Asimine.—The "North American papaw," or "custard apple" (*Asimina triloba*, Dunal.) is an anonaceous shrub that occurs on the banks of streams in the middle, southern and western states of North America, and probably received one of its names on account of its edible fruit, from negroes who were acquainted with the papaw of the tropics (*Carica Papaya*). The plant is not at present used in medicine, but as the bark and leaves have a disagreeable smell and bitter taste different parts of it have been submitted to examination by Messrs. Lloyd (*Pharm. Runds.*, Dec., p. 269). Only the ordinary constituents were found in all the parts except the seeds, from which an alkaloid was isolated that has been named "asimine." The pure alkaloid is described as being colourless, odourless and tasteless, insoluble in water, readily soluble in alcohol and ether, and less soluble in chloroform or benzol. It could not be obtained in the crystalline form, but the hydrochlorate and some other salts were easily crystallizable. In some of its reactions asimine closely resembles morphine, and it will probably be made the subject of physiological experiments.—*Pharmaceutical Journal.*

A New Medicinal Plant.—A new medicinal plant is referred to in a recent number of the *Therapeutic Gazette* under the name of Cacur, and is said to be used by the Kaffirs in Southern Africa as an emetic. The plant is said to be Cucumis myriocampe, and the green or yellowish-green fruits are the parts used. The form of administration, as pursued by the Kaffirs, is to heat the fruits, and squirting the contents into their mouths, to swallow them. The contents of two fruits are considered a dose for an adult, and one for a child. The plant grows largely in gardens as a weed, especially where Melons and Pumpkins are cultivated, and it produces its fruits very abundantly. These fruits are about the size of a large Gooseberry, at first green but turning yellow on ripening, and covered sparsely with short soft prickles. The soft viscid pulp has a faint odour of Cucumbers and a decidedly bitter taste. From experiments made with the pulp of the fruit it seems to be decidedly emetic in its action and purgative in non-emetic doses. The chemistry of the plant has not yet been satisfactorily ascertained; so far as it has been done there seems to be "no trace of any alkaloid, the activity seeming to depend upon a bitter neutral principle readily soluble in water or in 80 per cent alcohol."—*Gardeners' Chronicle.*

CINCHONA IN JAVA.

[The following Report shews that Mr. Van Romunde is a worthy successor to Mr. Moens, for the interest he takes in his work, and the experiments he carries on, of the results of which we shall hear in future Reports. Mr. Van Romunde's full Report for 1885 covers five pages of the January number of the *Tropical Agriculturist*, and contains much very suggestive information.—ED.]

REPORT ON THE GOVERNMENT CINCHONA GARDENS FOR THE 3RD QUARTER OF 1886.

(*Translated for the "Ceylon Observer."*)

The weather during the past quarter has been pretty dry, though it was occasionally varied by slight showers of rain, which were very beneficial to the young plantations and nurseries. Frosts at nights, which generally take place during severe droughts and strong East winds, were nowhere observed.

In the beginning of this quarter some thousands of strong grafts were put out in the open ground, and are thriving as well as could be wished.

The harvest of 1886 up to the end of September amounted to 300,000 Amsterdam pounds of bark, of which 260,288 pounds were sent to Batavia.

This produce was obtained by thinning out closely planted Ledgeriana and Succirubra plantations, whilst a not unimportant quantity of pharmaceutical bark was harvested by rooting out some old succirubra and Josephiana gardens.

Much care and expense were bestowed on the nurseries of Ledgeriana and Succirubra seedlings for the purpose of replanting the old gardens, which have been uprooted as well as those remaining to be uprooted.

A vigorous commencement has been made in the preparation of the ground for this planting out, as also in the clearing of wooded ground for extending the plantations of the graft planting at Tirtasari, which graft planting will be increased during the coming West monsoon to the extent of 30 bouws.

During the past quarter only a few public sales of cinchona seed were held, the gross proceeds of which amounted only to *f*165·25. The greatest quantity of seed did not begin to ripen till the month of September. At the sale of the 5th October a considerable amount of seed was announced, of which a portion was obtained from grafts of selected mother trees, the bark of which yielded over 10 per cent of quinine. In consequence of combination among private planters, this sale only realized *f*203·50.

Advices have been received of the sale of the second half of the produce of the harvest of 1885 on the 29th September last. The results of the sale are not yet known here.

At the request of parties interested in the cinchona trade, and in concert with the Netherland trading Society, the Minister for the Colonies has decided that as a trial eight sales of cinchona bark, each year, shall be held during 1887 and 1888.

The researches made for ascertaining the influence which the Succirubra stem has on the constitution of the bark of the Ledgeriana grafted thereon, have been carried on during the past quarter, but have not yet been completed, so that the results will not be made known until the next quarterly report shall be sent in.

(Signed) VAN ROMUNDE,

Director of the Government Cinchona Undertaking.

BANDOENG, 7th October, 1886.

STATEMENT SHOWING THE POSITION OF THE GOVERNMENT CINCHONA PLANTATIONS IN JAVA FOR THE 3RD QUARTER 1886.

(8 plantations from 1,250 to 1,900 feet above sea level.)

Plants in the Nurseries :—Total of different kinds.—Ledgeriana, 1,249,000*a*, Succirubra 560,000.

Plants in the Open Ground :—Total of different kinds.—Ledgeriana 755,700*b*, Calisaya en Hasskarliana 74,000, Succirubra en Caloptera 556,000, Officinalis 234,000, Lancifolia 8,000.

Plants in the Nurseries.—Total of all kinds 1,809,000.

Plants in the Open Ground.—Total of all kinds, 1,627,700.

General total number of plants 3,436,700.

a Including grafts.

b Including cuttings and grafts.

(Exclusive of more or less 3,500 original Ledgerianas).

Translated for the "Observer" from the Extra Supplement of the Javasche Courant, ("*Government Gazette*") issued Dec 18th, 1886.

IMPORTANT TEA DELIVERY CASE.

A case of some importance has recently been tried in London in the Queen's Bench, in which the question of short weight was concerned. The plaintiffs, Messrs. Lister and Biggs, purchased of Messrs. Barry & Co, 96 chests of Tea of the declared nett weight of 9,225lb. When the Tea came to be weighed at the London wharf it was found to be 587 lb short. The defence was that the sellers acted simply as agents and were not responsible for the declared garden weights. Although the amount in dispute was only 25 lb, the case is necessarily of considerable importance to owners and Agents here, and it is to be hoped that it may induce more care being exercised as to Garden weighments in future. It would seriously tend to a want of confidence in the home market if such cases were to become at all common. In this case the chests are reported to have been in good condition. The only conclusion that can be come to, therefore, is that the scales at the garden must have been defective, for, of course, intentional fraud in such a matter is quite out of the question. Managers would do well to have their scales periodically tested, as they are liable, of course, to get out of order, and during weighment a European assistant should invariably check the native weighman, with whom, perhaps, inaccuracy of weight sometimes lies. The judge, in summing up, dwelt on the great importance of this case to Tea owners, because, as he remarked, on the one hand there was a sort of imputation that fraudulent conduct had been pursued somewhere, and on the other hand a custom had been set up which was a dangerous one,—a custom which required a great deal of watching. He held that a man buying a given quantity was entitled to receive that quantity, custom or no custom notwithstanding. The jury naturally enough concurred in this view, and found for the plaintiffs with costs and a certificate in a special jury. So that by the time all charges are paid, the expense will not be trifling. That, however, is of less account than the injury which such a case is likely to do to the reputation of Indian shippers. Fortunately, publicity in such matters, is as a rule, avoided, and we think Messrs. Barry & Co. showed an unwise discretion in disputing the claim. Whenever a claim in respect to short weight is made at home, it is almost invariably at once allowed by the wholesale seller, and we think it is only fair that this should be so, even though the loss may have occured through pilfering at the Bonded Warehouse, because the purchaser has nothing to do with this. It is the owner or his agent alone whose business it is to protect his own property, or, if he is unable to do so, to hold himself liable for the loss. That a good deal of pilfering goes on in the bonded warehouses we fully believe, and it is strange that so little heed is paid to the matter. It is not very long ago that a prosecution of some employees of the Bonded Warehouse revealed the fact that tea stealing was constantly carried on there, and wholesale sellers, as we say, were frequently in the habit of allowing, without question, for such deficiencies. We think, however, in justice to their friends on this side, they should not take the matter so easily, but should induce the authorities at the Bonded Warehouse to look a little better after their employees.—*Indian Tea Gazette.*

TRAVELLING SHOW OF AGRICULTURAL IMPLEMENTS IN SOUTHERN INDIA.

The following Resolution of the Madras Board of Revenue, is dated 13th November :—

"The Director's report on the operations of the Travelling Agricultural Show, sanctioned in G. O., dated 10th June 1886, will be submitted to Government. The show, under the superintendence of the Assistant Director, Mr. Benson, travelled for two months, July and August, along the line of the South Indian Railway through the districts of South Arcot, Tanjore, Trichinopoly, Madura and Tinnevelly; it visited some twenty of the more important towns of those districts, and at each place the working of improved ploughs, seed drills, harrows, rice hullers and other appliances was exhibited with success, and, as a result, some 300 ploughs of an improved type were sold by the agent whom Messrs. Massey & Co. had deputed to accompany the expedition. What its cost was does not appear, but, under the orders of Government sanctioning it, that cost will have been met from the allotment provided for the ploughing matches, whose place it takes. The Director recommends that these tours should be continued and the Board support him; he proposes the permanent deputation of a trained student to take charge of them, and the employment of a competent blacksmith, the time of both to be given wholly to the work. The former proposal has the Board's support, the latter has not; it is not desirable that the people should be taught to be dependent on a itinerant Government blacksmith to the discouragement of the local smith, nor, in any case, would it be fair to the latter that the former's work and material should be given gratis. It must be brought home to the people that it is to their profit to buy spare shares, which should be readily available; and, if it cannot be shown that it is to their profit to do so, then the plough stands condemned and the fact should be honestly admitted; if the ploughs cannot command themselves to the public on their own intrinsic merits, without the assistance of gratuitious repairs by Government, then any temporary advance that they may make must be looked on as a mere paper advance, and not as a permanent fact. The Director suggests also that the exhibitions should be limited to the working of ploughs, but this does not appear to the Board to be necessary; the exhibition of ploughs should certainly be the main object of the expedition, but it will not be possible to be ploughing always, and the spare hours may usefully be spent in the exhibition of other appliances, to the existence of which, if not to their use, the native mind will gradually become accustomed."—*Madras Mail.*

NATIVE AGRICULTURE AND AGRICULTURAL EDUCATION IN CEYLON.

From one of the most estimable and intelligent of Sinhalese country gentlemen we are acquainted with—Mudaliyar D. C. Ameresekere of Hanwella, a friend of Sir C. P. Layard—we have received the copy of a letter which he sent to the Public Instruction Office so far back as October 1884. No acknowledgment has been received, but very probably some of the Mudaliyar's ideas have been acted on. We quote as follows:—

1. That the children of the agricultural classes now attending the village schools stay in school for a very limited period and leave it in a helpless condition. The little learning which is not very often more than an imperfect knowledge of reading and writing is of no avail for them to get a permanent livelihood, nor are they accustomed to do any trade that their parents have hitherto done. Moreover, most of the lads at the present day think it a disgrace to work in a field or garden after having been in school for sometime. These lads when they are grown up try to earn food and clothing in various trifling and ineffectual ways and failing to attain their object, they resort to vicious and unlawful means, loathing work and those who work. It is, therefore, perceptible to all, and to me particularly, (being a resident in the interior) that in this manner the island is gradually going down in wealth and civilization.

2. That my opinion as regards the establishment of village schools is summarised as follows:—An allotment of jungle land of the extent of ten acres or more, a sufficient supply of agricultural implements, and a teacher should be given for each school by Government. The parents of the children should fell down the jungle and put up a school bungalow with accommodation for the teacher to reside in. The school should be kept for six hours, three of which should be spent in learning reading, writing and arithmetic (of the native language) and the remaining three for garden work. The land in this case may be divided among the pupils of the school, and be planted with coconut, jak, arecanut and other fruit-bearing trees, together with yams and vegetables of different kinds according to the nature of the soil. When the school is in existence for five years the entire land allotted for the school will in this way be planted and the greater number of the trees will be bearing. An acre of the land will then be worth about R300, the same acre in its wasteful state would not have been disposed of by Government for more than R10. One-half of the planted land should be given to the pupils of the school, the other half to Government. By this means a considerable sum may be added to the revenue also. The schoolmaster should be entitled to half the yams and vegetables grown on the land, and the pupils to the other half. The teacher is here able to raise a considerable sum, hence a schoolmaster who is now working for R20 per mensem will be willing to work for R15, as he will be able to raise over R5 a month by his share of vegetables, &c.

3. When the land has been fully planted, the school may be shifted to a like piece of ground and the same operations being carried on, like results may be obtained. A child who attends school at the age of five will be able to cultivate three pieces of land before he reaches 20. At this age he can leave school as a civilized and experienced cultivator with a certain amount of property which is probably worth more than R500, and with a thorough knowledge of reading, writing, and arithmetic. The descendants of these refined agriculturists will then have reason to think that these two (cultivation and learning) are the natural courses that children have to take up, and will no more entertain that erroneous idea that work is a disgrace.

4. When village agricultural schools are established in the manner I have indicated, the parents of the children in the interior will be too glad to give a helping hand to education for its dissemination. I am of opinion, therefore, that this method will be one of the best plans by means of which the wealth and civilization of the island may be raised to a higher standard. —I remain, dear sir, yours obediently, D. AMERESEKERE.

CEYLON TEA IN AMERICA.

We call attention to the letter of Mr. J. McCombie Murray on this subject, (page 524,) which may be taken as addressed to "The Ceylon Tea Syndicate"—if such a body is still in existence—per favour of the press. We have from the outset maintained that America—the United States and Canada—presented the most favourable field of operations for a Tea Syndicate. Far more so, in our opinion, than the Australasian Colonies with their limited population, less all told than

is contained in many single States of the Western Republic. The United Kingdom is even now effectually worked and private enterprise is likely to do all that is required there in the way of extension. There may be room on the Continent of Europe to make Ceylon teas better known and to endeavour to encourage consumption—to create a demand, now that coffee is getting so dear. But it is surely among the 60 millions of English-speaking people, between the Atlantic and Pacific, most of them tea-drinkers or the descendants of tea-drinkers from our common mother-country, that we may look for encouragement and success from the working of a Tea Syndicate, in placing good sound Teas before the consumers, without the interference of New York buyers or mixers. There may be technical objections to some parts of the scheme of Messrs. Pineo and Murray; but in its broad outlines, it seems to present a feasible plan of working and one by no means unfavourable to the Ceylon producer. We trust it will be taken into the careful consideration of the Planters' Association and the Syndicate Committee. If all large proprietors promised a few thousand lb. of tea each, in support of the experiment, there would not be much difficulty in guaranteeing a sufficient quantity to try the American market thoroughly for a year at least. Perhaps Mr. Rutherford would consent to make the schedule he originally drew up, form the basis of a new guarantee in favour of Messrs Pinoe and Murray. Both these gentlemen are too well-known in Ceylon, and have too close a connection with the island, to be otherwise than sincerely and wholeheartedly anxious to do their best for our produce. Indeed, there would be the best of guarantees to this effect, namely, that their own interests would be indentical with those of the Ceylon planters. We trust, therefore, that the present opportunity of getting a fair trial for our teas on the Continent of North America, and especially in the middle and Western States, may not be slighted, but that through the good offices of the Planters' Association and its Committee, steps towards the establishment of a Syndicate for this purpose, may shortly be taken.

CEYLON UPCOUNTRY PLANTING REPORT:

CURING OF TEA IN COLOMBO—RAMASAMI'S IDEA OF PUNCTUALITY.

17th Jan. 1887.

Is the curing of tea in Colombo which is already being tried, the beginning of a big thing or an expiring effort of the old system? If fuel is going to become expensive and hard for estates to get, the sending of green leaf by train to Colombo, may be one way to yet over the difficulties. Anyhow, thirteen cents a lb. which I understand is paid at present, should suit some of the low-country places, and with a cheap freight and a night train even some that are higher up. If fuel has to be imported, it may become a question whether it would not be cheaper to have large factories in Colombo for the manufacture of tea. To meet the freight of the leaf, there would be the saving on the carriage of lead, fuel and manufactured tea. Of course it would be only estates near a railway which could avail themselves of this plan. There would require also to be special trucks for the carriage of the leaf to allow a man to pass through them, who might stir up the leaf to prevent its heating; and the factory to take delivery from the planter at the railway station. By this means one man travelling with the train might look after the pluckings of a good many places, and land them in good condition at the terminus.

Now that the cooly is feeling that he is again becoming of some importance in Ceylon, he is waking up to a sense of his rights, and is evidently not to be trifled with. A striking illustration of this I heard the other day. A head kangani presented his "durai" with a Waterbury watch so that he might blow the horn regularly at four!

PEPPERCORN.

COFFEE DISEASE IN THE PROVINCE OF RIO DE JANEIRO.

On the 18th Nov. the president of the province addressed a circular to the various municipal chambers calling attention to the report of Sr. Glaziou, in which he claims to have discovered the origin of the coffee disease. Sr. Glaziou's report is of sufficient interest to warrant our translating it in full.

To the Coffee Planters:—

After repeated investigations I have had the fortune to discover, on the plantations of "Boa Esperanca" belonging to Major Belieni and "Serra Vermelha" belonging to Sr. Francisco Dias Ferreira, in the municipality of Cantagallo, on October 22nd and 23rd ulto. the manner in which arises the propagation of and the inoculation by the parasitic insect constituting the present disease of the coffee trees in Brazil; and, what is better, a positive and practical manner to destroy it in little time. The cause of so lamentable a damage is a microscopic insect which lives and grows in the filiform roots of the coffee tree, introducing itself into its radical spongioles where it destroys the cellular structure of the plant in search of food, and when adult it creates in these same roots its nests, formed into knots, which reach a diameter of one to three millimetres. In these knots, or nests, the insect deposits its thousands of eggs. Concurrently the small radical fibres attacked by the insect rot away, dropping into the surrounding ground the thousands of eggs deposited by the insect and which may be compared to the *sporidia* of a certain group of mushrooms, as well from the exterior appearance as from their incalculable number.

It is in consequence of this pest that one sees the coffee plant wither, assume a yellowish color, lose its new leaves at the extremities of the branches and drop its fruit, already blighted by the deviation of the sap which the nutritive organs had condensed from the soil for the benefit of the normal life of the tree. Thus attacked the plant quickly dies, bequeathing to the soil the totality of the evil which has caused its destruction.

Such cases have occupied my attention for some five years, and even more the manner in which planters might free themselves of them, and this I have positively discovered. It is this: examining with my own eyes through a microscope, excavating the soil myself in the coffee plantations, I recognized that the cause of this lamentable disease exists in the heaps of weeds hoed up, and nearly always drawn around the coffee shrub. There these weeds rot, forming little heaps of humus very light and very fertile, which attract the newer roots of the coffee plant, and as there they are more tender and more vigorous than in any other place, they are immediately invaded by the pest up to the very smallest fibres in a most disheartening manner. The heaps of humus formed by the residuum of decomposition of these weeds are later on dissipated by the rain and scattered in all the depressions of the soil, and thence their animal contents penetrate so much deeper into the porous soil, as this is proportionately fertile. The penetration is less frequent in compact, argilaceous and dry soils.

Convinced of this fact, I hasten to recommend to interested planters never to heap the weeds and leave them to rot around the coffee trees, but to scatter them between the rows, where there is sufficient sun, that they may be dried as speedily as possible, and once dried to collect them into heaps and burn them, leaving the soil of the coffee orchards perfectly clean. If there be any difficulty in burning the weeds, it is absolutely necessary to carry them out of the orchards

and place them in uncultivated spots, far from the plantations, and above all from orange trees, for these latter are also liable to attacks, from and destruction by this same pest which so miserably destroys the coffee plants; the same thing occurs with the *pawpaw* (*mamoeiro*) where I have also discovered the pest. By following these indications, I am convinced that, in less than two years, the coffee orchards of the municipality of Cantagallo and of others will return to their pristine condition, maintaining a favorable position and repaying to planters and to the State a return for their labors. —*Augusto Francisco Maria Glaziou.*—"Rio News."

Artificial Fuel for Tea Curing.—We regret to learn that the result of enquiries is to shew that although crude Kerosene oil could be applied as an efficient heating agent, the cost of carriage would bring the cost up to double the price of coals, while coals seem to be in most cases twice the cost of wood fuel. Our own hope is in the residuum of coal wells, compressed into bricks, the freight of which, as ballast for ships, might be very ow. In any case we cannot doubt that a cheap artificial fuel will, ere long, be discovered.

Coffee Disease in Brazil.—We call attention to an interesting extract on our last page, from the *Rio News* by which it will be seen that a Brazilian attributes the coffee disease which has ravaged the province of Rio, to a minute insect, fostered by heaps of decaying weeds. We suppose this is the *Cemiostoma* referred to by the late Mr. Cruwell in his letters to us from Brazil, although no scientific name is given by M. Glaziou. We doubt very much whether this gentleman's remedy will be as successful as he anticipates.

Cheap Quinine: A Practical Question.—Can any of our readers find out through relatives or friends, whether the people in the Fen districts of England or away down in Essex and Kent about Gravesend and the mouth of the Thames, have benefited at all by the cheapness of quinine? Quinine is of as much consequence to them as to the people in the Southern States of America. Do the resident clergymen, and other ministers and philanthropic people generally, know that quinine can be got for 2s 6d or 3s per ounce? Who will enquire?

The Advance in Kowrie Gum.—For a number of years past statements regarding the growing difficulty of gathering kowrie gum have reached this market at different times, almost invariably with the result of causing a stiffening of prices here. Recently similar reports have been received, with the added information that the diggers have now to seek for the gum so far from the settlements that the expense of transportstion adds materially to the cost of the article when put upon the market. The long depression in trade in New Zealand has induced a large number of people who engage in the occupation only as a last resort to go to work at digging for the gum. Still, notwithstanding the increased number of diggers, supplies come in very slowly from the interior. —*New Field Drug Reporter.* [Gums of all kinds are advancing in price.—Ed.]

Kapok.—Under this Malayan name the Silk-cotton tree of India and the Archipelago, and which is indeed common throughout the tropics, is known. Botanically it is the Eriodendron anfractuosum, a plant well known to botanists, and, when collecting seed-vessels was in vogue some forty years ago, to amateurs also. It was always a mystery why the silky fibres attached to the seeds of this plant in such profusion, were not utilised. Certainly it was from no fault of the botanists. Now we learn that it forms a large item in Australian trade, Melbourne being now supplied from India and Ceylon. It is chiefly used for upholstery purposes. In 1886, 7,995 bales, worth between £26,000 and £27,000, were imported, principally from Java, where special care is taken in cleansing and packing the fibre.—*Gardeners' Chronicle.*

Correspondence.

To the Editor of the "Ceylon Observer."

CEYLON TEA IN AMERICA.

Philadelphia, Pa., 12th Dec. 1886.

Dear Sir,—Your editorial "*re* The Ceylon Tea Syndicate" appearing in the Overland issue of the 29th October has been read with interest. That "it is to a Syndicate of the main body of those interested in tea-growing in the Colony that we look for the full realization of our desire" is, perhaps, a matter of fact more easily understood than fully realized, that is if any dependence is to be placed by the Ceylon growers upon the American market as a fall-back. Before advancing any arguments, let me mention that I am indebted to the invaluable information afforded me by Mr. Pineo (with whom I am about to co-operate) for a more or less intimate knowledge of the tea trade as carried on in America. You refer in your editorial to the practices of "unscrupulous parties" in Britain to the unscrupulous means used for trade purposes in dealing with our Ceylon teas. A passing glance at the American tea market would turn the *veryest* abuses in England into the most honest trade. I speak of what I *see* and what I see, I *believe*. There are two classes of people who are identified with the tea trade—the seller and the buyer, or, I may say, the seller and the sold. It is difficult to understand how a people, proverbially sharp in business and oftimes unscrupulous, can themselves be so easily swindled in their turn, but so it is. Fortunately for us, we are yet in the position of power. We *might* be deceivers if we *would*, but to be so there is no call, and we cannot be deceived ourselves so long as we act with wisdom and forethought.

Our Indian rivals, as I intend showing, were unfortunate inasmuch as they failed to *hold* their position by throwing their produce *en bloc* upon the American market. The value of the same was, from that moment, a matter for the Americans to decide, the result as may be expected a heavy loss to the members of the Indian Syndicate, and a marked improvement in the *Japan* teas without the shadow of benefit to the name of India as a tea-producing country.

It surprized me to hear from as interested and acute an observer as Mr. Pineo, that to his knowledge there has not been a pound of Indian or Ceylon tea retailed in the country, save what came through his hands. Is not this sufficient proof that the means used by the Indian Syndicate were inadequate to serve the real interests of the Indian tea trade, or to meet the requirements which a *proper introduction* calls for? As the result has proved, the energies of the Indian Tea Syndicate have been most successfully devoted to raising the value of *Japan* teas in the opinion of the American people and nothing more. If I might make so bold a surmise, I should say another cause of the failure of the Indian Tea Syndicate might have been a very half-hearted interest, in, if not actual discouragement of the business on the part of the Calcutta Agents, who natuarally enough, would take no favourable interest in a scheme which took business past their portals.

Do I hear the Ceylon producer say: "The more reason why the Ceylon Tea Syndicate should die a natural death—we'd better let well alone! As for myself I'll send *my* tea to the London market as long as I get prices that pay." Just so! Every seller is at perfect liberty to sell in the market of his choice, but that in no way interferes with the abuse of your tea in America. Your tea is bought

today by Americans for *mixing* purposes, but *that* in no way assists in the introduction of your produce into America. It merely aids in placing the rubbishy Japan teas *on a higher level*. Is *this* the end for which you work? Be assured of this, O proprietor, (and you can place this letter in a safe place for reference about three years hence) that should you find prices go down in England, you will have considerable difficulty in disposing of your produce profitably when you find that you *are obliged* to sell your tea, unintroduced to the consumer, in the open American market or sell as best you can in Mincing Lane.

Unless Ceylon tea is very soon placed before the American people as *a specialty;* unless the taste of the American people is educated to it, and thereby a *demand* for it *created*, it will yet have to play second fiddle to Indian tea as a medium for mixing, and share with it the *honour* of raising Japan tea to a higher standard and securing for it the monopoly in the country. We have considered the fate of Indian tea, as also the probable fate of our Ceylon teas in this country. If I am right in what I say, it behoves us to consider how best to avoid such a fate for the produce in which we are all so deeply interested. My ideas and opinions have already appeared in your columns, and I fear I must repeat myself to a certain extent:—

First.—Interested agents must be appointed in America, whose business will be to sell pure Ceylon tea in registered packets only.

Why *interested* agents? Because no tea-dealer in America would undertake to *push* a tea which affords him less profit than the tea he deals in. The profits on Japan teas are larger than can be made on Ceylons. Why *should* the jobber disorganize his usual trade to please the Ceylon producer? It would entail talk, trouble and energy to no profitable end. His trade would be less, his profits would not and *could* not be increased one whit. On the contrary, they would be diminished.

Second.—The Syndicate, if formed at all, must provide itself with a certain amount of capital like any other business; and, moreover, it must be so organized that tea can be collected when called for, bulked, sifted, packed and dispatched at regular intervals, and in such quantities as may be demanded by the consignees. Any Syndicate formed on a basis of a less business-like nature will, to my mind, prove a failure if indeed anyone could be found on this side to take it up at all. It remains for the planting community to decide what they are to do in the matter. Personally, I have no pecuniary interest in the result as Mr. Pineo and myself have arranged to work on an independent basis. I do not mean to infer that we would not be willing to further the scheme. Nay, even devote our *entire* energies to further the ends of the Ceylon Tea Syndicate, but we could only do so on such terms as would prove remunerative to us as well as a reliable business to undertake.

That we could serve the interests of our own brand simultaneously with those of the Syndicate teas is impossible.

On the other hand we would be willing to *lend*, so to speak, the entire privilege of using our brand free of any charge, we ourselves looking for remuneration which will accrue from the advertisement of the same, and the benefit we derive therefrom when the Syndicate shall have ceased to exist.

Our brand I may say has been got up at considerable expense. The trade mark is a representation of the ubiquitous "Kootee" plucking a tea bush.

Let me here say that this subject was selected by Mr. Pineo some eighteen months ago and acted upon some six months back, so that there has been no piratical action in the matter. Neither party can be effected in any way by the coincidence, so there is no call for regret. As a guarantee that no loss will be sustained by the members of the Syndicate, we are willing to pay 10 per cent over the London valuation of tea consigned to us provided:—

First.—That the valuators be nominated with the common consent of both parties.

Second.—That the charges on such valuation be paid by the Syndicate.

Third.—That freight and all shipping charges to Philadelphia be pre-paid.

Fourth.—That the members of the Syndicate agree to wait for returns for each consignment until such consignment be sold out.

Fifth.—That we have the Sole Agency in America, with power to appoint sub-Agents wherever we may deem it advisable.

Sixth.—That the Syndicate guarantee to provide us with tea at *regular* intervals in such qualities as may be required by us, and that the quality of the same be kept up to their original standard.

We on the other hand agree to protect in every way the tea consigned to us. To push the sales of the same in our registered packets through our own retail trade, and that of all respectable grocers in the United States and Canada. To expedite in every way the sale of your tea, and pay in full the value of the same with the addition of 10 per cent on the valuation, on each consignment being disposed of

In conclusion let me add, that we know ourselves to be in a position, by the foregoing means, to dispose of almost an unlimited amount of Ceylon tea, and that the extent of business done will only be limited by the members of the Syndicate themselves. At the same time the aforesaid provisions would have to be rigorously enforced, especially Prov. No. 6, as any shortcoming on the part of the Syndicate would be a deathblow to the success of the undertaking.

