperature (giving shade from hot sun) to expand the flowers.—W. SLOOCK, *Hollycombe Gardens*.

FLOWER GARDEN.

THE HOLLYHOCK IN REGENT'S PARK.

THE Hollyhock is one of those good old plants that find favour with everyone. All are familiar with its stately habit and bright flowers that make a great show for a considerable season. How varied these beautiful blossoms are! Unfolding in early morning, what lovely tints are disclosed, vying with the Rose in extreme delicacy or in the brilliancy of their colouring, and

planted in the grass in the foreground of shrubberies and in other places.

The culture of the single Hollyhock is of the simplest description. Each year seed is saved from plants of good habit with the brightest blooms in various colours. Branching plants of moderate height are desirable, for the more stems there are the greater should be the show of flowers. Seed is sown thinly in the open ground about the end of March, and when ready the seedlings are transplanted into nursery beds. They grow quickly and require but ordi-

before coming into bloom. The careful preparation of soil in the flower garden is equally as important as that of the vegetable or fruit garden. It is in dry seasons that good culture tells. My practice is to supply the beds and borders with stable manure, which is placed under the roots of the plants to induce them to go downwards out of the way of drought. The Hollyhock is one of those accommodating plants that submit with a good grace to unusually free treatment; for instance, I regularly transplant them in May and June to fill vacancies after bulbs. If the operation is carefully performed they suffer very little. The plants shown in the accompanying illustration were removed to their flowering position at the end of May last. The Hollyhock season may be prolonged by pinching out the points of a certain number of young plants in groups or borders when the growth is about 18 inches high; these usually break freely, and produce flowers about the time the plants not so treated go out of bloom.

The method of staking is of importance; it need only be considered as support to the plant, and should allow its natural habit to continue unchecked. In the Hollyhock the stems proceed from the base and open outwards in an easy way. They should be supported in that position and not so rigidly upright as they frequently are. Under generous treatment these plants thrive for many years. As biennials, finer flowers are produced; as perennials, they give an excellent account of themselves that assures them a very high place amongst the garden flowers. C. JORDAN.

Group of single Hollyhocks in Regent's Park. From a photograph by G. A. Champion.

so daintily set midst an abundance of foliage on trusty stems that gently grow upwards until they become the giants of the flower border. When planted in large groups the effect is excellent; in smaller ones it is generally good, and is particularly so when massed at the end of a vista where colour is needed. The single-flowered variety is grown in Regent's Park, as it is considered better for decoration than the doubles. There are groups of hundreds together, as well as settings of a few dozen or so

nary attention for the remainder of the season, when they should be strong roots. They are perfectly hardy in most parts of England. It is to be observed that this applies to plants grown in open positions, for if crowded in nursery beds or in flower borders they do not stand severe weather. In the following spring the seedlings may be planted in their flowering quarters in borders or any other place where there are prepared stations, and then they require little more than staking and tying

Castor-oil plants.—Apart from their value as fine foliated plants in the summer and autumn the flowers of the *Ricinus* are now very attractive. The very deep bronzy-leaved kinds, such as *Bronze King* and others, do not, however, produce such highly coloured blossoms as the green-leaved kinds, nor do they look so well against the leaves as all are of one colour. I have a tall-growing variety with leaves of a deep metallic green, and the flower-heads of this are the brightest crimson imaginable. It is a seedling from a mixed packet of seed, so I do not know the name of it, if it has one.—H.

Pentstemons.—I have seldom had so good a display of these as this season, and even now (October 9) they are quite gay. Large old clumps do not produce such fine flowers as seedling plants or plants from cuttings, but it is remarkable what a long time they keep in flower. I have a large number of seedling varieties, some with flowers almost as large as *Gloxinias* when at their best in summer. Cuttings strike easily in a cold frame in autumn, and the resulting plants may be put out in spring. Seed may be sown at any time of the year, and either of these methods is far preferable to breaking up old plants.—H.

Liatris pycnostachya.—The greater number of herbaceous subjects now in bloom belong to the order *Compositæ*, and this is no exception thereto, but at the same time it is in general appearance so widely removed from the others in flower that at a casual glance it would not be recognised as a near relation of the *Asters*, *Sunflowers* and such things. This *Liatris* forms a tuft of narrow leaves from whence are pushed up spikes that reach a height of 4 feet or 5 feet. The upper half of the spikes is crowded with bright purplish rose blossoms, a decidedly uncommon tint. Just now there is a fine tuft with numerous spikes in the rock garden at Kew, and few, if any, subjects are more admired than this. It is a native of North America, and was illustrated by a coloured plate in *THE GARDEN*, April 8, of the present year. It thrives in dry soils better than many other subjects.—T.

Daffodils.—The force of circumstances has allowed this year for a big planting of Daffodils in

a situation that will show them off to the best advantage. In common with many places in the south of England where the soil is dry and light, we had this summer a slight fire in the pleasure grounds, originating from a spark from a rubbish fire. It was, fortunately, discovered before it had made much headway, and by isolating the space it gradually burnt out after damaging more or less some 800 square yards of Laurels and common Rhododendrons. After getting out all the old stumps the ground was bastard-trenched, working in at the bottom of the second spit a quantity of decayed leaves. Plenty of Daffodils were available in several varieties, a lot having been removed from a border that is likely to be required for other purposes, and I have planted about 5000 or 6000 of them on the fire cleared space. The site, as mentioned above, is an ideal one at the end of a long glade, where they will have the grass as a foreground and be backed and flanked by masses of Rhododendrons, the background sloping gradually upwards. The front, as it was, ran in a straight line, but certain portions of the grass have been taken in to admit of some curves.—E. B.

MAY-FLOWERING TULIPS.

Now that the season is again with us for planting nearly all kinds of bulbs, a word may be said in favour of the tall-growing Tulips, which are not met with so frequently in gardens as their beauty and usefulness deserve. There are many who are always ready to add something of interest to their bulb garden or herbaceous borders, and it is in these positions the Tulips referred to find the best home, simply because they are or should not be lifted each spring the same as the dwarfier growing varieties generally used for spring bedding and window boxes. It is certainly a mistake to plant what is known as the Gesneriana and breeder Tulips in ordinary flower beds, where they have to be lifted directly they have passed out of flower to provide room for the summer occupants. They are not only not seen under the best conditions when used in this way, but what is worse, the bulbs generally are of little value the following year, owing to having been disturbed before growth was properly completed and the bulbs matured. A permanent position should always be selected for them, as the bulb garden proper, or established in the herbaceous borders, and when massed in fairly large clumps, they are unsurpassed during May for brilliancy of colour or for cutting. In planting a collection of these it is best to prepare the ground thoroughly first, as it is not desirable to disturb the bulbs afterwards. In selecting the different sites, it should be remembered that many of the varieties send up flower-stems nearly a yard high; therefore, when planting in the mixed borders they should not be placed too near the front. It is always advisable to have the different varieties distinctly labelled; and to properly mark the exact spot where the bulbs are situated, it is a good plan to drive in a strong stake that will stand out of the ground a few inches and which is stout enough to last for several years. Having marked the position in this way, from a dozen to thirty bulbs may be dibbled in round each stake, allowing, say, 4 inches space between each. Clumps formed in this way are easily supported to one neat stick before the tall flower-stems are fully developed to prevent them being twisted about by wind, which is not convenient to accomplish when each plant is separated some distance away from its neighbour, while being massed they present a more pleasing feature.

As regards varieties, the one most generally grown is undoubtedly Gesneriana and its variety major. Each has dazzling scarlet flowers, which are further set off by being backed up

with some evergreen shrubs. A good companion to the above is retroflexa, which should certainly find a place in every garden. The flowers are of a beautiful clear yellow. When fully developed the petals recurve most gracefully. If my list were limited to three varieties only, I would add Picotee, though there are several others well worthy of being represented. In the three named, however, quite distinct colours are secured, as Picotee is of a creamy white, shaded with delicate pink, a truly beautiful flower which is much appreciated for table decoration. Another important point connected with these Tulips is that they flower freely in the open during May and early June, when it is yet too soon to expect much variety from the open borders, and, moreover, as they travel well and last a considerable time in a cut state, a good collection would prove a boon to most gardeners who have to supply their employers with flowers at that season miles away from their country residences.

R. PARKER.

NEW CACTUS DAHLIAS.

MANY new forms were exhibited at recent meetings; all more or less fine as staged on wire frames. Of course, from such a way of seeing them one cannot judge exactly of their merits, because the habit of growth is known only to those who raise them. The taste now seems to be for a light arrangement of the florets, and elegant indeed some of the new sorts are. Mrs. J. J. Crowe is a light yellow, with a still lighter shade on back of each floret. This lighter tint is noticed here and there in the bloom, and does not detract from its beauty. The form is excellent. Mrs. Carter Page, a lovely shade of wine-crimson, and the flower of first-rate shape, is a very attractive variety. Uncle Tom is a very dark maroon, which is an improvement in formation upon other dark kinds in cultivation. Green's White is a capital addition; the best of the colour yet introduced. Eclipse is the most beautiful of yellows—so clear in colour and the shape quite perfect. The narrow florets stand out in star-like form to the centre, which is full. This variety may be considered the first of a new and refined type. Innovation is a fine form in which crimson and white are combined—most of the former shade. Not unlike Arachne, a sort that always creates interest, it is an improvement thereon, being larger and having a bolder look. Emperor is a large, rather heavy-looking flower of a plum-purple colour. Mrs. Saunders has flowers of a rich deep yellow, but to me it does not appear to have enough petals to make it an acquisition. Major Tuppenny is a curious variety, large, of nice form; colour a brown tint, with a heavy shade of yellow in the centre, which makes it distinct. Zephyr is a charming sort in the way of colour, which is lilac-pink, soft and pleasing. The form of the flower did not strike one as being among the best. Elsie may be named as an especially pretty variety, primrose ground, shaded pink, with everything in the way of shape and size to recommend it. Sylph is a pretty sort, not unlike Lucius, with longer florets. The latter I fancy is the better. Whirlwind belongs to a shape of which Fantasy is the type, narrow petals, which incurve towards the centre of the bloom; this shape is not the least charming if less showy than other forms. Loyalty is of similar shape, the colour being a brick shade of red. This is a full, handsome flower. Augustus Hare has richly formed blooms, crimson-brown, with lighter shade on the edges of its petals. This gives it a distinct character. Ajax is a fresh-looking buff-shaded flower of the incurving Fantasy type. Decima, still another of that form, has pink and salmon shades.

H. S.

Sea Lavenders.—In last week's GARDEN is a note on a new *Statice penduliflora*. Is this a distinct variety or only a form of *latifolia*? I have been led to the query from the fact of the last

named varying so much from seed, not so greatly, perhaps, in habit, but very considerably in size of panicle, colour of individual blooms, and still more in the time of flowering, this being a great advantage. Some few years ago when planting a border that was to be devoted almost entirely to autumn flowers, I selected a corner for alternate clumps of *Statice latifolia* and *Anemone japonica*, and the effect is very pleasing. Both are among the few herbaceous plants that will flourish for years in the same spot, and once planted give no further trouble except an annual winter mulching. Writing of autumn plants reminds me to note wonderful displays this year of *Chrysanthemum uliginosum*, especially in low-lying situations where the soil is deep and good and rather moist. Although this plant may lack, so far as its flowers are concerned, the substance of some of the best forms of *C. maximum*, it is from its light and graceful habit even more acceptable in a cut state.—E. B.

LILIUM RUBELLUM.

THE notes by Mr. Peter Barr concerning this and the beautiful *L. Krameri* should prove valuable. It is not often that dwellers in the British Isles have the opportunity of embracing such information as Mr. Barr's letter affords. It is the more valuable because of Mr. Barr's enthusiasm in his endeavours to grow this or that Lily with success in this country. Undoubtedly, as Mr. Barr says, knowledge gathered on the spot would have had an untold value in the past, but it is none the less welcome to-day, for there are hosts of people that would devote a goodly space in their gardens did they but possess the knowledge of how best to treat the bulbs when received. The information given by Mr. Barr obviously resolves itself into one of conditions and suitable environment, and as I have so frequently in the pages of THE GARDEN urged this very companionship of tree root and fibre in the successful culture of some of the more frail-growing Lilies, and to which Mr. Barr attaches no little value, the notes have interested me greatly. Some few Lilies that come to us from Japan may, and indeed are, freely manured when planted, and this to their advantage. I refer to the *L. speciosum* group more particularly. There are others, however, to which this manure is so much poison. The stony and poor soil, which is also the poorer for the free intermingling of roots and fibres to which reference is made at page 255, is just the soil I should expect to find either *L. rubellum* or *L. Krameri* succeed in. This is why I have more than once urged the planting of the latter in beds of Rhododendrons or *Azalea mollis* as the nearest possible resemblance to a perfectly and constantly drained condition. In these or similar plantations there is not only the root condition reared as nearly perfect as possible, but in spring again the branches afford an oft-time needed protection from the late spring frosts. Nor should the fact be overlooked that some of the finest *Lilium Krameri* probably that have been grown in this country were grown under these very conditions of root protection by the late Mr. Macintosh in his garden of Rhododendrons at Weybridge. These plantations of Rhododendrons were mostly composed of steep banks, that alone afforded a very efficient drainage. A chief difficulty, of course, is in securing fresh and sound bulbs of these frail and beautiful kinds, and once this is overcome many more groups may be seen in British gardens.

Mr. Barr is evidently surprised at the poorness of the soil in which he found these Lilies in such promising health, and he is deserving of all praise for the very prompt manner in which he has given the experiences he has gained. Sooner or later this information will assuredly be of service, and when good, sound, and fresh bulbs are obtainable, these should be planted as nearly as possible on the lines suggested by Mr. Barr. Those not possessing beds of Rhododendrons will be able no doubt to form groups in places where the bulbs may receive the benefit and companionship of tree roots of some kind, or small slopes may be

planted specially with suitable subjects with a view to establishing the plants named. This reminds me also of how well I succeeded with the more gorgeous *L. auratum* in a position much too dry for most things, but which suited this kind exceedingly well. The spot was beneath the shade of a fine Beech tree and some 30 feet distant from the trunk. A bed was made of peat screenings, leaf-mould, and clayey loam, in itself of a very adhesive nature, to obviate which a very liberal addition of read sweepings was given. *Azalea mollis* and *Daphne Cneorum* were the chief plants, the bulbs of the Lilies being planted around these things and not in the ordinary way of grouping them. The Lilies were quite a success, and permanently so, as they remained for nearly ten years without disturbance. Mr. Barr has also referred to *Lilium rubellum* as a pot plant, in which state it may be said to have made its *début* in this country, having been thus grown and exhibited at the Temple show about eighteen months ago. It is worth stating, too, that it is an early Lily naturally, so that those growing it in pots will have no occasion to force it unduly; rather should forcing be left out of the question, and the flowering be brought about in the more congenial temperature of the greenhouse. — E. JENKINS.

— This charming Lily is the most recently introduced, and without exception the most beautiful of Japanese Lilies for pots. During the last two years it has been sent to the European and American markets in large quantities, but, unfortunately for the shippers, at a considerable pecuniary loss, through their not sufficiently appreciating the requirements for the packing of the bulb. The buyers, on the other hand, have not been successful in their cultivation. The blame for this is due to the exporters not giving their clients a description of the conditions which surround this Lily in its native habitat. It grows in the northern part of Japan, and is therefore quite hardy. It is found in Pine forests with a dense undergrowth of Bamboo, &c., the soil being dry and poor. It follows that success is likely to attend its culture only by keeping the above information in mind. It is therefore suggested that a poor, stony loam be used, with 2 inches of drainage and three bulbs to a 5-inch pot, keeping the soil slightly moist. Over-watering is sure to be disastrous. The pots should be kept in the shade, but not such as would naturally draw the plants. The Lily attains a height of 1 foot, and is compact and sturdy in growth. This character should be maintained. It may safely be said of this pretty Lily, which blooms in April or earlier, that it will prove to be the gem of the greenhouse, conservatory, or sitting-room. In Yokohama, out of doors, it flowers at the end of April and beginning of May. It should be grown on a raised bed of poor, dry soil and out of the sun's rays, or plant on a dry bank facing east or north. We in Yokohama grew it under deciduous shrubs close into the roots, where the condition of dryness is natural and protection is secured from the sun's rays. *L. Krameri* grows in the south of Japan under the same conditions as *L. rubellum*. It flowers one month later, requires the same cultural treatment, and attains a height of 3 feet. — G. W. ROGERS, Yokohama.

Pompon Dahlias.—It is now nearly forty years since my admiration for the pretty little pompon Dahlias was first aroused, and at that period the now numerous forms of Cactus and single flowers were quite unknown. Despite the fact that formal blossoms are not admired at the present time, I think a well-flowered specimen of one of the pompon varieties a very beautiful object. The blossoms are borne well above the foliage and on good stout stalks, so that they are little affected by the wet. True, they are lumpy and of a hard, formal outline; still, their regular symmetrical shape is not at all displeasing. The huge blooms of the show and fancy varieties are not nearly so effective on the plant as those of their smaller relatives. Some of the pompons,

too, are of remarkably bright and attractive tints, and good bushy specimens of them are hard to beat during the latter part of the summer. At the present time Cactus Dahlias held the sway and form the subject of many notes, but the pretty little pompons are seldom referred to.—H. P.

Dahlias at the Westminster Aquarium.—I have to thank Mr. J. F. Hudson for his information as to the certificates awarded to seedling Dahlias at the Aquarium Dahlia Society's show. Being, as I have said, there on the second day, not only were the flowers faded out of all recognition, but the gummed labels or slips originally stuck on the receptacles had fallen or disappeared, for I saw very few indeed. Now that the certificate-awarding season to Cactus Dahlias is over for this year, will Mr. Hudson, as the secretary of the National Dahlia Society, kindly inform readers of THE GARDEN how many have received such awards from the National Dahlia Society and the Royal Horticultural Society this year. I can but

a lovely form; colour light yellow, with just a tint of buff as the flowers become fully open.—H.

Helenium nudiflorum.—As Mr. Burrell (p. 285) appears in favour of a shorter name for the plant originally called *H. grandicephalum striatum*, one can only suggest the adoption of the above, which is the up-to-date name and somewhat shorter than the original, which is certainly a cumbersome one.—E. H. JENKINS.

ROSE GARDEN.

ROSA MOSCHATA (R. BRUNONII).

AMONGST all the floral beauties to be met with among the Roses, *Rosa Brunonii* as grown at Mount Usher, Co. Wicklow, would be hard to beat. It covers the entire roof of the old kiln-house, and in July is a wilderness of snowy blossom, spires like that in the illustration being produced at every joint on shoots 15 feet or 20 feet long, the growth of the preceding year, each raceme bearing thirty or forty flowers and buds, which are pure white, with golden stamens, and with a most delicate perfume. It is a native of Nepal, was introduced in 1822, and is said to be one of the parents of the Noisette Roses of our gardens. Mr. Walpole tells me he has had the plant some ten or twelve years, and that it has never been pruned. It is now covered with great masses of richly-coloured heps. G. P.

Rosa moschata (R. Brunonii). From a photograph by Mr. Greenwood Pim, Dublin.

think that the information will show that these awards have been rather lavishly if not loosely granted. So far as I have seen the very best have been Green's White, Major Tuppeny and Mme. Medora Henson, a very true Cactus, but the general run show little or no advance on such beautiful varieties as Mary Service, Starfish, Magnificent, Charles Woodbridge and a few others universally grown. It is high time with these very popular flowers that a very severe standard should be set up. But if it be found that from twenty to twenty-five certificates have been awarded to new ones in one season alone, then will it be evident that only a mediocre standard exists.—A. D.

NOTES AND QUESTIONS.—FLOWER.

Cactus Dahlia Ethel.—This was new a year ago, but somehow few seem to have noticed it. It is

Those of Meg Merrilies are of a brighter crimson tint new than when opening for the first time. All are very hardy and sweet, and are now covered with the bright red heps.—SUFFOLK.

Rosa sericea.—To grow this pretty Himalayan species merely for its attractive wood and foliage would be a sufficient inducement to many admirers of hardy trees and shrubs; but when we know that it also produces lovely single white flowers with a faint lemon tinge not unlike those of *R. spinosissima altaica*, then it becomes doubly valuable. Upon young bushes the richly-coloured wood is most marked. One-year-old bushes at the present time are sending up young growths of quite a lovely ruby-red colour and adorned with immense black prickles. Upon the elder growths this rich colour is not so brilliant, but even these are of a very interesting dull red colour. Good hard pruning of the oldest wood will compel the production of the very

Rosa Pissardi.—This is a charming semi-double Rose, especially useful for autumn flowering. Allied undoubtedly to the Musk Roses, its fragrant flowers are always welcome. I can recommend the variety with every confidence, for it is so continuous in flowering, and the beautiful corymbs of blush-white blossoms produced upon erect growths make it a useful Rose for the shrubby border, where such Roses should be located, provided they obtain sun and are not smothered, which is often the lot of many beautiful flowering shrubs.—P.

Sweet Brier Meg Merrilies.—This has proved one of the best of Lord Penzance's hybrids here, the growth being strong and vigorous and the flowers of great beauty shown up well by the deep green foliage. It is the only one that has flowered the second time this year, though last season the pretty yellow and coppery Lady Penzance gave a few blossoms.

attractive younger growths, but, of course, if a profusion of blossom is desired this must be done with judgment.—P.

Rose Mme. Lambard.—The cooler days and light frosts at night have spoiled the beauty of many of the Teas, but it only seems to increase that of this lovely variety. I have a large bunch of it on my table now, and the small pointed buds, the half-opened ones, and the full-blown blossoms are all equally beautiful. Such a fine Rose so hardy and free flowering deserves to be planted in every garden, and to those who force Roses in spring its fine colour and the readiness with which the blossoms open under unfavourable conditions make it especially useful. Isabella Sprunt is another that opens well now, and the pretty shades of yellow in this contrast well with the reds in Mme. Lambard.—H.

Rose Alfred Colomb.—This excellent Rose, which ranks as one of the best light red varieties, has been exceptionally beautiful upon outdoor-grown pot plants this autumn. It is always very free in autumn and good at all times, but I do not remember seeing it so fine at this late season of the year. There is much resemblance between this Rose and Marie Baumann, but while the latter is grand when at its best, it is not nearly so reliable as Alfred Colomb. Certainly the latter does not droop—a bad fault on the part of Marie Baumann. The flower is a very double one, of globular form and high centre. It is usually cited as a typical high-centred Rose. Perhaps this variety is at its best upon maiden or one-year-old plants, but I have seen it very good upon cut-backs. Our American friends introduced a variety named Marshal P. Wilder, which they described as an improved Alfred Colomb, but our own growers are agreed that the two kinds are identical.—PHILOMEL.

Rose General Jacqueminot planted out under glass.—This old Rose still holds its own as one of the best brilliant scarlet-crimson kinds either for the garden, for exhibition, or for early cutting. Certainly the best method of growing it under glass is to plant out in good soil. The bushes then make almost incredible growth. I have seen this Rose make shoots quite 8 feet in length in one season. From such vigorous bushes one is not afraid to cut the flowers with a 2-foot to 3-foot stem, and as this appears to be the prevailing fashion, every gardener who has a great demand for brilliant Roses would do well to plant a houseful of this during the coming season. It is far better to devote one house to one kind than attempt a house of mixed varieties. A little experience will soon teach an observant man what is really the best treatment for each variety. In these days of cheap glass structures I am surprised there are so few houses erected for Roses. They need not be of a very elaborate description, and if just sufficient heat is provided to keep out frost, blooms of the first quality may be had at but very little expense. Every four or five years the bushes should be transplanted, when the soil may be enriched with some bone-meal and cow manure. As the plants grow, instead of coddling them, afford plenty of air at first and syringe with cold water, then, if cold draughts are avoided, little or no trouble from mildew will occur. I think this trouble of mildew often deters many gardeners from growing indoor Roses, but if the bushes are planted out and an even, buoyant temperature is maintained this fungus will rarely appear.—P.

Thinning out climbing and pillar Roses.—It is not yet too late to perform this very helpful operation. Obviously if the plants are relieved in autumn of all the very old wood the remaining growths stand a better chance of ripening, and, of course, would consequently pass through a severe winter with a diminished risk of injury. The eggs of the troublesome insect pests are usually deposited upon this old wood, and to destroy such means less trouble in the spring. Climbers either upon walls or arches or pillars that are only summer-flowering I prefer to thin during August, but the autumnals may be left

until a somewhat later period. It is surprising how vigorous growing Roses are helped by cutting away the worn-out wood. Whilst this is allowed to remain, the fine eyes at the base are prevented from breaking, and, as every gardener knows, the strong young wood is the very life of a climbing or pillar Rose. What a difference in the trusses of blossom produced from wood not more than two years old from that emanating from miffy, twiggy shoots. I would rather see a wall plant flowering low down upon good healthy growths than a specimen bare for some feet at the base and a few flowers high up the wall. It is quite true many individuals make a mistake in planting the very rampant sorts upon moderate walls. The proper kinds for 8-feet to 10-feet walls are really such as Safrano, Homère, &c. I saw Safrano quite recently growing against an 8-foot wall, and it had almost reached the top, not one thin branch, but bushy right from the ground. Where Roses upon trellises, arches, &c., have been neglected and are now a tangled mass, the present would be just the time to clear away a lot of this superfluous growth. Perhaps one cannot thin such plants as one would wish, but a start should be made, then if they are annually treated as advised, a great change for the better would be manifest.—P.

PLANTING ROSES.

THE earlier in November Roses are planted the better. Any time, in fact, after the beginning of October is suitable for the work, provided sufficient rain has fallen to moisten the ground and enable lifting to be carried on without injury to the roots. Where the plants are obtained from a local nurseryman it is much better to send a conveyance and have them lifted and placed into it at once than to have every bit of soil shaken off and the plants possibly delayed after packing. The careless way in which Roses are often treated when sent from a distance deserves the severest censure. Often not a bit of anything damp in the way of Moss or litter is placed round the roots; they lie about often in a piercing cold, dry wind with their roots quite exposed, and are then simply wrapped and tied in straw, the consequence being that when unpacked, the foliage as well as the wood has quite shrivelled. The best thing to do is to unpack them directly they arrive and place the roots in water for an hour or two. This will plump them up and invigorate the plants a little. A little trimming will usually be necessary, and, in planting, some of the finer portions of the soil must first be placed over the roots. If carried out in suitable weather, the soil may be somewhat firmly trodden as it is filled in, and the top tier of roots may come within a few inches of the surface. A mulch of loose material completes the work, this being of a manurial character if the soil is poor and needs it, otherwise half-decayed leaf soil and refuse of potting and other soils will suffice.

In preparing quarters or beds for Roses, deep cultivation is absolutely necessary. Soils inclined to be heavy are usually looked upon as most suitable to Roses, and if they are well tilled there is no doubt that they grow the finest Roses. A soil that is wet and cold in winter and cracks badly directly the sun reaches it in summer is not the best by any means, though it may be heavy. When such a soil can be brought into a friable state by the addition of opening material, as ashes, road sand, and leaf soil, then it is the ideal one for Rose growing. Light, sandy soils, on the other hand, require the addition of clay, brick earth, marl, or some such substance to render them more holding. Here cow manure is preferable to that from stableyards, while additions of fresh and fairly heavy loam should be made as often as possible. The manure in this case should

be placed in the bottom of the trenches when the soil is being prepared, and Tea-scented kinds, as a rule, especially the strong-growing climbers, make great headway when planted in them. On the red sand in Gloucestershire, one of the very worst of soils for producing Roses of good quality, I have had excellent results when separate beds have been treated in this way. The Mme. Isaac Periere and Victor Verdier class used to make immense growths, that, shortened a little and pegged down, gave a very large number of excellent flowers. Niphotos, too, was a notable success, but the Comtesse de Nadailac and similarly habited Teas, strange to say, did very little good.

A good medium soil needs little beyond trenching a couple of spits deep to fit it for Rose culture, and feeding from the surface will be necessary annually, applying the manure in the form of a mulch in spring after the pruning is done. Anyone with such a soil may with advantage plant the free-growing, constantly flowering Tea-scented section in quantity.

H.

NOTES AND QUESTIONS.—ROSES.

Rose Daisy.—This is a very free and constant flowering variety, but I have failed to discover any other merit in it. It is undoubtedly a seedling from Mrs. W. J. Graut, for the growth and colour of flower show this. Unless a Rose is distinct and has some claim as an improvement upon existing kinds, why burden our already prodigious collection with such an addition as this? In Killarney, presumably another seedling of Mrs. W. J. Graut, the lovely semi-double flowers were very fine during the first few days of October.—P.

Rose Augustine Guinoisseau.—Of the autumn-flowering Roses the above lovely sport of Ja France is very generally esteemed. It will hardly bear comparison with its parent in the Rose season, the flowers then being devoid of substance, but just now it is delightfully fresh and attractive, and, moreover, it is one of the most fragrant kinds. The lengthening nights seem to be just suited to the proper development of the variety. Being nearly white with just a tinge of flesh-pink, a mass of it is probably the first to arrest the eye even when viewing a large collection.—P.

Roses on own roots.—A couple of months ago I was in just your position. I am making a new garden, and I was determined to have a lot of the best Roses all on their own roots. I wrote to the leading nurserymen and found that no one could supply them. Then I wrote and asked for quotations for cuttings. F. Cant, Colchester, was the lowest. He sent me excellent cuttings at about 7s. 6d. per 100. I got cuttings of other Roses which he had not got from other firms, and am getting a few remaining ones to-day from France. I put these cuttings into a close frame without heat, some in fine gravel, some in cocoa-nut fibre. I sprinkled them twice daily. Already some 90 per cent. of them have struck.—A. K. BULLLEY, *Neston, Cheshire.*

Rose Gloire des Rosomanes.—As a brilliant crimson autumnal there are few Roses to surpass this old favourite. How beautiful the semi-double Roses are at this season of the year. Just now the new growths of Gloire des Rosomanes are each crowned with trusses of buds, which being semi-double have a fair chance of expanding; whereas very full kinds would decay on the plant. A good hold bed of the above Rose would be a grand feature upon the lawn. There is no set style in the growth of this variety as with many of the Hybrid Perpetual class. Gruss au Topf is surely a seedling of Gloire des Rosomanes, although it is described as being a Hybrid Tea. The growths of the two kinds are very similar, the same peculiar shiny green wood and whitish spines being evident in the later introduction. They would certainly harmonise together and form a very bright mass of colour for the autumn days.—P.

The toad.—From the earliest times the toad has been associated in the popular mind with a host of vague and ludicrous fancies as to its venomous qualities, its medical virtues, or, most commonly, the hidden toadstone of priceless

value. To these venerable creations of the imagination have been added others equally absurd, such as that touching toads will produce warts on the hands; that killing toads will produce bloody milk in cows; that a toad's breath will cause convulsions in children; that a toad in an open well will ensure an unfailling supply of water, or in a cellar will bring prosperity to the household, &c. The Massachusetts Hatch Station which has conducted an investigation of the habits and food of the American toad announces that a careful examination of the stomachs of a large number of toads showed that 98 per cent. of its food was animal matter, worms, insects, &c. "Eleven per cent. of the toad's food is composed of insects and spiders beneficial or indirectly helpful to man; 80 per cent. of insects and other animals directly injurious to cultivated crops in other ways obnoxious to man." Properly speaking, the toad is a nocturnal animal, feeding as a rule continuously throughout the night. It eats only living and moving insects, caterpillars, &c.

IMPROVING PLANTS BY SELECTION.

AN admirable paper dealing with selection and its effects on cultivated plants has just been issued by the United States Department of Agriculture. It was written by M. Henri L. de Vilmorin, of Paris, whose recent death inflicted a heavy loss on agriculture in all civilised countries. Of the plants referred to in the paper none possesses greater interest than *Brassica oleracea*, the wild type from which all the many forms of cultivated Cabbages have been derived. In its native haunts it may be found to-day on the limestone cliffs that border our coasts. It is a half-woody, half-herbaceous plant, possessing thick fleshy branches and leaves, the stem and root crown also being somewhat swollen. Ordinary Cabbages represent this plant reduced to its simplest form—that is, to a single erect stem bearing at its free extremity numerous large, thickened leaves, more or less closely crowded together, which, according to their shape and the manner in which they are laid one over the other, form heads that are oval, conical, spherical, or flattened. Similar outlines are found in the Savoys, which differ from ordinary Cabbages in the development of the spongy tissue between the little nerves of the leaves, imparting to the upper surface a blistered appearance. The same variety of forms is found among the red Cabbages, where the entire leaf is coloured a deep red. All these forms are the result of a patient and prolonged selection which has given to them almost complete permanence. These, however, are not the only modifications of *Brassica oleracea*. There are various headless Cabbages or Kale, well known to farmers, and especially to sheep feeders, which differ widely in size, shape, and colour. The Collard, for example, has round, spoon-shaped leaves, overlapping, but not crowded together to such an extent as to deprive those in the middle of air and light and thus blanch them, as is the case with the inner leaves of the head or hearted Cabbage. There are many varieties of Kale, with the leaves green or red, entire or much divided, flat or curled—Portugal Cabbage, Cow Cabbage, branched Kales, Palm Borecole, and many others, among which Brussels Sprouts is not the least remarkable. Taking advantage of the tendency of the stem to thicken, selection has established a form the entire stem of which becomes large and fleshy, and yields a product that can be used as a vegetable when young and tender, and is valuable as

A CATTLE AND SHEEP FOOD

in winter when it has attained its full development. If, instead of involving the entire stem,

the swelling is localised a little distance above the ground, the plant well known to English farmers as Kohl Rabi is formed, and there are numerous varieties—large or small, early or late, violet-coloured or white. The capability of becoming thickened and fleshy is not limited to the stem. The tap-root possesses it also, and plants which showed a marked tendency to vary in this way having been noticed and reproduced have yielded, under the influence of long-continued selection, the Turnip-rooted Cabbage with white flesh, and the Ruta Baga with yellow flesh. They are round, oblong, or flattened, and may weigh as much as 18 lbs. or 20 lbs. Selection has produced these numerous forms from a root that weighs no more than 2 ozs. in the wild state. The many kinds of Cauliflower—early or late, of varying size, white, yellow, rose or violet in colour, and of various degrees of hardness—have likewise been developed from *Brassica oleracea*.

Celery is an instructive illustration of the results of selection. The useful part of the plant being the leaf-stalk, efforts were, and still are, directed toward the development of this organ by reducing other organs to the smallest size compatible with the efficient growth of the plant. The self-blanching Celery was found in the neighbourhood of Paris a dozen years ago. The original plant yielded seed from which was raised a good proportion of the new variety, but also some green plants. By persistent selection the proportion of green plants has been considerably reduced, but they have not yet entirely disappeared. By way of compensation this race has yielded a pretty variation with rose-coloured ribs, which is becoming fixed. It had been noticed that the fleshy roots of Celery, on which the leaves are inserted, possessed a special flavour and were sweeter than the stalks, although not so clear in colour. By selection certain plants have been obtained in which the root has been modified into a large, well-shaped, and very regular, rounded enlargement, as in the Erfurt and Prague Turnip-rooted Celeries. The sugar Beet, the garden Beet, and the Mangold have all been produced from one common wild progenitor, *Beta maritima*. The deep red colour of garden Beets is of very great importance. But in sugar Beets the absence of colour—that is, the perfect whiteness of the flesh of the root—is a condition of perfection, and selection has effected this remarkable specialisation. There is no necessary or absolute correlation between the colour of the root and that of the foliage. In garden Beets a thick, tender, sweet, and richly-coloured flesh is much desired. Now, a variety may have these qualities without its foliage showing, at least for the greater part of the growing period, any particularly deep coloration. In England it has been the fashion to produce

VARIETIES OF GARDEN BEETS

with large and deeply coloured foliage, as in Dell's Dark-leaved Beet. Some authorities have not hesitated to say that this is putting colour to a bad use, that it is better to concentrate it in the root. As a matter of fact, the dark red Egyptian and Cheltenham Green Beets are living proofs that a variety may have finely coloured roots and at the same time preserve in its leaves a noticeable proportion of green surface. Up to the present time selection has been applied particularly to annuals and biennials, plants in which generations succeed each other rapidly. Under the management of corporate bodies it could be applied, for example, to forest trees, in which the difference between the best and the poorest specimens is, as is well known, extremely great. Since a well-

established race of sugar Beets has been obtained, why should not also a Cork Oak be bred, the cork of which should be of rapid development and faultless texture? The value of such cork would be double or treble that of the ordinary product.

It may be instructive to give the summary of M. de Vilmorin's conclusions. Selection, he maintains, is the surest and most powerful means that man possesses for the modification of living organisms. Variations are easily induced by change of environment and cultivation. The latter is an addition of especial importance, because it permits variations which are spontaneously produced to be easily observed and selected. These modifications may affect the external characters of form, shape, and colour, or the internal qualities of flavour, perfume, chemical composition, and others. Selection may modify organisms in any direction not incompatible with the preservation of life, but there are certain characters that are mutually antagonistic—individual size and number of parts, great productiveness and extreme earliness, relatively large size of a part and very intense coloration. In order to be effective, selection must be continued in one and the same direction. The value of the results obtained depends on the ability and judgment of the breeder; varieties may degenerate as well as improve under selection. The unit of selection is the individual. The superiority of one seed over others from the same individual, with respect to the transmission of characters, cannot be foretold.—*The Times*.

KITCHEN GARDEN.

FIELD POTATOES.

FIELD space is usually allotted to the growth of the main winter and spring supplies of Potatoes in all large establishments. Even the very latest maturing varieties are now quite ready for lifting, and it is great folly to delay the work any longer. When the ground is in a very dry condition and sharp frost does not occur all goes well, but if after repeated autumn soakings severe frost comes, those sorts the tubers of which lie very near the top of the ridges are sure to get caught. Moreover, second growth sometimes occurs, which ruins the quality. Some separate the seed from the eatable tubers as soon as lifted, others allow them to go together and sort them over in inclement weather. In any case sufficient should be stored in a cool shed and covered with dry Bracken or bags, the remainder being clamped or put into cellars as the case may be. When clamping is adopted, if the tubers are at all wet when lifted, the clamps should not be covered up at once, but allowed an interval of a few days in order that the wind may pass through and partially dry them, as under such conditions they keep much better. A good old-fashioned plan is to insert a Seakale pot at the top of the clamp to act as a conducting shaft for fresh air, this being blocked up with straw or Bracken in very severe weather. Where plenty of cellar space exists the labour of clamping may be spared, although in very mild winters such structures are liable to become too warm, the tubers losing quality in consequence. No better place than a cool cellar can be selected for storing the seed tubers, as they can then be examined at intervals, any decayed ones being soon detected. Schoolmaster is a good eating Potato at this time of year, and Magnum Bonum from light, warm soils may also be used. Those from stronger, more retentive land, the tops of which were somewhat green when lifted, will be all the better for lying several weeks longer before being used. Gloucestershire Kidney is still a most reliable all-round table Potato in most soils and eats well during the spring months. I do not advise clamping Regents where these are grown,

as being liable to disease they should be stored where they can be frequently examined.

B. S. N.

Oxalis crenata.—This tuberous rooted Oxalis is being grown in quantity this season at Dropmore, where its thick, fleshy stems and profuse leafage make it quite a conspicuous object in the garden. Were this Oxalis a desirable forage plant what a quantity of food per acre would it produce. What its fitness in that direction may be I do not know. Certainly the growth at Dropmore is very dense, some 18 inches in height and 20 inches through in a single row. The tubers when ready to lift in the winter are almost fir cone-shaped, but smoother and handsomer. They have reddish skins. Their edible value seems to be very much as is that of the *Stachys tuberosa*.

—A. D.

Climbing Butter Beans.—A gardener recently gave me a handful of pods of the Mont d'Or climbing Bean. They were flattish, of good length, smooth, and handsome. He remarked that not only had he found these Beans to withstand drought and to continue bearing more freely than did the Scarlet Runners, but also that the pods were so liked by his employers that they seemed never to tire of eating them. When the few pods were cooked and served with a little gravy I found them to be singularly tender and delicious, yet when pods have been tested elsewhere by cooking I have found them rather hard and almost flavourless. The fault seems to lie in allowing the pods to hang too long until they become thick, rounded, and the flesh certainly too hard.—A. D.

French Carrots.—In the Paris market the variety we call the Parisian Forcing is preferred, as even in the early autumn months this appears the most in demand. A variety named Carrote Rouge Hâtive, about twice the length of the Forcing variety, and doubtless a form of Early Nantes, is also much in request. I think these small sweet, quickly-grown Carrots are far more useful than our long-rooted kinds with so much hard core. I also noticed a very distinct Carrot, Rouge Demi-longue de Carentan, a beautifully-coloured root not so thick as the Nantes and a little longer. This is much liked on account of its small top and smoothness, as it can so quickly be prepared for use. It is also a splendid variety for forcing. These small Carrots are not so liable to grow out of the soil as the long-rooted kinds or become green at the crown.—G. W.

Potato British Queen.—Has "A. D." or any other correspondent any knowledge of the above-named Potato? I never heard of it until about a fortnight since, when I saw a grand lot of it in a greengrocer's shop in Norwich. He had a few days before been into Lincolnshire and purchased 100 tons, and, being a very practical man, would not have done so had he not previously proved them to be of first-rate table quality. In shape the tubers very much resemble Magnum Bonum, but the skin is rough, though not so rough as in some sorts. It is just the Potato to take the purchaser's eye, and, while fit for use now, will keep well till spring. My friend informed me that in Lincolnshire there were grand crops of Potatoes, but as the disease has already made sad inroads in some districts, the least delay in lifting now may have deplorable results.—J. CRAWFORD.

Some things better omitted.—It has often struck me what a waste of time and roots there is in staging Parsnips and long Carrots at the summer exhibitions. They are of no value for immediate use, and for storing, of course, they are quite unfitted. It is seldom, however, that attention is called to such useless expenditure of labour; indeed, I cannot recall an instance when it has been brought forward until "A. D.'s" note appeared on p. 242. I quite agree with him in the opinion that neither these, long Beets, nor Rhubarb are necessary for summer exhibition, and they should be accordingly struck out of all shows held prior to the end of August. Nor do I see the necessity for such early exhibitions o

Celery. While there are abundant salads of other kinds, Celery is uncalled for. September seems quite soon enough to commence digging Celery. What is produced by early sowing and forced growth earlier than that date is often of a seedy nature, and for salad useless. Parsnips, like Potatoes, cannot be judged by the leaf growth, and the digging of a sufficient number suited for even one class means a good deal of waste, particularly in some soils. The same remarks apply quite as truly to the long Carrots and Beetroot.—W. S.

Peas and drought.—Here we have not suffered so badly from drought this year as growers in the south, but in any season or situation the advice given by Mr. Molyneux on p. 264 is worth having. Now is the time to prepare the Pea quarters if the ground is vacant, and I have just finished one large quarter that was cleared of late Broccoli. Soil deeply stirred and well enriched now is mellow and warm in spring, providing a deep and good root-hold such as Peas delight in. I am glad to see Mr. Molyneux deprecate the time-honoured plan of digging manure into single trenches for this important crop. It is done in most cases just before sowing, and the soil has no time to settle properly, this allowing the sun to enter far more freely than is advisable, while the manure is in a raw state when the roots reach it. Thin sowing and mulching again are excellent details of Pea culture, but I can hardly agree with Mr. Molyneux that the tall varieties are best. I like the dwarf kinds that grow say 4 feet or 4½ feet high. The rows can be placed closer, while the cropping qualities, according to my experience, are quite equal, if not superior, to those of the taller kinds. Some of the finest flavoured and best coloured Peas I know grow to about this height.—SUFFOLK.

Savoy Cabbages.—The season has been very unfavourable generally to summer-planted Brassicas for a winter supply. Where got out early, especially in the case of Brussels Sprouts, the plants are now abnormally strong and yielding soft, coarse sprouts. Savoy Cabbages planted early turn in so soon in the autumn that they are quite worthless, and those planted during the summer generally are very irregular and unsatisfactory. A striking exception, however, is a breadth of Bijou, a rather dwarf, compact, and dark green variety. No gardener wants now or cares for the old Drumhead. It may suit the market grower very well as a field crop, and that class of consumers who are not very choicé as to their winter greens. But the Bijou, Early Ulm, Tom Thumb, and Dwarf Curled are very good, especially when got out fairly late and close together, because large heads are not wanted, neither, as a rule, are Savoys wanted before Christmas. No doubt there will be considerable scarcity of all descriptions of winter greens after the new year. Gardeners will have to husband their resources to the utmost, so far as greens are concerned, during the coming winter, and extra quantities of forced products, Seakale, Asparagus, dwarf Beans, &c., may be needed.—A. D.

Vegetable Marrows.—Notwithstanding the note by "G. H. H.," I must still hold to my expressed opinion as to this vegetable. It is watery and insipid in flavour, and not to be mentioned in the same breath with Runner Beans as a useful cottagers' vegetable. A cottager who makes a rubbish corner of a place where it is possible to grow good Marrows must be a rather wasteful one, for they require culture the same any other, and a warm, sheltered position if they are to arrive at a fruiting state by July, as I said in my note. And to take an average, I should say that for every dish of Marrow that finds its way to a cottager's table there are twenty of the Beans. It is true that Vegetable Marrows are sometimes saved for winter use, but unless they are growing under exceptionally good conditions, the production of two or three that will keep prevents the plant from producing any more that are fit for present use. This is not true economy by any means, for with far less trouble good Parsnips

may be grown, and these are superior in every way. As a variety Marrows are all right, but I have often judged at cottagers' shows where a dozen pairs of Marrows are put up, each showing careful culture, while many of the more useful and profitable kinds were represented by perhaps two or three.—H.

NOTES AND QUESTIONS.—KITCHEN.

Onion Cranston's Excelsior.—This is a very fine type of Onion. In many respects I consider it equal to Ailsa Craig. Early in September at Shobroke Park, near Exeter, I saw several bushels of this Onion. It was not a case of a few fine bulbs, but each one may be said to be a counterpart of the other; some of the largest weighed nearly 3 lbs.—J. CROOK, Forde Abbey.

Carrot Matchless Scarlet.—This season I grew this beside several other kinds, and when taking them up in the middle of October I found Matchless Scarlet by far the best. With me it grows clean and straight, and although not so thick as some, it is longer and of a better colour. Some of the roots from crown to tip were 20 inches long. They were thinned to 4 inches apart, as my object is to get a big crop of good, even-sized roots.—J. CROOK.

Coal ashes for Potatoes.—I am not sure that practical growers will agree with "J. R." as to the use of coal ashes for Potatoes. I think it is generally accepted that coal ashes have no manurial value, and the only use to which they can be put is to lighten very stiff, retentive soils. Further, I think that coal ashes are very conducive to scab on Potatoes, as I have seen this where the practice has been to dig in coal ashes when preparing ground for the Potato crop. The use of lime I fully agree with, and no doubt it is the feeding of soil year after year with no application of this valuable ingredient that is accountable for the whole or partial failure of many crops beside Potatoes.—G. H. H.

GARDEN FLORA.

PLATE 1245.

A HYBRID GARDEN POPPY.

(WITH A COLOURED PLATE.*)

THE plate to-day represents a very beautiful hybrid Poppy that appeared in the garden of Mr. H. G. Moon at St. Albans, where *P. orientale*, *P. pilosum*, *P. rupifragum* and other species were also grown, the inference being that the pollination was the result of insect intervention, or possibly of the wind. True hybrid Poppies are rare in gardens, but spontaneous hybrids now and then appear, as observed by Rev. C. Wolley-Dod, Mr. Carrington Ley, M.M. Vilmorin, and other growers of these brilliant flowers. On the other hand, some species are extremely variable as grown from seed in gardens, especially if due care is taken in selecting seed from distinct flowers, a plan adopted years ago by Rev. W. Wilks, to whom we are indebted for the Shirley Poppies, now so much grown for cut flowers. The Opium Poppy (*P. somniferum*) is said to have been a cultivated selection from the wild white-flowered *P. setigerum*, and varies enormously in colour, and to some extent in habit, as also in having both single and full double flowers. *P. nudicaule* has red, white, orange and yellow variations, and the dainty little *P. alpinum* and its form, *P. pyrenaicum*, have white, rose, or salmon-flushed flowers. Of late years, even *P. orientale* has varied from scarlet with a black blotch to flesh-white, rose-pink, and purple-rose apparently without any cross-fertilisation having taken place.

Mr. Moon's beautiful hybrid is, like Mr. Carrington Ley's variety, a little difficult to manage in its early stages, but when strongly

* Drawn for THE GARDEN by H. G. Moon in his garden at St. Albans. Lithographed and printed by J. L. Goffart.

THE WEEK'S WORK.

KITCHEN GARDEN.

WINTER CUCUMBERS.—Plants occupying pits and frames will in most instances be on the move, especially where the bottom-heat has had to be maintained by the aid of fermenting material alone. Both nights and days are too cold for new growth to be formed. This being so, a few fruits must be allowed to perfect on the earliest-planted batch of winter fruiterers. No more, however, than what are absolutely required for present wants must be allowed to remain on the plants, as what the cultivator must study is the retention of as much energy as possible, as such will be needed during the dull, sunless days which lie before us. Some time ago I advised the use of as little artificial heat as possible, and so long as fairly warm weather and frost-free nights continue, this practice must be adhered to, as short-jointed growth is the best guarantee for the plants passing through the winter free from attacks of spider or thrips. After October great care must be exercised in the use of the syringe, as wet foliage through hours of darkness will quickly produce the yellows and cause the tiny fruit to fall, and once the plants get into that condition they do not easily recover at this time of year. The best way is to take advantage of extra fine sunny days, then to close the house say at 1 p.m., giving the under surface of the leaves a vigorous syringing with tepid soft water, and when sun is absent, be satisfied with damping of walls and floors. Where evaporating tins exist, they should be filled with diluted farmyard liquid, the steam from this being helpful to growth and obnoxious to insect pests. Avoid crowding the growth and train them regularly and at frequent intervals to the trellis, pinching out the points of the leaders as soon as they reach their limit. Surface-dress each time fresh roots show on the surface of the beds, but by no means add more than half an inch at a time, as it only becomes sour. Sweet fibrous loam to which have been added some quite new horse droppings and a little crushed mortar rubble or plaster suits them well. Watering must be carried out very carefully, allowing the roots to need it, and then soak the mounds with sweet liquid manure at a temperature of 85° or 90°. Air very cautiously, a very little at this advanced date being sufficient to sweeten the atmosphere and prevent injury from scorching. If the house after closing early on fine sunny afternoons runs up to 90°, no harm will ensue. This early closing lessens the need for so much pipe heat through the night. If thrips appear, fumigate mildly two evenings running.

FORCING ASPARAGUS.—Where this vegetable is forced in quantity early in the season it will now be necessary to collect good quantities of Oak and Beech leaves for the purpose, also for forcing other kinds of vegetables in winter and early spring. Asparagus and Seakale will be the first to need attention, and where permanent beds of the former are furnished with pigeon holes, spaces between the beds may be filled with leaves about the second week in November. Where good leaves are not over-plentiful, use three parts leaves to one of stable litter, treading very firmly at frequent intervals. The surface of the bed may be covered with 6 inches or 8 inches of short litter, and, if at hand, spare lights placed over them resting on flower-pots. This latter arrangement keeps off heavy rains and snowstorms. The best way is to have a double number of beds, forcing half one year and the rest the next. From old age or other causes open-air beds sometimes get into an unprofitable condition, when it is best to lift the roots piecemeal and force them in ordinary hotbeds or in Cucumber or Melon houses. Make up the bed about 4 feet high at the back, sloping gradually towards the front, and when the heat has declined sufficiently, cover the surface with a few inches of leaves, and on these lay the roots, covering them with 3 inches of loamy soil. A testing-stick or bottom-heat ther-

mometer should be used and the glass covered with mats or Bracken, removing it when the grass makes its appearance. The same bed will answer for other hatches if the linings are renewed, but if an uninterrupted supply of Asparagus is needed, a second bed will have to be made up in a short time. Beds in Cucumber houses are useful for forcing this vegetable, as by using the chamber pipes a comfortable bottom-heat can be secured. As a rule, a top temperature of from 55° to 60° will be sufficiently high, as if a higher is given, a weak, tasteless growth will follow. These forced batches are much benefited by applications of manure water once weekly after growth commences. From the middle to the end of November is a good date to start the first batch, as, unless long enough rest is allowed, the crowns come away slowly and weakly.

GREEN VEGETABLES.—These will now be fairly plentiful, consisting of the earliest planted Coleworts and Cabbage sprouts, the result of heading back old plants of summer varieties. Cabbages which were sown especially for furnishing nice solid heads just as the frost commences will be tender and delicious. By the use of the foregoing, Savoys and Brussels Sprouts may be left alone for a short time longer, as a few rather severe frosts are required to impart the so much appreciated flavour in the two last-named vegetables. J. C.

OUTDOOR FRUITS.

PLANTING.—The one great object which the enthusiastic and up-to-date fruit grower will now have in view is to get through with all planting operations as speedily as possible, consistent with good workmanship, for trees of all sorts will now be in the best condition when they can be moved with the least danger of receiving a check, for, with their roots lifted in good condition and transferred to fresh soil without being allowed to dry up in the interval, they will immediately begin to push forth fibrous roots that will enable the trees to become at least semi-established before winter has set in. Trees planted in autumn, and well looked after as regards mulching and watering later on, will hardly feel the check of removal and may be allowed to carry a crop next year, a thing that it would be unwise to allow winter or spring planted trees to do. Nurserymen will scarcely be ready as yet to supply trees, as they do not care to commence operations until the leaves have fallen and the ground has become well softened with rain, but planting from home-raised stock need not be further delayed and the getting of these out of hand will help matters forward considerably and leave all available labour open to deal with bought-in stock in an expeditious manner when it arrives. Since my previous notes, dealing with the preparation of the ground intended to be planted, appeared there has been in this district an abnormal downfall of rain, over 4 in. having fallen in eighteen days. With a return to fine weather, I find that the soil which was dug and prepared as advised is now in a uniform condition, while that left undug is very wet in some places and very dry in others. Planting on the dug ground will be a pleasure, as one knows that it is in just the right condition to work among and about the roots. In taking out the stations for planting, make sure that the bottom is made firm so that there shall be little or no sinking, and allow for each tree only sufficient depth to admit the roots so that the upper ones may be quite near the surface and, above all, see that the stem is buried no lower than it has been previously. For heavy and damp soils I like to elevate each tree on a slight mound, the depressions between the mounds act as surface drains and the feeding roots are kept in a more wholesome state than they would be if planted on the level. On the other hand in very light soils any such elevation would be a mistake, as in dry seasons the roots would get burnt or dried up. If the trees to be planted are of a size to make staking necessary, the stakes should be driven down into the holes before the trees are planted, as this will prevent all fear of driving the stake on to any of the roots and

established it is very brilliant and quite distinct from any other Poppy known to me. One can only guess at its parentage; it may have been *P. pilosum* × *P. bracteatum*, or *P. bracteatum* × *P. rupifragum*, but that can only be proved by actual experiment, a by no means easy matter. These hybrids now and then appear in gardens spontaneously, owing to some fortuitous circumstances—some lucky fly, or tree or breeze-carried pollen—but nearly all actual attempts at cross-fertilisation made by cultivators seem, from some hidden cause or other, doomed to disappointment. So far as I know, the only authentic hybrids reared in gardens are those of MM. Vilmorin and Co. alluded to below. The difficulty, perhaps, lies in the initial stages, for true hybrids of the first generation seem always barren. This was so with MM. Vilmorin's plants, but by crossing these back again with *P. orientale*, a seed-bearing race was obtained.