I have already given you reasons why, with the exception of ourselves, no one will take in hand to push your interests. In corroboration of the assertion let me quote the expression of the principals of the well-known firm of Acker, Merril & Condit, when conversing with Mr. Pineo:—"We would not be bothered, or try to introduce Ceylon tea; nor would we even look at it unless a demand was created. Then, and then only would we handle it." In making the foregoing proposal to the members of the Syndicate, we are influenced not so much by the expectation of great pecuniary remuneration at first, but by a strong desire that Ceylon tea should be properly introduced into America; that it should be placed in the position of standing on its own merits and *eventually*, prove as it *must* if properly treated, remunerative to all who handle it and ultimately take its place as the *nonpareil* tea of the world! The teas required here would be of three grades (1) a Pekoe about 1s 5d to 1s. 6d, (2) a Pekoe Souchong about 1s. 1d. to 1s. 2d. and (3) a Souchong about 10d. to 11d. London valuation. All teas would have to be shipped to Philadelphia until further notice. It may not be generally known that our fine plantation coffee has yet to be introduced into America. Grocers are very much struck with the very regular and handsome appearance of the same when a sample is shewn them. We would like to have the assistance of the Syndicate in this line also, as we are sure we could do good business in it.

The matter may now be left in the hands of the Syndicate for consideration.—Yours faithfully,

J. McCOMBIE MURRAY.

P. S.—I enclose a table shewing how every member of the Syndicate can get his due according to

the valuation of exports in Ceylon. I expressed my views on this subject in a previous letter to the *Observer* while resident in the Island :—

		lb.	Valued in Ceylon at	Total Valuation	Proportion of each consignt. to whole	We suppose the 3 samples are valued in London and average 1s 2d per lb. The addition of 10 per cent would have to be added and freight and other charges to be subtracted, but we will suppose that the proceeds amount to 1s 2d per lb. all over. Value in London at 1s 2d.=	Proceeds in pence	Price received per lb.

PLANTATIONS AND INSECT VISITORS.

Lawrence, Dikoya, Dec. 1886.

Dear Sir,—Today's post takes you a tea tree branch, on the leaves of which you will perceive a yellowish bug-like insect. Can you tell what it is, or refer it to some one who can ?—I am, dear sir, yours faithfully, WALTER AGAR.

[Our referee's report : "19th Jan. 1887.—The males of a scale bug, species unknown to me. After being kept for about ten days, they became winged insects."—Ed.]

COFFEE AND INSECTS IN HAPUTALE.

Haldummulla, 31st Dec. 1886.

Dear Sir,—I send you by this post an insect I found on a coffee tree. I don't remember seeing one like it before. It was on a coffee tree which had a bad attack of "green" bug, and I can't help thinking, it may have something to do with that terrible pest. Perhaps your entomologist will tell us if it is the queen green bug or not! It much resembles the bug in form and colour, though, of course, much larger. I fear I killed the insect in catching it. Wishing you all a very happy New Year. HAPUTALE PLANTER.

[Our entomologist referee says :—"17th Jan. 1887 :—The larva of an insect belonging to the order *Homoptera*, family *Cerespidæ*, and allied to the 'frog-hopper.' It lives on the juices of plants, and can do no harm to coffee or tea, being seldom found in large numbers."—Ed]

THE HIGHEST PRICE OF COFFEE.

Colombo, 5th January 1887.

Dear Sir,—Since 1870 the highest price paid in Colombo for coffee per bushel is 27s (R13·50) : this for "Amunamulla" and "Rahatungoda." I am not quite sure about the f. o. b. price, but think a little over 125s (R62·50) was realized.—Yours faithfully,

E. JOHN, per REGINALD JOHN.

"BULKED UNASSORTED TEAS": MESSRS. RUCKER AND BENCRAFT KINDLY REQUESTED TO EXPLAIN MORE FULLY

St. Leys, Dikoya, January 10th 1887.

Dear Sir,—I read Messrs. Rucker and Bencraft's remarks regarding the break of tea referred to in my former letter, with much interest. The funny simile of the Doctor's prescription, is, I fear, wasted this time—for there was no attempt at special "Blending" with the lot of "Unassorted" in question. It was simply the *Bulk*, minus red leaf and dust, broken up, and thoroughly mixed. So the "exact proportions of fine and common teas" would be precisely the same as in the assorted lot, both being from the same bulk. A *new* light is evidently about to dawn on us—for I do not think I was alone, in having understood the meaning of "Bulked Unassorted" to be what the words imply. I hope, however, that Messrs. Rucker and Bencraft will act on your suggestion and more fully explain what *they* mean by it, and then we can try again.—Yours truly,

JAS. W. HOLT.

THE RELIEF OF THE "GOYAS:" LAGALLA DISTRICT AND SOME PRACTICAL ACTION.

Hoolankande, Madulkele, 16th Jan. 1887.

Dear Sir,—I read with interest A. G. K. B's. suggestions for the relief of the "goya" in the outlying and poorer villages.

I have for some time past been in communication with the Government on this subject more especially, with a view to obtain measures of relief for the villagers of the Lagalla and Tamankaduwa and Gongala districts.

It will interest you to know that the Government has already offered a grant of land for the establishment of an Experimental Garden; and as far as my experience goes, the officials—from the Col. Secretary to the Assistant Agent—seem to be desirous of carrying out any reasonable and practical measures for the furtherance of the object in question. The Wesleyan Mission has a fairly successful establishment in Lagalla, and I have no doubt that their aid would be freely extended to any undertaking, having for its object the relief of the poorer Sinhalese or their mental and moral improvement.

It is not difficult to propose measures of relief, without number; the difficulty lies in persuading the native to take advantage of them; experimental gardens hitherto have not met with much success; pepper, oranges, vanilla etc., are pretty things to see growing in a garden; but the native is of an enquiring mind and would like to see some one growing them to pay.

Nevertheless, as far as it is possible to see, an advance of cultivation and industry is the only remedy for poverty and its natural concomitants and to this alone must we look for a solution of the difficulty.

Besides the growing of economic products, the native should be encouraged to engage in minor industries, such as basket-making, carving in wood, rope-making etc.: carpentry above all should be encouraged. A man with a good house over his head, is altogether more of a man than his neighbour in the hovel. All these industries would require teachers, and the teachers would require pay, and a responsible person would be indispensable to watch the work, who would also require pay—altogether a good deal of money must be shelled out; but the work is worth the doing. Those interested should now communicate and obtain touch. You, sir, will doubtless use your influence on keeping the subject under discussion.—Yours faithfully E. G. B.

EFFECTS OF TOBACCO ON LAND.

There may be great profits in growing Tobacco (for a while), but I do not think we can keep it up long unless we are willing to spend a good share of the proceeds of sales in the purchase of manure and fertilisers to keep the yield up. So far as my observation and experience goes, I find Tobacco very exhausting to the soil. A heavy coat of manure is needed for every crop, and that is something that can hardly be said of any other farm product. We often read and hear it said that any soil that will grow a good fair crop of corn is all right for Tobacco. I do not find this to be the case. A very good crop of corn can be grown where Tobacco would be a comparative failure. Not only does the crop require an immense amount of fertilising material, but it seems to have a bad effect on the land for succeeding crops. As "Uncle Jotham Sparrow-grass" used to say through "Tim Bunker's" papers, "it seems to pizen the land." One of my neighbours raised last year an acre of Tobacco, putting on the land after it was ploughed a very heavy coat of fine manure, hauled at considerable expense from a neighbouring village. This was cultivated and dragged in thoroughly, so that there could have been no loss to speak of from evaporation or washing. That acre is the corner of a field which he has planted this year to corn—last year's Tobacco land and all. He told me several times that he expected a big crop of corn on that acre. I have seen the field almost daily during the season, and if anything, the acre corner is under the average of the field, notwithstanding it received so heavy a coat of manure while the balance of the field received none. It hardly seems possible that the one crop of Tobacco could have absorbed the manure applied. Until I find a more scientific and satisfactory explanation, I must fall in with "Uncle Jotham" when he says "it pizens the land." Unless the farmer makes a speciality of it, and buys manures constantly to keep his land up, I think the less he has to do with Tobacco the better off will his land be. It is no fit factor in ordinary farm operations with regard to rotation or aught else. While it is no doubt of a more permanent nature it is something like the Hop craze that went through the country a few years ago—every one is rushing into Tobacco growing. Even away up north of the 44th degree, where a crop is never safe from frost, people are expending thousands of dollars for outfits. The business will not wear long under these unfavourable conditions.—W. D. BOYNTON, in "*Farmers' Review*," Oct. 23.

BRICK TEA.

(BY "PERIPATETIC PLANTER.")

I hear that enquiries are afloat in London among the makers of tea-compressing machinery for a press for a firm in India. Now this is a matter *requiring special* information, or a well conceived idea may be shipwrecked by being directed along the wrong course. Compressed-tea, it is as well to make clear at once, is quite a different thing from brick-tea. Compressed-tea will do for the Russian market, and for certain colonies, and for the mercantile marine, but it will *not* do for Thibet. I am personally acquainted with the different kinds of tea-compressing machinery, and I know the traps that exist, in the path of the unwary, or indeed of the wary but uninitiated, here. If the enquiry, mentioned above from India, is with a view to making brick-tea for Thibet, *none* of the existing machinery for making "compressed" tea will be of the least use, and for reasons which it would take too much space to give in detail here. There are two or three types of hydraulic machinery for *compressing* tea and one mechanical press, all capable of exerting 60 tons pressure on the cake of tea, one of these I know to be admirable, another useless as deficient in speed, and in cost of the dies—these costing £70 the set alone—as to the mechanical press only one I believe has ever been constructed expressly for tea, and that was sent out to China, and no report has been received here as to its work. Another press, not included in the above remarks, was forwarded to India through the India office here, ostensibly for the Russian trade, but in reality I understand for commissariat purposes. I have only recently got upon its track, but shall soon have all the facts concerning it too; at present I know nothing except the makers' name. Compressing tea improves its quality at the cost of setting free additional tannin. The tea is compressed simply by the tremendous pressure to which it is exposed for a second, nothing whatever is mixed with it. It is as pure as when it leaves the tea-house, and is as hard as leather. It takes a green appearance as all the calcined black surface is pressed into the bulk of the leaf. Tea thus pressed is in an excellent condition for withstanding a damp climate or for campaigning or for use at sea, as the damp has only a small surface to act upon, which can be scraped off. But this, as I have said, is not brick-tea, nor is it what the Russians have been accustomed to, though prejudice with them would not be the barrier that it would be in the case of the Thibetans, the size of whose bricks of tea has become established with all the force which protects an article that is used as currency in place of money. In the case of Russia, too, it would doubtless pay to study custom and to offer a brick of the usual size. To make such bricks as well for Thibet as for Russia requires a special press. No such press exists, though specifications for such a press exist, and bricks of tea, one being in my possession, have been made on the principle involved in that specification merely as samples by an adapted press just to prove the process, but not as a commercial venture, as of course in an adapted press arranged merely for sampling purposes speed of outturn was no object. To make such bricks at a remunerative speed requires the application of heat, for which no existing presses are constructed. I have gone into this matter very thoroughly, and I have been induced by that inquiry from India, and from other signs of a movement being on foot in this direction to dwell on this subject here, and I may return to it again hereafter, as it is an important one. There is doubtless a great future for brick-tea before Indian planters, and it would be a pity to find that money was being wasted by a start being made in a wrong direction, especially as the machinery being somewhat costly, failure might frighten others and nip the new enterprise in the bud. Should any firm be thinking seriously of going into this matter, I should be very pleased to show their representatives here the brick I hold, which cannot be beaten for Russia—other shapes would be required for Thibet, which is merely a detail in the construction of the moulds. This brick will surprise anybody who sees it for the first time. I should also be very glad to give the necessary particulars, if the applicant really means business. The firm to whom I should have to send such applicant to see trials, &c., being a busy one, I cannot presume upon their time by sending people whose only object is the gratification of a pardonable curiosity. The time may come when Indian planters will find a market for their prunings. —*Indian Planters' Gazette.*

[Note.—We shall be glad to forward any communications addressed to "Peripatetic Planter" on this subject.—ED. *I. P. G.*]

PRINTING BY ELECTRICITY.—The *American Inventor*, of Cincinnati, a large monthly journal, says: —"We print this month's issue for the first time by means of electricity. The Sprague motor is used and is an immense advance on any other kind of power. We are running four presses with a single motor, and it is quite a novelty in action. The motor is built in a very substantial manner, and there are no parts that wear rapidly even with ordinary care. The expense for repairs cannot amount to 10 per cent. of that required for either steam, gas, or hot-air engines, and we now see no reason why it will not give, for many years to come, as good results as at present."

"FRUGES CONSUMERE NATI."

[A Vegetarian Restaurant has been opened in the Strand opposite the Royal Courts of Justice.]

I have always loved a vegetable dinner, I delight
In the Crécy soup or Conde on the *menu* of the night;
The Potato needs no praises, there is rapture too I ween
On the face of every *gourmet* at the mention of the Bean;
And, likewise Sir Henry Thompson, I can feel my heart aglow
At the thought of all the merits of the pleasant Haricot.

I am very fond of Cabbage, and the tender Spinach begs,
Though it isn't quite *en règle*, to be served up with poached eggs;
Then the Cauliflower is charming, and the Celery when viewed
Fresh and crisp from out the garden, or artistically stewed.
While surely on one esculent we're all unanimous,
Is there aught that's more entrancing than thy taste—Asparagus!

All must love the lively Lettuce; we have reason too to bless
Cruciferæ for sending us the piquant Watercress;
Upon any list of salads let the true Tomato stand,
With the Endive and the Beetroot as supporters of each hand;
There the Cucumber awaits us, and we fain would keep alive
Both the Tarragon and Chervil and insinuating Chive.

There is poetry in Mushrooms, and the Lentil too can please,
And a thrill goes through my midriff at the thought of early Peas;
I am grateful to the Turnip and the Parsnip looking pale:
There's the Salsify seductive and the delicate Seakale;
But the bard shrinks back from one task, for no mortal ever can
Do full justice to the comfort that the Onion is to man;

Then we'll hasten to the Griffin, for a little way beyond
Are the Vegetarian dining-rooms of Messrs. Spiers and Pond;
And the Doctors too are with us, men of note in London town,
Risdon Bennet, Milner Fothergill, and also Crichton-Browne;
They have told us very plainly that of health we should be winners,
If we ate less meat, indulging in more vegetable dinners.

—"*Punch*," *November* 20.

SOURCES OF NITROGEN AS PLANT FOOD.

A correspondent ("P. T. I.") in asking the following questions opens up a wide and an important enquiry:—

1. Nitrate of ammonia being the chief compound from which the roots of plants absorb nitrogen, is the greater amount of it formed in the air (and carried to the earth by rain) or in the earth?

2. In reference to the nitrate of ammonia formed in the soil, how is its nitric acid formed, and how is its ammonia formed? Is its ammonia chiefly produced by the decay of organic substances, or absorbed from the air, or brought down by rain?

3. Do the roots of plants absorb ammonia uncombined with any other substances, but merely dissolved in water?

4. Do the roots of plants absorb sulphates, carbonates, and phosphates of ammonia in a state of Nature?

5. Is ammonia, uncombined with any other substances, brought down to the earth by rain?

6. In reference to the ammonia present in the soil, is the chief amount of it (*a*) brought down to the earth by rain, (*b*) absorbed from the air by the soil, or (*c*) produced by the decay of organic substances in the soil?

Plants obtain the elements of which they are built up partly from the atmosphere and partly from the soil. The water and most of the organic matter, making on an average from 90 to 95 per cent of the total weight of the plant, comes from the atmosphere, either directly through the leaves or indirectly from the soil by rain, and then to the plant through its roots. Nitrogen exists in soils in three combinations—with carbon, with hydrogen, and with oxygen. When in combination with carbon it is very insoluble in water, and it is in this form that we find by far the greater part of the nitrogen that exists in soils. The nitrogenous organic matter of the soil has been derived either entirely from the decay of vegetable *débris* left in the land by preceding generations of plants, or possibly to some extent from past applications of farmyard or of other organic manures. It is also a fact that besides the residues of crops soils receive certain amounts of nitrogen from the atmosphere in the form of ammonia and nitric acid, but the quantity of these substances contributed annually by rain varies in different years and places. The average of many experiments on the Continent gives 10·23 lb. of nitrogen per acre. The average of some English experiments is but 7·29 lb. Rain also furnishes small quantities of alkaline chlorides, especially in the neighbourhood of the sea, and about 18 lb. per acre per annum of sulphuric acid. Although the amount of ammonia directly absorbed by the soil from the atmosphere may in some soils be much larger than is shown by the analysis of the rain, yet the total nitrogen acquired, though most important as tending to counterbalance the losses of plant-food which the soil annually suffers, will have little effect on the present fertility in comparison with the large accumulation of nitrogenous matter resulting from previous crop residues, and decay of animal refuse. In all kinds of soils there exist very minute underground organisms, called "bacteria," invisible to the eye, the function of which is to separate the carbon and hydrogen from the nitrogen, and to unite it with oxygen. But to effect this lime must be present in the soil, and the compound so formed is called nitrate of lime. Nitrogen in combination with hydrogen forms ammonia, and the substance with which most gardeners are acquainted as ammonia-salts is obtained from an extinct vegetation. Nitrogen in combination with oxygen forms nitric acid, these combine under the influence of the electric discharges in the atmosphere, nitrous acid being formed; this is converted into nitric acid by the action of ozone, or peroxide of hydrogen, and is brought down by rain. Ammonia cannot exist as such for any length of time in the soil, neither is it taken up by plants in that form. The facility with which ammonia and other nitrogenous substances are converted into nitric acid by the oxygen of the soil is so great, that nitrates become by far the most important source of plant food. The uncombined nitrogen of the atmosphere is not appropriated by plants. Plant roots take up all the diffusible substances which are present in the water which they draw from the soil; but the feeding power of roots is by no means confined to the taking up of ready formed solutions, for they are also capable of attacking some of the solid ingredients of the soil which they render soluble and then appropriate, for the building up of their vegetable fabric. The best of all manurial applications are those which supply both phosphates and ammonia or nitrogen.—*Gardeners' Chronicle.*

Gow's Tea Withering Machine has been erected on Mariawatte and, as telegraphed yesterday, pirvate trial was made of it yesterday, to be followed by a public exhibition of its capacities tomorrow. According, to one account, it is claimed for this machine that, by its means, perfectly cured tea can be packed within four hours of the green flush having been taken from the trees. If so, the machine will turn all existing ideas of fermenting and manufacture upside down.

TEA WITHERING AND MANUFACTURE:

THE PRESENT PRACTICE TO BE REVOLUTIONISED BY GOW'S PATENT TEA LEAF WITHERING AND FERMENTING MACHINE.

We call special attention to the very full and interesting report supplied by the Manager of Mariawatte estate on page 527, on the trial of Mr. Gow's new Machine on Saturday last. We have been waiting for an authentic statement of this kind before referring again to an invention which, from all we have been hearing of it lately, seems to possess "the promise and potency" of an entire revolution in the work of tea preparation. It cannot be denied that a good deal of scepticism has attended Mr. Gow's patient and prolonged experimental work in Ceylon, albeit he came amongst us with the highest recommendations of practical experience as a planter in India, as a tea-broker and merchant in London, and as one who has given special attention in conjunction with home scientists to the chemistry of tea preparation, the changes wrought in the process of fermentation more particularly. The expectation that Mr. Gow would work out a machine capable of placing the tea-maker in a better position even than if the weather for withering was all that he could desire—a machine that would save a great deal of the time, labour and space now required for the withering process—and, moreover, that would ensure as good, nay better results in manufacture,—was generally received with a smile of incredulity both in Colombo and upcountry. And we must confess that the first specimen of the machine erected at the Colombo Ironworks and the trial that took place with tea-leaf from Kalutara—even though the resulting samples of tea were well reported on—did not appear to have much "promise and potency" about it. It was regarded by some as clumsy, inconvenient, expensive and doubtful in results. With Mr. Jamieson's letter before the public and in the face of the many practical tea-planters present at Saturday's trial, Mr. Gow and his Agents, Messrs. John Walker & Co., may, however, now well say *Nous avons changé tout cela*. But before any experiment was made in Ceylon, the new Patent had been tested in the planting districts of India with results which may best be judged from the following testimonials:—

Extract from a letter from J. H. Warren Esq. Manager Teendaria tea estate, Darjeeling district, who was present at a trial of the "Monarch" Withering Machine.

1. The machine can keep two rolling machines going with withered leaf, whereas to do this on the old system of withering lofts would entail great expense in the erection of withering godowns. Gow's machine only occupies a very nominal space.

2. With wet leaf Gow's machine can give good withering in a very little longer time than with dry leaf, whereas under old system, wet leaf sometimes lies for days before it can be properly withered, and then all flavour has vanished.

3. By the evaporation of the excessive moisture in the leaf in Gow's machine, the constituent parts which give good flavour are not carried off in the rolling process as under the old system they were, again the roll in Gow's machine comes from the rolling machine in a sticky and half dry condition and can be more rapidly dried, this gives briskness to the out-turn not to mention the saving in fuel to dry the roll with. Under the old system the roll comes out very wet and the expense in drying into pucca tea is very considerably augmented.

4. Lastly in old tea concerns where there is any amount of withering accommodation, Gow's machine might not be so much required, but in continual rainy weather, even in such places, they would be invaluable in so far that they place you in a position of independence of climate, and manufacture can always be carried on without a hitch. In new concerns where large factories have not been built nor withering godowns erected, expense might be avoided in the matter of building by purchasing Gow's withering machine, as they fit into a small space.

Springside Tea Co., Ltd. Kurseong, 4th June, 1886.

Messrs. Mitchell & Co. Calcutta, Dear Sirs,—I am in receipt of your Mr. Mitchell's letter of the 1st. The agents of this Company were good enough to allow Mr. Gow to erect a small Model of his withering and fermenting machine at this factory last year, and I worked it steadily for nearly two months. After this a full sized one 8' by 8' was put up at Mohurgong in the Terai, and was worked there for some little time with great success.

The results were good, and I think the machine improves the Teas very much. Mr. Gow in his pamphlet has stated what the machine will do, and I can only say that the statements he has made are perfectly correct.

I expect you will have a large and increasing sale for the "Monarch" when known. I regret very much that the first one has been removed from Mohurgong, as no doubt the Teas were much improved when passed through the machine. I found the withering done well and fermentation perfect, and also the percentage of fine Teas was larger.—Yours faithfully,

ALFRED H. WATHEN, Manager.

Apart from the satisfactory result obtained in the appearance and quality of the Mariawatte tea—and the test of the home market is alone required to establish this result—the importance of the Withering and Fermenting Machine is best realized from the great saving of labour and of withering space it will effect in average factories. In these respects alone the cost of a machine ought very soon to be repaid, to judge by Mr. Jamieson's letter. But the true value of the Machine can scarcely be judged in a factory like that of Mariawatte where, we suppose already, there is every convenience for tea preparation which a first-class garden can possess. And in Gampola and our lower districts generally the weather is seldom of such a character as to interfere with the process of withering. Very different is the experience in our wet seasons in the higher districts, and it is from Ambagamuwa up to Nuwera Eliya and again in Kellebokka, the Knuckles and Rangalla districts, that Mr. Gow's invention ought to be specially appreciated. It comes just in time too, for a large number of planters who are planning or have yet to plan, their factory arrangements and the direct economy offered in respect of ordinary withering arrangements should go far in turning the scale in favour of the inclusion of one of the new Machines in the Factory requisites of such gentlemen. Nothing could be more satisfactory in appearance and flavour to the ordinary lay judgment, than the tea samples Mr. Gow laid before us in the *Observer* Office two days ago, and we suppose professional reports will substantiate the general opinion. A trial of a Monarch Machine has been suggested on Abbotsford—as a typical high estate on which due "withering" during the monsoon months is attended with some uncertainty,—and we feel sure the proprietors would welcome such a trial and that they will not be behind in availing themselves of the help now offered by Mr. Gow in overcoming one of the few obstacles in the way of tea planters in high districts in Ceylon, so soon as they have satisfied themselves by examination of the working of the machine.

"The Withering and Fermenting Machine" is not to be Mr. Gow's only patent; he has already

entered another, in company with Mr. H. C. Harrison of Awisawella, for a Sifting and Sorting machine to cost from R350 to R400 which ought to effect a further marked saving in factory labour besides securing better work. This is to be called "The Elston Patent Tea Sifting Machine."

Mr. Gow leaves for England by the S. S. "India" on Monday, Jany. 24, but he hopes to return erelong to Ceylon in which as a tea country he has taken so much interest, and with which, through his patents and other circumstances, we trust he will, in the future, become still more closely identified.

PLANTING AND COFFEE IN JAMAICA.

A gentleman who is pleased to give a very high character for information and usefulness, to our *Tropical Agriculturist*, affords some interesting information respecting his experience past and present as a coffee planter in Jamaica. He has, of course, never been in Ceylon; but his estimates and mode of working will interest many of our readers:—

I have a coffee plantation here. Crops have been poor for the last two years, only fiftyfour tierces 1885-6 and about the same this year, 1886-7. In 1884-5 we made eighty tierces of 850 lb. each, not much of a return, seeing I weed 180 acres and "bill out" several patches of old coffee.

I have just planted 60 acres of virgin woodland with coffee, and found it no small undertaking. The practice in this part of the island (Manchester Hills) is to give out the land to the Negros rent free for three years, they undertaking to cut down and clean up and get the land in order for lining and pegging; after the pegging they are allowed to plant their provisions, yams, bananas etc., and when the coffee is planted, keep it free from weeds and give it up at the end of the three years, quite clean. The fencing is done by the Negros and very well done too as the estate's horses, mules and cattle would, if once they got into the coffee piece, make short work of the provisions.

I append the expenses of planting the 60 acres:—

Surveying, and planting pimento trees at the acre poles	£12	0	0
Lining and pegging	7	6	10½
Planting and pulling suckers	22	7	9
Cutting pegs, making coffee lines &c. ...	5	13	0
Making intervals (roads)	3	9	6
	£50	16	1½

The trees are planted 6 feet apart and topped at 4' 6".

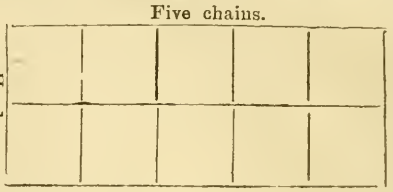
We are about 2,200 feet above the sea with a normal rainfall of 80 inches. I have found it considerably less till the last two years, 1883 not quite 40 inches; 1884 60·60; 1885 89·06; and to the end of October this year we have had 142 inches (nearly 50 of it fell in June, 36 inches between the 9th and 11th)

My coffee is fair plantation, the bulk of it realizing about 60s per cwt.; this year the peaberry sold for 78s. My separator (Gordon's) gave me 6 per cent peaberry, the machinery is of the "old time" sort and worked by mule-power 2, (there are no rivers in this part of the island) and it has the advantage, in these times of low prices, of being inexpensive. I can pulp 60 boxes an hour, our box holds 96 quarts; we calculate that 40 boxes of cherry give a tierce of good coffee plus the triage.

The barbecues are a flight of 25 each, 40 feet square. All my fields are quite a mile and-a-half from the works, but I pick quite 80 per cent of my coffee at 1s a box and the balance at 1s 3d and 1s 6d, the rat coffee at 2s: the latter amounts to about 4 per cent of the crop. Labor is plentiful enough. I manage to weed the whole of my fields in four weeks and at a heavy ripening have had 250 hands in the fields and have picked in over 400 boxes equal to 10 tierces in a week, that is up to Thursday afternoon. Quashie objects to work on Friday; they take that day for working their own grounds and on Saturday they go to market.

I find my coffee costs me within a fraction of 20s per tierce from the time it is thrown into the pulper loft to the time it is ready for the tierce; the tierce costs (including nails) 5s; cartage to railway 13 miles off, 10s; and the railway freight at 22s 7d per ton (gross), another 10s making a total for pulping, drying, grinding, fanning, sizing, hand-picking, tiercing and sending to the Wharf at Kingston of 45s per tierce of 850 lb.

All the weeding is done by tasks, which vary from 5 to 8 or 9 rows for a shilling; the rows are counted from the head of the acre, thus:—



The pruning is done by task at an average cost of 5s per acre. The management consists of a manager (Busha,* he is called by the natives) three rangers or headmen and myself. The climate is an excellent one, the mean temperature being 79° in the shade. All the flowers and most of the vegetables of Europe grow readily. There is plenty of fine timber still left such as cedar, bullet tree, mastic, bloodwood and bitterwood, the latter an excellent wood for indoor work as no insects will attack it and one nibble is quite enough for our friends, the rats. Mandeville, the nearest post-town and principal place in these mountains, is a charming spot very much like an English village. Church, school, stores all round the green, there are fine Municipal offices too, a good stone Court House, a Constabulary Barrack, &c., and a Post and Telegraph Office. The post is tri-weekly, eastward and westward alternate days and a fortnightly packet. Mandeville has become quite a fashionable health resort, every year an increasing number of Europeans and Americans come for the winter. There are Club, Lawn Tennis and Cricket Clubs and a Race-course and the roads are excellent.

[The cost of work as shown by our correspondent is not high; but nothing is said about draining which with a liability to 50 inches of rain a month (36 inches in 2 or 3 days!) ought to be an important work. Coffee yielding up to 3½ to 4 cwt. an acre is certainly not heavy bearing, more especially as the prices differ so widely from those paid for the famous "Blue Mountain Coffee." Our correspondent should tell us something about his Pimento cultivation and market.—Ed.]

ON THE EMPLOYMENT OF THE SEDIMENT OF COFFEE FOR STRENGTHENING THE PRODUCING POWER OF THE COFFEE TREES.

A German correspondent, formerly in Ceylon, writing from London by a recent mail, propounds rather an interesting idea in reference to the use of coffee grounds for restoring fertility to coffee trees and enough might be collected in Ceylon to try an experiment. As a manure, a substance containing 2·73 per cent of ammonia, could not but be helpful, but phosphate of lime is low and no potash is indicated. As an ordinary manure, we fear so great a bulk of inert matter would scarcely pay the cost of local carriage and application far less its collection in Europe and transmission here. But an experiment might be tried. Our correspondent's letter is as follows:—

To the Editor, Ceylon Observer.

I have the honor to submit for your information my ideas laid down in the enclosed treatise suggesting reimportation and the use of coffee grounds for the amelioration and the restitution of the coffee

* "Bass"!—Ed.

growth. It would give me great satisfaction, if my endeavours for the supply in the Colonies with coffee grounds as fertilizing substitutes shall bring me in a beneficial connexion again with your fine island, the connexion with which will always be considered by me as a source of life and intelligence.—S. Bensinger.

London, 20th December, 1886.

When intelligence of the deplorable effects of leaf disease and parasitical damage had been received some years ago, it was already tried by those interested in the growing of the valuable produce, coffee, to find out a remedy by which the weakened condition of the estates could be ameliorated. The continued deficiencies in the crops and their confining influence on trade now more sternly urge that means have to be found to restore the culture to its former healthy state and appearance, supplying it at moderate expenses with manuring matter, collected in the consuming countries and supplying it to those fields, where the indispensable fructiferous nourishment cannot sufficiently be derived from the soil.

It is obvious that the impoverishment of the coffee soil, which its alternate owners more or less caused by exhaustion of its properties, cannot be continued without proving still more fatal, and it is intended herewith to draw attention to that stuff, which, (after the roasted beans having been made use of for the preparation of the favorite stimulating drink)—becomes unfit for direct food-giving, but still possesses a great deal of reproductive qualities, hardly contained in any other fructifying application.

It will be understood, that it is not meant to promote forcibly the growth of the trees direct and solely by the material, a proceeding which was to be regarded not less offensive to production as the alluded exaction. It is left to the discernment of the planters to decide when and how those grounds may be applied as a manure, and if properly used they will prove a "merestone" in the coffee cultivation, by which future enterprises will find a hold especially in those tracts of ancient producing countries, where in the last decennium such great disappointment had to be endured for want of such means. Where the mischief has gone too far, the reposition of the fields with a lighter culture and with strengthening the ground for the later re-production of the coffee berry will be the mode applied with most success. Wherever the state of culture has not been too much affected and injured, the introduction of the sediment of coffee in its natural or prepared quality as a manure besides those being already in use, will surely repay its cost and when properly applied, it will not only store nourishment for the trees own requirements, but also support and restrain its parasite and nibbling enemies, rats, insects, etc., to which in its weak and unprotected state the plants could offer no resistance.

It may be hoped that the parties most nearly interested with the cultivation of coffee will consider the value, the great manuring strength and reproductive power to be derived from those many hundred thousands hundred-weights of coffee grounds obtainable every year and make use of them to the best advantage of their plantations.

"NEW GALWAY" DISTRICT REVISITED:

Coffee—Tea—Cinchona—Wattles—Hakgala.

The name being derived from Ireland,—(a Scotchman suggested it in compiling the "Ceylon Directory" for 1875 in honour of the Irish Governor, Sir Wm. Gregory,)—something in the nature of a bull is permissible, and as a matter of fact we could not revisit "New Galway," as that designation was not given to the group of estates of which The Ambawella Valley is the centre and the grand Hakgalla mountain the presiding monarch, until many years subsequent to our original visit in 1865 (22 years ago). We went under the auspices of good old Mark Kellow, a "Cornish" boy, true to the traditions of the twenty thousand who in the reign of James the Seventh were determined, if a Trelawney was to die, that they should "know the reason why." Mr. Kellow saw no reason why he should not open a coffee estate in the Ambawella Valley and call it "New Cornwall." The compiler of Ferguson's Ceylon Directory was surely as heedless of geography as the characters in "The Jackdaw of Rheims" were of grammar, when he included "New Cornwall" and "Warwick" in "New Galway." But "what's in a name?" as Shakespeare, (who by the way knew something of Warwick,) made one of his characters pertinently ask, especially when those chiefly interested take kindly to that name? Of one thing there can be no doubt: that the scenery and productions of "New Galway" as closely resemble what is to be seen on the ocean shores of old Galway, as they do the cliffs of Cornwall and the battlements of the castle of Guy of Warwick and their vegetation. It is a pleasant characteristic of the British race, Celtic as well as Saxon, to revive, in the far-off scenes of their migration and sojourn, names associated with pleasant remembrances of the old country, with its white cliffs, its "brown heath and shaggy wood," its fat pasture and exquisitely beautiful green sward, dotted with buttercups and daisies, and though last not least its dear old lanes, shaded by elms and brightened by hawthorn, woodbine and wild-rose. The traditions and the associations connected with the imported names given to estates in Ceylon, traverse the whole domain of the history and topography of the British Isles, "from the Land's End to John O' Groats,—and more especially Aberdeenshire and the Channel Islands, with their contrasted dialects of most ancient Saxon and Norman French patois respectively. [Of course English is spoken by one here and there even in "Aberdeen Awa," and since Victor Hugo's enforced residence in the Channel Islands, some of the inhabitants have learned pure French,—as pure as a language can be in which the people "call their mothers *mares* and their sisters *fillies*." N.B.—This note is meant to be conciliatory, but, of course it will give great offence to people who believe they speak the best English and the best French in the world. The best English and the best Gaelic (which is really the best French) are, of course, spoken at Inverness and the adjacent northern parts of Ross-shire !]

But "to return to our muttons" as the eminently pastoral French say and to our visit to the Ambawella Valley in 1865. En route from Nuwara Eliya we then called in at the scene, below the 1,500 feet sheer precipice of Hakgala (the jaw mountain,) which, from the resemblance of the hemate and country to what he had seen and ex-

perienced in the American homes of the fever plants (fever-curing, rather,) had been chosen by Mr. Clements Markham, for the introduction and cultivation of the cinchona trees in Ceylon. There we found poor, thin, delicate MacNicol hard at work propagating the precious plants by bedded cuttings, the commencement of a process which covered the mountains of Ceylon with more millions of *C. Succirubra* and *C. Officinalis*, and hybrids between the two and between them and the Calisayas than ever existed in the native habitat of the plants amidst the forests of the Andes,—the ultimate results being the swamping of the bark market and the cheapening of the most valuable febrifuge and tonic in the vegetable kingdom, so as to place it within reach of the millions of poor and suffering human beings. The work which MacNicol began, was well and efficiently carried on by Edward Thwaites, whose title to be remembered in connection with Hakgala is mainly connected with the work, remunerative to the Government and profitable to the country to which he was compelled to devote most of his time and of the money placed at his disposal. Even in his time, with what he was enabled to do under the direction of his accomplished brother, in introducing rare trees, flowers and fruits, Hakgala was an attractive resort to residents at and visitors to the neighbouring sanitarium. But to compare the Gardens of even a few years ago, to what Mr. Nock has now made them, (the changes and improvements in even in the past six months being wonderful,) would be to compare an ordinary garden plot to Paradise. The 14th of Jan. 1887, the day on which we started from Upper Dimbula, for our re-visit, was unmistakeably a rainy day. We met the rain and the cold wind which had accompanied it down the gorges from Nuwara Eliya soon after we commenced the magnificent ascent of Longden Road, but neither on our upward journey, in skirting the Lake, which is beautiful even in its shorn proportions out of regard for the race course, nor in the steep descent from "Baker's Farm" to Hakgala, did the weather prevent us from enjoying and admiring the beautiful mountain woodland, dressed in the tints of spring. Those tints, which by March will have passed into brilliant reds and crimsons, now present a soft, lovely plum colour, which contrasts exquisitely with the light green of the *Michaelias* and the orange and copper colours of individual trees, the blossoming *nilu* still brightening the jungle undergrowth. Soon after leaving the top of the pass near Baker's Farm we could not help wondering why fire, as it appeared to us, had been applied to the ferns, the balsams, the "Californian daisies" and other way-side plants, but we were more especially concerned at the blackened and apparently dead appearance of the cinchona plants on the edge of a fine plot about a mile below Nuwara Eliya. Tea at a higher elevation showed no sign of having suffered from the frost which was the real agency that had applied "decay's effacing fingers." Later in the day we noticed, that while cinchonas amidst coffee had portions of their foliage blackened, (this was a full mile below Hakgala, with an elevation of probably 4,700 feet,) the sheltered coffee underneath had escaped. It is cold, tearing wind and not frost, from which coffee suffers, as we had fresh opportunity of noticing in the Ambawela Valley, where the contrast between cultivation in places sheltered from the cold, fierce winds which swept over Ceylon in December, and that in exposed positions was most striking. There can be no question that while cold wind undoubtedly affects tea, especially when the plants are putting forth their tender flush after pruning, yet the power of the full-grown, vigorous tea plant, to resist cold winds and even frost (the latter practically unknown on the western side of the Nuwara Eliya range) is far superior to that of coffee and cinchonas. En route to New Galway we could not resist the temptation of turning in to have a look at Mr. Nock's revolutionary dealings with the Hakgala Gardens, and our exclamations of admiration and delight were loud and frequent as we found ourselves approaching the bungalow by a new drive, the raised embankments of which were beautifully turfed. A second lakelet has also been added to reflect ferns and other plants, as well as the stupendous precipice of the mountain face. We had scarcely got into the shelter of Mr. Nock's hospitable bungalow, rendered cheerful by the presence of children as fresh and healthy looking as their parents, when down came a regular rainstorm, lasting nearly an hour. We kept hoping that at least the ghost of the rainfall had crossed the range to Dimbula and our hopes were not disappointed, as we found on our return. During our enforced but pleasant stay, we learned from Mr. Nock that his experience leads him to look for at least ten rainy days after Christmas. As a rule it is not an over-plus, but a paucity of rain which is the trouble at Hakgala with its genial Uva climate, and the multiplication of little lakelets in the Gardens is desirable, not only on æsthetic principles, but for the storage of water. As soon as the rain had abated, we spent another delightful hour under Mr. Nock's guidance, examining his improvements and admiring next to the green sward embankments, the borders and beds of vari-coloured plants and flowers which were contrasted against them. I cannot dwell on details, but I have no hesitation in affirming that when all the improvements projected and in progress are carried out to completion, the Hakgala Gardens with their combination of mountain, valley, forest, ornamental plant, fern and flower scenery, will, for grandeur and beauty, vie with any in the eastern world. Nuwara Eliya, as a health resort, has attractions of its own, but extraneous to it and yet easily attainable are amongst other pleasant places, these gardens "beautiful exceedingly" in themselves, and additionally attractive from the views they command of the grand mountain on whose bosom they rest and of the forested ranges which close in the vast-stretching grass lands and rice fields of the vale of Uva.

I suppose it is the hope of placing the Forest Department on a complete footing which has so long delayed a grant being placed at Mr. Nock's disposal for experiments calculated to prove which are the best trees to grow on the patanas that adjoin and stretch away on every side from Hakgala. Meantime private enterprise has interposed and on Albion estate, about 1½ mile below the Gardens, has obtained some very striking results. Here amongst the limestone formations, there is a small coffee estate in full bearing, which we found laden with "cherries" after the fashion common when coffee was really monarch, unaffected or but inappreciably affected by the fatal fungus. There was but little sign of leaf-disease on this coffee, which is at the foot of the property and close to the road side. Up the patana-covered hillsides above, stretch, at pretty close intervals, shelter belts of *Acacia dealbata*, the so-called "silver wattle," from its silvery foliage. The growth of those trees, in height and density, in the four years of their existence, is somethin

marvellous; in density more especially. As most of our readers are aware, the marked characteristic of this species of acacia is to send up shoots, which in their turn become trees, from every horizontal root, and the roots are many and stretch to great distances. All that is wanted in growing these trees on the patanas, to encourage their tendency to form dense groves, is to clear away the grass from the surface soil in their neighbourhood. The tendency to send up innumerable shoots, indeed, is embarassing where paths are a necessity. In going down the sides of the belts on Albion we literally trod on a carpetting of young acacia shoots. From Mr. Wm. Cotton, who, with Mr. W. A. T. Kellow, accompanied us, we learned, as the result of his experience, that as a timber tree, *Acacia dealbata*, is excellent for all such purposes as hoe and axe handles, while nothing is better for charcoal. The bearing of these facts and of the rapid original growth and recuperative powers of the tree when coppiced, on the future supply of fuel for the tea enterprise, has an importance which can scarcely be exaggerated. Failing the discovery, or pending it, of a cheap artificial fuel, firewood or charcoal from hundreds of square miles of *Acacia dealbata* groves might be supplied! Of course other trees can be grown on the mountain prairies of Ceylon, and in Mr. Kellow's case the success of the black wattle, *Acacia Melanoxylon*, has been such, during the four years, that he has indented on Australia for large supplies of seed. This species of wattle grows into a fine, tall pyramidal tree, the tendency to send up shoots in its case being slight and easily repressed. So much is the "blackwood" timber of this tree valued in Australia, that when the eucalypts are "ringed" and destroyed, these acacias are carefully preserved. Nor need the selection of trees for the patanas be confined to natives of Australia, for amongst the wattles we saw, growing luxuriantly, numerous specimens of the European cherry tree which we were interested to find, grows readily from cuttings. Cherry tree wood is much valued in Britain. There can be little doubt the *Cryptomerio Japonica* and other pines, with *Toona cedrela*, and many other plants of various species and from different regions of the world, would flourish on and render profitable the at present vast expanses of waste patanas in Uva and elsewhere amidst the mountains of Ceylon.

(*Continued on page 537.*)

THE BRAZIL COFFEE PROSPECTS.

It is very perplexing to find Ceylon coffee falling, even though it be only one shilling per cwt., at the very time we expected it to rise. We refer to the following report published in the latest *Public Ledger* to hand, from a firm that evidently claims to be an authority on the subject of Brazil crops, to shew what we mean. It will be observed that the report winds up by saying that prices are bound to rise rapidly in January and to advance until the rates of 1873-4-5 are reached:—

(From the "Public Ledger" Dec. 28th.)

(From Messrs. Lacerda & Co.'s Report.)

We think it advisable, under present circumstances to supplement the remarks we had the honor of laying before you in our circular of 7th inst., with some further observations in reference to more recent occurrences; and in doing this we rely as we did in our earlier reports, on the knowledge and experience we possess of the cultivation of coffee in Brazil.

At the date above referred to we showed that o account of the circumstances being entirely differe nt there was no reason at all for expecting this year a late flowering in December-January, as happened in January, 1880, attributable to the drought which prevailed from May-June to October, 1879. Since the month of May last the rains have been regular and occasionally excessive. We propose submitting to you certain considerations which may afford you means of arriving at sound conclusions in spite of contradictory reports and rumours more or less unreliable, professing to gives estimates of the Brazilian crops.

After so many over-confident assertions, we think that a few observations concerning the method and conditions of production in Brazil may not be out of place here.

And, as a commencement, it may be of assistance to point out the order of the seasons in the Southern hemisphere where Spring commences on the 24th September, and does not end until 21st December, when it gives place to summer, which terminates on the 20th March, followed by Autumn, which holds sway until 21st June, which date marks the advent of winter.

It will be worth while also to recall the fact that coffee crops are alternately heavy and short, as is well known, at least to all those who understand the difference between cultivation by means of periodical sowings, and cultivation by plantation; in the former case the soil only is exhausted by production, whilst in the latter the exhaustion of the plant is added to that of the soil, which has a direct and sometimes long-continued influence on a production invariably of the same nature.

It will be equally to the point if we introduce here a few remarks on the subject of the influence of age on coffee plants in connection with their power to bear fruit.

Considerable time is required to bring a coffee plant into condition to bear fruit, and this period is generally calculated at from four to five years. From four to eighteen years of age the plant gives a regular yearly product and remunerates the planter.

From eighteen to thirty years of age the production becomes alternately good and poor, that is to say a year in which the plant gives a satisfactory return is followed by one in which the production is small.

When once this latter period is passed, the crops from such trees become more and more irregular and according to the geological and climatic conditions of the plantations, the productive power of the coffee plants goes on diminishing, and finally almost or entirely disappears.

It would be wrong also to omit any reference to what has been described as the disease of coffee plant. On this subject the *Jornal do Commercio* of Rio Janeiro, in its issue of 4th June last published the following:—

"Disease in the Coffee Plant.—The Minister of Agriculture despatched the day before yesterday the following notification to the Director-General of the National Museum.

"As it is desirable to obtain precise information respecting the cause of the disease which is devastating the coffee plants throughout a large extent of the province of Rio Janeiro, chiefly in the municipalities of Santa Maria Magdalena, S. Fidelis and Cantagallo, I have determined to charge Professor Emilio Goldi, sub-director of your museum, with the duty of following up this matter in the districts named, and after all necessary investigations, I wish him to present a detailed report on the subject, indicating at the same time the measures which he may judge to be expedient in order to diminish the effects of the disease, to arrest its further development, as well as to attack it in its very origin.

"The Professor alluded to will receive from you such instructions as you may deem useful, and you will please to demand of this department such facilities as may secure the success of the commission herein indicated."

The disease which is here alluded to is not attributable in our opinion to anything more than the advanced age of the Coffee plants, and to the fact that the oil is worn out, for it is to be observed that the municipalities to which reference is made are especially hose in which the cultivation of Coffee was first devel-

oped, after the primitive culture in the Serra abaixo, which was generally abandoned on account of the failure in the production.

In addition it may be remarked that this state of things is not confined to Brazil, for the diminution of the production in Ceylon must be in like manner attributed to the same cause.

These plantations, infected alike in Ceylon as well as in Brazil, give undeniable proof that the Coffee plant does not bear fruit for an unlimited period and that in this branch of cultivation after a certain period has elapsed, the soil becomes worn out, and as the plants become old and give a return continually diminishing the planters find that they can no longer get any result worth having, and are obliged to abandon the plantations.

In Java the production has also fallen off, a fact which calls for similar comment, and we cannot but believe that there also a like effect is being produced by a similar cause.

It is this also which should induce us to give due consideration to the statistics respecting the production of Coffee in Asia, that is to say, in Java, Ceylon, in British East India, &c.

In effect we see, on looking over these statistics, that in Asia the average production which during the quinquennial period from 1872-73 to 1876-77 was 2,519,400 bags, had fallen to 2,383,000 bags during the succeeding quinquennial period—1877-78 to 1881-82—preparatory to a further diminution during the triennial period from 1882-83 to 1885-86, as regards which the disastrous result of the last season leaves no doubt whatever.

The falling-off in the production, as given by these figures, is a fact beyond all dispute. The recurrence of heavy crops in Brazil takes place about every three years, whilst between these come crops of only medium size.

But in addition, there are also to be taken into account meteorological occurrences, which, as regards the plantations, may produce consequences of the highest importance, and which are nearly always entirely unforeseen, as, for instance, rain, hail, frost, or drought.

It is possible, therefore, for any one acquainted with the facts to determine in advance, with more or less exactness, what the crops will produce, and this even before the period of flowering.

It is clear that unless there is a wish to hazard estimates, at once capricious and badly supported, there can be no great differences of opinion in regard to our crops; it is of course expedient to employ in such a matter very great prudence, and to watch the course of events in order thereby to modify in case of need, the opinion one may have formed. This is certainly the course which we ourselves follow.

Let us now examine the actual position of things, and in order to illustrate by example what we have previously stated, let us go back to what happened last year. In 1885 the season of blossoming was full of promise, but the drought, which continued until the autumn, spoilt everything. Nevertheless, in the province of San Paulo, whose rich uplands are covered with plantations of recent growth and considerably exposed, where vegation is relatively more vigorous, the fears which at first were entertained were only partially realised.

If then for this last crop the plants have had to suffer from the drought, which was prolonged from spring to autumn, and if this drought has exhausted them to such an extent as to involve a partial failure in the fructification; if these plants, weakened already, have been unable to recover themselves in the rigorous, season which has followed, for indeed vegetation suffers a period of suspension during winter, how can it be maintained that we can have a good flowering this year, and consequently a good crop.

It is for these reasons, and after inspecting the plantations, that all persons who are authorities on this question of coffee cultivation in Brazil have arrived at the conclusion that this year the crop will be small, and that this opinion, which is also our own, is now shared by the most influential and most experienced of the houses engaged in the export trade from Brazil.

In effect, in response to our inquiries on the same subject, our friends in Brazil, Messrs. J. F. de Lacerda and Co., have communicated to us the following telegraphic reports, upon which comment is needless.

From Rio Janeiro: However favorable circumstances may turn out, we do not think the crop can exceed 3,000,000 bags.

From Santos: Advices in regard to the crop are generally unfavorable, the damage is serious, and we estimate the coming crop at 1,500,000 bags.

Summing up these arguments then, we may state as a fact established very clearly now that the production in Brazil, which sufficed to make up for the deficiencies caused by the diminished production in Asia, cannot any longer do this in view of the bad seasons of 1885-6 and 1886-7, which fact indeed is rendered sufficently evident by the general diminution in the stocks in the consuming countries. In addition to this, the reduced volume of the next crop will render the statistical position of the article yet more favorable, by making clearer than ever the progressive diminution already indicated in the production of Coffee.

It is therefore with very good reason that we reaffirm our entire confidence, and maintain what we stated in our recent circular, repeating strongly our advice to our friends to make continued purchases at the very fountain head, seeing that during this season those who, up to the present, have made direct importations of Brazil Coffees, cost and freight, have done extremely well, and because, in the course of next January, every one will have to admit the force of our arguments, and the rise will be so rapid that there will be little opportunity of making ready for it. It is necessary therefore that our own immediate connection should take every precaution to protect their interests, by making direct purchases, cost and freight.

In our judgment there is no reason to trouble ourselves about speculative fluctuations; as we said recently, we are convinced that the rise will carry us to the prices of 1873, 1874 and 1875.

Bullock Gearing for Tea Rollers.—Hearing that Mr. Alfred Scovell of Bitterne, Maskeliya, was using Bullock gearing for driving a Barber's Tea Roller, we wrote to him asking for some information about it, and received the following reply:—"In answer to your enquiry, I have been working a Barber's roller (converted Thompson's) by means of a cattle mill, during the last few weeks, and quite successfully. "The mill takes 8 cattle at a time, and I have been getting through 250 lb. withered leaf per hour on an average, and very good work at the same time; revolutions of the dishes being about 35 per minute. No doubt on estates where water and fuel are scarce, provided facilities for keeping up a fairly good cattle establishment are present, a cattle mill would prove to be an economic motor. The bullocks require some training and must be shod." We are very pleased to find Mr. Scovell has made such progress in the training of his bullocks as to enable him to obtain an outturn of 250 lb. per hour from his machine. We should, however, like to know how many bullocks are used *at same time* to drive the mill. In India only two are worked at one time, and after two hours' work they are replaced by others. Seeing the very low cost of bullock mills, we anticipate they will be more generally used in Ceylon than at present, more particularly for Barber's Rollers which require so little power to drive them. For the guidance of Planters we give the following approximate prices for bullock gearing in Colombo:—

Light one Bullock or horse gear with doubled speed	R225·00
Two bullocks gear, double speed ...	260·00
Two bullock gear extra strong ...	275·00
Above arranged for three bullocks ...	300,00
Four bullock gear, exceedingly strong ...	475,00

THE APPLICATION OF LIME TO CEYLON PLANTATIONS.

Watagama, Jan. 20th.

DEAR SIR,—I have to thank you for kind notice of my favorite district in which I have worked the last 28 years with such good success, *Panwila and Watagama*. I am glad Mr. Hughes has brought forward the great benefit to be derived from the application of lime, for I can without fear of contradiction say it has been more by the application of country-burnt coarse lime with small quantities of manure when wanted, and forking now and again, close draining at 1 in 30, not 1 in 15, using the soil* out of drains with the manure when forking, that Maria first and now Raxawa (a fine tea and cinchona estate near Panwila) have been made valuable and paying properties. I propose for the soil that is hard or stiff in coffee, tea, cinchona or cacao, to use burnt country-lime which as a rule is coarse, in preference to the finely burnt coral lime; as I found in practice the former proved the most beneficial and acting on the soil much longer. In working up soil with lime for grain culture no doubt, Mr. Hughes' recommendation of fine lime is best. In Ceylon, and in the low-country particularly, it is well once every five years to sow kurakkan seed and when 6 inches high to give a lime dressing and then fork it in. This I have proved a great success and not very expensive; this here takes the place of clover in England. I also find that 20 bushels per acre is quite sufficient to act on the soil to be repeated after two years. You must, however, either apply compost manure or fork in young kurakkan when required.—Yours truly, J. HOLLOWAY.

GOW'S PATENT TEA MANUFACTURING MACHINE, "THE MONARCH."

Mariawatte, Gampola, Jan. 21st, 1887.

DEAR SIR,—The above machine has been erected in Mariawatte factory by permission of Mr. Rutherford, and was tried under Mr. Gow's personal supervision, on the 15th and 16th instant, with satisfactory results, the work on the 15th being done in the presence of the following gentlemen amongst others:—Messrs. Megginson, Davidson (Kalutara), W. D. Bosanquet, Blackett, T. N. Orchard, J. Drummond, T. C. Owen, J. Anderson (Matale), S. Hayes, Carry, Gibbon, J. C. Ferguson, &c.

Notes having been more carefully taken on the 16th than on the 15th, it will be best to give particulars of that day's work. The leaf plucked on the 15th amounted to 4,000 lb., and a commencement was made at 9 o'clock a.m. on the 16th, with a charge of 350 lb. about a quarter withered, which, after being worked in the "Monarch" for 45 minutes was ready for rolling. The whole of the leaf was worked off in charges increasing from 350 to 628 lb., according to the progress of the natural wither, the last charge (628 lb. of nearly full-withered leaf) being ready for rolling at 3 o'clock p.m., after being 30 minutes in the "Monarch."

The leaf was rolled heavily, and, when taken out of the rollers, broken up, sifted &c., was ready for the dryer, the usual time taken to ferment being thus saved.

The first charge consisted of part of the previous afternoon's leaf, the last charge being part of the morning leaf, so that the last of the leaf was put into the rollers about the time when, according to the ordinary system of manufacture, the first of it would have been only fully withered. As there seems to be an impression that leaf can be brought in from the field and manufactured at once by means of this machine, it may be well to mention that it must be partially withered on the tats before the work can be begun. Green tea can, by means of the "Monarch," be made from newly plucked leaf.

The consumption of fuel to make 1,000 lb. tea was as follows:—For the boiler 3 cubic yards, for the "Monarch" 4 cubic feet, for the "Victoria" 2½ cubic yards. It took only 10 to 15 minutes to get the heat in the "Monarch" up to 180°, and it was kept at 140° to 180° during the work with the above quantity of wood.

The machine takes about 2 horse-power to drive it.

The tea made was of a good black colour, with a fine show of bright tip, and the liquor was pungent and flavoury, and creamed down well, while the fermentation was bright and even. Some of the advantages claimed for this machine, which in this trial seem to be borne out by the results, are:—That it perfects the withering and fermentation by artificial means, and thus saves time in manufacture, obviating the necessity, in wet weather, of keeping the leaf on the withering tats for more than one day; that it gives a good, even fermentation within a given time; that, after commencing manufacture, the leaf can be worked straight through all the other processes without any intermediate delay; that, with the machinery used here, a great saving can be effected in fuel for the boiler and "Victoria" dryer, owing to the continuity of the manufacture; and that night work can, to a great entent, be avoided.

Mr. Gow also contends that the leaf, in consequence of its gummy condition on leaving the "Monarch," rolls better, and that this advantage is apparent in the sorting; that the tips are multiplied by the opening of the convoluted buds in the fermenting process in the "Monarch."

The great test that remains to complete the success of the machine is the London Market, and if teas made on this system pass muster favourably there, I think Mr. Gow may well be congratulated, and will deserve the thanks of tea planters for having conferred such a boon on them. —Yours faithfully, GEO. D. JAMIESON.

NOTES ON COFEEE AND TEA (BY A TEA PLANTER).—Have been for a long trip upcountry and was surprised to see a lot of coffee looking A1 over Dimbula and Dikoya. Tea ideas are again being turned topsy-turvy: Mr. Gow says he will make as good tea as can be made, in a few hours from plucking and certainly his experiment was "fearfully and wonderfully made" according to old ideas. Some men are discarding the spheroid in Barber's Roller and two men told me that it rolled better without spheroid.

TEA.—It is curious to note that, in spite of the rivalry of Indian gardens, the Chinese find it profitable to export a by no means inconsiderable quantity of tea to Calcutta. During the last official year they sent us 52,123 lb. The trade is said to owe its existence solely to the very inferior quality of the tea, which is sold at a correspondingly low price; a principal consideration with many who from choice or necessity regard its cheapness as the first essential of a purchase. The trade, however, is steadily declining, and ten years ago the importation amounted to 692,852 lb. —*Times of India.*

* Soils were not considered good by some, but I know the soil and what I could do with it in our district.

THE UNIVERSAL FIBRE DECORTICATOR.

The want of a thoroughly adaptable fibre-cleaning machine has long been felt in India. Handsome rewards have, from time to time, been offered for the best decorticator, and it was only in December 1884, that the Bengal Government awarded the prize of R2,000 to Messrs. Death and Ellwood of Leicester, for their Universal Fibre-cleaning Machine, invented by a Mr. H. C. Smith, as being the best out of nine machines tried at Calcutta, under the management of two gentlemen appointed by the Government of India to carry out the experiments with these machines. When this award was made, it was thought that perfection had been reached as far as it was possible to attain that distinction, and it was confidently expected that Messrs. Death and Elwood's machine would hold the foremost place among decorticators. But the New Orleans World's Exposition has taxed the inventive genius of the American nation, and there is every reason to believe that a powerful rival to Death and Ellwood's invention has been on exhibition at the New Orleans Exposition. The American papers are full of descriptions of this machine, which are so flattering to its general usefulness and adaptability that we have from time to time noticed it in these pages; but as it promises to excel all other fibre-cleaning machines, our readers will perhaps wish to know something in detail about it.

Mr. Jules Juvenal, who recently lectured at the New Orleans Exposition on ramie, or rhea, describes this machine, which is called the Universal Fibre Decorticator, as consisting essentially of three pairs of rolls and a pair of endless aprons. The machines are of two styles. One is designed so as to enable the feeder to deliver the stalks. The other requires a workman at the rear end of the machine to take the cleaned fibre, the feeder being constantly employed in supplying the machine with material. In the first style the front rolls are smooth; the second are fluted, running about seventeen revolutions per minute. The third pair are armed with scraping blades, rigidly fixed to their periphery and winding spirally around the rolls. These rolls are also hollow, with perforations through their shell, through which water is allowed to flow for the purpose of keeping blades clean from gum; also to wash the fibre, running 300 revolutions per minute. The material is placed on the table, and is passed half-way or more into the machine, then run back on the table, reversed, and the other end cleaned in the same manner. The second style of machine has scraping rolls in place of the smooth rolls, as in the first style. These rolls perform the office of feeding rolls, and also of cleaning the passing ends of the material by reversing the pairs of rolls, instead of the material being operated on.