Apart from Mr. Moon's plant, one of the best of all the hybrid Poppies, according to the Rev. C. W. Dod, is Mr. Carrington Ley's hybrid of *P. orientale*. Mr. Dod states that he has had several plants this season 4 feet across and bearing thirty to forty flowers open at the same time, the flowers supporting themselves on elegantly curved stems at various heights from the ground. This hybrid is the offspring of *P. rupifragum* × *P. orientale*, and originated in Mr. Carrington Ley's garden near Maidstone. Mr. C. W. Dod also mentions spontaneous hybrids between *P. caucasicum* and *P. Rheas*, which are of annual duration only and do not appear to seed.

At the hybrid conference at Chiswick in July last, the late M. Henri Vilmorin, of Paris, gave a very interesting account of a successful attempt at hybridising the Opium Poppy (*P. somniferum*) with *P. orientale* or *P. bracteatum*, the hybrids of which did not produce seed until they were again cross-fertilised with *P. orientale*, when a permanent race of showy plants that grow freely from seeds was obtained. The fact that this race is the produce of an annual and a perennial species is a point of considerable interest. F. W. B.

Nicotiana sylvestris.—Two appreciative notes have recently appeared on this beautiful Tobacco plant. The writer of the earlier note (p. 194) had evidently not seen the plant in its greatest beauty, as he only alludes to its effect as a fine-foliaged plant. True, it has massive leaves and a good habit of growth, but if it had to depend on these for popularity it would have to give place to other and better-known plants. In the face of some grandly-flowered plants which I recently saw it is strange to read that "the foliage is the thing, of course, but when joined with beautiful flowers the plant is all the more worthy." To my thinking, the lovely flowers put the foliage effect entirely in the shade. Those who have not yet seen the plant may imagine something of its beauty and worth from the fact that it bears tall spikes, each with about a score of pure white flowers very like those of the older *N. affinis*, but longer in tube and slightly less in diameter, and, best of all, without that unfortunate defect which makes the older variety appear to be dead or dying during the greater part of the day, for the flowers in the new variety do not close even in bright sunshine, but simply hang at a sharper angle on the stem, assuming a stiffer habit as evening approaches. The lateness of its flowering adds to its value, as it lasts till quite late in the autumn; indeed, only the approach of winter puts an end to it. Personally, I propose substituting it largely for *Hyacinthus candicans*, as it lasts much longer in flower and is of such a pure white. I look on it as one of the best of new introductions, and predict for it greater popularity than *N. affinis* ever gained.—J. C. T.

injuring them. Cut away all damaged portions of roots, severing them at the point of junction with a branch root wherever possible, then the cut surface will heal over instead of dying back. When putting the tree into position remember that most trees grow best and quickest on the south or south-west side, and to one of these points of the compass the worst side of the tree should be turned. By following this out and by judicious pruning well balanced trees will eventually be made out of what now may seem rather unpromising material. Work some of the best soil well in among the roots, so that no hollows or badly filled crevices may be left, but refrain from ramming the soil immediately round the roots with a rammer or boot from treading it. These operations should be left until sufficient soil to protect the roots from injury by direct contact with rammer or boot has been added. If the roots are too plentiful to allow the soil to be worked in among them in a satisfactory manner by the hand, then by all means use water to wash it in and leave the filling up and finishing off until another day. Of course, a little water is of no use. It should be a thorough soaking, sufficient to melt the particles of soil and cause them to settle down close together. The foregoing remarks may be taken as applicable to the planting of all sorts of fruit trees, but we have also to consider individuality as well, and to add to the soil, if possible, those ingredients which tend to promote the best type of growth. For general purposes I know of no material which has such a good effect as wood ashes or those made from the burning of all sorts of garden rubbish, in which a good deal of garden soil is usually included. For Apple and Pear trees this alone is an admirable and sufficient addition to ordinary garden soil, but for stone fruits I am never satisfied unless I can include a plentiful supply of lime, as I am convinced that they need it in considerable quantity either as a natural or an added constituent of the soil they occupy. Another thing that stone fruits generally require is a considerable depth of soil, the Apricot especially revelling in a well-made deep border provided it has been well drained.

GATHERING FRUIT.—By this time most fruits will have been gathered, though there may still be some of the latest Pears hanging, and Medlars, too, will still be on the trees in many places. The first dry day should be chosen to finish up all the work of gathering, for the fruits will get no good by being left on any longer. Pears, except perhaps the hardest of the stewing varieties, should always be stored in single layers where they can be easily seen and got at, as they require looking over often and very careful handling, as they bruise readily from the time they commence to soften. Medlars should never go into the same store as other fruits, for the moisture arising from the latter will be sure to spoil them. The only kind of place in which they will “blet” properly is a dry one, where they can be kept cool as well. Heat and moisture they will not put up with. They go mouldy at the crown under such conditions, and the very slightest touch of mould on the fruits spoils their flavour at once. Walnuts which have been gathered and placed in heaps should now have the pulpy outside casing removed from the shells, which latter should be rubbed dry and the Nuts then stored in Seakale pots placed upon a stone floor, a position in which I have found both Walnuts and Filberts keep really well.

FRUIT ROOM.—In the fruit room proper it will be necessary to overhaul the fruit, frequently removing all that show the slightest signs of decay. It is during the first few weeks after storing that such fruits are found, for in spite of every care some blemished fruits are sure to find their way to the benches. As early sorts of Apples are cleared off, the later ones may be given more room, and it is advisable to do this as soon as possible while the fruits are still hard and green, then there is less chance of bruising them. A mixed fruit room is an evil, and a very common one, for the conditions which suit the Apple

crop best are bad for ripening Pears, and it ought to be the rule to have at least a small portion of the store room which could be divided off and kept warmer and drier for the benefit of ripening Pears, as these are so much better when ripened in a temperature that would be too warm for Apples to be kept in. Pears being taken to the table should be tested day by day, as many sorts are liable to go sleepy almost as soon as they ripen, and in the early stages of this defect it is almost impossible to detect it from outside appearance.

CORNUELIAN.

CHRYSANTHEMUMS.

EARLY-FLOWERING CHRYSANTHEMUMS.

THE present season will be remembered as one in which the early-flowering Chrysanthemums in most gardens were distinctly later in blossoming than has been the case for many years. Varieties which in an ordinary season have been at their best during the earlier half of September were not seen in anything like proper condition until quite three weeks later. This may not be altogether an unmixed blessing, as this type of the flower appears to find more favour with many persons, when advantage may be taken of the profuse display which the early sorts are just now making. Nurseries and gardens during the declining days of September and the earlier days of October were quite gay with the wealth of blossoms which most of the early sorts provide the grower with, and the most pleasing character of such displays is the charming variety of colour in which they are now obtainable.

The recent show of the National Chrysanthemum Society included a display of some of the most useful varieties now in commerce, and the class in which the competition was provided stipulated that the blooms should be cut from plants grown in the open air and not disbudded. This appears to be a step in the right direction, and cannot fail to have a stimulating effect in inducing others to take up the culture of the early-flowering varieties. Each of the exhibitors in the class just mentioned staged large bunches of fresh, clean, and freely-grown sprays of blossoms, and those whose business it is to keep up a supply of cut flowers through the early autumn and until the midseason Chrysanthemums are ready for cutting will find in the early sorts a useful class of plants. The severe disbudding, which is the orthodox method of culture practised with the later varieties, apparently does not suit the early sorts. The grace and beauty which characterise most of the early Chrysanthemums when grown freely and naturally seem to be absolutely lost when the same varieties are severely disbudded. Then for the best decorative work, no matter what form the decoration may take, the sprays of buds and blossoms in various stages of development have a charm which the larger exhibition blooms fail to give, and the former also are admirably adapted for the numerous small receptacles which are now so frequently used indoors.

Another most important aspect from which to view the subject under notice is the value of the plant as a hardy border one. For years a certain few enthusiasts have repeated as occasion offered the merit of the early sorts in keeping the hardy border bright and gay during the dull period usually intervening between September and November. The value of their notes was confirmed when the trial of some 141 stocks of early-flowering Chrysanthemums was made in a sunny border during the latter part of May, 1897, by the Royal Horticultural

Society in their garden at Chiswick. It was there acknowledged that the plants “made a magnificent display of bloom, and were greatly admired by visitors to the gardens.” A few varieties commenced to flower in July, a larger number in August, and throughout September and October this extensive trial exceeded in beauty and effect the most sanguine expectations of those more deeply interested. In the parks and open spaces in and around London and many important provincial centres appreciation of these plants has been shown, and instances could be given where puny plants placed in their flowering quarters during May have attained dimensions by the early autumn that hardly seemed credible. It is pleasing to note the increasing variety in the borders each successive season, showing clearly how the interest is deepening. Probably one of the most popular sorts is Mme. Marie Masse, a good lilac-mauve, but becoming richer in colour as the season gets older. This is an ideal spreading and free-flowering plant, and is nice and dwarf, too. A recent bronzy crimson sport, sent out under the name of Crimson Marie Masse, is a good thing, and another season is sure to be largely grown. This is a colour which is needed. Mr. Jones’ group at the Royal Aquarium also included a new sport, this being a kind of rich cream colour, with a salmon-cerise base to the petals. The colour promises to be much better later. Each of these sports is similar in habit and free-flowering to the parent variety. Mme. Eulalie Morel is another excellent sort, deep cerise, shaded gold. Although not so branching and free as many others, it is one of the best. Harvest Home has jumped into public favour this season both in private gardens and for market work. Its crimson and gold colours are much appreciated thus early, but the habit leaves something to be desired. Francois Vuillermet is little known, but its pretty little rosy blossoms, each on a useful foot-stalk, and also so remarkably free and dwarf, stamp it as a most desirable plant for the open border. Sam Barlow can be had at the same date. Its lovely salmon-pink blossoms are always admired, and it is also a profuse blossoming sort. M. Gustave Grunerwald is very fine in certain seasons, and the present season has suited it admirably. The blooms have been large, and the colour a good bright rosy pink. The habit, however, leaves much to be desired. Mychett White has improved since being planted outdoors, the constitution getting more robust, until there now appears to be a prospect of keeping the plants progressing in this direction. I know of no other white flower of the early sorts that has so charmed me with its display as this has done. Grown in a natural manner without disbudding, there has been a display of the most lovely blossoms imaginable, and if this sort can be grown away from the smoke of towns, a large area might well be devoted to it. Lady Fitzwygram, another white, on the other hand, needs to be grown differently. Disbudded to a dozen flowers, the result is excellent, but grown freely, the blossoms are poor and weedy. Mr. Godfrey’s new soft yellow sport when properly grown should prove a useful flower. I do not share the opinion expressed in a recent note that the colour is poor and washy. We need the soft tones of colour as well as the richer ones, and the new one should therefore be grown. Ivy Stark has over and over again proved its usefulness for early work, and although an orange-yellow colour early in the season, this becomes more intense as the season advances, the orange colour at last being most pronounced. An

early Source d'Or is an excellent description of this sort. It is very profuse. Louis Lemaire, the pretty rosy-bronze sport from M. Gustave Grunerwald, has not been so much in evidence this season, but it may be classed as a very useful flower. Queen of the Earlies (pure white) and its new golden-yellow sport, named Golden Queen of the Earlies, are being taken in hand by the market growers. They can be grown on the large bloom principle, or in a natural manner, in which way they are very free-flowering. Their habit is good. Mme. C. Desgrange (white), G. Wernig (yellow), Mrs. Hawkins (richer yellow), and Mrs. Burrell (straw-yellow), all members of the same family, are still largely grown, more particularly the two first mentioned. The stock of these appears to be getting much less robust, and when the plants are freely flowered they are inclined to be weedy, and will not compare with many of the newer kinds.

The above sorts are all Japanese and embrace the leading varieties, flowering usually during September. Those flowering in October may well be considered quite apart from the earlier kinds. D. B. CRANE.

Highgate, N.

Chrysanthemum Mrs. Hawkins.—Among the early-flowering kinds this is a very useful variety both for its freedom and for its colour. Its weak point perhaps is its uncertain colour, and the way in which it reverts to the older yellow sport known as Mrs. G. Wernig is at times rather perplexing. Even so long ago as when this kind was the subject of litigation a splendid golden variety appeared in my batch, and its identity was vouched for by the firms chiefly interested at that time. The plant was easily distinguishable among its fellows at fifty yards, and the colour being so good and seeing a whole plant had thus sported made me anxious to raise a stock for future use. This I did, and without working the plant to death, as it were, satisfied myself with a few hundreds, a large number of which of course were tops of the earlier-rooted ones. But generally the thing was disappointing at that time and since; so many revert to the original, that it is hardly worth the trouble of separating. Two years since I again selected several dozens of the richest gold, but many of these on flowering were but Mrs. G. Wernig, and some even lighter than this kind. I do not know if the experience is general, but the richer deeper yellow in my case is somewhat later and generally less free in flowering also. Each year one sees the sports and reversions of this group, sometimes a limb, sometimes half a flower, and frequently a whole plant, though so far as I know the sporting has been confined to the yellow shades.—E. J.

Chrysanthemums in Peach houses.—The worst sufferers in consequence of the rage for Chrysanthemums have been Peach trees, Vines, and fruit trees under glass generally. In many gardens there is not half enough accommodation for the hundreds—and in some cases thousands—of Chrysanthemums grown without encroaching on the fruit houses, every inch of border being in many instances blocked up with the plants. I have sometimes seen them set on the bare soil, the pots touching each other, in which case the top 3 inches or 4 inches of the Peach border become, by the time the Chrysanthemums are removed, a soddened mass—the very thing that should be avoided if healthy, fruitful Peach trees are desired. Even where the pots are arranged on bricks, tiles, or boards, the presence of the plants in the house renders the atmosphere stuffy and unhealthy at a time when a free and bracing current of fresh air is needed to harden and mature the wood. All gardeners know well enough that exposure to a moderate amount of frost during November and December is of immense benefit to Peach trees under glass, yet on account of the Chrysanthemum blooms the ventilators have to be closed if frost threatens.

When crowded into vinerias at rest the evil is just as great, the Chrysanthemums for the time having the preference. It is the small and medium-sized gardens which suffer most in this respect. In many of the larger establishments there is a special Chrysanthemum house, this being used for a variety of other things during summer. In many more where glass accommodation is limited the erection of a similar structure would be profitable.—B. S. N.

FED VERSUS UNFED CHRYSANTHEMUMS.

A FEW days ago I saw in a town garden a valuable batch of Chrysanthemums, and the house in which they are accommodated lies in a low, damp situation, this fact necessitating great care to avoid wholesale destruction of the blooms by decay in foggy weather. The plants were well clothed with healthy green foliage right down to the pots, yet the gardener assured me that not one drop of liquid or artificial manure had been given. It has been proved that excess in the use of liquid manure produces, it may be, large, but flabby blooms, which inevitably fall a prey to fog and smoke, and the supply for decoration soon comes to an end. The plants in question were growing in pots about 10 inches in diameter, one plant in each, good friable, turfy loam, with good drainage, being the rooting medium. Now that the buds are considerably advanced, a little stimulant will be given. It is pleasing to observe that rigid disbudding in establishments where the flowers are required for cutting is being gradually abandoned, and doubtless it is the stems wreathed with medium-sized highly-coloured flowers which give the best effect when cut. The most serviceable batches of Chrysanthemums I ever grew were rooted at the end of January, pinched once, and confined in pots from 8 inches to 10 inches in diameter. A manure-free loam was given, this being kept open by a little old mortar rubble. No disbudding of any kind was practised nor feeding resorted to until these small pots were crammed with roots. The growth was firm and wiry as compared with that of plants flooded with soot and sheep manure water through the early stages of growth, and I always had plenty of blooms several weeks after my neighbours, who went in exclusively for big blooms. If wanted to flower late, they may be protected in the open with rafters and canvas. Early and excessive feeding is doubtless answerable for a great proportion of blind growths. J. B. S.

NOTES AND QUESTIONS.

Chrysanthemum Miss Alice Byron.—In this we have a distinct gain in the Japanese section. The blossoms are large, with long, broad, incurving florets of good substance. The habit is dwarf, about 3 feet. Those who know Western King may appreciate the variety under notice, which is said to be an improvement on that excellent variety.—D. B. C.

Chrysanthemum Soleil d'Octobre.—The October show of the National Chrysanthemum Society has again proved the undoubted merits of this lovely semi-early Japanese kind. Most stands contained excellent examples of it, and as it is one of easy culture and also possesses a good habit, it may be classed as a standard variety for October flowering. The blossoms are large, of graceful form, and of a pleasing soft yellow colour. It deserves extended cultivation.—C. A. H.

White-flowered Zephyranthes.—There is a deal of confusion regarding the white-flowered Zephyranthes, two or three names being used indiscriminately. An instance of this occurs in the number of THE GARDEN for September 16, where on page 223 is a charming little cut of Belladonna Lilies and Zephyranthes candida flowering together at Kew. The writer, "E. J.," in referring to Zephyranthes candida (Peruvian Swamp Lily), states quite correctly that it is an evergreen species, or nearly so, the pretty white Crocus-like blossoms appearing in plenty during the autumn months. In continuation, the writer says: "A closely allied species is the Atamasco

Lily (Z. Atamasco). This flowers in spring and has somewhat channelled leaves, while Z. candida has decidedly flat surfaces to its leaves, the latter being also very polished and smooth." All this, except the spring-flowering of Z. Atamasco, is entirely in accordance with "W. W.'s" article on the entire genus in vol. xxxvii., when a coloured plate of Z. candida was given. Next on p. 230 of the same number for September 26 we are told that at the meeting of the Royal Horticultural Society two different exhibitors showed Z. Atamasco, which should surely read Z. candida, but being prevented from attending the meeting, I cannot say from personal knowledge; still, one would not expect a spring-flowering subject to bloom in the middle of September. Z. candida has also before now been labelled Z. tubispatha, which is a far more delicate species.—H. P.

DESTROYERS.

WASPS.

THERE has not been the same outcry against the ravages of wasps this summer as in some recent summers; nevertheless, there have been districts badly infested. Usually they make their appearance in the early part of August. This year none appeared with me until the end of August, but, though late, they have been none the less active, numerous, and destructive. Plums and Pears have suffered severely from their depredations, and the quantity reduced both for immediate use and storing. It is not the amount of fruit directly eaten that gives cause for complaint, but the numbers that are spoilt. The smallest hole made in the skin causes the fruit to decay if a use is not found for it early, and it is curious how soon decay sets in when Apples and Pears are taken indoors to be stored after being pierced by the wasps. Stewing Pears seem quite as attractive to them as dessert kinds—at least two sorts grown here were seriously injured by them. These were Gilgil and Bezi d'Heri. It has been necessary to gather early to save the fruit, and the crop being a light one, the loss is greater in proportion. Destroying the queens in the spring months is, perhaps, the better way to reduce their numbers or stamp them out. Some horticultural societies give prizes for queens at their summer shows—a most commendable practice, worthy of much greater extension. County or parish councils might do something towards this useful practice by offering prizes for queens collected where district flower show societies do not take it up. In some localities there is a difficulty in getting the matter taken up even when a fairly liberal payment is offered. In wooded districts nests are not so easily found. By the end of September wasps had ceased to be troublesome this year, owing to the great change from heat to cold and the frequent showers that followed each other. Wasps do not seem able to withstand cold and wet weather. Although they were so late, they appeared in strong force spontaneously, and they were not so easily combated as I have known them in other seasons by the use of cyanide of potassium. They hatched so rapidly, that unless the nest was dug out promptly a second application was necessary. I find, too, that the cyanide solution should be freshly dissolved as required, and a new stock procured each summer from the druggist. If any reserve supply is carried over from one summer to the next, a perfectly dry place must be chosen and the bottle kept tightly corked; otherwise there is a great loss from evaporation.—W. S.

I do not think that wasps have been so generally numerous this year as during some seasons, which is curious when we take into

consideration the last mild winter and the past summer. Wasps in a vinery are no doubt an intolerable nuisance, and a question that has often been discussed is, what is the best means of keeping them out? It is true of wasps that whenever they commence on any fruit they never leave it so long as there is any left. To lay traps of sweet things, such as a mixture of beer and sugar, is, in my opinion, only a way to encourage more wasps. Thin gauze bags are often sold for protection against wasps, but it is almost impossible to adjust them without marring the appearance of the Grapes. Others, again, recommend hanging sheets of light tiffany over the open ventilators to prevent the pests getting in, but this also prevents the requisite current of air, and the houses get too hot and stuffy. After all, the simplest and best means of protecting fruit of all kinds from wasps is to destroy the nests. My own practice when wasps appear is to set a few boys to scour the immediate neighbourhood in search of the nests during the daytime, and to stick up a small flag close to each. Then at dusk, when the wasps have returned, a man goes round with a can of gas tar. If a little of this is poured into the nests and a clod of earth placed over the hole, no further trouble is encountered. I have destroyed as many as 100 wasps' nests in a few days, and surely this wholesale eradication of the evil is the safest means of ensuring the safety of the fruit.—H. H.

STOVE AND GREENHOUSE.

LINDENIA RIVALIS.

THIS, belonging to the order Rubiaceæ, is a small American shrub of great beauty and apparently very free-flowering. The plant here illustrated bloomed fairly well in the summer of 1898, but the flowers were not very numerous. This summer, however, each shoot was terminated with crowds of buds and flowers, and when the photograph was taken (early in August) it was a very beautiful object, the pure white flowers standing up grandly, the coral tubes being each 5 inches to 6 inches long. The plant has been in bloom four months, and there are still flowers on it (third week in September). It has been grown in a 9-inch pot, kept on the dry side after flowering, and fed liberally with liquid manure when coming into bloom. Thrips have a very decided fancy for its leaves, and have to be continually watched for, or the plant would be soon ruined. It strikes very readily from cuttings.

Sispara, West Hill, Putney. R. H. B.

Choice room plants.—Whatever may be its fate later in a cool room, at least during the summer in a room looking west a good plant of Pandanus Veitchi has done remarkably well for the past summer, and even now that it is colder shows no signs of suffering. If grown where gas is not habitually burned there are several other plants that are charming for rooms. Thus, plants of *Asparagus plumosus nanus* started in warmth, then hardened in a cool greenhouse, will keep singularly fresh and green for six months in a room. Another very beautiful room plant is *Araucaria excelsa*, not large, but well seasoned in ample light and air before being taken indoors. Several of the smaller-leaved *Crotons* and *Dracenas*, and, not least, the fine-leaved *Begonias* do admirably also, retaining their fine colour and foliage for a long season.—A. D.

Carnation Reginald Godfrey.—I would advise those who grow winter-flowering Carnations to give the above variety a trial, as I hear from a reliable source of its excellency. All will admit that Miss Joliffe when well grown is an excellent Carnation, as it is a very free bloomer and the lovely pink shade appreciated. It was said that Mme. Teresa Franco would supersede it, but those whose aim is to fill the basket have

found it barely worth growing. Reginald Godfrey is said to be equally as free both in habit of growth and flower-production and more easily grown, as it is not everyone who is regularly successful with Joliffe. If this be so, this comparatively little-grown Carnation will prove an acquisition. Although I cannot speak from experience of the value or otherwise of the system, I have heard of tree varieties being propagated in spring, planted out in May in frames or pits, I presume, and lifted and potted in September, excellent all-round results being thereby obtained. At any rate the plan is worth a trial, and for my own part I cannot see why it should not answer, as in the case of *Bouvardias* and similar things.—C.

Hibiscus Manihot.—In your issue for February 9, 1898, appeared an excellent coloured plate of the above-named beautiful plant as flowered in the new Mexican house in the Royal

Lindenia rivalis. From a photograph sent by Col. R. H. Beddome, *Sispara, West Hill, Putney.*

Gardens, Kew. In the spring of this year Messrs. Sutton offered seed of a plant under this name, which doubtless was bought by many in the expectation of getting the fine plant portrayed on THE GARDEN plate. In this expectation, however, they were disappointed, as the plants when they bloomed (as they are now freely doing in pots in the greenhouse of a friend of mine) produced flowers of the same colour, but about half the size of those represented. The plant is, however, nevertheless, apparently correctly named, as there seem to be no less than three varieties of *Hibiscus* named *Manihot*. One, of which a coloured drawing is given in volume 41 of the *Botanical Magazine* on plate 1702, had flowers of a much deeper shade of yellow and about the same size. In the second, with the additional name of *pal-matus*, figured in volume 59 of the same work, on plate 3152, the flowers are exactly those of the plant raised from Messrs. Sutton's seed. A coloured plate for a forthcoming number of the *Botanical Magazine* has been prepared of the Kew variety, and when that appears Sir Joseph Hooker will doubtless give it some further distinctive

name to distinguish it from its brethren mentioned above. This last-named fine species is not suitable for pot culture; whereas the other two apparently are.—W. E. GUMBLETON.

Forcing Solomon's Seal.—This is very useful for the embellishment of the greenhouse in early spring if the plants are forced gently into bloom, as the long arching shoots studded with their small drooping blossoms form an exceedingly pretty feature. They are generally seen with several spikes in a pot, to obtain which established plants are lifted in the autumn from the open ground and divided into single crowns, selecting only those for potting that are stout enough to flower well, the others being planted to yield a supply the following season. These selected crowns may be grouped in any way that is likely to be useful, about half a dozen spikes in a pot 6 inches or 7 inches in diameter being convenient for general purposes. The forcing must be gradual, as if too much heat is used the spikes will be weak and greatly inferior to those brought on gently. If possible, home-grown crowns should be chosen for forcing, as many dealers often supply them too weak to flower in a satisfactory manner, while more than once I have seen the smaller and much inferior *Polygonatum officinale* sent instead of the true *Solomon's Seal* (*Polygonatum multiflorum*).—H. P.

Curcuma Roscoeana.—This is remarkable for its attractive blossoms, which are very distinct from most other subjects, unless it be some members of the same genus. Its usual season of blooming is towards the end of the summer and in early autumn, but still it occasionally flowers earlier. The foliage is decidedly ornamental, not unlike that of a *Canna*, while the flower-spike is pushed up independently of the leaves. The blossoms are arranged on the upper part in a cone-like head, but it is not the flowers themselves that form the choicest portion of the inflorescence, but the large lip-like bracts which partially hide them. These bracts are of a reddish orange tint and retain their beauty a considerable time. There are several species of *Curcuma*, but this is one of the best known, though even now it is rarely seen. Except one or two which occur in Australia, the *Curcumas* are all natives of the East Indies. They need a period of rest during the winter, at which time they should be kept moderately dry without being actually parched up, then on the return of spring the tubers should be shaken clear of the old soil and repotted in fairly light compost. The *Curcumas* are essentially stove plants.—H. P.

Rust on Carnations.—This disease is, perhaps, the most troublesome when it attacks the leaves, because it is often unseen if the grower be but a casual observer. Grappled with in its infancy, there is little danger to be feared. The rust may be noticed by small blotches mostly on the outer portion of the leaf. These blotches eventually burst and send out numberless spores which obtain a hold on other leaves, and in their turn spread. Some sorts are more liable than are others. The plan then is to watch the plants closely, and if tiny brown specks are seen, cut away and burn the affected part at once. If in pots, isolate such plants and go over them daily. That a collection containing some thousands of plants can be kept absolutely clear of this disease is proved, even if at one time and another badly infested specimens are imported into it. Such a collection is that of Mr. F. A. Wellesley, Woking, who regards this rust with something akin to horror. That he is well rewarded for this continual watchfulness is certain, the healthy, clean-leaved young plants being a picture in their way, and they will give the owner an infinite amount of pleasure throughout the dull winter months. This disease is different from the ordinary black spot, which is brought about by moist surroundings. To prevent this, a second trouble, the aim

should be to keep everything about the plants as dry as possible and airy. If in frames it is well to raise them, so that air may pass underneath, and also see that there is no drip inside from the glass.—H. S.

Amasonia punicea.—During the autumn months this is seen in its most attractive state, while a very desirable feature is the length of time over which the beauty of its inflorescence extends. It is a somewhat upright-growing plant of a shrubby character, whose toothed leaves are from 8 inches to 1 foot long, while the spikes of flowers are longer than that. The blossoms themselves are tubular and of a pale yellow colour, but they play a minor part in the embellishment of the plant, by far the most important being the leaf-shaped bracts which accompany them, and which remain bright for such a lengthened period. The largest bracts are situated at the base of the spike and they gradually lessen in size to the top. They are of a bright red colour, a very attractive tint, and a few well-flowered examples are particularly valuable for grouping purposes. It is not at all a difficult subject to cultivate, succeeding as it does with the treatment given to the general run of stove plants. Like *Acalypha hispida*, this *Amasonia* seems to have been known to a certain extent for many years previous to its introduction. It is a native of a considerable district in Tropical America, and was first introduced and distributed by Messrs. Veitch about fifteen years ago.—T.

Rhododendron retusum.—The name *Rhododendron* suggests comparatively large, showy blossoms, but this is quite an exception to the rule, the plant altogether being decidedly unassuming, though wonderfully pretty when in bloom. It forms a neat, freely-branched bush clothed with small deep green leaves, which when young are prettily tinged with red. The flowers, which are often produced in the autumn, are different from those of the other *Rhododendrons*, suggesting rather an affinity to some of the *Fuchsias*, the colour being nearest to that of the distinct *F. triphylla*. *Rhododendron retusum* is a native of Java, but will hold its own in a lower temperature than the other species from that region; indeed, it will succeed in an ordinary greenhouse. It has not been much employed by the hybridist, the only varieties in which it has played a part as far as my knowledge extends being *Prince of Wales*, sent out in the early sixties by Messrs. Rollisson, and *Daviesi*, which was obtained by the late Mr. Isaac Davies, of Ormskirk, by the intercrossing of *R. retusum* and *R. javanicum*. The flowers of *R. Daviesi* are in size about midway between the two, and its glowing orange-red flowers are very showy, but it seldom makes a shapely plant, and often fails to grow in a satisfactory manner.—T.

The Scarborough Lily (*Vallota purpurea*).—Two or three times recently attention has been directed to the present neglect of this beautiful old bulbous plant, whose brilliantly coloured blossoms were at one period so universally met with. It might be supposed that as large numbers of bulbs are sent to this country from South Africa every year it would become far more general, but this very circumstance, I think, militates against its popularity, as there is a considerable mortality among these imported bulbs, and many of them regarded from a flower point of view are inferior to the old type, at one time so common in gardens, being taller, with in many cases more starry blooms. The South African bulbs generally reach this country in a dormant state during July and August, and if potted at once and kept fairly dry during the winter, some of them will usually flower in the spring. The change of seasons is of course accountable for this. I have found a considerable amount of variation among these imported bulbs, not only in the shape of the flower, but also in the colour thereof, for while some are richly tinted, with occasionally a whitish eye, there are a few with blossoms of a pink or salmon-pink tint, while I have also heard of a pure white form, but have never yet seen it. With regard to imported bulbs, the mortality seems to arise from

an internal excess of moisture, and however dry they may be kept, many bulbs perish from this cause. Even if they grow and flower it is difficult to get them permanently established after the manner of the old-fashioned form. Like many other bulbous plants, *Vallotas* will stand for years in the same pot and flower well every season, even when the bulbs are closely packed together.—T.

Forcing our native Viburnum.—The *Lilacs* are of all the shrubs that bloom in the spring the ones most commonly forced for the sake of their flowers in winter, and next to them for this purpose comes the *Viburnum Opulus*, a graceful shrub with very white, globe-shaped heads of bloom, to which it owes its popular name of *Snowball Tree*. The species of this family are very many, and are remarkable for the dimensions of their heads; some, indeed, like *V. O. macrocephalum*, originally brought from China by Fortune, produce heads equalling in size those of the *Hydrangea* at least. What hinders cultivators from forcing these shrubs for the adornment of the house in winter would seem to be an ignorance of the means of increasing them. The plants are generally obtained by slips or budding, but grafting under a bell-glass in the spring is an easy and successful way of propagating the finest varieties. Put in the ground they produce in a few months some very pretty plants, which admit of very easy forcing. These plants are the more sought after because so long in bloom, and it is by no means rare to see bushes not more than 20 inches high with upwards of thirty heads upon them. Forcing is an easy matter in the hothouse, given plenty of light and air. The gardener who knows his business takes care to remove the extremities of the branches on placing the plants in the hothouse, as the flower-buds will then develop better. As soon as blight appears, copious syringings with rain water should be given, and even tobacco water in case of need. Before removing the plants to the dwelling-house they ought to be kept for some days in a rather lower temperature than that in which they were forced. Plants so forced are not lost, and if well pruned after flowering, in three years time can be forced anew.—*Revue de l'Horticulture Belge*.

PEAT-MOSS LITTER.

TO THE EDITOR OF THE GARDEN.

SIR,—Doctors differ, and so it appears do gardeners. In your issue of September 30 is published a short, but scathing article from "H. H." on peat-moss litter, and in reply I beg to offer you my experience of this material. I have used it now for twelve years, and at the present day I use no other manure. I make all I can and the rest I buy. I therefore am unable to pity the poor gardeners who are obliged to use it or none at all. I can only envy them if they can get all they want for nothing. "H. H." contends, "That compared to good straw litter manure it is not worthy of the name. In itself the manurial properties are very small. After lying in the ground a whole season it turns up in the same condition as when dug in. In bog peat nothing grows naturally to any perfection. It is unfit to mulch Strawberries with," &c. Now my experience is that it is infinitely better, stronger and more lasting than the best stable manure. It cannot help being so if properly treated, for it contains all the droppings and all the urine, which straw litter does not. The manurial properties before being used are probably small, but what would be the manurial properties of unsoiled straw? Straw is a very bad sponge and moss litter is a very good one. The former drains, the latter absorbs. The result is obvious. I believe that many things will grow in bog peat when drained. Peat-moss litter is drained and dried, and it will grow many

things. It is certainly unfit to mulch Strawberries with; but that is not the fault of the material, but of the man who uses it without thinking. One may occasionally find a large lump that has not rotted, but this lump has given its essence to the earth and has helped to keep the soil open and moist, which is a benefit not to be ignored, particularly in heavy soil like mine and in such seasons as we have had for the last three or four years. But there ought not to be any large lumps, and the place for moss litter in the majority of cases is not in the top spit, but forked liberally and roughly into the second spit. For grass land it is excellent, but it should be spread straight out of the cart, and not be left in heaps till Hodge has time to spread it. It is too strong to be left in heaps. On the surface it is excellent for *Begonias*, *Pansies*, *Lilies of the Valley*, and many moisture-loving plants. My interest in peat-moss litter is limited to gardening, and I am prepared to prove all I have advanced to "H. H." or anyone else who will come and see for himself.—J. WHITWORTH SHAW, *New Place, Lingfield*.

I quite agree with "H. H." with regard to this material. There is no doubt it is one of the worst nuisances a gardener has to contend with, for though it would seem that by its nature it would be useful on heavy soil, in reality it is not so, while on light soils it is worse than useless. I used to have to deal with tons of it, and have tried laying it by for months with lime and oddments of soil, but all to no purpose.—H.

PROSPECTS FOR WINTER.

In the kitchen garden there has seldom been a season when prospects for a good all-round supply of vegetables looked better than now, for though there has been ample growth on most things of a green nature, the dry, hot weather early in the autumn and the cool, though dry, weather now prevailing have, in this neighbourhood at least, made this growth hard and sturdy and less likely to fall a prey to severe frosts later on should these occur. A hard winter would not be an unmixed evil this year, for since the memorable one of 1894-95 there has been no severe or long-continued frost, and a consequence of this is a great increase in certain garden pests, notably caterpillars of various kinds, slugs, and wire-worm. Brussels Sprouts and winter and spring Broccoli, Kales, and different winter greens all look hard and likely to stand well, while the same is true of salading plants generally, such as Cern Salad, Endive, and Lettuces. Roots, such as Parsnips, Carrots, and others, are showing that their season of growth is past, and the outlook is good, for almost every root lifted is clean and well developed already, and they will be well finished by lifting time. Potatoes are not only a good crop, but of excellent quality. I lifted a few perches of *Magnum Bonum* that were on land required for tree planting, and was surprised at the number of fine, well-shaped tubers. One root had just over 9 lbs. of good saleable Potatoes besides a few trashy ones, and when *Magnum Bonum* crops like this there are few more profitable varieties. Artichokes are almost entirely free of disease this year, the result of a couple of doses of old, dry soot and sulphur thrown over them on damp days in spring.

The fruit room, unfortunately, will have no such satisfactory tale to tell. Birds have played sad havoc with the few Pears left on the trees to ripen properly, while Apples are conspicuously absent. The trees of all kinds are, however, in a very promising state, and the rather heavy showers we have recently been favoured with have all been in their favour. Young Apple and Pear trees have splendid clean-looking wood bristling with fruit-spurs, and foliage of that hard, leathery character that all fruit growers like to see. The leaves, in short, look finished and the buds prominent and hard at their

bases, so there is every probability that next season the trees will be as fruitful as they are barren this year, unless, of course, weather of a very unkind character occurs next spring. H. R.

Suffolk.

TREES AND SHRUBS.

OLD OLIVE TREES IN MAJORCA.

IN the equable temperature of the Balearic Islands vegetation of all descriptions flourishes. In the town of Palma, with its fine old cathedral, many houses are in mid-April sheets of rosy lake with the blossoming Bougainvilleas. In the thirteen-mile drive from the town to Miramar, the picturesque seaside estate of the Archduke Luis Salvator, every available inch of ground is cultivated. Almond trees of large size occur in extensive plantations, bearing towards the end of April nearly full sized fruit. Beneath the spreading branches, vegetables, such as Cabbage, Cauliflower, Cos Lettuce, Onions, and Broad Beans, are grown, while at that season of the year Barley and Oats are in ear and in many places rapidly yellowing. Here and there are small walled plantations of Prickly Pear (*Opuntia*), and as the distance from Palma increases, large Fig trees and Karoubas or Locust trees (*Ceratonia siliqua*), which bear the Carob Beans, to a certain extent replace the Almonds. Further on, toward the end of the level country, and just previous to the road entering the pass that threads the range of precipitous hills which divide the plain of Palma from the slopes of Miramar, a particularly interesting sight meets the view, for here on either side of the road stretches a wide plantation of Olive trees, evidently very old. The age of the trees is popularly supposed to be a thousand years, but all record of their planting has naturally been lost in the dim vista of bygone centuries. On every side stand the fantastic ruins of these time-worn veterans, many of them possessing but little semblance to trees. Now and again the remains of a giant trunk would consist of nothing but from six to a dozen gnarled and contorted sections of the outer layers of the trunk and bark, from 2 feet to 4 feet in circumference, whose serpentine coils, in the absence of the central wood, resembled huge cables, covering at their bases a circumference of several yards, and which thickened and met again at a height of 12 feet or 15 feet, a mere distorted skeleton of what was once a solid trunk. So quaint and grotesque were the forms assumed by many of these hoary patriarchs, that a couple of hours might well have been spent in selecting subjects for the camera, but such a delay *en route* for Miramar being out of the question, I was forced to be content with two photographs taken not far distant from the road, one of which is reproduced in the accompanying illustration. The tree on the left was one of the largest in its immediate neighbourhood, its bole measuring about 40 feet in circumference at the ground level and in an excellent state of preservation compared with many of its adjacent comrades. When these aged trees were first pollarded it is impossible to say, but, as may be seen in the illustration, a few comparatively youthful fruiting branches still spring from the misshapen trunks, which are subjected to an heroic method of pruning, branches thicker than a man's thigh having been evidently sawn off many of the trees shortly before my visit, while some of the most distorted wrecks were

denuded of all their branches except one or two barely as thick as the forearm. All the older trees in Majorca Olive plantations are pollarded, but the younger are apparently allowed to make less restricted growth. The ground beneath the trees was being worked in places by very primitive ploughs consisting of a metal share fixed to a beam, which was elongated into one short handle, the implements in question being drawn by a pair of oxen. Large heaps of manure, chiefly animal, had been collected in parts of the plantation, from which it appeared that the necessity for well fertilising the ground was appreciated in Majorca.

S. W. F.

Hibiscus (Althæa) cœlestis.—Many of the double forms of *Althæa frutex* are of a poor and

now when the leaves are changing colour. Though some individuals even of the same kind, owing to position or other circumstances, vary considerably in their autumn tints, the neat-growing variety with small or medium-sized leaves is usually the brightest of all, while that with large, deeply-lobed foliage generally dies off more or less tinged with brown, and is therefore dull and sombre compared with the other. Just now a large quadrangle at Kensington Palace, which has three of its sides more or less densely clothed with this *Vitis*, presents a most interesting and delightful feature, owing to the numerous tints represented in the masses of foliage. Different shades of green occur, from a light tint suggestive of spring to a deep olive hue, and from that to bronze and bronzy crimson, till a bright glowing crimson is reached, which is in the sunniest spots lit up by leaves of a vivid scarlet tint. A vigorous plant of the small-leaved form has

Old Olive trees at Majorca. From a photograph by Mr. S. W. Fitzherbert, Torquay.

undecided colour, which takes away from their value as late-flowering shrubs. The new variety mentioned above has no such fault, and when seen grouped as I saw it a few weeks back at Gunnersbury House it forms quite a charming feature in the garden. The flowers are very large, single, and salver-shaped, almost true blue in colour, and with a rosy purple base. They are very freely borne, and the plants had a freshness about them that made one think of spring rather than autumn. It only needs a few such showy varieties as this to make these hardy forms of *Hibiscus* very popular for the shrubbery. The aim of the raisers should be to develop large-flowered single instead of double forms.—J. C. TALLACK.

Vitis inconstans.—There are certainly several forms of this charming climber, and while their distinctive features are very apparent from spring to autumn, they are particularly noticeable just

mounted to the top of a high wall from which it droops in a dense fringe, the long, cord-like shoots being clothed with a profusion of small, neat leaves, which, owing to their full exposure to the sun, are of a uniform scarlet hue.—T.

Caryopteris mastacanthus.—This shrub well deserved the award of merit given it at the meeting of the Royal Horticultural Society on September 26, but it surely is not entitled to be spoken of as a recently introduced shrub, as was lately done in THE GARDEN. It was first sent from China by Fortune in 1844, then lost after a time, and reintroduced by Maries when travelling for Messrs. Veitch in 1879 or 1880. It was soon widely distributed and obtainable at a cheap rate from many nurseries. A hot season and a sunny position suit it best. It cannot in a general way be considered quite hardy even near London, but succeeds best at the foot of a south wall or in some similar spot. This *Caryopteris* usually dies

nearly to the ground during the winter, but it breaks up freely and flowers in the autumn. It is one of the few shrubby members of the Verbona family that are fairly hardy in this country, most prominent of the others being *Clerodendron trichotomum* and *Vitex Agnus Castus*. The flowers, borne in rounded clusters from the axils of the upper parts of the shoots, are of a bright purplish blue tint, while the value of the plant is still further enhanced in that it blooms in the autumn.—H. P.

BOOKS.

MORE POT POURRI.*

WE are glad again to welcome our beloved Mrs. Earle, with her varied basket of good things; she is so sympathetic with all kinds of good work, and a real gardener. The great success of her first work has led her to give us another instalment. The best idea, perhaps, we can give of the book is to quote a few examples of the pot pourri from it. Such a brilliant success naturally carries its own lessons to author and publisher; but we almost wish that, as there is so much that is charming about young women and children, the book had been called "Women and their Babies." She tells us of the deplorable effects of the popular evergreens in Italian gardens, and she is quite right:—

Italian gardens.—The villas of the rich that I saw round Florence—and, of course, there are a great many which I did not see—are to be recognised by the fact that the Vine and Olive, Lemon and Pomegranate, Fig and Mulberry, are turned out for the planting of Laurels, Deodars and other conifers, Rhododendrons, and coarse-growing, unpruned shrubs. The beautiful old walls are often levelled to the ground to make a slope of coarse-growing grass, or the wall formerly used for the trained and well-pruned Vine is smothered with a mass of untended creepers. The newly-planted Crimson Rambler is doing very well and making excessive growth, though it will never be a general favourite, as it flowers too late and is not a marketable Rose; so the gardeners despise it, which is lucky, as its colour is not good. The greatest crime of all as regards the spoiling of Italian gardens is destroying the effect of space and coolness, and at the same time entirely shutting out the view by planting trees—say, even a row of Poplars. The old gardens as perhaps Dante and Boccaccio saw them are now smothered in Virginia Creeper, and made to look as much like a villa at Hampstead or Putney as possible. Magnolias are crowded out, and Camellias seem no longer cultivated (I suppose, because they are out of fashion in English conservatories); and instead of the cool grey gravel, so easily kept raked and weeded in the old days, unsatisfactory grass paths are attempted. In the garden that I especially remember, having spent months there twice in my life, the view towards the city and the Val d'Arno right away to the Carraras—which on favoured evenings are rubies or sapphires or beaten gold against the sky—all this, so ineffaceably impressed on my memory, is now hidden from sight by a dark, gloomy, tangled mass of evergreens.

Mixture for killing Carnation disease.—When in Germany I was much struck by a greenhouse full of the healthiest Tree and winter-flowering Carnations I have ever seen. The gardener told me that the secret of the entire absence of injured leaves and spots from rust was that from July onwards, whether they are in pots or planted out, he syringed them once a week with the following mixture, which is also good for many other plants that are often blighted, especially Hollyhocks and Madonna Lilies:—

(1) Two pounds of vitriol (copper); (2) four

pounds of lime, fresh slaked; (3) twenty-seven gallons of water; (4) two pounds of sugar. (1), (2) and (3) should be mixed together till no longer blue, but clear. Then mix the sugar with the rest. Syringe with an insecticide every week in the early afternoon. The syringing should be done quickly and finely. The ordinary garden syringe with a fine rose does quite well.

Bordeaux mixture.—Here is the real Bordeaux mixture, slightly different from the last recipe, used throughout the whole of France against the phylloxera on the Vines; it is also a cure for the Potato disease:—

Dissolve three-quarters of a pound of carbonate of copper in a little warm water; place it in a vessel that will hold six gallons of water. Slake half a pound of freshly-burnt lime and mix it with the water so that it is about the thickness of cream. Strain it through coarse canvas into the solution of copper. Then fill up the vessel with water.

With these two recipes it seems to me possible to try endless experiments on plants in any way affected by disease or rust. I shall certainly try it on *Humoa elegans* when the plants begin to go off. For a few years I gave up growing this charming annual, the disease always making its appearance.

There is a little heresy here and there—from our point of view, of course—and we feel sure the Maple "recipe" would spoil many a garden.

Maples in the garden.—A well-planted white variegated Maple ought to be in every garden, but it should not be allowed to get large and coarse. A contrast should be planted near it in the shape of broad-spreading leaves of some strong-growing, dark-foliaged plant.

Coltsfoot in the garden.—The bright yellow flowers of the improved Tussilago (Coltsfoot), sold by Cannell, are now just coming out, and the gravelly corner where they grow is a bright mass of buds. These flowers that come before their leaves, like the autumn Crocus, are attractive, though the size of their leaves when they do come puts one sometimes out of conceit with them, especially if crowded for room; though it is astonishing how corners can be found in even small gardens for all sorts of things if one gives the matter constant attention. Having everything under one's eye, one never forgets to notice how they get on; the greatest danger for the beds and shrubberies is the forking over in autumn. It is far better left alone if it cannot be done with care and knowledge.

The worst of such introductions to the garden is, that getting them out is not at all so easy as getting them in.

Can Mr. Geo. Muirhead, or any bird-lover among our readers, tell us more about the little owl to which the following verse of Shelley refers? It is quoted by Mrs. Earle.

Sad aziola! many an eventide

Thy music I had heard

By wood and stream, meadow and mountainside,
And fields and marshes wide,—

Such as nor voice, nor lute, nor wind, nor bird

The soul ever stirr'd;

Unlike, and far sweeter than them all.

Sad aziola! from that moment I

Loved thee and thy sad cry.

Pumpkin soup.—Here is a true French recipe for Pumpkin soup. Cut up the slices of Pumpkin (say, about half a large one) and boil them in water. When well cooked, strain off the water and pass the pulp through a sieve. Boil half a pint of milk, add a piece of butter, very little salt, and a good tablespoonful of castor sugar. Pour this boiling milk on to the Pumpkin pulp. Let it boil a few minutes. The soup must be thick, and small fried crusts should be sent up with it. This recipe is enough for two people. Dried Vegetable Marrow is not supposed to be so good, but I had some soup to-night prepared exactly in the same way from a large dried Vegetable Marrow,

and it was excellent, though it had not quite so much flavour.

Nature best at last.—Nothing, I think, tempts me so much to neglect all duties and to forget all ties as gardening in early spring weather. Everything is of such great importance, and the rush of work that one feels ought to be done without a moment's delay makes it, to me at least, feel the most necessary thing in life. A friend wrote to me once: "The best thing in old age is to care for nothing but Nature, our real old mother, who will never desert us, and who opens her arms to us every spring and summer again, warm and young as ever, till at last we lie dead in her breast."

While thoroughly recognising and realising the charm of the first "Pot Pourri," I feel bound to confess, after reading Mrs. Earle's new book, that with pot pourri, as with many other things, one can have too much of a good thing. No doubt there are many grains of gold scattered amongst the heterogeneous notes that come pell-mell from lands far and near about habits, ways, life; about gardens, flowers, pictures, housekeeping, cooking, and admonitions to young and old. Without any continuity we move from thought to thought. Beside an Italian translation of "Hark! my soul, it is the Lord," we find a recipe for cooking Zucchini, a small sort of Cucumber one gets abroad. We descend from Newman's delightful description of an ideal garden—

By a garden is meant mystically a place of spiritual repose, stillness, peace, refreshment, and delight

—to discussing the merits and qualities of separated milk and the advantages of living on a non-meat diet. After perusing a most useful list of Irises, giving the different times at which they bloom, we pass on to a recipe for varnishing plaster-casts which was used by Sir Edward Burne-Jones—

Quarter of an oz. of gum elami, 2 ozs. white wax, half a pint of turpentine; add a small squeeze from an oil-paint tube of raw umber when a small quantity of the varnish has been poured into a saucer ready for use. Apply with a brush, and spread quickly and evenly. This has to be done three times, with a day between each coating, and rubbed hard with a silk handkerchief between each painting. It gives casts and plaster figures the colour of old ivory, and makes them useful and decorative in a way they can never be without it. The varnish on the casts lasts for ever, never becomes dirty, and the dust can be rubbed or even washed off quite easily.

The great use of a book like "Pot Pourri" is in collecting for us interesting scraps of information taken from various sources. How often do we come across charming, quaint, or instructive notices in the daily papers, or various reviews, which pass from our minds because we do not know what use to make of them or where to store them for possible reference.

In speaking of *Tropeolum speciosum*, which has become such a favourite of late and may be seen in every garden, our authoress tells us

That the great secret is digging the holes quite 4 feet deep, filling them up with leaf-mould and the light earth, or planting the roots a foot below the surface, and then they have 2 feet of loose soil to work down into, &c.

In instructing us about the secret below ground she omits the secret for the growth above ground, and that is by letting the creeper grow up a piece of garden netting stretched between two poles, which enables the plant to sway in the breeze and lets the air and sun play freely round it. Against a wall it shrivels and withers for want of the freedom it gets in its native state growing on loose hedges.

* "More Pot Pourri from a Surrey Garden." By Mrs. C. W. Earle. London: Smith, Elder and Co., 15, Waterloo Place.

Many of the cooking recipes are excellent; some are taken from Mrs. Ronndell's good cookery book and some brought from foreign countries. How nice it would be if some of our English cooks would take some of these foreign recipes to heart. We all enjoy "Spaghetti" when we have it in Italy, and yet how few of us insist on our cooks making it in England. Again, "Timbale Napolitaine" is an excellent dish, and so is "Asparagus salad."

The advice to young men and women at the end of the book is of that character that depends so entirely on the individuality and circumstances of those concerned, that no general law can be laid down, and though it may be of interest to the world at large, it cannot be considered very original in thought or helpful to young men and women who may be in doubt and difficulty about the crucial facts of life.

M. C. D.

VEGETABLES FOR EXHIBITION AND HOME SUPPLIES.*

MR. BECKETT is a most successful grower of vegetables, and is equally capable of conveying his experience and practices in a concise, lucid form. In the book under notice he has given much sound advice, and, if the truth must be told, has omitted details that a learner would have been glad to have found noted. For instance, why did the author fail to give approximate dates for sowing such kinds of vegetables as Beans, Peas, Lettuces, Turnips, and the like, with a view to having the produce at its best just when wanted for exhibition? It is to be hoped that when he is called upon to produce a new edition this omission will be rectified. I would also point out that original illustrations, a few of which are given, are much to be preferred to a greater number of catalogue blocks, with which most of us are already tolerably familiar. It also occurred to me as I read the book that some of Mr. Beckett's methods are, to say the least, somewhat extravagant, and either uncalled for or beyond the imitation of the majority of his readers, who have neither the time nor the wherewithal to expend. I will give a few instances of what I consider extravagances. On page 57 brief hints upon forcing Carrots are commenced, and this is the kind of compost thought necessary for the frames, or, what are preferred by the author, heated pits:—

Fresh soil should be used for each sowing, a compost of a variety of stuffs such as old potting soil, road grit, old mortar rubbish, peat, well decayed leaf-soil, and light sandy loam in about equal proportions suiting them. To every fifteen barrowfuls add one of wood ashes and a half bushel of bone-meal, passing the whole, which should be well mixed, through a quarter-inch sieve and kept at this season in as dry a state as possible. In the bottom of the pit place a layer of 3 inches of old Mushroom bed manure, and place the mixture on the top to the depth of 18 inches at least, and make moderately firm.

Not satisfied with this, we are further advised to top-dress after the plants are freely thinned out with finely-sifted Mushroom bed manure, and to give occasional slight applications of some artificial manure, which should be thoroughly watered in. Further extravagances occur when advice is given as to growing long-rooted vegetables on soils unfavourable to the production of faultless specimens. The old-fashioned plan of forming deep holes and filling them with suitable compost is recommended, but why make them so deep or far apart? Thus for Beetroot, the holes, according to Mr. Beckett, should be 15 inches apart in rows 18 inches apart, and he formed 4 feet deep; for Carrots, 13 inches apart and 3 feet deep, and for Parsnips 20 inches apart, 2 feet from row to row, and 5 feet deep. I readily admit that Mr. Beckett exhibits perfect Beet,

* "Vegetables for Exhibition and Home Supplies." By E. Beckett. London: Simpkin, Marshall, Hamilton, Kent and Co., Limited.

Carrots, and Parsnips, but surely he could do equally as well if the figures I have given were considerably reduced all round. He rightly protests against coarseness in vegetables generally, but in my opinion recommends practices that in most cases would lead to the production of vegetables much larger than desirable.

The chapter devoted to the preparation of the ground is all too brief, and the writer having had such good experience in various parts of the country might with advantage have advised upon the special treatment different kinds of soils need. He is a great believer in deep cultivation, but a little too emphatic, as witness the following:—

Like everything else worth doing, trenching requires to be thoroughly done; many advise keeping the bottom spit at the bottom, especially should this be of bad quality, but this practice I do not agree with, and always insist on the bottom spit being brought to the top to be acted upon by the weather and the surface-dressings.