This gentleman does not pay a high compliment to the experiments conducted at Calcutta under the auspices of the Government of India in 1884, which awarded the prize of R2,000 to Death and Ellwood for their Fibre-cleaning machine; nor does he hold this machine in very high estimation. He says:—

The competition at Calcutta, made under impossible conditions, retarded the invention of a practical machine; for, besides the difficulties presented by distance and the absence of material for experiment, the European mechanics were asked to produce machinery which could accomplish the delicate and tedious hand labor of the Chinese workmen, who made a pound of ramie a day by scraping with a wooden knife a part of the gummy and resinous matters. If experiments had been made in London instead of Calcutta on green stalks coming from Jersey, the absurdity would have been quickly ascertained of asking of practical machinery more than the mere separation of the fibre, which in the green state is easily accomplished, leaving for chemical agents the task of eliminating the gummy and resinous matter adhering to the bark. There lies the whole secret. If all inventors of decorticating machines some of whom are very clever, have heretofore failed, it is because they have aimed at filling the conditions imposed for the Calcutta competition; that is, to make a machine capable of producing directly the China grass. This, nevertheless, came near being accomplished last year at Calcutta; but with what paltry results! The Smith machine, of London, which obtained a prize of 2,000 rupees, or (£1,000) (£200?) produces, with two men and a three-horse power, sixty pounds a day.

Under such conditions ramie would be twice as high as silk. What is needed is a combination by which production, cleaning and fabrication will give a silky fibre ready for the loom at a cost from twenty to twenty-five cents, about the price of first rate flax. —*Indian Agriculturist.*

Cinchona Seed from Java.—No apology is needed for calling attention to Mr. du Perron's consignment—which is becoming an annual institution—of some of his finest cinchona seed for sale here. Some enterprising Ceylon Planters should after a similar fashion try the Java market, for there can be no doubt that an interchange of seed is calculated to be beneficial to both countries. We do not suppose that discouraging as recent prices for bark may be, the cultivation of cinchona will be given up in Ceylon and there can be no question of the advantage of using not only foreign seed, but seed from high-class trees such as Mr. du Perron sends for sale by Messrs. Somerville & Co., next Tuesday, Jany. 25.

A New Witherer.—Mr. Gibbons has devised a simpler form of his Tea Witherer. He says "these machines are so constructed as to combine strength and economy, and are provided with shelves placed at such an angle as just suffices to move the leaves gently without lifting or bruising them. The leaves being fed in at one end pass out at the other ready for the tea rollers. These revolving Witherers can be packed in very compact form for shipment, and are easily put together on arrival, and can be supplied at the most moderate cost. For example, a small one for use with the hand fan, suitable for the smallest gardens, could be shipped f. o. b. at £25, and from that price upwards they will range from £40 to £200. The larger sizes being calculated to save an enormous amount both in labour, delay, and waste." -*Indian Tea Gazette.*

Diphtheria and Kerosine.—A contemporary says :—"The latest discovery in the etiology of disease is rather startling. It is nothing less than that kerosine oil is one of the causes of diptheria. Owing to the prevalence of the disease in Connecticut, an enquiry was instituted by the State Board of Health, and the result is that the insiduous enemy has been detected. The observations were conducted at Meriden, where diphtheria was rife, and it was found that not a single case occurred in any house that was lighted with gas or candle. The Board maintains that the discovery is fully established, and if so, there can be no doubt that it is a matter of great importance. Kerosine oil has come as a boon and a blessing to India, but it has probably never been suspected of promoting illness. What with salicated Pilsener and deleterious kerosine, a new terror is added to Indian life, and the responsibility rests with the medical faculty."—*Pioneer.*

Root Pruning.—In the Saharunpur Botanic Garden an experiment was tried in root-pruning upon young and over-vigorous Peach trees. A plantation of these was formed three years ago in a very rich piece of ground formerly used for vegetable cultivation. The trees were of astonishing size for their age, but their vigour all went to stimulate the production of wood rather than fruit: thus they were fit subjects for the experiment. A trench 2 feet wide, 2 feet deep, and 3 feet from the trunk of the trees, was dug around them in December, and every root met with was cut by the spade. The soil was thrown back liberally mixed with manure, and frequent waterings were given for sometime afterwards; at the same time the branches were thinned out and shortened where necessary for symmetry, but not in any way severely pruned, as native gardeners are in the habit of doing. The treatment given has been quite successful, as every branch and twig is now laden with fruit. —*Gardeners' Chronicle.*

"NEW GALWAY" DISTRICT REVISITED.

(*Concluded from page 533.*)

Before leaving Albion I must notice the limestone formations which crop out here so abundantly and from the "white cliffs" of which, the estate probably derives its name? On the soil which is doubtless largely impregnated by decayed calcareous matter, the natives cultivate considerable quantities of onions (the small species which subdivides, identical with that which is so largely produced on the recent lime formations of the Jaffna Peninsula,) and garlic. Mr. Alexander Dixon was of opinion that the Uva dolomite, passing under the Nuwara Eliya and Dimbula ranges, crops out again opposite Gongalla in the shape of the Meddecombra cliffs. The limestone formation is valuable wherever it occurs, being better we were told as a mortar than coral lime, although the latter is superior for finishing off and for whitewashing. The coral limestone, too, (almost pure carbonate of lime, with no admixture of magnesia,) is superior as a fertilizer, were the carriage not so expensive. But the great interest to us of the limestone on Albion was the presence in it, not of gold coloured iron pyrites as is usual, but of a wealth of beautiful sapphire-blue crystals of spinel. We spent a considerable time in selecting and loading a cooly with a basket of exquisite specimens, in which the deep blue of the spinel contrasted beautifully with the white of the limestone and the bright-glancing mirror-like crystals of mica. As ornaments for a drawing-room mantlepiece, or a boudoir or as cabinet specimens, there are few things so beautiful and interesting, and we were not surprised to find that Mr. Kellow has many requests for specimens. Our previous attempts to get pieces polished into paper weights at the Colombo cemetery works, were not a success, the limestone taking a dark colour in the process of smoothing; but persons obtaining specimens of the spinel limestone will be interested to learn that the intensity of the blue of the spinel crystals and the brilliancy of the mica can be greatly heightened by smartly rubbing a piece of clean chamois leather, over the rough specimens, as blasted or hammered. As yet Mr. Kellow has blasted only one large boulder, we believe, but the probability is, judging by analogy, that the spinel permeates much of the limestone and that regular spinel sapphires have been found or can be found in the detritus below. It does not seem likely that a people so much given to gem-digging as the Sinhalese, have neglected search in this formation, but there can be equally little doubt that the supply, especially in the rock matrix, cannot be exhausted. The intrinsic value of sapphires and rubies found in limestone is low in comparison with the prices paid for crystallized and coloured clay, but spinel gems if large and flawless, have a value of their own. Not long ago, when Mr. Kellow showed us his first specimens, we gave full and detailed information on the subject, including the alleged facts that very large and pure spinel sapphires and rubies from Burma had sold in the European market at prices equal to those realized by the gems derived from the crystallization of argillaceous matter. Mr Kellow has had door-weights made of the Albion spinel limestone, and flower-pots cemented over with small fragments look very beautiful, hung in the verandah of his bungalow. It would be preferable, however, we think, to form vases thus ornamented in which to place ordinary porous flower pots. But for the weight of the material, (our collection severely tried two coolies), a good market for the beautiful blue-crystalled mountain limestone might thus be opened up. It is possible, too, notwithstanding the failure of our experiment, that slabs for tables may yet be sawn and successfully polished. Contrasted specimens of masses of red garnets which we collected on the Blackwater slip, and the blue-crystalled limestone which we took from the vein below Hakgala, on Albion estate, have excited great admiration, each being beautiful in its own way. While on the subject of mineralogical specimens I must not forget to mention that on the occasion of my original visit to New Cornwall, under the auspices of the late Mr. Mark Kellow, he led me down through the bottom of the valley, by a path long since disused, to a formation near the outlet of the stream, known then and still known as "the plum-pudding rock." Some conglomerate, no doubt, but whether ironstone, as is probable, or some form of quartz or limestone, I cannot say as, on this latter occasion, I was not able to get to the position of the plum-pudding rock. A curious peculiarity of the specially rich soil of this limestone region is its very dark chocolate colour. This dark shade must indicate the presence of fertilizing substances specially favourable to the growth of coffee, for the stems which we saw as we descended the steep sides of the cup-like Valley of Ambawella, thick as a stout man's thigh, were wonderful contrasts to the best growths we had ever seen in Dimbula.* Produce in the prime of this secluded district, (reminding me strongly of the scene of the richest gold mine in the world, the Walhalla in Gipps Land, Victoria,) was in proportion, and Messrs. Cotton and Kellow, still shew splendid coffee, Mr. Kellow indeed adhering to his first love, coffee, and not yet "going in" for tea. Mr. Cotton, however, has gone on the two-string theory, while the proprietors of Ambawella are scattering tea in all directions: in the valley; on its rim and down outside of it, until the high road below Hakgala is reached. There can be no doubt that where coffee grew so well tea will also flourish. Looking at the soil, I said to my companion, "We have soil over the range quite as deep, quite as free; the difference with us is the lighter colour, brown inclining to yellow, in which coffee, but for leaf disease, would have done fairly and in which tea luxuriates." I had just been reading Dr. Griffith's account of the expedition of Dr. Wallich and himself to the habitat of the indigenous tea in Assam, nearly sixty years ago, and I did not fail to note that where a group of tea trees was found growing in the Assam and Upper Burma jungles, the almost invariable description of the colour of the soil was "yellow." The fact seems to be that tea, with its powerful tap-root, rejoices in a pretty stiff clayey

* At the distance of nearly twenty-two years, I have the most distinct and vivid recollection of the exquisite scene which greeted two of my senses, as I rose on the morning of the second day of my visit in April 1865. The whole expanse of coffee spread over the valley appeared as if during the night fairy agencies had been at work, showering over the trees a dense covering of jasmin-scented snow-flakes. As I walked through this scene of amazing beauty and powerful perfume, I gathered specimens of a small, indolent bee-like beetle which, in immense numbers, was feeding on the nectar of the flowers. I sent the insects to the late Mr. Neitner (Author of "Enemies of the Coffee Tree,") who assured me, that the beetles were innocuous. Alas, that a similar verdict could not apply to the fungus which four years subsequently developed with such fatal fecundity and destructive energy, over similar vast expanses of once profitable but then doomed coffee culture, the contemptible pest, breaking not merely fortunes but human hearts!

soil with a proportion of iron in it which coffee did not like. Outside the Ambawella Valley I saw tea growing well in patana soil and learned from my good friend, Mr. Cotton, that although there is some difficulty at first in reconciling the plants to the grass-land soil, they seem at once to be at home when the tap-root gets well down into the subsoil. Unless Mr. Kellow resolves to devote his patana land on Albion to timber tree growth, I cannot doubt that tea will do well between his shelter belts of wattle, and the result of my revisit to New Galway and its neighbourhood and what I saw, is to convince me more strongly than ever that a very considerable proportion of the better patana lands of Uva are calculated to grow, not only timber trees but tea, well and profitably. All Ceylon knows about the splendid fruit, peaches and especially plums grown by Mr. W. Cotton on Warwick. The large Ootacamund plums are especially famous and Mr. Nock is grafting this kind on the smaller plum, which has about as great a tendency to send up shoots as has the silver wattle. Here, as at Hakgala, we were struck with the magnificent foliage of the tree tomato. As an ornamental plant, it is worth growing; but the fruits are really nice (much like gooseberries) when ripe and eaten for dessert; while as a stew or jam, it is most difficult to distinguish them from apricot. The tree tomato and the *cho-cho* are great successes with Messrs. Cotton and Kellow (whose bungalows are in close proximity, while the stores of the three estates are also close together at the bottom of the valley); indeed the *cho-cho*, (the cooked fruit of which closely resembles vegetable marrow,) is so prolific that the surplus fruits are already used to feed pigs. The tree tomato, the *cho-cho* and the edible passion fruit, are great acquisitions on estates and seem to flourish everywhere at high altitudes. A gentleman from Assam tells us that there the gigantic passion flower, the grenadilla of the West Indies is common and the fruit largely used. We do not know why this fruit has gone out of view in Ceylon. We remember its introduction, (by Mr. David Baird Lindsay of Rajawella * we think,) more than 40 years ago, and it used to be grown at Colombo, climbing up jak trees. For many years we have seen it only as an escape in the Holnicot jungle above Nawalapittiya. From New Galway we brought a gigantic citron, weighing 3 lb which may for this week be seen (and scented, the smell being delicate lemon) at the *Observer* Office. —Although we could not revisit the plum-pudding rock in the depths of the Ambawella Valley, Mr. Kellow led us to "View Point" at the mouth of the Valley, whence we looked out upon the larger portion of Haputale, the Church and some of the stores gleaming white in the sunlight. Up above the deep Ambawella Valley we got a glimpse of the patana on which the Ambawella station of the long delayed Uva railway is to be placed, and from "View Point" we saw well into the Idulgashena Gap, through which the line will pass on to the shelving grassy range along which it will seek its present terminus on the Haputale pass. Here and in our journey to Albion we enjoyed views of the different divisions of Uva, which, in the fine weather which followed the rain, were inexpressibly grand and beautiful: while in passing upwards between the massive Hakgala and the beautiful wooded and patana ridges opposite it, the scenery was in some places sublime. But from "View Point" it was sad to look down on the remains of the first and second Ambawella bungalows: there is now a third in quite a different position. In the earliest built of all, in April 1865, my brother Highlander, Mr. Allister MacLellan, "in the dress of old Gaul" entertained me to pipe music,—music which is heard to chief advantage amidst the echoings of mountain valleys. I fancy I appreciated Mr. MacLellan's music more than the late Mr. Cruwell is said to have done. "That will do! that will do! that is beautiful! that is enough!" the musical German is described as exclaiming in ill-concealed agony, while MacLellan responded, "Man, I have not yet begun the *chune*! That is only the over—*chure*!" The Highlander probably did not think the German "capable of giving an *opeenyon*" on the music so dear to the sons of the Gael. Alas! Cruwell and MacLellan, and my original host and guide the elder Kellow, and so many more, are all gone, so that "the place which once knew them, shall know them no more for ever." I heard of a roll of names including about a score of Superintendents on Ambawella, the larger proportion being dead. I, close on my 71st birthday, paid a pathetic visit to the elder Cotton, bed-ridden from an accident in his 77th year. Here on Warwick, besides the kindest hospitality, I thus met three successive generations of Europeans connected with Ceylon. Old Mr. Cotton came to the island in 1844, never again leaving it, I believe. His son William born in Ceylon, I imagine, married a Scotch lady from Aberdeenshire, and they have children in Ceylon and "at home." To one of them, a young lady just returned from "Home,'; we were indebted for "low and sweet" strains of song and piano music, the most complete possible contrasts to poor Allister MacLellan's "skirling" pibrochs of twenty-two years ago. With this pleasing reminiscence it is fitting and congenial I should close my record of "New Galway Revisited."

* It is flourishing on Pallikelle still.

BRITISH INDUSTRY IN CENTRAL AFRICA.

A telegram in *The Times* of Tuesday informs us that the German East African Company mean to start plantations of coffee, sugar, and other cultures in the immense territory (70,000 square miles) recently acquired by them from the Sultan of Zanzibar. In this connexion it will be of interest to give some account of what has been done further south in the Lake Nyassa region by an English company, the "African Lakes Company," who have been working quietly for eight years, with very marked success—a success, indeed, which seldom accompanies enterprise in Africa.

Those familiar with Livingstone's later explorations will remember that this investigations resulted in the discovery of the great Lake Nyassa, which empties its waters into the Zambesi, the Shiré serving as a conduit. The dream of his life was to utilize the extensive waterway for the introduction of commerce, in order that the tribes which furnish by far the largest quota of human chattles to the slave-trader of East Africa might have a chance in turning the natural wealth of their country to good account, and not be dependent on a bloodthirsty set of half-castes for every yard of calico or string of beads. But Livingstone's purse was a very short one as African expenditure goes nowadays. He nevertheless sank nearly his whole means of developing this idea, which had but one result—his failure showed to those who were to come after just what should be avoided in the future, and what insisted upon. As a reconnoissance it was all valuable; but it sorely crippled him. In common with all African rivers the Shiré has its staircase of cataracts, and thus a clear run from the Indian Ocean up from the Zambesi to Lake Nyassa is impossible. A "portage" of 75 miles half-way between the lake and the Zambesi is a necessity. However, there were plenty of Livingstone's countrymen north of the Tweed who had such faith in the doctor's hard-headed wisdom that, with

the help of some of his old comrades, a new attempt was resolved upon in the year 1878. Mr. E. D. Young a gunner in the Royal Navy and Livingstone's factotum had seen just where the breaking point lay previously and when he was invited to assist in resuscitating plans all tending to relieve the natives of the Shire highlands from the incubus which lay upon them, he rendered invaluable service. Sent out by the Royal Geographical Society to investigate the story of Livingstone's reported murder in 1866, he was able to try tho oughly the experiment of transporting boats in sections. "Mild steel" was then in its infancy, and, if we are not mistaken, Mr. Young's boat, the "Search," was the first vessel of any kind constructed of this material. She was put together at Chatham under the supervision of the Admiralty authorities, and proved a perfect success during Mr. Young's well-known and most successful adventure. With the experience of this last trip in hand Mr. Young received a commission from the Established and Free Churches of Scotland to provide them with a steam vessel made of the same material. Mr. Yarrow built the Ilala under Mr. Young's immediate directions, and again with undaunted perseverance he placed her on Lake Nyassa at the service of the missionaries who accompanied him. It is right to mention this because we now hear of steam vessels on most of the great inland seas of Africa, and notably the Congo river, but to Mr. Young's energy is due the fact that the Ilala led the way in 1876. Sir Samuel Baker's steamers were second in order on the Albert Nyanza in General Gordon's service. It speaks well for the future when we now learn that Emin Pasha has the abovenamed vessel still afloat. The Ilala is reported "tight as a bottle" after ten years of amateur and professional seamanship, during which she had to weather many a heavy gale and many a bump.

The African Lakes Company took shape in 1878, not as a mere trading venture, but to assist the various missions which were then established, and to work out Livingstone's schemes. It had its ups and downs, its days of small things and its successes. Now it can boast of steady development through all. Twenty-five Europeans are dotted about at trading stations stretching from Quillimane on the coast to a point half-way between the Lakes Nyassa and Tanganyika. These stations are 12 in number, and three steamers ply on lake and river with very great regularity. At a pinch the company has shown itself equal to conveying a steam vessel in sections across from Lake Nyassa by the Stevenson road (of the company's engineering), and she is now on Lake Tanganyika with the staff of the London Missionary Society. But the point which the company has settled is this:—During the eight years in which it has extended the ramification of its trade over this immense distance, it has proved that it is possible to trade in indiarubber, wax, oilseeds, and in ivory to an enormous amount, without defiling the list of their barter goods with a single keg of trade rum, or the all-representative "square face" of the West Coast trade. It is something to have established proof before us that it is not necessary to carry ruin and desolation headed up in Hamburg casks and Dutch gin bottles to a new country before you can hope to see tusks and dividends. The Messrs. Moir, who are intrusted with the concerns of the company, testify that they have already exported (December, 1885) 40,815 lb. of ivory, and not imported a glass of spirits. We can only trust that when some of the ventures which are in the air take form and shape, either on the Congo or in the Soudan, this invaluable precedent may encourage or shame as occasion may require.

Little short of romantic are some of the incidents connected, with the company's progress. Making very bad weather of it for many years, two little stunted coffee plants led a miserable existence in the Edinburgh Botanical Gardens. It was a happy and kindly thought a ways when the Curator asked Mr. John Moir to take them away with him to the Shire highlands. In due time they arrived; the fittest survived. Too much happiness, perhaps, killed the other. The survivor took a new lease of life, struck deep roots into the warm, red soil of the hills, and burst out with berries and cuttings in the glorious air of the highlands. Photographs lie before us in which plantations filled with heavy-laden coffee trees are depicted. The gardens on Mount Zomba, of the Buchanan Brothers, are a thing to see, and it was stated in *The Times* some years since that samples of their produce had been priced very highly in Mincing-lane. But to this old patriarch of the Edinburgh Gardens is every berry traceable. It is computed that 100,000 trees claim direct descent from him, and Scotland may claim to have put some of her own energy and pluck into his fibre. Nothing seems to be such a favourite article of barter with the natives as soap. Equal to the occasion, the Lakes Company contemplate making both soap and candles for the market which already exists. They express abundant oil for their steamers as it is from ground-nuts, which do not pay to export. But the company pride themselves on the alteration they are bringing about in the ivory trade of the interior. Hitherto it has been the custom of the Arabs to buy, or more often to seize, such stores of ivory as they know of in the country. The tusks are generally borne to the coast by unfortunate slaves, who after a tramp of several hundred miles are got rid of for what they will fetch. The burden the man has carried may bring in from £25 to £30; the bearer may change hands for $5. Now the trading stations of the Lakes Company "cut" this traffic half-way; the Arabs are glad to dispose of their ivory midway at the lake. We much regret that it is not in our power to report any diminution in the traffic in slaves across Lake Nyassa, coastwards bound. On the contrary, it seems that it is increasing largely. The slave trade is in the hands of Arab agents and powerful lake chiefs, with whom the company has no licence, even if it had the power, to interfere.

The very existence of the large mission stations of the Scotch Churches and the Church of England on and around the lake depends on communication with the outer world, and this becomes only a second charge on the company's exertions. To keep up with requirements under this heading a large sternwheel steamer is just being put together on the Zambesi, whither she has been borne in sections from the Clyde. It would be very interesting to point to the work, both industrial and evangelical, which is being carried out in these regions, but it hardly comes within bounds, nor can we do more than mention again the fact that, with the company's operations as a basis, some very excellent Scotch farmers and engineers have founded a flourishing settlement on Mount Zomba—perhaps one of the healthiest and most picturesque spots in Central Africa. With abundant streams and a network of irrigation, not only do they dispose of their coffee, sugar, and oil seeds to the Company, but some of the rarer drugs and spices are being brought under hand. Surely the very spirit of Livingstone must wander now and again through those regular lines of coffee trees? He dared to dream and to talk of such possibilities in his lifetime; his hard-headed, energetic countrymen have indeed given a backbone to his visions since he died on the shores of the neighbouring lake. But a great deal too much harm has been done already by picturing tropical Africa as the coming colony for Europeans of all classes. It is murderous folly to entice men on to its alluvial lands and swamps to dig and delve, to plough and sow. Only here and there can such things be done; even then the white man must manage and direct alone. But, rightly understood, this very fact tells in favour of the natives. Born cultivators are they; no new discovery this, as Cuba, Brazil, and the Southern States of old can tell; but heads for such details as the merchant's ledger requires will not ache over figures for a generation or two. Then there is no prospect of the African being elbowed off his own land by the incoming settler, be he of the "Ma Dutchi" tribe (as the natives already call the Germans) or from Ireland, England, or Sweden. The natives must command their own price; they do now at the company's stations and on Mount Zomba, but it is not in rum, we repeat.

Pleasant would it be to round off such a story of brave experiment, and, let us add, monetary success, without dropping a hint of care and embarrassment, but then it would not be Africa. Nothing goes right in Africa," is a proverb from Cape Town to Cairo, and the Lakes Company has its troubles. Ever since Lord Palmerston's day the Portuguese have endeavoured to claim everything and everybody situated behind their seaboard on the east coast, and so across the continent to the western side of Africa—a pretension which has been as often contested. It will be seen that the country in which the company's operations lie falls within this section. The recent "scramble for Africa" has made the dry bones of these old disputes have their say. Germany has treated them in her own off-hand way. It was enough, surely, that poor Livingstone discovered with chagrin that he had only been exploring for the purposes of convicts and slavedealers at Senna, Mette, and Quillimane; it would be too much now to witness any attempt made to nullify this true-hearted effort to emancipate the natives from their wrongs, and the countrymen of Livingstone must look to it and see that it does not take shape to the detriment of the new industries.

[We have the impression that the late British Consul, Captain Moore, R.N., indented on Ceylon not only for cinchona seed, but for coffee, and we can only hope that the fungus was not carried with the coffee.—Ed.]

CUPS THAT CHEER.

Botanic beer can hardly be erased from the list of our national beverages without a struggle. The Excise has lately declared against it, with the support of the Courts, but surely some effort will be made to reverse the judgment. We know nothing of the compound more specially in question; and of "herb beer" we can say no more than that we believe it to be well meant. It is understood to be teetotal in its tendency, and in the nature of a pious fraud. It has something to the colour of the lighter beer, and well shaken, it evolves a lather, which enthusiasm may call a head. With a pipe of herb tobacco it completes the outfit of the blameless, intent on "going it" without a headache. It may be all very well, yet, it ought not to represent the final effort of invention to improve the quality of our non-intoxicating drinks. There is no more reason why a certain person should have all the nice beverages to himself than why he should have all the nice tunes. The coffee palaces are, no doubt, admirable institutions, but the coffee they sell leaves much to be desired. The same thing may be said of their tea. If they only brewed with half the scientific care of the brewer they might sooner drive him out of the field. They would certainly confer a great boon on all of us, for where they led, the kitchen might follow, and in time we should have tea and coffee fit to drink. As it is, people make both of these beverages with an appalling lightness of heart. Some own to a sense of responsibility as to coffee, but it is a common belief that anybody can make a cup of good tea. Sages have not been of that opinion. The late Mr. Ayrton, who had better claims to that title than it is now the fashion to admit, made tea as seriously as he audited a public balance-sheet. He had thought it all out, as he had thought out Indian administration, and the result was a certain solemnity of preparation not unsuggestive of a Hindu rite. He made tea with awe; and those who denied him the quality of reverence had never called on him in the afternoon. He made only just as much tea as he wanted—no more—and he had a rich variety of teapots to enable him to take the measure of every need. He allowed the tea to stand for five minutes, and then drank it all up, or at least poured it all out, at once. It was delicious. If he could have made tea for Sir J. Hooker they might have been friends for ever. The poor man's cup, and especially the poor woman's, often stews on the hob for hours, and it is really not much more than a decoction of tannic acid when all is done. Tea should never be a decoction, but only an infusion. Even the tea of the drawing-room usually stands too long. The replenishing of the teapot with fresh water, common both to the mansion and the cottage, is a positive abuse of the gifts of nature. There can be no good gossip on the stimulus of drink so made. The finest talk must degenerate into tattle when the tea has stood for more than seven minutes at the outside.

With our tea a comparative failure, our coffee is, of course, almost past praying for. Our very pretensions go no further than tea. We lose a good deal by the meanness of our ambition. Good coffee is the finest drink in the world, and it would surely defeat half the intoxicants on their own ground. It is the most generous of stimulants, and it induces activity and alertness of brain without the faintest trace of elevation. Should any further recommendation be wanted, we may add that, like pure water, it will kill, if you take enough of it, or, rather, too much. Mürger died of excessive coffee—not unflavoured with cognac—but far more people have to thank it for the prolongation of their lives. It is far beyond tea as a dietetic, though perhaps nobody but Merlatti could wisely venture to make it his sole support. Indeed, high authorities say that it should never be taken without something solid, as an accompaniment. Anything will do—a piece of bread, or, failing that, even a waistcoat button, according to the Oriental proverb quoted in an admirable lecture on the subject at the Parkes Museum. It improves with age like the other generous drinks, though not of course when it is in the state of infusion. The green berry may be kept for fifteen or twenty years, and it will gain in flavour every day. Brown Java, which leaves Mocha far in the shade, is supposed to owe a good deal to its long sojourn in the island before exportation. It lies in store sometimes for seven years.* The roasting should always be deferred to the very last moment. Roast, and brew at once is the golden rule. First get your Brown Java—for that matter, one of half a dozen other kinds will do. Then make a smokeless fire, of coal, or gas; toss your green berries into an earthenware pipkin, if you have nothing better at hand, and there need be nothing better; hold it over the flame for fifteen or twenty minutes, to dry it merely, not to burn it, stirring it all the time, and your task is done. Grind or pound in a mortar—pounding, they say, is better. The Turks find that the pestles improve with use, as the coffee improves with age, and they sell the old ones at a high figure. Two ounces of coffee to the pint of water is the happy mean, and those who want it weaker had better weaken it after the brew. A common jug and a strainer are all you need for the final rite, but people who like to part with their money often insist on more.

Coffee is best with absolutely no adulteration, but some plead for chicory with it, owing to vices in their bringing up. Dandelion root, roasted acorns, dried cabbage stumps, "or any other form of vegetable offal," ought certainly to be left out of the pot. And, if there must be chicory, let us have it pure. There is often an adulteration of the adulteration, in the shape of an admixture of venetian red, roasted pulse, damaged wheat, mangel wurzel, oak-bark tan, logwood, dog biscuit, or baked liver of horse. But for the greater facility of adulteration, coffee might be as largely used in this country as tea. Tea is better protected because it is easier to protect. We seem to drink less and less coffee every year. Some go so far as to say that the adulteration is systematically encouraged by the Government, but this seems unfair. It does appear to be systematically endured. The Customs have been known to advise their officers not to attempt to distinguish dandelion roots from chicory "on their own responsibility." They ought not to let themselves off so easily. A people that had once tasted really good coffee could never afford to forget that joy. It is much rarer in England than almost

* If this were true, which we do not believe, twice the ordinary price would not pay the producer—Ed.

any other delicacy. The exporters, no doubt, send us of their best, but we do not know what to do with it when we have it. The Turks might send us a coffee mission, or even, if this unhappy business in Egypt were settled, the French. The taste is ready, and it only awaits the means of gratification. The only proprietor of an English coffee-house who knew how to make coffee as it is drunk in favoured localities abroad soon realised a fortune. If the French would but teach us how to make coffee we might teach them to improve their make of tea, on the principle of an exchange of lessons. They are wofully benighted in this matter, even in the centre of civilization. In the outlying districts they have a rooted idea that tea is physic, and they have been known to offer it, pending the arrival of the doctor, for the relief of a broken limb. They never make it strong enough; their tea is emphatically but hot water bewitched. And the instrument of witchery is apparently the old familiar one of a birch-broom.—*Daily News.*

INDIAN COFFEE CULTURE.

BY AN EX-PLANTER.

Though the cultivation of coffee by Englishmen is of no great antiquity, yet for the last 50 or 60 years, it has had a peculiar fascination for our ambitious "younger sons," and that this charm still holds good the captains of outward-bound passenger steamers know full well. It is for those whose thoughts have thus turned down this new and curious road to fortune that these notes are put together. For them we attempt a suggestive and sufficient sketch of this attractive labour, as well as profitable enterprise; while others, whose connection with coffee is confined to the refreshing matutinal draught or after-dinner digestive sip, may be curious to see how their sons or brothers defy malaria and fever, living a life of hardship and adventure imperfectly pictured by those at home.

Coffee thrives in many parts of the world. A map coloured to show the regions where its cultivation is profitably carried out would exhibit a broad zone of habitation on both sides of the Equator completely circling the globe. One or two districts thus included, by some happy combination of climate and soil, have attained to fame through this product alone. There is Brazil, in South America, where scores of hundreds of miles of admirable volcanic soil are clothed with bushes, and the revenue of an empire fluctuates with its good or bad seasons. In Jamaica, under the British flag, this mild beverage has almost eclipsed the profitable production of a stronger drink for which the island has been famous. On the opposite African coast, again, the negro state of Liberia rears a lowland species named after the locality, and indigenous. Caffa, on the Abyssinian tablelands, is held by many to be the native home of coffee, and it is still grown there in a rough-and-ready way. But from sandy Syrian terraces above Mocha comes perhaps the most famous growth of coffee—that variety which made the beverage famous in Constantinople and Europe more than two hundred years ago. Its superlative strength and aroma are due largely to the care exercised by Arab cultivators in marketing only the ripest and choicest cherries. Many of the lesser Pacific islands grow coffee, but in a scattered, careless fashion, amongst those teeming jungles where the sunbirds flash and parrots nest, so brilliant in feather that one might well believe nature had used them to wipe her most lavish paint box out with.

Fiji, since the annexation, has become prosperous. Its coffee is rising in estimation, but there crops up in an acute form the labour difficulty, perhaps the most serious question of all those which can vex a planter.* Home labour in this delightful island is instinctively lazy, and, moreover, pampered by a well-meaning but "grandmotherly" Government. Consequently, resource is had to labour ships, which scour the Pacific picking up every man or boy who is willing to apprentice himself for three years. But for this single matter we should say to the hesitating novice, "Try Fiji!" The climate is pleasant and the land is unquestionably of wonderful fertility.

But it is to Ceylon and India that most young men's eyes turn when they think of seeking this manner of fortune in new lands. Ceylon, "the brightest jewel in the English Crown," has been a very Garden of Eden to the tropical adventurer: in our opinion its soil is to-day as unexhausted as it ever has been. True, the island is not just now so vividly prosperous as some years ago, but this in great measure is the result of overdoing the coffee enterprise, and flooding the high-class labour market with an endless stream of "chick dorees," all willing enough to work, only without a particle of practical knowledge. But the great shadow that has been upon Ceylon is that of the dreaded *leaf disease*. This terrible little fungus spots coffee leaves with yellow, finally stripping and killing the bushes over whole mountain ranges. It has sent down the value of estates 50 per cent all over the island. Before the disease appeared you could hardly grow coffee in any style without realizing something of a profit. On certain estates—"on Patna soil"—40 per cent for money invested has been returned year after year; and now—well, some cynical proprietors, well qualified to speak, say the only way to make coffee pay in Ceylon is to pull every bush up, planting tea in its stead.

Good coffee is grown in Southern India. Here labour is generally fairly abundant, and very good in quality. In most districts the climate is healthy: "jungle fever" may be reduced to a minimum by a cautious planter, and there is generally some sport to be had near at times.

It is with a by no means unpleasant sense of freedom the wanderer goes up to his jungles, his last link with home broken when the big ship that has borne him over seas went down on the horizon, and all the rich future opening before him. He goes up-country as far as the railway will take him, and then has to rely upon country carts, the muchlah or hammock suspended from a pole, or horseback if he can get a mount.

The first evening alone in his Traveller's Bungalow is the pause before the curtain rises to-morrow, and he sees those hills and gorges in which he must live and work for the next 10 or 20 years—which perhaps, indeed, he may never quit; but he puts away this latter thought if he be of stuff stout enough for a pioneer, and gives himself up keenly to the novelty of his surroundings. Blasé indeed must be the wanderer who has forgotten how dark was that Indian evening under the fig trees of the little English station, how obsequious the native attendants seemed, how the multitudinous voices of the night, the jackals yelping on the maidan, the squirrels chirruping overhead amongst the rafters, bats and owls outside, and a world of insects in the brushwood, combined in one continuous concert. Fire-flies hovered about the trellis of the verandah, and inside the heavy monotonous flap of the punkah overhead lulled him to repose; for the rest, all he remembers of his first evening is that it seemed he had hardly sought the shelter of sheets and mosquito curtains when his servant shook him gently by the shoulder and thrust a suggestive cup of hot coffee upon his attention.

Making a start by moonlight—that wonderful silver radiance that floods a tropical landscape with mellow light—or, perhaps, at very earliest dawn, he has turned his face to the blue hills that tower before him long ere the sun is due in the East. Through slumbering hamlets, in their heavy green shrouding of bananas, he passes, disturbing a cooly or two asleep before the doorstep of some better-housed countryman, and the peasants start up to stare, or salaam—if they can get their wits about them in time—as the sahib canters by, his heavy baggage in country carts, drawn by amiable white oxen, trundling after him. Broad rivers are crossed, all black and silver in the moonlight, where the carts go into the flood up to their axles or higher, and the cattle drink as they plunge and sniff through their sparkling bath, while each driver shouts and twists their tails until they may

* More serious in the case of coffee is the introduction in its very infancy of the fatal leaf fungus.—ED.

be heard to crack audibly. Deep groves of figs are passed, where shadows are so dense we cannot see our horses' ears or the first man, who chants monotonously as he staggers under our hammock pole, and the exit at the end of the avenue tunnel shines with a dazzling brilliancy, and then dawn comes as the foot hills are reached; the thin curls of aromatic blue smoke go up from the hotels of wayside huts, parroquets rush tumultuously screeching from palm tope to palm tope, the hum of the night-time drones into silence; and while the sky overhead of lavender is shot with fiery yellows and crimsons, the day comes, the bee-eaters take up their perches, the great black and crimson swallow-tail butterflies hover amongst the yellow cactus flowers, and the "gorgeous East" is awake again.

The best coffee lands lie for the most part above the bamboo region, which rings the hills, and to reach it we have to pass through a waving forest of that giant grass. Zigzaging up the Ghaut road, we come at last to a plateau, three or four thousand feet above the sea; and here, all around us, in these undulating glens and corries, clothed in dense and gigantic jungle, is the chosen soil and congenial home of the coffee bush. Lonely, indeed, will be the lot for a time of him who goes to a really brand-new region, where the foot of man has never before penetrated. But, to tell the truth, such places are scarce nowadays, and we may safely suppose there is a friendly, though strange, hand to welcome the newcomer to the woods, and give him shelter and food until he shall have had a chance to establish himself. This previous settler will put the "Griffin" up in the local regulations, and smoke a cheroot or two over the best spot for a new garden, and the formalities attending its purchase.

Much the same method of taking up land holds good on all Crown forests. The would-be purchaser, if he is bent on opening forest for himself, "prospects" until he finds what he thinks will be a likely bit. This is notified to the local authorities, who fix a day and put the hillside up to public auction at a reserve price of from 10*s.* to 2*l.* per acre. The hardship of this arrangement is that occasionally the man who has been to all the trouble of making a selection is outbidden by some wealthier rival, who carries off the prize. But suppose it falls to the prospector proper, at a price which will vary infinitely with soil, climate, aspect, accessibility, neighbourhood, &c., but may approximately be put at 2*l.* to 3*l.* per acre; then the owner pays down 10 or 12 per cent, and enters into practical possession. A Government surveyor comes up and marks out the limits of the land by clearing a broad path or "blaze" through the forest all round, and for this about 4*s* (R2.) per acre is charged.

Then the Englishman sets to work. If there is another planter within a mile or two of the jungles which are going to blossom with coffee an arrangement is generally made by which the new chum stays with him for a time, going to and fro every day; but if the district is quite unsettled, the "Griffin" must establish himself. The first necessity is some labourers. To obtain these recourse is generally had to maistries or headmen—gangers we call them here in England—who are well known on the outskirts of all agricultural districts. They wait upon the sahib, and, with much salaaming, hear how many men he wants, and when. For each man, woman and child they promise to produce by a stipulated date in the future garden an advance of three or four rupees has to be made. Much of this goes straight into their own pockets, no doubt, but the rest enables the coolie labourers to provide a few necessaries for their migration. It is an eventful day when they come streaming up the rocky hill roads, 50 or 60 of them, perhaps, in Indian file, carrying on their heads and shoulders an infinite variety of baggage and movable property, with bags of rice slung across the backs of bullocks, a choice assortment of little black and brown native sheep, and bunches of miserable cocks and hens hung in festoons, heads downwards, from bamboos. They encamp, and, under the energetic supervision of their maistries, set to work erecting long rows of low sheds, or lines, as they are locally called. These are very roughly made for the time of strong uprights fixed in the ground, walls of matting made of split rattan cane, and heavy roofs coming low down to the ground of lemon-grass or fan-palm leaves. The Englishman's first hut is a few score yards away, and only a little more carefully finished than the natives.' Round it are the stables for his pony, the tool sheds and store houses. The site for such a settlement should be carefully chosen. Hollows must be unconditionally avoided, so should windy gaps too high up. The best place is a spot on the open grass hillside, by the side of a good stream, with natural drainage, and well above the level of the tree tops in the valley below. The planter cannot take too much care of his men, or treat them with too much consideration and justice. They are no more "niggers" than they are Esquimaux! And he might remember with advantage how many of them belong to races distinguished for valor and culture when his own ancestors were still in the barbarism of woad and wolf skins. It is, besides, wise policy to cultivate a good repute with them, for they are great gossips, canvassing their chief's peculiarities and habits very keenly over their evening fires, and transferring their alliance and labour to other quarters very readily when they are ill-used. Himself and his men hutted, his provisions and his tools arrived, the Englishman commences the interesting part of his enterprize—an adventure in which we hardly know whether to say the pleasures or the pains are on the average, in the ascendant, but one certainly with no lack of picturesqueness about it.

Perhaps it will give a better idea of a coffee garden if we say that as a general rule it may be taken that there is no level ground in a district where the plants flourish; everywhere the ground undulates with more or less steepness. The typical plantation is one clothing a rugged hillside, where the rich soil lies in pockets between rocks, or the hollows between ridges, and the plants cover the rise and falls with their glossy leaves, between which show up stones and those scattered logs and stumps once forming the primeval forest. Of course, this "jungle" while it stands, is a considerable obstacle to any sort of cultivation, and has to be brought down in whole or in part. The great trees—the teaks, the sals, the cedars, or yellow-wooded "Jack"—are by nature sown close together, and consequently reach a great height before they branch, then making a canopy overhead often almost impenetrable even by an Indian sun. Then creepers form festoons from branch to branch, and curious orchids, with star-like white and yellow flowers blossom, after the rains, far out of reach overhead. In the nullahs or watercourses wild sago grows in waving beds, and a little higher up the banks white-rooted ginger and the tall sticks of broad-leafed, pleasant-barked cinnamon flourish. This is the kind of land to grow coffee and make our fortunes! A good, deep, peaty soil of chocolate colour, generally characterised by such vegetation as the above, and an aspect neither too much exposed to winds or the mid-day sun, are the great desiderata.

Perhaps the first thing to be done is to make a nursery plot for young plants, to be subsequently put out into the open. A nice piece of ground is chosen somewhere about the middle of the estate, and within a few yards of a perennial water supply. All underwood and litter is then put back from a space of about an acre or so, some of the trees taken down, and the ground very carefully dug up, before being divided into long narrow rows parallel with each other. In these we sow, when the annual wet weather is expected, the little coffee beans in the parchment or thin silver skin covering them. In a few weeks they are up and making little glossy leaves, but they are not properly ready to plant until their primaries or first branches have been formed. Constant watering in dry weather, careful weeding, and artificial protection from a meridian sun, are requisite here, repaying the active planter by a stock of strong, healthy young plants, which it will be a pleasure for him to plant out. While these are growing he has to get his clearings ready. With a compass, a surveyor's theodolite, and a long cord divided by coloured rags at

regular intervals, according to the distance apart his future bushes are to be, he laboriously, day after day, marks out in the still standing forest long parallel lines, punctuated at regular intervals with 18-inch bamboo pegs. In a single clearing, if we are going to have the coffee 5 feet by 4 feet apart, there may be room for 22,000 of these pegs. When this "pegging" is done comes the "pitting," *i.e.*, holes 18 inches square being made where every peg stands, and the good top soil of vegetable mould hidden away from the conflagration that follows.

Many a long day have we spent in the green arcades of the forest superintending these ant-like labours of our men, or armed with compass and theodolite, enjoyed the broaching of quiet valleys that no foot but the silent sambours had ever troddeu before, and the pioneering of shady hollows that had kept their repose unbroken since the beginning. Such a wealth of tree, fern, and pendant creeper swings overhead, and casts a shifting patchwork of light and shadow on the ground as the light breezes swing them. But, alas, our errand was generally one of destruction. We came not to admire and withdraw, but wage remorseless war with fire and steel. A belt having been drawn round the jungle, the work of clearing commences. The first trees cut are along the line of the lowest ground, and then another tier above them is deeply notched, but none of these are cut through completely. Half a clearing will be thus treated on a still and windless day. When all is ready the first axeman goes above the highest rank of forest giants, and, with a few vigorous blows, topples over a medium-sized sapling. In its fall it brings two others with it. These are matted together by rattans with others, which give way under the sudden strain, and so tier after tier rocks and swings as the stress spreads, the bamboo clumps splinter and crackle like a winter fire, the big trees toss their arms aloft, the great yellow rents fly up the bark of the "Jacks," and you can hear the innermost sinews of the cedars cracking like pistol shots —and then suddenly, with a mightly roar, the hillside is unlaced, and a thousand years of timber go to perdition with one huge, far-resounding crash that startles the ruminating sambour to his feet a mile down the glen, and sends the wild sheep flying over the grass ledges of those blue crags away in the distance that catch and echo the gigantic disaster!

For six long hot Indian weeks the prone timber lies baking, and then comes a period of animation. Choosing a warm morning, with a steady breeze blowing, the planter goes to a windward corner, and striking a match, drops it into a cluster of withered leaves. The first thin blue smoke curls up to the sky in a delicate blue spiral laced with flame, and then, as the wind bends it down, the twigs sparkle and the sparks fly, the flame seething out into the open, gathering strength as it goes, and, advancing in line of battle, storms and carries every log-encumbered hillock, and runs across giant stems that bridge the streams, until the whole "clearing" is a witches' caldron, and from the neighbouring heights looks like the fiery crater of Etna. But, fierce as the conflagration is by day, it is infinitely more startling and grand in the night time, when the standing jungle—ebony in the shadows and copper where the light catches cliff and trunk—surrounds such another rocking "pillar of smoke and fire" as that one which rested before the Israelites at "Elim in the desert."

Planting out the tender green coffee bushes after the burn, when we hunt for and draw those deposits of leaf mould we have made in the unfelled woodlands, is pleasant and grateful work, the long lines of greenness winding in our track across the hills, and the weather being at this "planting season" mild and showery. Staking the plants, making roads, opening new forests, building bungalows and "lines" for the natives, with elaborate and costly pulping houses, drying sheds, "godowns," and cattle houses, occupy the planter's time very fully, until he has been at work three long years, and his first maiden crop—the earliest reward he can look to for labour and money expended—is at hand.

He wakes up one morning during the third spring to a pleasant sight. From the steps of his verandah to the sal trees half a mile away, the rows of bushes on which he depends for fortune are loaded with white blossoms, jasmine-like and strongly scented, crowning the bushes with their stars, near by and extending in the distance like long lines of breakers upon a sandy shore. The planter breakfasts at his window, and prays for sunshine. It all goes well, in a month or two a rich crop of fruit, resembling cherries, has succeeded to the brief floral display, and he watches them change in the hot sunshine through green and yellow to crimson and purple.

By the time they have reached the latter stage, the increasing attacks of animals and birds suggest to their owner it would be as well to get them into safety. Big black monkeys come down from the hill tops in organised gangs, under leadership of an experienced white-bearded patriarch; delicate little squirrels, who still bear the four stripes on their backs which Vishnu's caressing fingers left, chirrup and scamper down the fallen logs with "cherries" in their mouths; jackals and sambour deer stroll along the rows under the moonlight, pillaging the ruddy crop while the planter is safely enveloped in his mosquito curtains. Even elephants like coffee thus *au naturel*: so for a busy month we put it beyond their reach, and all day long the encouraging shout of the maistries echoes over the clearings, the white-turbaned coolies sing as they send down an endless stream of crimson berries to the pulping mills, and at night there goes up with the smoke of their wood fires shouting and laughter, and the clash of wild music as they grow cheerful over their accumulating "extra pay." Two more operations, and that ever memorable and delightful first cheque for "crop received" comes to hand from our agents in the lowlands. The soft fruit we have brought in to our stores—it may be some fifteen or twenty tons for a maiden crop—is soaked in great vats, then "pulped"—*i.e.*, the flesh separated from the kernel by pressure between gigantic revolving nutmeg-graters —dried again, and finally peeled in a stone mill worked by steam or water, when the parchment, a thin brittle skin, is cracked off, and our merchandise—the unroasted coffee of our shops—is ready (after a final winnowing) for the bags and shipboard.

If our lonely friend gives a sigh of relief as the long file of white bullocks paces off down the Ghaut road to the plains, it is hardly to be wondered at. He has worked hard enough in all truth for that precious grey freight they carry. Up every morning at 6 a.m., he is off to "the good greenwood" while the shadows are still purple in the hollows, and the lower grounds are hidden in a silver sea of mist, through which rock pinnacle and bamboo stump pierce, like islands in some strange pearly ocean. The forest paths are cool enough while the day is young; jungle fowl crow and scratch in the undergrowth, little hog deer trip timidly home through the long grass, spiders of extraordinary colours shine amongst the dewdrops and cozen incautious flies, orchids bloom overhead, and ground thrushes in lavender and green, epauletted with sky-blue, chuckle on the stumps. But the sun of the hot weather "wipes out" this pleasant morning interlude. By mid-day the planter's world grasps, for breath, and breakfast at noon is an effort with "the sky as brass and the earth as iron." The "tub" preceding the meal is a pleasant item, it must be owned; so is the running postman, who generally appears jogging down the path as we sit with slippers and lightest coat in the verandah awaiting his arrival and breakfast.

With good health we may do all the hard work—the planning, the overseeing and the conceiving of an estate in its earlier years—without any great discomfort. It is when the malaria rises in May or June, and fever lays hold upon us, that we groan at the sultry length of the Indian days; and as we toss restlessly to and fro on our charpoys, consumed with a purgatorial thirst there is no quenching, are tempted to curse those giant creepers that swing so monotonously from the branches, and those villanous

insects of the sunshine that keep the grove all tremulous with their eternal hum—

. . . and the day has a sun
That shall make thee wish it done.

But evening brings relief to the fiercer stages of "junge fever" as to the ordinary work of a plantation. At sundown a stalwart coolie exercises his vigour in oscillating the clapper of a heavy bell that hangs between two posts at a central spot, and from all quarters converge the ready coolies, who have been squatting on their heels and waiting for this sound for some time. Men, women and children, they file in, collecting in a great circle round the rough backwoods desk, where the owner is ready with his day book, and everyone's work is entered against his name as he answers to it. If it be pay day, then a glittering heap of silver coin percolates from the log counter to the dusky hands of the labourers—two-pence a day for the men,* a penny for the women, and a "retaining salary" for the little children, who come up in turn, and duck their shaven heads in comical homage to the great white sahib as they hold out small brown hands for the price those same hands are supposed to have earned at a halfpenny a day. When he has seen his horse fed, has locked up his stores and sheds, counted back his tools, and doctored, perhaps, a dozen of coolies, who come up to his verandah steps to be cured of every sort of ailment of which Asiatic nature is capable, the planter has a spell of well-earned repose.

The hardest part of his life is this first part. As soon as his prosperity is assured his way lies amongst pleasant places. His permanent bungalow crowns some palm-fringed hilltop, and courts the winds of Heaven to play amongst the cuscus-grass mats that serve instead of doors: perhaps it is his good fortune to have a wife there with him, and half the sting of exile vanishes in the glamour of her presence. He will enjoy more time, too, for sport when the land is planted up—ridding the district of a rogue elephant, on whose vindictive tusks perhaps half a dozen men have been spitted, and following such a beast through the mazes of the forest on foot is as thrilling a sport as could be desired. Or a tiger may work havoc amongst our herds of tame cattle, and then we sit over a recent "kill" and watch while the stars describe a parabola overhead, for the soundless approach of the lordly beast, who dies forthwith upon the body of his victim. Deer are generally abundant in new regions. In India there is the sambour, a noble example of his kind, given to stealing at twilight into the coffee—moreover, generally coming down to drink at the same stream night after night. A successful shot at a "stag" often will stock the district for a week or more, utterly discomfiting the native butcher, and respiting his flock of tough, meagre, brown shearlings. The spotted deer lives a peaceful life amongst the bamboo thickets. While the "ibex" or hill-sheep of the planter, tempts him up to the breezy crags, where lemon grass waves in endless savannas, and the climate resembles that of an English April. This is about all the big game he sees though "bison"—the exile's nomenclature is very careless—of glossy black hide, brown hill-bears and wild pig share the jungles with larger species. For lighter amusement there are abundant jungle fowl—no bad imitation of pheasants, but hard to bag, owing to dense cover—pigeons of gorgeous hue, a dozen of which we have often tumbled out of one fig tree which without quitting our verandah, and plenty of lesser birds for the amusement of him who is blessed with a solacing love of natural history.

His chances of social relaxation depend much on where he may be located. But he must have got very deep indeed into the wilderness if he does not manage to bestride his hill pony every other Sunday, and, with his rifle across his knees, to trot down to some country-man's shanty, where the news of the day is to be heard, and an hour or two whiled away in friendly gossip and discussion of crops and prospects. To "the hills," where English society congregates in the scorching summer, he looks throughout eleven months of the year with longing and affection. It is there those tender children of his go to school and cultivate a little colour on their pale cheeks in an air approaching that to which they were born. It is there his club is—that elysium of good fellowship—and the church where he can slip a gold mohur into the alms bag to condone fifty enforced absences. Saxon girls, it may be added, never seem so fair as after a long dwelling amongst those whose complexion is "the swarthy livery of the burnished sun," and his countrywomen, whether in ball room, tennis court, or galloping after jackal across the rolling hill pastures, are not the least pleasant of the memories which the bachelor squatter takes back to his lonely hut from Ooty, Simla, or wherever he may have spent a delightful month in touch with civilisation.

In this brief chapter we may not enter into the technical details of the curious art of coffee planting—a tortuous but (if carefully followed) promising road to fortune. Those who would know more should consult some modern handbook on the subject, such as the well-known firm of Whittingham, in Gracechurch Street, can supply, and study at their leisure all the details of the craft. In these few lines we have only attempted to show that there is more romance and "adventure by field and flood" represented in such a fragrant cup of coffee as that we sip at breakfast or after dinner than is perhaps generally known. How hard our "younger sons" (and some older ones too) work for it, is often little suspected; and to touch in, though hastily, the lights and shadows of their rough life, and to show how they cut a way, against overwhelming difficulties, to an honourable ambition, has been the purpose of this little sketch.—*Colonies and India*.

* A long obsolete rate of wages.—Ed.

Sugar and Fruit in Fiji.—Amid the surrounding depression, the sugar output continues most satisfactory. The mill managers, shareholders, and proprietors speak with hopeful confidence of the future, and they have evidently derived a very considerable accession of this confidence from the perusal of the article on "The Position of the Sugar Industry," which appeared in the *Australasian* of September 26th. On the Rewa, even the crushing power of the Colonial Sugar Refinery Company's machinery, which collectively constitutes the largest mill in the world, is found to be insufficient for requirements, and the erection of what will virtually be the fourth mill under the one roof, is to be proceeded with almost immediately. The works at Koronivia and at Ba are progressing slowly, but in both cases there is a very large area planted up, which will be fit for the rollers when the new mills are ready. On the Dreketi River, Vanua Levu, the collapse of the little old worn-out Pioneer mill did not long suspend operations. Another mill has already been erected in its place, and it is reported that it commenced crushing last week with admirable results. Unlike the sugar growers and manufacturers the fruit cultivators and shippers are still experiencing the cold shadow of adversity. The banana disease is spreading. It smites the tree as with a curse. The leaves put forth half developed, with a wrinkled and unmatured appearance; The calyx bursts prematurely. The flower comes out blighted. The fruit forms black and blasted, and never approaches maturity. The trunk swells half-way down, and from it bursts an untimely growth of puny leaves in tuft, which never attainto one-twentieth of normal dimensions. The tree is in every part of it as brittle as a dry twig, and its whole aspect is that of an unprofitable deformity. The Suva Chamber of Commerce has taken the matter in hand, and it has forwarded diseased and healthy trees, with respective soils, for examination and report by competent authorities. The immediate cross for the fruit-shipper is the quarantine of the Sydney boat at this end, which has spoiled every case and bunch of fruit brought in for her. By the law of compensation there should be a very bright future in store for Fiji, for it would certainly seem as if for the past few years even the stars in their courses have been fighting against her.—*Australasian*.

CEYLON AND ITS PLANTING INDUSTRIES.

(TO THE EDITOR, "THE ECONOMIST.")

SIR,—The Ceylon commercial season closes on the 30th September each year, and the Colombo Chamber of Commerce tables are made up as soon after as possible.

The actual results arrived at for our staple export trade cannot fail to be of much interest to those who have watched the gradual development of other planting industries since appearance of the leaf fungus, which so wofully affected our coffee. Having drawn the attention of West Indian planters, through the columns of the London *Times*, in August, 1884, to the way in which Ceylon planters had developed "new products," to make up for the failure in coffee, I would again venture to trouble the home Press with a few figures, in support and illustration of the position I then took up.

Tea is rapidly becoming the main staple of the planters of Ceylon, and everything points to our export of this important new product rivalling that of India in about ten years time. So far, it is comparatively the day of small things, but the following figures show the beginning of an important enterprise. It will be observed that the export progresses more nearly in a geometrical than an arithmetical ratio. The Ceylon exports of tea have developed as follows:—

TEA.

						lb.
Total exports from	1st Oct.	1885	to	30th Sept.	1886...	7,170,329
do	do	1884	do		1885...	3,796,684
do	do	1883	do		1884...	2,262,539
do	do	1882	do		1883...	1,522,882
do	do	1881	do		1882...	623,292
do	do	1880	do		1881...	277,590
do	do	1879	do		1880...	103,624

do	do	1877	do		1878...	3,515
do	do	1876	do		1877...	1,775

Cinchona bark shows the next chief development among new products, as the following figures will show :—

CINCHONA.

						Branch and Trunk lb.
Total exports from	1st Oct.	1885	to	30th Sept.	1886...	15,364,912
do	do	1884	do		1885...	11,678,360
do	do	1883	do		1884...	11,492,947
do	do	1882	do		1883 ..	6,925,595

do	do	1878	do		1879...	373,511
do	do	1877	do		1878...	173,497
do	do	1876	do		1877...	56,589

For a medicinal bark, and the preparations therefrom, there is no such scope for demand and consumption as in the case of tea. But to a fairly remunerative market it is believed that Ceylon can supply 7 to 10 million lb. of cinchona bark annually without any difficulty; while if there were only the market, the export of the past season could probably be maintained for some years to come.

Cacao, or the cocoa or chocolate-yielding plant, has not succeeded quite so widely as was expected in Ceylon, but there are certain districts in which the cultivation has proved very successful. Some mistakes were made at first in the mode of planting but these are now generally rectified and there is the fair promise of increasing returns. This is especially the case during the present year, the weather having been very favourable to cacao. The annual exports have been as follows:—

CACAO.

						Cwts.
Total exports from	1st Oct.	1885	to	30th Sept.	1886 ...	13,347
do	do	1884	do		1885 ...	6,758
do	do	1883	do		1884 ...	9,563
do	do	1882	do		1883 ...	3,588
do	do	1881	do		1882 ...	1,018
do	do	1880	do		1881 ...	479
do	do	1879	do		1880 ...	122

Cardamoms had been for many years quite a minor article among our products, but since the European planter has given his attention to this spice, the colony has taken the foremost rank for its export—Ceylon, in fact, now ruling the European market for cardamoms as well as for cinchona bark. The exports of this spice have risen as follows:—

CARDAMOMS.

						lb.
Total exports from	1st Oct.	1885	to	30th Sept	1886 ...	236,056
do	do	1884	do		1885 ...	152,405
do	do	1883	do		1884 ...	66,319
do	do	1882	do		1883 ...	21,655
do	do	1881	do		1882 ...	23,127
do	do	1880	do		1881 ...	16,069

In contrast with these evidences of steady, continuous progress, with what may be called "new products," I have to place the return for our old staple, coffee, showing an equally steady decline, consequent on the weakening effects of the fatal leaf fungus. The export figures are as follows:—

COFFEE.