The first garden I was connected with was thus treated at the outset, and it was a case of 6 acres of land spoilt, re-trenching only partially getting rid of the "horrible clay" first brought to the surface. Much good advice is given as to preparation of vegetables for exhibition, with hints upon packing and staging the same, the chapter ending with a hint that ought not to be lost upon some growers who frequently mar miscellaneous collections by the addition of faulty produce, which, as Mr. Beckett remarks, simply increases the number and also certainly reduces the chances of obtaining honours. All kinds of vegetables are treated upon, culture under glass and the production of ordinary outdoor crops receiving a fair share of attention, while the selection of varieties must be regarded as thoroughly reliable. To Onions are devoted several pages, Mr. Beckett evidently making a speciality of this crop, and which he is invariably most successful with. He is equally enthusiastic with Peas, and evidently takes great pains in their production over a long period of the year. Nor does he overlook the value of Maize or Indian Corn as a summer vegetable. In dull, sunless summers this crop, according to my experience, is a failure in this country, but given a comparatively hot and dry summer it succeeds admirably and is a fairly good substitute for Peas, the latter, as it happens, failing in seasons that suit Indian Corn. According to Mr. Beckett,

A sheltered, sunny spot should be chosen for Indian Corn, and this ought to be thoroughly manured and trenched during winter, leaving the surface as rough as possible till spring. The seed should be sown about April 15, thinly, in boxes, in heat, and be made quite secure against mice. The young plants are very tender, so care must be taken to properly harden them off in cold frames before planting out, which should be done towards the end of May. The ground should be pricked over and made fine, after which plant in rows 3 feet apart and 18 inches from plant to plant. Abundance of water must be given at the roots during dry weather, and frequent hoeing to promote quick growth. A sowing may also be made the last week in April. The seed should be planted with a dibber and buried 3 inches. It is advisable to plant just as thick again as it is intended to grow them, thinning out when large enough to the proper distance. Some of this sowing may also be transplanted if required, but the practice of sowing under glass is much to be preferred. The cobs of corn should be gathered when fresh and green, and when well grown it is surprising what a large quantity a small piece of ground will produce.

A calendar of operations in the kitchen garden and a short chapter on the enemies of vegetable crops, including their life history and a few good remedies, are given at the end of the book.

W. I.

The weather in West Herts.—A cold week, more particularly at night. On six consecutive nights the exposed thermometer showed from 2° to 7° of frost. The difference between the night and day temperatures has been very great, and on the 10th amounted to 34° in the thermometer screen. This, with one exception, is the greatest difference I have yet recorded here in any day in the month of October. At both 1 foot and 2 feet

deep the temperature of the soil is at the present time about 1° colder than is seasonable. No rain at all has fallen during the last six days, but in the previous six days nearly 2½ inches of rain fell—equivalent to nearly twelve gallons of water on each square yard of surface. During the last four days the sun has shone brightly on an average for nearly 7¼ hours a day. Throughout the week the atmosphere has been remarkably calm, the mean rate of movement at 30 feet above the ground amounting to little more than a mile an hour.—E. M., *Berkhamsted*, October 13.

The days have been mostly warm during the week, but low temperatures have prevailed at night; indeed, since the month began there has been only one night which has been in any way unseasonably warm. On two nights the exposed thermometer showed 6° of frost. Both at 1 foot and 2 feet deep the temperature of the ground is now 1° below the October averages for these depths. During the last fortnight rain has fallen on only one day, and then to the depth of but about a tenth of an inch. No measurable quantity of rain-water has come through either percolation gauge for three days. The sun shone brightly for 6½ hours a day during the week.—E. M., *Berkhamsted*.

NOTES OF THE WEEK.

Aster N.-B. densus.—Among the dwarfed Michaelmas Daisies this is, perhaps, one of the best coloured, though not of the largest size. What is not forthcoming in size, however, is made up in numbers, and the plants are a veritable sheet of fine blue. It is in this particular one of the most acceptable of this section. It is 2½ feet high.

Aster N.-B. lævigatus.—This charming kind with a maximum height of less than 2 feet should be in every collection of these plants. Indeed, if half a dozen only were grown this should be one of them. The mass of rosy lilac blooms and the dense, dwarf habit render it not only a perfect plant for the flower garden, but a most serviceable one for pot culture also.

Solanum melongena.—In the No. 4 range at Kew at the present time may be seen quite an attractive variety of Solanums in fruit. In some instances the capsules containing the fruits are of the size and form of an ordinary hen's egg, the colour being that of the egg when hard boiled and bereft of its shell. Others have the fruits coloured with purple and shaded with a similar tone, yet not so attractive as the whiter kinds.

Physalis Franchetti.—The value of this plant in open beds is now well known and justly appreciated. Its use as a pot plant, however, is much more limited, though equally valuable by reason of its striking effect when brought into the greenhouse. Grown in large pots, with a good supply of rich loamy soil, and plunged to the rim during the summer in an open position, the plants would be less likely to suffer from dryness. Both water and liquid manure may be supplied freely to encourage an early growth, as unless this is done, an undue dwarfness may rob the plant of much of its value.

Fruiting of the Wistaria.—Can any reader of THE GARDEN kindly say if it is usual for the Chinese Wistaria, or Kidney Bean Tree, as Nicholson calls it, to produce fruit in British gardens? I am led to ask this question because Mr. T. Walpole has just brought me a fruit or pod 7 inches in length covered with soft silky tomentum, and having about half a turn or twist in its length. This fruit was produced by a rather young plant of the white-flowered *W. sinensis* at Rossanagh, Co. Wicklow, and it is the first fruit I have seen or heard of as growing in Ireland.—F. W. B.

Autumn Crocus in grass.—Very pretty just now quite near the main entrance on the green to the Royal Gardens, Kew, are the single white *Colchicum autumnale* and that fine autumn Crocus, *C. speciosus*. There is no attempt at massing in either case, though a very pretty picture is the result of a free sprinkling of both kinds in the turf, the planting extending in the direction of the large succulent house. When we remember that these things push their way

through the well-nigh solid turf, it is surprising so many appear each year. Naturally in such soil the increase of the bulbs would be very slow, and these who would undertake similar planting would do well to secure a more open and free-rooting medium.

Nepenthes at Kew.—A year or two since, when the fine collection of Pitcher Plants was but indifferently housed in the No. 7 range, it was possible only to get an equally indifferent view of the plants. All this is altered now, and the plants have a structure to themselves in so far that other things are in a way subordinate. At the present time, the multitude of pitchers is encompassed by a hanging and well-coloured screen of *Cissus discolor* that trails nearly to the floor. Of the luxuriance of this stove climber some idea may be formed when it is stated that aerial roots upwards of 2 feet long depend from the branches more or less through the house—a proof of the effect of the tropical humid heat on the plant in question.

Cassia corymbosa.—In spite of the frost it is interesting to find this pretty and useful old plant still flowering abundantly and clothing the bed in which it is growing with its elegant foliage. The foliage is so freely produced, as to form quite a dense covering to the bed. In most bedding plants a centre is formed of one and a margin of another, usually to hide the stems and cover the defects of the former. This *Cassia*, however, completely furnishes the ground in which it is planted, especially when growing quite in open beds. Just now this old plant fills one of the beds in the Royal Horticultural Society's gardens at Chiswick, and its comparative hardiness as well as its late flowering should tempt others to try it. The rich golden yellow flowers, too, are very showy, and in this respect also the plant is not likely to have many rivals.

Tropical Water Lilies in the open air.—If we could make sure of having heat and sunshine as during the past summer, no doubt we should be able to flower many of these plants in the open air by sheltering them during winter, carefully forwarding them in spring, and then dropping them into shallow tanks in May or June when the water had become warmed by the sun. My object in now writing is to ask if the *Victoria regia* has ever bloomed in the open air in England? Wherever there is a supply of clean, warm water from a factory it might possibly be done. In Haydn's "Dictionary of Dates," under *Victoria regia* I find the following statement: "It was grown in the open air in 1855 by Messrs. Weeks, of Chelsea." Can any reader remember this having been done, and tell us if the plant flowered, and under what conditions as to heating of the water, &c.?—F. W. B.

Anemone japonica elegans.—That this is a pretty form of the Japanese *Anemone* there can be no doubt, while in its freedom of flowering it is quite the equal of the other older forms. Blocks of each of these are always most effective in the late autumn. To be sure of retaining these things, however, sufficiently late to be of service, a special position must be chosen for them. Perhaps the best place would be a west or slightly north-west border, where the plants would be less influenced by the morning sun. In case of frost again much harm is done by the sun shining on the blossoms while these are still more or less frozen. These disastrous effects are considerably modified when the frost is dispelled before the sun reaches the flowers, and the position suggested is probably one of the best. Some years ago a very fine batch of the white and red forms flowered well into November, the position being at the base of a high wall in much the aspect suggested above.

Eucomis punctata.—It is gratifying to read the appreciative notice upon *Eucomis punctata* by Mr. Tallack in THE GARDEN of October 14. It is the more agreeable to read, as one of my correspondents, whose judgment with regard to matters of the kind is worthy of the highest con-

sideration, criticises my remarks made on p. 252 as being much too laudatory. One is, however, glad to see that one has the support of Mr. Tallack in one's endeavour to call a little attention to a neglected plant which is not enough grown in the open. Much as one admires bright and effective colours, there are many plants whose charms do not lie in brilliancy, but in modest colouring or in singularity of form. Those who can appreciate these things will not be likely to regret growing the *Eucomis*. Mr. Tallack has done justice, but no more than justice, to the plant in his clear and faithful description of its appearance. It is one of those plants which is not likely to appeal to the multitude, but one which gives individuality to the garden in which it is grown.—S. ARNOTT.

Anemone blanda.—There is no doubt that the plate of *Anemone blanda cypriana*, with the accompanying letterpress by "E. J." in THE GARDEN of October 7 will be the means of the lovely Greek Windflower being more largely made use of in our gardens of hardy flowers. This *Anemone* is so beautiful in its several forms, that no apology is needed for a brief note in corroboration of the requirements referred to by your correspondent. In the article referred to some stress is laid upon good soil for the seedlings and older plants. As one who has had a good deal of experience in growing this and other plants on light soil, I may add that in very light soil *Anemone blanda* is rarely satisfactory. It is neither so vigorous nor is it so long-lived. In such soil also it does not produce so many self-sown seedlings, probably because they do not make free growth at first and fall an easy prey to dry weather. Nowhere does *Anemone blanda* thrive better than in a heavy soil almost approaching clay in its texture. There is here a good deep blue form called Mr. Ingram's Deep Blue. It was for some years in light soil without producing more than one or two flowers, although it increased in size.—S. ARNOTT.

Helianthemum amabile fl.-pl.—I am obliged to Mr. Cornhill for his note as to this plant, which, as he supposes, is the one referred to a short time ago as the Carton Sun Rose. Through the kindness of Mr. P. H. Normand, of Aberdour, I have had the opportunity of comparing and verifying the plant. Although this disposes of the question as to what this Sun Rose is usually called, it opens up a fresh one regarding the nomenclature of the *Helianthemums*. There is no *Helianthemum* named *amabile* to be found in current books of reference. The plant in question is apparently the one known formerly as *H. venustum fl.-pl.*, but the "Index Kewensis" refers *H. venustum* to *H. variabile*. Neither Paxton's "Botanical Dictionary" nor an old edition of the "Cottage Gardener's Dictionary" mention *H. amabile*, though both name *H. venustum fl.-pl.* I have searched several other works for the purpose of finding the name of *amabile*, but it has not come under my observation. For garden purposes we must, I suppose, either call it *venustum fl.-pl.* or *amabile fl.-pl.* The former is the name by which it was known to gardeners for many years. By whom was that of *amabile* first applied to it?—S. ARNOTT.

Stenoglottis longifolia.—This Cape species of terrestrial Orchid appears to have been shown by Messrs. Sander & Co. at the meeting of the Royal Horticultural Society on October 10. This Orchid is one which seems to grow and thrive with comparatively little care, and to give in return a satisfactory display of flowers, which have the great merit of lasting a long time either in a cool greenhouse or in an ordinary sitting-room. A plant sent me in the summer of 1898 bloomed very satisfactorily during the greater part of last winter. For more than a month it flowered in my sitting-room, although it had been in bloom in the greenhouse for some time previous. When it was past flowering it was returned to the greenhouse, where it has remained until the present time. Although no fire-heat has been applied this autumn, *Stenoglottis longifolia* is now sending up

several flower-spikes, and the blooms upon these will open shortly. Although some do not consider its flowers bright enough, it is yet a pleasing plant with a considerable degree of beauty. I am told that it is figured in the *Botanical Magazine*, vol. cxvii., table 7186, but I have not at present access to the volume. It may be commended to the notice of amateurs and others who desire to grow a few comparatively rare plants which may be cultivated without much difficulty.—S. ARNOTT.

Caryopteris mastacanthus.—I do not quite see the force of "H. P.'s" recommendation (see page 294) for giving this plant "increased attention for flowering under glass," as experience points rather conclusively to the fact that it is this shade of blue that so quickly fades when given the method of culture "H. P." suggests; indeed, the colour of the flowers referred to at Kew, and which agrees with the description, "lavender-blue," is distinctly paler than that of plants of it grown in the open. It is as a hardy plant that this Japan shrub will prove of the greatest value to our gardens, particularly as an autumn-blooming plant when blue-flowering shrubs are not at all common. Why these paler shades of blue under glass so readily lose their colouring I am not able to say, for the well known *Salvia patens* or *Agathæ celestis*, which are deeper in tone, retain their colour much longer. I do not know how long the plants had been in the greenhouse at Kew, but, as seen on October 14, many of the whorls were quite pale-looking. The distinctness of the plant, together with late flowering and hardiness, are items that should go a long way to make this pretty shrub popular. All the plants I have seen have been freely furnished with growth buds on the oldest branches close to the soil, an indication of its inclination to break well from the base.—E. J.

Rhus Toxicodendron radicans.—This Poison Tree is one of the plants we are inclined to despise until autumn comes round, when it assumes its bright leaf colouring. Throughout summer it has no particular attractions, but may be used as a low carpeting shrub of creeping habit. In autumn we are struck by the beauty of its leaves. As is the case with most leaves which are parti-coloured in autumn, it is hardly safe to attempt to describe their colours. These change from day to day, and a clump will give much variety. A few leaves just gathered and now in a glass before me show much variety of hue. Some leaves are pale yellow, spotted and flecked with green. Others are a brilliant and beautiful combination of almost crimson, bright yellow, and green. The worst of the plant is its poisonous reputation. One fears it is not possible to claim for it that it is innocuous, but the statement in a leading work of reference that the typical *Rhus Toxicodendron* of climbing habit is "poisonous to the touch" does not appear to apply to the creeping *radicans*. It has been here for a good many years as the memento of a visit to the Manchester Botanic Garden and its then curator, the late Mr. Bruce Findlay. It has been transplanted more than once, and I have frequent occasion to come into contact with its leaves and stems, but have never had any reason to avoid touching it. There may be some, as in the case of *Primula obconica*, to whom the touching of this *Rhus* would bring painful consequences. One has, however, to speak of plants as he has had experience.—S. ARNOTT.

Crocus cancellatus.—Few things are more pleasing at the time when the outdoor garden loses so many of its attractions than a collection of the autumn-flowering *Crocuses*. They are so delightful in their fresh brightness, that one cannot pass them by without pausing to enjoy for a little longer the charms of their little cups. Those who think them unseasonable are not likely to be long in changing their opinion once they have an opportunity of seeing a few of these lovely flowers on a bright autumn day, such as the one on which this is being written. One is convinced that greater familiarity with them

would lead to their greater popularity. Among those in bloom here at present are two forms of *Crocus cancellatus*. This is a variable species in its colouring, and is, moreover, one of those which has the habit of mimicing in its native habitats the other *Crocuses* with which it grows. The forms in my garden are a white one and a blue one known as *C. cancellatus cilius*. Of the two I prefer the white, as being more unlike *C. speciosus* and the others of allied colour at present in flower. In its native habitats it is a variable species, and one would like to possess a few more shades of so pretty a little *Crocus*. Mr. George Maw tells us that its segments vary from white to light purple, and self-coloured, or feathered with purple markings. The western forms are generally white, and the eastern blue with various markings. It is a neat and pretty little *Crocus* with orange anthers, style, and stigmata. The Cilician variety here is taller and more vigorous than the white.—S. ARNOTT.

Sternbergia lutea.—If the "Lily of the Field," as *Sternbergia lutea* is called by John Parkinson, could be flowered regularly in every garden, it would supply the want some of us feel—that of a yellow *Crocus*-like plant to bloom with the autumn *Crocuses* and Meadow Saffrons. It is, however, not everyone who can flower it regularly, and I must confess that hitherto I have been unable to bloom either this species or *Sternbergia macrantha* for two years in succession in this garden. It is more correct, indeed, to say that it will only flower the year after planting. This has been a great disappointment, and one is always glad to have any treatment suggested which would give one the pleasure of enjoying a pleasing flower without purchasing and replanting it yearly. I have it in bloom to-day (Oct. 16) from bulbs sent me by a friend who has had a wide experience of plants and their ways, and who has kindly, from his store of knowledge and practice, suggested a method by which one may perhaps have happier fortune than in the past. He had been disappointed with his failure until he removed to a place where his garden is on the chalk. In this garden, it appears, *Sternbergia lutea* grows remarkably well and blooms regularly. The bulbs he kindly sent me from his garden are now in flower, and his experience makes one hope that the use of lime-rubbish and limestone may lead to one having the same enjoyment of the flowers of this and other *Sternbergias*. One says this with some reserve, as districts and the gardens within them often give varying results from the same treatment. I must admit that I am now more hopeful than I have been for long of inducing this delightful plant to bloom yearly. There are many others who have had similar disappointments with it. Perhaps this note may help some to a way of escape from this tantalising experience of blooming this *Sternbergia* for the first year only. As one looks upon it to-day, with its clear yellow flowers open to the October sun, one feels more than a passing pleasure at the sight. Even when in bud it is beautiful, and the appearance of its unopened flowers makes one realise how our older florists classed it with the Daffodil. When in bud its aspect carries us—in fancy, at least—forward to the time when we once more delight in that incomparable flower of spring.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Grotesque flower gardening.—Some of the superintendents of American public gardens seem to surpass all others in the grotesque ugliness of their bedding arrangements. Below is a description of a battleship in flowers. We are pleased to see that one of the American gardening papers (the *Park and Cemetery of Chicago*) condemns these wasted efforts.

"In dark red lettering near the base the words 'Erected by the Michigan Central R. R. in Remembrance of the Maine' are plainly set out. The design consumed 1820 *Alternanthera versicolor*, 3010 *A. aurea uana*, 980 *A. spathulata*, 2200 red *A. paronychioides major*, 2985 *Echeveria metallica*, 365 *E.*

secunda glauca, 8540 *Sedum variegatum* and 100 *Oxalis corniculata*."

Although these outrages against good taste are happily getting less common in our country, we are still not free from them, and this summer there was in Dulwich Park a pretentious absurdity of the sort, consisting of the arms of Dulwich College with a Latin inscription, all done in carpet-bedding plants.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

THE next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, October 24, in the Drill Hall, James Street, Westminster, 1 to 4 p.m. A lecture on "Growth of the Fruit Trade" will be given by Mr. Geo. Monro at 3 o'clock. The War Office having asked for the Drill Hall of the London Scottish Volunteers (in which the meetings of the Royal Horticultural Society are held) to be placed at its disposal for the temporary accommodation of 300 soldiers *en route* for South Africa, it is probable that the society's meeting on October 24 will have to be held in the Drill hall of the Queen's Westminster Volunteers, which adjoins that of the London Scottish, being actually the next door. If this should be the case, Fellows and exhibitors are requested to make the best of unavoidable inconvenience, which, it is hoped, will not have to be repeated.

The following dates have been fixed provisionally for meetings in 1900: January 9, 23; February 13, 27; March 13, 27; April 10, 24; May 8, 23, 24, 25 (Temple); June 5, 19, 27 (Richmond); July 3, 17, 31; August 14, 28; September 11, 25, 27, 28, 29 (Crystal Palace); October 9, 23; November 6, 20; December 4, 18; January, 1901, 15, 29; February 12. Gentlemen willing to lecture on any of these dates are requested to communicate with the secretary, 117, Victoria Street, S.W., at once.

Trials will be made at Chiswick in 1900 with the following subjects: (1) Tulips for outdoor decoration.—Twelve bulbs of each variety should be sent at once to the superintendent, Royal Horticultural Society's Gardens, Chiswick, W. Each variety should be marked with its colour, and whether early, midseason, or late. (2) *Phlox decussata*.—Two plants of each should be sent on or before March 1. (3) Cactus Dahlias.—The 1899 trial will be repeated. Any new varieties, two plants of each, should be sent in April. (4) Potatoes.—New varieties, twenty tubers to be sent before February 1; also a trial of distinctly early Potatoes, both old and new varieties requested. (5) Tomatoes.—For outdoors only. Seed before February 1. (6) Peas.—Half a pint to be sent in January. (7) *Celeriac*.—Seed in January.

The Royal Horticultural Society will hold its next examination in horticulture on Tuesday, April 17, 1900. For syllabus, apply to the secretary, Royal Horticultural Society, 117, Victoria Street, S.W., enclosing a stamp.

Carnation Mrs. G. Foster.—As the raiser of this variety, I must protest against your remarks in THE GARDEN of September 30. Had your reporter understood his work, he would have noticed that the growth of the plant was that of a perpetual bloomer. Because the blooms are much larger and have smoother petals than the ordinary Tree Carnation, it is hardly fair to brand it as a late border variety. It has been grown here in quantity these last four years, and I have had it in bloom nine months out of twelve. I have proved it a much better perpetual bloomer than *Uriah Pike*, which has repeatedly been recommended in THE GARDEN as a Tree or perpetual.—G. FOSTER, *The Gardens, Glendoragh, Teignmouth.*

* * * We can only deal with things as we find them. In this instance every flower has badly

burst the calyx, which fact we stated with regret. The plants exhibited, one of which was in a 7-inch pot and the other in a 5-inch pot, had a total of three open flowers, the larger plant being obviously grown upon the border plan, and displaying the current as also the former growth unmistakably. Mr. Foster is probably not aware of the way the plants were shown, and the best way to prove the perpetual character would be to send the same plants on Tuesday next. Evidences of perpetual growth were entirely wanting, 6 inches of the base in the older plant being leafless and bare. That this variety has been flowered "nine months out of twelve" does not alter the matter. Miss Audrey Campbell, also a yellow, has been flowered in every month of the twelve, and still figures as a good border Carnation notwithstanding.—Ed.

PUBLIC GARDENS.

The Metropolitan Public Gardens Association.—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, on Thursday, Mr. Hugh Leonard presiding, it was stated that the amendment proposed by the association to the Commons and Open Spaces Bill of last Session had been accepted, and that the Bill having since passed into law, all county councils were by means of this amendment able themselves to acquire and maintain land for public recreation or to assist municipal and district councils and other local authorities to do so. It was also mentioned that the clause promoted by the association for the protection of open spaces had been inserted in the Local Government Act. A number of letters were read asking for the assistance of the association in the preservation of Albert Square, Commercial Road, E., which was offered for sale as a building site, and it was decided to approach the various local authorities concerned and the London County Council, urging them to jointly acquire the site if obtainable on reasonable terms. A letter was read from the Bethnal Green Vestry offering to maintain Marian Square, Hackney Road, if the association would undertake to lay out and fence in the ground. It was agreed to take further steps in the matter, and it was stated that out of the £106 required for the fencing, £80 had been promised. Many proposals were under consideration, including schemes for the acquisition and laying out of sites in Fulham, Earlsfield, Westminster, Essex Road, Shadwell, and Enfield. Among a number of new members joining the association were Princess Louise and Sir Edward Malet.

Names of fruit.—*F. F. P.*—1, Fearn's Pippin; 2, Ashmead's Kernel; 3, Sam Young.—*Henry Oliver*.—1, *Beurré Hardy*; 2, please send better specimen; 3, *Blenheim Orange*; 4, *Striped Beaufin*; 5, *Lord Suffield*; 6, *Bess Pool*.—*E. F.*—1, *Queen Caroline*; 14, *Dutch Miguonne*; 23, *Cox's Pomona*; 24, *Winter Hawthornden*; 45, *Emperor Alexander*; 47, *Ashmead's Kernel*; 63, *Warner's King*; 69, *Cellini*; 77, *Striped Beaufin*.—*J. Morrison*.—1, *Felix de Leim*; 2, *Marie Louise d'Uccle*.—*F. Hussey*.—1, *Hoary Morning*; 2, probably *Peargood's* Non-such out of character; 3, *Maltster*; 4, *Norfolk Beaufin*; 5, *Minchall Crab*; 6, *Hampshire Pearmain*.

Names of plant.—*R. Blenkinsop*.—*Arauja* (*Physanthus*) *albans*.—*Bannerman*.—*Berberis vulgaris*.

"The English Flower Garden."—*Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d.*

Bound in 2 vols.—*sage-green morocco*—for library or presentation, one guinea. Of all booksellers, &c.

"Worth more than all other books on flower gardening and landscape gardening ever published. Whatever success I have made as a landscape gardener I owe to the inspiration of this book. It not only teaches good gardening, but, what is quite as important, condemns bad gardening, giving reasons that are convincing for both."—*J. W. ELLIOT, Pittsburg, Pa.*

ORCHIDS.

DENDROBIUM FORMOSUM GIGANTEUM.

This beautiful Dendrobium is well grown by Mr. Hudson at Gunnersbury House. The whole of the front stage of one of the largest lean-to houses was filled with plants of this species carrying between 600 and 700 expanded flowers. Many of us who saw the same plants exhibited last year were struck with the wonderful size of the blooms. This season if anything the flowers are even larger and with more substance. Many of the plants carried from twenty to forty blooms each; one truss I particularly noted carried fifteen flowers. Mr. Hudson is to be congratulated on the successful culture of this species, which, generally speaking, is found to be one of the most difficult of the Dendrobium family to deal with. The plants grow and flower freely for the first two or three years after they have been imported. After this period they generally deteriorate and become practically fit only for the rubbish heap. Some of Mr. Hudson's plants have been grown for over five years, and instead of deterioration the bulbs made this year are larger than any previously made. To illustrate still further the success of the treatment, I may mention that when the last batch of imported plants came to hand three years ago some seed must have been imported among the roots and about the base of the plants, for after they had been potted, or rather basketed a few months, this seed began to germinate, and ultimately seedling plants were developed. I took the particulars of the progress made in the three years' growth, which was as follows: The first year's bulb was an inch long, the second 3 inches, and this year, which is the third season, the growth measures 5 inches, showing that the cultural conditions are satisfactory in every degree. The conditions under which the plants are grown might be adopted in other places where fruit growing is a speciality. The plants are easily procured. There is certainly not a more useful Orchid for cutting during the months of September, October, and the greater part of November. The durability of the plants

and the lasting qualities after they are cut leave nothing to be desired.

The system of culture followed at Gunnersbury is as follows: The plants are grown in the span-roofed houses used for growing Figs, the glass with which the roof is glazed being unusually large in the individual squares, thereby affording abundance of light. A bar reaches from end to end. This is fixed to the roof on either side over the walk which passes through the centre. In this position the plants naturally obtain the benefit of the full rays of the sun. The houses are not shaded at any time of the year. The atmosphere is also maintained in a humid condition, and the plants are not allowed to become dry at the roots. They are also freely syringed overhead as frequently as are the other occupants of the house. This is continued until the growths are matured and the flower-buds commence to develop. When the blooms expand the plants are removed to a warm house where the atmosphere is less humid. Full sun is still afforded until they have become fully expanded; then a thin canvas blind is placed over to protect the flowers during the hottest part of the day. After the flowers have been removed, the plants are kept drier at the roots, only sufficient moisture being given to maintain a plump condition of the bulbs. Cooler conditions also are afforded, and the plants receive a thorough rest until the return of spring, when they are again placed in the position above referred to in the Fig houses.—H. J. C.

—The usefulness of this Dendrobe is well known, but it is doubtful if there are not many private gardeners who would envy the man who can produce 630 open flowers at one time. This Dendrobe is often looked upon as an indifferent one in its growth; it flowers freely enough when there is the necessary strength in the pseudo-bulb. A narrow stage in the front of a warm house at Gunnersbury House accommodates about forty plants, on which I counted over 600 flowers, with many buds yet to open. For several seasons they have contributed a similar display. They are growing mostly in baskets, which are thickly packed with active feeding roots, showing that the culture is of the best. Orchids are not grown largely at Gunnersbury, but

vigour and freedom of flower characterise those which I noted in the several plant houses. *Vanda cœrulea* seemed as happy as the Dendrobiums both in cool and warmer temperatures, the flowering season extending over several months. Mr. Hudson's treatment of this useful Dendrobe would form an instructive lesson to many growers.—W.

—It will be generally conceded that this is one of the most valuable, as it is one of the most beautiful of late summer and early-flowering Orchids. This is apparent in the size as much as in the substance, and not least in the freedom of the flowers, especially in those instances where the culture of the plant is fully understood. In not a few instances has failure, either wholly or in part, followed the second flowering of the imported plants of this unique kind. It is in these circumstances, therefore, that we refer to the splendid lot of plants recently noted in bloom in one of the Fig forcing houses at Gunnersbury House. It is not, let it be clearly understood, a splendid array of flowers appearing from already matured growths upon imported plants; it is really the flowering in the main of a fine lot of cultivated examples, some of which, as may be proved by the plants themselves, had been on the downward path. But the way these plants have responded to an altered treatment is alone an object-lesson. Plants with pseudo-bulbs less than the small finger of the hand four and five years back have now finely proportioned growths, many 15 inches long. It is quite a stock saying when a good plant of this kind is seen in flower, "What about it this time next year?" Well, the answer, so far as the Gunnersbury plants, is "better still." The plants are the very embodiment of health and vigour, and the entire secret—if there be secret at all—is full light and heat, with moisture. The Orchids are suspended by a wire to the rafters, the glass is very large squares, and there are no shade and no obstruction. The Figs are plunged in leaves, and doubtless the heat and moisture arising therefrom are an influence for good on these Orchids.—E. J.

Lælia rubescens.—Though a striking and pretty species, this is none too plentifully represented in collections, though it has been in cultivation a number of years. Of dwarf habit, it throws up its spikes to the height of about a foot, and each produces half a dozen flowers, the sepals and petals of which are rosy lilac, the lip similar

in ground colour with a fine purple blotch. Plenty of water while growing and a raft or shallow basket where the roots can penetrate to the air freely, and a position close to the glass in the Mexican house suit this plant well.

Dendrobium bigibbum.—This is one of the prettiest of autumn-flowering Dendrobiums. The blossoms are magenta, with a white centre to the lip in most varieties, these appearing in the centre of the young growth and from the sides of older pseudo-bulbs. Given ample heat and atmospheric moisture while growing, a light position and small pots, *D. bigibbum* usually thrives better than the majority of the Australian kinds, but it dislikes severe drying or too cool a temperature while at rest.

Pleione præcox.—In habit and general appearance of plant and flowers this very closely resembles *P. Lagenaria*, but it has usually paler tints in the lip and blooms later. The late autumn and winter months may be brightened considerably by these pretty little Orchids, but the common method of growing them in large pans is not so good as giving them small pots, so that when they are in flower the absence of their own foliage may be got over by associating them with small Ferns. The compost should consist of equal parts of peat, Moss and loam fibre, with sufficient opening material, and repotting should take place directly the flowers are past.

Lælia elegans Stelzneriana.—This is a pretty variety of this most useful *Lælia* belonging to the same section as *L. e. Schilleriana*, but having larger flowers than the majority of this set. The sepals and petals are broad and well displayed, usually of a very faint rose, but some flowers are more deeply coloured than others. The lip has a bright margin of rich purple on a mauve ground. The plant is not difficult to cultivate, thriving well if treated like *Cattleya* bicolor or others of the slender-stemmed kinds in medium-sized pots filled with peat fibre and moss. The plants must be well watered during the season of growth.

Trichosma suavis.—In spite of the small size of the blossoms, this pretty species is always admired when presented in good condition. Weak and unhealthy bits do not throw the flowers out of the sheath properly; they are unsightly and not at all showy. The stems on strong plants are 8 inches high and bear each a pair of tough, dark green leaves, from between which the flower-spikes are produced. In growing *T. suavis*—which is the only species in the genus—a cool, moist and shady house in summer is necessary, and during winter as much light as possible. In mixing the compost use rather more Sphagnum than peat, and a few fairly large lumps of charcoal or crocks help to keep the whole open. Drain the pots well, choosing those of medium size compared with that of the plant. By these means a healthy, clean growth is ensured, and as long as this is the case plenty of flowers will be forthcoming. The individual blossoms are about 1½ inches across, the sepals and petals white, the lip white, with a brownish crimson and yellow crest.

Oncidium Lanceanum.—This superb species is now finely in flower, and out of a somewhat extensive batch noted recently there would be no difficulty in picking out a number of varieties. The plant, indeed, is a great deal more variable than many that have obtained a number of varietal names, the chief difference, of course, being in colour, which in its best forms is very rich. The most usual colour is a greenish yellow with numerous spots of chocolate-purple, and the lip has purple side lobes with white or nearly white centre or front lobe. The spikes rise from the base of the great spotted leaves, which on healthy plants are from 18 inches to 24 inches in length, very thick, and doubtless acting in the same capacity as pseudo-bulbs. The plant will not, however, stand the same winter drought as many pseudo-bulbous kinds. Without a doubt they are rather severely dried in their native place, but in this country the growth is not so

well ripened by exposure to sun and air, and in consequence not able to stand the drying treatment so well. I have found clean Sphagnum Moss with only a little peat a better compost for it than the usual mixture of half and half, as the Moss in its decay does not form a close mass like the peat, and the plants dislike disturbance. For temperature a brisk sun-heat in summer is desirable with warm, if fairly dry, quarters in winter. It is named after Mr. J. H. Lance, its discoverer, who found it in Surinam in 1834 growing on various tropical trees. It was first flowered in this country by Messrs. Loddiges, of Hackney.—H. R.

FLOWER GARDEN.

ASTER AMELLUS AND OTHERS.

NEARLY every week in early autumn we read a note that *Aster bessarabicus* is now in flower and is very beautiful, but what it is and by what characters distinguished from *A. Amellus* I have in vain tried for many years to discover. I have seen in gardens very different flowers, each of which I have been assured is the only true and genuine var. *bessarabicus*. The original authority for this name is said to be Bernhard in Reichenbach's "*Flora Germanica*," a work to which I have not access. De Candolle, who recognises var. *bessarabicus* in his "*Prodromus*," mentions slight differences in the shape of the leaf and the bracts, differences which certainly exist amongst the forms called *Amellus*, and no doubt whatever may have been the original distinctive characters have disappeared in cultivation, and the name *bessarabicus* is now added in the most casual way. About twenty years ago I received from a Devonshire garden, from which I have had many rare and choice plants, var. *bessarabicus*, having the flowers flatly open and the rays narrow and acute. This is a distinct form of flower from the general type *Amellus*, which has the rays broader, somewhat incurved and obtuse, but after growing for a generation or two from seed, the two forms seemed by no means constant, and I gave up the name *bessarabicus* as representing in gardens no definite form. Still, the large garden form of *Amellus*, whether the flowers are flat or cupped, is very different from and very superior to the only type of *Amellus* I have ever seen wild. It abounds in Savoy near Aix, and though the colour in its native air is good, the flowers are small and the habit top-heavy, and it does not improve when brought into cultivation, though I have never seen it in England except in my garden. A so-called white form coming from the same district has flowers of a dull cream colour, with sparse and irregular rays, and is a very inferior garden plant. Still, the *A. Amellus* of Savoy is certainly the *Amellus* of Virgil with which that poet was familiar as a boy in his native meadows of Lombardy. He describes it as making a large bush of stalks from a single crown, as having golden flowers surrounded by many violet-coloured rays, with leaves of a rough, bitter taste—a description we can hardly mistake. Still, the *Amellus* of South-eastern France and Northern Italy is not the *Amellus* of English gardens, which does not look like a development of it. Perhaps our garden plant is the Greek type, which Sibthorp found plentiful in Attica, and it was called in Gerard's time the Attic Starwort.

As for varieties of *Amellus*, I have grown several crops of the plant from seed ripened in Devonshire, for it seldom ripens in Cheshire. The handsomest flowers are those with large incurved rays and semi-double. I have never succeeded in raising one really blue, but some

have far less red than others in their mixture, and the less the better. Some are of a rich imperial purple, and they show better in the subdued light of morning or evening than in sunshine. A really white *Amellus* of the best class of flower is a great desideratum, as a mixture of white sets off the colour of the others; but I have an excellent large-flowered seedling white hybrid of just the same stature and time of flowering which I grow side by side with *Amellus* to good effect.

While speaking of other Michaelmas Daisies, I may say that they are very late this year in Edge garden, and in some situations were quite ruined in the hot July by oidium like that which covers the leaves of Swede Turnips after hot, dry summers. Where they escaped this and were not broken to pieces by the furious storms of September, they continue to be good. I am glad to see by notes in THE GARDEN that the plan I have always advocated of raising Michaelmas Daisies from seed of the best flowers and improving them by selection every year is being adopted. At Edge I have already superseded nearly all the Conference Asters; yet I do not claim to have done better than other amateurs where they are selected in the same way. I have named about thirty of my seedlings, some of which have found their way into commerce. The naming has been done very casually in some such way as this: A visitor to my garden admires a pretty pale blue seedling flower, which I promise shall be named Nancy after her. In a few days six sisters who have heard of this come to me and say that they are nearer neighbours and older friends of mine than Nancy, and each of them must give their name to a flower, and so the number of names grows, and as the multiplication of roots in this class is endless, they get distributed, carrying their chance names with them.

A very few years ago I set up a neighbour (a Cheshire squire) with Michaelmas Daisies, advising him to practise selection from seed. Last year he asked me how my stock was getting on, and so I sent him a tin box full of more recent specimens. He wrote back saying that mine were nowhere compared with his, and sent me specimens in return. Of course, I thought his nowhere; but the incident suggested two things: First, that we all are apt to over-rate our own children; and secondly, that when Aster flowers have been packed up for twenty-four hours they get a withered and sleepy look, which obscures their merits, and they do not recover from it in water. They should always be judged growing, as so much depends on their habit.

Where this last advice can be followed, what I am going to say is of less consequence, but I never can see the use in the case of flowers which are certainly nearly all hybrids of dividing them under such heads as *A. lævis*, *A. Novi-Belgii*, *A. versicolor*, &c. The points which amateurs, if they cannot see flowers, care to know are the height, the relative time of flowering (early, medium, or late), the colour, and perhaps the size of the flowers. A heading—"cordifolius," for instance—would to most growers of Asters suggest dense panicles of minute flowers; but *cordifolius* makes many hybrids, few of them of much merit, in which the heart-shaped character of leaf is retained, with flowers of every size up to those of the type *lævis*. It seems to me that nearly all Asters of the Michaelmas Daisy type are prone to cross, and as the progeny is often fertile, it is not only puzzling, but, from a gardener's point of view, useless to class them according to their specific characters.

Edge Hall, Malpas.

C. WOLLEY-DOD.

SILVER VARIEGATED PAMPAS GRASSES.

FOR many years past I have grown a very prettily variegated form of the above-named plant received from a London nurseryman under the name of *Cortaderia* or *Gynerium* *Lambleyi*, but as to the correctness of this name I have for some time felt strong doubts, as I had never come across this specific name anywhere else. From a French nurseryman in the course of last autumn I received two varieties of variegated Pampas Grass under the respective names of *Cortaderia* *Wesserlinghi* and *C. Stenakeri*; these are now both in flower, and on comparison of the inflorescences I find that *C. Wesserlinghi* is identical with what I have hitherto known as *C. Lambleyi*. It is an exceedingly distinct and desirable variety, and when established very free-blooming, as my old plant, though only of medium size, is now bearing thirty-three of its ornamental plumes, which are of a perfectly upright habit and of a pleasing pale rosy hue rather difficult to describe with exact accuracy, and unlike in form those of any of the many other varieties known to me. It is also of an admirably dwarf, compact habit of growth, and is, I consider, a distinct and desirable addition to any collection of ornamental grasses, however choice. It is also apparently perfectly hardy. The other variety named above as *C. Stenakeri* is also most desirable and of quite distinct appearance, having a much whiter variegation and perfectly white plumes.

W. E. GUMBLETON.

THE EDINBURGH BOTANIC GARDENS.

Most botanic gardens possess attractions for those who care for the variety which is to be found in the world of plants. The Royal Botanic Gardens of Edinburgh are no exception to the rule. They have for some time been undergoing extensive alterations, which must very materially interfere with the ordinary work of the staff and prevent many little details of cultivation from being carried out. Much still remains to be done before the alterations are completed, and one can hardly judge of the general effect of the changes until they are finished. At present one can, however, say that the enlargement of the glass structures has not only enabled Professor Balfour to add to the collection of plants, but also to display the others to greater advantage. The gain to the public is no slight one, as the plants can be viewed with comfort and in a more thorough way. The new paths in course of construction will also give easier access to the different points of interest.

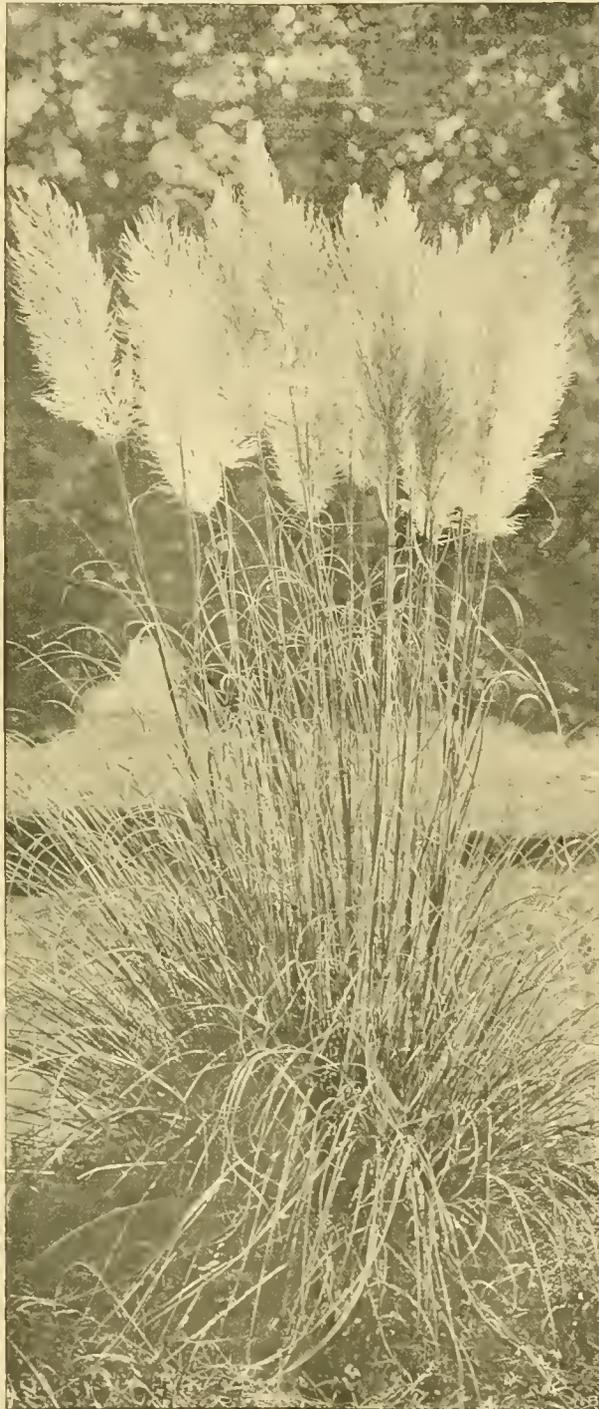

The middle of September is not the most attractive time to see the outdoor plants to advantage, yet one can at all times find something worthy of notice. Dwellers in Scotland will find it worth their while to examine the shrubs on the wall in front of the terrace. Here they will acquire an idea of what may be suitable wall shrubs for cultivation in the north of Scotland. Some of those on this wall receive a little protection, but care is taken that there is no "coddling" and that the covering is not applied too early. There are several *Escallonias*, among which I saw *illinita*, *ptero-cladon*, *exoniensis*, *rubra*, *punctata*, and *viscosa*. One of the hardiest at Edinburgh is *E. Phillippiana*, a plant whose pleasing appearance is much admired. *Jasminum floribundum* was coming into bloom, but *Buddleia intermedia* had just gone out of flower. *Azara integrifolia* and *A. Gilliesi* both looked healthy. *Calycanthus floridus* and *C. occidentalis* were seen in good condition. The pretty *Berberidopsis corallina* was in bloom, while others not in flower were *Lonicera Standishi*, *Olearia macrodonta*, *Magnolia grandiflora*, *Elæagnus macrophylla* and *E. glabra*, *Ilex latifolia*, *I. cornuta*, *Lupinus arboreus*, and *Raphiolepis japonica*. One is doubtful if the last will live long

at Edinburgh. *Vitis Coignetæ* and *V. striata* (Baker) were also on this wall, which is, unfortunately, too low for some of the shrubs upon it.

At so late a season one could not expect to see many things in bloom in the beds, as it ought to be remembered there is no planting for effect. The popular *Clematis Davidiana* was in flower,

and as fine a piece as I have ever seen in a garden. A very conspicuous plant was *Cnicus pannonicus* var. *divaricatus*, and the distinct *Helenium striatum* was also effective. *Pulicaria vulgaris*, about 1½ feet high, seemed rather a nice little yellow composite, and I was pleased with a nice specimen of *Liatris cylindrica* with bright flowers. As one who thinks the *Lupines* rather neglected flowers, I was glad to see in bloom *L. Cruickshanki*, whose fault of short spikes is partly atoned for by the blue, white, red, and yellow colour of the flowers. Perhaps the prettiest of the tall plants in the beds was *Gypsophila Steveni*. This is not the flower usually grown under the name given, which is inferior to the one at Edinburgh. *Eryngiums* and several other genera, interesting though they are, must be passed over.

The pond in the Royal Botanic Gardens is not large enough for water gardening as it is practised at the present day, and it has become crowded up with *Aponogeton distachyon*, to the disadvantage of some of the new *Nymphæas* only recently planted. The *Water Hawthorn* is, however, so pretty in itself that it could ill be spared. By the side of the pond are some grand *New Zealand Flaxes*, which look as if they delighted in the moisture at their roots. A clump of *Rodgersia podophylla*, large in leaf and with the fine bronzy colour so much desired, grows by the margin also. *Polygonum affine*, *Saxifraga peltata*, and *S. aquatica*, with other plants, are equally at home. A dry season like the past is not the best for the famed rock garden, and in consequence of the drought, coupled with the late spring frosts, an unusually large number of plants has been lost. Of course, newly-put-out plants have suffered most, and as alterations were in progress, there has been a large percentage of deaths. Still, even at so late a season for alpine flowers the rock garden was worth seeing. Among the prettiest things was *Anemonopsis macrophylla*, a flower which has been in the hands of the trade for some time, but has not yet found its way into many private gardens. It is a pretty *Anemone*-like flower with white blooms, and is a good plant for the border or rock garden. *Dianthus Noëanus*, although not showy, is a neat single white *Pink* useful for its late blooming. It is of trailing habit. Worthy of remark, too, is *Oxalis Valdiviana*. If—and this is not proved—its tuberous roots do not resist our hard winters, the plant is as good as a perennial one, as it comes up and flowers annually either from the roots or

Cortaderia Lambleyi foliis variegatis. From a photograph sent by Mr. W. E. Gumbleton, Belgrove, Queenstown.

and a number of dwarf annuals relieved the dullness of places where perennial flowers were over. Among the *Mulleins* I noted *Verbascum repandum* as being pretty with its branching spikes of yellow flowers. *V. speciosum* has large yellow blooms which, but for being larger, are much like those of *V. Thapsus*. In one bed there was a mass of *Pratia angulata*. It was over 2½ feet in diameter,

seeds. Its colour is in its favour, as we have few hardy yellow flowers of its character. A pleasing little plant is *Antirrhinum asarinum*, which seems quite hardy at Edinburgh, where it rambles among the stones, looking well with its creamy flowers. Two pits sunk below the level of the upper part of the rock garden are, I believe, to be slightly altered for better access. On the per-

pendicular sides are some thriving *Ramondias*, including *pyrenaica*, *pyrenaica alba*, and *Nathaliae*. The pretty, but rather difficult to keep, *Lithospermum graminifolium* seemed to be happy in such a position.

The privilege kindly afforded me of an inspection of the plants in the frames showed one that there is likely to be no falling off, but rather an increase, in the number of new plants on view. These are, however, too numerous to speak of at present. Nor can one do more than allude to the *Veronicas* and other plants in the beds on the terrace. A necessarily hurried walk through the houses gave much pleasure. One who has for years grown a few Cacti and who has still a liking for their quaint forms and brilliant flowers cannot but be pleased with the Edinburgh collection, small though it is compared with that at Kew. *Mesembryanthemums*, *Haworthias*, *Crassulas*, and other genera of succulents are also in considerable numbers. Insectivorous plants have for long been grown in the gardens, and, now that they are better displayed, the public take more interest in them. *Nepenthes* are well grown, and it is interesting to see at what an early stage seedlings begin to show miniature pitchers.

Among other plants, more or less uncommon, which were in bloom are some nice hybrid *Passifloras*, *Calceolaria Burbidgei*, with yellow flowers; the effective *Begonia luxurians*, which would appear as if it might be valuable to the hybridiser; *Lantana Camara*, with the beautiful *Lantana hybrida alba* on a wall in the corridor; *Cassia corymbosa*, the Nash Court variety of *Lapageria rosea*, *Diplacus coccinea*, with a few nice Orchids and miscellaneous plants were also in bloom in the houses. Palms, Ferns, and stove plants were generally in capital order. The further extension, which will connect the Palm house with the other glass structures, will be a great convenience not only to the staff, but also to visitors, besides giving the additional room still needed.

S. ARNOTT.

LOBELIA FOR STOCK.

In the remarks on p. 254, pot culture during summer is suggested by "H." as a good way whereby to secure stock of the above. A little reflection, however, will not fail to show how difficult this method of culture would be in a summer like that of the present year; indeed, if carried out as advised there is frequent trouble in damping during winter. A far better plan, entailing much less labour and no daily watering in summer, is in spring, when the bedding out is finished, to plant out a few in a reserve plot of ground where their flowering is not needed. Nothing more will be needed till the first week of August, when the whole of the tufts may be cut closely over with scissors or shears, leaving an inch of growth at most remaining. A week or two later, say towards the end of the month, the cut-back plants will be full of new growth, which by reason of the hard pruning will be genuine shoots as opposed to flowering shoots. At any moment the plants may be lifted, pulled into quite small pieces, and planted in sandy soil in boxes placed forthwith in a cold frame or a manure frame just losing its heat. If very hot, shading may be needed. Fresh root action quickly follows. Propagating trays 8 inches wide, 15 inches long, and 1½ inches deep will take about fifty plants. No drainage is required beyond the screenings of the soil by reason of the shallowness of the trays.

By the end of the year the plants will have grown into one complete carpet, and all that is necessary is a cool place with freedom from drip. One such box as I have stated will yield more than a dozen pots. I have adopted this method since 1876, when it occurred to me quite accidentally, having previously had some considerable trouble in securing supplies. A decided advantage is that a very early start may be made, and if only a moderate supply is needed, cuttings of the ordinary stamp are not necessary, as by dividing and replanting the stock boxes abundance can be obtained. The above method, both

for its simplicity and for its advantages over the old method of lifting and potting the worn-out plants, cannot too widely be known. Even when requiring from 30,000 to 50,000 plants of *Lobelia* alone I have been content with planting about five or six dozen in the early summer, so great is the supply of growth later. But where large lots are needed, it is perhaps better not to let the stock intended plants flower at all, cutting them over twice instead of once, and the first time more lightly. The same method holds good for *Alternanthera*, *Ageratum*, and other things of like character. That one time popular carpet plant, *Mentha Pulegium gibraltaria*, may be increased on similar lines to the *Lobelia*.

E. J.

MICHAELMAS DAISIES.

STARWORTS are *par excellence* the flowers of September, and numerous are the species and varieties that decorate the borders with their suave colour gradations, ranging in tint from deep purple through infinite shades of mauve, lavender, and palest blue to white. *Aster Amellus bessarabicus*, the first of the Michaelmas Daisies to expand its blooms, commencing its display early in the month of August, is one of the most enduring of the whole family, often retaining blossoms until late in October. During September this variety, with its large purple-blue, gold-centred flowers borne in countless profusion, is a most attractive sight. This Starwort is particularly well adapted to small gardens, as, in addition to its striking decorative qualities, it possesses the additional merit of being easily kept within bounds, which is far from being the case with the majority of the perennial *Asters*, many of which are far too rampant in growth for small borders. *A. acris* is effective for grouping, informal masses along the edge of a shrubbery providing charming autumnal pictures with their dense sheets of soft colouring thrown up by the evergreen background. *A. laevis* and its varieties are also ornamental, *A. l. Apollo* being especially taking. Of the *Novi-Belgii* section the first to open its blossoms is the white *Harpur-Crewe*, this being one of the best of the pure white varieties. The centres of the flowers at the time of their first expansion are yellow, but soon assume a deep brown tint. Other good, but later whites are *niveus* and *polyphyllus*. *A. N.-B. Robert Parker*, which grows to a height of over 6 feet, is without doubt the most graceful of the tall-growing kinds, bearing long slender shoots with delicate side sprays studded with large pale mauve blossoms, which are not so closely set as to detract from its elegance. For arranging loosely in tall vases this variety is not to be excelled. In this section *Pluto* and *Autumn Glory* are two good dark-flowered forms. *A. puniceus pulcherrimus* is a robust growing variety, attaining a height of from 5 feet to 6 feet and throwing up sturdy flower-stems, which are smothered in a profusion of good-sized blooms of palest lilac, which become white soon after they are fully expanded. *Aster Arcturus* is an attractive Starwort with deep purple-blue flowers and almost black stems, while *A. cordifolius* and *A. cordifolius elegans*, the former bearing countless small white blooms on branching stems and the latter blossoms of a pale mauve tint, are valuable both for the border and for supplying cut flowers. *A. ericoides*, with minute white Daisy-like blossoms thickly set on flower-sprays, whose foliage resembles that of the *Heaths* and is answerable for the plant's distinctive name, is one of the loveliest of the whole genus, while the dwarf-growing *A. dumosus* and *A. diffusus horizontalis*, the latter one of the oldest favourites in cottage gardens, with spreading branches densely set with small maroon and white flowers, though not possessing the attractions of the earlier-mentioned varieties, should find a place in representative collections. Starworts of the *Novae-Angliae* section are scarcely so decorative as those of the *Novi-Belgii* race, since their foliage is denser and their flowers produced in less abundance. Their blossoms are of various shades of purple and dull red, the most striking

varieties being *Melpomene*, deep purple, and *ruber*, rosy-crimson. *A. grandiflorus* can scarcely be classed as a September flower, since even during dry seasons in sunny gardens in the south-west it rarely expands its earliest blossoms before the concluding days of the month, and is seldom at its best much before the close of October. It is, however, an extremely handsome plant, some of its violet-purple, golden-centred blooms attaining a diameter of over 2 inches, and remaining in beauty, should frost not supervene, until the middle of November. *Aster (Chrysocoma) lino-syris*, a plant that is found wild in some parts of South Devon, and which is popularly known by the title of *Goldilocks*, is a particularly useful autumnal subject, producing dense terminal corymbs of bright yellow flowers, and is often to be met with in cottage gardens, though rarely to be found in the herbaceous border.

When Starworts are used for indoor decoration it is advisable to split up the stems to a length of 4 inches or so with a sharp knife, dividing the stalks into four sections before placing them in water, as when so treated they are enabled to absorb more moisture and to retain their freshness for a far longer period than if this precaution has not been taken.

S. W. F.

RAISING BIENNIALS.

OWING to the dry summer and want of water I could not sow the biennial seeds in June and July, such as *Hollyhocks*, *Canterbury Bells*, *Antirrhinums*, &c., for blooming next summer. Can I sow them outdoors now, or would it be better to do so now under glass and let the seedlings winter in a cold house (which has no heat any time in the winter), or should I sow them in heat in February and harden off in May and plant out? In this latter case, will they bloom in the summer of year they are sown?—BEESWING.