						Plantation Cwt.	Natives Cwt.	Total Cwt
Total exports from —								
1st Oct.	1885	to	30th Sept.	1886	...	215,576	8,117	223,693

do	1876	do		1877	...	851,201	91,846	943,047

It is satisfactory to know that tea is so fully taking the place of coffee, over, 130,000 acres being now planted with this product, which grows well, not only within the limits of climate suited to coffee, namely, from 1,500 to 5,000 feet above sea-level, but from a few score of feet above, or almost at sea-level, to our plateau, at nearly 7,000 feet altitude. The tea plant is, in fact, one of the hardiest on the long list of the sub-tropical planter, and nowhere has it found a more congenial home than in moist hot Ceylon. The cry of overproduction has, indeed, of late been raised in reference to tea, but if English-speaking folk in America take to drinking tea in place of their favourite coffee (now likely year by year to decrease in supply) there will be a wide demand added to the present one. Moreover, so far as Ceylon is concerned, it has been shown that through the great advantages possessed by the colony, tea of a superior quality can be produced more cheaply here than in its great rival India, so that the remote districts in the latter country must first suffer.

The exports in which the Ceylonese people are chiefly interested—*i.e.*, cinnamon, plumbago (our only commercial mineral), essential grass oils, and the products of the coconut palm, *i.e.*, oil, copra, and coir fibres, keep well up, although the crop of coconuts is liable to alternate, according to the season. In a favourable season, the number of nuts gathered in Ceylon is now estimated at a thousand millions, the greater portion, however, being utilised locally for the food of the people.

Briefly, the total value of our staple exports for the past season may be put at 2,400,000 lb. sterling, while for the current commercial year—October, 1886, to September 1887—the following estimate, framed for the *Ceylon Observer*, from district returns, indicates a very considerable advance:—

Season 1886-7.—Probable Shipment of Staple Exports:—

		Quantity	Value £
Coffee	...	185,000 *cwt. at 75s	693,750
Tea	...	14,000,000 lb. at 1s ½d	787,500
Cinchona Bark	...	12,000,000 lb. at 8d	400,000
Cocoa	...	22,000 cwt at 80s	88,000
Cardamoms	...	300,000 lb. at 2s	30,000
Coconut Oil	...	280,000 cwt at 27s 6d	385,000
Copra	...	150,000 cwt. at 14s	105,000
Coconut poonac	...	50,000 cwt. at 7s	17,500
Cinnamon	...	1,500,000 lb. at 1s 3d	93,750
Do Chips	...	500,000 lb. at 5d	10,416
Plumbago	...	200,000 cwt at 8s	80,000
Coir of all kinds	...	110,000 cwt. at 15s	84,000

* Rather too high we fear now, seeing that up to 20th January we have only sent away 32,294 cwt. against 78,545 cwt. at the same date last season.—ED.

	Quantity	Value £
Ebony	7,500 tons at 100s	37,500
Deer Horns	2,000 cwt. at 50s	5,000
Sapan wood	2,500 cwt. at 40s	5,000
Kitul fibre	1,800 cwt. at 50s	4,500
Essential Oils	6,500,000 oz. at 1d	27,000
Total		2,853,716

—I am, sir, yours faithfully,

J. FERGUSON

Of the *Ceylon Observer and Tropical Agriculturist.*
Colombo, 26th November, 1886.

EAST AFRICAN DRUGS.

Of curative drugs, the East African manifests but little knowledge. Near Lake Ugombo, a small wild aloe, when the green skin has been peeled off, forms an ice-cold and healing application to burns; and in the neighbourhood of Dar-es-Salaam, a highly aromatic plant, with hairy purple stalks, called *arcazamudi*, is reputed a good native cure for pains in the stomach. The Somalis occasionally eat the local variety of dragon's blood, a resin of acidulous flavour obtained from the *moli* tree (*Dracæna schizuntha*). Between Zanzibar and Dar-es-Salaam occurs a creeper with bean-like, hairy, S-shaped pods having severe stinging powers; it is about four inches long, of yellowish brown colour, and is called *upupu*. The pain yields to cowdung and wood ashes. In the same region, a broad-bladed grass, called *mwanga mwitu*, enjoys some fame as a styptic.

Arrow-poisons come much more prominently within the range of native study, and most tribes use some description of vegetable poison for anointing their spears and arrows. The most important is a species of *Strophanthus*, either *S. hispidus S. Kombé*, which will probably prove to be the sole source of this class of poison used on the eastern coast, from Zanzibar to Somali-land, and even far into the interior. The plant is a runner, bearing large, rough-ribbed leaves, arranged in clusters of three or four together Each shoot consists of three branches, of which one bears the seed and the other two the leaves. The flower is yellow, with curiously tailed petals. The seed has the form of a huge military frog-button, with lobes nine inches long, and is the direct source of the poison. This, according to St. Vincent Erskine, is called *umtsuli* in Gaza or Southern Mozambique, and is so energetic that men wounded by arrows in the fleshy part of the leg have been known to die within three hours, and with small bucks the poison takes effect before they can run out of sight. He likens the active principle to strychnine. These facts quite accord with the description given by R. W. Felkin and A. W. Gerrard (*Pharmaceutical Journal*, April 9, 1881, p. 833) of the poison used by the Wanika and Wakamba tribes, west of Mombasa, except that several roots are supposed to contribute to the deadly effect. These authors mention an antidote composed of sundry roots reduced to charcoal, which, however, proved a failure on trial. Careful investigation of the *umtsuli* reveals the fact that it is a powerful cardiac poison, as powerful as digitalin, and more powerful than veratria, when injected under the skin. But it causes only nausea, vomiting, and some weakness when taken by the mouth. The flesh of animals killed by this poison is eaten by the blacks without ill effects. Probably identical with this is the "poison tree," from the roots of which the natives of Somaliland extract a black and pithy substance for poisoning their arrows. Perhaps, also, the pitch-like poison obtained from the boiled-down bark of a tree used on the Rufiji river for application to arrows, lances, and even bullets; and the *muavi*, or poisonous decoction of the bark of a tree, employed in the trial by ordeal of the natives of the Nyassa and Zambesi valley, is the same article under another guise.

Indulgence in narcotics appears to be confined to tobacco, which is very commonly grown under cultivation. It is a special product of the Hendei district, whence considerable quantities of the sun-dried leaf beaten into little round flat cakes about two inches in diameter, are sent down to Pangani for export. The tobacco is coarse and strong, but of fairly good flavour. The Kiswahili use water-pipes (*kiko*), made of gourds of various shapes. They swallow the fumes in smoking, and seem to enjoy the paroxysm of coughing which results.—*Journal of the Society of Arts.*

THE LONGEVITY OF MATTER.

In your September number is a very interesting paper on the above caption—the leading idea being that the germs of plants are infinitesimally *small* and comparatively indestructible. I have given this subject more thought and experiment than any other in agriculture.

1st. My attention was first called to it by the fact that lands once in forest and cultivated, when fenced up and left fallow, produced the original growth of trees.

2d. When I was a boy, tobacco was cultivated by my father; this was put into a tall building to cure, and the basement was used to feed the work-horses, being far off from the home-stables. Probably twenty years afterwards, I pulled down the house, having no use for it so far off, and spread the manure, which was several feet deep, over the adjoining grass fields. The result was a luxurious growth of red clover on all the manured spots. This set me to speculate upon the vitality of seeds. I do not believe that the forest growth was an original growth and renewal of the old trees; still less could we believe that in a few days red clover was made anew by natural laws. Nor shall I discuss here the question whether God or long centuries of Nature's forces made all the Fauna and Flora.

3d. The vitality of seeds is proven beyond cavil. Now if the clover germ lasted, say twenty years, till favorable surroundings, sunlight, moisture and plant food burst it into the living plant, why not so lie dormant for centuries?

4th. The Irish potato, up to my times, was believed to be and called by scientists a *tuber*, like turnips or beets. But I proved by the microscope and logic, that it is in fact a bulb; that is like the onion or tulip, having *many* "germs" or "ova," instead of *one*. From Northern seedsmen, rare potatoes were cut very closely, the eyes of the seed end being so near each other that they had to be set into slips of carrots; but they, when planted, produced as large potatoes as any.

5th. I found out also that the old theory of the surroundings of seeds *nourishing* the *plants* is a fallacy. Like the germs of other plants, the "*eyes*" of the potato are a perfect "ovum" by which nature, forcing itself into the soil, and failing to reach it, dies, notwithstanding the starch, water, &c., which compose the edible part of the potato, are in reserve. This is proved by the experiment, when potatoes were laid upon the soil, they at once took root in the sod, the potato remaining comparatively whole and unchanged. When the potato was put in the same cold frame not touching the ground, the plant shoots put out feebly and then *perished*, the potato being a little *shrivelled* only. Now if the potato meat nourished the "ovum" shoots, it should have been used up before the plant perished. What, then, were the agents of the temporary plant growth? They were the water in the potato and the elements of the air—no more—which, being supplied elsewhere, do not need the food of the potato meat at all.

6th. Now, then, we are prepared to answer whence came the "germs" or "ova" of the second growth pines or oaks, or other trees? They came from their *invisible* germs, which, having the ordinary covering, decayed, yet remained vital in the soil, to spring anew into plants when the needed forces ensued. All of this is to my mind as logical as any demonstration in Euclid. I used the term "ova" as the most intelligible term for the Fauna and Flora.

7th. One more experimental proof: When the McAdam road was made from Richmond to Lexington,

at the "Walnut Hill" the grade was cut about twelve feet deep through a red clay. In the succeeding spring, mullein, poke and dock plants and others grew in great size and thickness. Now, whence came they but from ancient germs? The rag-weed only comes on my farm in very wet summers; now but *very sparsely*. On the neighboring farm an *immense crop*, because I cut them before the seed ripened, and they are nearly extinct near the surface. Hence comes the foolish idea that wheat grows from the seed, but "chess" from abortive wheat. The truth is, the season unfavorable to wheat just suits "chess," and nature is ready for all contingencies. So you see much nonsense is based on so-called "evolution." I have read all the modern scientists, and I see no reason to discard the Mosaic theory. For even, if the Fauna and Flora arose successively in different climes and long eras, the language of the Bible is generic enough to cover the facts.—C. M. CLAY.—*Southern Planter.*

COFFEE.

A breakfast should always consist of a good cup of coffee. The simple thing of making coffee has to be done three hundred and sixty-five times yearly in almost every family, yet how few know how to do it, and fewer still know how to order it done. Breakfast is a meal which should be lightly partaken of, its very name implying the breaking of the fast, so all such little things as coffee must be made nice and appetizing, so as to tempt the dainty appetite of the morning. Speaking of coffee reminds me of a story of a young married couple. During six weeks of matrimony did the young husband at breakfast table make up hard faces over his coffee. At last his patience gave out, and one morning after tasting what he denominated duck puddle coffee he relieved his overcharged mind by saying: "Well, Minnie, I don't know how it is that our coffee is always so bad? You know mother's never was so. There is not a bit of taste to this!" "Well, my dear, I don't know I am sure. I buy the best Government Java; at least it ought to be the best, for I pay the highest price for it." "That may be so, Minnie, and yet it tastes like anything else than that mother used to give us." "Well, Walter," replies the young wife who by the by was a graduate from some seminary, "I made that coffee myself, exactly as Mrs. Thomson told me, and you know she thinks nobody can equal her in cooking anything. I took two spoonsful of Java and poured a quart of hot water on it, and then let it boil for fifteen minutes as hard as it could. Mrs. Thompson says it is the simplest way. "O, yes," said Walter, "the way is simple enough. I dare say, but not half so simple as my dear little wife is to try it." So Walter told his wife he would not be home to tea, but would meet her at his mother's, and asked her to go over and spend the day, and learn from his mother the secret of making coffee. Minnie was well up in mathematics, but a beverage she had breakfasted on for twenty years she knew not how to brew. The fact is, like many of our young housekeepers, she needed a few lessons in a cooking school. Two human beings, chained by love and strong ties of matrimony, were both sickening for a comfortable meal, and so after Walter had gone Minnie got her work done, and went over to Mrs. Powers, and told her the whole story. Mrs. Powers laughed at the girl and and said: "Never mind, dear, it is never too late to learn," and so she told her her way of making coffee, and gave her the family cook book; and now Minne is a splendid cook, and they are a very happy couple. Minnie will give you her way of making coffee for breakfast, which I think is a good one: Take one-half cup Government Java, pour over enough cold water to cover it; let it stand over night covered with a damp cloth, stir in in the morning one egg and shell; put this in your coffee pot, in three pints of hot water; let it simmer a minute on the stove, but not come to a boil; then set on the back of the stove, and it is ready for use. The beautiful aroma which arises from boiling coffee is what you must save. When you hear your husband say in the morning, "How good the coffee smells!" you may know that the aroma which makes it delicious has gone out through the kitchen window.—*The Household.*

[As a matter of fact we believe excellent coffee can be made by pouring boiling water on well roasted and recently ground beans, the hot water being allowed to percolate through the coffee.—ED.]

PORTABLE FOREST TRAMWAYS.

By D. BRANDIS, *late Inspector-General of Forests and* MAJOR F. BAILEY, R.E., *Conservator of the School Forests.*

The Decauville portable tramway was invented in 1876 by a French gentleman of that name, for use in his business; but he very soon began to manufacture the rails and trucks for sale. He Exhibited his invention at various agricultural and other shows in France and also in Belgium and Norway, obtaining gold medals and other prizes. In 1877 the tramway was shown in England and Ireland and as orders began to come in rapidly he was obliged in January 1878 to increase the number of men employed upon its manufacture from 35 to 100. Since then the development of the use of the tramway has been extraordinarily rapid, and the number of workmen employed by M. Decauville had, by the middle of 1884 risen to the large number of 900, a railway station on the Paris-Lyons railway having been built near the works. Between 1878 and 1884 the invention was exhibited in Austria, Italy, Buenos Ayres, Calcutta and Japan, orders having been received from the Russian Government who required the tramway for use in Turkestan, from the French Government for use in Tunis, from England and Australia and many other countries. It is at the present time, almost without doubt, the largest establishment of the kind in the world. * * *

Two portable forest tramways have already, we understand, been laid down in the Nellore district of the Madras Presidency, and others have probably ere this been established at other places. We assume that the construction of such tramways is generally well understood in India, and that it will suffice to mention a few points relating to the one we have mentioned. The gauge is 0·60 metre, or about 2 feet. The ground is almost level, here and there with very slight undulations. The main line may for the present be regarded as permanent, the position of the branches being changed from time to time to follow the progress of the cuttings. The main line is laid in lengths or sections of 7 metres, on sleepers of wood or iron. The rails, both of the main line and the branches, are of steel, their weight is between 6 and 8 kilogrammes per running metre. The sleepers are at one metre apart, and the rails are rivetted into the iron or spiked down into the wood. The seventh sleeper supports the joint. The sleepers are laid in ballast at the side of the central metalled portion of the road. The joints are made with fish-plates.

The branch lines are laid upon the natural surface of the ground, which is not levelled in any way. They consist of sections, 2 meters long, supported at each end by a wooden sleeper. These sections weigh 38 kilogrammes (84 lb.), and are, therefore, easily carried by one man. In the system here used the sleepers of the branch lines are always made of wood, which from its greater rigidity is found to be more suitable than iron for laying upon an uneven surface. The sleepers being nearly 2 meters apart, the rails used are stouter, and they weigh about 8 kilogrammes per running metre. There is sufficient play in the joint to admit the line being curved to some extent, in order to avoid stumps of trees and other obstacles. For greater curves spinal sections with curved rails are used. The essence of this arrangement is, that the branch line is brought alongside of the logs as they lie, and that the logs are loaded upon the trucks without having to be previously moved from the place where they fell. This of course leads to the line being carried over broken ground, small ditches and pools of water In such cases the sleepers are supported by rough pieces of wood or turf, hastily laid. In this manner

2 kilometres of branch line were laid in two days by two men, and trains of heavily laden trucks pass over it without accident. One kind of truck serves for the carriage of material of all kinds.

When used for the carriage of logs a horizontal revolving plate is fixed on the top, furnished either with an iron crescent-shaped support or a horizontal bed on which the ends of the log rest between movable vertical arms. The revolving plates admit of a pair of trucks with the log loaded upon them being taken round curves.

For lifting the logs on to the trucks, numerous devices have been invented. The two in use in the Kottenforst, consist of a double crane, which raises up the log vertically, and an inclined plane, up which it is rolled.

The crane, which is capable of lifting 9,900 lb. is placed astride the log. It consists of two uprights joined at the top by a movable pin. The uprights are made of wood, strengthened with iron, and they are hinged into horizontal pieces, which rest upon the ground. The log which has been previously rolled on the rails, is gripped by a powerful iron pincers, and is then raised by chains and pulley worked by two hand levers. By this apparatus logs of considerable size are easily raised to the required height by two men, working at the two levers. The log having been raised high enough to clear the top of the truck (2½-3 feet) the two trucks are passed underneath, and the log is gently lowered upon them. It is then secured by chains terminating in conveniently shaped wedges which are driven into the log to make all fast. An oak log measuring about 36 cubic feet was raised upon the trucks and secured in four minutes. Each half of the apparatus is easily carried by one man.

The inclined plane is formed by two bars or beams built of iron and wood, resting partly on the ground and partly on the truck. To each beam is attached a chain which is passed round the log and over a wheel, and the chains are then hauled in by means f hand levers similar to those used with the crane previously described. The log is thus rolled up over the trucks, when the beams are removed and the log is allowed to lie between the rests on the revolving plates. This arrangement is regarded as safer for the workmen than the crane.

A third arrangement, which from its easy construction may perhaps be more suitable for work in India, but which is not in use in the Kottenforst, consists of a tripod. From the apex a set of pulleys is suspended, by means of which the log is raised.

When a sufficient number of logs have been loaded up, the trucks are coupled together, a coupling pole being put in when the logs project, so that the ordinary chains and hooks are too short. The horse is attached by a chain to the last truck, so that the driver is able to see the whole train before him. It is said that on level ground one horse will draw a train loaded with about five tons of timber. The short train on which we travelled, was formed of three pairs of trucks with logs aggregating about 110 cubic feet of oak timber, and it was dragged along on the main line at a sharp trot without slacking speed at the curves, not the slightest difficulty being experienced. The trucks are provided with brakes to be used in case of necessity.

In order to carry fuel, a platform about 12 feet long and 4 feet wide, is laid on a pair of trucks. When earth or gravel has to be carried, an ingeniously arranged tip cart is substituted for the platform.

The cost of the whole line laid down, including rolling stock and all apparatus, was 25,000 Marks paid to the manufacturer, plus 800 Marks expended on the earthwork for the main line. This corresponds to an average cost of £252 per running mile, and it is estimated that the plant will last 15 years.—*Indian Forester.*

[It is possible that a similar tramway might be profitably used in some of the forests in the North-east portions of Ceylon.—ED.]

DISPERSION OF PLANTS BY BIRDS.—In an interesting article in *Nature* (Dec. 16, p. 151) on the dispersion of plants by birds, Mr. D. Morris points out that the pimento industry in Jamaica depends entirely for its existence on the offices of frugivorus birds. It is thought by the planters in the island that the seeds in passing through the birds undergo some fermentation which fits them better for vegetation than those gathered immediately from the tree, and that no other plan is likely to produce good pimento walks, although it has been shown in the Botanical Garden there that young plants can be raised otherwise if carefully treated. —*Pharmaceutical Journal.*

FIRMING THE SOIL.—Considering that the best farmers so long knew the advantage of rolling their fields after seed sowing, it was always a matter of surprise that the practice had never become part of good gardening, and still more of a surprise when Mr. Henderson's paper on firming the soil appeared in our columns, at the objections some made against it. Yet the evidences of the value of such a practice could be stumbled against almost any day. The *American Agriculturist* recently gives an illustration of this, which is worth repeating here. "Peter Henderson, the author of 'Gardening for Profit,' in insisting upon the great importance of firming the soil over seeds and plants, writes us: 'It was rather an amusing incident that first brought to the attention of a truck farmer, of Charleston, S. C., the importance of firming the soil. It seems that a gentleman of color, having the constitutional weakness for chickens peculiar to some of his race, got into a hen-roost and helped himself bountifully. In evading a high-road, he struck a bee-line through a newly sown turnip field, where he left tracks that led to his detection. But these tracks did more. They showed to Squire Buncombe, whose chickens had suffered, that wherever the foot of the colored citizen had fallen, there he had a "stand" of turnips and nowhere else (for they had been loosely sown and the weather was dry). The lesson was heeded, and has been worth tens of thousands of dollars to the farmers of South Carolina, who, it seems, were never before sufficiently alive to the importance of firming the soil until the unfortunate negro showed them the way.'"—*Gardeners' Monthly.*

FIJI AND ITS INDUSTRIES: OPIUM, BANG, AND GUNJAH.—The Governor of Fiji gave his official consent on July 28 to two Ordiances affecting these drugs. Ordiance XI. 1886 is "To prohibit the growth and use of bang or gunjah. Bang consists of the dried leaf of the Indian hemp, and gunjah or gunja of the flowering tops of the female plant. They are favourite narcotics of the coolies from Hindustan. Indian hemp, *Cannabis Sativa* is the same species as that grown in Europe for fibre, but it does not excrete its narcotic resin in cold climates. A penalty is now imposed in Fiji on everyone proved to be growing bang or gunja for private use or otherwise, or found in possession of or selling or giving to any person either of these articles, £25 or imprisonment for three months for the first offence, and £60 or six months imprisonment for the second. Registered medical practitioners and registered licensed chemists and druggists may sell bang or gunjah for purely medical purposes, but the burden of proof rests on the vendor. Police officers may visit suspected places and seize all the prohibited articles found; owners or managers may destroy any found growing on their plantations; and part of the fine paid into court may be awarded to informers. Ordinance XIV. 1886, "to amend Ordinance VI. of 1878 with regard to Indian Immigrants," by section 6 imposes a penalty of £20 or three months imprisonment on any Indian immigrant found in possession of opium or any preparation containing opium or any of its ingredients, and the same punishment on any person selling or giving the same to an immigrant. Any opium or its preparations found in possession of an immigrant may be seized by plantation managers or the police. The manufacture of copra has been utterly abandoned in some quarters, by Europeans and natives alike, for more remunerative enterprises. —*Chemist and Druggist.*

VEGETABLE PRODUCTS IN CRETE.

In a report on the trade of Crete for the year 1885, dated Crete, October, 1886, referring to the Olive crop, it is stated as a rule, that a year of abundant Olives—which is the staple product of the island—alternates with one, very seldom with two, of failure. The value of the Olive oil manufactured therefrom varies in the former case from £600,000 to £800,000; in the second, from £60,000 to £80,000; but there are years when it does not reach to £40,000, and exceptionally bad seasons when it hardly attains half that sum. Allowing for all irregularities, the yearly average may be set down at £450,000. It being reckoned that the 86,000 families forming the population of the island consume yearly about 100,000 cwt., which represent £150,000, there remains a balance of £300,000 for exportation in kind or in manufactured soap. The vegetable products of Crete which find their way to the United Kingdom are Olive oil, Locust Beans or Carobs (Ceratonia siliqua), Valonia, and a few raisins. The quantity of Olive oil forwarded to Great Britain in 1886 was 800 tons, representing, at £31 10*s*, per ton, £25,200, against 1,159 tons, at £30 per ton--£34,770--in 1884. The exportation to other countries was 5,192 tons, of a value of £150,817. Only 1,000 tons of Carobs, of the value of £3,120, were forwarded to this country; the only other countries to which Locust Beans were shipped for much higher values were Italy and Russia, amounting together to £17,000. Valonia is only shipped at Rethymo, which is the central district where it is produced. Raisins have begun to be forwarded to Great Britain within the last two or three years, and represent as yet an insignificant value, but it is probable that as they become better known in the British markets the trade may attain a considerable importance. They are grown and prepared on an increased scale from year to year and represented, in 1885, 133,000 cwt., of the value of £22,365.—J. R. J.—*Gardeners' Chronicle.*

WHAT IS GINGER?

As usually seen ginger is in the form of a grayish-yellow powder, but if you go to a drug-store and ask for "race" ginger, you will be served with the article unground, and you will see that it is the dried root-stock (often called root) of some plant. Race—as applied to whole ginger in commerce—is from the Spanish *rais*, "a root." The botanical name of the ginger plant, Zingiber, is from a very similar old Sanskrit name. It was formerly placed in the same family with the banana, but botanists at present give it a family by itself. The fleshy root-stock throws up reed-like stems three or four feet high; these bear long and narrow leaves. The flowers are borne upon a separate, leafless stem. This bears a cone-like spike, between the scales of which the flowers appear. The flowers are yellowish-white in colour, with purple markings. Ginger is supposed to be a native of Asia, in the warmer parts of which it is generally cultivated, but it is not known in the wild state. It has been introduced and is now cultivated in nearly every warm country, especially in the West Indies, from which ginger was exported to Europe as early as 1547.

In cities there is sold, in autumn, at drug and grocery stores, fresh or green ginger root. This is the root-stock, just as it comes from the ground, and is used for flavouring preserves. The pieces have one or more green buds attached to them, and if planted in a pot and kept in a sufficiently warm place, will grow. But a very small share of the crop is sold in this state; the ginger, after it is dug, is washed and then exposed to the sun until perfectly dry. This is the ordinary "race ginger" of commerce, and is the kind ground for use. What is called Jamaica ginger is prepared by scraping the rhizome when fresh to remove the outer portion; these are then bleached by placing them in a solution of chloride of lime. Considerable lime adheres to the surface, and the pieces look as if they had been whitewashed. On account of its nicer appearance Jamaica ginger is preferred for medicinal uses, and is used by some families. There is still another form in which ginger is imported—preserved ginger—which comes from China in porcelain jars. The young and tender "roots" are preserved in sugar.—*American Agriculturist.*

VARIATION IN PLANTS.

In spite of the assertion, by De Candolle and other authors, that "a cultivated species varies chiefly in those parts for which it is cultivated," we find great degrees of variation affecting different organs, and often extending to other parts of the plant structure. This statement applies both to plants in a wild state and to those under the care of man, when in the latter case the conditions may be considered more or less artificial. The reasons for this similarity of variation, both in a wild and cultivated state, will be obvious when we consider that a plant must originally vary spontaneously, before man can in any way affect it, at least by selection. This is especially the case where we have obtained by selection in the course of many generations a number of distinct races, descendants of one species, as in the Apple, Pear, Chrysanthemum, and others. It simply comes to this, that man cannot so far alter the conditions, as to cause plants to abandon their natural tendencies, nor to vary except in accordance with natural laws. Therefore in spite of the fact that man desires to select seedlings presenting the requisite variation in one organ or set of organs only, it very frequently happens that there is a correlation between the homologous parts of plants causing them all to vary more or less evidently in a similar manner. Cases of albinism will serve to illustrate this point.

Plants producing red, pink, purple, yellow, or even blue flowers normally, often both in a wild or cultivated state, give birth to seedlings with pure white flowers. Some authors would describe this as a case of reversion. The converse more rarely happens, but Lychnis vespertina, sometimes producing red flowers, and Primulas belonging to different species, are cases in point, both in a state of Nature and under cultivation. In connection with albinos amongst plants, not only are the flowers white, but the foliage and the whole aspect of the plant bears an unmistakably pallid hue, and such plants can often be recognised in the absence of flowers. This paleness in the colour of the foliage does not owe its existence to man's selections, but is more often an undesirable feature than otherwise. This correlation of homologous parts is exemplified in white-flowered varieties of Lychnis chalcedonica, L. diurna, Silene armeria, Linaria cymbalaria, Campanula rotundifolia, Thymus Serpyllum and Dianthus deltoides. The same may be said of Impatiens flaccida, which has dark foliage and stems more or less striped with purple, but in the white-flowered variety has pale foliage and pale green unstriped stems. White-flowered varieties of Primula sinensis have pale foliage and dark-flowered forms are characterised by foliage of a similar tint, more especially evident in the petioles, the midrib, principal nerves, and the underside of the leaf generally. There is also a correlation between the colours of the underside of the leaf and that of the flowers in Senecio cruentus and other species.

The tuberous roots of the Dahlia afford another striking instance of the variability of plants even in the parts that are not specially selected either for the benefit or pleasure of man. Some have large, or even short, thick and very succulent tubers, while in other cases the individual tubers are elongated and spindle-shaped, or long, slender, gradually tapering to a point, and radiating or projecting in all directions. Nor is this variation confined to form, but in a collection of any extent, considerable variety of colouring is found to prevail, such as yellow, white and purple, or violet. This is frequently unnoticed because of no interest to the general cultivator, nor presenting anything valuable either for economical or ornamental purposes. There is also a more or less evident correlation between these colours and that of the flowers. Uncared or and generally unimportant though frequent and considerable variation extends to the foliage stems nd flowers of different individuals,

What applies to the Dahlia applies still more forcibly to the Potato, notwithstanding the fact that the tubers form the only part specially selected. This is the more remarkable, considering the number of varieties in cultivation at an early period of their history even in this country. In the northern parts of Britain, before the ravages of the Potato murrain became so severe, numerous favourite and valuable sorts enjoyed an extensive cultivation, ranging over wide districts. Now these sorts were so distinct both in the subterranean and aërial parts, that anyone possessed to an ordinary degree of the faculties of observation, could tell to a nicety by the stems and leaves alone what particular variety would be found on digging up the plant. Of the twelve to eighteen varieties coming under my observation, and mostly cultivated in the field, I could readily distinguish at sight all, except those which were mere sports from other varieties, differing in the stripes, flakes or markings of the tubers, but having stems and foliage perfectly similar. This fact amply testifies to the amount of variation in the aërial parts of Potatos, notwithstanding that they have not been selected on that account, nor particularly desired for such. Between the stems and tubers there was generally a more or less pronounced correlation in colour. This is the less remarkable when we consider that stems and tubers in this instance consist of homologous parts modified to perform each their own particular functions. Excepting chlorophyll, or the green colouring matter of plants, the other colours are much less affected by light or its absence, so that the relation between stems and tubers of Potatos becomes more apparent, rendering their correlative variation a matter of common and expected occurence. In striking contrast to the deep purple, almost black, tubers and purplish stems of some varieties may be mentioned their white flowers, while other sorts with white tubers have pink or purple flowers.—J. F.—*Gardeners' Chronicle.*

OFFICIAL REPORTS ON CEYLON TOBACCO AND OILS.

(*From the "Times of Ceylon."*)

No one can read the reports we publish to-day without being struck with the possibilities they open up for the future. We give them in detail *(See Supplement a-h)*, that our readers may note what is said of other products than those to which European planters have as yet given any attention. It is as well, however, not to be led away by the favorable nature of the report of the Committee on Ceylon tobacco, for no product is more fickle in its financial results, and none requires greater personal care and attention than this one. Speaking generally, nothing but loss has resulted from the many attempts made by European planters to cultivate tobacco in Jaffna, Tangalla, and other suitable localities, though it seems hard to believe that the care and foresight of intelligent Europeans are unable to compete with the haphazard and wasteful system of natives. But such is the verdict of the past. The Committee, which inspected the samples of tobacco sent from Ceylon, report, as will be seen, very favourably upon them, but, though many tropical countries in the eastern and western hemispheres are noted for the excellence of their tobacco, and though the industry in America and Java may be said to be exceedingly prosperous, yet, with all our natural advantages for the growth of such a product, Ceylon has not as yet been a competitor in the production of the fragrant weed. However this may be, we expect our readers will be surprized to hear that as much as 6,645,129 lb. of tobacco were raised in Ceylon during 1885. But so says the Government Blue Book for that year. We subjoin the acreage estimated to be under tobacco in 1885, the quantity raised, and the rate per acre in each province of the island, which we have compiled with some little trouble from the Government Blue Book, as follows:—

Province.	Acres.	Quantity. lb.	Average ℔ acre.
Northern	5,897	6,013,667	1,019
North-Western ..	1,677	283,600	169
Eastern	716	260,565	364
Western	456	67,670	148
Central	93	14,490	156
Southern	85	3,787	44
North-Central ..	7	1,350	194
	8,931	6,645,129	av. 744

The previous Blue Book gave 16,910 acres as under tobacco in Ceylon (1884), but it is quite evident from the above table that no reliance whatever is to be placed upon the Blue Book returns. We have the yield per acre in the Northern Province and Jaffna set down at 1,019 lb, whilst that of the Central Province it said to be 156 lb. per acre, and of the Southern Province 44 lb. per acre! Such returns show the carelessness with which Provincial Agents compile their returns, and reflect the greatest discredit upon the Government. We will, however, leave the inaccuracies of the Blue Book and its incompleteness to be dealt with on another occasion, for that is a subject to which we intend to invite the attention of the public and the Government as soon as possible. We think that it cannot be denied that the cultivation of tobacco, not merely amongst Europeans but amongst natives also, is declining in popularity in Ceylon. But a few years ago and Uva tobacco was well known as even more fragrant in the form of cigars than the Dumbera leaf, but who ever hears now of such a thing as Uva cigars? We imagine, with regard to the above figures, that the only items of any accuracy in them are the figures for the Central Province, the greater portion of which acreage lies in or near the Dumbera Valley. A practical planter, writing in the Handbook and Directory for 1877-78, said that "tobacco cultivation is not suited to European colonists. The necessary skill can only be acquired through a series of blunders, and, when it is acquired, it can only be applied as far as one pair of eyes can reach." But surely this dictum is capable of modification. What is possible of accomplishment by Dutch planters in Java and by American landowners in Virginia is surely not beyond the abilities of Ceylon men, given a climate suitable to the plant—a climate which is to be found in the Northern, North-Western and parts of the Eastern Provinces. It seems strange, therefore, not only that failure should hitherto have attended all the efforts of Europeans to cultivate the leaf in those localities, but stranger still that these few failures should have prevented many other attempts being made by enterprizing planters, who could easily acquaint themselves with the most profitable methods of cultivation and curing. If the question had been put to a representative coffee planter ten or fifteen years ago—"Why do you not grow tea instead of coffee?"—his only answer would have been that nothing could possibly pay better than coffee, and that he knew nothing of tea which was very difficult to manipulate. In fact, it was generally thought that the manufacture of tea was a secret art of the Chinese, unknown to Europeans, so complicated and intricate as to necessitate the employment of a large number of skilled hands. As these did not exist in Ceylon, it was thought quite impossible to introduce the cultivation of tea as a European enterprize, though the fact that the shrub would *grow*, and that tea could be made in Ceylon, had been demonstrated many years before that. Is it not probable, we would ask, that a similar result may await us in the matter of tobacco cultivation? That it will *grow*, and that it is even possible to cure it, and smoke it, is known to all of us, but because the process of manipulation and curing is said to be difficult, the cultivation is neglected by Europeans. In such cases as this the Government should give every possible encouragement to planters, both here and elsewhere, by the free grant of land to commence operations. If Deli planters and others with a full knowledge of tobacco cultivation were induced to make a commencement in suitable localities in Ceylon, the result might be satisfactory.

SPIDER SILK.—Mr. Duthie, Superintendant of the Saharunpur Botanic Garden, reports that he caused to be collected spider's web to be used for weaving purposes. The total weight collected in the season was only 10 lb., and the cost of collection will probably prove too great to render the material of any commercial importance.—*Gardeners' Chronicle.*

THE GERMAN POTASH TRADE.—The production of chloride of potash for 1886 is announced at 1,923,994 centners, to which stocks at the beginning of the year must be added, viz., 103,737 centners, in order to get at the quantity open for sale, viz., 2,027,731 centners. The sales amounted to 2,041,849 centners up to November 30 (though, of course all had not been delivered) so that the sales of 1885 will be considerably exceeded this year. The improved condition of the river Elbe has been of great service to the chloride of potash trade lately. Orders for about 300,000 centners of goods of high percentage have arrived from America this month, and a large spring demand may be counted on from that country. The industry is at present in a very gratifying position.—*Chemist & Druggist.*

THE NILGIRI NETTLE.—From recent advices from Madras we learn that there has been formed at Ootacamund a society for furthering the acquirement of more intimate knowledge of the botany, geology, and ornithology of the district. The society has been named the Nilgiri Natural History Society. Mr. Lawson is the first president, and Mr. David Hooper, the Government quinologist, acts as Secretary. At present, meetings are held fortnightly and excursions are also made. It is contemplated to form a museum of the specimens which are collected on these excursions. At the last meetings of the society Mr. Hooper read a note on the sting of the Nilgiri nettle (*Girardinia Palmata*). This nettle yields a useful fibre, but from the number of stings that clothe all parts it is very difficult to collect it. The stings, or glandular hairs, resemble in shape those of the common nettle *(Urtica dioica)*. They leave no abrasure of the skin or dangerous symptoms the next day. The result of Mr. Hooper's examination of the secreting fluid of the sting is that he has found it to contain formic acid, the body to which is due the irritating effects of the sting of such insects as red ants, bees, and mosquitoes As the nature of the sting of nettles has been a point of uncertainty, Mr. Hooper's observation is of considerable interest.—*Chemist and Druggist.*

SOUR POMELLOE.—A notice appeared in a recent number of the Society's Proceedings under the above heading and in reference to it, Mr. Bartlett writes as follows:—"I observe in your published Report of Proceedings for the month of October, that mention is made of a *Sour Pomelloe.* Dr. Bonavia writing about this lime expresses a wish to know the history of its introduction into Calcutta, and you add that no information is traceable in the records of the Society on the subject. I am glad to be able to throw some light on the matter. Some 40 years ago a relative of mine, who was then residing at Augurtollah, in Independent Tipperah, found the lime in question growing wild at that place, and he sent me a plant, which he designated, in default of a better name as the "Family Lime," probably in allusion to the circumstance of the fruit yielding an abnormal quantity of juice; but unfortunately he did not give me the native name of the plant. On its fruiting in my garden, several of my friends asked me for grafts, and I obtained a large number and distributed them to the extent I was able; at the same time I sent one to the late Secretary for the Society's garden, which no doubt is the identical lime you speak of. It is a free cropper, bearing from 50 to 60 fruit every season. From each of the larger fruits I have obtained a quart of juice. I always found seeds in the fruit. No ill effects were produced from the use of the juice, though intensely acid, and more sharp than that found in any of the others of the family that I know. I also found the rind, with the thick coating of pith attached, excellent candied. No doubt Dr. Bonavia must have seen the fruit in the Lucknow gardens, to which place I sent a plant some years back, as a Member of the Eurasian Association of Mysore met with it at that garden, and, learning from whence it was obtained, wrote to me for seeds, with a view to the introduction of the plant in the farms they were then establishing, accordingly I forwarded about one hundred seeds. —*From the Proceedings of the Agricultural and Horticultural Society of India.*

COCONUTS.—Veyangodu, 21st January.—Yesterday's fall gauged 25 of an inch, and more seems in store for us. The result of the rain is that coconuts are dropping freely. This, I suppose, is owing to a process of fermentation or heating of the sap being induced by its being partially cooled by a small shower of rain. Observation shows that a good heavy plump of rain after a rainless period is not followed by such disastrous effects as a slight shower is, when the effect is almost immediate. *Re* coconut Oil, what if analysis should prove that our Oil is poorer than Cochin oil in stearine, and a chemist suggest remedies? How many proprietors will adopt improved or rational cultivation? Unlike Coffee, Tea, and other products in the hands of Europeans, the bulk of our Copperah is produced by small peasant-properietors. If improved methods of cultivation be adopted by enlightened Proprietors resulting in an increase of stearine in the Copperah and therefore oil—apart from its whiteness, the value of each lot of Copperah will have to be tested by analysis, as in the case of Cinchona. This will hardly pay unless the test be easy and inexpensive.—"Examiner".

PUDDLING CLAY.—It is stated in the *Aberdeen Free Press* that Mr. Thomas Fraser of King Street, Aberdeen, has discovered a new method of preparing clay for preventing leakage in reservoirs, water tanks, &c. and has taken the necessary steps to have his invention patented. Hitherto it has been the general practice, when clay has been used in connection with the construction of waterworks, and for other similar purposes, to apply it in a thoroughly wet and plastic condition. From a series of scientifically-conducted experiments, Mr. Fraser has come to the conclusion that far better results can be obtained by drying the clay, and reducing it to a fine powder, before applying it to the bed of a reservoir or to anything which it is desired to render watertight. A long connection with the brick and tile business led him to study closely the properties of clay, especially when used as a preparation, out of which a variety of articles had to be manufactured. He learned from observation that in a wet state, clay had reached its extreme point of expansion, and that water would then filter through it. Having ascertained this fact, he concluded that if clay were used for puddling in a dry compressed state, it would absorb a certain percentage of water, expansion naturally following and rendering the layer water tight. The greater the pressure of water, the more satisfactory the results are said to be. Mr. Fraser began his experiments by selecting his clay from a special bed, out of which he cut a square. The specimen was carefully measured and weighed. After it was thoroughly dried, its dimensions and weight were again taken, when it was found that the clay had lost 25 per cent in weight, while the shrinkage was 10 per cent. Clay in this dry state is extremely hard and compact, and if put into water and not allowed to expand, it would require a long time before water would penetrate to the centre of a 3-in. tube. Another specimen of clay, from the same bed as the former one, was dried, and reduced to a fine powder. In this loose condition it absorbed about 75 per cent of the water, which filtered through it. When the clay was prevented from expanding, it was found to absorb 50 per cent of water, which filtered a little. Powdered clay to the depth of 6 in. was pressed into a tube 8 ft. long by 3 in. in diameter, and having 2 in. of perforated zinc at the bottom. The tube was then filled with water, with the result that the clay absorbed 35 per cent., but there were no traces of filtration. Mr. Fraser is confident that the method he has hit upon, besides being more efficient is also more economical in every way than the manner of using puddled clay now in vogue. He is sanguine that it could be beneficially applied in covering arches, in preparing a perfect bed for street cause-waying, or, in fact, for the prevention of leakage in any description of work that has to be made waterproof from internal or external pressure. —*Indian Engineer.*

Inclined Railroad for China.—At Hong Kong a cable tramway is constructed from the town to the Peak a range of very steep hills, on which are fine villa residences, and where the climate is more salubrious, than near the harbour. The incline where they have to work is 4,800 feet long, and the line, which is partly single and partly double, is laid with 35-pound steel rails on steel sleepers. The gradients vary between 1 in 2 and 1 in 10, closely following the natural contour of the ground. The total height to which the carriages have to be raised is 1,300 feet, and the ropes, of which one is the working rope and the other the safety rope, run on separate sets of friction-rollers. The carriages are attached to each end of the ropes, and as one pair of carriages ascends the incline, the other pair descends. Each car is to contain 60 passengers, the maximum load being 7½ tons at each end of the ropes. The working rope is passed over a pair of drums 8 feet in diameter, and the safety rope over one drum, the drums being fixed at the top of the incline and driven by two compound steam-engines, 40 nominal horse-power each. The speed of the cars is to be six miles an hour.—*Indian Engineer.*

Tropical Dew.—Having had occasion to lay out a large quantity of iron hoes and picks without handles, on the hard ground of an open inclosure in one of the driest districts in India (Bellary), where in fact these implements had been collected in the face of a scarcity, it was found, after they had lain a couple of months, that a thick, weedy, but luxuriant vegetation had sprung up, enough, though there had been no rain, to almost hide the tools. The effect depositing tools on grass has had in stimulating its growing the writer has observed in the tropics before, but was at a loss to account for it, except upon some irresolvable theory of radiation or magnetism. The whole phenomenon is cleared up by Mr. Aitken's paper on "Dew" in "Nature" of January 14 (page 256), dew being proved deposited, not as generally, thought, from the air above, but rising and condensing from the soil below; and the ground in India is always hygroscopic. The outer surfaces of the iron tools radiate of course quickly at night, and the stratum of air inclosed between the metal under surfaces and the earth is, therefore, saturated with condensing moisture. That iron gratings laid on bare ground will raise a rank vegetation in places with only 10 or 15 inches of annual rainfall, and exposed to tropical heat, is a not unimportant fact, as being a readily available substitute for irrigation water, worth further investigation.—*Nature.*

Double Manure Salt.—The market for double manure salt or sulphate of potash, is now lower than ever before known, and as recent heavy arrivals have unsettled values, a lower range of prices may prevail. The easy position of the article is not owing to decreased consumption, but to over production, and consequent larger shipments, and unless some arrangement is made at the source of supply whereby exports are curtailed, the future will be anything but promising. We hear rumors of a probable combination abroad, but there is no reliable information upon which to base an opinion as to what action if any will be taken to remedy the present depressed feeling in the market. For five or six years, double manure salt remained on a steady basis at one and a quarter cents per pound; then the price broke to one dollar and seven cents per one hundred pounds, and the feeling gradually weakened until ninety cents was reached, which is the present nominal value for lots on dock, with some parcels in store limited to one dollar and ten cents. Low prices have stimulated trade to some extent and we understand that the salt has been substituted for muriate of potash, but not in important quantities.

[The above from the *Drug Reporter* would seem to shew that now is the time for purchasing potash salts to mix with cattle manure as an appliation to tea.—Ed.]

Queensland (*Calophyllum Inophyllum*).—During the debate on the Pearl Fisheries' Bill in the Assembly on July 23, a clause was specially inserted to protect trees of the species *Calophyllum inophyllum* on Thursday Island, on the motion of Mr. Palmer. A fine of £10 is inflicted on any person who cuts down or injures either one of these species, or a coconut tree, or any other tree bearing edible fruit. Mr. Palmer said that the oil was valuable, worth £90 a ton, the wood useful, and the bark a good tanning material. Mr. S. W. Brooks and Mr. Sheridan both supported the motion, the former gentleman remarking that the tree was known in Tahiti as *tamano* or *delo*, and the oil was a specific for rheumatism. The Bill was passed by the Legislative Council on August 19, and now awaits royal consent. [Baron Ferdinand von Mueller writes to us on this subject as follows:—Concerning the *Calophyllum inophyllum*, as early as 1855, I found the tree on one of the islands of Hawick's group, on the north-eastern coast of Queensland. Other localities of this species as recorded in my *Fragmenta phytolog-Austral.* ix., 185, are Adam's Bay, Cape York, Rockingham's Bay, Edgecomb's Bay, Fitzroy's Island, and Goode Island; but I have no specimen from Thursday Island. Still I should think it most likely to exist there, as the tree has a wide range along the coasts of tropical Asia, extending to eastern Africa and to Polynesia. My collection of Thursday Island plants is not complete, so the mere absence of the plant from there is no proof of the tree not occuring in the locality. I may incidentally remark that a second species of *Calophyllum* occurs in north-eastern Australia, namely, *C. tomentosum*, but it is as yet only known from near Rockingham's Bay and Johnstone's River; its fruits are considerably smaller than those of *C. inophyllum.*" —*Chemist and Druggist.*

Sweet Girl Graduates in Prussia.—The *Journal de Pharmacie d' Anvers* states that the Prussian Minister of Education has prohibited the admission of ladies to the Prussian universities, either as students or to lectures.—*Chemist and Druggist.*

The Museum of the Pharmaceutical Society has been greatly enriched during the past year by many large and valuable donations. Some of these have been received from well-known wholesale firms, or from private individuals, but the most extensive additions have been made through the liberality of the Commissioners of the Colonial and Indian Exhibition, and of several of the exhibitors, some of the latter having handed over their entire exhibits to the Society. Among the last-named are the valuable exhibits of Dr. Ho Kai and Messrs. A. S. Watson and Co. in the Hong Kong Court, the former including over four hundered specimens of Chinese drugs, and the latter, several valuable models. Not less important are the exhibits of Dr. Brooks, including vanilla and valuable specimens of essential oil, from the Seychelles, and that of Mr. Fersson, of Demerara. The Indian Court contributed a most useful series of sections of the trunks of the cinchona trees cultivated in that country, which show the mode of renewing the bark. The whole of the collection of Ceylon drugs (three hundred and fifty specimens) has been acquired by the Society, as well as the collection of Chinese drugs in the Straits Settlements Court, the latter having been presented by the Executive Commissioner. Valuable contributions to the Museum have also been received from the Executive Commisioners of the British Guiana, West Indian, Victoria and Fiji Courts. The materia medica of the Cape of Good Hope is now represented in the Museum by an entire series of the drugs exhibited in that Court, presented by Mr. Sidney Cowper. In addition to these, a very extensive and valuable collection of essential oils, many of them of great rarity, has been presented by Messrs. Schimmel and Co., of Liepzig. Dr. Aitchison has handed to the Society a collection of the drugs obtained by him in Afghanistan, and specimens of considerable interest have been received from the Director of the Kew Gardens, from Dr. Dymock of Bombay, Dr. Ondaatje, of Ceylon, Mr. Murai, of Japan, and many others. The large contributions to the Museum during the last few years have raised it to the first rank as a Museum of Materia Medica; so that it has lately been classed in a well-known periodical (*Nineteenth Century*) with the National Musem of Natural History at Kew and the British Museum.—*Pharmaceutical Journal.*

CEYLON UPCOUNTRY PLANTING REPORT.

ADVERTISING TEA AT HOME—ABSURDITY OF DELAYING THE SALE OF GOVERNMENT FOREST LAND AT KALUTARA —SMALL BREAKS OF TEA—CULTIVATION OF COCA IN CEYLON—COFFEE AND CACAO CROP PROSPECTS

31st Jan. 1887.

Judging from the tea advertisements which have appeared at home, by parties desirous of pushing the Ceylon tea trade, and which have from time to time been copied into the *Observer* columns that portion of the public which receive their knowledge of Ceylon and its teas from such sources, have had for mental food rather "confused feeding." It is a pity that this educational agency cannot be rendered more effective, and that when knowledge is being imparted it should not be more exact. The article which calls it forth is good, and it were well that the information were also as good. Still as long as the teas sell, and get into general use we need not perhaps be too particular on this score. Besides, there seems to be a demand on the part of the public for information regarding Ceylon and its teas, which is spreading even to the provincial towns and those who supply it evidently do the best they can, dr wing pretty much on their imagiuation for their facts. A friend of mine writing from one of the towns in Scotland says that a grocer there has a bill in his window stating "that the finest tea that comes to Europe is grown in Ceylon on mount ains 7,000 feet high!" This high class article was sold at the moderate price of 2s 6d a pound. "We got some of it," says my correspondent, "and found it good."

Regarding the forest land at Kalutara—the 5,000 acres which you referred to the other day—it does seem absurd that the Government should delay the selling of it, or indeed that they should not put it up in smaller blocks. If it be the case as is generally supposed, that all this land is to be put up at once, the result will be an unfortunate one for the Government. Why should not, say the half of it have been sold before now, instead of delaying? Better prices would certainly have been got for this than can possibly be secured if the limited demand for land is to be glutted by this extensive area thrown in the market all at once. I suppose that it is hopeless to expect that the principles which regulate ordinary business, can be found operating in such things as the sale of Crown lands. Even yet, although the surveys have been for some time completed, no plans can be got, whereas if the Government had gone in for a 2,000 acre lot, the work might have been all finished, plans issued, land sold, and in all likelihood at better rates than will be got later on if the whole be put up at once. I suppose it must be known to some of the officials that the S.-W. monsoon is generally considered to be the best for planting; but the knowledge of this fact does not seem to stir them any in regard to the Kalutara lands, indeed one might question whether they were aware of it.

The combination among tea buyers to neglect the small breaks is not likely to lead to much good. Indeed, I suppose, it has even now come to nothing. I already know of some who say that if they are forced to store their teas until they have what may be termed a good break, that they will ship it, rather than offer it locally. If they cannot get fair value in the local market for such breaks as they can send, they will adopt the other course. One of the chief advantages of the weekly sales in Colombo has been that the planter has been able to turn his produce into money at once, and get a fair value even although the breaks were small, but if he is to be kept out of this advantage, by any kind of combination, he may as well have a trial of the London market at first hand. A parcel of tea was reported on lately by some Colombo authorities, and the result was a very poor report. It was a pleasant surprise to the shipper when the break was sold in London to find that it realized 1s 4d a lb.!

The cultivation of coca in Ceylon is not extending very rapidly, nor likely to. And yet you do hear of it growing here and there, and the plants which were for sale at the Peradeniya Gardens, at 12½ cents each, all found buyers. I understand that its use as a local anæsthetic, is bringing it more and more under the attention of scientists, who are studying its nature and will in all probability extend its use. It is quite within the range of possibility that this concentrated attention, may lead to some important discovery regarding it, which will induce a demand for the coca leaf such as does not exist at present. Even as it is, I have heard of one who has been promised a shilling a pound for all he can send home, a price, I understand, which will pay well enough.

Last week's rain did a lot of good, and brought out a scattered blossom on what coffee was in heart. There remains a promise for something better later on.

The cacao crop is winding up, and it has been a very good one. The new blossom for the next crop is somewhat tardy in parts, but there is plenty of time yet. The trees are particularly healthy, most of the pests which plague and worry are in abeyance, and long may they so continue.

PEPPERCORN.

TEA.

The following is the annual report of the tea trade by Messrs. W. J. and H. Thompson.

The past year has again been unsatisfactory to the importer, while statistically for the first time for many years the total deliveries show only a fractional increase, the most serious feature being the falling off in home consumption, a decrease of 1¾ million compared with last year.

This possibly may be accounted for by some disarrangement with regard to the deliveries in 1885, consequent upon the expectation of an increased duty or to the largely increased use of Indian and Ceylon teas, which possess much more strength than those from China, and at the present moment contribute to the extent of one-half of the total consumption. The export is satisfactory, being two millions in excess of last year. China: Prices early in the year were well maintained in prospect of reduced stocks, and the commoner grades advanced in value. On the receipt of news of hurried and heavy shipments, combined with the large increase from India and Ceylon, a general decline took place. The new crop met with little attention, and the finer qualities showed a reduction of 4d to 8d per lb as compared with the current prices of former years. The medium grades were not equally affected, and the common kinds maintained comparatively a high range, owing to a moderate supply. The lowest point reached was in October, but since that period there has been some slight rally. The total export from China is expected to be about the same as last year. Indian tea: the year opened with stocks of high average value and only a small supply of low-priced Tea, the effect of which was to restrict business and cause a decided decline. When the new crop arrived in the autumn, the market being in a sound position, a good business at steady prices resulted, until it became apparent that the crop would be a heavy one and consist largely of low grades, when rates began to fall for all but the best qualities, and at last reached a lower range than has ever been known. This fall

has greatly stimulated consumption, which for the past three months has risen to the rate of 80 millions per annum, while in December Indian and Ceylon deliveries together for the first time amounted to one-half the entire home consumption. The season's supply of Indian is estimated at 75 millions, eight millions more than the previous crop. At the present rate of delivery the consumption would be equal to 75 millions, showing an increase of 13 millions. To the growers the result may prove better than present prices indicate, as the reduced cost accompanying a large yield forms some compensation for the lessened values of inferior grades, while for those who made fine teas the market has been favourable throughout. Ceylon Tea: This branch of the trade is beginning to assume large proportions, the imports and deliveries being double those of 1885, while the demand has been sufficient to maintain an average for some time past of 1s 2d per lb. due to the success of planters in keeping up a high standard of quality, for in the spring when the average value of other teas was higher than now, Ceylon fell as low as 10½d per lb., the portion of the crop then arriving being of inferior quality. Java Tea: The quality has been of an average class, and the deliveries have been about the same as last year.

Messrs. Layton and Co.'s Circular says:—Looking back upon the last year two unfavourable features are noticeable, viz., (1) the continued fall in the value of fine Tea, and (2) the increasing tendency of Indian to drive China Tea out of consumption in this country. As to the first of these, it is probable that we have now arrived at a pitch when some reaction must take place and indeed prices of really good Kaisow or Moning are decidedly firmer already than a month since, although no great advance can as yet be quoted. As regards the second of these facts, we believe that it must continue for some time to come, and until the low prices current for Indian descriptions stop the production of increased supplies year by year. This is hardly likely to occur at present, because the extensive use of improved machinery in India has more and more reduced the cost of manufacture until an average price of only 8d per lb., which a few years ago would have been considered quite an absurd quotation, is found to leave growers a margin of profit. It seems probable, therefore, that unless China can send an improved article to compete on better terms with the more pungent liquor and more even leaf of India, no permanent change can be hoped from the present very unfortunate state of things, and the downward course of the China Tea trade for so many years can hardly be arrested. During the past year the total deliveries of China Tea for home trade showed a falling off of 5,881,000 lb. compared with 1884, while the consumption of Indian showed an increase of 5,770,000 lb.; it is startling to find that whereas the deliveries of China Congou are less than in 1871, those of Indian Tea have risen from 13,500,000 lb. to over 70,000,000 lb. in the same period. The landings of Indian Tea in December were on a larger scale than ever previously, amounting to 14,113,590 lb. against 9,227,394 lb. in 1885, and though the deliveries were exceedingly heavy for the time of year, being 6,594,546 lb. against 5,241,228, the stock on the 31st ult. was further increased to 32,887,308 lb. as compared with 24,751,920 lb. in the previous year. The general favour in which Ceylon Tea has gradually risen continues and all grades have brought comparatively high rates the style and liquor of several invoices being highly approved.

The market for Indian Tea which closed on the 22nd ultimo was reopened on the 3rd instant with a small sale, and during the week 18,000 packages have been offered. Prices at first were irregular, but since then there has been more competition for Pekoe Souchongs at from 7d. to 10d., and Pekoes from 9d. to 1s 1d. per lb., quotations for which show a advance, especially for the latter. Common Broken Pekoes under 1s are lower, but medium and goond medium have sold briskly at many previous rates. The demand for finest descriptions keeps limited The deliveries for December were 6¼ millions, which is satisfactory, and for the past six months they show an increase of fully six millions as compared with last year. Owing to the excessive arrivals in December the stock appears unusually heavy. Ceylon: The sales comprising 1,700 packages passed with a little more animation as compared with the closing sales of 1886. Java: Partly due to the limited quantity brought forward lately, the 460 packages offered this week met with attention, and for the useful parcels there was fair competition. The figures for the past six months, as compared with previous years, are as follows:—

	1886 Imports.	1885
Indian ...	52,038,000 lb. ...	42,681,0 0 lb.
Ceylon ...	3,834,000 lb. ...	2,320 000 lb.
Java ...	1,788,000 lb. ...	1,605,000 lb.
	Deliveries.	
Indian ...	35,670,000 lb. ...	29,472.000 lb.
Ceylon ...	4,092,000 lb. ...	2,110,000 lb.
Java ...	1,860.000 lb. ...	1,841,000 lb.
	Stocks Dec. 31.	
Indian ...	32,887,000 lb. ...	24,752,000 lb.
Ceylon ...	1,660,000 lb. . .	1,028.000 lb.
Java ...	944.000 lb. ...	675,000 lb.

Messrs. Beebe's New York Circular of Dec. 23rd says:—A large business has been done in most descriptions of Tea at improving prices. The speculative feeling indicated by the transactions referred to in our last became more pronounced early in December, and large sales and resales of Formosa and Amoy Oolongs here and to arrive, followed, leading to an advance in values of about two cents per lb. all around. But little of either class remain in first hands, dealers and speculators holding at the close most of the stock. Considerable sales of Foochows have also been made, mainly of cargo grades, and the advance on them is fully equal to that on Formosas and Amoys. Greens have been in more demand, Country packed as well as Pingsueys, and chop values for them may be quoted one to two cents higher than when we wrote last. Japans, other than Common to Good Medium, are comparatively unchanged. These grades close at an advance of one to two cents. Sales and resales reported at private and made under the hammer foot 200,700 packages, including 20,200 Country Greens, 17,000 Pingsueys, 18,800 Japans, 62,300 Formosas, 54,000 Amoys and 25,000 Foochow Oolongs, and 3,400 Congou. 29,700 of these were made in the auction room. Green Teas have met with more inquiry during the past three weeks, and values at the close show an advance of about two cents average on the better chops of Moyune and Teenki, and one or two on Pingsueys and the lower grades of Country packed. Holders are less inclined to press sales either at public or private, and a further improvement in value seems probable in the near future. Japans find some increase in the demand, but mainly for Common to Good Medium. These grades are realising one to two cents more in the auction room, while Fine to Choice show little or no improvement over last month's values. Oolongs have been very freely taken both in the regular way and on speculation, with sales and resales aggregating about 140,000 packages. Of these Formosa kinds cover 62,000; Amoys, 54,000 and Foochows, 25,000. An average advance of fully two cents is established on all grades other than Finest to Choice, and the market closes firm at the improvement. Congous are practically unchanged, with but little inquiry for other than Common Cargo.—*L. & C. Express.*

CINCHONA IN BENGAL.