* * Some of the biennial flowering plants may be sown in the early part of the year, and will flower the same year somewhat later than they would if sown in the ordinary way during the previous autumn. Of those mentioned by "Beeswing" the *Antirrhinums* and *Hollyhocks* would do well, but the *Canterbury Bells* would not be worth troubling about, and it would be in their case preferable to buy in young plants, which may be got cheaply enough from many nurserymen. *Hollyhocks* require the best of attention to raise and flower them in the same year, but they deserve all the trouble, and many gardeners who have been troubled with the *Hollyhock* disease have adopted the system during the past few years and have had the satisfaction of seeing their plants so raised entirely free from the unsightly fungus which formerly made *Hollyhock* culture a misery. We should not advise "Beeswing" to sow now, especially as he appears to have command of some heat from February onward. The better way would be to sow in heat as early as possible after the turn of the year and to keep the young seedlings growing as freely as possible in a temperature of about 65°. When the young plants are ready, prick them off round the edges of 5 inch pots filled with good soil, and later on pot them singly into 3 inch pots. When the roots have got established in these, gradually harden the plants till it is safe to put them into a cold frame, which should be protected from frost at night, and in May put out where the plants are to flower, giving them a good rich soil. Protect the young plants, if necessary, by putting an inverted flower-pot over each on frosty nights. This protection will not be needful for long, but is a great help at first. A sharp look-out must be kept for green fly, as this, if allowed to establish itself, will entirely cripple the young plants.

The *Antirrhinums* may be raised in the same way, but it is not necessary to pot these off singly; they may be pricked off thinly into boxes of light soil, and soon develop into nice plants that will flower freely up to the end of autumn. If seeds of either of the above plants are bought from a reliable firm, the percentage of poor flowers will be very small indeed, and the rest will make a fine display.—ED.

STOVE AND GREENHOUSE.

ACACIAS IN CALIFORNIA.

ALTHOUGH the leading species of Acacias have been grown in California quite as long as the Eucalypti, they are far from being so popular among planters, and one never sees large areas set to these valuable trees. If California did not have extensive forests of Tan-bark Oaks and deserts abounding in Canaigre, the tannin-yielding Wattles would be more often planted. The rapidity of growth, under favourable conditions, of *Acacia decurrens* is surprising, particularly to those who know the Acacias only as greenhouse shrubs. The illustration shows a tree growing at the Southern California sub-station near Pomona, Los Angeles County, conducted by the State University. This tree was raised from seed sown in 1893, and was photographed in 1898. It was therefore five years old and had stood four years, being removed from the nursery at one year. Its height is more than 30 feet. It has received no irrigation; the amount of annual rainfall has varied from 12 inches to 18 inches. Acacias are being planted more freely in recent years, since they are so ornamental in bloom, and the timber is found useful for many purposes. In time they will doubtless form a striking feature of our landscapes.

CHAS. H. SHINN.

FREESIAS FAILING.

I AM sending you some Freesia bulbs which have gone quite hard. Every summer the bulbs are left in their pots, which are put into a cool greenhouse near the glass to bake all summer. They have then in September been repotted and have bloomed magnificently, but after this hot summer, when they were shaken out of the earth, they were quite hard. Why is this? Several gardeners around have found the same. The soil in the pots is never watered in the summer, but allowed to bake hard. I have never failed before.

—BESWING.
* * If the Freesia bulbs sent with this query were a fair sample of the stock, they had never really finished their growth, as they were perfectly smooth and without wrinkles such as well-developed bulbs, whether large or small, have. The probabilities are that the drying off was commenced too soon after flowering, the result being a sudden check to growth; the bulbs being then in a soft and unfinished state could not stand the severe baking to which they were subjected during the past long and hot summer. I have never met with a similar case and have never been able to over-bake Freesia bulbs with sun heat, but then I have always been careful to allow growth to be complete before reducing the water supply, after which no harm comes to them, and the more baking they get the more certain they are to flower. The bulbs sent were quite dead, and I can compare them to nothing but pieces of soapstone or of exceptionally hard prepared chalk. On them can be discerned through the microscope a few very minute brown spots that look like the spores of some fungi, but these appear to me to be the result, and not the cause, of death. The bulbs appear quite mummified. Fortunately, Freesia bulbs are now very cheap, and "Beeswing" can easily make good his loss, but flowers from bulbs potted up now will be late and not so fine as those from bulbs potted up in August. I should advise care in the early stages of ripening and care also in choice of soil to see that it contains no fungoid growth. I have been particularly successful with bulbs grown in half loam and a quarter each of river sand and dried cow manure, the latter rubbed up fine. —CORNUBIAN.

Begonia Gloire de Lorraine.—In spite of this most useful winter-flowering *Begonia* being infertile, it is very certain that the type is not

fixed, and that it either sports or else the stock sent out by the raiser was the result of many seedlings from the same cross. I saw recently Mr. Hudson's plants of the new variety Mrs. Leopold de Rothschild, which recently gained an award of merit from the Royal Horticultural Society, grouped in a house also containing a similar number of plants of the dark variety, which must be, I suppose, taken as the true type. The difference was most marked, and at that time was all in favour of the new variety, as the flowers were larger, and in colour a nearer approach to pink. It may not prove so showy for midwinter, as it will naturally be paler then, but a batch of it for early flowering will be very useful, and to many people the elimination of the magenta tinge will be considered a great im-

provement. I do not know what may be the experience of others, but from the stock here I could select three, and probably more, varieties that would appear perfectly distinct if grown in bulk and stood side by side. The lightest coloured forms of each batch, consisting of plants of the same age, come first into flower. —J. C. TALLACK.

Acacia decurrens in California—five years from seed. From a photograph by Prof. C. H. Shinn, Berkeley, California.

provement. I do not know what may be the experience of others, but from the stock here I could select three, and probably more, varieties that would appear perfectly distinct if grown in bulk and stood side by side. The lightest coloured forms of each batch, consisting of plants of the same age, come first into flower. —J. C. TALLACK.

Allamanda Hendersoni.—This plant makes a most effective climber if a stove heat and ample room be given it. I met with a remarkable plant of it at Bramley Park the other day. The specimen has been growing a number of years and covers the whole of the wirework the length of a

HOUSING TREE CARNATIONS.

I GREW winter-flowering Carnations for many years, and always found it of the utmost importance to protect the plants from heavy, soaking rains in autumn.

If the ball once becomes thoroughly soddened, it frequently in the case of plants in, say, 8-inch or 9-inch pots, and which are not in a semi-root-bound condition, takes several weeks for them to again become dry. In the interval, what is known amongst Carnation growers as the yellows attacks the growth, and from which they very rarely thoroughly recover. The knowledge of this induces some to house their plants full early, but sooner than do this I would lay the plants on their sides in stormy weather, as I think the first week in October quite soon enough to get them into their winter quarters—at least, in midland and southern counties. Frequently the plants do not receive sufficient attention after being placed under glass, but if the weather is dry and sunny, or even windy, the atmosphere becomes too arid and a considerable check is given. Where the plants are elevated on wooden stages in the old-fashioned way, frequent damping of floors and stages should be practised throughout October, and on bright, sunny days overhead syringings as well. From November till February the soil in the pots will supply sufficient atmospheric moisture. Market growers, however—and I think they are right—prefer low houses furnished with slate or wooden benches, these being covered with sifted coal ashes. In such a position the plants can be kept in a growing condition, as the ashes retain the moisture, and in such structures evaporation is slow. Another important matter is fumigation. The plants should be fumigated twice mildly whether aphid is visible or not. The plants also should, if practicable, be watered by one man, and, provided they are not pot-bound, manures of any kind are best avoided. Later on, when the plants are opening their flowers freely, liquid manure the colour of pale ale may be given at every alternate watering.

C. B. N.

LILY OF THE VALLEY.

THE time will soon arrive when those who require an early supply of Lily of the Valley will have to place the crowns in heat. Much annoyance is caused by the crowns either refusing to start or by a sudden collapse of the growth when half completed. Very often the failure is attributed to an immature condition of the crowns, but I

think more frequently the cause lies in a fluctuating bottom-heat. A bottom-heat which is one temperature to-day and another to-morrow has not calculated to produce satisfactory batches of Lily of the Valley. Many a good lot of crowns is spoiled by being plunged in a bed of leaves and manure, which retains a heat of, perhaps, 80° or 90° for ten days or so, and then suddenly falls to 65° or 70°. The former figure should be maintained from the time the crowns are plunged until the flower-spikes are well advanced. For many years I succeeded well with early batches by placing a thin board over an evaporating pan of the hot-water pipes in a Pine stove, standing the pots on this and packing Moss firmly around and between them. An inverted pot was placed on each of those containing the crowns, and water given at a temperature of 95° every morning, as if the soil once became dry, failure followed. Under those conditions I seldom had a patchy lot, as the temperature remained unchanged from first to last. I allowed the inverted pots to remain on until the lowermost bells expanded, when the plants were removed to a warm house to finish opening. When once fully out, the flowers last much longer in a temperature of, say, 55° or 60°. As regards open-air culture, many beds fail through being literally starved. This flower requires good drainage, but it is very easy to add too much leaf-mould and light soil to the beds when forming them. Some of the best crowns are grown in Norfolk, and a good deal of cow manure is used. A friend of mine in that county allows plenty of room between the rows, and the second season a furrow is made with a special tool between each row, this being filled in with cow manure, which is trodden in firmly and the soil again placed on. The roots of the Lilies rush into this larder very eagerly, fine foliage and crowns resulting. Mulching and watering are also regularly and liberally followed up in dry summers. I was informed by my friend that a most important point in open-air culture is keeping the crowns well above ground, so that they may become thoroughly matured by sun and air. As a rule, the longer the crowns rest, the better they start away when forced. J. B. S.

SEPTEMBER IN SOUTH DEVON.

THIS year the month of September has shown few signs of the advent of autumn. Even in the concluding days of the month the verdant foliage of the trees gave but sparse hints of the gorgeous transfiguration that will shortly illumine the woodland groves, though here and there the leaves of the Limes have assumed a pale tint that borders on yellow, and an occasional Chestnut fan shows a ruddy stain. The Mountain Ashes are bright with their scarlet berry-clusters, and a red glow, that will increase in brilliance as the leaves fall, is stealing along the hedgerows from the crimsoning hedges that in countless thousands stud the Thorn bushes. The Holly berries, of which this year there is an unwonted profusion, are turning from green to scarlet, and the feathery trails of the Traveller's Joy are slowly assuming a smoke-grey tint, but the foliage of the Brambles, studded with profuse clusters of Blackberries of all shades of colour, from greenish-red to sable, still shows an uniform green hue, flecked here and there with occasional maroon-spotted, yellowed leaves, but evidencing no signs of changing its tint for the purple-black and crimson that precede the falling leaf. Swallows and martins have remained in considerable numbers throughout the month, and were to be seen each day hawking the fields in pursuit of their rapidly diminishing food-supply, for during the latter half of the month a decided fall in the temperature suggested the commencement of fires in the living-rooms. On the last day of September I noticed 23 swallows collected on a short length of telegraph wire, so that it is probable that before many days their numbers will be materially diminished. Although insect life has generally proved abundant during the summer and autumn and another "clouded yellow

year" has occurred, *Colias edusa* being unusually common, the absence of wasps has been remarkable, their numbers, even where ripe fruit was present in quantity, being reckoned by units instead of by the usual scores and hundreds. The high lands of Dartmoor have presented a glorious pageant of purple and gold—breadths of purple Heather and acres upon acres of golden Gorse—colours that merge and grow less definite as they recede into the distance, melting afar into the infinite blue of the atmosphere or losing their distinctive hues beneath the lawny mist-wreaths that veil the tors. Fine autumnal colour-effects are obtainable by the grouping together of flowers of varied shades of yellow and red. One such border presented a brilliant display in mid-September. At the back stood masses of perennial Sunflowers and scarlet Cactus Dahlias, while double African Marigolds, ranging in colour from rich orange to pale lemon, occupied the middle distance, and in the foreground scarlet tuberous Begonias and the golden Aster *linosyris* were flowering. A fair amount of rain has fallen during the month, but bright, sunny days have largely preponderated, and September has been a far preferable month to the corresponding period of 1896, when only two out of the thirty days were rainless. In the matter of wind, September has also been fortunate, no gales having been experienced throughout its duration.

In the garden, *Achillea ptarmica* fl.-pl. The Pearl has continued to bear its sprays of clustering white blossoms, while the picture produced by the arching leaves and tall flower-rods of the great *Acanthus* has lost none of its nobility of form. The so-called blue Paris Daisy (*Agathaea cœlestis*) has been starred with its soft blue flowers, and the high bank that, for a length of 15 yards or more, the Sweet Alyssum has veiled with a cloud of countless white blossoms has filled the surrounding air with the fragrance of honey. Large plants of *Anemone japonica alba* Honorine Jobert have been white with their single gold-centred flowers through the greater part of the month, a particularly pleasing colour-effect being produced in one case where the purity of the snowy blossoms was enhanced by the crimsoning leaves of a Virginian Creeper that clothed the southern wall immediately behind. The pale flesh-pink variety of this *Anemone* is also a most attractive flower, but the magenta-red type, at one time the only form known in the flower garden, is of a singularly unpleasing tint. The white variety is invaluable for indoor decoration, the simple flowers associating charmingly with other subjects in bloom at the same season, either in the way of decided contrasts, as with *Lobelia fulgens*, *Salvia patens* or *Montbretias*, or with the soft yellow of the Paris Daisy and the flower-lace of *Gypsophila paniculata*. The

Tuberous Begonias have provided one of the most brilliant effects of the month with their vivid colouring, while the spreading foliage has effectually concealed every particle of the underlying soil. At the commencement of the month *Amaryllis blanda*, the green-stemmed form of *A. Belladonna*, was in bloom, followed a fortnight later by the type. As a rule, the former variety bears a greater number of flowers on a scape than *A. Belladonna* and produces longer flower-stems; the variety *rosea perfecta* has also been in flower in a neighbouring garden. Some of the dwarf *Campanulas* have borne a few blossoms, and *C. pyramidalis* was still in flower in the early days of September. The large-flowered *Cannas*, although yet producing bloom-spikes, have lost something of the brilliance that distinguished their colonies during the preceding month, but the Marguerite Carnations with their blue-green leafage and varied tints have created increasingly harmonious pictures in many gardens. *Chelone barbata* and *C. mexicana* were in flower at the beginning of the month, followed later on by the purple-blossomed *C. Lyoni*. On railway embankments and cliff ledges the *Valerian* (*Centranthus ruber*) in its three colours of pink, deep red, and white has been flowering, and the early *Chrysanthemums* are in full beauty

in beds and borders. The so-called autumn Crocuses are in flower, *Colchicum autumnale* having a pretty effect on the grass, while the purple-red *C. speciosum* makes a spot of soft colour. Late sowings of the Cornflower and annual *Coreopsis* are still brightening the garden, and large bushes of the white *Cosmos bipinnatus* are starred with their refined flowers. *Crinum capense*, *C. Powellii*, *C. P. album*, and *C. Moorei* have been in bloom in various gardens, as well as the white variety of *C. Moorei*, known on the Continent as *C. Schmidtii*, and *Crocus speciosus* has commenced to expand its violet-purple blossoms.

Cactus Dahlias have provided a brilliant display. New varieties of these handsome flowers are certificated with such liberality, however, as to render it almost impossible for amateurs to keep abreast of the times in the matter of innovations, many of which, moreover, will be found to exhibit little, if any, advance on older varieties. Green's White gives promise of taking the lead in that colour, and the large and brilliant Red Rover, though not certificated, should certainly prove a gain to the garden. In sheltered nooks hardy *Cyclamens* are blossoming profusely, and here and there secondary blue flower-spikes may be seen on the *Delphiniums* or a large, tall-stemmed golden star on the *Doronicum* clumps. *Erigeron speciosus*, after many months of blossoming, still holds some pale mauve golden-centred blooms, and the Mexican Daisy (*Erigeron mucronatus*) is thick with flower. The *Eschscholtzias* are bright in hanging rockeries, and the Coral Tree (*Erythrina crista-galli*) was bearing its long crimson-flowered spikes at the commencement of September. Hardy Fuchsias, such as *F. gracilis* and *F. Riccartoni*, in cottage gardens have presented lovely pictures during the month, the bushes in some cases being 9 feet or 10 feet in height and as much as 6 feet or 8 feet in diameter. Every arching shoot is thickly strung with the drooping crimson flowers, and in the bright sunshine the great bushes glow at a little distance with surpassing brilliance. *Funkia grandiflora* has borne its large-flowered white bloom-heads, and *Gaillardias*, *Gazanias*, and scarlet Geums have given colour to the borders. The Cape Hyacinth (*Galetia candicans*) was still bearing its tall spires of pendent ivory-white bells in the early days of September, while towards the close of the month the *Gerbera* produced a second display of orange-scarlet bloom. *Hedysarum multijugum* has been in flower, and in sunny positions *Hedychium Gardnerianum* has borne its scented yellow flower-spikes. This plant will, as a rule, pass through the winter in the open ground in the south-west, but under such circumstances rarely perfects its blossoms sufficiently early in the year, except in situations conducive to early maturation. The

Perennial Sunflowers are at their best in September, and create splendid breaks of bright gold where grown in large masses. *Helianthus rigidus* Miss Mellish and *H. lætiflorus* are amongst the finest varieties of the month, and the pale yellow *H. giganteus*, lifting its tall flower-heads to a height of 8 feet or 9 feet, is extremely effective when thrown into high relief by a verdant background. Annual Sunflowers and Hollyhocks, though for the most part past their best, are still ornamental in cottage gardens here and there, where *Helichrysms* occasionally create a bright spot of colour. The *Heliotrope* plants are covered with blossom and the surrounding air is heavy with their incense. *Hunnemannia fumarifolia* has produced its handsome golden Poppy-like flowers above its glaucous foliage, and appears tolerably hardy in sheltered gardens. Though introduced seventy years ago, it is rarely seen in cultivation. *Hydrangeas* have provided delightful effects throughout the month, giant bushes laden with their massive blossoms, in many cases Forget-me-not blue in colour, bordering shrubberies, flanking wooded drives, or mantling stiff cliff verges with lavish wealth of flower. *Hypericum Moserianum* has also been in bloom, and the Torch Lilies (*Kniphofia*) have made breadths of

vivid colour with their scarlet spear-heads. *Lobelia fulgens* has borne its tall flower spires of intense vermilion, and *L. rosea* its softer-tinted blossoms. The common Marigolds (*Calendula*) and French Marigolds (*Tagetes*) have been brilliant with their varied shades of yellow, and *Matricaria inodora* fl. pl. has had its Fennel-like foliage smothered with double white flowers. Early in the month the

Montbretias were displaying their orange-scarlet flower-scapes, *Etoile de Feu* being one of the most brilliant of the named varieties. Late-sown plants of the sweet-scented Tobacco (*Nicotiana affinis*) are still effective in the garden, and *Oenothera Lamarckiana* continues to produce its widespread yellow blossoms. Tufted Pansies are also still in bloom, and are at the present time in far better condition than was the case at the same period of the two preceding seasons; and the Paris Daisies (yellow and white) are bearing flowers, though not with the profusion that marked the months of July and August. Ivy-leaved Pelargoniums have afforded a marvellous display during the summer and early autumn, as with three mild winters in succession many old plants have made prodigious growth. As a rule, where large masses of these subjects are seen clothing a wall with bloom, they consist of the shell-pink variety known as *Mme. Crouse*, the flower-trusses of which when borne in profusion over an extent of wall create charming breadths of soft colour. In one case this Pelargonium had run up the south-western angle of a creeper-clad house and covered it from eaves to ground level, a height of over 25 feet, with a veil of blossom, while many other instances have occurred in the south-west where sheets of flower from 10 feet to 15 feet in height have been formed by the same plants. Pentstemons have been in bloom throughout the month, and *Phygelius capensis* bore its tall spikes set with drooping scarlet flowers during its earlier days, at which time the herbaceous Phloxes had not entirely concluded their season of brightness, and the annual Phlox Drummondii had lost but little of its rich colouring.

The Winter Cherries (*Physalis Alkekengi* and the later-introduced *P. Franchetti*, with its enormous orange-scarlet, glistening calyces) have assumed their brilliant autumnal hues and will soon be ready for cutting for winter decoration, an operation that should be performed before the calyces are injured by heavy rains and gales if they are to preserve their beauty intact through the winter months. If the stems are left uncut, the calyces usually become skeletonised by the ensuing spring. The leaves should be removed as soon as the stems are cut, as they soon wither, but the calyx-studded stems associate charmingly with dried grasses, autumn-tinted Bracken, feathery trails of Traveller's Joy, Ivy, or other dark foliage, and retain their fresh appearance for many months. The soft blue of *Plumbago Lar-pentæ* is apparent on all sides. The plant grows like a weed in the south-west and seems totally indifferent as to the character of the soil in which it is planted, flourishing alike in heavy and light staple and in damp and dry situations. At this period of the year it presents a particularly pleasing aspect, clothing rockeries with foliage that has partially assumed a reddish bronze tint, and which is liberally besprinkled with its blue flower-heads. *Polygonum capitatum* has been covered with its dense pink bloom-spikes, and *Pyrethrum uliginosum* has borne in profusion its narrow-rayed white stars on tall flower-stems.

Roses, though not so plentiful in September as in June and July, are by no means things of the past. The Hybrid Perpetuals, belying their name, can scarcely be considered satisfactory autumnal bloomers, though they provide a fair scattering of flowers, the old favourite General Jacqueminot being one of the most prolific at this season of the year. Teas and Hybrid Teas have, however, borne an ample display of blossoms, Safrano being especially noticeable in this respect, though these naturally lack the size of the earlier crop, but the China Roses have proved the most free-flowering of the family, the salmon-

pink Laurette Messimy being particularly decorative, while Queen Mab, Irene Watts, and Souvenir de L. Guillet, with their subtle colour gradations of scarlet, rose, apricot, chrome shell-pink, and allied tints, have afforded many delightful blooms, and the old Fellenberg has been smothered in flower. The single white Macartney Rose is one of the loveliest of autumn flowers, and expands its chaste, delicately-scented blossoms without intermission until the advent of the first frost. The individual flowers are about 4 inches in diameter, and are produced in continuous succession from mid-July onwards, two or three dozen often being open simultaneously on a large plant. *Rudbeckia Newmani*, *R. nitida*, and *R. purpurea* have been in bloom, and the *Salpiglossis* has displayed its gorgeous shot-silk colouring. The deep blue of *Salvia patens* has been a feature of the garden, while *S. fulgens* and *S. coccinea* have borne their scarlet and crimson flowers, as have specimens of *S. rutilans* which were planted out from pots in May. This subject, sometimes termed the Pine-apple *Salvia* on account of the strange resemblance borne by the aroma of its leaves to that fruit, will often exist in the open through the winter, but in such a case rarely matures its blossoms. Old plants of *S. fulgens* and *S. coccinea*, however, that have been growing in the open for some seasons flower yearly during the autumn months. *Scabiosa caucasica* has borne its pale blue flowers on spring-sown seedlings, and *Sedum Sieboldi* and *Senecio pulcher* have been in bloom, as has the Golden Rod (*Solidago ambigua*), a handsome plant when massed in the wild garden.

Sternbergia lutea, the Winter Daffodil, has produced its golden flowers, and *S. macrantha* in Mr. Archer-Hind's garden at Coombefishacre has thrown up large golden blooms almost Tulip-like in size. *Stokesia cyanea* has perfected its purple blossoms not very dissimilar from those of the single Aster (*Callistephus*), but lacking the yellow eye of the latter. Why, by the way, is the beautiful single Aster rarely or never seen in the gardens of to-day? In its form and colouring it leaves little to be desired, but, like the single scarlet *Ranunculus asiaticus*, another lovely flower, it has been "improved," until in the multitude of double forms the single and far more graceful type has been entirely lost to sight. Late-sown Sweet Peas and Sweet Sultans have been in flower during the month, as have *Tradescantia virginica* and *Tritonia aurea*. Violets are commencing to blossom in some quantity, and in this district the plants have suffered less from the red spider pest during the past season than they did in 1898, thus proving that the occasional heavy thunder-showers considerably mitigated the effects of a dry summer. *Zauschneria californica* is bearing its vermilion flowers, and *Zephyranthes Atamasco* and *Z. candida* have been in bloom in a neighbouring garden. There being some doubt as to whether the former was correctly named, flowers were submitted to Kew and the nomenclature authenticated. S. W. F.

Torquay.

A useful glasshouse.—It is not in every garden that a convenient range of glasshouses is found. Where such exists it is a comparatively easy matter to secure successional supplies of fruit and flowers. Often, however, very good results may be achieved by a little forethought in the internal arrangement. One of the most useful structures that has ever come under my notice was a rather lofty lean-to, having lights some 3 feet long, slanting from the top of the house at the back, these serving as ventilators, and of course admitting a good deal of extra light to the back wall. Trained to the wall are various kinds of Figs planted in narrow boxes. These, after reaching the top of the wall, are allowed to travel a short distance down the main roof facing the south, being secured to wires. Good crops were secured from these trees, the fruit being gathered from the top of the slanting stage which occupied the body of the house. In each corner of the house near to the front lights another slate

box was fixed, a Peach being planted in one and a Nectarine in the other, these being trained to a trellis over the pathways at each end of the stage. During winter, when the fruit trees were at rest, the stage was filled with Tree Carnations, the smaller shelves being furnished with Primulas, Cyclamens and Solanums. In spring, when the Carnations were past and the cuttings taken, the stage was cleared and refilled with Tea Roses, which in their turn were placed in cooler quarters to harden off, pot Figs being then taken in to fill their place. A stout shelf along the front of the house accommodated a row of early pot Tomatoes, the plants being trained to a temporary trellis suspended on hooks over the front pathway some 15 inches from the glass. The various arrangements here described might be profitably imitated in many places lacking space and convenience.—GROWER.

KITCHEN GARDEN.

VEGETABLE REFUSE FOR PEAS.

EVERYONE knows that the past season has been a very trying one for Peas, especially on light soils. In a garden where the natural staple is very porous I was surprised to find some of the heaviest crops I have ever seen; *Duchess of Albany* and *Autocrat* especially were grand. The gardener told me that he could not get any manure, but had to rely entirely on leaf-mould and decayed vegetable matter generally. He made a practice of collecting all the leaves he could. These were kept one year, turned over in the winter and mixed with lawn sweepings and other things. In the winter, trenches were taken out and a liberal amount of this mixture put into the bottom, so that by the time the Peas came into bloom their roots began to take possession of this store of good food. In very light soils I believe this to be the best way of growing Peas, as the roots are tempted to go deeper and are thus more out of harm's way in a time of severe drought. Probably partly decayed vegetable matter is more enticing to the roots than is rank manure when buried some depth in the ground. I am inclined to think that raw manure is not always so beneficial as is commonly supposed. I have noticed that when heavy dressings are applied in spring the effect, especially in a dry summer, is not nearly so marked as one might imagine would be the case. Quite raw manure is never acceptable to plants; it must in some way be acted on by earthy or atmospheric influences before roots will travel freely in it. Not only is this the case, but fresh manure can never be finely subdivided, but goes into the ground in lumps, so that many of the roots have to travel some distance before they find any benefit from it. In the case of an esculent which requires such a great amount of food and which is so liable to failure through lack of strength to resist climatic vicissitudes, it is important that plenty of food in a form that is of easy assimilation should be at the disposal of the roots from the time the flowers are formed. It is just at that period that Peas are apt to go wrong, and it often taxes the grower's ingenuity to discover the cause of failure. The primary cause in most cases would, I think, be found in defective nutrition, either caused by the soil not having been sufficiently worked or by a deficiency of food of the right kind. I know of one garden where vegetables of most kinds are remarkably well grown, and it is the gardener's boast that he hardly ever uses manure. In this garden, which is an extensive one, a large amount of decaying vegetable matter is annually collected, and fires are from time to time made to char branches of deciduous and evergreen trees and shrubs. In this way there is every spring a big

heap of decayed and charred matter at disposal, which can be liberally used for the Pea crops, which in this garden constitute an important feature. In the case of Peas, I am inclined to think that the system pursued by some farmers for Mangold Wurtzel would be beneficial. They give a liberal dressing of manure in November, ploughing it in, but not deeply. In April the land is cross-ploughed, so that the manure which has been acted on by the soil during the winter is broken up into small bits. Another coat of manure is then applied and ploughed in, and the land is ready for a crop. It stands to reason that in this way the young plants feel the benefits of the manure from the very commencement of their life, and as a fact fine crops are raised by this method. J. C. B.

Late Celery.—From the second week to the middle of November is a good date to give the latest rows intended for blanching the final earthing up. Where work is pressing, earthing up may in light, warm soils be postponed for ten days or so, provided the weather remains open. If the work is neglected beyond the date named on strong soils, repeated heavy rains may get it into a sticky condition, rendering earthing-up difficult. I like to choose a dry, windy day for earthing up these late rows, as the plants in these if fairly stout are often more serviceable than earlier blanched batches, as growth being slower and longer exposed to frost and wind, the tissues are harder, standing wet better, and being less liable to rot. Where, as is sometimes the case in very large gardens, a few short rows of late-planted stock remain unblanched for flavouring, they will take no harm if protected with straw or Bracken in case of severe frost.—C.

NOTES ON TOMATOES.

We have to thank our many correspondents throughout the country for kindly replying to the following queries submitted to them, and trust the information given will be of service to our readers:—

- (1) Which do you consider the best Tomatoes, new or old, taking into account freedom of setting and flavour?
- (2) What do you consider the best outdoor kind?
- (3) The best kind for winter and early spring crops?
- (4) Do you consider a Tomato a fruit or a vegetable?

— Ham Green Favourite and Frogmore Selected are, I consider, the best Tomatoes for general use that I have grown. Chemin Rouge is the best for outdoor cultivation, and All the Year Round for winter. I consider the Tomato a fruit, but for exhibition I prefer it to be classed amongst vegetables.—THOS. COOMBER, *The Hendre Gardens, Monmouth.*

— I consider Perfection the best Tomato. It is of a very handsome shape, of first-class quality, and a good setter. It is also good for outdoor crops and fairly early. I grew Perfection Tomato last year (1898) over 2 lbs. in weight. I had a good many 1 lb. each outdoors on a south wall. I consider the Tomato a vegetable.—R. J. CARTER, *Wiveliscombe.*

— The sweetest Tomato I grow is The Peach (probably too sweet as a Tomato for some palates); next to it comes Peach Blow, a dash of the flavour of Perfection infused into The Peach; Golden Nugget and Horsford's Prelude come next. The four are heavy croppers. I find but little difference in the way of flavour among what I term cookers—The Old Red, Challenger, and Perfection types—under whatever name they appear. Scarlet Queen is distinct and of good quality, but I must give it another season's trial ere I pass a definite verdict. Of course, strictly speaking, a Tomato is a fruit; but I am not qualified to pass an opinion

as to whether it should be admitted as such in collections of fruits, &c., at exhibitions, or left to grace the vegetable table as hitherto. I have been inclined to the latter course.—JNO. ROBERTS, *The Gardens, Tan-y-bwlch, R.S.O., North Wales.*

— The season so far has suited Tomatoes, both indoors, on walls, and in the open. Up-to-date is the favourite variety for indoor and outdoor culture. It is very hardy, sets freely, commencing low down near the ground, and is an enormous bearer. Twenty to twenty-six Tomatoes I have seen repeatedly in clusters. It is also a great favourite with those who sell Tomatoes. It is of good colour and flavour, thin-skinned, and takes five or six to the pound weight. Where hundreds of customers go in and ask for half-pounds and pounds this is a great point in its favour. A Tomato that grows large is not wanted. Growers will find the medium ones the most in demand. Golden Jubilee I like immensely. I think it quite the best Tomato I ever tasted either in the salad bowl or grilled. Its appearance is very taking either growing or in the shop window, or when served up it gives variety either cooked or for a separate salad-bowl. The Tomato is a cooking fruit, and is as out of place in a collection of dessert fruits as would be a dish of ripe Capsicums.—WM. ALLAN, *Gunton Park.*

— In answer to your question, "Do you consider the Tomato a fruit or a vegetable?" I consider the Tomato as much a fruit as a Gooseberry or a Melon, but it is not a dessert fruit in the same sense that Grapes, Peaches, Plums, and Melons are, and it will never become popular as such, even with the most advanced acquired tastes. I have a variety which I raised here some time since, and I grow no other for indoors and outside.—A. PETTIGREW, *Castle Gardens, Cardiff.*

— The best Tomato I consider is Best of All. Next I am in favour of Ham Green Favourite. The best outdoor kinds are Laxton's Open Air and Sutton's Abundance. I find Earliest of All the best winter and early spring variety. I consider the Tomato a vegetable.—G. H. PARRATT, *Bradgate Park Gardens, Leicester.*

— Early Prolific, Leicester Red, Crimson King, and Up-to-date I find satisfactory in every detail. Outdoor Tomatoes are plentiful as regards varieties, &c., but after many trials of various kinds I am well pleased with Early Prolific, being a very free setter and all you can desire as regards flavour. To succeed this for a second crop Crimson King is a very fine fruit both in flavour and size. I had last year from the open plenty of trusses with eight and nine fine fruits, many of them 1 lb. in weight. I consider the Tomato a vegetable.—H. WAGG, *Ossington Gardens, Newark.*

— To some tastes the Tomato has an agreeable flavour eaten raw as dessert; to these it is a fruit. Others enjoy it cooked in various ways, but dislike it in a raw state; to such it is a vegetable. If I were judge at a fruit show and there was a prize for a collection of twelve varieties of fruit and one of these Tomato, I do not think I should be justified in withholding a prize in consequence; but, suppose there was another collection, eleven dishes equally as good as the other, and one dish of Gooseberries instead of the Tomatoes, then I think the collection with the Gooseberries should receive the prize. I consider Conference, Chemin, and Duke of York the best early varieties, and a good selection of Hackwood Park and Ham Green Favourite the best Tomatoes for general crop.—W. O., *Fotts.*

— I grow Frogmore Selected, Perfection, Chemin Rouge and White's Majestic. I find the first and third best for spring or winter work and set freely. I consider the Tomato a vegetable, as it hardly comes into line with dessert fruits in my opinion, which are chiefly of a sweet nature.—W. CRUMP, *Madresfield Court, Great Malvern.*

— I am growing Satisfaction and Frogmore Selected. The latter grows too tall for house work. I like my own selection better than any I have tried. It is a dwarf grower, free setter, and grows better than any I have tried both inside and out of doors. The colour is not quite so good

as in Frogmore, but I am getting that well up to the mark. The above I find to be the best for all purposes. Wherever I go judging, Tomatoes are shown in a collection of vegetables, and classes are given for Tomatoes, but never have I seen them shown as fruit.—WM. WHALLEY, *Addington Park, Croydon.*

— It seems to me that there are far too many so-called distinct varieties of the Tomato. Sutton's Best of All has proved itself in these gardens to be the best of all doers—it is of fine flavour, fine appearance, both in form and colour, and an abundant cropper. It grows with me about 8 feet high under glass. For a short run of say about 3 feet I have found nothing to equal Maincrop for quality and quantity. Best of All being of better appearance, I prefer it in houses when space will permit for it to grow away. For winter and early spring I should prefer Earliest of All. The Tomato is a fruit, but probably owing to its adaptability to being consumed in every shape and form, is more popular as a vegetable. I consider Best of All and A I Tomato equally as good for outdoor culture, and would prefer them for south walls; but for the open I like Maincrop, on account of its dwarf and sturdy habit, free-bearing and fine flavour.—T. PLUMB, *Shobdon Court, Herefordshire.*

— The present season has been very favourable for Tomatoes. My choice for general purposes indoors and out, is Earliest of All, Conference, Challenger, and Hackwood Park, which are hard to beat. I look upon the Tomato as being as much a fruit as a Peach or Nectarine. It frequently forms a dish on the dessert table, and I know many prefer Tomatoes to any other choice fruit.—W. SANGWIN, *Trellick, Truro.*

GARDEN FLORA.

PLATE 1246.

CLIVIA MINIATA CITRINA.

(WITH A COLOURED PLATE.*)

BEFORE the introduction of this new variety from Zululand we had only the Natal type, which has reddish orange flowers tinged with yellow on the lower half of the segments. This has been in cultivation nearly fifty years. According to Mr. Baker, it was introduced by Messrs. Backhouse and Sons in 1854, when a figure of it was published in the *Botanical Magazine* (t. 4783). Since that period many seedlings, more or less differing in the shade of red and form of the flowers, have been raised in English and continental gardens, and there are now numerous named sorts. A comparison of some of them with the type as represented in the figure above cited will show how little variation has so far been obtained. Much of the so-called variety of size and colour is due to cultural conditions. I have seen twenty named varieties grown together for two or three years, and at the end of that time they were all alike —C. *miniata* simply.

In THE GARDEN, vol. xxi., p. 358, along with a plate of Marie Reimers, the best seedling form of that period, will be found an excellent article by Mr. James O'Brien on these plants (there called *Imantophyllums*), in which it is stated that about fifteen years after the introduction of the type by Messrs. Backhouse a variety called *superba* or *maxima* was imported, presumably from S. Africa, by the late Mr. Wilson Saunders, and that progress in breeding new varieties may be said to date from the advent of that variety, which differed from the type in having the flower segments almost white at the base.

It is probable that the distribution of C.

* Drawn for THE GARDEN in Mrs. Powys Rogers' garden at Burgoose, Perranwell, by H. G. Moon. Lithographed and printed by J. L. Goffart.

miniata extends considerably beyond the limits of Natal, and that colour variations of it will continue to be found as the countries adjacent to Natal become more explored. That such may be the case is seen in the appearance of this entirely new variety from Zululand, where it is said to have been collected wild by Captain Mansell, and first flowered by Mrs. Powys Rogers, of Perranwell, in 1897. It had, however, been sent previously to Kew by the Rev. W. H. Bowden, of Bow, North Devon, who had also obtained it from Zululand. His plant flowered at Kew in April this year. As will be seen by the plate, this variety resembles the type in every particular except colour, which is a clear pale cream or lemon-yellow, tinged with orange at the base. The flowers lasted at least a month, and they were followed by fruits, which are now ripening in a warm house at Kew. The soft buff colour of the flowers cannot easily be represented on paper, but of the charm of the flowers there can be no doubt. If the introduction of such a slight variation of the type as *superba* is resulted in the breeding of such varieties as *Mario Reimers* and the newer *Admiration*, *Favourite*, *Optima*, &c., much more may be expected from crosses between the variety *citrina* and some of these. Apart, however, from its value as a breeder, the plant itself is a beautiful addition to greenhouse plants. W. W.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

FIGS.—Where fruit is required in March, the stock of pot Fig trees should now be overhauled and the most promising brought under glass in readiness for a start in the course of a week or two. The earliest varieties, such as *St. John* and *Pingo de Mel*, will be the most reliable at this date, as these can be depended on to carry their fruits through to ripening if they are dealt with in a fair way. Certainly in point of quality or fitness for travelling they do not equal *Brown Turkey* and some others that are not so readily forced, but the demand for earliness must be met, and it is these varieties that meet it provided they are grown in pots. I should like to insist on the latter provision. A forecast of the probable unsatisfactory state of these varieties planted out was given by a writer in these columns last year, and since that time I have proved that both, and especially *St. John*, make altogether too strong growth when planted out, even though the border is quite a narrow one, and I should strongly advise those who may have intended to try them under similar conditions to give up the idea and stick to pot culture, leaving the planting out for later work and better varieties. Before the trees are got into position, the wood should be sponged over with one or other of the least harmful of insecticides, and this should not exceed the strength recommended by the vendors, for the Fig is easily injured with strong insecticides and the young wood near the tips of the shoots is especially tender, so that rather than use full strength I prefer to go over the same trees two or three times with a weaker solution. This is quite as effective and less dangerous; indeed, no one who has to deal with mealy bug should rest content with going over Fig or any other fruit trees once only during winter. Those trees which have not been repotted should have a nice top-dressing of loam, bone-meal, and a little wood ashes, to make room for which a little of the surface-soil, especially next the pots, may be removed without doing any injury to the roots. I do not advise as yet the building up of the usual banks of top-dressing material, but only a little to encourage the new roots which will commence to grow directly a little heat is given to the house. For the present and up to the time of starting, which will not be

for about a fortnight, the night temperature should go down to from 40° to 45° at night, and when the trees are actually put to work the night temperature should not exceed about 50°, ranging to 70° with sun-heat by day, until they are perceptibly on the move, after which they should be plunged in the bottom-heat material, only a very gentle fermentation being induced and the top temperature gradually raised. From the first it will be advisable to use the syringe once or twice a day, and on fine, bright days oftener than this, using tepid soft water always.

LATE HOUSES.—Roof or wall-trained trees grown for later work should be pruned, and after the house has been thoroughly cleaned down throughout the trees may be washed and re-tied. If bug is present, however, it will be better to only loosely sling the branches, so that they may come down again for another wash over whenever the opportunity arises. In pruning these trained trees I stick closely to the extension method of training, and cut a few of the main branches right back to the base when they have got beyond bounds to give room for others which have been led up to take their places. The Fig is particularly amenable to this treatment, as it does not appear to resent in the least degree the removal of quite large branches when the necessity arises, and in this way one is able to clothe the whole trellis with wood of fruiting size instead of being hampered with big limbs. There will also be some young wood to remove, *i.e.*, growths of the current year. In selecting these, position is one of the most important things to look out for, so that the trellis may be well clothed. But there is another item which must not be overlooked, and which is even more important still when we are considering fruitfulness, this being that the most fruitful wood is found in shoots of medium size and not in the stoutest pieces; therefore those removed should be first the very stout growths, and next those which are altogether too weak. The medium growths will be the best ripened, and it is these we must reserve.

POT STRAWBERRIES.—Just at present we are enjoying a spell of fine weather, which will do the Strawberry plants much good, especially if an opportunity is taken of turning the pots around. This will do good in two ways—first by exposing the shady side of the plants to the sunlight, and again by disturbing any roots that may be running into the ashes on which the plants are standing. In my case it has been almost impossible to apply the usual quantity of liquid manure water which I like to give them during the autumn, as the rainfall has been sufficiently heavy to keep the soil wet without aid from the water-pot, and as I do not believe in giving artificial manures at this time of the year, they have had to be content with what Nature has sent, and I must say they look none the worse for it. For the present there will be very little in the way of cultural detail to carry out, but the plants ought to be divested of any weakly side growths which they may have developed, leaving only the strong crowns. Runners, too, should be picked off as they form.

FORCING MATERIAL.—With the forcing season so near at hand, it will be advisable to get together a good heap of leaves and manure, and to give a good, lasting, but not violent heat, perhaps the best mixture is about three-quarters of good hard leaves, Oak or Beech, to a quarter of stable litter. This will be quite enough of the latter; in fact, where litter is scarce, the leaves alone will form a very nice hotbed. In these days of improved hot-water appliances, the younger generation of gardeners is apt to overlook the value of hotbeds in forcing houses, but with the loss of the hotbed there is also the loss of the genial growing atmosphere so grateful to those of an older school, whose training taught them to value at their fullest the benefits to be derived from the use of leaves and manure, and to spend both time and labour in bringing them to a proper state for use. It is not sufficient to gather

the materials and then to let them lie in a heap until required. To bring them into condition, the heap should be well mixed and turned at intervals varying from a week to a fortnight, according to the condition it is found to be in. At each turning a little fresh material should be added until sufficient for one's needs has been gathered. Soft leaves should not be used, and the gravelly sweepings from walks should also be rejected. CORNUBIAN.

KITCHEN GARDEN.

A good deal of work comes under this heading at this season, as the time at command for completing it is but limited, wet, unsettled weather being likely to set in at any moment. The Pea season being practically at an end, all exhausted haulm, also stakes, must be removed from the ground, being tied in bundles according to their respective lengths and stored in some out-of-the-way corner. Unless made of such hard material as Ash or Hornbeam, the bottoms generally decay more or less the first season, and shortening becomes necessary before they are again usable. Those which have been used for supporting 4-foot Peas will again prove useful next spring after being duly shortened. They will then answer well for such dwarf early sorts as *Chelsea Gem* and *William Hurst*, also *Stratagem*, a Pea which should be grown in every garden. The same remarks apply to Bean stakes, and although these, being stouter, sometimes do a second season without any shortening, any that are reduced will prove useful the following summer for staking rows of runners which are pinched, instead of being allowed to run their normal height, or for the newer forms of climbing French Beans. Stems of *Autumn Giant*, *Walcheren*, or other sorts of autumn Broccoli which have been cut over should be pulled up and thrown away at once, as damp, foggy weather quickly induces decay and a most offensive smell. This is of paramount importance in gardens lying in close proximity to the mansion. It is not everywhere that well-decayed manure can be obtained in sufficient bulk for winter use, and the most has to be made of opportunities. Where straw litter has to suffice, it must be properly prepared previous to finding its way on to the vegetable quarters. Turn it over at intervals of a fortnight, well soaking it with farmyard liquid as the work proceeds. This treatment will induce fermentation and decay. Such manure is valuable for working into stiff, retentive soils, decaying less rapidly and assisting to keep the staple open. I have frequently used spent Mushroom manure for crops of a non-exhausting nature, adding at the same time a percentage of artificial manure. Where nothing but ordinary manure has been used for years, a good change consists in a mixture of burnt prunings of fruit trees, old vegetable refuse, the clearings of potting sheds and compost yards, and a little lime. This makes a thorough change, and its value is seen in the vigorous crops it produces the first season. The present is a good time to rectify all faulty drains, renew gravel walks, and straighten edging tiles, which are liable to become displaced by pressure from the garden roller. It is not good policy to put off this kind of labour till frost and snow set in and a sticky condition of the paths prevails.

WINTER SPINACH.—I am afraid this important vegetable will not be over-plentiful this year, as rain in many districts was so late in coming. The greatest scarcity will be on shallow, hot soils. Those who are fortunate enough to possess a good healthy bed will find almost any amount of trouble well repaid. Give now a good sprinkling of soot between the rows, using the Dutch hoe afterwards; this will not only assist growth, but ward off slugs and grubs. For sowing seed in February, the ground cannot well be prepared too soon. Wireworm-infested soil should be treated to a liberal dressing of gas-lime, and a rich larder given. Moderation in picking must be observed, as if too closely pinched the plants get a check, and growth proceeds slowly during the winter.

WINTER TOMATOES.—The present time is rather a critical one for the main batch of Tomato plants intended for winter fruiting, although it is true the weather of late has been finer than could have been expected. The blooms must be examined daily at noon and advantage of solar heat taken to fertilise the flowers. Cultural mistakes at this period may prove fatal to success, and a very common one with the inexperienced is maintaining a too high, stuffy atmosphere, especially during hours of darkness. This produces a soft growth, from which the meagre crop of flowers falls, or if they set, malformed fruit is all that can be expected. All the same, a warm atmosphere must be kept up, or say from 55° to 60° on warm nights. Above all, guard against much damping down, as the surface of the soil in the pots will supply sufficient moisture. Admit air constantly when actual frost or cutting winds do not prevail, and let all floor-washing be carried out in the forenoon of sunny days. Beware of stimulants, as a comparatively small but wiry growth is essential if a good sprinkling of useful fruit is to be secured. On the other hand, a starved condition must be guarded against. To plants which are being brought forward for fruiting in say March or April careful treatment must be accorded when removal under glass takes place. A temperature of 55° maximum, a position near the roof-glass, which must be kept quite free from dirt in order to admit all the light possible, and careful watering will be the most essential things for the next two or three months. If needing it, do not scruple to pot now into 6-inch pots, as a root-bound state will end in yellow and impoverished foliage. J. C.

BOOKS.

THE STRAWBERRY MANUAL.*

MUCH has been published at different times on the subject of Strawberry culture, but the latest addition surpasses any monograph that has preceded it, and from the beginning to the end is replete with interest and instruction. It is thorough without being pedantic; gives advice that the authors know to be sound without being dogmatic; and further, contains much collated information that is of the greatest interest to Strawberry lovers generally in a most concise readable form. Commencing with the origin and history of the Strawberry, the wood, alpine, Hautbois, scarlet, Chili, Pine, and Indian Strawberries all receiving attention, we next come to a chapter on hybridisation. In this mention is made of all who have done good work in intercrossing species and improving varieties, including Mr. T. A. Knight and Mr. Michael Keens, to whom we are indebted for the good old Keens' Seedling, sent out in 1820, while in those days Mr. C. M. Hovey was doing good work in the United States. From 1840 to 1860 Mr. Myatt, of Deptford, more successful than other raisers, succeeded in producing British Queen, Eleanor, Admiral, and Filbert Pine, the first named still maintaining its reputation for high quality. About this time Mr. Barnes, of Bicton, was at work raising Strawberries, his most noteworthy introduction being Bicton Pine. Another raiser, Mr. Wilmot, of Isleworth, does not appear to have been very successful, but Mr. Trollope, of Bath, or, more properly, Bradford-on-Avon, Wilts, from one batch of seedlings (at least so an old friend of mine who was well acquainted with Mr. Trollope once informed me) selected Trollope's Victoria and Princess Alice Maud. Victoria, though popular for a time, is a worthless thing, but Alice Maud still retains its well-deserved popularity with some growers. From 1850 to 1860 good progress was made in the direction of raising new varieties. Mr. Powell, of the Royal Gardens, Frogmore, was responsible for several novelties, including Cockscomb, and Mr. Samuel Bradley, Elton Manor, Nottingham, gave us

* "The Strawberry Manual." By Laxton Brothers, Bedford. Hulatt and Richardson, Bedford.

Oscar, Dr. Hogg, and Sir Joseph Paxton, the last-named being still one of the best varieties in cultivation. Novelties were also raised by Mr. Cuthill, of Camberwell, and Mr. Kitley, of Bath, several continental raisers also doing good service, the most noteworthy novelty being La Grosse Sucrée, raised by De Jonghe, of Brussels. It was at this time that the late Mr. Thomas Laxton commenced his experiments, and these he continued "most assiduously for about thirty-five years." The results of this patient care combined with thoroughness and intelligence I need not particularise beyond mentioning that Laxton's Noble for a time took us by storm, while in Royal Sovereign we have an early variety that has simply superseded all other early Strawberries, or at any rate it is by far the most popular. The good work so well begun by Mr. Laxton has been ably continued by his sons, who have given us Monarch, Leader, Mentmore, Fillbasket, Trafalgar, and other distinct and more or less valuable new sorts.

Novelties have also been raised by Mr. J. Douglas, Dr. Roden, of Kidderminster, and Mr. Allan, of Gunton Park, who has been particularly happy in his efforts, having raised such sterling novelties as Gunton Park, Lord Suffield, and Empress of India. Mention ought also to be made of Mr. W. Carmichael, Messrs. J. Veitch and Sons, and the continental raisers, Herr Goeschke, Dr. Nicaise, F. Gloede, and De Jonghe, in this connection.

The chapter on seedling Strawberries is a summary of a paper read by the late Mr. Thomas Laxton at the Strawberry conference in 1890, and from this it appears he was convinced that American raisers were following the best lines, inasmuch as they aimed at raising varieties with a strong constitution and capable of doing better under trying conditions than are the less robust continental novelties, none of which have gained much favour on this side of the Channel. What Mr. Laxton aimed to raise was novelties remarkable for (1) constitution and moderate vigour, (2) fertility, (3) solidity and external firmness to adapt the fruit for transit, (4) flavour and quality, (5) size and appearance. Judging from Mr. Laxton's experience, the lot of the raiser of novelties in Strawberries is not a particularly happy one, and it would almost appear that luck rather than judgment in pollinating the flowers materially affects the results. This is what he says with regard to forthcoming results:—

As to forthcoming results, it may be anticipated that as the cultivated Strawberry is a cross-bred fruit (probably an admixture of the blood of all the edible species), there will be considerable variety as well as some wide breaks in the progeny from intercrossing, but generally the offspring will show characters intermediate between the parents, and with perseverance it will be possible to gain the end sought. Having practised Strawberry crossing so long, however, it is somewhat discouraging to know that Noble was obtained without artistic intervention. In 1884 I grew and sowed the seed from a large and handsome fruit of Forman's Excelsior (a fine and good-shaped, firm-fleshed Strawberry on light soils). From this sowing I obtained only five plants, one of which proved bolder than the rest, and subsequently became "Ennobled;" the remainder were not acquisitions. Now, considering that I have during the past thirty-two years from my own work of cross-breeding raised at least 10,000 seedling Strawberries, and out of these few have as yet been sent to the world, although all have had to be tried, and many, after being largely cultivated for years, have had ultimately to be abandoned, and that out of a small batch of five from natural fertilisation there should be one distinct gain. I feel that the work of a cross-breeder is not altogether satisfactory, nor, I may feelingly add, profitable.

A close perusal of the more matter-of-fact cultural details that are given confirmed my first impression, that there is in the book under notice very little to find fault with and much that old hands will consider correct. When dealing with soils the following paragraph ably sums up the whole question:—

The requisites for success in the cultivation of the Strawberry plant in gardens can be briefly enumerated,

and the details may then be readily dealt with. (1) To ensure the best results, deep and thorough cultivation is needful, for the plant roots deeply and freely. (2) Fertility must be maintained by judicious applications of manure, as though there are soils where Strawberries have been successfully grown for a time with very little or no manurial help, yet these are exceptions, and the good results are seldom sufficiently prolonged to warrant the omission. As a rule generous treatment in the matter of food supplies is well repaid in Strawberry culture. (3) Though free working is desirable, a loose soil must be avoided, and consolidation is therefore a requisite that must have attention. (4) A constant and liberal supply of moisture is essential, for the Strawberry is a thirsty plant; in consequence, all competitors in the shape of weeds must be vigorously suppressed and the preservation of soil moisture aided by frequent hoeing.

Manures receive a fair share of attention, while the hints upon increasing stock, forming plantations, planting, routine management, protection, gathering and keeping the fruit are equally to the point and reliable. The chapter for market growers is particularly interesting, and contains a few startling facts as to the extent to which the Strawberry growing industry has reached. It is stated that around the metropolis Strawberry growing has for many years formed an important part of the market garden industry, and that within a short radius of London there is a greater area of land under Strawberries than in any other district in the world. Kent has become the great Strawberry-producing county, and though it was claimed in 1880 that the largest farm in the world devoted to these fruits was at Norfolk, in Virginia, United States, where 250 acres were under Strawberries in bearing, in Kent this has been far surpassed. A year or two since, one firm at Orpington and at St. Mary Cray had 650 acres under these fruits, while at the present time near Swanley about 2000 acres are devoted to fruit, a large proportion being planted with Strawberries belonging to one firm. As many as 75 tons of Strawberries have been sent from Swanley Junction alone in one day. Market growers' methods are plainly and correctly described, and the hints upon forcing Strawberries, though brief, are equally commendable. In the replies to a few questions submitted to numerous Strawberry growers, it transpired that Royal Sovereign is by far the most popular variety for forcing, gaining fifty-seven votes; whereas the next to it in point of popularity—Vicomtesse H. de Thury—was favoured by twenty-eight growers only. Diseases and insect pests are duly commented on, and remedies given. A reference is made to the experiments with Strawberries being carried out at the Woburn Experimental Fruit Farm, and a brief description given of the principal varieties of Strawberries in cultivation. W. I.

THE TEACHING BOTANIST.*

THIS is a handy and well-printed guide in the main devoted to structural botany. The author believes that structure lies at the root of all good and practical teaching at the present time, and that it should be used as the basis of a course on which to build up as best one may the physiology and ecology of plants—this latter phrase meaning, I presume, the economical growth, or adaptability of plants generally to external conditions. We are told, for example (p. 37), that "practically, physiological experiments most profitably come along with the particular structures which they best explain. Thus experiment upon absorption of liquids should accompany study of the structure of the root, photosynthesis (leaf work in sunlight—assimilation) that of the leaf, respiration by the action of growing seeds," &c. The notion is that if physiology is studied before structure, the student would be plunged at once into a sea of unfamiliar phenomena, and his atten-

* "The Teaching Botanist": A manual of information upon botanical instruction, together with outlines and suggestions for a comprehensive elementary course. By William F. Ganong, Ph.D. New York: The Macmillan Co. 8vo, pp. 270, with illustrations and index. 1899. 5s.

tion distracted by the use of many unfamiliar instruments and methods.

The contents table of the book is wide and comprehensive, there being chapters on: The place of the sciences in education and of botany among the sciences—What botany is of most worth—On things essential to good botanical teaching—On scientific recording, drawing, and description—On laboratories and their equipment—On botanical collections and other illustrations—On botanical books and their use—On some common errors prejudicial to good botanical teaching. Then comes in part 2 an outline for a synthetic elementary course in the science of botany, followed by division 1, which treats of the anatomy and growth of seeds, roots, stems, shoots, leaves, flowers, and fruits deduced from familiar examples; while division 2 of this section treats on the natural history of the groups, such as the Algae, Fungi, Lichens, Bryophytes, Pteridophytes, the Gymnosperms, and the Angiosperms, &c., followed by a fairly good index. The author at p. 151 emphasises the fact that plants alone possess the power of absorbing carbonic dioxide, minerals and water from the air and the soil in which they grow, and from which by the aid of sunlight they form starch or a related substance, which is really the food of the plant. New living tissues and plant products are thus formed and nourished, and, owing to the facility with which plants can turn their starch to sugar and the sugar back again into starch, we have that wonderful transference of energy and material from one part of a plant to another, results which are seen in all our garden and field crops.

But little is said of the dynamics of plant growth, that silent and wonderful power which enables a tender fungus to uplift the heaviest flag-stones, and tree-roots, to throw down walls and other heavy structures by sheer upward or lateral growth pressure. But the great central miracle of plant life is that power of green leaves and sunlight to turn dead materials into living tissues filled with energy and vital power, a silent and mysterious resurrection continually going on before our eyes. Any chemist or maltster can turn starch into sugar and diastase, but no chemist has yet been able to turn sugar back again into starch, as the plant does in a silent and apparently automatic way. There is one term in particular used a good many times in this book, viz., "ecology," its meaning being the relation of structure to use, and we find at p. 208 the combination "physiologic-ecologic," by which the relations of function and structure to use are presumably intended. The author is careful to point out that from cut specimens in the classroom the student can do little more than guess at their ecology, for, removed from their native homes and surroundings, portions of a plant can give little or no idea of its habits. In the author's list of books there is no mention of "A Manual and Dictionary of Flowering Plants and Ferns," by J. C. Willis, M.A., now director of the Botanic Garden in Ceylon (2 vols., Cambridge Press, 1897), one of the most handy and useful aids to the teaching botanist published during recent years. It is mentioned here in connection with Dr. Ganong's, "The Teaching Botanist," because I know of no other one work that gives such a distinct and clear bird's eye view of technical botany and plants generally in such a concise and handy form.

Scattered through the pages of this book will be found a good many practical hints and suggestions, and it is a work that will be especially valuable to teachers who are commencing their career, and more especially to students of an advanced type who intend to take up the teaching of botanical science as a profession. The book will also be of interest to many as showing the methods and apparatus devised and adopted in the United States as contrasted with those more familiar in this country. If a second edition should be called for it might be an advantage to add a glossary of the terms used in the work.

F. W. B.

TREES AND SHRUBS.

THE BUSH HONEYSUCKLES.

THE bush Honeysuckles include a large number of shrubs that are beautiful in habit and showy in flower and fruit. The light greyish stems and close branching habit of some species and varieties give a very pleasing effect in winter when they are planted in large masses. The nomenclature of the *Loniceras*, like that of the *Spiraeas* and *Philadelphuses*, is in a somewhat confused condition. It is no uncommon thing for the same plant to be sent from different nurseries in the United States and Europe under several different names. Some beautiful forms, of free growing habit and said to have originated in Russia, have recently appeared. The earliest of the bush Honeysuckles to come into bloom are

Lonicera Standishi and *L. fragrantissima*.—*L. Standishi* is deciduous and *L. fragrantissima* is almost evergreen. The flowers appear before the leaves and are fragrant. They usually come into bloom here about the middle of April and after mild winters very much earlier. *L. fragrantissima* is by far the handsomer of the two. In severe winters here both suffer considerably. They are thought by some botanists to be forms of one species. However that may be, they certainly are very distinct in appearance.

L. ciliata is a small, native, early-flowering shrub, abundant in North-eastern American woods. It is useful for undergrowth.

L. oblongifolia is another early-flowering, small, native shrub, having about the same distribution and the same merits as *L. ciliata*.

L. cœrulea is a rather pretty compact shrub of considerable value. The small flowers are followed by pretty inconspicuous blue fruit in late summer. This shrub has a wide native distribution, occurring in the northern parts of the American, European and Asiatic continents.

L. cœrulea var. *graciliflora* is a much more robust and stronger growing plant than the type. It is sometimes found under the name of *L. Kirilowi*. It is probably of nursery origin.

L. tatarica in its numerous forms is the best known and the most familiar of all the shrubby *Loniceras* in cultivation. Its freedom of growth, early leafing habit, abundant blossoms, showy fruit and absolute hardiness account for its popularity. It has, however, one serious fault—a somewhat general tendency to lose its leaves between late summer and autumn. Some of the Tartarian varieties have remarkably beautiful flowers, notably *speciosa*, *virginialis grandiflora* and *splendens*, and they far surpass the type in general excellence.

L. Ruprechtiana is a very distinct species from Manchuria. It has large pale green leaves, a little downy on the under side, and numerous straw-coloured, rosy tinted flowers, followed by bright scarlet, transparent fruit. There are several varieties of this species that differ slightly in the colour of the flowers. The type and all its forms are perfectly hardy here.

L. Morrowi is a Japanese species somewhat like *L. Ruprechtiana*, but the leaves are smaller and lighter in colour. It makes in time a very symmetrical bush, and bears abundant, showy, red fruit in July, and is very hardy.

L. Xylosteum, commonly known as the English Fly Honeysuckle, is not so tall growing as some of the former species and its flowers are much less conspicuous, but it bears very handsome dark scarlet fruit of considerable size. Of this species there are several distinct varieties with white and yellow berries, and all are hardy. It is probably the oldest of all the *Loniceras* in cultivation.

L. orientalis is an inconspicuous flowering shrub, native throughout the temperate Himalayas. It has a compact manner of growth, and is distinct from most other species in bearing large black fruit.

L. Maximowcizi comes from Eastern Manchuria. It has oblong-shaped leaves and makes a neat compact bush about 4 feet high. The flowers are rosy tinted and inconspicuous, followed by irregularly round red berries, ripe in August. It seems to be hardy.

L. Alberti is a native of the mountains of Eastern Turkestan. It requires rich, moist soil to see it at its best. The habit is low and pendulous, and the branches are clothed with smooth, light green foliage. The flowers are rosy lilac and showy about June 1.

L. quinquelocularis, said to be a native of Northern India, is a tall, rapid-growing bush, with yellowish flowers about June 10. There is no particular beauty in the flowers or fruit. It is not quite hardy here, being occasionally killed back in severe winters. This species is sometimes found under the name of *L. translucens*.

L. gracilipes is a shrub of good habit, and does not appear to grow over 4 feet high. It has rosy tinted flowers early in the season, followed by oblong-shaped red fruit. Of the native country or origin of this form I have no knowledge.

L. bella in its different forms is a remarkably handsome type of bush Honeysuckle. The form under the name of *L. bella albidata* is the best of all. I know of no bush Honeysuckle that displays such a wealth of flowers as *L. b. albidata* when it is in good condition. Other conditions being equal, it retains its leaves until quite late in autumn. When the branches are loaded with the showy Red Currant-like fruit in the month of July it is really magnificent. The different forms of *L. bella* are said to be the result of crossing *L. Morrowi* with some of the Tartarian varieties, and to have originated in Russia.

L. notha is another handsome form of hybrid origin. The habits of the different kinds are good, flowers showy, and the fruit conspicuous. The parentage of *L. Ruprechtiana* can easily be observed in these forms, and perhaps that was crossed with some of the best Tartarian varieties.

L. minutiflora is another handsome spreading bush of hybrid origin, said to be the result of a cross between *L. micrantha* and *L. Morrowi*. It gives a handsome display of yellowish red fruit.

L. salicifolia has Willow-like foliage. It is also of hybrid origin, said to be the result of crossing *L. micrantha* with *L. Ruprechtiana*.

L. iberica is a very pretty compact shrub, and about the latest of all the erect species to bloom. It has red berries in September. It is a native of the Trans-Caucasian region, and has been in cultivation for a great many years, but it is seldom seen. It is perfectly hardy.

L. Lsdebouri from the Western United States has yellowish red flowers, and is not uncommon in cultivation.

Bush Honeysuckles should be carefully pruned in winter or when they are dormant, and the old and weak wood thinned out, leaving all the best healthy young wood full length, unless some of the branches have gone too far for the general symmetry of the bushes. Never under any circumstances trim or shear them back. Pruning after they have done blooming is recommended by some, but that should never be attempted by inexperienced persons, as indiscriminate summer pruning has a weakening effect on all shrubs. Unless one has a thorough practical knowledge of cause and effect in the general principles of pruning, I would advise him to leave summer pruning alone. The best six bush *Loniceras* are *Lonicera bella albidata*, *L. Morrowi*, *L. Ruprechtiana*, *L. fragrantissima*, *L. Alberti*, and *L. tatarica* var. *speciosa*.—JOHN DUNBAR, *Rocheater, N. Y.*, in *American Gardening*.

Cytisus nigricans.—During July this is one of the most charming of the family. It carries its flowers on tall, slender, perfectly erect spikes terminating the present summer's growth. The

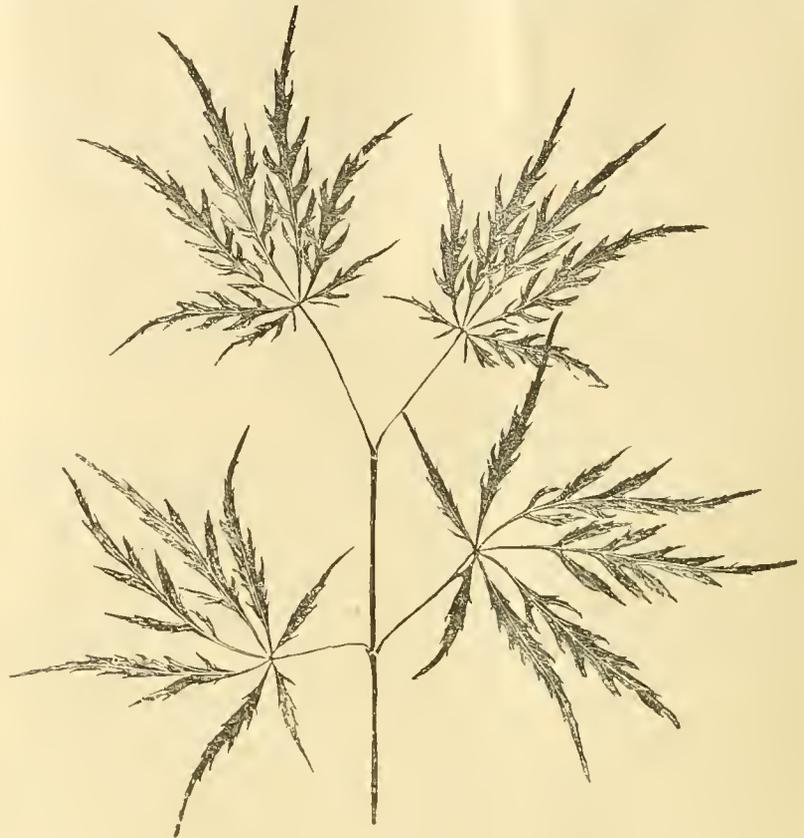

blooms commence to open at the bottom first, and a long succession of them extends over many weeks. They are bright yellow, the name of nigricans referring to the peculiarity of the plant turning black when dried. As soon as it has done flowering the upper part of the shoot bearing the seed-vessels should be removed, these being so abundant as to weaken the plant if the whole of them are left to ripen. They may be shortened still more in spring before growth recommences.

THE MAPLES.

THESE, mostly of northern regions, are often of the highest value in pleasure-ground planting, some of the species breaking into a great number of varieties. The best kinds are the Silver Maple (*A. eriocarpum*), naturally a very beautiful tree, though we get from it variegated and other forms which are not of much value, except the cut-leaved one, which is good. The Norway Maple (*A. platanoides*), also a beautiful tree, has many varieties, the purple ones being very effective. The common Sycamore Maple (*A. Pseudo-platanus*) has also a number of varieties, though none of them better than the natural tree, which is very fine when old. The variegated forms are usually tree rubbish. The Virginian or Red Maple (*A. rubrum*) is a beautiful tree, as is also the Sugar Maple (*A. saccharinum*). The Colchic Maple (*A. letum*) is an elegant tree. The Japanese Maples are interesting and beautiful, but not quite hardy and robust, except in the most favoured districts. Moreover, the fine varieties are often grafted, which makes them still less able to endure severe weather. *A. Negundo* is the kind which has given us the much overplanted variegated Maple so common in gardens. *A. Ginnala* is worth mentioning as a low tree—almost a shrub—whose leaves die off a rich red in colour. The North American and European species are hardy as forest trees and thrive in almost any soil, but the Southern American kinds and Japanese Maples want warmer soils and positions to thrive in our climate. The variegated varieties in this family are too many, and our nurserymen insist upon send-

The known and cultivated species are the following: *Acer campestre*, Europe; *caudatum*,

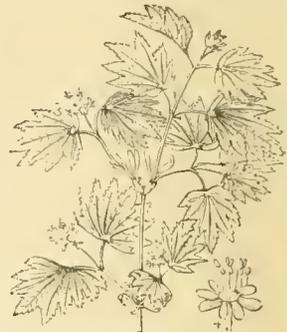

spreading leaves quite a Palm-like appearance. One of the most ornamental shrubs of September

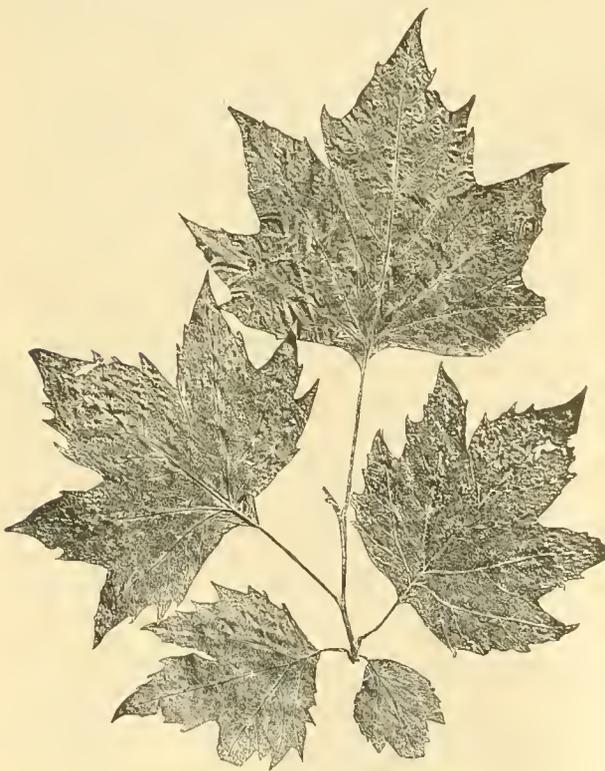

Acer palmatum.

N. India; *circinatum*, California; *cissifolium*, Japan; *carpinifolium*, Japan; *cratogeifolium*, Japan; *creticum*, Asia Minor; *diabolicum*, Japan; *distylum*, Japan; *eriocarpum*, N. America; *glabrum*, N. America; *grandidentatum*, N. America; *Helveticum*, E. Europe; *heterophyllum*, E. Europe; *hyrcanum*, Caucasus; *insigne*, Persia; *japonicum*, Japan; *Lobeli*, S. Italy; *macrophyllum*, California; *micranthum*, Japan; *monspessulanum*, S. Europe; *Negundo*, N. America; *nikoense*, Japan; *opulifolium*, Europe; *palmatum*, Japan; *pectinatum*, N. India; *pennsylvanicum*, N. America; *pictum*, Japan; *platanoides*, N. Europe; *Pseudo-platanus*, Europe, Asia; *rubrum*, N. America; *rufinerve*, Japan; *saccharinum*, N. America; *Sieboldianum*, Japan; *sikkimense*, N. India; *spicatum*, N. America; *tataricum*, E. Europe; *Vokreni*, Caucasus.

has been *Caryopteris mastacanthus*, specimens 4 feet or 5 feet in height and as much in diameter studded with a profusion of pale blue flower-heads presenting a most attractive appearance. At a little distance this subject is not unlike *Ceanothus Gloire de Versailles*, a shrub which was still in bloom during the early days of the month. In a neighbouring garden *Cassia corymbosa* is bearing its clusters of golden blossoms, and the Mexican Orange Flower (*Choisya ternata*) is in many cases carrying an autumnal crop of scented blooms. *Clerodendron trichotomum* has borne its odoriferous white flower-clusters and *C. Bungei* its rose-coloured corymbs, while here and there plants of *Cytisus racemosus* may be seen golden with an autumnal display of bloom. *Crataegus Pyracantha* is brilliant with its thickly-set bunches of scarlet berries, *Escallonia macrantha* is in some gardens bearing a sparse second crop of rosy pink blossoms, and at the commencement of the month *E. montevidensis* was displaying its white perfumed flower-heads. The *Habrothamnus* is bearing its drooping clusters of tubular crimson blooms, and the varieties of *Hibiscus syriacus* have been in flower. Large bushes of the snow-white form, *H. s. totus albus*, which is decidedly the most attractive of all, when covered with blossom present a most decorative appearance. *Leycesteria formosa*, without being a strikingly handsome shrub, has a certain value owing to its unique character. Its long, pendent whorls of purple bracts, termi-

Acer circinatum.

Acer heterophyllum.

FLOWERING SHRUBS IN SOUTH DEVON.

ABUTILON VEXILLARIUM has continued to produce its crimson and yellow blossoms on its arching shoots throughout the month, and *Aralia (Fatsia) japonica* is still bearing its Ivy-like inflorescence, while the spreading, deeply pinnate leaves of *Aralia spinosa* are crowned with ivory-white flower-plumes. This *Aralia* has a particularly decorative effect where it is kept to a single straight stem, all side growths being removed to a height of 12 feet or so, as when grown in this manner it produces with its tall, slender shaft and wide-

ing out many forms which, however attractive they may appear to them in the hand, planted out soon give a poor and harmful effect.

growths being removed to a height of 12 feet or so, as when grown in this manner it produces with its tall, slender shaft and wide-

Its long, pendent whorls of purple bracts, termi-

nated here and there by solitary white blossoms, now hang from its cane-like shoots, rendering the plant a distinct feature in the shrubbery. The Venetian Sumach, or Smoke Bush (*Rhus Cotinus*), has formed a charming picture with its clouds of purple red feathery clusters, and the Sea Buckthorn with its grey-green foliage, lighted up by countless berries of bright orange hue, has been a conspicuous object. Huge bushes of Tamarisk are now in the zenith of their beauty, their long, slender shoots of feathery foliage that flutter beneath the slightest breeze being now terminated by plume-like sprays of inflorescence, whose tints range from ruddy pink in the unexpanded blossoms to flesh-white in the fully opened flowerets. Many varieties of the shrubby Veronicas are in bloom, and Yuccas of different species hold aloft their splendid spires of ivory white blossoms. During the month I saw two noble specimens of the variegated form of *Y. gloriosa* in fine flower. The variegation of the plants in question was particularly distinct, being quite as marked as in the case of the variegated form of the New Zealand Flax (*Phormium tenax*). This, however, is far from being the general experience, since plants sold as variegated forms of this Yucca often exhibit but little departure from the normal colouring in their leaves. The Pampas Grass (*Gynerium argenteum*) is now commencing its autumnal display, and taking the place of the earlier-flowering New Zealand Reed (*Arundo conspicua*). The Eulalias are also throwing up their flower-shafts, large clumps presenting a most ornamental appearance. A week ago I saw on the grass in a beautiful garden an enormous clump of *Eulalia zebrina* 18 yards in circumference. The large standard *Magnolia grandiflora* has continued to produce its ivory white, perfumed chalice in abundance, and bids fair to surpass itself in the number of blooms borne in the year. S. W. F.

ORCHARD AND FRUIT GARDEN.

IS POTASH A CURE FOR CANKER?

THERE are, I am afraid, few fruit growers who are unacquainted with canker. The Apple, perhaps, is most often attacked. Apple trees are also much more prone to fall victims to it on some kinds of soil than on others, and to such an extent is this the case that it is often a difficult matter to find an Apple tree free from it in some collections. These are, of course, extreme cases; nevertheless, they exist, and the owners both of these and where less serious cases occur would no doubt be only too glad to hear of an antidote for the disease. Some kinds of Apples, too, are given to canker much more than others, of which the Ribston Pippin may be cited as an example. There are several other sorts that become nearly, if not quite, as badly affected in some places, and Blenheim Orange when grown as a restricted bush also comes under the same category. The continual pinching and pruning necessary to keep these bushes within bounds seem to aggravate the evil. It is through having to deal with some bush trees of Blenheim Orange that had got into a bad state from canker that I am induced to pen this note and to record the steps I took to combat the disease, and give the results of the treatment up to the present time. The trees in question are about eighteen years old, and have been an eyesore to me for a long time, but I did not care to destroy them. The ground beneath these and neighbouring trees being required for vegetable growing, it is obvious they had to be kept much restricted. Having made other arrangements two seasons ago, I was enabled to allow all these trees to make more free growth, and then I was determined to see what could be done to alter the condition of these canker-stricken trees. The great thing

was to overcome the canker if possible by inducing the trees to make free, healthy growth and so to grow out of it. Some of the branches had become eaten nearly half way through with the disease, which had spread to most parts of the trees, even the young wood being affected by it. To stop this was the first thing to be done, and for this purpose potash was given, and as a further help the trees were given their heads and allowed to grow away at will in the summer months. Another remedy was to wash the trees and all the wounds and scars on the branches with caustic alkali solution, which killed all insects and fungoid germs there might have been hibernating or resting there. The potash was applied liberally to the surface in the winter months soon after the ground had been lightly pointed over. So well did it answer, that I could not but help noticing the improved condition of trees as the season advanced, and how nicely the cankered portions of the branches began to heal over. This season the potash was again used, but in conjunction with other ingredients, and the result is a still further improvement. The additions to the potash were superphosphate of lime and best quality bone-meal. This was mixed as follows: To 1 lb. each of muriate of potash and superphosphate of lime were added 3 lbs. of bone-meal, which was afterwards well incorporated together. This was strewn on the surface of the ground to as far as the trees extend at the rate of 2 ozs. to each square yard and afterwards raked in. This was applied just as the trees started to grow and again at the latter end of August. The trees bloomed well, and for the first time since they were planted are bearing a good crop of fruit, which is large in size and likely to be highly coloured by the time it is ready for gathering. The side shoots or spur growths were shortened back in the summer, but the leading shoots at the extremity of each branch were left intact, and will be merely topped at the winter pruning. I am very much pleased with the results, and shall certainly follow up the treatment another season, by which time I hope the trees will be quite restored to health, nothing but cicatrices on the branches being seen in place of the cankered wounds. I am a firm believer in the value of muriate of potash for fruit trees, and its use has led to some excellent results here this season with Peaches, Nectarines, Pears and other fruits. The result of its use is a clean growth and great depth of colour in the fruit. This same form of potash, when mixed with the other ingredients already mentioned, forms a fine manure for fruit trees of all descriptions, also for Vines. When combined, these constituents, in addition to promoting healthy growth and imparting colour to the fruit, also induce great fruitfulness. A. W.

Puzzled amateur fruit growers.—I have had lately one of the most instructive experiences in respect to the merits of extension *v.* restriction that I have ever come across, showing how hopelessly handicapped the inexperienced amateur is who trusts to the directions of others. Two friends of mine, one an engineer and the other a builder, had large well-planted gardens adjoining. Both wanted Plums and planted Victoria, one against a low wall and the other in the open as standards. Both pruned vigorously and closely, hacking in the long wand-like shoots produced every season in consequence of the cutting back, and both had no crops and—wondered! At last the engineer got tired of his barren trees, which by this time had reached the top of the wall, and left them in disgust to grow as they pleased. The result in two or three years was a big head of branches above the wall, and soon

after a heavy crop of Plums. I took to this garden while the present year's crop was still unripe, and I think I never saw such a crop of Victoria. Then my neighbour the builder told me "the strangest thing he ever knew," viz., that although he and his neighbour planted their trees at the same time there was still no fruit on his trees, and he had continued to prune "as regularly as ever." I guessed the cause, and found his trees (standards) with stumps of heads bearing a crop of shoots of this year's growth like Willows and nearly as long—not a fruit-bud on them. Of course, no gardener, even though a pruner, would have cut the trees in so hard, but my friend is not a gardener, and followed the gardener's counsel rather closely. He has not been at the tree yet with his knife this season, and after having the mystery of buds and fruit-buds, &c., explained to him, he has promised not to go near the trees with a knife in hand for the next two years. It is pitiable to see what losses cottagers and amateurs sustain in their gardens from ignorance of simple gardening operations. The French small cultivator is far ahead of us.—S.

AUSTRALIAN STOCKS FOR APPLES.

SEING an article in THE GARDEN of April 15 on "Australian Stocks for Apples," with a request from the editor for further information, I will give you the result of my own observation. Winter Majetin was the first Apple used in the colonies as a stock capable of resisting the woolly aphis, and it is practically blight-proof. Although cuttings of the root 6 inches long and from the thickness of a darning-needle to, say, 1½ inches in diameter, planted with the tops of the cuttings level with the surface of the soil, will grow, yet cuttings of the Northern Spy roots from 2 inches to 4 inches long, grafted into Spy cuttings of from 4 inches to 6 inches long, and planted with one bud above ground, will give strong, straight stocks the first year; whereas, the stock from the root-cuttings will be irregular in strength and rather crooked for a year or two. Where no Northern Spy roots for grafting are available, cuttings of Spy as mentioned above may have an upward cut from within three-quarters of an inch of the base of the cutting and have a small piece of any Apple root 2 inches or 3 inches long and as thick as a crow-quill, cut wedge-shaped, and inserted and tied in. The root will keep the cutting alive until the cutting pushes out a mass of fibres from the base. At the end of the first year the cuttings would have to be taken up and the common Apple roots carefully removed, or they might take the lead. The roots on the cuttings at the end of the first summer would be large enough for starting next year's batch of stocks. If a root is inserted more than three-quarters of an inch from the base of the cutting, the base of the cutting will probably rot, and instead of having a Spy stock you will have a Spy grafted underground on a Crab, and therefore a supply of food and a retreat for the Apple blight underground.

Trees grafted on Spy or any other Apple that is free from blight will not be free above the graft because of the stock they are grafted on, but they will have no blight on the roots or on the stems below the grafts. Spy and Majetin will not come true enough from seed to be of value as blight-proof stocks for other Apples. I also saw some remarks on propagating *Cydonia japonica*. Where an old plant can be dug up, its roots, if cut into 4 inch lengths and planted with the tops of the cuttings 1 inch or 2 inches under the soil, strike very freely and make the best of plants with the least trouble, even yearling plants giving roots that would grow. A. ALLISON.

Latham, Wanganui, New Zealand.

Apple Cox's Orange Pippin.—I have seen many excellent crops of this delicious Apple this season, but the best was in an enclosed garden on the Chilworth Manor estate, near Southampton, the soil being a thin stone brash, in which

for many years vegetables had been grown before the trees were planted. The garden is exposed to south-west winds, but is well sheltered on the north and east by Fir woods. Here were trees, large ones, carrying from three to four bushels, and smaller ones a bushel each, but all grandly cropped and the sample very fine and richly coloured. The trees had in several cases to be propped up to support the load. The smaller ones had been well mulched and occasionally saturated with water. On such a soil this Apple always bears; indeed, poor as the soil looks, it seems to suit Cox's Orange.—A. D.

Wasps and fruit.—The attacks of these insects have been short and sharp this year, and there are now signs that they are beginning to disappear for the season. The earliest nests taken this year were a fortnight later than those of last year, and I have not taken as many by half. I can find nothing better than cyanide of potassium for the purpose, and always keep a stock of it ready mixed in well-corked bottles. When a nest is found it is left until a warm sunny day when the wasps are busy, and a couple of table-spoonfuls of the cyanide well diluted poured in. All the insects are killed as they return to the nest, and this is dug out next day. When the nests are in trees or in places where it would be difficult to pour in the cyanide, an old sponge or a piece of Moss is well soaked with it and placed in the entrance to the nest. Where wasps attack ripe fruit in vineries or on the walls, a little wasp destroyer placed in some damaged fruit will drive them away. But the effect of this is not always lasting, and it has to be repeated, or the insects return in strong force again. The large flies that are always to be found about fruit when once the wasps have started on it are equally mischievous, and the wasp destroyer has the same effect upon them.—SUFFOLK.

Grape Buckland Sweetwater.—It is not often that one sees really good examples of this Grape now-a-days, and yet it has many points in its favour. When properly finished in the early summer it assumes a rich amber tint, and in point of quality it is superior to Foster's Seedling, though the Vine is not such a prolific and certain bearer. I have grown Buckland Sweetwater in a first early house along with the Black Hamburg and Foster's Seedling, and though not so reliable as either of these it never failed, and when ripe the fine large berries were highly appreciated in the dining-room. It is not to be discarded as an exhibition Grape when staged at summer shows in conjunction with Black Hamburg, and only this summer I saw a couple of bunches staged, which proved it to be anything but an inferior Grape for the show board.—H. H.

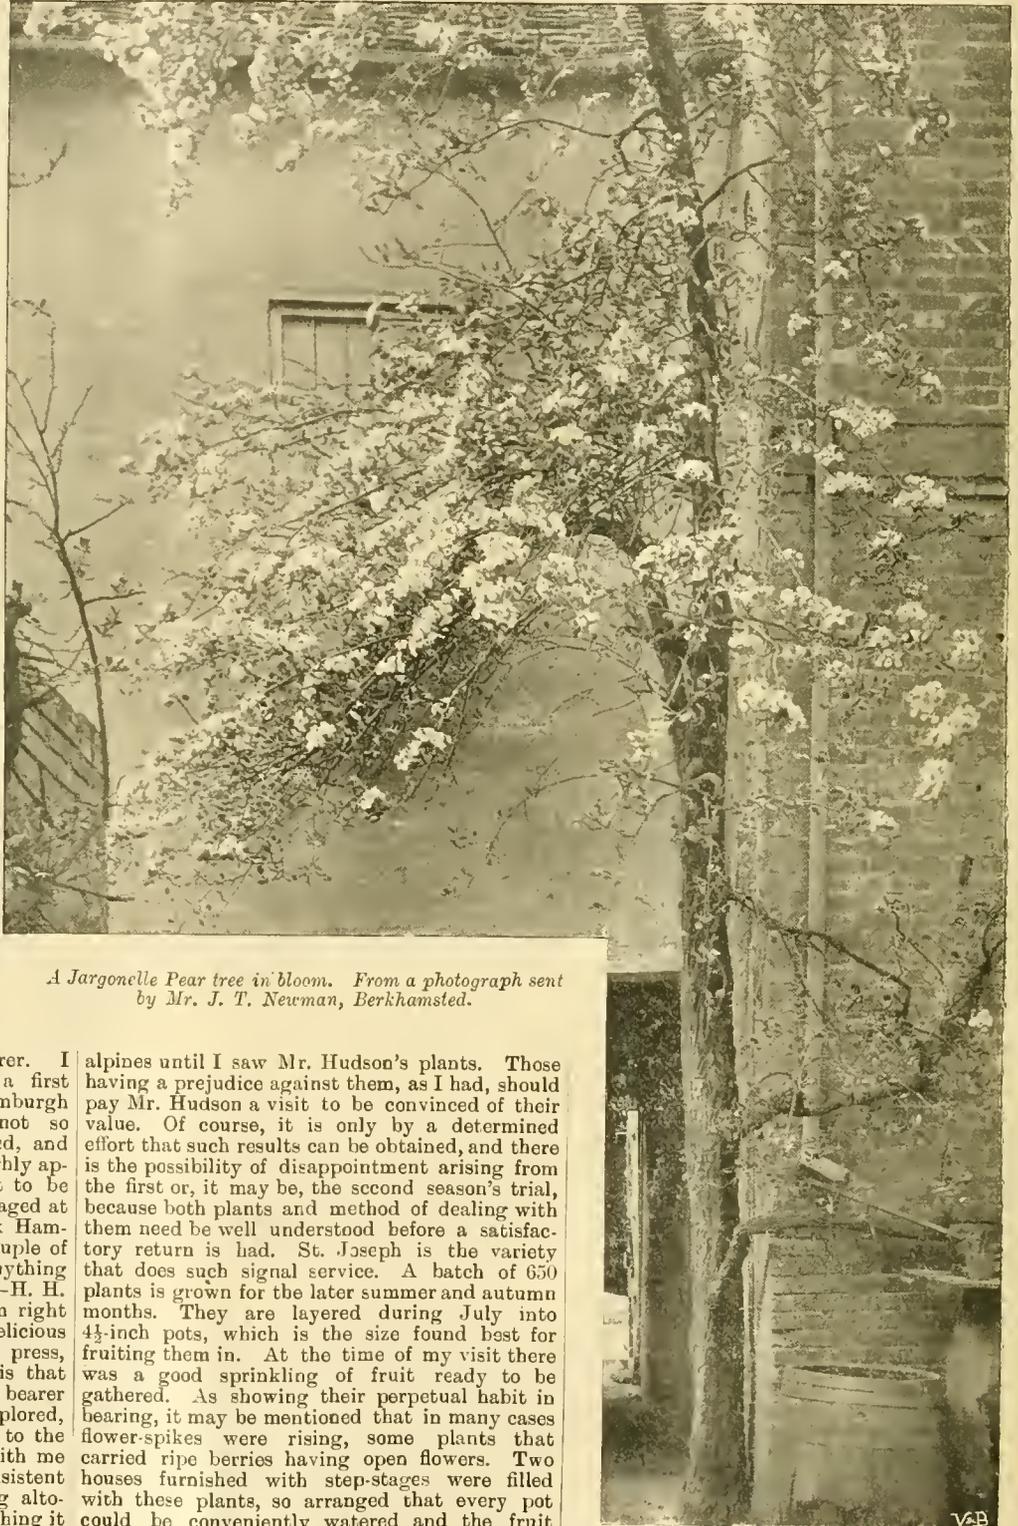

Plum Webster's Gage.—I think I am right in saying that it is but seldom this delicious Gage is referred to in the horticultural press, though why I cannot conceive, unless it is that the tree is tender, or else that it is a shy bearer elsewhere. If such is the case it is to be deplored, as it is nearly, if not equal in all respects to the old, but highly esteemed Green Gage. With me the tree, if not a heavy cropper, is a consistent one, as it is seldom that it misses bearing altogether. I grow it as a cordon, and if anything it is rather inclined to make too strong growth, which necessitates an occasional root-lifting. Under these conditions it succeeds very well, and always sets plenty of fruit-buds. As regards the fruits, they are somewhat larger than Green Gage, rather more oval in shape, and of a yellowish green colour. When fully ripe the flesh

is yellowish, tender, soft, juicy, and richly flavoured.—A. W.

Strawberries at Gunnersbury.—Most of THE GARDEN readers are aware that the alpine varieties receive much attention at Gunnersbury House. I must confess I did not care for the

THE JARGONELLE PEAR IN HEREFORDSHIRE.

THE above Pear, one of the oldest varieties in cultivation, is well known in every district throughout this country. It finds great favour

A Jargonelle Pear tree in bloom. From a photograph sent by Mr. J. T. Newman, Berkhamsted.

alpenes until I saw Mr. Hudson's plants. Those having a prejudice against them, as I had, should pay Mr. Hudson a visit to be convinced of their value. Of course, it is only by a determined effort that such results can be obtained, and there is the possibility of disappointment arising from the first or, it may be, the second season's trial, because both plants and method of dealing with them need be well understood before a satisfactory return is had. St. Joseph is the variety that does such signal service. A batch of 650 plants is grown for the later summer and autumn months. They are layered during July into 4½-inch pots, which is the size found best for fruiting them in. At the time of my visit there was a good sprinkling of fruit ready to be gathered. As showing their perpetual habit in bearing, it may be mentioned that in many cases flower-spikes were rising, some plants that carried ripe berries having open flowers. Two houses furnished with step-stages were filled with these plants, so arranged that every pot could be conveniently watered and the fruit gathered when ready. None but these alpine and hybrid Strawberries could be fruited from runners layered during the current summer, and though few could devote so much space to them as does Mr. Hudson, many, I am sure, would attempt a few could they but see how useful they are late in the season.—W. S.

in this county as an early variety and is somewhat extensively grown. Very large trees are to be met with covering the gable ends of farm buildings and oftentimes the principal front of the farmhouse is also given up entirely to the cultivation

of this Pear. Not far from where these lines are being written there exists a very fine example, which has been trained so that the entire south front of what is a large old-fashioned farmhouse is covered from within a few feet of the ground to the eaves with its branches. Judging by the size of the bole, this tree must be of great age, yet it is perfectly healthy and vigorous and bears good crops of large-sized fruit. Its roots no doubt extend into the kitchen garden, situated some 30 feet or 40 feet from where the tree is planted, and as the ground generally receives plentiful supplies of farmyard manure annually, the vigorous and healthy condition of the tree is thus accounted for. The above is really the best method of growing the Jargonelle Pear, as, on account of its being such a vigorous grower, it must have plenty of room to extend. To try and restrict it either by root-pruning or constant pinching back of the growths is to court failure, or if it does not result in failure the returns are at the best but poor. Allow the branches to extend so that a large area of space is covered with them, and the tree then gets rid of its superfluous energies, so to speak, bears heavy crops of fruit, and continues to do so for many years if proper attention be paid the tree. For this reason I should never advise the cultivation of Jargonelle where it would be cabined and cramped for room. If ample training space can be afforded it, then by all means plant it for the earliest supply. These large old trees invariably set an abundance of fine bold fruit-buds, and the floral display which follows in the spring is well worth anyone's while making a special journey to behold.

The accompanying illustration, which shows an untrained tree growing in a back yard, conveys a very good idea of the beautiful effect produced by the Jargonelle when in full bloom. That it is a hardy prolific variety we have abundant proof; otherwise it would not submit to the rough-and-ready treatment often accorded it when grown on farm buildings. When given anything like adequate attention, magnificent fruits can be produced in this county which for size and quality would compare favourably with those produced in the most favoured districts. The drawback with regard to the cultivation of this Pear is, of course, the fact that the fruits keep but such a short time; but there is never any difficulty in getting rid of the surplus, provided they are sold before they are too ripe. Of course, the market grower is on the alert and bears this fact in mind, but there is a tendency among amateurs to let the fruits become too ripe before disposing of them; consequently, they will hardly bear handling, and bruise badly. When marketed in good order remunerative prices are to be obtained, particularly if the small and rough-looking examples are kept back. The Jargonelle also succeeds as a standard, but the individual fruits are not so large as those produced by wall trees. As a bush I must—as far as my experience goes—pronounce it a failure, as it grows far too rampantly on the Pear stock to be cultivated in the kitchen garden. On the Quince it cannot be induced to make sufficient growth to form anything like a respectable-looking tree. Otherwise it bears well, the fruits are of good size and highly flavoured. The most successful way of growing Jargonelle, therefore, is to accord it a position on a wall where it can extend both in an upward and lateral direction, as from such trees the finest produce is invariably gathered. A. W.

Strawberry Latest of All.—"A. D." calls this one of the most valuable late varieties in cul-

tivation, which reveals his knowledge of Strawberries, because it is really only a second early and inferior to others at that. It comes in several days after British Queen, according to the raiser's own description—a very fine distinction indeed—and British Queen succeeds Keens' Seedling, a well-known early kind, both kinds being used for early forcing. Whoever heard of any gardener forcing a naturally late sort like the Elton Pine, which "A. D." avers is now seldom grown; whereas, in THE GARDEN of September 23, in the paper on "Fruit Farming in Scotland," the Elton Pine is said to be one of the only two sorts grown, and that six or seven of its fruits, selected at random, have been known to weigh one pound. "A. D." says Latest of All has not a British Queen flavour. Has he forgotten that it is claimed to be quite equal to the British Queen in flavour, and had a first-class certificate as a seedling from British Queen? Helena Gloede, said to be one of Latest of All's parents, the raiser of Latest of All thinks so much of that he has expunged it from his catalogue of Strawberries. My own belief is that Latest of All has not a drop of Helena Gloede blood in it, and that it is neither more nor less than an inferior variety of British Queen, and now admitted by "A. D." to be without the chief quality claimed for it, viz., a British Queen flavour. One of your correspondents, agreeing with my description a few weeks back of Elton Pine, says he has had it fine in September in the south. I challenge "A. D." to produce a dish of Latest of All within a month of that date.—J. S.

CHRYSANTHEMUMS.

HOW TO USE LARGE EXHIBITION BLOOMS.

THE columns of THE GARDEN have for years deprecated the way in which blossoms of high quality have been exhibited, the monotonous lines of boards of blossoms leaving much to be desired. Ordinary visitors—persons who are not growers, whom it is hoped to interest in the Chrysanthemum by a visit to an important show—are usually highly pleased with the first few exhibits they inspect, but when these are repeated time after time and the same method of arrangement on boards always followed, the inspection becomes monotonous. Keen observers have come to the conclusion that, except in a few cases, interest appears to be on the decline—at least, so far as the ordinary visitor is concerned. Is it not fairly safe to say that this may be largely attributed to want of enterprise, lack of novelty, and, above all, the want of practical illustrations of the uses of the Chrysanthemum for all forms of decoration? It is the large-flowered types of the Chrysanthemum which have for years remained in the background from a decorative point of view. We may therefore gladly welcome the innovation of the National Chrysanthemum Society at their exhibition on November 7, 8, and 9 next.

The chief class on this occasion will be for twelve vases of specimen blooms of Japanese Chrysanthemums, distinct, each vase to contain five blossoms of one variety. The vases will be each 18 inches high, and not less than 6 inches of the stem of each flower must be shown above the rim of the vase. Chrysanthemum foliage must be added, but upon separate stems. This latter condition is a wise provision, for if the large blooms be exhibited with their own foliage adhering they very soon collapse; whereas by stripping the stems of their foliage and supplementing this by foliage of other Chrysanthemum plants the freshness of the blooms is retained. It will thus be seen that each exhibitor will have to stage sixty blooms, and if some half a dozen or more entries are

received for this one class, they will make a fine display. The society has received the generous support of Messrs. James Green and Nephew, of Queen Victoria Street, E.C., who have designed and specially prepared glass vases for this purpose, and are lending them solely for this unique display. Each exhibitor will have vases alike, and as abundance of space for each vase will be allowed, it will readily be seen that the prospects of a striking display are good. There is good reason to suppose this class will be arranged in St. Stephen's Hall, where cooler conditions always prevail. The liberal awards, viz., a large gold medal and £20 for first prize, a similar medal and £15 for second, with two other handsome prizes should ensure a display of high quality. Smaller classes for six blooms Japanese Chrysanthemums, one variety only, arranged in a vase, are in two instances provided for less ambitious growers. A step in the right direction has also been taken with regard to single Chrysanthemums. Provision has been made for exhibiting these in vases, and two classes, one for twelve and another for six vases of these interesting flowers, are provided. Each vase is to contain six blossoms—a distinct advance upon the old method of dumping sprays of three blossoms on boards, as heretofore observed. Both the large-flowered and small-flowered types are included, so we may rest content that at last these useful blossoms will be represented in a fitting manner. Not the least interesting is a class providing for a collection of cut blossoms of Chrysanthemums illustrating the different types of form, colour, and size. It is specially stipulated that each exhibit must contain examples of not less than six of the ten sections enumerated in the National Chrysanthemum Society's Jubilee edition of the catalogue, and there must be at least one representative of both the pompon and single types. Each collection is to be arranged on a separate table, and set up in specimen glasses or small jasper vases. Most persons will agree that an exhibit of the kind just described will serve an excellent purpose, and ably illustrate the respective merits of each type of the flower. Apart from these new features there are several classes for tables containing bouquets, wreaths, &c., illustrating the decorative value of the Chrysanthemum; also others for epergnes, vases of pompons, hand-baskets, and posies, in which there is usually a very keen and spirited competition. D. B. CRANE.

Foreign Chrysanthemum shows.—The French National Chrysanthemum Society will open its fourth annual show and conference on November 3 next. The place of meeting will this year be Lyons. There will be a three days' show, and during the conference, papers will be read on various subjects relating to Chrysanthemums by members of the society. The exhibition is expected to be a very fine one, and visitors from very distant parts are to be present. M. Viger will preside. The Paris Chrysanthemum show will open on November 8, and will be held, as before, in the gardens of the Tuileries. The Italian National Chrysanthemum Society will hold its second show in the Palace of the Fine Arts at Milan. The date fixed is November 9 to 12.

NOTES AND QUESTIONS.

Chrysanthemum Wattle Blossom is a distinct colonial novelty. It is a Japanese, very globular in form, but having long twisted grooved florets. The colour is a fine deep shade of lemon-yellow.—C. H. P.

Chrysanthemum Kathleen Rogers is a Japanese incurved flower, with very broad, grooved florets, which are long and very substantial. It is said

to be an easy one to grow and the colour is a very chaste shade of white.

Chrysanthemum Lemon Queen.—This variety is little known, but it is an excellent early-flowering one. Its blooms are deep yellow rather than lemon, and in quality they are first-rate. Not, however, for large flowers, but for the supply of a short bushy specimen plant to give a wealth of colour or for cutting this sort is to be recommended.—S.

Chrysanthemum Ambroise Thomas.—It is a pity this brilliantly coloured kind is so late in flowering—too late, indeed, to be of much service in the open ground. While not exactly of the same tone, it is sufficiently near to remind one of the brilliant and dwarf kind Tokio, now only rarely seen. The above variety, however, is of better habit and produces larger clusters of flowers.

Chrysanthemum M. Louis Remy.—Amongst the numerous sports from Mrs. C. Harman-Payne a novelty called M. Louis Remy is just now in very good form. This is a sport from the white form Mme. Louise Remy, with which it must not be confounded. In form M. Louis Remy is similar to the parent, but the colour is a very pale yellow of the purest shade.

Chrysanthemum Mrs. White Popham.—This variety gives a pink colour at once pleasing and effective. It produces blooms of large size and noted for the depth of build. The florets recurve and curl slightly at the tips. Somewhat early, it is now fully expanded and sturdy in growth; at least, it is not of tall habit and is easily grown. This, I believe, was raised from seed in England, and is likely to be esteemed for exhibition.—H. S.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 23.

THE meeting of Tuesday last was a very full one, and at the same time quite representative in each department of gardening. Possibly the exhibits of fruit by private growers and the trade constituted the chief feature. From the former sources there were large exhibits of Apples and Pears by well-known supporters of the society, notably from Frogmore, The Hendre and Syon, whilst another capital exhibit came from Handcross Park, whence plants are more frequently sent. A smaller collection of highly-coloured fruit came from Dropmore. All of these exhibits were thoroughly representative of their various districts. Vegetables, too, were present in good quantity, a trifle over-large amongst the roots perhaps, but shapely nevertheless. The exhibit around which there were the most sightseers was that of Covent Garden produce sent by Mr. Monro, this exhibit being illustrative of his lecture during the afternoon, viz., "The Growth of the Fruit Trade." Here was to be seen the cream of the produce sent to Covent Garden at this season of the year, both of home growth and by importations.

Amongst flowers the Chrysanthemum held the sway, and it is safe to say that no more beautiful exhibit will be seen this season than that from Framfield by Mr. Norman Davis. In many respects it was an ideal exhibit of this popular autumn flower, being illustrative of the best methods of arrangement in baskets, vases, and the like. Japanese varieties largely predominated; pompons, too, were beautiful; but, singular to say, the old type of incurved was noteworthy by its absence—yet not singular, perhaps, when one thinks how little these formal flowers lend themselves to purposes of artistic decoration. Quite in contrast to this exhibit was another—a group of plants in pots, each plant to its regulation height from front to back, right to left, as formal as it was possible to make it. This exhibit was, all the same, of capital quality, being further set off by groups of highly coloured Crotons and Dracenas, one on either side. Another group of Chrysanthemums consisted of October varieties for cutting and for outdoor uses. Of cut blooms there was a splendid lot, well arranged, from Devon and a smaller lot from Surrey (Earlswood). Amongst these latter were some tasteful arrangements of decorative varieties. The useful Begonia

Gloire de Lorraine was shown from Edmonton, being prettily intermingled with Ferns, &c. Roses were present, but not in any great quantity, but of the berried plants, as the Pernettyas and Skimmias, there was a first-rate exhibit from Highgate, very profuse in berry. Orchids were not numerous, but at the same time they added greatly to the attractiveness of the meeting. Cattleyas were largely shown, notably *C. labiata* in its infinitude of varieties. A few lovely hybrids also were staged, chiefly *Lælio-Cattleyas*. *Cypripediums* do not now come to the front so frequently. A most notable hybrid present at this and the previous meeting is *Cattleya Mantini*, which at any rate has *C. Bowringiana* as one of its parents, to all appearance *C. Bowringiana* × *C. aurea*. There was a distinct improvement in the attendance at this meeting, and the hall was thoroughly well filled with the exhibits. The material at the command of Mr. Wright on this occasion lent itself to producing a good effect, and he took the opportunity of making the best display possible. Fortunately, the hall was not required by the Government officials; hence the anticipated removal for one meeting to the adjoining hall was not necessary.

Orchid Committee.

Awards of merit were adjudged to the following:—

LÆLIO-CATTELEYA DUCHESS OF YORK (*L. crispata* × *C. Gaskelliana*).—This is in the way of *L. C. exoniensis*, the sepals and petals almost white, faintly tinted with delicate rose. The front lobe of the lip is bright crimson-purple except the heavy fringe on the margin, which is bright rose. The side lobes are pale rose, shading to primrose towards the base, the whole of the centre area through the throat rich crimson-purple. The plant carried a four-flowered raceme. From Messrs. J. Veitch and Sons, by whom it was raised.

CATTELEYA PRINCESS (*C. Luddemanniana* × *C. Trianae*).—This is a desirable hybrid, the sepals and petals of fine form and substance, deep rosy lilac; the broad lip rich crimson with a darker shade at the base; the side lobes deep rose-purple, with some yellow at the sides. There are numerous light lines through the base of the throat. The plant has the intermediate characteristics of the parent species. From Messrs. J. Veitch and Sons.

LÆLIA MRS. M. GRATIX (*L. cinnabarina* × *L. Digbyana*).—In this the sepals are deep yellow, the petals a little lighter than the sepals, the heavily fringed lip deep yellow, suffused and veined on the front with orange-scarlet, the base pale yellow. It is a distinct and desirable hybrid, giving promise that with age it will develop into a really fine thing. From Messrs. J. Veitch and Sons.

Mr. Ed. Kromer, Roraima Nursery, Bandon Hill, Croydon, sent a fine group, consisting of about two dozen plants of *Cattleya labiata*, many of the varieties being remarkable for the intensity of colour both in the sepals and petals and on the front lobe of the lip. One peculiar variety was wholly lilac, the malformed lip flat throughout and almost white in the centre. Several good *Cattleya intermedia*, a good form of *Cattleya granulosa*, and the rare natural hybrid *Cattleya venosa*, in which the sepals and petals are buff-rose, the lip white, shading to yellow, veined with rose in front, purple in the centre, were also shown. *C. Loddigesii* was also prominent. Several good forms of *Lælia præstans* and *Sophranitis grandiflora* were also included. A silver Banksian medal was awarded. Messrs. J. Veitch and Sons, Ltd., were awarded a silver Flora medal for a small but choice group. In the back row were some finely-flowered plants of *Oncidium varicosum* Rogersi. A fine *O. incurvum*, several good varieties of *Cattleya labiata* and *C. Wendlandiana* were also noteworthy. In *C. Eurydice* (*C. labiata* × *C. Aelandiæ*) the sepals are deep rose with a bronzy tinge, the petals lighter in colour; the front lobe of the lip rich rosy crimson, shading to yellow at the base; the side lobes rosy lilac. The

plant carried a three-flowered raceme. *Lælio-Cattleya Hermione* has the intermediate characters of the parents. The lip is deep crimson-purple on the front lobe, shading to pale rose, and again to white in the throat. In *L. C. Wellsiana* the sepals and petals are deep rosy lilac, the large lip rich crimson-purple, veined with a darker shade of purple, shading to bright yellow through the throat. *L. C. Epicasta* has the sepals and petals deep rosy lilac, the lip bright rosy crimson, shading to yellow in the throat. Some good forms of *Cypripedium vexillarium*, *C. Charlesworthi*, a nice coloured variety of *Sophranitis grandiflora*, and the lovely *Sophranitis eximia* were also included. Mr. F. Knight, Thundersley House, Thundersley, Essex, was awarded a silver Banksian medal for a nice group, consisting principally of finely-flowered *Dendrobium Phalaenopsis*, some nice plants of *D. formosum giganteum*, several good varieties of *Cattleya labiata*, and *Cypripedium Charlesworthi*.

The most prominent among the amateurs' exhibits was a fine group from Mr. J. Bradshaw, The Grange, Southgate, containing three finely grown plants, beautifully flowered, of *Cattleya Mantini*. The variation among the *C. labiata* was remarkable, the most distinct among the natural varieties being *C. l. glauca*, a pretty form, having a distinct shade of blue in the sepals and petals, the whole of the front lobe of the lip having a decided plum-purple tint, with some yellow in the throat. In *C. l. leucochila* the sepals and petals are deep rosy lilac, the lip creamy white, with a blotch of purple in the centre, veined and suffused with rose around the margins. *C. l. alba vera* is a lovely form with pure white sepals and petals, beautifully fringed on the margins and having a large blotch of crimson-purple in front of the yellow of the throat. Some good varieties of *Lælia autumnalis* and *L. pumila* were also included. A silver Flora medal was awarded. Sir F. Wigan sent *Lælio-Cattleya Gottoiana marmorata*; the sepals and petals deep rose, mottled with purple; the lip reddish crimson, veined with a darker shade of colour, with a yellow tint through the throat. A cut spike of three flowers of *Cattleya Hardiana Lowia*, a lovely form in which the centre of the sepals and petals is suffused with white, and *L. pumila magnifica* with three flowers were also included. Mr. H. Little, The Barons, Twickenham, showed two fine spikes of *Cattleya Bowringiana*, one raceme carrying eighteen flowers. Mr. E. Stanley Clark sent an ordinary form of *C. Mantini* as *C. M. nobilior*. Mr. H. Tate, Allerton Beeches, sent a form of *Lælio-Cattleya Schilleriana* as a hybrid between *Lælia tenebrosa* and *Cattleya Hardiana*. Mr. J. W. Moore, Rawdon, showed the white form of *Cypripedium Charlesworthi*, better known as *C. F. Hardy*. From the Duchess of Northumberland, Stanwick, Darlington, came a fine cut spike of *Vanda cœrulea* with twenty expanded flowers, showing good size and substance.

Mr. Veitch, as chairman, called attention to the sad loss the society and committee had received in the death of Mr. Sidney Courtauld. He drew attention to the many useful ways in which Mr. Courtauld had given his services, not alone on the committee, but also as a member of the council of the Royal Horticultural Society. It was then moved that the council be requested to forward a letter of condolence with the widow and family.

Floral Committee.

An award of merit was given to each of the following:—

CHRYSANTHEMUM FLORENCE MOLYNEUX.—A grand pure white kind that should at least satisfy the most ardent worshipper of big blooms. Apart from purity and size the variety is of great depth, and likely to be in the front rank for exhibition. From Mr. J. C. Garnier, Rookesbury Park, Fareham, Hants (Mr. N. Molyneux, gardener).

CHRYSANTHEMUM MISS ALICE BYRON.—This is a pure white, in which the purity and exquisite finish are in the highest degree perfect. It is one of the best white-flowered kinds we have seen, the solid blooms also well proportioned. From

Lord Byron, Thrumpton Hall, Derby (gardener, Mr. Weeks).

CHRYSANTHEMUM MISS EDITH PILKINGTON.—This is a Japanese of the drooping type, and not unlike Edith Tabor, flowers very full and of a rich golden hue. From Mr. J. C. Garnier, Fareham.

CHRYSANTHEMUM LE GRAND DRAGON.—Chrysanthemum growers regarded the blooms of this as a maximum for size, the centre being also well filled, a weak point in this being the reverse. The rich gold of the variety is well known. From Mr. W. J. Godfrey, Exmouth.

CHRYSANTHEMUM J. HOOPER PEARSON.—This variety made its *début* a year ago, and is without doubt a splendid kind even among yellows. For richness it has probably few equals, and in every exhibit is one of the first to attract attention. From Mr. W. Wells, Redhill, Surrey.

ADIANTUM BURNI.—At a slight distance there is much in the fronds of this to remind one of *A. amabile*, particularly in the graceful character and general texture. The rootstock, however, is quite distinct, as also the dark stems of the fronds. The pinnules are small and delicate pale green. The entire fronds are of good size. From Mr. W. J. Burn, Cromer.

The Drill Hall on this, as on many former occasions, proved none too large. Strongly to the front, while the season is yet young, is the Chrysanthemum. Mr. Norman Davis, Framfield, Sussex, made one of his superb displays of the flower. In these displays there is none of the endless variety, the dense mound or the overloading of tables with any and every scrap of bloom that perchance had a petal unfolded for the particular day, but in place thereof a few, and indeed a comparatively few, kinds were made the most of by the application of care, forethought and judgment in arranging. There is much to be learnt from such an exhibit; indeed, it may be said to be an object-lesson on how to use the Chrysanthemum. The exhibit occupied either side of one of the centre tables. Giant vases in the midst 3 feet high were filled with handsome blossoms of such as Lady Byron and Mutual Friend, both sterling white kinds; other vases of somewhat smaller size at either end contained blooms of General Paquie and Pride of Madford; and again smaller vases alternately with the largest were occupied with Annie Provost, a lovely bronze, and Mrs. Coombes, a new pink, and, by the way, a pink of a decided pink hue. This latter is indeed a lovely tone and supplies a long-felt need in this particular colour. For the rest, vases and baskets were occupied in the most pleasing manner with a variety of good things. A vase of Soleil d'Octobre, with the aged fronds of Bracken here and there inserted, another with the pink quilled Rayonnante, then a basket of Mychett Beauty, and another of the pretty Mlle. Elise Jordan, the model of the pompon forms, were noteworthy. One or two boards had their quota of good blooms, including Mutual Friend, the lovely pink Amy Ensoll, Miss A. Byron, white; Lord Cromer, crimson; Miss Maud Douglas, purple-pink and white; and Lady Phillips, purple-amaranth. Then in pleasing relief were Michaelmas Daisies here and there, and these with the warm-tinted Bracken made a very pleasing and instructive whole, for which a silver-gilt Flora medal was deservedly awarded. Mr. H. J. Jones, Lewis-ham, had an extensive miscellaneous group on the floor arranged in three half circles, the centre being of Chrysanthemums in pots, that on the left of well-coloured Crotons, and that on the right variously composed of *Dracænas*, small Palms, Pandanus, and such things, the whole backed with Palms and tall Bamboos. Among the most conspicuous of the Chrysanthemums were R. Hooper Pearson, rich gold; Dr. Harper, fawn; L. Humphreys, bronze-crimson; Miss Brown, pink; Soleil d'Octobre, &c., these being margined with Mychett White, with again an outer margin of Ferns (silver gilt Banksian). Mr. John Peed, Roupell Park Nurseries, had a small group of Crotons, Palms, *Dracænas*, *Aralias*, and such things, margined with a pretty *Sonerila*. Messrs. Wm. Paul and Son, Waltham Cross, had three

baskets of Roses, very nice for the season. They were Boadicea (Tea), large, pink, and fragrant; Sulphurea (Tea), a pretty bud and delightfully fragrant; and Exquisite (Hybrid Tea), a reddish carmine, the foliage greatly resembling that of the Hybrid Perpetual class. Messrs. R. and G. Cuthbert, Southgate, had a large group entirely composed of Chrysanthemum Mrs. Wingfield, a pretty pink kind of about 3 feet high. The variety is full of promise as a decorative kind, and in this direction its pleasing colour should stand it in good stead (silver Banksian medal). Mr. T. S. Ware, Tottenham, had a large group of early-flowering kinds, grown apparently in small pots plunged in the open. The group included many of the best kinds, such as Mychett Beauty, Francois Villermot, Gloire de Mézin, orange-gold; M. Chauchard, orange-fawn; Lyon, Blanche Colomb, Ivy Stark, &c. (silver Banksian medal). Messrs. John Laing and Sons, Forest Hill, had examples of topiary work in Box, Yew, and other such things. Messrs. Cannell and Sons, Swanley, had a small group of cut Chrysanthemums. White Quintus is very free; Mrs. E. Vere Freeman, a fine crimson, 3 feet only; Mrs. Frank Gray-Smith, orange bronze Japanese incurved, a very handsome flower; General Paquie, florets strap-shaped, chestnut red, free and showy; and Ella Curtis, golden, with broad petals, being some of the best.

Mr. J. Forbes, Hawick, brought a group of small plants of *Begonia* Gloire de Lorraine and *Begonia* Caledonia, which is nothing more nor less than a pure white form of Gloire de Lorraine. In each case, however, the plants shown were very small, the foliage pale, and the flowers equally so. The plants had in all probability been subjected to too much heat or insufficient light. All the same, there is no doubt as to the affinity of Caledonia, which has a bright future before it. Mr. H. B. May, Edmonton, had a fine group of *Begonia* Gloire de Lorraine, the plants being models of cultural skill, the flowers richly coloured also. In a setting of choice Ferns and the subdued light of the Drill Hall the plants were very effective. A small batch of the pretty white *B. Dregei* was also shown (silver Banksian medal). A group of berried plants from Messrs. W. Cuthbert and Sons, Highbury, was distinct among so much flowering material, and comprised varieties of *Pernettya mucronata* and *Skimmia japonica* (silver Banksian medal). Messrs. J. Cheal and Sons, Crawley, had examples of shrubs displaying autumn tints. Thus, *Ribes aureum* had deep crimson foliage, *Cornus sibirica* also crimson, while *Berberis Thunbergi* was almost scarlet. *Quercus concolor* is pretty, but the finest of all is *Q. coccinea*, a very telling plant indeed. Mr. W. J. Godfrey, Exmouth, Devon, had a large table of choice Chrysanthemums, mostly arranged three in a line, in which way a decided idea was obtained of their colour value. The following occurred to us as good: White Swan, a hairy kind, very compact; Mrs. B. Anderson, white; Mme. J. W. Budde, purplish pink; Le Grand Dragon, in very fine form; Queen of the Exe, white, broad short florets; and Corsair, red-crimson. Large Princess flower-holders in the background were filled with Mrs. E. Vere Freeman, crimson; Syrene, a very pretty pink, and Emily Grunderwald, a good yellow. Miss Mary Godfrey, pink, and Ettie Mitchell, soft orange, in the way of a refined Source d'Or, were also very pretty. The entire group, considering the long journey by rail, was highly creditable (silver Flora medal). From Earlswood, Mr. W. Wells brought a collection of cut Chrysanthemums, some as large blooms and others of the decorative class. In the former, such as Etoile de Feu was shown in two ways—blooms the result of selecting the second crown bud, which produced chestnut coloured flowers, and others from the terminal bud, of a rich crimson hue. Kathleen Rogers, a fine white; Sir Redvers Buller, crimson and gold, a really fine colour; M. Fatzer, gold tinted orange, and Mrs. Coombes, pink, possibly the finest of this shade, were excellent. Of the deco-

rative kinds, Nellie Brown and Mme. Liger Ligneau were both good, a plant of the latter lifted from the open, though protected from frost, being full of bloom (silver Banksian medal). Mr. N. R. Hoffmann, Thurlow Park, West Dulwich (Mr. Thos. Tomlinson, gardener), showed a batch of seedling *Caladiums* to show the variation of colour, all the plants having been raised "from one pod of seed." The term "pod," however, is a somewhat vague and indefinite description in the case of an Aroid, and a single spadix may embrace many ovaries. Mrs. Harry Veitch and Alfred Bleu are said to be the parents, fertilisation taking place April 3, 1899, and seed sown May 17, 1899. Some fifty small plants were shown, these being about one-third of the batch raised, facts which alone prove the inaccuracy of the above statement as coming from "one pod." Messrs. Jas. Veitch and Sons sent trusses of their hybrid *Rhododendrons*, and Mr. J. Warren, Handcross Park, Sussex, had three *Dracænas*—D. Offeri, D. Warreni, and D. Marchamiana. These are all of the narrow-leaved type, though not displaying any improvement on existing kinds.

Fruit Committee.

Awards of merit were given to the following:—

APPLE PARROQUET.—A conical fruit like Adams' Pearmain, but richly coloured, flesh white, soft, and pleasantly flavoured. From Mr. C. Ross, Welford Park, Newbury.

GRAPE REINE OLGA.—In this the bunches are narrow, tapering, berries round, red, sweet, and pleasantly flavoured. Sent as an outdoor variety, having so ripened. From Mr. W. Taylor, Hampton.

There were several very fine collections of Apples and Pears. A specially good one came from Mr. Thomas, The Royal Gardens, Frogmore, comprising 100 dishes of Apples and Pears. Of Pears, very fine were Marie Louise, Beurré Clairgeau, Louise Bonne, Conseiller de la Cour, Beurré Diel, Beurré Superfin, Van Mons, Easter Beurré, Beurré Baltet, and others, and of Apples, Gloria Mundi, Stone's Pippin, Lord Derby, Newton Wonder, Peasgood's Nonsuch, Hollandbury, Sandringham, Claygate Pearmain, Scarlet Nonpareil, Adams' Pearmain, Ribston, Cox's Orange, Emperor Napoleon, and Gascoigne's Scarlet (gold medal). Mr. Coomber, gardener to Lord Llangattock, The Hendre, Monmouth, put up a superb lot of sixty dishes, fruits generally finely finished. He had of Apples Peasgood's Nonsuch, Tyler's Kernel, Bramley's, Belle Pontoise, Sandringham, Prince Albert, Golden Noble, Dumelow's Seedling, Blenheim Pippin, and others; also of dessert varieties, Cox's, Ribston and other Pippins, Wealthy, American Mother, &c.; and of Pears, Durondeau, Beurré Baltet, Beurré Hardy, Beurré Diel, Doyenné du Comice, Beurré Fouqueray, Louise Bonne, &c. (gold medal). Mr. C. Herrin, The Gardens, Dropmore, Slough, had a collection of thirty-six dishes of finely finished Apples set up pleasingly with foliage and small plants, also a good dish of Braby's Late Gage Plum, one of the best keepers. The richest coloured Apples were Cox's Pomona, Striped Beaufin, Tyler's Kernel, Newton Wonder, Mère de Ménage, Adams' Pearmain and Gascoigne's Scarlet. Warner's King, Bramley's Seedling, Gloria Mundi, Grenadier, Lord Derby and Peasgood's Nonsuch were also excellent (silver Knightian medal). A fine collection, some 100 dishes in all, of these fruits came from Mr. Wythes, Syon House Gardens, Brentford, a far from desirable fruit-growing locality. Of the Pears there were very fine Pitmaston, Marie Louise, Beurré Gris d'Hiver, Marie Benoist, Charles Ernest, Glou Morceau, Beurré Diel, &c., and of Apples, Blenheim, Cellini, Prince Albert, Lord Derby, Barker's Seedling, Alfriston, Golden Russet, Hornead's Pearmain, Hibberd's Pearmain, Margil, Allington Pippin, Cox's Orange, Ribston and other Pippins, and American Mother (silver-gilt Knightian medal). Messrs. J. Laing and Sons, Forest Hill, also had a collection of fifty dishes of Apples (silver Knightian medal). Mr. Marcham, gardener to Mr. J. Warren, Hand-

cross Park, Sussex, had a collection of eighty dishes of fine fruit, Golden Noble, Mère de Ménage, Wellington, Betty Geeson, Gloria Mundi, Curtail, Ribston, Cox's, Blenheim, and Egremont Russet being excellent. Pears were varieties that have been previously mentioned (silver-gilt Knightian medal). Mr. Pope, gardener to the Earl of Carnarvon, Highclere Castle, set up a superior collection of vegetables, some thirty dishes in all, including Ailsa Craig, Excelsior, Aristocrat, and Ne Plus Ultra Onions, Perfection, Scarlet Model, and Early Gem Carrots, Tender and True and Hollow-crown Parsnips, Ideal, London Hero, Reading Russet, and Abundances Potatoes, fine Early Rose and Al Celery, Beet, Brussels Sprouts, Polegate and Best of All Tomatoes, &c. (silver Knightian medal). Messrs. Cannell and Sons sent from Eynsford a very large collection of vegetables. Autumn Giant Cauliflower, Defiance Cabbage, Ailsa Craig, Excelsior, Cocoa-nut, and other Onions, forty handsome dishes of Potatoes, Parsnips, Carrots, &c., made up a particularly fine display, to which a silver Knightian medal was awarded.

Messrs. Bunyard and Co., Maidstone, sent Apple Mrs. Phillimore, from Mother Apple x Cox's Pomona. Mr. Barnett, Chichester, had Grapes Black Hamburg from south wall and White Sweetwater from east wall, admirably ripened. Mr. G. Wythes sent three small Melons, The Duchess, all nicely flavoured, but over-ripe. Mr. Ross had Apple Rival, same parents as Charles Ross, but, whilst flesh was soft, it lacked flavour; also Apple Opal, which had previously had an award of merit. Mr. Camm sent Apple as Margil, shown at the Crystal Palace as such, and disqualified there. It was found not to be Margil. Mr. Blake, the Gardens, Clendon Park, Guildford, had a fine dish of Round Winter Nonsuch, a fine variety and great cropper, but still little grown. Messrs. J. Veitch and Sons showed Apple Royal Late Cooking, but which seems to be rather early, and a basket of St. Joseph Strawberry, runners in small pots fruiting. Mr. C. Webster, Gordon Castle, N.B., had Plum Princess of Wales, like a Gage. It is a clingstone and flavourless.

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening last a meeting of the executive committee was held at Carr's Restaurant, Strand, when Mr. Percy Waterer occupied the chair. The minutes and preliminary details having been disposed of, the chairman in a few well-chosen remarks alluded to the services rendered by his predecessor in office, Mr. T. W. Sanders, and explained that owing to the delay in the execution of the society's new medal the testimonial voted to Mr. Sanders at the annual meeting could not be presented before. He had much pleasure in asking Mr. Sanders in the name of the society to accept the illuminated address and gold medal that had been awarded to him. Mr. Sanders responded in suitable terms. The chairman reported upon his attendance as delegate to the meeting of the horticultural section of the British Commission for the Paris Exhibition, and Mr. Harman-Payne alluded to the formation of a new Chrysanthemum society in Denmark, the secretary of which had made inquiries as to affiliation. He also called attention to the Paris, Lyons, and Milan shows, and offered every information to intending exhibitors or visitors. The report of the sub-committee appointed to examine the relations between the parent society and its affiliated branches excited a vast amount of discussion, with the result that it was finally received and adopted. It is intended that the same shall be submitted to the annual general meeting. The report was discussed in sections, the principal speakers representing affiliated societies being Messrs. Weeks, Rundell, Newell, Smith, Cole, Stainton, and Berridge. A statement was presented showing that £45 11s. 6d. was paid in prize money at the recent October show, and the awards of medals were confirmed. The dates for the 1900 shows of

the society were fixed as follows: October 9, 10, and 11; November 6, 7, and 8; December 4, 5, and 6. Eight stewards were nominated for the forthcoming show at the Aquarium, and fifteen new members were elected.

NOTES OF THE WEEK.

Chrysanthemum Miss Alice Byron.—When we see such kinds as this it is obvious that the opportunity for improvement in the flower is not yet exhausted. Exceedingly pure, beautifully refuted, and superbly finished is but a fair comment on this sterling novelty raised by Mr. W. H. Weeks.

Primula capitata.—In a low position in the Kew rock garden a nice group of this species was flowering well a few days since. Many fine heads were well expanded and many more advancing—too late though, as we imagined, to satisfactorily complete their flowering without ample protection.

Androsace lanuginosa.—Though this trailing alpine is among the earliest to bloom in early summer, its profuse flowering is such that it ever lingers with the very latest of flowering plants till far into the autumn months. For its free-flowering as much as its easy culture it is always a welcome plant. In all probability even this flowering, prolonged as it undoubtedly is, may be materially lengthened in warmer, sunnier regions.

Alyssum maritimum.—Quite recently at Chiswick we noted a large number of patches of this pretty plant, evidently the result of self-sown seeds, the plants cropping up here and there among other things on the border. What attracted particular attention was the great mass of pure white blossom that quite hid the foliage from view. Single plants a foot or more across were a pure white mass. It is further worthy of note that these plants have appeared within the past three months, so that anyone desiring a late carpet plant such as this may do well to note the same.

Vitis Coignetiae.—By the same post I am sending you a few trails and leaves of *Vitis Coignetiae*. You will observe what a brilliant colour it is—in fact, it is, along with other autumn tints, much brighter than usual. The plant now covers a wall 26 feet by 12 feet, and has quite taken possession of a large Laurel at the end of the wall. The Snowy Mespilus, Flowering Ash, and Mountain Ash have been most beautiful here.—J. MORRISON, *The Farm, Narrow Water, Warrenpoint.*

* * * Lovely in colour in all ways, the Virginian Creepers are far surpassed in beauty by this superb Vine.—ED.

Kuiphofia multiflora.—I did not expect to have this remarkable species in flower this season. Suddenly, however, two medium-sized plants began to push up their spikes. The leaves of this new species on my strongest plant are each 6 feet long by 3 inches broad. The flower-spike of this one, I suppose, will be over 7 feet in height. In the plants now flowering the dimensions are smaller; the stalk thrown well above the recurring foliage is 4½ feet, the flowering part 1 foot by 2 inches. The individual flowers thickly beset the spike. They are comparatively small, pure white, with long protruding stamens; the pollen is bright yellow. All in all, this species is not so gaudy as some of the red-flowered ones, but it is a very striking and desirable species.—MAX LEICHTLIN, *Baden-Baden.*

Saxifraga peltata.—Despite the fact that this Saxifrage is always cited as a moisture-loving subject—and there is little doubt that the plant revels in moisture—I have never seen it finer in England than at Kew in the uppermost part of the herb garden near the Cumberland Gate. Here there is a bed of it some 9 feet by 6 feet, the growth being thickly spread over the entire area. It only remains to be said that the petioles in a dry season like the present were fully 4 feet high, strong, vigorous, and self-supporting, the leaf-blades being in proportion. Doubtless a good bed of soil exists for its roots, and so fine a group

may also have been well watered. Of this, however, I have no information. But this would scarcely account for all this vigour, which is that of plants in a bit of wet, boggy ground. The position is partly shaded.

Callistephus hortenensis.—Those who know the so-called China Aster by the latter name only will naturally be a little surprised, when ordering the above as a novelty of some rank, to find on flowering it they have a very near approach to, if not, indeed, the identical article they have so rigorously eradicated from their flower-beds in the past. Large business houses of repute will doubtless take some trouble to make this clear to their patrons, and if others are not like-minded, not a little disappointment will result. These single forms, however, are now to be obtained in several colours at a few pence per packet, and for filling in vacancies in the mixed border such things will be very useful. Quite a good show of them has been made at Kew this year in just this way beside the No. 7 range, the free-flowering of the plants being quite noteworthy.

Enlarging Brockwell Park.—Mr. C. E. Tritton, M.P., lately presided over a meeting of the executive committee formed for the purpose of acquiring 42½ acres of wooded land at Herne Hill for the purpose of enlarging Brockwell Park. The price asked by the trustees of the Blackburn Estate was considered reasonable. Mr. Albert Larking, the honorary secretary, read a letter from Mr. Lawrence W. Chubb, secretary of the Commons and Footpaths Preservation Society, guaranteeing a contribution of £1000 from a member of that body, provided the extension of the park were secured in two years. The chairman, Mr. Tritton, guaranteed £500 towards the expenses in promoting the scheme, and Mr. A. B. Stevens, M.B., a member of the executive, did the same to the extent of £100.

A mean theft.—On Thursday morning or Wednesday night last one of the boxes we have in our vineries for contributions from visitors in aid of the Royal Gardeners' Orphan Fund was forcibly removed. The box stolen was the one in the most prominent place in our vineries, and always had most in it. I am extremely sorry that such a deserving institution should suffer, and am doing all I can to find out and punish the dastard thief.—JOHN THOMSON, *Clovenfords.*

Grubs in Celery (H. R. Lover).—Your last consignment of Celery stalks and grubs reached me in capital condition. The latter are the grubs of a small fly, probably the Celery-stem fly (*Piophilapia*). I do not see how these grubs can be dealt with, as they cannot be reached by any insecticide, living as they do within the leaf-stalks, and the flies are such inconspicuous little insects, that it is difficult to devise any way of destroying them, though spraying the plants with some insecticide at the right time if that were known might be useful. As I suggested in my previous reply, as soon as the crop is off every vestige of it that remains should be collected and burnt, and the surface soil to the depth of 3 inches or 4 inches should be buried as deeply as possible, so as to bury the chrysalides so deep that when the flies try to reach the surface they may be unable to do so.—G. S. S.

"The English Flower Garden."—Thoroughly revised, with full descriptions of all the best plants, their culture and arrangement, beautifully illustrated. Medium 8vo, 15s.; post free, 15s. 6d. Bound in 2 vols.—sage-green morocco—for library or presentation, one guinea. Of all booksellers, &c. "Worth more than all other books on flower gardening and landscape gardening ever published. Whatever success I have made as a landscape gardener I owe to the inspiration of this book. It not only teaches good gardening, but, what is quite as important, condemns bad gardening, giving reasons that are convincing for both."—J. W. ELLIOT, *Pittsburgh, Pa.*

CHRYSANTHEMUMS.

PROSPECTS OF THE SEASON.

THE blooms appear to be rather late in opening this year. Why this is so I cannot say, for the great amount of sunshine we have had should tend to an early flowering season. Probably early selected buds have something to do with it. These usually end in disappointment by not only taking a long time to open, but in the blooms coming not at all true in character. "Many a slip 'twixt cup and lip" is truly applicable to cultivators of Chrysanthemums who endeavour to produce the wonderful specimen blooms so much admired at shows. All appears to be going on satisfactorily, and the hopes of prize-winning are bright until the flowers should be opening their florets; then it is so many mistakes are noticed and the loss of so many buds is felt. Many failures, again, are caused by persons crowding their plants too closely when under glass. This crowding is very frequently met with, and can only be remedied by growing just the number of plants another year to suit the amount of glass that each can command. One notices, too, that an unnecessary amount of fire-heat is often employed, which is harmful. Chrysanthemums opening their flowers in a hot, close temperature do so at the expense of substance. Just enough heat to expel moisture and to keep the air of the house buoyant is all that is needed, because we should not forget that this is a hardy plant. In a few collections that recent trouble which is known as rust is causing considerable anxiety, and is indeed far more killing in its effects than I at one time believed. Yet I am sure that if growers would strive to take measures in spring when the fungus is in its infancy, or in a stage when it may be stopped, the troubles later in the season would be reduced to a minimum. I have known several instances in this neighbourhood where this has been done. The cuttings and young plants have been watched, and should a leaf exhibit

a sign of the fungus it has been promptly removed. Now these same collections are free, or if not quite free, only a spot here and there is observable.

The season is likely to see much improvement in the matter of new varieties. Some of the English-raised novelties are most promising, not only in the production of fine blooms, but in the dwarfness of growth—a merit that has perhaps been somewhat neglected in the rage to get something larger in flower than we have seen before. R. Hooper Pearson already exhibits splendid properties, and is a variety that marks an epoch in its way. It is a distinct advance in colour, the yellow being deeper and richer than that found in any other sort. In substance it is also most remarkable, whilst the shape leaves nothing to be desired. The growth also is robust. Another kind opposite to the above in shape is Mme. Gabriel Debrie, and equally fine in its advance upon existing ones. It is a large, loosely incurving form of exceeding richness, the florets being remarkable for length and substance. The colour is a shade like that of the Malmaison Carnation. This last was produced by M. Nonin, a French raiser, and others of his raising are full of promise. Mme. F. Daupias and President Lemaire may be named in this connection. It is pleasing to note a new French raiser. Good Chrysanthemums from that country have lately meant M. Calvat's only. Those of the latter raiser are certainly fine as usual, but he sends us too many. Some thirty kinds each year is a large number. About half a dozen are found worth growing, the others fit only for the rubbish heap. M. H. Martinet of this year is a first-rate new kind; it gives us a colour much wanted—namely, crimson. Others not yet very far advanced in opening look distinctly promising. His variety of last year, General Paquie, was, I think, quite the best variety exhibited at the recent Aquarium show. It is rich bronzy yellow in colour, and in form not unlike Mme. Carnot. The sort is dwarf, easily grown, and an early and abundant bloomer.

A new rule of the National Chrysanthemum Society in respect to its floral committee is already causing a certain amount of strife. Rules relating to the award of certificates to new flowers should be stringent, and the members, too, should make it a point to be present so as to form a quorum. Personally, I do not see anything wrong in requiring that three-fourths shall vote for a new kind before it shall obtain the coveted award. This will set a very high standard, which is right. There is a danger of getting too many varieties of Chrysanthemums. New shades of colour and improved forms are desirable, also better and sturdier growth, but to go on increasing whites and yellows that differ so little from those already in cultivation will end in disappointment. Much interest also centres in the new way cut Chrysanthemums are to be exhibited in an important class at the forthcoming National show. I do not suppose the old-fashioned mode of showing specimen blooms on boards will for some time be done away with, but we have never had a similar class—in London, at least—where so many vases of well-grown flowers are likely to compete for prizes. It should therefore be one of the features of the season. Another novelty is provided by a well-known specialist. Single specimen blooms will be exhibited in competition of the most distinct shades of colour from white to crimson. This should be most interesting.

It is to be hoped that this season we will see better grouping of Chrysanthemum plants. In London and the larger provincial shows there is little that one can find fault with. The smaller exhibitions, however, have much to learn in the matter. Competitors endeavour to crowd as many plants into as small a space as possible and these are placed to give the whole a geometrical outline. I would suggest, then, that fewer plants be used and the plants stood in a more natural way, so that the individual excellence of each can be seen. Groups as generally seen would not be so arranged by the

same men to decorate conservatories at home, and less strictness as to tying each bloom perfectly upright and less care to get the whole perfectly flat would tend to a far more telling arrangement.

H. S.

FED VERSUS UNFED CHRYSANTHEMUMS.

I NOTE with interest the remarks of your correspondent "J. B. S." upon an important item in the successful culture of Chrysanthemums in town gardens. I believe that even under the most favourable conditions for the flowering of these plants many failures can be traced to indiscriminately gorging the plants with liquid manure and fertilisers. The action of nitrogenous manures always induces an increased luxuriance and growth, and the two articles specified by "J. B. S." are used essentially for their nitrogenous virtues. Their application is attended, therefore, with considerable risk when frequently used, because often no adequate effort is made to supply any deficiency of mineral constituents in the small amount of soil a pot contains. Without a plentiful available supply of such substances as potash and lime notably, the extra growth often remains immature and rank, and consequently, although large and promising buds are produced, there is, as your correspondent suggests, not sufficient inherent strength to withstand the foggy and damp weather that October and November certainly bring in their train in a town garden. The natural sequence to this lack of solidity and maturity is that when the plants are housed, perhaps in suitable houses, interrupted and diminished light, less air, less room, and higher temperature speedily cause a breakdown in the enfeebled system of the plants, and the gorged buds fall an easy prey to damp and decay. Given a good soil from the commencement, it contains all the necessary organic and inorganic materials for the plant's growth, and in such a sturdy, mature, and ripe growth without feeding can easily be had, producing a plant that will give little anxiety when under glass.

The plan that I adopt is to use a good mellow loam, and in the final potting a small amount of wood ashes and a little manure from a Mushroom bed of the previous autumn are added. Pots varying from 8 inches to 10 inches are used, and after potting they are plunged to their rim in either a bed of cinder ashes or the open border, as I find sheltering the roots from the scorching sun is a distinct advantage. The plants so treated this present season are as fine as one can see anywhere, in every case the dark leathery leaves being retained right down to the pot, notwithstanding some varieties have reached nearly 7 feet high. For the most part they carry three flowers, but others from four to nine. No artificial manure has been used at all outside, but they have had one application of sulphate of ammonia since housing; still, they will receive no more.

In spite of the damp and foggy weather that has been so prevalent in London, no difficulty has been experienced with the flowers that have opened and none is anticipated with those that remain, although the house that accommodates them is in a specially damp situation.

Finsbury.

A. B. J.

Rust on Chrysanthemums.—This season there are, judging from my own experience and observations, more complaints of the ravages of this dreaded disease than last year, and what is worse is that it sets in the more rampantly after they are taken indoors and the blooms are developing. Veltha, a specific for fungoid diseases, has been used by many, and in one instance I have met where it has been constantly used throughout their growing season there is no trace of disease among several thousand plants. This is a remarkable testimony for the fungicide, because last year the same grower had nearly the whole collection spoilt with it. Petroleum followed up is a good remedy, and plants syringed with this often, I find, are not much given to ordi-

nary mildew, an item certainly of importance and worth bearing in mind for another year. In my own case the disease has been much more virulent than in any previous year; indeed, there have been only a few plants infested before. Some kinds seem much more subject to the disease than others. Golden Gem, Golden Gate, and Lady Lawrence, the two first named in particular, are instances in which the disease is the worst, and the rapidity with which it spread on these was amazing. Veltha or petroleum must be freely used from the cutting period onward. It is curious that from some gardens rust should be quite absent.—S.

Chrysanthemums.—Discarding old varieties.—We have grown a considerable number of varieties within the past fifteen years and discarded a great number too, but I sometimes think there are old sorts which would give a good account of themselves if cultivated as they used to be and placed beside the favourites of today. This thought occurred to me at the recent Aquarium show when a fine bloom of the variety Nyanza was seen in one of the stands. This is uncertain, I know, but the rich crimson colour with old gold reverse is rich indeed, the wide petals forming a strikingly handsome flower. If Mrs. C. H. Wheeler could be seen as it used to be, few kinds of the present day could equal it in effect. Then Mme. C. Audiguier occurs to me. The tall habit of growth is against it, but the rich mauve colour and its wonderful arrangement of petals give it special attractions. Belle Paule again. What grace of form and delicate Pico-tee-like shades this used to give. In Thunberg we obtained a perfect informal pyramid of clear golden yellow. Triomphe de la Rue des Châlets used to be compared to a new flower-pot upside down, so rich was it in its terra-cotta shade. Criterion, nothing like it now, and Mlle. Lacroix gave blooms of most charming form and finish. Col. W. B. Smith is another splendid kind. Jeanne Délaux is not even now beaten in dark crimson colour. I would not like to grow exhibition blooms entirely from the old material, yet venture to state that if the above were produced now in their old form one would stand a very good chance indeed in competition.—H.

CHRYSANTHEMUMS AT EARLSWOOD.

MR. W. WELLS' nursery at Earlswood is generally one of the most interesting places during the Chrysanthemum season, for, besides having the advantage of being far enough away from the metropolis to secure good light and pure air, which always do so much to improve the general appearance of the plants, one is sure to find a very extensive collection of the newest and best novelties of the season. The cultural skill brought to bear upon the plants has resulted in some grandly developed blooms, and as the month advances, so the flowers will be proportionately more numerous than at the time of our visit, which was rather earlier than usual. On entering the large span-roofed greenhouse in which the plants are displayed, the visitor will not fail to observe some very handsome blooms of Kathleen Rogers, a noble white Japanese of fine form with broad grooved, drooping florets, and then close at hand is R. Hooper Pearson, whose fine massive deep golden yellow blooms make it a most conspicuous object. Very pretty and smaller in size is Mrs. Coombs, of a delicate lilac-mauve. Then towering high aloft are several monster blooms of Mrs. White Popham, with which Mr. Wells was so successful last season and which for exhibition may take a front place on the show board. Lord Ludlow (yellow), Emily Towers, Lady Phillips, Jane Molyneux, the new white Japanese, and others are all in excellent form, and well maintain the credit of the home raisers.

Continental varieties are always a feature at Earlswood, and are as well done there as anywhere. Of these, Calvat's recent novelties are best dealt with separately, and it may be said that one of the very best is Le Grand Aragon, a huge golden yellow Japanese of a most attractive

kind. M. Fatzer and President Bevan are both big, solid, compact incurving Japanese flowers, varying in their tones of yellow. Mme. Lucie Recouru is quite new this year, and is a large purple-amaranth-coloured flower. Soleil de Décembre belongs to the broad-petalled Japanese incurved group, the colour rich golden yellow. Others from the eminent French raiser include M. Chenon de Leche, always good and unique in its beautiful mingling of warm salmon-rose and gold; M. H. Martinet, crimson and gold; Mme. C. du Terrail, General Paquie, warm terra-cotta, very pretty and effective; Mrs. J. Lewis, Mme. Gustave Henry, another one with a reputation; Marie Calvat, Mme. Aristide Rey, and many others too numerous to mention. Other French raisers, of whom M. Nonin, of Paris, is perhaps the chief represented in Mr. Wells' collection, contribute some very useful and promising novelties. We specially admired François Pilon, a very deep rich golden yellow with long florets and a very large flower. A very interesting pale yellow sport from the white form of Mrs. C. Harman-Payne is found in M. Louis Remy. Amateur J. La Chaplais is an unusually fine exhibition type of bloom, and has grooved florets of a reddish salmon colour with golden bronze reverse. Some others from the other side of the Channel were Mlle. J. Lieber, President Felix Sahut, Mme. G. Debrie, Le Marcadeon, Etoile de Feu, and Marguerite L. Silhol.

It is curious that there seem to be no new American seedlings this year in spite of the competition that arose from this source a few years ago, but in place of it we have now to consider a wonderful addition to our lists from the Australian colonies. Like all those mentioned previously, the varieties belong to the various types of the Japanese section; we saw nothing in the way of an incurved or Anemone-flowered variety, and, indeed, the Japanese seems to monopolise the field wherever introduced. Some of the Australian seedlings are well known, such as Oceana, Pride of Stokell, Mr. T. Carrington, Australie, Pride of Madford, and others. In addition to these, Nellie Pockett, a beautiful white, and John Pockett, deep crimson and gold, were seen in excellent form last season and with good results, and this year they are quite up to their reputation. Mermaid is a new fine white Japanese of good size, but not so large as some in the same colour. Wonderful is a large, promising variety, having a broad floret of chestnut-crimson, with reverse of golden bronze. Lady Janet Clark has very long quilled florets, colour purple-amaranth. Wattle Blossom is quite new and is a fine addition; the florets of great length, drooping and twisted, and the colour a pale lemon-yellow. J. R. Upton is another of similar tone. Miss Lucy Cheeseman is yellow, but has a greenish shade with it. There are many others from the colonies which promise to be valuable in one way or another, but many of these are not yet named. Miss Ida Barwood, Silver Queen, Lord Salisbury, Australian Belle, &c., will be worth looking out for during the season.

NOTES AND QUESTIONS.

Chrysanthemum Klondike.—This possesses richly coloured and moderate-sized blooms that are of greater service than the more ungainly ones for general use. But in the colour, which is a chief attraction, there is something of that refined beauty which carries great weight even on the market. It is only about 4 feet high.

Chrysanthemum R. Hooper Pearson.—Possibly no finer yellow-flowered Japanese than this has ever appeared, and the number of blooms shown of it are to some extent proof of its suitability to several phases of culture. When blooms of any variety appear good in each and every stand there is hope for the amateur who cultivates but a few plants.

Chrysanthemum Mrs. Wingfield.—The fine group of this kind at the Drill Hall on October 24 showed the pretty tone of colour to advantage. The plants were only 3 feet high, pot included, and the pleasing pink of the flowers attracted attention. In the open ground, however, the plant this year is

not a success, the heat and drought being responsible, we presume, for its all-round blindness. In other respects for the open it would appear somewhat late to open satisfactorily.

Chrysanthemums at the Drill Hall.—Exhibitors of Chrysanthemums who were fortunate enough to be present on Tuesday last were enabled to have an object-lesson in the arrangement of cut blooms, whether it be large flowers of the finest Japanese varieties or the smallest of the pompons. More of such tasteful exhibits as that in question would be a boon to all lovers of the Chrysanthemum. The vase arrangements were really splendid, bold, massive, and imposing, yet in excellent taste.—CRITIC.

ORCHARD AND FRUIT GARDEN.

LATE STRAWBERRIES FOR PROFIT.

THERE can be no two opinions as to the desirability of extending the Strawberry season so that a full supply of fruit could be maintained in the markets of our large towns several weeks longer than is now the case. The Kentish, Hampshire, and Surrey growers are fully aware of the advantages they would obtain by lengthening the gathering time, and they would be only too glad to get the benefit of the considerably higher prices that prevail after the middle of July. It is a fact that in some seasons the great supply almost suddenly ceases, and fruit that ten days or so previously was sold at 3d. per pound would, if then put on the market, command a ready sale at from 6d. to 1s. per pound, according to quality. In a hot dry season it is surprising what a difference a few days make in the amount of fruit sent into the London market. Those who grow several hundred acres of the fruit would heartily welcome any means of prolonging the gathering season, and we may be sure that if culture alone would suffice, it would have been practised years ago by men who are too keenly alive to their interests to neglect any cultural method that would be the means of increasing their profits. Even by utilising the latest kinds we have and cultivating them in the very best manner, I do not see how it is practicable to secure any quantity of fruit after July, in the home counties at least. What can be done in this way in private gardens is no guide to the grower for profit. By growing such kinds as the Elton, Sir C. Napier, or Frogmore Pine liberally in a free, open situation and removing them to a north border in October one may obtain a supply of good fruit several weeks after the same kinds have ceased bearing in the open quarters. Even by this method it is difficult in many years to extend the Strawberry season in the southern counties beyond the first week in August. I grow a limited quantity of outdoor Strawberries for local trade, and am naturally anxious to prolong the gathering time as much as possible, for I find that if the weather happens to be very hot about the middle or end of July the demand for this fruit is very brisk; in fact, I never can quite meet it even at higher rates. My late-fruited kinds are so situated that they are quite screened from the noonday sun. The soil is tolerably holding and the situation rather damp, so that they suffer less from drought than in most places in the locality. In spite of these advantages, I finish gathering in a general way in the first week in August, and this year I had no fruit in the last week of July.

I am afraid that we cannot rely on the hybridiser to help us in this matter. It would seem that a past generation of Strawberry raisers reached the limit of precocity and lateness. We have, I think, no earlier Strawberry than the old Black Prince, and late varieties

put into commerce within the last few years are no later than Oxonian, British Queen, and Elton Pine. I believe that it is possible to have Oxonian at a later date than any other Strawberry in cultivation, and as regards Latest of All I agree with "J. S. W." that this variety is in no wise worthy of the name given it. I saw it growing by the side of Royal Sovereign this season, and there at least it was not more than a week later than the early variety. In connection with this subject, it would be interesting to know whether any of your readers have given the new race of perpetual-bearing kinds a trial, and whether there is any good reason to hope that they may be the means of furnishing an abundance of fruit when other varieties are over. I see that a French firm is putting into commerce several varieties which they declare to be a great advance on Sir Joseph, which is presumably one of the parents. Judging by the high prices asked for them, the raiser or distributor must have a very high opinion of their perpetual bearing powers. A secondary light crop would not, however, do for market growers. It must be possible to obtain a fairly heavy crop, or these perpetual-bearing Strawberries are not likely to find favour in this country with those who must have profitable returns for labour involved in the culture. It is possible that a race of perpetual bearers may in the course of time prove serviceable in extending the Strawberry season, but I fail to see why the London markets should not be plentifully supplied by using the kinds now commonly grown for a period of six weeks after picking from the late-bearing varieties has finished in the home counties. In the extreme north of England Strawberries begin to ripen quite a month later than they do in Kent, and in some parts of Scotland picking does not commence before August. I am acquainted with families in London that are well supplied with this fruit from their country seats in the north for several weeks after they have become scarce in the London markets. The wonder is that it has not occurred to Strawberry growers for profit to give more attention to those localities where, owing to the late ripening of the fruit, it could be placed on the London markets just as the great glut is over. There should be plenty of land in the northern counties available for Strawberry culture, and I feel assured that it could not be more profitably employed. The cost of carriage would, of course, be more than in the case of fruit produced near London, but the grower would undoubtedly be recouped by the higher prices realised. In August good samples would make from 8d. to 1s. per lb., and it is doubtful if anything in the way of an outdoor crop would give better returns. Although convinced that there would be a brisk demand in our large towns during August for the fruit, I am not so sure that such would be the case in the following month. The appetite for fruit varies according to the season, and with an abundant supply of Pears, Plums, and cheap foreign Grapes to choose from, I doubt if Strawberries, however good and plentiful, would find much favour with consumers in September. The fact that good hot-house Grapes have been sold as low as 9d. per lb. during the past month shows how abundant the supply of fruit has been.

J. C. B.

Variableness of the Apple crop.—In the majority of orchards in this part of East Anglia Apples are very scarce. At Blickling fruit of most sorts is scarce, even the so-called never-failing Lane's Prince Albert not bearing. There is, however, one notable exception. A variety named

Colonel Harbord, of which there are some five or six trees, is literally weighed down by the weight of fruit. Mr. Oclec told me that for the last twenty years the trees have not missed a crop. They are standards, and occupy different positions, which is a double proof of its hardy constitution. Colonel Harbord is a local Apple, known only, I believe, in Norfolk and Suffolk. In contrast to this scarcity, a friend of mine who recently visited Wisbeach assured me that thereabouts Apples were abundant, one grower in particular having large quantities. These, if keeping sorts, will, of course, realise good prices.—NORWICH.

The Pitmaston Pear.—I was pleased with "A. W.'s" note on this often misrepresented Pear. Of course, one does not covet the monstrous specimens the produce of trees growing on south walls, and which, by the way, are often less sugary and more quickly become mealy than fruit gathered from pyramids or bushes. I have not "A. W.'s" note by me, but I think he mentions the fact that the latter are usually more russety and of better all-round quality. Such is my experience; indeed, fruit from an espalier tree, although of much less bulk, was firmer, ripened more gradually, and kept a much longer time. It strikes me that many imagine that this variety must have a wall to do it justice, and I must confess to having at one time been sceptical, but was convinced of the suitability of Pitmaston for open garden trees by seeing a number in a midland garden bearing excellent crops. The trees, or most of them, were grafted on other unprofitable sorts and were in pyramid form. The soil was a stiff clayey loam, and the fruit in consequence did not ripen until comparatively late, and was at its best when wall-grown Pears were past. Like "A. W.," I quite think this variety will eventually become a popular market variety.—N. N.

The value of north walls.—We have got so accustomed to look out for southern aspects for all our choice fruits, whether it be on walls or under glass, that I fear we greatly underrate what can be done on north walls, for we too often find them covered with useless creepers, as if the production of really good dessert fruit on them was out of the question. The past season has been a remarkable one in many ways, not the least being that what is considered the favoured southern part of the kingdom was a good deal worse off for fruit than more northern and less favoured parts. I think the crop of Plums was in this locality about the shortest I ever remember, for even the Victoria failed to carry a crop, and one might go along whole walls of Plum trees and hardly be able to count as many Plums as there were trees. The only exception that I saw was on walls with a northern aspect, where some trees were literally loaded with fruit. These trees were planted more as an experiment than with the idea of their proving superior to those on the sunny side, yet such has generally been the case, and doubtless many who have to supply dessert fruits late in the autumn would do well to pay more attention to north walls for Plums, Cherries, Gooseberries, and Currants, for if the trees received as much attention as those on the southern aspects, I believe they would in the majority of seasons prove more reliable.—JAMES GROOM, Gosport.

Grape Mrs. Pearson.—Having on several occasions lately seen this Grape in excellent condition, I consider the fact worth recording, as it is only here and there that it is a success. In each of the above instances the Vines were carrying most excellent crops, the bunches long and tapering—a few only having large shoulders—and they were evenly set with berries from tip to shoulder. The colour and finish left nothing to be desired, the berries were of good size, while the flavour was distinctly that of the Muscat, and delicious. These Grapes had, of course, been grown for private use only; nevertheless, there were bunches among them which would not have disgraced any exhibition table. Taken altogether, they were the finest lot of Grapes I have ever seen of this variety, and my own inability to

succeed with it is the more regretted since seeing it in such excellent condition elsewhere. Soil has, I think, a great deal to do with its succeeding or otherwise, as on the heavy loam here I cannot produce a decent bunch. In each of the above instances Mrs. Pearson is growing in soil of a light description, and which appears to exactly suit its requirements. It is a Grape, too, which likes and really needs Muscat treatment to bring out all its best qualities. It is so delicious a Grape, and such a good keeper withal, that when it does succeed a position at the warmest end of the late vineyard should ungrudgingly be accorded it.—A. W.

YELLOW IN PEACH TREES.

THIS malady is too familiar to the majority of Peach growers, causing great disappointment, trees apparently healthy suddenly turning from a green to a sickly yellow shade. Some soils seem to favour the disease more than others, the worst cases of yellows probably occurring in strong retentive mediums. In such the roots of the current year do not mature in autumn, especially if such be wet and sulless, and the evil effects are visible the following summer. Cases of yellows, however, though, I think, less frequent, occur amongst glass-covered trees; faulty drainage, notwithstanding which the roots receive a maximum amount of water through the growing season, being the chief cause. In such mediums biennial or, at the most, triennial lifting of the roots is the only means of keeping the yellows in check, adding a large percentage of old mortar rubble, charcoal, or the sweepings of walks and drives, also burnt garden refuse and prunings. In the case of outdoor trees, the roots should be kept above the surrounding level and covered with not more than 3 inches depth of soil. If this is carried out say in October or during the early part of November, according to the season and condition of the trees, just, in fact, when the foliage is assuming a yellow colour, the work being followed by a mulch of leaf-mould or old Mushroom manure, applied not as a stimulant, but as a preservative of the newly-disturbed roots against severe frost, a more healthy and generally satisfactory condition of the tree may be expected the following season. Mixing a small portion of soot with the compost is good in cases of yellows. In none too well drained borders a depth of 6 inches of rubble may be placed beneath the new compost, as the roots in consequence of the occasional lifting practised will not become established lower down. Very firm ramming is also essential, this helping to keep the roots at home.

Trees that are replanted thus shallow will require a good mulch of manure of a short nature the following spring, also occasional waterings, or drought will be liable to affect them, the trees then going from bad to worse. I have noticed that some varieties of Peaches and Nectarines are more susceptible to attacks of yellows than others, and I am convinced that unsuitable stocks which, owing to the increasing demand for trees now-a-days, are frequently used are accountable in some instances for this disorder. I strongly advise those who have a strong soil to deal with to plant on stations, in order to prevent the descent of strong tap-roots, also to raise the border, use plenty of correctives, lift the trees at least every third year, and in order to counteract the evils of drought mulch liberally and feed frequently. I have found that Lord Napier Nectarine and Hale's Early Peach are particularly liable to the above disease. NORFOLK.

Plum Reine Claude de Bavay.—This is one of the last Plums I would recommend for planting in the open air. Even on walls in cold, late districts I never made much headway with it myself, but have heard of its ripening well in the warmest counties. Those, however, who have an orchard house in which the occupants are in pots or planted out will do well to find a place for this Plum. Here it will grow well if duly attended to

at the roots, set good crops and not fail so readily as some sorts when stoning. I once had a grand tree in a pot which passed the blooming stage in a light, airy greenhouse, but after completing stoning it was removed to a Cucumber house, the being wanted by a certain date. The rapidity with which the fruit swelled convinced me that it was a heat-loving Plum.—J.

Peach Violette Hative.—The advice given to "H. R." by a famous fruit grower always to grow Violette Hative was, as he admits, good. Indeed, I very much question if a better all-round Peach could be named either for gardener or amateur, for Peach house or open wall culture. I admit I have seen partial failures with it where a too rich larder has been given or indifferent culture displayed, but failures with Violette Hative are certainly the exception. When Peaches were to be met with in nearly every garden of any pretension in the eastern counties, clothing high, long walls from summit to base, Violette Hative always made a brave show, and to-day it can hold its own for beauty, high colour, and rich flavour. It is a free, constant bearer, and not liable, like so many varieties, to drop its fruit when stoning. Certainly no Peach house or wall is complete without a tree of it.—B. S. N.

Apple Hawthornden.—I am glad to find that "H. R." has a word of praise for this old Apple. I can remember trees of it growing in Essex orchards nearly forty years ago. As "H. R." states, the trees have a very beautiful appearance when in full bloom, and no better variety can be named for shrubbery or pleasure-ground adornment. Its usefulness is enhanced by the fact that it keeps much longer than such sorts as Lord Suffield and Lord Grosvenor. I would not, however, advise its being planted in cold clay or very retentive soils, as the tree is then liable to canker and the fruit to crack and develop scab. As "H. R." points out, it is well worth planting in espalier or bush form in small gardens that are warm and well drained. I am afraid this Apple is sometimes confounded with the New Hawthornden, which is a much later keeping Apple, though I question if its cooking qualities are so good.—NORFOLK.

Pear Van Mons Leon Leclerc.—I fancy there is an impression abroad that the above Pear is of a coarse, inferior character, but in reality it is, unlike many of the large varieties, of most refreshing and pleasing flavour. Not only so, but with careful storing it lasts longer than many others ripening about the same date. I have noticed that it will hang a considerable time on the tree when on a west wall, and is slower in coming to maturity than such sorts as Marie Louise, Thompson's, and others. The best and most even dish I ever saw was exhibited at Ipswich some years ago. My experience is that the tree is somewhat shy for a few years, but when once it makes a start it yields more or less annually. I have never seen it doing well as a pyramid, or, indeed, in any other position than against a sunny wall even in the most favoured counties. With very liberal thinning and feeding the fruit sometimes attains to a great size, these monstrosities having, I am afraid, told against its popularity. With judicious all-round culture the fruit reaches only dessert size, and then it is a grand Pear.—B. S. N.

Apple Rambour Franc.—Although said to be a very old Apple, Rambour Franc does not appear in catalogues of the present day—at any rate I do not find it in any I have. When I took charge of these gardens a few years since I found one tree, and so struck was I with its crop of handsome fruit that I at once decided on increasing it. This I did in the spring of 1893, and the remarkable growth of these grafts has been often commented upon by those who have seen them. It has a vigorous constitution, free from the attacks of canker or American blight, and usually bears good crops of handsome and distinctly shaped fruits. Here it is growing on a free stock, and forms a large open bush. On the

Paradise stock it should make a fine variety for garden trees as a bush or pyramid. The skin, when the fruit is kept for some time, becomes yellow, and fruits exposed to the sun put on a dull striped red, which much improves its appearance and alters its character from that of those grown under the shade of its somewhat heavy leafage. There are undoubtedly many Apples commonly cultivated that are devoid of the striking characteristics of Rambour Franc. It is, moreover, a fine cooking sort, having a firm yellow flesh with a brisk and sugary flavour. Its season is given as September and October, but it might be kept some time later than this where the conditions for storing are favourable. It is described as 4 inches broad and 3 inches high. In my case the height is greater by 1 inch than the breadth, and in other points it scarcely agrees with the fruit as grown here. It is probable that my tree was obtained many years since from some continental source.—W. S., Rood Ashton, Wilts.

STRAWBERRY ELTON PINE.

A GOOD deal has been written of late about late Strawberries, and Elton Pine has been named by some. It strikes me the variety which will beat it all round for late use when properly grown has yet to be raised. I saw several rows of plants in an East Anglian garden this summer growing by the side of Royal Sovereign, President, and others in an ordinary sunny position, and could perceive very little difference in individual vigour, while the gardener assured me Elton Pine crops well. At p. 313 "A. D." speaks somewhat at random when he says Latest of All will give a peck of fruit to every fruit given by the Queen. I have seen British Queen in soil which suited it growing and fruiting as freely as President or Paxton, but it is capricious, and the same remark applies to Latest of All, though in a less degree. There are gardens in which this, I think, over-rated Strawberry is anything but a success, and as to its lateness, I saw it shown in July in company with Royal Sovereign, Gunton Park, McMahon, and others. Its shape, which although only perhaps of secondary consideration, is the reverse of handsome, added to which is its objectionable green point. One noted grower for sale describes it as a late, but not the latest Strawberry, a fact which the inexperienced and amateurs intending planting should be made aware of, as its name is misleading. "A. D." says that Elton Pine does not do well everywhere, this being evidenced by the fact that it is now seldom grown. But many good old Strawberries are now seldom grown; even the valuable Vicomtesse, which will succeed in all soils and situations, has been to a great extent discarded in favour of perhaps larger, but coarser and worse flavoured sorts. EAST ANGLIAN.

Apple Peasgood's Nonsuch.—In a recent issue of THE GARDEN "H. R." commented on the fact of his not having seen such fine fruits of this variety of Apple as he did in the previous season. Hereabouts it has done remarkably well, and both in size of fruit and depth of colour the produce is quite equal to that of last year. During the last three seasons a standard tree near here has borne heavy crops of exceedingly fine fruit, which realised high prices when sold. Bush trees in these gardens have also cropped well this season. The single dishes of Peasgood's Nonsuch at the Crystal Palace show were very fine, but I think they were hardly equal to those shown last year. "H. R." says the best results are obtained from wall trees. I have never seen it so grown but once, and that was by Mr. Coleman at Eastnor Castle Gardens some few years ago. I shall never forget the splendid colouring and size of the fruits when I saw them, and have often referred to them when the merits of this Apple have come up for discussion. Mr. Wright (now of Chiswick) when at Glewston Court used to produce magnificent samples of Peasgood's Nonsuch, and which realised prices that to many would appear incredible.—A. W., Stoke Edith.

CHALLIS'S FRUIT TREE ARCADES.

THE illustrations show a Peach wall with glass coping 30 inches wide, the glass (26 ozs. to the foot) being supported at the back by a groove 1 inch deep inserted in the wall plate, and on the front by two copper clips to each square, which are secured to the front plate by two half-inch screws. The front plate is supported by wood standards 2 inches by 2 inches, fixed into cast-iron shoes or sockets, which are driven into the ground at the required angle, the supports at the base being 5 feet or 6 feet from the wall, according to its height. These supports

wood supports to the top, where two shoots are trained horizontally, right and left, in a line with the front plate immediately under the glass to the centre, midway between the supports, where they meet. Two side shoots are also taken from the base of each tree and are trained diagonally right and left to the wires up to the top of each support, crossing each other midway between them. Half way between each Pear tree, and in the same parallel line to the wall, the best late, most beautiful, moderate growing varieties of Apples are planted, or, if thought more desirable, Plums, Cherries, Pears,

pending two or three Strawberry nets from the front plate immediately under the spouting, allowing them to remain till the danger from spring frosts is past, and then permitting one to remain to protect the fruit when ripe. By these means the great expense and continuous labour of providing and manipulating movable blinds or canvas coverings are obviated, ample ventilation and light are consequently secured, climatic conditions nearly similar to those of Southern Europe are obtained, and not only can every tree, branch, and leaf be conveniently inspected, but the necessary work of pruning, training, and cleansing can be performed in any kind of weather without the least inconvenience to the operator.

It may possibly be contended that the trees growing on the front trellises obstruct too much air and light from those growing on the back wall, but experience has proved that such is not the case, and in bright seasons similar to the two last this very partial shade is decidedly advantageous. It may also be objected that the trees growing in these arcades require to be frequently washed and watered, and this is undoubtedly the case, but not more so than trees fully exposed require to be. This apparent disadvantage is more than counterbalanced by the means these arcades afford of withholding water either to the roots or leaves when deemed desirable either for the preservation of the fruit or the due ripening of the wood, especially as the roots of every tree are restricted to the enclosed area. These fruit tree arcades are found to be equally suitable for all aspects as well as for each kind of fruit tree. They completely change the appearance of the monotonous and sometimes unsightly garden walls, and when fully furnished with trees and fruit, represent a money value which, when compared with former systems, is very favourable. When viewed from any point or at any period of the year they do not offend the eye, and when the trees are either in flower, leaf, or fruit, they form arcades of beauty that are charming and picturesque. VISITOR.

Challis's fruit tree arcade. From a photograph sent by Mr. T. Challis, Wilton House Gardens, Salisbury.

are arranged at intervals of 8 feet from each other parallel to the wall. Light cast-iron spouting is fixed to the front plate immediately under the front edge of the glass, down shoots being arranged at intervals of 80 feet so as to convey the rain-water from the coping either into the outside border or into drains, as deemed most desirable. At the base and on the inside of each support are planted the best late and the more tender varieties of Pears, or, if desired, Apricots, Plums, Cherries, Gooseberries and Currants may be so planted. The central shoot from each tree is trained up the

Gooseberries or Currants may be substituted. These trees are trained horizontally to the right and left and are allowed to grow to each upright support where they meet. The branches of all these trees are trained on the cordon system, being pinched or pruned as close as practicable consistent with fruit-bearing, so as not to obstruct the air and light too much from the trees growing on the wall.

It is at once quite evident how conveniently these trees can be protected from the effects of spring frosts, as well as from the depredations of birds when the fruit is ripe, by simply sus-

Grape Gros Colman on Foster's stock.—In his excellent article on early and late Grapes, Mr. Iggulden advises those who may have hitherto failed with Gros Colman on its own roots to try it worked on Foster's Seedling. That his advice is worth taking is proved by the splendid Vines a friend of mine has inarched on that stock. Not only are the bunches long and large—much longer than is usually the case when the Vine is on its own roots—but the berries are of immense size, many of them quite as large as Orleans Plums, and the colour in September is invariably that of the Damson. Other plants of this Grape on their own roots in the same range of vineries, although bearing very creditably and finishing fairly well, are not to be compared either for fruitfulness or general quality with the grafted ones. The house, a lean-to, is not started till the beginning of March, and then for economy's sake only a very little fire-heat is given, the house being closed with plenty of sun-heat when growth becomes active, and yet the Grapes are always black early in September.—B. S.

Apple Stirling Castle for small gardens.

—Mr. Iggulden does good service in bringing this invaluable Apple to the notice of readers of THE GARDEN. In spite of its prodigious cropping character and all-round merits, it is seldom mentioned either in reports of fruit crops or general correspondence. I believe it is more commonly met with in Scotland than in England. I think it has been ignored for orchard planting in standard form on account of the slow growth it makes, but the trees may be planted thicker than ordinary varieties, and in fairly good soil they form neat, compact heads. Probably bush trees of Stirling Castle are as profitable as any, and no

grower for market who contemplates planting should omit this variety from his list, as for small gardens and amateurs Stirling Castle is, as Mr. Iggulden remarks, invaluable. Whether in bush, espalier, or cordon form the trees crop regularly and heavily; so much so, in fact, that unless timely thinning of the fruit is resorted to the trees soon suffer and growth becomes stunted. The individual fruits are of fine shape, though just a trifle flat, skin very smooth, and excellent either for cooking or exhibiting.—C. N.

Late Raspberries in East Anglia.—A few years ago I referred to the excellent supplies of Black Currants and Raspberries in Norwich market late in the season. This I attributed to the climate and the close proximity of the market gardens to the sea coast. This season, in spite of its tropical character, is no exception to the rule of a late supply, as in Yarmouth market on September 9 quantities of excellent Raspberries, as well as Red Currants, were offered for sale, and, needless to say, found ready buyers. Probably it is the autumn fruiting varieties which produce these extra late consignments, but I do not think they could be found in any quantity elsewhere so late in the season. I have, however, previously expressed the opinion that market growers stood in their own light by not turning attention to the production of late small fruits generally. By a little careful study as regards varieties, aspect and general treatment, not only Raspberries and Red Currants, but also Gooseberries might be forthcoming at the date above-named and substantial returns realised.—J. C.

The Logan Berry.—This deserves to be far more widely known than it is at the present day. In habit it partakes somewhat of the Bramble, throwing out from its base, long, vigorous trailing growths clothed with dark green foliage. The berries are of great size, long and rather tapering, of a dark red colour when ripe, and of a very agreeable flavour. It is very suitable as dessert, but more especially is it useful for preserving. The fruit is produced in bunches in great profusion, on wood made the previous year after the habit of the Raspberry. It gives a supply lasting from three weeks to a month, and that period could be considerably extended, by planting on walls facing north and south, &c. It seems to thrive on almost any soil, and is a useful adjunct to either the cottager's garden or the mansion. It is being tried on the estate here as a covert plant, and from what I saw of small bushes planted the previous autumn, will answer the purpose admirably. They had made a quantity of strong leafy growth running away in all directions, while the fruit is readily eaten by the birds. In gardens the best method is to plant at the base of a wall or fence about 12 feet apart. The wall need be no higher than 5 feet or 6 feet. After the fruiting season is over all the old wood can be cut away, and the young wood for next year's fruiting be laid in, in a horizontal direction along the wall. Care should be taken not to tread on the young growth during the gathering season, as it is very apt to get under the feet and be bruised.—P. S. FOLLWELL, *Alwick Castle Gardens.*

Gros Maroc and Gros Colman Grapes.—I was somewhat struck with the opinions given in the reply on early and late Grapes (page 227), particularly as I had only just read some remarks by a well-known gardener in a contemporary, which presented a peculiar contrast to the views of your correspondent. Mr. Iggulden speaks highly of Gros Colman as a late Grape, asserting it to be far ahead of Gros Maroc so far as quality is concerned. The writer in the contemporary referred to states that Gros Maroc is fast taking the place of Gros Colman as an exhibition Grape, because it colours easier and is superior to it in point of flavour. Here we have two statements flatly contradicting each other, and what wonder then if the amateur is puzzled when experts disagree to such an extent. It appears to be another of those instances where circumstances alter cases, and where the conditions of cultivation have marked bearing on the result. It will be news to many to know that Gros Colman is better

when worked on Foster's Seedling stock than when on its own roots; but it is quite reasonable, for, as is generally admitted, the stock has influence over other kinds of fruits. Why should it not be so with Grapes? As regards the qualities of the two Grapes under notice, I do not consider either of them equal to Lady Downe's, and appearance in most instances is their chief recommendation. In comparing the two it is evident that opinions differ widely. Gros Colman is certainly a fine-looking Grape and its flavour must vary considerably, as I am afraid there are few who can from experience give the Grape so good a recommendation as Mr. Iggulden does. In size, colour, and shape of bunch Gros Maroc is, in my opinion, ahead of the former, and if asked to give a note on the flavour, I should be obliged to record in favour of Gros Maroc, though certainly I have not tried Colman on the Foster's Seedling stock. It would be interesting to learn whether other growers who are also readers of THE GARDEN can champion the cause of Gros Colman as one of the best late Grapes in cultivation. It certainly is not generally recognised as such.—G. H. H.

PRUNING APPLES AND PEARS.

I THINK as a general rule close pruning, such as must be practised with espalier and wall trees of Apples and Pears, will be much less in evidence in the future than it has in the past. Closely pruned trees will be kept in their proper place, and that is where there is not room for a more rational and natural form of training. Some of the advocates of espalier trees cling to them because of the few fine fruits that such trees occasionally produce, and there is, of course, something in this, but as a matter of fact the produce of properly pruned trees grown under less restrictive methods is very little behind that of espalier trees, if any; while a tree, say, six years planted and allowed its head will give more than double the amount of fruit an espalier tree of the same age will. Either form of tree if properly treated will go on and improve after this for a number of years, but a year or two of neglect in the case of espaliers or other tightly-trimmed trees will do far more mischief than in the other case, as many of us have found when taking charge of a neglected place. Yet there will always be positions where espaliers are useful, and it is necessary to study these rather carefully from the pruning point of view.

There is a great want of thought in the manner these are treated and the barbarous methods of pruning that have so long been practised have done more than anything else to bring espalier trees into disrepute. A man is told off to do the pruning, and he snips off every branch as he comes to it to within a couple of eyes of where it started the previous season. In many cases he cuts off fruit-spurs and all to make what is considered a tidy job of it, much as he would trim up a Quick or other hedge. Such methods, of course, need no condemnation from me, but there are others who prune for fruit all right, but allow their trees to push elongated ugly spurs, and by never thinning these gradually get them into a close, thick mass. Small and indifferently flavoured fruit follows, especially if the variety be one that requires room like Blenheim Orange and Bramley's Seedling Apples or Williams' Bon Chrétien Pear. Such kinds as grow very strongly are the least suitable for this method, but by proper pruning of roots and branches may be kept in check so that they give a few good fruits. At the first it is wise not to let any kind of Apple or Pear that has to be afterwards restricted grow away too quickly. Form the branches gradually, and so ensure a uniform number of young growths—afterwards fruit-spurs

—along their entire length. Bare places once caused along the branches can never be filled up, but when there are too many spurs it is easy enough to thin them, and the branch at that point always shows a disposition to throw out fresh shoots, which may be made use of if necessary. As regards the actual work of pruning, it is the worst of mistakes to do it by rule of thumb. If a prominent and healthy-looking fruit-bud appears a few joints farther up the shoot than one really wants to leave it, there is no harm done by letting it fruit and cutting it away the ensuing year. But in the formation of the fruit spurs that are to be permanent in a manner, it is very important that no more are left than can obtain ample light and air, and in pruning for these a sharp knife must always be used, never secateurs, which, unless they are in the best of order, bruise the bark. As a rule the stronger the breastwood the longer the shoots may be left at pruning time, but the spurs in this case will naturally elongate more quickly, and in consequence the work of thinning down and renewing these will have to be begun early. They should never be allowed to get so numerous or so long that the sun cannot reach the main branches, otherwise these lose their power of recuperation to a large extent and weak, spindly shoots or none follow the removal of old spurs.

But it is a constant fight against Nature this pinching and cutting back of wood, and where there is room to let the tree grow in accordance with its own will, good results are surer and longer continued. And the work of pruning here is practically *nil*. There are unruly shoots occasionally that take too much of the energy of the plant to the depreciation of the others, but if noticed in time and pinched the temporary check diverts some of the sap to other parts where it is needed, and by causing the shoot to break into two or more prevents grossness. When it is quite obvious that nothing short of root pruning will check the trees, then get at them early in autumn just before the leaves have all fallen and do it thoroughly. Owing to a very short crop of fruit most of my young trees are growing quite vigorously enough this year, but I see no need of interference, and I am sure that from about fifty trees, three years planted, I shall not take an ordinary hand basketful of wood. All they need is a few thin weakly bits removed, for the soil is firm and only moderately rich, consequently the wood though strong is hard and fruitful-looking. H. R.

Pear Triomphe de Vienne.—For some years I have grown this as a cordon, but have never been able to obtain such fine fruits as Mr. Woodward staged at a recent meeting of the Royal Horticultural Society, and which received an award of merit. I am not sure that the best mode of culture for this Pear is a restricted form such as is necessary with cordons, as the tree is a strong grower and the continual stopping is detrimental. Those who have grown it as a bush or pyramid will doubtless have obtained much better results. No one who needs a good early Pear will regret planting Triomphe de Vienne. Fruits grown in the open have the best flavour. I do not know in what position Mr. Woodward's fruit was grown, but there was no question as to flavour, the fruits also being large and handsome. This Pear will be found useful to follow Williams' Bon Chrétien.—S. H. B.

Apple Red Beitingheimer.—It would be very interesting to learn how this variety of Apple succeeds in other parts of the country. Here it is a success, and the one tree I have has produced some remarkably fine specimens this season. In former years the fruits have been what I have considered to be large in size, but

this season they have quite eclipsed all that have been previously produced, both for size and colour. The smallest specimens have not been less than half a pound in weight, while the generality have scaled from three-quarters to one pound each. If it succeeds elsewhere as well as it does here it should prove a profitable early cooking Apple to grow for market, as it possesses both size and great depth of colour, two most important requisites for market work. The tree I have is growing on a heavy red loam some 3 feet in depth, beneath which is a solid bed of the old red sandstone. The tree may be described as a free-growing bush, and beyond keeping the branches thin and properly regulated and pinching in spur-growths in summer-time it receives no other pruning beyond shortening the leading growths back somewhat during the winter months.

early in September. The fruit does not hang long after ripening, and, in consequence of this, during seasons of glut they are of little value to the growers. Plums this season, however, have been most erratic. In most districts the crop has been very light, but there are here and there a few exceptions where trees of the Kentish Bush Plum have been laden almost to breaking point. In these fortunate instances the returns have been favourable, and the growers have realised the true value of this old and common kind.—H. H.

Pruning Vines.—It is a much debated point whether it is advisable to half-prune Vine laterals now or leave them the full length until pruning time proper comes round. The usual idea is that the shortening helps to plump up the basal eyes, but I am doubtful if much good is done thereby.

one season may be closely pruned the next, but the heavier the crop one year, the more latitude must be allowed in that ensuing.—A GROWER.

Caterpillars and Gooseberries.—Your correspondent, Mr. Iggulden, in an interesting article on the Gooseberry mentions the cuckoo's fondness for caterpillars. I am afraid, however, a cuckoo is too erratic a bird to make himself useful in a garden. This year in July I observed that some of my Gooseberry bushes were attacked by caterpillars. I at once purchased some hellebore powder, and the next day was about to use it when I found that the caterpillars, instead of increasing, seemed to have for the most part disappeared. The reason was soon plain; a twitter in a tree close by showed me a blue-headed tom-tit, and he was carrying a caterpillar in his mouth to his nest. In a few days the bushes were quite free from caterpillars and the hellebore not required. I cannot say anything in favour of this tom-tit's kinsman, the black-headed coletit, which is a dreadful pest in a garden, devouring green Peas and spoiling fruit.—J. H. W. THOMAS, Belmont, Carlou.

LATE APPLES.

MANY present-day planters of Apple trees have wisely decided to include a good percentage of late-keeping varieties, and such seasons as the present must convince us of their value. Early and second-early sorts, particularly those of the Codlin section, are this year behaving very badly, several Apple vendors I have spoken to assuring me that no sooner are consignments stored than decay sets in, rendering them unsaleable. It seems to me that what is wanted in new Apples is a few good firm cooking sorts that will succeed the Sutfield, Grosvenor, Oldenburg, and Ecklinville types and remain in usable condition for a couple of months until the actual winter varieties, which need time to develop flavour, come into use. As far as really late varieties, or those usable, say, from February to May, are concerned, everyone at all versed in the culture and sale of Apples well knows that even in what are termed good Apple seasons it is at the above-named date that sound good tart and sauce varieties fetch the price. Yet, strange to say, in provincial towns at least, one has in the majority of instances to be satisfied with Baldwins and other imported sorts at the new year. There are a few so-called late Apples which, although prodigious bearers and most useful over a limited period, are by many planted far too freely. Lane's Prince Albert, for instance, one word against which will, I doubt not, be by many deemed heresy, is never a firm Apple, and although I have kept it till the middle or end of April, and outwardly it has shown no signs of deterioration, it loses weight and quality in March and needs an injurious quantity of sugar to render it palatable.

I am convinced that some of the very old sorts which seem to be elbowed out of cultivation would still pay well to grow. Mère de Ménage is a grand solid cooking Apple which keeps its weight longer, I think, than any Apple I know, but, according to my experience, it is, like Bramley's, very uncertain as to when it will commence to bear—at any rate as a standard-aged tree apparently being the most profitable. A few of the extra late varieties lack size, which is objectionable in the kitchen, the good old Sturmer being one, but what it lacks in size it gains in quality, the latter being so good, that one eminent fruit grower has pronounced it deserving of a wall. For pies or sauce I know of no better Apple, and that its constitution is hardy is proved by the fact that a tree I had in an orchard exposed to the blast invariably bore a crop in inclement seasons, when the majority of other sorts shed all their blossoms or cast their fruit in infancy. Another grand old keeping Apple is Hambleton Deux Ans. The tree forms a large, spreading head and lives to a great age. I saw it a few years ago in a Lincolnshire orchard, it

Challis's fruit tree arcade. Showing mode of protecting fruit. From a photograph sent by Mr. T. Challis, Wilton House Gardens, Salisbury. (See p. 353.)

The tree is a free grower, and seems to have a very hardy constitution. Perhaps some reader of THE GARDEN who grows this variety will kindly relate his experience of it and express an opinion as to its merits, as no doubt there are others as well as myself largely interested in fruit culture who would be glad to know how it succeeds elsewhere.—A. W.

The Kentish Bush Plum.—This is a very popular Plum for market in Kent, and is extensively grown in nearly all parts. Generally speaking, it is a prolific bearer, and though not of high quality, it is good for cooking and preserving. The trees are grown in orchards and plantations, and often they may be seen planted closely together in rows as a protection for hop gardens and patches of more tender fruits. The fruits are round, purple when ripe, and fit for gathering

It is a good way of getting rid of some of the leaves out of the way of Chrysanthemums and other plants, and may in the case of Vines allowed to run wild do a little good in other directions, but where the laterals were pinched at a suitable length and the sub-laterals kept well back to single or two eyes there is really no need of it. Where, as is sometimes the case, the back leaves have fallen, *i.e.*, those nearest the main rod, then no harm is done. In fact, the Vines may be properly pruned back if more convenient, this resulting in an early and complete rest, especially good for such as are forced early. There is no need to prune back so closely as has often been done in the past, for although Vines may be kept tidier, the chances of getting a regular crop of fine bunches after carrying a heavy one the previous year are lessened. Vines lightly cropped

being the sheet anchor of the fruit room from March onwards. Why has the late Apple of our forefathers, Rymer, been almost elbowed out of cultivation? I have seen my father fill hampers with it in Essex to send to his employer's town house in the late spring months. Colonel Harbord's Pippin is a fine variety for extended planting, the trees, large and weeping in character, being every year laden with medium-sized firm fruit of first-rate quality. It is a purely local variety, but I hope it will eventually find its way into all gardens. Other late sorts which work with every confidence be planted are Norfolk Beautin, Yorkshire Greening, and Hanwell Souring. J. CRAWFORD.

NOTES ON THE CRYSTAL PALACE FRUIT SHOW.

I WILL first take the judging by way of showing that, though a person may stage the finest examples, this is no guarantee that he will receive the highest awards. The Royal Horticultural Society, who issue rules for judging, should be careful to employ competent men. I will point out a few of the most glaring blunders. A person to be a competent judge of fruit ought to know each variety, its merits and demerits, so that he could form a comparison. Take single dishes of Pears first, and in looking down the tables note Baurré Diel. It is generally understood that the award should be made to the cleanest, best-grown specimens. The lot that took first prize was certainly a fine dish, but they were coarse and some of them a little specked, while those awarded second prize were a very fine, clean, well-grown lot, and, in my opinion, ought to have been placed first. I should like to know the opinion of other competent judges on this point. It is very strange that while Pears are given every encouragement to be shown coarse and large, the Royal Horticultural Society should put themselves out of the way to state that certain Apples must be small, well-coloured specimens. In the case of Blenheim Orange Apple the wording of the schedule was such that the judges were to make the award to small, highly-coloured specimens. Now all gardeners should know that such can be gathered off trees that are in a very sickly condition, or that have been watered with a solution of sulphate of iron, but such fruit does not possess the flavour of a natural grown specimen from a healthy tree. It would seem that the society has gone from one extreme to the other here. One could hear that the judges differed very much as to this class; they had undoubtedly acted in accordance with the schedule in giving the award to small specimens. It is difficult to account for people's tastes, but the Royal Horticultural Society seems to have peculiar ones over this variety. Some years ago they encouraged the production of large specimens, then they discarded them from the dessert classes both in single dishes and collections; now they say small inferior fruits are admissible so long as they have colour, no matter what their flavour. One more point before leaving the Apples. In not a few instances was fruit wrongly named, and some dishes contained more than one variety. In looking over the sieves that were packed for market, much astonishment was expressed at the way some of them were heaped up. It was impossible to send such by rail without having the fruit bruised when one hamper was placed on the top of another. To pack for market, no fruit should be higher than the side of the basket, or it is liable to get bruised. The aim of the Royal Horticultural Society is undoubtedly right, but it is very misleading to those who visit this great show with a view to seeing the most approved methods of packing to find that awards are given to packages whose contents are exposed to such risk. Much good has been done by these great autumn shows, and since the society has divided the classes so as to show what each county is capable of producing, there has been a greater inducement for people to compete. I will next take the show from a commercial point of view, and see what the shopkeepers and

general public have to say about these large specimens, which are chiefly bought to make a show in the first-class fruiterers' windows. Being too large to be sold by measure, they are not much sought after. What is required is nice even-sized specimens of from 6 ozs. to 8 ozs. each in the cooking varieties, and from 2 ozs. to 6 ozs. in dessert kinds. Cox's Orange Pippin when well grown is a first-class variety, not too large, and the same may be said of Ribston and others of a like size. Packing to be effectual should be done in such a manner that the fruit can be examined without handling. The fruit, too, ought to be of even size, then, if packed in boxes that will hold just half a bushel containing only two layers, these could be exposed in the shop windows, and would therefore save much handling. Cheap, light boxes similar to those used by the salesmen in Covent Garden for Peaches would be far preferable to the old-fashioned wicker sieves, as these bruise the fruit even when paper is used. It would pay to devote a little more attention to this branch, and if the cost of box were added to the fruit, the purchaser could then please himself as to returning it. None of the examples exhibited presented that neat and tidy appearance one could wish. Why not give prizes for the neatest packed 12-lb. box of choice Plums, and, again, for 24 lbs. of four varieties in so many boxes, the same for dessert Apples and Pears? It is not always the length of journey that should be taken into consideration, for half a dozen or a dozen packages might be put into a train at Edinburgh or Glasgow and would not get shifted until they arrived in London; whereas in going only a short distance on cross country railways they are transferred several times, often wheeled a considerable distance along a platform with other luggage, and stood on their ends or sides, so that distance is not always a criterion to go by. The Palace in some respects is a good place for holding such an exhibition, but it is so out of the way, that too much time is taken up in getting there. C. P.

CLEANING FRUIT HOUSES.

THERE is no greater hindrance to the proper cleansing of Vines and fruit trees under glass generally, and the houses in which they are grown, than the very prevalent custom of flowering nearly the whole of the stock of Chrysanthemums in these structures. To do the cleaning properly of any house, everything else but the permanent trees or Vines should be cleared out. I always begin by having the whole of the trees untied from the trellises, whether these are on the roof or across the house, and the heads are then tied into loose bundles to facilitate getting between them. Rough trellises or boards are laid on the borders, as unless this is done the surface, after getting wet, is trodden into a pasty mass. The roof-glass and rafters should be soaked with water from the syringe or the hose and then be scrubbed with hot water in which soft soap and a little paraffin have been dissolved. Another good soaking of water applied with a good force clears off any chance insects and dirt that remain. All the joints of iron tie rods or trellises should be very carefully attended to, and where it is impossible to get the scrubbing brush in, a small brush should be dipped in turpentine or paraffin and well rubbed in as far as possible. Great care is necessary in using either of these that none is allowed to drop about on the trees. Both are excellent insecticides, but have often worked mischief in careless hands.

At the winter cleaning of Vines, those that were badly infested with red spider should come in for the most drastic measures. Much as I dislike skinning the rods when there is no need of it, it is safest to remove most of the loose bark in these cases, for it is not easy to reach the insects when hidden up under this. Soft soap and sulphur, with a liberal addition of tobacco water if thrips are present, is one of the best winter dressings for Vines. I am not in favour of painting the rods with soot, clay, and other nostrums. The soft soap and sulphur should be thoroughly rubbed

in two or three times, or even more if the insects have been numerous, and with an old blunt pruning knife the loose material from about the old spurs may be removed. Careless pruning of Vines in the early stages has much to answer for in the way of forming a harbour for this troublesome insect. So has planting immediately behind hot-water pipes, where it is difficult to get the hand or a brush to work. These two points should be kept in mind by those planting or pruning young Vines.

Peach trees are even more troublesome than Vines to properly clean, the soda and potash mixture, now well known, being a very useful wash for these either inside or out. It may be used at its full strength for the main branches and stems of the trees where the bark is hard, but it should be weakened considerably for the small green shoots. Careful use of this alone has completely cleared of red spider and scale an old tree of Noblesse that was formerly outside and had a house built over it. The Fig trees under glass are especially subject to scale, and I know of no better way of getting rid of it than by washing with the mixture mentioned and keeping the syringe going at every suitable opportunity while the trees are in growth. All brickwork and other walls should be washed with hot lime. H.

LATE FIGS.

THE value of nice dishes of late Figs is considerable, and most of us are glad of them for dessert at this time of year. I was struck with the generally poor quality of the fruits shown at the Crystal Palace, for, whether grown outside or in, the Fig is so valuable, that it should have due attention to feeding at the roots in order that late fruit may swell up properly and be of good quality. The majority of gardeners perhaps make a mistake in just the opposite direction where they have Figs under glass, and with the idea of swelling off as many as possible of the second crop, apply considerable heat just now when the trees should be steadying down for the winter. For the last two months I have been sending in dishes of Brown Turkey, large, well-ripened fruits from the earlier parts of the new wood, and there they will go on until the fall of the leaf. Yet nothing has been done but to lightly feed the trees with liquid manure after each watering, and the wood for bearing next season is just of the right class, hard and short-jointed without being starved or puny. There is no comparison between wood of this class and that with weak foliage, caused by giving heat and moisture thus late in the season. The effect of overcrowding, too, at this time of year will be only too manifest in spring. I have often been in Fig houses at the end of the year where it is almost impossible to see through the thick mat of foliage overhead. The consequence of this is that the late Figs now being produced do not get proper light and are therefore of poor flavour, while the wood does not finish properly, and therefore produces small, inferior first crop fruits in spring.

To prevent this occurring it is not too late yet to assist the ripening process by thinning out the wood, carefully reserving that which is best placed and which by its position seems most likely to develop properly. Few fruits, if any, will form after this date, and in such a case as the above it will be wise to remove the whole of the fruit now that is too large to stand over the winter—any, in fact, of which the shape can be clearly seen. Respecting the injury supposed to be done to the trees by allowing the late fruits to ripen as described above, this is simply alarm on the part of cultivators. It is quite natural for the Fig to ripen this crop of fruit, and, provided there is proper plant food in the soil and the trees are healthy, not the least harm is done. H.

Apple Manks Codlin.—Referring to this Apple, an illustration of which appeared on page 226, I am surprised it is not met with more frequently, as it appears to be one of the most

useful and reliable Apples we have. For many years I grew it as a half standard in an orchard situated in an exposed locality in the midlands, and it was one of the few sorts that never failed to bear. As a bush tree it does not appear to answer so well, as a market grower in Kent recently informed me that with him Manks Codlin as a bush was so unsatisfactory that he had cut all the trees back and worked another variety on the stems. My experience exactly coincides with Mr. Iggulden's respecting the meagre growth, which I agree with him is owing to habitual heavy cropping. On this account trees may frequently be seen bearing fruit not more than half the normal size, and I have found that to get really fine examples of Manks Codlin the fruit must be judiciously thinned. The Apple is often used direct from the tree, but it is by no means a bad keeper.—G. H. H.

Peaches in Sussex.—After the adverse opinions in the spring, that the Peach crop was to be a failure owing to the severe frosts when the trees were in bloom, one is happy now to look back and report the crop to be over the average. Our trees had 17° of frost in succession when they were in full bloom, but owing to a protection of double fish-net and one thickness of tiffany, no damage was done. I think the covering had a double effect, keeping frost off the trees in the first place and afterwards keeping the early sun off, which generally does more damage than the frost itself. Without a single exception our trees have carried full crops of good quality and with exceptionally few split stones. The outdoor Peach season has been a long one. I gathered Amsden June and Alexandra on the 8th and 9th of July and Salway in the third week of October. Those readers that have not given the Salway Peach a trial should do so. The plant, which is young is on a south-west wall and has carried some 160 fine fruit. The fruit is of a good size, well coloured, and of excellent flavour.—W. RUSHTON, *Cowdray Park Gardens, Midhurst.*

NOTES AND QUESTIONS.—FRUIT.

Late keeping Apples.—I find that all kinds of late keeping Apples were very much more affected by the drought than early sorts, for all the Codlin type swelled out to a good size, but late keepers, such as Wellington, refused to swell even where they were kept well watered.—J. G.

Apple Bismarck.—The majority of large Apples are deficient in colour, but this has both size and colour to recommend it, and, moreover, it is one of the most regular croppers that we have, for although the past few summers have not been anything like good Apple years, the trees of this variety have not failed to carry a good crop. It is especially suited for growing as a dwarf bush tree.—J. G., *Gosport.*

Pear Beurle Bosc.—This variety must vary considerably in different localities, for many gardeners give it a very second-rate character, but with me, on a light, warm soil, it is one of the surest croppers that I have, and as to flavour, very few Pears give more general satisfaction. It makes an excellent bush or pyramid tree, and the long russet fruits are even better flavoured from these than from wall trees. In the market few sorts find a more ready sale, for when not overcropped it produces fruit just the size for the retailer.—J. G., *Gosport.*

Peach Desse Tardive.—A tree of this Peach occupies the back wall of a Peach house at Blickling. It has done good service in the past, but is now on the wane. Mr. Ocle, however, has decided not to discard it, but to lift the roots and relay them in fresh, sweet compost with a view to giving the tree a new lease of life. It is a variety deserving greater attention—in fact, one of the best late Peaches for flavour. It was sent out by the late Mr. Rivers' father many years ago. Under good culture Desse Tardive grows very large and is of very striking appearance.—NORFOLK.

Pear Clapp's Favourite.—I think it was "A. W." who recently spoke well of this large, handsome Pear. He appears to have been more successful with it than myself. I once had a tree in a pot which produced a few extra large, very showy fruit, but another on a sunny wall grew vigorously enough, but never produced a single fruit. The tree was not by any means gross, so as to need root-pruning, but it

failed to form bloom-buds. I am of opinion that Clapp's Favourite is not what may be called a general Pear—at any rate, one seldom reads of it in reports of fruit crops. All the same, when at home it is a useful autumn variety, though short-lived.—C.

Plum Winesour.—I have frequently referred to the value of some of the reliable latest sorts of Plums, so invaluable are they to the private gardener, and no less profitable to the market grower. To-day I saw on a hawker's cart what I believed was a sample of the true Winesour. The fruits were large individually for that variety and apparently in splendid condition. It hangs well, and, indeed, improves up to the second or third week in November. The tree is hardy, invariably crops well, and the fruit is also valuable for jam. I think market gardeners lose much by not planting this Plum more extensively.—NORWICH.

KITCHEN GARDEN.

NEW VEGETABLES.

ALTHOUGH there will never be cessation to the efforts of raisers and seedsmen to introduce new varieties of vegetables, for new kinds seem to be almost out of the question, it does seem just at present as if there had been something of a lull in the rate of progress or of production previously seen, and that resting was the policy. It is possible that some persons may take exception to this aspect of production in novelty on the ground that they have put this, that, or the other into commerce; but the mere act of doing so does not constitute absolute novelty or distinctness. Even in the Tomato there is practically little that is new. The most marked variety as novel is that beautiful lemon-coloured sport from the Red Peach, which originated at Chiswick, and will be issued to the Fellows in seed shortly. Probably a good deal will be heard of this Chiswick Peach Tomato presently, as it exhibits the best of flavour the fruits produce. The small fruited but immense cropping Glory of Italy is a remarkable variety to grow by those who like the small fruited. Peas seem to have had made to them no notable addition. So wonderfully good are these now, that something remarkable as a cropper is needed to excel the older varieties. Certainly nothing remarkable has cropped up during the year, although there has been no lack of ordinarily good seedlings. Potatoes again show little advance, the two varieties that received awards of merit after trial at Chiswick, The Sirdar, of tallish form with rather deep eyes, and Ellington Seedling, white, having pink eyes, whilst good croppers, were yet not better than many others, but were fortunate enough when cooked at Chiswick to show very fair flavour. In what direction it may be found possible to materially improve Potatoes except in getting into them superior flavour it is difficult to say. The Potato still stands practically alone amongst tuberous roots as edible vegetables. Jerusalem Artichokes, even with the addition of the white-skinned variety, remain just about what these products were fifty years ago, and the *Stachys tuberosa* and *Oxalis crenata* do not promise to ever make popular table products. We are just where we were with Carrots, Parsnips, Beets, and even Onions, for recent introductions have added nothing of value to our stocks. We have nothing better for large bulb production than Ailsa Craig. Large bulbs have so much of the Red Tripoli bluen in them that they soon become worthless, even if they do not crack and split out of doors. A much-vaunted flat Onion has proved to be but a reproduction of others precisely alike to it. We still grow Celeries several years in commerce, and which none new excel, and the same may be said of Leeks, also of Turnips, Lettuces, Broad and climbing Beans, and in-

deed of dwarf ones it is doubtful whether any newer ones excel standard varieties like Ne Plus Ultra, Magnum Bonum, White Advancer, or Canadian Wonder. One or two new Cucumbers have been introduced quite excellent of their kind, but they do not exhibit any advance on the varieties that have been three or four years in commerce. Generally there is stagnation in the production of novelties, and no harm is done that it should be so for a time. During the past twenty years there has been great advance, always made slowly. But that great advance renders further advance now all the more difficult. A. D.

Tomato Up-to-date.—For freedom of cropping this is deserving of mention, even though there is such a host of varieties to choose from. In a market nursery visited during the autumn this variety was very highly prized, both because of its free-bearing and smooth fruits, which are of medium size. Many kinds set their early flowers well, but when they advance in growth there is a falling off in the number of fruits on individual trusses. This did not happen with Up-to-date, but, if anything, they were more freely borne on the later trusses. I was so impressed with its all-round merits that I decided to give it a trial another year, and I advise those desirous of growing a good Tomato to do the same.—S.

Cauliflower Veitch's Autumn Giant.—In common with many another good and popular vegetable, this fine Cauliflower is not always kept true, and on several occasions this year I have seen the result of sowing poor strains of seed. The cultivator is at the mercy of the seed merchant in this matter, of course, and though firms of repute doubtless do all they can to grow and purchase clean and true stocks, there is no criterion. But, taken all round, few kinds have stood the test much better than Autumn Giant, and it has now taken its place with what may be termed standard kinds. Over-large Cauliflowers are a mistake, and if grown on very rich soil those of Autumn Giant are apt to be too big, but, given firm soil in good heart and an open position where they grow quickly, the quality is excellent. Many of us have perforce to grow Cauliflowers between rows of other plants, and these in such positions are never so good as where a crop, say, of the earliest Peas is cleared off and the plants allowed all the ground. The seed should be sown in March, and as soon as in the rough leaf the seedlings should be transplanted to firm soil, eventually planting with a crowl on well-prepared land. The produce is very useful from early in October till December.—A GROWER.

Coal ashes for Potatoes.—The value of coal ashes for Potato growing is very small, as "G. H. H." points out on p. 320, and for producing scabby-surfaced tubers there is nothing that can equal them. I had an object-lesson in this way from a gardening friend when living in Hampshire not likely to be soon forgotten. He had an ambition to grow Potatoes for show, and accordingly obtained a collection of the best sorts for that purpose, and prepared his ground well by trenching and manuring. When planting he opened deep drills with heavy drag hoes, and, as he thought, to make success a greater certainty, he scattered a quantity of screened ashes along the open drills prior to covering them. The haulm growth was very fine, but out of all that he had planted he failed to find one single dish of tubers free from scab, and he was so disappointed that he banished the idea of Potato competitions from his mind. In the same ground he had previously grown beautiful clear-skinned Potatoes, which had given rise to his ambition, but his zeal outweighed his judgment for once, at any rate. For improving the working of heavy or badly-drained land coal ashes have a great value, but they should never be freshly given to that which has to be planted with Potatoes. Coal ashes have no manurial value of themselves, but are useful

for mixing with night soil or other powerful manures to increase their bulk and so render them more safe to use.—W. S.

NOTES ON TOMATOES.

— I have not grown any that I like better than Hathaway's Excelsior, or Stamfordian. It is a good early variety, most prolific, produces large, smooth, round and heavy fruit. I think it a good winter sort, though the fruit does not attain the same size as in summer. Perfection is another good variety and very similar to the above; it is also good for planting outside. With me, well hardened off plants put out the beginning of June on a south wall grow from 6 feet to 8 feet by the autumn and produce fruit the whole length of the stem. Most growers have their own special sorts, but for general purposes I do not think the two foregoing sorts can be beaten. I should say the Tomato is decidedly a vegetable. Many persons eat it in a raw state, but I cannot see how it can be classed as a dessert fruit any more than a ripe Vegetable Marrow or Pumpkin.—H. FISHER, *Flixton Hall, Bungay.*

— I have found the old Tomatoes, such as Conference, Chemin Rouge, and Challenger, the best, but I can highly recommend Dickson's Crimson King. Although I have tried many other kinds, I have never found one to equal Early Ruby for outdoor culture. Superb is the best kind I have met with for winter and early spring crops. I consider the Tomato a fruit.—J. FITZ-SIMMONS, *Gaulston Park, Killnean.*

— The best Tomato I know is Chemin Rouge, and find nothing to compare with Dickson's Crimson King for outdoors. For early work I find nothing better than Dickson's Early Ruby. I consider the Tomato a vegetable.—T. MARSH, *The Gardens, Penhros.*

— I cannot find a better Tomato than Perfection. It is large, handsome, and has good flavour, also sets well. I use this more than any other kind, both inside and out. For early spring crop I find Polegate better than Perfection, as it does not produce such dense foliage, and therefore lets what little sun we have play on the fruit. I have discarded all yellow kinds. I think the Tomato should be called a fruit.—W. J. HARVEY, *Frampton Court Gardens, Dorchester.*

— For several years I have grown but little else than those of the Duke of York or Perfection type. They are alike good in colour, shape, and quality. There are others that set more freely, but the fruit is of inferior quality, and, taking all things into consideration, I have found none to surpass these. The yellow ones, as a rule, do not find favour with the cooks, though for my part I consider them equal, or even superior, in flavour to some of the coarse red ones. I have from time to time tried most of the recent introductions, some of which are enormous croppers, but their size and shape are inferior to those of the Duke of York and Perfection. My soil and situation are unsuited to the growth of the Tomato in the open owing to late spring and early autumn frosts. The soil, too, is heavy, and when there are heavy rains in the autumn the plants soon go off. The best variety I have tried for outdoor cultivation is Carter's Canadian Express. The fruit grows quickly and the plants are robust. It is a good cropper, but the fruit is too much ribbed to be of special value. None of the tender varieties will succeed at all with me in the open, as they grow too rank when the autumn rains set in.—H. C. PRINSEP, *Buxted Park, Uckfield, Sussex.*

— The Tomato is so extensively grown now-a-days, and there are so many varieties, that it is difficult to say which is best. My plan is to make a selection of the finest fruits and save seed for the following season. That is for the general crop. For free-setting and flavour I have found none better than Eclipse. There are plenty of varieties much larger in their individual fruits, but few of those are so solid, or yield the same weight per plant. For winter and spring crops, I have found Hathaway's Excelsior, which I grow

in 8-inch pots give capital results. The limited root run I consider an advantage towards getting a good set, and in winter the balls can be more readily kept at a uniform temperature and moistness, than would be the case where a greater body of soil is allowed. It is almost needless to try Tomatoes in the "open" in Scotland, especially in this part, the season is too short for maturing the fruits. I think as long as we have the Tomato cooked in so many different ways as a vegetable, we must class it as a vegetable, although, when speaking or writing we say the fruit of the Tomato. We are all accustomed to seeing Tomatoes in collections of vegetables on exhibition tables, but I have never seen a dish of Tomatoes staged in a collection of fruit.—J. MACGREGOR, *Clifton Park Gardens, Kelso, Roxburghshire.*

— Lawrenson's No. 3 put into commerce this season, is the best setting Tomato that has come under my notice. I have counted as many as 18, 19 and 20 in a cluster, all serviceable fruits, and for flavour it is everything that can be desired. I have grown this for the last three years. Hackwood Park, Ham Green, and Frogmore Selected are first-class. The best outdoor kind is Large Red. The best kinds for winter and early-spring are Frogmore Selected and Early Ruby. I consider a Tomato a fruit.—A. CUNNINGHAM, *Kirkclevington Hall, Yorks.*

— I have found Ham Green the finest flavoured Tomato, also free setting. Vick's Criterion and Austin's Eclipse are also favourite varieties and worthy of cultivation. I find Laxton's Open Air to be the most suitable for outdoor work. The varieties before mentioned are what I use here for early spring and winter. Most decidedly a fruit. I have always understood that whatever followed a flower was designated a fruit, though sometimes classed as a vegetable.—F. BOYD, *Callender Park, Stirling.*

— The best Tomatoes, I consider, are Eclipse and Perfection. They bear nice, even fruits, not too large, and are good croppers. I consider the Tomato a vegetable.—W. PRIEST, *Eglinton Castle, Irvine, N.B.*

— The Tomatoes I have chiefly grown for inside of late have been Glenhurst Favourite and Ne Plus Ultra. Both have done well with me. Outside I chiefly depend upon Stamfordian and The Trophy. I think from the number of people that have acquired the taste for uncooked Tomatoes we might term the Tomato a fruit.—W. MARCHAM, *Wentworth Gardens, Virginia Water, Surrey.*

— I consider that the old Perfection and the many kinds more or less distinct that have been selected from it are far superior in flavour to the smaller fruited kinds that are generally recommended for flavour. I mean those of the Dessert, Peach, and Currant types. The former have a refreshing juiciness and acidity that are peculiar to the Tomato, and although the taste for it may be an acquired one, it is more likely to last than that for the smaller and sweeter types. We have plenty of sugary fruits of better flavour than this class of Tomato, but nothing in fruit or vegetable anything approaching the former. Perfection is not a sure setter unless carefully grown, and very apt to come with brown tip, and, taking the two points into consideration, I should say that Conference, Eclipse, Earliest of All, and Hackwood Park are four of the best varieties in cultivation. Earliest of All is a fine outdoor kind, but slightly corrugated. For early and winter crops I should group it with Chiswick Red and the old Large Red. Although, of course, the Tomato is a fruit, botanically considered, and many people, including myself, appreciate it in an uncooked state, I think it would be going too far to admit it to a first-rate collection of dessert fruit. That is to say, it ought not to carry the same weight as a dish of good Strawberries. But when we see such things as unripe, home-grown Oranges and Citrons exhibited in otherwise good collections, then I certainly see no reason why a dish of nice ripe Tomatoes should be excluded. One is palatable and wholesome, but no one who had arrived at years of discretion would eat the other,

and unless Tomatoes were distinctly excluded from the schedule, I should give them the preference were I judging a collection of fruit. It is a fruit undoubtedly, and the time is bound to come when it will be recognised as such, and it is also a vegetable. A good dish should carry weight in a collection of either, but it must always rank highest as a vegetable.—H. R. RICHARDS, *Coldham Hall, Bury St. Edmunds.*

GARDEN FLORA.

PLATE 1247.

CROWN IMPERIALS.

(WITH A COLOURED PLATE OF FRITILLARIA IMPERIALIS LONGIPETALA.*)

THERE is nothing among bulbous plants flowering in the early days of spring that can equal the Crown Imperials in general vigour or robustness, to which also may be added their showy character and freedom of flowering. One of the things that surprises not a little those taking up their culture for the first time is the rate of their growth. In this respect these Fritillaries are quite unique when we remember that their bold vigour or stateliness is all put on in about a month or thereabouts. Seeing, too, that from well-grown examples—or in the case of freshly-planted roots, strong bulbs would be a more correct description—a stem some 2½ feet or 3 feet high is produced, a good idea may be formed of the progress made.

There is no difficulty in the culture of these plants, for their requirements are of the simplest description. There is, however, fear that late planting and using excessively dry roots may have something to answer for when at the end of a season successes and failures are duly recorded. To plant these things too early is impossible; to plant them very late without the best of reasons or absolute cause is quite unnecessary. Quite unlike a large number of bulbous plants, these do not require the same absolute rest even as do other species of the same group, while to long retain them in the dry state is to rob them for the time being of a part of their stature, and if unduly prolonged to produce blind growths into the bargain. Frequently has the experiment been tried to delay the flowering of these showy subjects, and strong-flowering bulbs have to this end been kept in the dry state till early in January. Instead of doing what was intended, the plants without exception flowered in their natural season, or nearly so, though at about half their usual height and strength. Nor can the loss be said to be complete here, as it is impossible for these long dried roots to perfect in the same degree the same vigorous roots for the year ensuing. I have mentioned these particulars to show that little or nothing is to be gained by any attempt to delay their flowering. Early to flower and early also in maturing, these Fritillaries may with impunity be planted quite early in July should occasion require. At this time, however, it is not possible to obtain supplies from the ordinary bulb merchants, who rarely receive the early supplies before August. This in the ordinary way would be considered quite early, and as a fact any time to the end of November may be taken as reasonable for making a start or planting a fresh plantation. The replanting of one's own stock should, however, be done much earlier. Any good and deep well-enriched garden soil will grow these things quite well, though I have

* Drawn for THE GARDEN by H. G. Moon in Mr. Elwes's garden, Colesborne Park, Gloucester. Lithographed and printed by J. L. Goffart.

never seen them more vigorous and stately than in the clayey soils of Gloucestershire. Here the established plants will reach 3½ feet high.

The bulbs should be planted quite 6 inches deep, and where this is done and room given for development, several years may pass without any disturbance being needed. The kind in the coloured plate to-day is that of a life-size flower with the crown of foliage at the summit. It is certainly one of the very finest of the red forms, of which several are in commerce. Besides this there are good self-yellow kinds and others with beautifully marked or variegated foliage, forming an additional attraction to these stately plants of spring. E. J.

THE WEEK'S WORK.

OUTDOOR FRUITS.

PRUNING.—Most of the leaves having now fallen, it will be advisable to push on with pruning and nailing on all favourable opportunities. The general rule in dealing with wall trees is to leave those on the north walls until last, but, out of consideration for the workers' comfort, I prefer to do these while the weather is still mild, and an early start enables one to spread the work over a longer period, so that there will be no necessity for carrying on work of this sort during very inclement weather. The favourite fruit trees for growing on north walls are Morello Cherries, and these if well looked after give the most satisfactory crops that can be produced in such positions. In pruning the Morello the best method is to cut away the weakest of the young wood entirely and leave the rest to its full length, for the spur system is not suited to the trees. When the weak and ill-placed shoots, including with the latter all foreright growth, have been removed, there is still in many cases too much wood left for the good of the trees, and crowded trees never carry the well-developed, juicy fruits that one likes to have. This crowding is best dealt with by the *holy* removal of some of the worst branches, *i.e.*, those which show signs of loss of vigour, after which the remainder will want regulating, so that the wall space may be covered with young wood at as nearly equal distances apart as possible. Before nailing or tying the trees they should be gone over with some insecticide, dealing lightly with the young wood, but scrubbing the insecticide well into the crevices of the old bark, and the walls, too, should be treated with something fatal to insect life, especially if they have not been lately pointed. No matter how thorough the cleaning of the trees themselves may be, the labour will scarcely be repaid unless the walls are also attended to, for there cannot be a doubt that the obnoxious insects which infest our trees during summer hibernate largely in the walls and not on the trees. When re-nailing, the operator should keep an eye to the natural trend of the branches and twigs, placing the shred so that whatever pressure there may be shall be towards the loop of the shred away from the nail. A lack of discrimination in this way, though a small matter in itself, frequently leads to after trouble, for with the pressure against the nail a nasty wound may be formed, and in trees like the Cherry, which are liable to gumming, such wounds rarely heal.

RAISING YOUNG TREES.—The home nursery should be an adjunct of every garden where fruit culture is carried out in the best way, as one can raise a great portion of one's young trees and have them at home and in good condition whenever there is any planting needed. I should like to plead for a good position set apart for all the purposes of a nursery. It is not sufficient to select an out-of-the-way corner hemmed in too much by walls or trees. A nursery ground should be well in the open, and the fact that so very few private nurseries are so placed is sufficient to account for

the unfavourable way in which home-raised trees compare in general appearance with those bought in from a good nursery, where the ordinary details of cultivation are supplemented by a good open position, where the roots have only their fellows to contend with and where the exposure leads to well-ripened wood. Supposing that some such satisfactory arrangement has been made in former years and that the best of the trees intended for planting this year have already been dealt with, the remaining work necessary will be to lift and regulate those intended to be left in the nursery for one or more years longer, root-pruning lightly all those which show a tendency to run far afield, as this will promote the more fibrous condition that one likes to see at the roots. In replanting keep the collars well up, allow plenty of room to each tree, and turn the worst side towards the south to regain the needful balance of branch growth. Trees lifted last year and intended to be planted out permanently next autumn will be best left alone till then, but the gaps in the rows made by taking out those planted this autumn should be filled up by the forwardest plants out of the next set. Younger trees such as those now at two years from the graft should also be treated in the same way, for trees which have been frequently transplanted while young make by far the best for planting and come into fruiting soonest. In planting the nursery stock, supposing the land to be in good heart, or rather that the soil is a good one, I would strongly discourage any manuring, as what is required is a firm woody growth as distinct from that of a gross and sappy nature, and if one imagines later that the trees are not growing freely enough, better results follow from a spring or summer mulching of manure than from digging it into the soil when replanting. The foregoing remarks are intended to apply to Apples and Pears in a young state, and before leaving these I must allude to the necessity of getting good stocks for grafting. For the past few years I have been in the habit of raising seedlings from Apple trees that appear to have the necessary attributes of a good stock, *viz.*, freedom of bearing, healthy and not too vigorous growth, and, lastly, well coloured fruits. I find that stocks so raised are preferable to seedling Crabs, which one can obtain from the hedgerows and from other wild places, but which are sadly mutilated about the roots in the getting. For Pears one may raise Quince seedlings, very slow of growth except in moist soils, or take rooted suckers from free stocks of trees which throw them. The latter are the best in dry soils if one can afford to wait for fruit, but the merits of the Quince in the way of producing early fruiting trees cannot be denied. The latter stock may also be raised from suckers; indeed, this is the usual way, but I prefer seedlings, and once one gets into the habit of sowing a batch of these things yearly, the apparent delay vanishes after a year or two, when those first raised become big enough for working.

HOME-RAISED BUSH FRUITS are also useful and do not take much room. A few cuttings put in yearly will keep the stock replenished; and were this done systematically, only raising just sufficient for the purpose and giving this limited number good attention, fewer of the cankered and worn-out old bushes would be seen in gardens. For cuttings of Gooseberries and Currants, select medium-sized pieces of straight wood, cut into lengths of about 1 foot, and keeping a heel of the older wood to each cutting. Black Currant cuttings should be put in with the buds intact, but all the lower buds of Gooseberries and Red and White Currants should be rubbed out to prevent them from developing into suckers. Notch out the ground with a spade, making the miniature trench about 7 inches deep and with one solid side, against which the cuttings should be placed, and see also that they rest firmly on the bottom; then fill in with soil and tread firmly, so that no air crevices are left round the cuttings. Water the rows in if the soil is at all dry; indeed, it is advisable to use water in any case to close the soil round the cuttings. Then in a day or two

after run the Dutch hoe between the rows to loosen the surface soil.

THE WINTER MOTH.—In orchards where the winter moth is present or feared, no delay should take place before adopting precautionary measures by grease-banding the trees, or using some other means of preventing the female insects, which are now active and taking to their winter quarters in the trees from the ground, from attaining the only positions in which they can prove dangerous to next year's crop. It seems almost impossible to entirely rid our orchards of these pests, but simultaneous efforts in this direction must eventually lessen the evil, and those who have the best interests of fruit culture at heart will not fail in doing their share in the good work. CORNUBIAN.

KITCHEN GARDEN.

STORING ONIONS.—As a rule time cannot be spared for stringing Onions when they are cleared from the ground, this being performed by outdoor hands in wet or unfavourable weather. Take the first opportunity of overhauling the main batch, as sometimes faulty bulbs are not noticed, and if left in bulk soon contaminate others. Lay aside all such, also those inclined to grow out at the neck, in order that they may be used at once, and string on strong tar twine a good percentage of the best and firmest, suspending them from the roof of a cool, airy loft or even outhouse. The remainder lying loose can then be spread out over a larger area, receiving the advantage of more air. Some seem to treat Onions as if they were easily injured by a little frost, whereas the fact is a certain amount of this is actually beneficial, though dryness is essential, drip soon causing decay. I have seen well ripened bulbs hung on walls beneath the eaves of cottagers' dwellings keep plump and sound till late in spring, but there is usually an absence of grossness in such samples. Those lying on floors should be turned over once a week. Choose a dry day for going over the autumn-sown varieties, weeding the rows and drawing out the very small inferior plants. The soil can then be made firm so as to render them more frost-proof. If left in a loose state high winds are sure to loosen them still more and severe frost injure them, especially in heavy, wet soils. Previous to firming, run the Dutch hoe through the rows. Give a liberal dressing of soot and wood ashes in equal quantities, as although it is more often in spring that the bulbs fall victims to the dreaded grub, yet a free incorporation of these ingredients now renders the root-run more obnoxious. It is at the junction of the bulb with the roots that the attack is first made. When speaking of firming Onions, I may also mention the advisability of treating young autumn-planted Cabbages similarly, drawing a little soil up to the stem afterwards.

TURNIPS.—All roots of the Orange Jelly and yellow section generally, also white varieties which have grown to their normal size, had better be lifted and placed in some position, as, for instance, beneath dry Bracken overlaid with coal ashes. Chirk Castle is so hardy that it will stand almost any amount of wet and frost without rotting. It should be mentioned that it is best to use a little less covering on Turnip than on Potato clumps, as overheating in very mild weather causes crown growth, and consequent loss of quality.

THE ROOT CROPS.—The beginning of November brings a considerable amount of labour in the way of lifting Beetroot and Carrots. It is not altogether a question of hardness, but also of the inconvenience of getting at the roots in time of hard frost. Sometimes severe weather sets in unexpectedly early in November, taking the gardener off his guard, but even then matters may be made easier by a little timely forethought in the way of covering with loose littery material, removing the same as soon as a thaw occurs. I do not care for Beet to be exposed to more than 7° or 8° of frost, and I have sometimes adopted the plan of a good old kitchen gardener under whom I served, *viz.*, mowing the Asparagus beds

and laying the baulm lightly over the Beet beds. In the case of the longer varieties of Carrots, such as Long Red, Surrey, and Altringham, which are to be kept till late in the season, a thicker layer of soil or sand should be placed between the roots. Where a large number of Parsnips are grown, a portion of the crop may be left in the ground, drawing up a little soil to the roots with a hoe. Beet may also be treated similarly if sufficiently covered. For general winter use I prefer to lift Parsnips, lay them in soil in a sheltered nook or corner, each root being buried up to the crown, and the whole bed finally covered with Bracken. Thus treated, they are easily reached even in the sharpest or most snowy weather. Salsafy and Scorzonera may also be treated similarly. Jerusalem Artichokes retain their quality better when left in the ground, and after lifting a sufficient quantity of tubers to last for some time the rest of the bed may be covered with Bracken to protect from hard frost.

BROCCOLI.—In many gardens of only limited extent Broccoli is not grown so much as formerly, as gardeners find themselves in an awkward position should these be cut off. They are wise who have substituted the Rosette Colewort, as this will stand the most trying winter, and there is always something to cut at. Nothing, moreover, can be more delicious when well hearted and after exposure to some degree of frost. A few rows of Self-protecting Autumn are always manageable, and being in an advanced hearting condition—at any rate in most autumns before injurious frost occurs—lifting and laying in can be successfully practised, and the supply prolonged often until nearly Christmas. Rough home-made straw hurdles are invaluable for covering shallow brick pits containing this vegetable, as also for protecting Lettuce, Cauliflower, Cabbage, and Endive.

J. C.

ORCHIDS.

ORCHIDS AND FINE-FOLIAGED PLANTS.

THE increasing number of fine-foliaged plants has made it much easier to keep up a bright display in the Orchid-flowering house than formerly. When there is a scarcity of blossom many of these come in very useful, but there is just a danger of this kind of thing being overdone at the present day. I much prefer a group or house of Orchids without any fine-foliaged plants at all other than Ferns, but this is not everyone's taste, and if only sufficient care and selection in arrangement are brought to bear, very pretty effects may be produced. Quite recently I was looking round a garden where Orchids are well done, and a nice lot of *Cattleya aurea* was in flower. This was grouped with some highly-coloured Crotons and small, well-grown bits of *Heliconia*, and the lovely flowers, usually so prominent in any group in which they are used, seemed quite lost by contrast. This is the kind of thing to avoid. Again, yellow *Oncidium*s with green and golden coloured *Acalyphas* or Crotons are wrong. Even against green Ferns, unless the latter are deeply coloured, the effect is not really good, and they want something of a warmer tint. When the spikes stand out as it were from a groundwork of small plants of brightly-coloured *Fittonias* they look much nicer, and this will make a corner to a group that will always be admired. White-flowering Orchids, such as *Odontoglossum crispum* and *Dendrobium Dearei*, look best on brightly-coloured foliage, unless a few more brightly-tinted Orchids, such as *Epidendrum vitellinum*, can be associated with them.

Large healthy specimens of any kind of Orchid always look well in groups, but these, unfortunately, are not much grown now-a-days. It is a little remarkable that a dwarf species

like *Cœlogyne cristata* should be so frequently grown on to specimen size when it is not really one of the best or most suitable, while grand old Orchids of the distichous-leaved section, such as *Vandas* and *Aerides*, are represented by little bits. Not that large plants of *Cœlogyne* are without beauty by any means, but there is a certain flat look about them, and I always think small, well-grown plants are prettier. These require no other greenery than their own pretty foliage, but a few bits of brightly-coloured *Croton* arranged with them are usually admired. All such Orchids as have no foliage or very little at the time of flowering should be arranged with Ferns only, as these make up for loss of green leaves. In this category come a great many of the Moulmein *Dendrobies*, also *Calanthes*, *Pleiones* and others. Any of the drooping species should be suspended or propped up on small pedestals, never tied up to stakes, as is so frequently done. In the latter case the flowers always look upside down, and it destroys the beauty of the plant as a whole. Many growers object to placing fine-foliaged plants among Orchids because of the liability to propagate insect pests, but this is simply alarm, for Crotons and other plants grown for their foliage are naturally just as cleanly as Orchids. It is only when neglected there is danger, and those who neglect their Crotons usually also neglect their Orchids. In finishing the front of a group consisting of fine-foliaged plants and Orchids, not much originality is usually shown. A fringe of *Panicum* or *Tradescantia*, with a few plants of *Isolepis* or *Caladium argyrites* at regular intervals, seems about the limit of many imaginations. All these are beautiful plants for the purpose without a doubt, but they should be so placed that each plant shows distinctly from its neighbour. It is not treating them well to use them simply for hiding pots in which Orchids and other plants are growing. This could be done with green Mosses or *Lycopodium*, and the pretty little fine-foliaged plants given the advantage of this setting. H.

Cypripedium Fred Hardy.—This is a distinct variety. It is no doubt an albino of *Cypripedium Charlesworthi*. The habit of growth is much smaller than in *C. Charlesworthi*, leaves pale green, spotted, with numerous brown markings on the undersides. The dorsal sepal is white at the top and around the outer margins. Towards the disc there is a very faint tint of colour. The disc is pale green, with a few darker green veinings. The petals are pale green, suffused with brown, and veined with a darker shade of brown, the lip pale pea-green.—C.

Cattleya luteola.—This quaint and interesting little plant is now in flower, and although it is not sufficiently large or showy to become really popular, it is well worth growing. The pseudobulbs are small and the flower-spikes do not push up above the leaves as is usual in *Cattleyas*, but cluster just above the top of the former. Each flower is about 2 inches across, yellow, with purple lip markings. In its native place *C. luteola* is said always to grow in dense shade. If kept in a good light position in an intermediate house it will usually be satisfactory. Small pots or baskets are best, as the plants are not very strong-rooting.

Epidendrum purum.—Among the less-known species of this large genus are several pretty Orchids that would be well worth a place in all collections. *E. purum* is not at all showy, but its quaint appearance and the delightful fragrance given off by the blossoms make it welcome as a variety. It grows about 18 inches high, and the flower peduncles are drooping and full, the flowers pale yellow. Like others in its class, *E. purum* is easily cultivated, and thrives well in rather small pots of peat fibre and Sphagnum

Moss over good drainage. The temperature should be that of a cool intermediate house, and ample moisture should be given all the year round.

Cattleya Hardyana.—Quite a number of fine varieties of this beautiful natural hybrid have turned up lately among importations, and in many cases from *C. Dowiana aurea* rather than from *C. gigas*. It is one of the finest of all *Cattleyas*, and many growers, now that its origin has been proved, without doubt will be raising it from seed. Those who have for years been watching importations will be anxious to see how the home-raised plants turn out as they flower, for that there will be good and peer varieties among them one may be perfectly sure. But in any case it is a grand Orchid, of which we ought to have more, and it will be long before our Orchid collections are over-stocked with it. Its culture does not differ much from that usually practised with its parents, the plants liking a position near the roof glass in the warmest and lightest part of the *Cattleya* house.

LÆLIA DORMANIANA.

This plant is not very constant in its time of flowering, the blossoms appearing at quite opposite times of the year. But the pretty olive and crimson blossoms are always acceptable, and I was pleased to note a nice batch of it recently flowering abundantly. The pseudo-bulbs or stems seldom grow more than 9 inches or 10 inches high, but the leaves give the plant the appearance of being taller. The flower-spikes occur at the top of the former. Like many other *Lælias* and *Cattleyas*, its roots are not of that constitution that will push a way for themselves through a great thickness of Moss and peat. To be satisfactory the plants must be crowded into their pots or baskets, leaving only very little room for compost, so that the roots push through it readily and outwardly into the congenial air of the Orchid house. It seldom suffers from want of room, the pseudo-bulbs being very thin and needing much less sustenance than those of the labiate *Cattleyas* or *Lælias* of stouter build. Some of the healthiest plants I have seen were grown in small teak baskets suspended from the roof at the lightest and warmest end of the *Cattleya* house, and this suggests another important point that must not be lost sight of. Many growers are not careful enough when damping between Orchid pots; and the watersplashing on to the compost, one never knows whether it is really dry or wet, and a dry bottom and sodden surface are about the worst state that Orchids of this class can get into. It is bad enough for the strong growers; for the weak ones it is simply fatal if allowed to go on too long. But a position near the glass prevents any danger of this, and if it can be spared it is the best place for *L. Dormaniana*. It is only necessary to see that the young shoots from the base of the old stems are not too suddenly exposed to sunlight in such positions, especially should they have been growing where the light is not so good. Careless watering at the same time is responsible for many of these young leads decaying. Cold water thrown over them or allowed to gather in the young sheaths means their certain death. Just now the roots will be fairly active, and it is important that they are not unduly dried. Kept well up they will ripen the growth made, enabling it to stand cold or other checks in winter, when the water supply must be considerably reduced, but never entirely withheld. *L. Dormaniana* was discovered by Mr. H. Blunt at a considerable elevation in Rio de Janeiro in 1879.

Cynoches maculatum.—Although the individual flowers of this species are not so large as in a representative form of *C. chlorochilum*, it is, nevertheless, a fine Orchid, and the spotted flowers on the drooping racemes are sure to be admired. It is by no means a common species, and only a few plants of it are known, though it was introduced many years ago. In a fairly warm and moist house growth is very free, but

considerable care is necessary when young growths are pushing up that water is not allowed to gather in the centre of these. After the pseudo-bulbs are fully made up and matured the plant needs a long dry rest, and unless it rests well it is very unlikely to flower much. Equal parts of peat fibre, loam, and chopped Sphagnum suit it well for compost, and it looks well grown in baskets suspended from the roof.

A distinct natural hybrid Odontoglossum.—Most Orchid growers are familiar with the natural hybrid *O. excellens*, which is derived from the intercrossing of *O. Pescatorei* and *O. triumphans*, but a cross between *O. crispum* and *O. triumphans* is quite an out-of-the-way occurrence. I recently noted a plant which will, I have no doubt, prove to have been derived from the intercrossing of the last-named species. It may be described briefly as a glorified *O. excellens*. The flowers are each upwards of 3 inches in diameter, the sepals upwards of three-quarters of an inch broad, pale creamy yellow, with a bright yellow suffusion. In the centre there are numerous small bright brown spots, forming almost a solid blotch. The petals are of good shape and substance, yellow on the outer margins, white through the centre and basal portions, as in *O. excellens*; there are also a few brown spots. The lip is upwards of an inch broad, becoming pointed at the apex, the ground colour white, with a large brown blotch in the centre, the toothed disc bright golden yellow.

VANDA CÆRULEA.

This useful *Vanda* does not receive the attention it deserves at the present day. In Orchid collections it is generally fairly well represented, but in the plant houses of most private establishments one seldom sees a plant. This is to be regretted, especially in places where there is a great demand for plants in flower during the months of September, October, and November, or even well into the month of December. One generally finds that where only a few Orchids are cultivated they mostly consist of summer-flowering varieties, which are often in perfection when the family are away and at a time when there is plenty of other things to use as cut flowers. The winter-flowering varieties, with the exception of *Calanthes*, are almost totally ignored. There are many species which will be flowering during the next two months that would be useful were they afforded the room now occupied by the less useful summer-flowering ones. None of the species are more deserving of attention than *Vanda cærulea*, the long racemes of azure-blue flowers being always appreciated and most useful for cutting. In a recent conversation with a well-known collector, who has probably imported more plants of *V. cærulea* into this country than all the others put together, the altitude at which the plants are found growing in their native habitat was one of the subjects referred to. He informed me that he had gathered flowers in the early morning covered with white frost. To still further confirm the cool conditions under which it grows, Messrs. Veitch in their "Manual of Orchidaceous Plants" give the following interesting information:—

In the Oak woods near the village of Lermaj (Khasia Hills) *Vanda cærulea* grows in profusion. The high, grassy hills which it inhabits are elevated from 3000 feet to 4000 feet; the trees on which it grows are small, gnarled, and very sparingly leafy, so that the *Vanda* is fully exposed to the sun, rain, and wind. There is no Moss or Lichen on the branches with the *Vanda*, whose roots sprawl over the dry bark. The atmosphere is, on the whole, humid, and extremely so during the rains, but there is no damp heat or stagnation in the air, and at the flowering season

the temperature ranges between 60° and 80° F. There is much sunshine, and both air and bark are dry during the day. In July and August during the rains the temperature is a little higher, but in winter it falls much lower.

I have long advocated a cool, dry resting season for this *Vanda*, but have generally removed the plants to warmer and more humid quarters during the growing season and up to the time the flowers expand, when they have been removed to cooler and drier positions, so that the flowers may be retained longer in perfection. After the flowers have been removed the plants are kept drier and prepared for the resting season, which then commences. The potting compost used consists wholly of living Sphagnum Moss and clean broken crocks. The repotting is best done in the spring.

I was rather struck recently, when on a visit to Mr. Hudson at Gunnersbury House, to see a fine batch of plants, many of them pushing stout flower-spikes, growing suspended in a lean-to house, the front stages of the house being filled with *Begonia Gloire de Lorraine* and its sport *B. Mrs. Leopold de Rothschild*. The *Vandas* were hung at the back close to the roof ventilators, where they have had the benefit of a free circulation of air during the excessively hot and dry summer both by night and day. I have never seen a more robust and healthy lot of plants. Other plants which had been grown under the same conditions were removed to slightly warmer quarters to form a succession of bloom. Several plants had open flowers, which were remarkable for substance and size, and the lovely marbling of deep blue and white on the segments. This is by far the nearest approach to the conditions of its native habitat in which I have met the plants in such fine condition, and illustrates the fact that where a suitable position can be found under cool conditions the plants do much better than when grown in the warmer parts of the stove, which are generally thought to be the right treatment to meet the requirements of *V. cærulea*. Under cool treatment the tints are much deeper than when the plants are grown and flowered under warmer conditions.

H. J. C.

WINTERING SMALL ANGRÆCUMS.

ALTHOUGH the larger growing species, such as *A. eburneum* and its varieties, are able to take care of themselves during winter, considerable anxiety is always felt about the smaller members of this genus. It is very important that such subjects have a good hold upon their adopted home, whether this is a piece of Tree Fern stem, a basket, or a small pan or pot, and for this reason no disturbance of the roots ought to take place after the early summer. Again, the Sphagnum about the roots grows very vigorously during the summer months, and will often at this end of the year be almost as high as the plants themselves. This, it is hardly necessary to state, holds far too much moisture about the roots during the winter months, for one good soaking would keep the plants wet for a week or more; besides, its power of absorbing moisture from the atmosphere must be considered. The Moss, then, must be somewhat closely clipped off where it has grown too freely, but where only a moderate growth has been made, let it remain, as it forms a fairly reliable index as to the state of the compost, whether it is or is not sufficiently moist.

Regarding the amount of water needed, *Angræcums* of small growth are a good deal like *Phalenopsis*. They are easily injured by too much, but they need sufficient to keep the roots gently moving. As a rule, it is quite feasible to wait for a nice bright day to water the majority, though—in town collections more especially—some watering must perforce be done in dull and wet weather. When in doubt, however, leave

the plants for another day, or even two, rather than water too quickly. Of great help to all this section is a clear light during the winter, when for a week or more there is no sign of the sun, and for this reason the glass from now onward must be sponged inside and mopped down outside as often as possible. The baskets or pots containing the plants must be brought up as near the glass as is compatible with their safety on frosty nights. The plants themselves, too, where fogs prevail need frequent sponging to remove the sooty deposit that settles upon them in winter. H.

Dendrobium superbum.—While most of the deciduous species have finished their growth, and the earlier kinds, such as *D. aureum* and *D. crassinode*, are being removed one by one from their growing quarters, the stems of *D. superbum* are still progressing. Few of the species, indeed, require so long a season of growth, and I think that it is partly owing to their not being properly ripened that the stems of this kind are so frequently met with in a shrivelled state in spring. It is necessary now to push them on with all speed and in the lightest position possible.—T.

Odontoglossum Uro-Skinneri.—Flowers of this species come for a name from "C. C." They are characteristic of the kind, but this can hardly be styled a first-rate one. The pseudo-bulbs bear large deep green leaves, and the spikes sometimes rise to the height of nearly a yard. The blossoms are a little over 2 inches across, the sepals and petals brownish with green markings, the lip rose. Altogether the plant at first sight looks as much like a *Zygopetalum* as an *Odontoglossum*. Fortunately, it is of very simple culture, thriving well in the cool house under the same treatment as *O. grande*, but, being stronger in growth, it needs more pot room.

Oncidium incurvum.—The flowers of this pretty little plant last remarkably well, and this, fortunately, without injuring the plants to any appreciable extent, as it does in other and larger-flowered kinds. It is one of the prettiest of all *Oncidiums*, and its colours—white and rosy purple—are not at all common in the section to which it belongs. During the time the plants are in flower I usually place them in a cool, light house, which effects the consolidation of the growth and preserves the blossoms. Repotting may now take place if it is necessary, but *O. incurvum* is a plant that dislikes frequent disturbance; consequently, if top-dressing will suffice it is not wise to pull the plants about at the roots. I have large old plants here that have not been repotted for seven years, but by annual top-dressings they keep in excellent condition and flower every year. Repotting should be done thoroughly with these large plants, removing almost the whole of the old material and allowing the plants a little extra warmth afterwards to get over the check.—H. R.

Oncidium crispum.—This grand species is again flowering, and is the typical kind of a somewhat numerous set of the very showiest in the genus. It has bronzy green pseudo-bulbs and leaves, and the spikes spring from the base of the former when fully matured, rising to a height of a couple of feet and containing a large number of the fine showy blossoms. *O. crispum* is best grown either on a raft or in a very shallow basket, so that it may be suspended from the roof in the best light, this hardening the foliage and pseudo-bulbs, making them more able to withstand the check of flowering, which, when the size of plant and flower-spike is taken into consideration, must be considerable. The healthiest and strongest plants in other ways are always those that take on the rough feel and colour that are peculiar to plants grown in ample light and air. At no time ought the roots to be much dried. When growth is active, of course much more moisture is necessary than when at rest, but shrivelling of the pseudo-bulbs, though it may take place in a state of Nature, is not permissible under cultivation. The blossoms last about a month, but if the

plants are weak it is not advisable to leave them so long, or indeed flower them at all. The Cat-tleya house suits it well.

FLOWER GARDEN.

THE SINGLE WHITE PÆONY.

In its season the white single Pæony is queen of the garden. If the *Nymphaea* assume

Single white Pæony. From a photograph sent by Mrs. Lawrenson.

royal sway, as with every petal set heavenward it lies floating on its dominion of water, so does this fair Pæony reign over hardy plants by reason of its dazzling purity and crown of golden stamens. In the sunshine its white satin petals gleam with radiance, and a flush like the dawn of rosy morn lies within the shimmering cup that holds the cluster of golden stamens, while in the shade or towards evening the petals fold to sleep like a globe of pearl. The original plant was found in an old north country garden. In constitution it is free and vigorous, the flower-stems 4 feet high and the dark green foliage very luxuriant. For indoor decoration it is exquisite when used in low bowls, as thus the blossoms remain fresh and fair for several days. Pæonies when cut with long stalks wither quickly, the stems being too woody to allow of water being freely absorbed.

A. L. L.

Prunella grandiflora *Webbiana*.—The end of October may seem an unsuitable time to choose for drawing notice to a flower which is not at its best in late autumn, but in summer. While this is so, the way in which blooms are produced so late in the season makes such a plant worthy of a place in the garden. I know of some who consider this a coarse plant, and it may be that it is not to be ranked as one of the highest order for the choicest border or the collection of select plants. Those who deny it the possession of any beauty may bring as an advocate for their depreciatory views the expression of Ruskin regarding the Labiate: "Full of various balm and warm strength for healing, yet all of them without splendid honour or perfect beauty." If this Self-heal has not perfect beauty, it has at least some share of that quality, which is at the root of our liking for the flowers we grow. We no longer

appreciate the *Prunella* or *Brunella* because of its healing virtues, but as a flower to help us in our gardening. Webb's large-flowered Self-heal is, however, superior to the ordinary form by reason of the greater brilliancy of its flowers. In the type they are purple, but in *P. Webbiana* they are crimson. It is not a new plant, but is not very often seen in gardens. It was figured by Maund, who gives us a little information regarding it. From his account we gather that it was cultivated in 1844. It is said to be a native of Austria, and to have been sent home by Mr. P. B.

Webb, after whom it has been named. It is, even in summer when flowers are plentiful, a useful plant in the outdoor garden, because it helps with the diversity of form, which is one of the charms of gardening. When flowers grow scarce outside, as now, one can the better appreciate its large heads of light crimson blooms. Near the front of the border or on bold rockwork is the best place for Webb's Self-heal, which is easily grown in almost any soil. One may lay stress on the need to stipulate in ordering the plant that the true variety, and not that with purple flowers, is to be supplied. I have had personal experience of the inferior *P. grandiflora* being sent.—S. A.

Ixias in open beds—*Ixias* are, on account of their great value for cutting, grown in pots or boxes, but seldom does one meet with them planted out. All the same, they submit to that mode of culture in warm, well-drained, and sheltered gardens. Perhaps the safest way is to start the corms in small pots, placing say three in each, and then to transplant at the proper date, or when some 2 inches of growth have been made. Cool quarters should be given from the very first, and when planting is performed, the balls of soil should not be broken, nor the corm divided, but dropped into a hole made with a trowel. The compost most suitable is a rather light loam, with some leaf-mould added, mulching the surface with old Mushroom manure when the warm weather comes. One or two good soakings with liquid manure are most helpful.—NORFOLK.

Callistophus sinensis.—This is without doubt one of the finest plants for the hardy flower border from August until the end of October, or until it is cut down by a severe frost. I have a large bed of it about 25 feet by 10 feet. The plants are sturdy and bushy, and yet produce strong, wiry stems 12 inches to 18 inches, or even 2 feet long, rendering the flowers useful for cutting. The beautiful mauve flowers, with a golden centre, are each 3 inches to 4 inches and more across, and last quite fresh for more than a fortnight when cut. Everyone who has seen it persists in calling it a Marguerite, and perhaps the Chinese Marguerite would not be at all a bad popular name for it. The culture is very simple. Seeds are sown in shallow boxes about the end of March or beginning of April, and when the seedlings are large enough to handle easily they are pricked out into similar boxes about 3 inches apart. They soon grow away and make strong, sturdy plants. By the end of May they are fit for transferring to the open border. A light

and rather dry sandy soil seems to suit them best. A few I have grown on rich loam do not appear to have the vigour or freedom of flowering those on light soil in a fully exposed, sunny position have. To obtain anything like a fine display it should be planted in large masses, say about a dozen plants in a group, each 12 inches to 15 inches apart. For cutting it is excellent, as it may be cut with long stems.—JOHN WEATHERS, *Isleworth*.

THE THORN APPLE.

(*DATURA STRAMONIUM*.)

In the wilderness or deer enclosure at Greenwich Park the Thorn Apple has been known to exist for fifty years at least. It is scattered over an area of about half an acre, but principally on the sloping banks of a disused gravel-pit, where amongst the decayed and decaying vegetable matter it attains to giant proportions. As an ornamental-foliaged plant the Thorn Apple deserves attention, the big Maple-like leaves, deeply cut and toothed, having a pleasing effect when seen in full sunshine. Even the pure white *Convolvulus*-like flowers, which are at their best about 8 o'clock in the evening, are by no means unattractive, as also are the prickly Apple-like fruits, which are borne in abundance. For massing in the wild garden or other portions of the woodland the Thorn Apple is well suited, but it wants shelter, else the ample foliage gets cut about badly.

Some of the specimens in Greenwich Park, notably that here reproduced, have attained to nearly 5 feet in height and from 6 feet to 8 feet in diameter.

A. D. WEBSTER.

Protecting double Violets.—Violet growers are sometimes caught napping, though I do not mean to assert that a few moderate frosts will do the Violets permanent injury. But remembering the severe October frosts which, through catching *Chrysanthemums* standing out of doors, have made growers of the latter shy at leaving them unprotected later than the first week of October, Violet growers should have their plants where, if need be, lights can be drawn over them by the second week in October. I am afraid red spider will have made its mark in gardens where the subsoil is gravelly and labour has been scarce.

The Thorn Apple growing wild in Greenwich Park.

If the leaves are the least yellow in colour, I would advise laying the plants on their sides after lifting, and syringing with sulphur water. See that the rooting medium is thoroughly moist down to the lowest roots a day or two previous to

lifting the plants, or much ball breaking and permanent injury will result.—C.

LILIUM SUTCHUENENSE.

Of the various countries which during the latter part of this century have contributed the most to our collections of Lilies, China and Japan take a first place. The number of species from these countries amounted in 1884, according to Elwes, to ten only, three of these being doubtful; now it reaches, possibly exceeds, twenty-four out of the fifty known kinds. Of these twenty-four one half are already in garden culture, *L. speciosum* and *L. tigrinum* being notable examples. To them can be added the species the subject of this note, which for some years now has been cultivated by MM. Vilmorin at Verrières. Judging by its elegance, as also the relative ease with which it can be grown, this Lily will no doubt find a place in gardens. The Société Nationale d'Horticulture de France recently awarded it a first-class certificate.

Lilium sutchuense, so named and described by Franchet (*Journal Botanique*, Sept., 1892), was discovered by the Abbé Farges in Eastern Su-Tchuen, and was received in the form of seed by M. Maurice L. de Vilmorin. He, it is well known, was greatly devoted to the study of introductions of this kind, those of ligneous growth especially, and the efforts he made to acclimatise them were nearly always crowned with success. The seed of *L. sutchuense* was sown almost as soon as received. The germination was good, and the plants transferred to pots formed little bulbs which two years later (in 1897) flowered for the first time, to the number of one to three on each stem. The same bulbs, preserved and replanted in 1898 and again in 1899 in beds, became stronger and produced flowers in greater numbers. One of these identical plants bearing seven flowers was exhibited before the Société d'Horticulture, and several others bore two to five or six flowers according to their strength. A stem of *L. sutchuense* grown in the above manner is from 16 inches to 20 inches high, slender, flexible, and covered with fine white specks. The leaves are numerous, regularly spaced, and slender, diminishing in length as they approach the summit, the longest being a little more than 9 inches in length, channelled on the upper side and very finely stippled on both sides. The flowers number one to seven on a vigorous plant (single, or two to four in the wild state), in colour light orange-red, with brown stippings in the centre of the divisions, the stamens being a light orange. The plant flowers at the commencement of July and ripens its seed in cultivation.

Allied to *L. tigrinum* and *L. tenuifolium*, and having the same country of origin, it comes between these as regards its size. It is a stouter plant, and its flowers, though appearing at the same time, are more numerous and nearly double the size of those of *L. tenuifolium*, although less bright, and it differs even more from *L. tigrinum* in being a much smaller plant, much narrower in leaf, in the absence of bulbils in the leaf, and in its rather smaller flowers, which, though of the same shade of red and form, make their appearance much earlier. *L. sutchuense* has therefore the merit of elegance and distinction, in addition to which it is of easy cultivation and increase. It can, like the other two species I have named, be grown in beds of, preferably, light and fertile soil, or in deep pots, separately or in threes at most, in a mixture of loam and peat or leaf-mould, with the addition, if need be, of a little

sand (river sand preferably). I do not, however, guarantee its hardiness, as up to the present the bulbs have been wintered in sand or in the receptacles in which they first took plant form. Like other Lilies, they should be planted early in the spring—in March, for example—and at a good depth (2 inches to 2½ inches below the level of the soil), so that the roots which form at the base of the stem can live and nourish the plant. Unlike many of its race, and notably its own allied species, *L. sutchuense* produces seed freely in cultivation. Up to the present it has been raised entirely from seed, as all the bulbs have been unproductive. The seed, sown in pots in the spring in peat soil and under glass, sprouted after a few weeks, and the plants transferred to other pots formed in the first year little bulbs the size of peas. Some of these bulbs even produced one or two flowers, but only in their third year's growth attained to nearly normal size.—S. MOTTET, in *Revue Horticole*.

GUNNERA SCABRA.

If the article upon *Gunnera scabra* by Mr. Jenkins induces those who have dry gardens with no great supply of water to grow this effective and interesting plant, it will prove of much value. I have no desire, from want of room, to grow my plant of *Gunnera scabra* to the dimensions of that at Tooting spoken of by your correspondent. I have, however, now grown it for a number of years, and my experience of it on light and dry soil quite confirms what Mr. Jenkins says about it. There is no reason why anyone with such a soil should refrain from trying either *G. scabra* or *G. manicata*. I think, however, that *G. scabra* is more adapted to dry gardens than *G. manicata*. *Gunnera manicata* derives much of its value from its bold and rugged grandeur of effect. In dry soil it cannot reach its full dimensions, and, in consequence, is shorn of its greatest merit. *G. scabra*, on the other hand, is far from ineffective even when comparatively small, and it always has an attraction to garden visitors besides that it possesses to its owner. I have had a number of opportunities of observing the *Gunneras* in Great Britain and Ireland, and the best specimens I have seen were in comparatively light soil where moisture was present. Even with moisture it generally takes some time for the plant to become established. Until it has done so the results are comparatively disappointing. One thinks also that the supply of manure annually has a good deal to do with the production of the immense growth of the finest specimens of *Gunnera manicata*. It is not everyone who can give a specimen of the *Gunnera* an annual supply of three cart-loads of manure, yet this is what is supplied to some of the finest specimens in the kingdom. These are, however, of such grandeur that one can hardly say that the treatment is not justified by the results. Of course, those who look for pecuniary returns from their gardens would look upon this as a sheer waste of material which would be more usefully applied in the kitchen garden. The uses of a garden are not confined, however, to the supply of food, and those who have good reason for thinking that the aspect of gardening which appeals to the higher feelings of humanity is worthy of consideration will not consider such care misapplied. One may be permitted to add to what Mr. Jenkins has said about the requirements of the *Gunneras* the important one of shelter from strong winds. This is absolutely essential for *G. manicata* and little less needful for the allied but dwarfier *G. scabra*. Here, where we have a superabundance of wind, I find that it has its leaves injured by severe gales. This takes much from its beauty. S. ARNOTT.

Carsethorn, by Dumfries, N. B.

Nicotiana sylvestris.—"J. C. T." (p. 321) apparently misread my note on p. 194. When I

said "the foliage is the thing," it should have been clear to him what my meaning was. I was speaking of fine-foliaged plants, and in beds such as I described the foliage is undoubtedly the chief attraction. Of course, anyone seeing this fine plant, as "J. C. T." appears to have done, for the first time in full bloom naturally thinks more of the flowers and less of the foliage than those who have watched the development of the latter from the seed-leaf onwards. Again, when it is planted in clumps or long lines the individual effect of the plant is in a manner lost. I will candidly admit that when I wrote the note referred to in August I had not seen the plant in its fullest beauty, for the plants I had in flower at that time were in very poor soil. The larger plants came into bloom soon after, and instead of a score of flowers that "J. C. T." speaks of, I should say that three score is far nearer the number that good single spikes produce. If my note seemed in any way disparaging to the plant I am very sorry, for it was certainly not my intention, and I can fully bear out every word that "J. C. T." says in praise of it. I also hope that his prediction as to its future popularity will be justified.—H. R.

MR. MOON'S HYBRID POPPY.

ONE is glad to have the plate of this new Poppy in THE GARDEN of October 21. I have not yet had an opportunity of seeing it, but one feels much interested in it, more particularly from having the pleasure of possessing the hybrid raised by Mr. Carrington Ley. There appears to be a considerable resemblance between the two if the colouring of the plate is as good as usual. If anything, Mr. Moon's appears to be the lighter of the two in shade. I am, however, speaking from recollection, as my plant of Mr. Ley's hybrid, which bloomed twice this year, is now out of flower. The latter is not a plant to be judged from a solitary bloom or even from a small plant with one or two flowers upon it. This year my plant is of fair size, and I have seen reason to form a more favourable opinion of it than in the previous seasons during which it has flowered. It is of neater habit than many of the varieties of the Oriental Poppy, and the colour of the flowers is good also. It does not produce seed, and does not thus lend itself to reproduction by this method. This is probably an advantage, as its seeds might have produced plants resembling one or other of the parents of the hybrid—a not uncommon occurrence which often operates to the confusion of the purchaser of the progeny raised from seed of hybrid flowers.—S. A.

Referring to Mr. Burbidge's notes on this subject in THE GARDEN of October 21, it may be as well to state, or to re-state (for I believe the facts are already embedded somewhere in the back volumes of THE GARDEN), that the plant of *P. rupifragum* which produced the hybrid Poppy alluded to as originating in my garden continuously produced the same thing for several years running, nor has it in fact ever produced anything else, or reproduced itself, though there are several other plants of *P. rupifragum* in the garden which are almost a nuisance in this latter habit. This fact, whatever may be its interest, contributes, it must be admitted, nothing to the elucidation of an obscure subject, for on the "doctrine of chances" it goes some way to dispose of the "lucky fly" theory to which Mr. Burbidge alludes. I have not made a sowing of the seed very recently, and have not noticed any young seedlings round the plant this last year, but if Mr. Burbidge cares to try the experiment I will send him seed next summer, and I have little doubt that if it germinates at all it will produce the same Poppy in Dublin as it has done in Kent and in Cheshire.—J. CARRINGTON LEY, *East Farleigh, Maidstone*.

Four Poppies almost exactly like the plate in THE GARDEN of 21st ult. flowered here this season. They appear to come from two plants of *P. rupifragum*. Another hybrid flowered here for the first time in 1897, and was noticed

in THE GARDEN of that year. The flower-stems of this are about 3 feet in length, but generally trail on the ground. The flower is something like that of a gigantic *P. pilosum*, 5 inches in diameter, but the colour is poor. Another hybrid which flowered in 1898 has leaves similar to those of *P. rupifragum* and a flower like Royal Scarlet. This is the only one of the above hybrids which produced seed, but so far it has not germinated.—E. C. BUXTON, *Coed Derw, Bettws-y-Coed.*

—My Poppy does not bear any seed. It is not a chance seedling, as Mr. Burbidge says, but was fertilised by me and is a cross between *orientale bracteatum* and *rupifragum*. I have now raised four different batches of seedlings which grow very freely, and have had plenty of seed by cross-fertilising, but my plant of *rupifragum* has never produced any seed itself.—H. G. MOON.

Sternbergia lutea.—Can it be that Mr. Arnott's difficulty about this plant arises from not letting it be? Twelve years ago I bought a quantity of it, and put it at the foot of a south wall, and it is now a mass of beautiful colour. The first year or two it did not flower so well, but now it blooms with greater regularity than any *Crocus*, and the border is never dug. A year or two after it was planted I put some of the blue *Bindweed* on top of it, and they flower all the summer, and when nearly over the *Sternbergia* begins to push through. This year for the first time the little brown *Wood Sorrel* has sown itself among them, and now the mass of clear yellow flowers is relieved by the fine colour of this little weed.—W. R.

Anemone Pulsatilla from seed.—I have been told by good hardy plant growers, and it is so stated in some gardening works, that the seeds of this *Anemone* are of very slow germination, not usually coming up for twelve months after sowing. This season I sowed some seeds of my own saving, and to my surprise they germinated in less than a month from sowing. I am curious to know if any of your readers have had a similar experience, or is mine very unusual? As a fact I did not even sow as soon as ripe, which is of course advisable in the case of seeds that are slow of growth, but kept them until the first week in August in a cool place. I sowed in the usual way, plunging the pots to the rims, as is my usual practice in the summer season, in a cold frame. By September every seed had germinated, and the young plants have now their second leaf. When they first appeared, I thought I must have made a mistake when sowing. I could not believe that the seeds of this *Anemone* would come up in half the time taken by those of the *Crown Anemone*, sown at the same time and under identical circumstances.—J. CORNHILL.

Aster Coombefishacre.—The name of this *Starwort* is a puzzle to those who are unaware that it is that of the place of Mr. Archer-Hind, whose name at least is familiar to hardy plant growers. It is an *Aster* whose beauty leads to frequent inquiries as to what it is called. As it is one of my prime favourites, I can with every confidence speak of it in terms of highest praise. I like its elegant bushy habit, besides enjoying the crowds of pretty flowers it produces on its graceful stems. For many purposes *Starworts* of similar habit are preferable to those of tall growth with erect stems and, in some cases, stiff habit. The size of the flowers is also, as it were, a compromise between the small blooms of the type of *Aster diffusus* and those of the *Novi-Belgii* section and others of similar style. The flowers of *A. Coombefishacre* are, I see, described as flesh colour. In the nomenclature of flower colouring this is a wide expression, which does not always convey a very precise meaning. It is impossible to pourtray in words the exact shade of colour, but I should be disposed to call it a very pale lilac, though this hardly conveys my meaning. This *Aster* grows about 3 feet high, and is at present in flower with me.—CARSE-THORN.

ROSE GARDEN.

A FINE OLD ROSE.

THE single climbing cream-coloured *Rose* figured to-day grows along the eave of the roof of two or three small houses in Delgany. It was in such luxuriance this year, that I got it photographed in order to send to THE GARDEN as an illustration. The seed of this *Rose* was brought by one of the *La Touche* family (of Bellevue, Delgany) from India. One of the seedlings was planted some fifty years ago. This was told me by the last surviving member of the generation preceding the present owner of Bellevue. EDITH WYNNE.

Glenowen, Delgany, Wicklow.

Roses growing too freely.—Doubtless there are many readers of THE GARDEN whose *Roses* grow too strongly. Certain kinds will make enormous shoots that, as a rule, are but indifferently ripened owing to the rapidity of growth. The cause may be a soil too rich in

lift the plants sufficiently to sever their tap roots, return them to their former position, and tread the soil around moderately firm. Sometimes the work can be better and more expeditiously executed if two labourers are employed, they simultaneously lifting the plant upon opposite sides. I am firmly convinced that the adoption of some such measure as this, together with a dressing of lime every second or third year, will produce a healthy, mature growth that must result in a more satisfactory blossoming.—PHILOMEL.

Rose Safrano.—The remark that "Some old *Roses* require a lot of beating" is perfectly true of the above-named variety. Under good cultivation its blossoms are very beautiful, but, neglected, they are practically worthless. At Hoddesdon, Mr. Beckwith grows some thousands of this *Rose* for market, several houses each 300 feet in length being filled entirely with pot plants of it. As seen there in the early months of the year one would hardly recognise it, the colour being so rich and clear and the buds a good length. Florists much prefer this *Rose* to *Mme. Falcot*. In the autumn, outdoors, *Safrano* assumes a pretty orange-scarlet tint upon its under petals that much enhances its beauty. This

Rose over parish room at Glenowen, Delgany, Co. Wicklow. From a photograph sent by Miss E. Wynne.

animal manure and a lack of lime or chalk. The remedy may possibly be found in applying in winter a dressing of chalk at the rate of 1 lb. to 3 lbs. per square yard. The chalk should be broken up into fairly small lumps and well intermixed with the surface soil. As every rosarian knows, the best flowers are obtained from the hard wood of the current year, and to obtain such growths upon one's *Roses* should be the aim of every *Rose* grower. My desire in penning these few lines is to suggest a trial of the practice adopted by a few growers of *Roses* and by most cultivators of *Peaches* and other stone fruit trees, and that is periodical lifting of the plants in order to check their strong growth. *Peaches*, *Plums*, *Cherries*, &c., can be brought into a less coarse and more fruitful condition by triennial lifting, and why should not certain *Roses* that are notorious for their paucity of bloom be so treated? Some may say that this can be remedied by pruning or pegging down. This, doubtless, is the case with plants that possess plenty of good hard wood, but not so those kinds that are full of gross, unripened growths. Therefore I would advise all who have such plants to try lifting some this autumn. Do not dig the plants out of the ground; merely take a deep spade, force it into the ground as far as it will go, then

tinting *M. Vilmorin*, in his excellent paper upon "Flowers of the Riviera" in *Journal of the Royal Horticultural Society*, attributes to the effect of cold upon the flowers when in the bud. *Dean Hole* more than ten years ago said that out of every hundred bushes grown on the Riviera ninety belong to the *Safrano* tribe. It is possible fashion may have changed this since then, for *Papa Gontier* and some few others must be very extensively grown there. *M. Vilmorin* says that the great merit of *Safrano* lies in the fact of its developing buds at a temperature too low for other *Tea Roses*. This I have proved upon pot plants in cold houses. An excellent plan to obtain a quantity of its valuable buds late in the year is to keep a number of plants growing outdoors during the summer, and as buds appear to pinch them off. Continue this until September or October, then the subsequent growths are allowed to bloom, and will do so for some time in a house where a little heat is turned on at night and on dull days to ward off damp. The origin of *Safrano* is not positively known, but some think it is a descendant of the yellow *Tea Jaune*. It has doubtless given many seedlings, for *Mme. Falcot* and *Mme. Charles* always appear to me to be descendants of *Safrano*. As a standard or moderate climber *Safrano* is very useful.—P.

BOOKS.

CALENDAR OF FLOWERING TREES
AND SHRUBS.*

We are pleased to see one of our young amateurs taking an interest in the neglected subject of trees and shrubs, and this very pretty book comes to hand just at the right time—in the planting season. It is a well printed, attractive book, with very good coloured drawings by Miss Gertrude Hamilton, and very nicely reproduced. The plan of the book is a distinct one—that is to say, first we have a list of the trees and shrubs that flower in the different months, then follow the descriptions of the plants themselves, and, lastly, selections for different purposes and localities, whether town, seaside, sheltered, sunny, nature of the soil they require and so on. The main and the most interesting part is the descriptive, and in this with no pretence to botanical technicalities, which indeed would be out of place, there is a good deal of useful information from the garden point of view. We mean useful as far as it goes, as it really does not go far enough. The things dealt with are properly dealt with, but not comprehensively so. For instance, there is only one Jasmine—the Winter Jasmine—and one Daphne, no mention being made of any other, and while all the handsome and important Honeysuckles are left out, two of much less value are given; the Japan the Dutch, and our native Honeysuckles, which are as good as any, being taken no notice of. No doubt these omissions will be put right in another edition should there be one.

The coloured illustrations are very good; the form of the book, however, is too open and loose. The modern publisher, in getting away from the nice old 8vo size, very often makes an awkward book through not considering the proportion of the type to the page in the way the old printers used to do. As an example of the descriptive part of the book, we quote the following:—

Cæsalpinia japonica is a beautiful deciduous shrub that does not grow more than 4 feet high, but will spread vigorously and have a very uncommon appearance. It produces its bright canary-yellow flowers in June in racemes, which will remain fresh in water many days after they have been cut. Its stems and branches are armed with a number of red, curved prickles, which show up well against the light green bark. A mixture of loam and leaf-mould suits this best. The plant is not easily increased, but the best way is to take cuttings straight from the growing shrub and plant them in heat, in sand, with a hand-glass over them.

BOUILLIE BORDELAISE.

This is made by dissolving in a vessel in a small quantity of water 3 lbs. of sulphate of copper, and in another vessel in a like quantity of water 2 lbs. of unslaked lime. When the solutions are complete, pour the lime slowly into the sulphate, stir the mixture well, and then add enough water to bring the whole up to 25 gallons. Spray the mixture all over the parts requiring protection, using a syringe. The precipitate is insoluble, but is held in suspension by the movement of the liquid. Once deposited on the leaves the water evaporates, but the precipitate adheres. Use only wooden vessels. The figures given above are not intended to be exact, but the proportion is so. For example, the quantities can be diminished in order to have a bouillie less concentrated; thus, 1½ lbs. copper sulphate and 1 lb. lime. The efficacy of the protection is not neces-

* "Calendar of Flowering Trees and Shrubs," By Henry Hoare. Richard Flint and Co., 48 and 49, Fleet St., E.C.

sarily in direct ratio to the concentration of the bouillie, but it is important that every part of the plant should be well drenched with the liquid. Bouillie Bordelaise is very effective in most cases of disease caused by fungi. Two or three dressings may be relied upon to preserve Vines from mildew and Pear trees from spot (though much less easily), but they leave very visible traces of their use, which in fruit of choice varieties is a drawback, and another inconvenience attending its use is that it leaves a coating of precipitate on the utensils.

PEAT-MOSS LITTER.

I HAVE not had experience with this myself as a manure, but some of my acquaintances have and speak favourably of it. Nothing could be more opposed to each other than the experience of Mr. Whitworth Shaw and "H." as related on p. 325 of THE GARDEN. Like Mr. Shaw, I take exception to "H.'s" statement that "In bog peat nothing grows naturally to any perfection." I do not know what your correspondent means by growing naturally. I can assure him that bog peat is capable of growing first-class vegetables, as we have ample evidence in this district (Preston), where thousands of acres are under cultivation. It produces the best of Potato crops, and Celery such as is seldom seen elsewhere, one grower to my knowledge taking two crops of it annually from the same piece of land, the first crop being hastened on in frames, and as it is dug and sent to market another batch is planted, and makes saleable stuff about Christmas. Cabbages have been grown to an enormous size. I have seen Carrots come from the moss-land, as it is termed here, as big as I have seen anywhere, and the same may be said of Cauliflowers and Mangold Wurtzel. Onions are also well grown, so are Cucumbers and Vegetable Marrows. Some of the tenants by excavating holes come across marl, which is added to the peat, and on such land it is nothing uncommon to see Oats over 5 feet high. Some of the Celery growers use a good deal of sewage, but the majority of them depend on manure, which is applied in very small quantities compared with what is usually used in gardens. The traveller from Liverpool to Preston by the Lancashire and Yorkshire Railway will travel some miles through bog land, but covered mostly with some kind of vegetation. A few miles from Preston, on the east side of the line, he will see stacks of peat turves drying for fuel after being treated with tar and rose oil. It is also used by wheelwrights, blacksmiths, and carriage builders for heating wheel hoops. In some instances the peat is cut a depth of 8 feet as turves before it is laid out for crops, and the area is becoming annually less. Some of the land thus reclaimed brings from £4 to £8 per acre, the price depending more on the locality perhaps than the quality of the soil. I consider bog peat a most valuable substance; added to clay it lightens and warms it; added to sand it cools and consolidates it.—COR.

— I observe that Mr. J. Whitworth Shaw on page 325 recommends peat-moss litter as manure. His remarks contrast strangely with the short note on the same page from "H.," who asserts that "it is one of the worst nuisances that a gardener can have to contend with." Mr. Shaw says that the value of the peat-moss for the ground before it has been used as manure is as great as that of straw, but I doubt it. Admitting that neither is of great manurial value, it is well known that the ploughing in of straw stubble is beneficial to land, but would a farmer accept peat-moss for the same purpose if it were offered to him? I readily admit that moss litter is a capital sponge, and therein very often lies the evil. By the use of moss litter on retentive land in a wet season, the obvious result, so far as my experience goes, is that the moss litter may give off the urine, and then it collects moisture and holds wet in the ground which would otherwise drain through, and this I have proved by digging out lumps that have resembled a water-laden sponge. Straw litter supplies

humus, it decays quickly and becomes part and parcel of the soil itself; whereas, as Mr. Shaw admits, the peat-moss remains as an absorbent, making the land wetter and colder in a damp season. On the other hand, if the summer is hot and dry, when the moisture in the moss litter has been spent, dry material remains, possessing no manurial value in itself.—H. H.

THE PRESERVATION OF REMARKABLE
TREES IN FORESTS.

THE authorities over forests and rivers in France have sent the following circular to all the agents in France and Algeria:—

"In many forests on private estates and in communes there are often trees famed throughout the country for some historical episode or legend which is attached to them, or they are known for their great beauty or for their exceptional size. These trees form part of the æsthetic riches of France. They add to the beauty of its landscapes and attract visitors to places which, without them, would be out of the usual routes of tourists. They make our forests loved and appreciated. The surrounding population has a sincere attachment to these witnesses of a distant past, and never sees them disappear without regret. It is then of the greatest importance that their protection should be the constant aim of all employed by the authorities of forests and rivers. Under no pretext whatsoever ought they to be felled so long as they give any sign of life. To secure their preservation the chief of this department must give a detailed account of the trees, giving the name of each of them, the exact position, the size and the reasons for their preservation. Should it become absolutely necessary to fell one of these trees, this, in the future, cannot take place without the special authority and permission of the Conservator of Forests and Rivers. The conservators are requested to visit in the course of their annual inspections the trees which ought to be preserved, and thus personally assure themselves that they have been looked after."

This is a good move on the part of the Director of Forests and Rivers. Let us hope that its agents will take the greatest care that the directions are diligently carried out.

Sad Aziola.—Apropos of the interesting review of "More Pot Pourri from a Surrey Garden" which appeared in THE GARDEN of the 21st inst., the verse of Shelley's early poem (1821) is quoted ("To Aziola"), and the reviewer asks to what owl the lines refer. The reference is to the tawny owl, or *Strix stridula* (Linn.) The late Lord Lilford, for many years president of the British Oritologists' Union, described the almost unceasing cry of the hawk owl (*Surnia ulula*, Linn.) as "very melancholy," but I question if Shelley was acquainted with the "music" of this bird. Other poets besides Shelley have made references to the "sad," "melancholy," and "mournful" note of the tawny owl, happily still plentiful in our woodlands. Gray ("Elegy written in a Churchyard") has these lines:—

Save from yonder Ivy-mantled tower,
The moping owl does to the moon complain.

Burns ("A Vision")—

As I stood by yon roofless tower,
Where the Wa'flower scents the dewy air,
Where the howlet mourns in her Ivy bower,
And tells the midnight moon her care.

Many other poetical passages of a similar nature could be quoted, all referring to "Sad Aziola," *alias* the tawny owl.—G. W. MURDOCH, Naturalist Editor, *Yorkshire Weekly Post*.

The weather in West Herts.—A St. Luke summer. Each day during the past week has been unseasonably warm, while the nights, on the other hand, have been about as unseasonably cold; consequently the daily range of temperature has been on most days unusually great. On three nights the exposed thermometer showed about 5° of frost. At the present time the

soil both at 1 foot and 2 feet deep is of about a reasonable warmth. The air has been unusually dry lately in the warmest part of the day, but there has been more or less fog on most mornings and evenings. No rain has now fallen for nearly a fortnight, and during the past ten days no measurable quantity of rain-water has come through either percolation gauge. On the 22nd the atmosphere was remarkably calm, the total velocity at 30 feet above the ground for the 24 hours being only nine miles, making this the calmest day yet recorded here in October. Throughout the week ending the 22nd the wind came exclusively from the same point of the compass—E.S.E. The sun has shone on an average during the week for nearly 4½ hours a day.—E. M., *Berkhamsted, October 27.*

—A week of very variable temperature. For instance, on the night preceding the 27th ult. the exposed thermometer never fell lower than 53°; whereas a few nights afterwards the same thermometer registered 3° of frost. At 1 foot deep the ground is now about 1° warmer, and at 2 feet deep about 2° warmer than is seasonable. Rain fell on three days, to the aggregate depth of 1½ inches—equivalent to 7 gallons of water on each square yard of surface. The past month, taken as a whole, was, if anything, rather a warm one. The fact is the days were nearly all warm, but, on the other hand, during the first three weeks there was only one night which was not more or less cold. Consequently the average difference between the highest and lowest temperatures was unusually great—in fact, greater than in any other October of which I have here any record. Rain fell on only ten days, but to the total depth of rather more than 3 inches, or about the average quantity for the month. Nearly the whole of the total fall was deposited on four days—the 1st, 26th, 27th, and 29th. The sun shone on an average for 4¼ hours a day—making it the most sunny October since that of 1893. With the exception of 1897, this was also the calmest October of the series (fourteen years).—E. M., *Berkhamsted.*

NOTES OF THE WEEK.

Cereus triangularis.—A large plant of this Mexican species trained to the roof of the large succulent house at Kew has been flowering freely of late, at least so far as freedom may be applied to such plants. The distinctly triangular growth is more or less of a climbing nature and in this way covers a very considerable space. The blossoms are yellowish and usually appear during the autumn months.

Late-sown Eschscholtzias.—After all the bad weather we have been having lately—weather which has cut down Dahlias and even injured Chrysanthemums—some clumps of Eschscholtzias sown broadcast on June 7 are quite fresh and showy. The value of sowing a successional batch of such hardy annuals is clear when, at the end of October, bunches of half-open buds can be cut. The buds open well in water.—T. J. W., *Woodside Park, N.*

Tacsonia Van Volxemi fruiting.—Mr. Renshaw asks whether the fruit of *Tacsonia Van Volxemi* is eatable. A few years ago when I had a plant of it in my greenhouse I used to eat the fruit. Anyone who likes the peculiar flavour of the fruits of *Passiflora edulis* and of the *Granadilla* (*P. quadrangularis*) will like them. They are not so acid as the fruits of *P. edulis*, but are a good deal like them otherwise.—C. W. STRICKLAND, *Hildenley, Malton.*

Abutilon Golden Fleece.—This richly-coloured kind is one of the most free-flowering of this useful group of greenhouse shrubs, and once it begins to bloom it continues in unbroken profusion till nearly the end of the year. During the several months that the plant remains in flower many hundreds of blossoms must be produced, particularly where, as is the case in the No. 4 range at Kew, a well-established plant occupies a good position against the roof glass. Here health, vigour, and freedom of flowering go hand in hand.

Horminum pyrenaicum album.—The typical *Horminum pyrenaicum* is not a plant which commends itself to me. There are, however, some who consider it a plant of considerable value and

worth growing in the border or in the rock garden. They may, perhaps, like to know that there is a white variety in cultivation. It does not appear to be much grown, as I have no recollection of having seen it in bloom until September last, when I came across it in a nursery in Scotland. It is, I think, equal in point of merit to the type.—S. ARNOTT.

Quercus cocinea.—In the early days of autumn there is perhaps no more beautiful a tree than a well coloured example of the Scarlet Oak. The fine colour is always greatly enhanced by the bold, handsome leaves, and in the case of some of the best examples we have seen the colour is not easy to describe. Even in the smaller specimens that of late have found their way into not a few gardens the effect is very fine, if not indeed quite unique. Of its beauty and worth a few well coloured sprays recently noted at the Drill Hall acted as a useful reminder.

Begonia Credneri.—Among the more vigorous and robust growing kinds of Begonias, this when in flower is always effective. It is somewhat closely allied to *B. Haageana*; indeed the two may be but forms of the same species. In the huge mass of blossoms, however, the two have much in common, not merely in the dense cluster and the drooping character of the same, but equally in the creamy colour of the flowers which are slightly tinted here and there with rosy lilac and more or less heavily bearded externally. The foliage is abundant in both kinds.

A warning note—Ampelopsis Hoggi.—I wish to put people who grow this wall shrub on their guard against its virulently poisonous properties. The plant usually grown under the above name is a species of *Rhus*, nearly, if not quite, identical with *Rhus Toxicodendron*, or Poison Ivy. A friend was here some time ago and asked for cuttings, which were sent. In cutting them off and packing no one suffered, but my friend's son, who received them, was laid up for several days with a painful burning rash or eczema. Like *Primula obconica* and other plants capable of setting up a painful rash, &c., in some individuals, this *Rhus* or Sumach only affects certain people, but it behoves all to beware of the scandent or climbing species, especially in handling them for pruning or propagating.—F. W. B.

Alyssum maritimum.—A reference to this pretty sweet-scented annual on page 348 reminds me of a beautiful little plant which is said to be a variety of *Alyssum maritimum*, and which I have met with in only some two gardens. I think the name was given as *A. m. compactum*. I first saw it at Carton some three years ago, and Mr. Black thought highly of it there. This autumn I again met with it, but this time it was at Tynningham, where it is equally valued by Mr. Brotherton, the gardener there. As an edging plant this form is quite an acquisition, its compact habit and neatness adapting it admirably for such a purpose. It is quite possible that it may be a different species from *A. maritimum*; it is, at any rate, more distinct from it than one would expect in the case of ordinary variations.—S. ARNOTT.

Anemone blanda scythica.—To avoid a mistake becoming permanent I beg to state that the figure lately published is that of *Anemone blanda scythica*, and not of *cyprina*. This latter occurs with blue, white and reddish flowers on the island of Cyprus. Moreover, it is the worst form. Just opposite Cyprus, on the mainland and stretching into Asia Minor, a better and deeper coloured form is found, best represented by Mr. Ingram's variety. *A. b. scythica* flowers a fortnight later than these and has the most refined flowers as well in shape as in colour; the white is purest, and the ultramarine has a peculiar tone difficult to describe. I have not been able to find out where Kotschy had gathered the specimens which he brought to Vienna some forty years ago, the flowers of which were white, with a blue rim.—MAX LEICHTLIN.