The report on the working of the Cinchona Plantations in Bengal during 1885-86 shows that there were upwards of five million trees in various stages of growth on these plantation. The major portions of these trees comprise the red and yellow species (*succirubra* and *calisaya ledgeriana*). The most important feature of the year's operations was that the planting out was exclusively confined to yellow bark trees, of which 187,000 were of the hybrid variety, and 239,000 of *ledgeriana*. The crop was not a large one, and amounted to 205,410 lb. of dry bark, most of

which was red. The bulk of the crop was as usual made over to the febrifuge factory.

The demand for the febrifuge was not as great as in previous years, and this is ascribed to the presence at the three presidency depôts of a large quantity (7,000 lb.) of London-made febrifuge, sent for sale under instructions from the Secretary of State. Until, therefore, this large supply has been absorbed, the demand for the Bengal febrifuge must necessarily be limited. Why the Secretary of State should send out London-made febrifuge for sale to India,* when it can be as well manufactured here, is not quite clear. It cannot have any other than a deterring effect on the Indian industry, which at present is very largely in the hands of the Government of India, not to speak of private enterprise. The outturn of febrifuge from the factory is regulated by the demand, which fell from 6,464 lb. in 1884-85 to 4,743 lb. during 1885-86. This "demand" was limited owing to the 7000 lb. of febrifuge having been sent out by the Secretary of State, and thus the connection between the two is established. The Indian revenue from this source has, therefore, suffered. The cost of manufacture was also more than in preceding years, owing to the introduction of an improved method of working the factory. So that although the cost of manufacture increased by five annas per lb. in the case of ordinary, and eight annas per lb. in the case of crystalline febrifuge, the percentage of febrifuge, obtained from the bark was raised by three per cent by the new method. The increase in cost of manufacture is also ascribed to the smaller quantity manufactured. It will thus be seen that the Secretary of State's venture has not proved a very paying one. The issues during the year decreased by 1,653 lb. as compared with the preceding year, having been respectively 5,499 lb. and 7,152 lb.

During the past year there was a heavy fall in the market price of quinine; the ruling price having been only R2-1 0 per ounce. To this cause is attributed the decrease in the sale of the febrifuge to the public. It is, however, anticipated by the Government that the depression in the price of quinine, which is ascribed to special causes, will not last. In this connection it may be as well to state that there has recently been an enquiry into the prevailing *high* retail prices of quinine, and that there is every likelihood of the present low prices being maintained. So that unless the Government see their way to reducing the prices charged for their febrifuge very much *below* that prevailing in the market for quinine prepared by London manufacturers, the falling off in the sales to the public may be expected to continue. The total expenditure on the Bengal plantations amounted to R79,728, which is R18,077 below the budget allotment. Of this the sum of R12,052 represents the capital expenditure on the young trans-Teesta plantation at Rungjung, which has not yet come into bearing; and the balance, R67,675, the working expenses of the old plantations at Mungpoo, including Rungbee and Sittong. Thus the capital account is now brought up to R1,096,255. It is, however, explained that this has been recouped by the saving effected by the substitution of cinchona febrifuge for quinine in Government medical institutions. The gross revenue derived from the sale of febrifuge, seed, plants and bark amounted to R93,476, against R124 225 in the previous year. The actual profit on the year's working is stated to have amounted to R30,221; but with the expenditure at R79,728, and the revenue at R93,476, the net profit would amount to R13,648. It is, therefore, not clear how the above figures are arrived at. In addition to the "actual profit," Dr. King points out that 2,054 lb. of febrifuge, supplied to Government medical institutions, and valued at R33,000, should be taken into account. The thanks of the Lieutenant-Governor of Bengal are very properly accorded to Dr. King for his continued efficient management of the department, and to Mr. Gammie, who held executive charge of the plantations and factory.—*Indian Agriculturist.*

* He sent out febrifuge manufactured in London from Government bark, as an experiment.—ED.

ASH OF CINCHONA BARK.

BY DAVID HOOPER, GOVERNMENT QUINOLOGIST.[1]

I have recently been engaged in examining the inorganic constituents of cinchona bark, and the analysis has been communicated to the Government of Madras for information of the cinchona planters of the Presidency. As the chemistry of this drug will always be of interest to pharmacists, I send some notes relating to the amount of ash and the quality of the ash occurring in barks cultivated in India.

In Flückiger and Hanbury's 'Pharmacographia' the following statement is made:—"The cinchona barks yield but a scanty percentage of ash, not exceeding 3 per cent, a fact well according with the small amount they contain of oxalate and kinate of calcium."

With regard to the quantity of ash, my experience is that cultivated barks yield over 3 per cent; the average of three hundred estimations made on samples from this country was calculated at 3·42 per cent. Renewed and old natural barks are the poorer in mineral constituents, but they never fall below 2 per cent. On the other hand, young and branch bark gives as much as 4 per cent, and it is interesting to notice that the leaves afford as much as 5, and sometimes 6 per cent. With regard to the species of cinchona, there is a marked difference in the amount of ash yielded by each, provided that natural bark is operated upon. The crown bark is richer in ash than that of the red, and the red richer than that of the Ledger; and knowing that crown bark grows at an elevation of 7000 to 8000 ft. the red at 5000 to 6000 ft., and the Ledger at 3000 to 5000 ft., the altitude may have something to do with this gradation of ash in the different species.

When gently incinerated at a low red heat, cinchona bark should always leave a greyish-white ash. If it is at all reddish, it points to the presence of dust or dirt adhering mechanically to the sample, if weighed, it will be found much in excess of that obtained from clean bark. The two most dirty samples of bark I have met with came from Ceylon, leaving when burnt a reddish residue of 18·8 and 19·5 per cent respectively, but as they were both labelled "dust," neither the vendor would be blamed for the impurity, nor could the purchaser rave on account of its poverty in alkaloids.

A complete analysis was made of the ashes of the two species of cinchona grown on the Nilgiris, the *C. officinalis* growing in the Dodabetta plantation, and the *C. succirubra* from the lower elevation at Naduvatam. Notwithstanding the barks were from different species and localities, the result of the examination shows that there is a great similarity in the composition of the ash.

	C. officinalis.	*C. succirubra*
Soluble in water ...	27·33	24·46
Soluble in acid ...	66·92	69·94
Residue	5 75	5·60
	100·00	100·00
Insoluble silica ...	5·75	5·60
Soluble silica	1·42	4·40

Chlorine	·45	·42
	100·00	100·00

The chief constituent is the lime which forms nearly one third of the whole, and exists in the ash in the form of carbonate. The next element of im-

portance is the potash, which amounts to one-sixth and one-eighth of the whole ash respectively.

About fourteen years ago P. Carles wrote a paper on the "Complete Analysis of Cinchona Barks," in the *Repertoire de Pharmacie* (new series), vol. i., p. 60 (which appeared in the *Pharm. Journ.*, March 15, 1873), and a complete analysis is given of the ash of Ilnanuco, calisaya and succirubra barks from South America. His examinations agree on the whole with the above, but he finds traces of copper and appreciable quantities of manganese present. Although there was quartz present in most of my samples, weighed as insoluble silica, yet there was no trace of copper; and the absence of more than traces of manganese is in accordance with the nature of the Nilgiri soils. I can confirm Carles in showing what a small quantity of chlorine is present. As to barks rich in quinine associated with abundance of lime salts, I cannot agree that there is any relation between the alkaloids and the mineral elements. The cinchonas of South America were poorer in quinine then than the India barks are now, and they yielded about half the amount of ash. On the other hand the Ledger barks, which are richer in quinine than succirubras, always contain less ash, and consequently a less amount of lime. There is not much lime in the Nilgiri soil, yet it seems an essential ingredient in cinchona bark, and is taken up in large quantities whether the cinchona is grown in India or America. However different the soils of these two countries may be, a comparison of the analyses of Mr. Carles and myself will show that cinchona bark appropriated to itself a peculiar arrangement of chemical elements. If the arrangement of the inorganic constituents of plants were at all constant, it would be a means whereby the chemist could assist the botanist in discriminating between different natural orders, genera, if not species of plants. —*Pharmaceutical Journal.*

THE BEVERAGES IN COMMON USE.*

BY PROFESSOR DUJARDIN-BEAUMETZ.

Under the head of aromatic beverages I propose to speak exclusively of such as contain a certain alkaloid, with the formula $C_8H_{10}N_4O_2$, which Runge, in 1820, found in coffee, and to which he gave the name *caffeine*, which Oudry, in 1827, found in tea, and which he called *theine* which Martius discovered in the *Paullinia sorbilis*, and which finally Hæckel and Schlagdenhauffen have isolated, along with theobromine, from kola nuts.

In order to simplify the exposition into which I am about to enter, I will admit that all these alkaloids are identical, although I know very well that it is by no means demonstrable that isomeric bodies have absolutely the same physiological action. I shall not touch upon the different hypotheses which have been put forth relative to the atomic composition of this body. I have already called attention to this point in a recent study on the derivatives of caffeine.† I have shown that if, according to Strecker, caffeine is only the methyltheobromine, according to Fischer, on the other hand, caffeine and theobromine are derivatives of xanthine; theobromine is the bimethylxanthine, while caffeine is the trimethylxanthine. But I cannot now take up your time with these chemical researches.

All the aromatic beverages containing caffeine (or the isomeric alkaloids above mentioned) for their bases are used in immense quantities all over our globe, and their employment is much more extensive than that of alcoholic beverages.

Many opinions have been put forth as to the physiological and hygienic action of coffee. These may be reduced to three hypotheses. Coffee diminishes the excretion of urea and is a waste-restrainer; it does not modify the urea excretion, and is a force-producer; or lastly, it acts as a food, supplying elements of nutrition.

The first view is supported by Schultz, Gasparin, Broker, Lehman, Frolish, Trousseau and Pidoux, Rabuteau, Marvaux, etc., who claim that coffee diminishes the quantity of urea excreted; that it does not nourish, but that it prevents denutrition. This is the waste-restraining-aliment theory.

But to facts advanced by these physiologists other facts are opposed, and we see Roux and Giraud in France, Binz in Germany, Brackenridge in England, maintain that coffee, as well as caffeine, in no respects modifies the figure of urea. Hence Gubler, basing himself on the researches of these authorities, affirms that coffee has no action on nutrition, but that it is a tonic, or, rather, a force producer.

Lastly, Payen has shown that coffee contains nitrogen, and this in quite notable proportion, since in green coffee this essential element exists in the proportion of 4·48 per cent, and in roasted coffee in the proportion of 1·75 per cent. He shows, moreover, that the admixture of coffee with milk, in ordinary usage in many parts of the world as a breakfast beverage, is one of the most nutritious of all drinks, a mixture of 500 grams of infusion of coffee, 500 grams of milk, and 75 grams of of sugar containing, according to his estimate, 49 grams of nitrogenous substance and 100 grams of hydrocarbon and salts.

This view has been adopted by Fleury, Bouchardat and Jomand, and is supported by facts being in accordance with the experience of entire populations (in England, Germany, Switzerland and the United States), who find sustenance in their breakfast dish of coffee.

Coffee is, then, by virtue of the nitrogen which it contains, a food, and you remember that in the primordial alimentary principles I included caffeine among the azotized substances. Moreover, recent experiments of Guimaraës show positively that augmentation of urea follows the administration of coffee.*

But is coffee anything but an aliment? It possesses special tonic properties on the circulation and nervous system. All experimenters are agreed in the fact that under the influence of coffee the beatings of the heart become more rapid and more energetic, the circulation more active, and the urine more abundant. Leblond's study has given us in this regard tracings of high importance. Moreover, whether by the activity which it impresses on the circulation, or by a direct action on the nervous elements, coffee directly affects the brain, and may be called "a cheering and thought-inspiring beverage."

This threefold action, on nutrition, on the circulation, and on the nervous system, makes coffee an admirable tonic, and we are justified in saying that it is largely by reason of the strong coffee, which habitually forms a part of their diet, that our troops have been enabled in the burning of climate of Algiers to endure the most exhausting campaigns.

It is also owing largely to the coffee, which is becoming more and more an article of daily consumption among the farmers in the country, that we see this class of people able to endure the great increase of toil to which they are subjected in haying and harvesting seasons.

Coffee, in order to be fit for nutrition, must first be torrefied. Payen has made a special study on the modifications which coffee undergoes by roasting, and has shown that during the process there is a breaking up of the chlorogenate of potassium and caffeine, and a setting free of a part of the caffeine held in combination.

I cannot here touch upon the different modes of preparing coffee, modes by which the properties of roasted coffee are doubtless more or less modified. While in Europe it is the infusion which is drunk almost exclusively, the inhabitants of the East prefer the decoction, and, if we may believe their statement, the decoction, while preserving the tonic and alimentary properties of the coffee, is quite devoid of the exciting properties which characterize the infusion.

* A lecture on Hygienic Therapeutics, delivered in Cochin Hospital. From a translation in the *Therapeutic Gazette.*

† Dujardin-Beaumetz, "On the Physiological and Therapeutic Properties of the Derivatives of Caffeine." (*Bull. de Ther.*, 1886, t. cx., *p.* 241).

* Guimaraës, "On the Physiological and Hygienic Action of Coffee" (*Arch. de Phys.*, 1884, t. iv., p. 253).

The different physiological properties of coffee have caused this food medicine, and its congeners, tea, Paraguayan maté, guarana and kola, to be applied to the treatment of a great number of affections. Its tonic action on the circulation has led to its use in the treatment of diseases of the heart, and Gubler, Lépine and Huchard have shown us all the advantages derivable therefrom. Its diuretic properties have led to its being recommended in dropsies, urinary gravel and gout; its cerebral tonic action has rendered it useful in the treatment of migraine and cephalalgia. Lastly, we see its utility recognized in intestinal strangulations and opium poisoning.

I have finished what I wished to say concerning coffee, leaving aside what appertains to infusions made from roasted acorns and chicory, which contain nitrogen, and probably have some food value, but are devoid of caffeine, and therefore of the tonic and excitant properties of coffee.—*Pharmaceutical Journal.*

REPORTS ON INSECTS INJURIOUS TO FRUIT CROPS

(Prepared for the Agricultural Department, Privy Council Office.)

We have already noticed two previous issues of these Government Reports, relating respectively to the insects affecting the hop and corn crops. The new publication is likely to be the one most generally popular, as private persons all over the country as well as fruit farmers are concerned about the insects which ravage fruit-trees. The Privy Council have done useful service in having this work prepared. In it Mr. Whitehead has compiled in a fairly popular style as much as has been ascertained concerning the nature and life histories of the weevils moths, bugs, and flies which are so ruinous to our various fruit-trees. The pamphlet is obtainable for so little cost that it is not necessary to analyse its contents at great length. We may, however, state that about thirty of the most familiar garden insects are figured and discussed. These include the chief devastators of the apple, pear, cherry, currant, raspberry, strawberry, and gooseberry leaves and blossoms. The details given under the heads, Prevention and Remedies, show that no royal means have yet been discovered for battling with these foes without a great deal of trouble. Some different details of treatment are suggested for each insect, but generally it is recommended that the trees or bushes infected should be well syringed with a mixture of soft soap (7 lb.) and quassia (6 lb.) to 100 gallons of water. After an attack the ground round the roots is generally to be well hoed, quicklimed, or sawdust with paraffine, or soot, or ashes well mixed in with the earth, and all cuttings from the tree to be perfectly cleared away. Hellebore is said to be an effectual dressing in some cases, but its poisonous nature forbids its use when any fruit, however small, is forming. It is much the fashion to attribute the attacks of insects to the east wind, as if it in some mysterious manner were the actual generator of sundry of the species which spoil the crops and destroy vegetation, or as if they literally came on the wings of the wind. Mr. Whitehead notices this old-fashioned theory, and attributes it to the fact that after a cold and variable spring, during which there has been an unusual amount of east wind, all plants, trees, and herbs appear to be more liable to attacks from insects, in consequence of certain chemical changes and the disorganisation of tissues rendering them more grateful to the tastes of their ordinary parasites.—*Chemist and Druggist.*

THE BHEL FRUIT, OR BENGAL QUINCE.

MR. E. JAMES, Ipswich, writes as follows:—"Reading in your valuable paper an account of the Exhibition, my attention was attracted to the Bael fruit (misspelt Bahl), which does not seem to have any attraction for your correspondent. It gives me great pleasure to draw the attention of Queenslanders to this valuable fruit, from an edible and medicinal point of view. The fruit is obtained from the *Ægle marmelos*, and belongs to the most valuable natural order, Leguminosæ. The fruit is about the size of a large orange, with a hard woody rind. The fruit is highly valued by the natives of India, which is its natural habitat, as an astringent in severe cases of dysentery, diarrhœa, &c. I have always taken it during my five years' residence in Ceylon, where it grows abundantly, and is considered by medical men in India, to be a most valuable medicine, a preparation of which is official both in the British and Indian Pharmacopœia. The preparation as in the B. P., is known as fluid extract of Bael fruit, but it is not equal to the fresh fruit. For further information see Fluckegar and Hanbury's Pharmœographia, which ought to be in the hands of every one who takes an interest in fruit growing."

Lindley gives a different spelling to either of the two above referred to—namely, "Bhel." The "Dictionary of Gardening" calls this fruit the *Ægle marmelos*. Order Rutaceæ (not Leguminosæ). It is described as "an evergreen tree producing very large fruit, which much resembles an orange in general appearance, very delicious to the taste and exquisitely fragrant. This genus differs from Citrus principally by its numerous disunited stamens. The pulp of the fruit is an aperient, and a valuable remedy in dysentery; the thick rind and dried unripe fruit are astringent. It thrives best in a rich loamy soil, and is propagated by ripe cuttings, which, if not deprived of any of their leaves, will root in sand under a hand glass, in heat. It grows to a height of 10 ft." We have to thank Mr. James for calling attention to a fruit likely to suit the climate of this colony, and also to be an addition to our horticultural resources. We shall also be glad to publish particulars of its growth and cultivation in this colony. Mr. Bernays, in his "Cultural Industries," says that a specimen at Bowen Park has flowered profusely, but not yet fruited, but that he has seen good fruiting specimens in the gardens on the coast from Bowen northwards.—*Queenslander.*

TRADE AND COMMERCE OF SANTOS.

(From the Report by Consul Cowper for the Year 1885.)

There is no new feature in the production of this province. Coffee still continues to be its staple and only article of export. Former reports have treated exhaustively this subject, and there is nothing to add to it, except the fact that the production of coffee shows a tendency to increase, notwithstanding the very great depreciation in its value during the last few years—a depreciation which barely leaves a margin for profits, and has reduced the revenue derived from it by several millions of pounds.

Coffee, as already stated, is the only article of export, and the shipments during the past year were larger than those of any of the previous ones, in consequence of the extension of the crops. Great Britain consumes but little of the San Paulo, or "Santos" coffee, as it is commonly called, hence the shipments thither are small and of no great consequence. New York, Havre, and Hamburg are the principal markets of the staple produce of this province.

The import trade of this province, carried on through the port of Santos, still continues to be of growing importance, and as long as the province develops its resources at the rate of past years, the import trade will increase in direct ratio to the same. There has been no diversion or new feature in the import branch of trade here. Great Britain, as heretofore, supplies the greater portion, both in bulk and value, of the imported goods, and entirely monopolises the trade in railroad and tram plant, and rolling stock, gas and waterwork materials, agricultural implements, hardware and machinery of every description, and coal. Although Germany endeavours to compete in cotton goods, British makes are preferred and command the market. Unfortunately no statistical information as to the volume and value of the importation from different countries can be given, inasmuch as the custom-house has never yet published statistical matter on the subject. There was a great falling off in number o

British ships entering the port of Santos in 1885, as compared with other years. Two years back British shipping, whether sailors or steamers, far exceeded that of any one nation, but last year steamers under the German flag, and sailing vessels under the Norwegian flag, considerably exceeded those under the British flag. The cause of this appears to be the much lower rates at which the Germans and Norwegians can equip and sail their vessels. The low freight, which now rules through excessive competition, apparently leaves no margin for profits, and the general cry of the shipmaster is that their vessels are sailing at a loss. This, in regard to British vessels, appears to be actually the fact in most cases, inasmuch as the sailing expenses of a British vessel are about twice as great as that, say, of a Norwegian vessel. For instance, in the first place, the Norwegian mercantile marine consists of principally English vessels bought up cheaply; second, the Norwegians victual their vessels at a much lower rate than the English; and lastly, the wages paid to Norwegian crews, whether master, mate or seamen, average half the wages paid to British seamen of the same class. British shipping cannot compete under such advantages, and if the Norwegian mercantile marine was sufficiently large they would, under circumstances noted, do the entire carrying trade.

Under the heading of exports it was stated that Great Britain consumed but little of the coffee exported from Santos; hence this branch of the trade, commercially speaking, does not interest the industries or trade of Great Britain. It is otherwise however with the import trade, inasmuch as with the exception of farm house and market garden produce, every commodity used by a civilised community, possessed of no productive industries of its own, is imported from such countries as can supply the demand for them to best advantage. The demand for foreign commodities and industrial production increases every year in this province with the expansion of its population and the development of its vast territories. The demand comprises household furniture, utensils and commodities, hosiery, ready-made male and female attire, boots and shoes, cotton, woolen, and linen materials, jewellery, wines, beers, groceries, flour, oil, kerosene, preserved meats and fruits, stationery, medicines, china and porcelain, hardware, cutlery, glassware, earthenware, agricultural implements, railroad stock and plant, waterwork plant, tram car stock and plant, and every description of machinery and iron work.

Great Britain, by reason of her practically inexhaustible stock of industrial products, unlimited productive power, and possessed of the facilities of capital, material, enterprise, sea transport, &c., ought to supply the non-industrial countries with her productions without fear of competition from countries less favourably situated. Such is, in point of fact, the case in this province. The importations from Great Britain alone amount to nearly half the value of the total import trade. Other countries, notably France, Germany, and America, are attempting competition, but with no marked success at present; the long-standing specialities of British industries always obtain preference.

In those cases where the productions of foreign industries compete successfully with, or are superseding those of Great Britain, the cause or fault is generally traceable to the British manufacturers themselves, who, often too conservative in style and design, obstinately ignore the tastes, wishes, and requirements of consuming markets; whereas, on the other hand, competitors in Germany, France, and America, with a keener eye to business and more mobile in disposition, spare no pains to adapt and supply goods in accordance with the wants and peculiarities of each country.

To exemplify this assertion, mention may be made of the earthenware and glass trade of this province to within very recently supplied from British industrial sources alone, but now almost entirely superseded by the introduction of German earthen and glassware. The diversion of this trade is solely due to the persistence with which the British workers, in the face of warnings from their correspondents here, supplied obsolete ware, heavy in weight and ungainly to the sight; whereas the Germans introduced an article of less weight, and always of the latest modern design, this at once competing advantageously with the British wares in several essentials, viz., modern forms and patterns to meet the generally diffused desire for "novelty" and lightness of weight, to harmonise cost of production, transport freight, and custom duties, paid by weight. By not giving thought to these simple matters a lucrative trade has been lost to British industries in this province; and what has happened to the earthenware trade may also happen to other branches of trade if British manufacturers through remissness allow their foreign competitors to steal a march on them.—*South American Journal.*

SILK COTTON.

Kapok, an article which at present does not figure largely among exports of Straits produce is now drawing great attention in Australia. Notwithstanding the steady inquiry for it there, this product is so little known that, doubtless, fuller particulars regarding the article will not be without interest. Kapok is the Malay and Javanese name for the *Eriodendron Anfractuosum* and the *Gossampinus Alba*. It belongs to the Bombaceæ family which comprises the Baobab the largest tree yet known, the trunk being sometimes 90 feet in girth, and the Durian tree. Kapok also known by the name of silk cotton, was imported for the first time into Europe in 1851 for the Exhibition held in London, that year, where, however, little notice was taken of it. In Holland more notice was taken and that country continue to be the only market for the article, until its value began to be better known in the Australian colonies. At the Amsterdam Exhibition held a few years ago, greater interest was taken in it than in 1851, but yet the results so far as its importation into Europe was concerned, Holland excepted, proved discouraging. This is the more extraordinary now that the article has with a wonderful success secured a commanding position in the Australian market. The first consignment of Java Kapok arrived in Australia, fifteen years ago. Owing to the trade being then in the hands of Hollanders and natives, supplies were irregular, and insignificant, the results being that sales were confined to small quantities only. In 1881 on occasion of the Exhibition at Melbourne, there came thither the first shipments of Kapok from British India and Ceylon. The article met with a ready sale from its fitness for bedding and upholstery purposes. Since then it has been imported into that port increasingly, but a lively demand did not spring up until the firm of Catherwood Welby & Co. of that city with praiseworthy perseverance and remarkable good fortune, imported and disposed of the article in large quantities. This took place in 1884, owing to Mr. Catherwood, when passing through Ceylon, becoming attracted by the Kapok he saw. He at once perceived its economic uses and the future there must be in store for it. This improvement with respect to Kapok, was not without influence on the market in Holland where, in December 1884, not less than 12,000 bales of it were stored up in warehouses at the prompting of a ring to keep up prices, while dealers on their part were firmly determined to stand out against them in the hope that further shipments would compel merchants to ease down stocks. They reckoned without their host, for unexpectedly the said firm secured two-thirds of the whole crop. These circumstances will have a material effect in raising the price of kapok in this part of the world by the operation of the well known economic rule that whenever the demand becomes greater, prices are bound to rise. The rapid increase of importations of kapok into Melbourne may be judged of from the fact that they rose from barley 1,000 bales in 1881 to upwards of 8,600 in 1886, of which 7,995 were from Java valued at £22,600. These figures show the leading position of Java among kapok-exporting countries. From Ceylon so little of it is exported as to be almost inappreciable. Comparison between Indian and Java kapok brings out the fact that

the former stands immeasurably inferior. In bales imported from British India, good and bad kapok is intermixed, and as if this is not enough, all sorts of foreign substances, such as sand and other heavy materials, are added to increase the weight, so that the bales require to be opened as a security against fraud. Moreover the packing leaves much to be desired. The kapok packed by means of hydraulic presses loses that peculiar elasticity which renders it so valuable. Moreover, by hard packing uncleaned stuff, a dark coloured oil is expressed from the seeds which is suffused over the kapok and consequently stains it. From these disadvantages, Java kapok is free, it is always well packed, brilliantly white in colour, and springy. Judging from the particulars available so far, there is every prospect of kapok having a bright future before it, and there is little doubt that, with the invention of proper carding and spinning machinery, it will be used in the fabrication of articles of clothing, and prove a formidable rival to its allied substances. It has already been used for making gun-cotton, a substitute for beaver fur, converted into half-stuff for paper-making, making silk buttons and fringes, and by the Indians, who make beautiful fabrics of it. In Bombay, the fibre of the bark is used as a substitute for flax, and in Bengal the natives collect the milky juice as a substitute for shellac and gutta-percha. The seeds have almost the same value as cotton seeds, being exported to Europe to extract the oil and fetch from £3 to £5 per ton.

Such is the opinion of experts Should their anticipations be soon realised, a new and remunerative industry will be called into being which cannot but be welcome in these hard times. Kapok being an indigenous article, plantation enterprise may be better directed to its cultivation than to that of foreign products requiring acclimatisation before they can thrive. —*Straits Times.*

PAPER.

The following interesting article has been forwarded to us by a correspondent:—We live in an age of paper. There is not perhaps any manufactured article that is in more universal use; trade, finance, arts, literature, science—everywhere paper occupies the first rank. For us, journalists, it is a most valuable servant; we confide to it our impressions, which then pass, in the form of newspaper, reviews, pamphlets, books, etc., from the hands of the printer into that of the public. Never has the paper trade received such an impetus, and made such progress, as in the last few years. It is a common thing now to speak of paper bottles, paper collars, cuffs and shirt fronts, paper napkins and towels; paper wheels, rails, carriages, roofs; paper soles, hats; paper chimney stacks, and innumerable other objects and commodities made of paper. Have we not seen, within the last few years a paper-boat gaily cruising over the waters of many European countries? Have we not now luminous wall papers? The United States are now organizing festive celebrations in remembrance of the introduction of printing in America; this seems to us a fit opportunity to glance at the manufacture of paper—this all important factor in printing—and at some of the most important features in connection therewith. Leaving aside the continents of Asia, Africa and Oceanica, in regard of which our information is extremely imperfect, we shall cursorily look at the importance of the paper trade in Europe and the United States. Europe produces a million tons of paper per annum. In France alone, the annual production is 178,885 tons, representing a value of £4,832,400 and employing in her 516 factories no less 33,371 hands, of which 17,816 are men, 11,596 women, and 3,580 children. Great Britain, which in 1588 only manufactured a coarse wrapping paper, and purchased all her better papers in France, produces more than 200,000 tons of paper per annum. The first American paper mill was established in 1690 in Philadelphia, and the United States, which at the beginning of this century scarcely produced any paper at all, now makes over 500,000 tons per annum. The paper trade consumes 800,000 tons of rags per annum. Water paper, straw, wood, old rope, etc., are employed for making paper to at least the same extent. The money value of these ingredients may be estimated as follows:—

	£
Rags	15,200,000
Straw and Wood ...	800,000
Waste Paper, Esparto, etc.,	4,000,000
Total ...	20,000,000 per annum.

These materials produce about 1,500,000 tons of paper, costing forty millions sterling, or about the same figure as the amount of capital invested in paper making plant, machinery and works in Europe and the United States. Of these one-and-a-half millions of tons of paper, 120,000 tons are used as writings, valued about six-and-a-half millions sterling; 300,000 tons serve for news, periodicals, etc., 80,000 tons for books 120 000 tons for administrative, official and trade purposes. Including ink and labour, three above categories of printing reach a total value of sixty-nine-a-and-a-half millions sterling. Card and millboard reaches approximately 600,000 tons per annum, wall papers 60,000 tons, and another 60,000 tons for other descriptions, such as blottings, silk paper, filtering paper, etc., of a total value of twenty-four millions sterling. To blacken so much paper we use annually £800,000 worth of steel pens, costing on an average at the works about sixpence per gross, about the same value in printing type; 8,000,000 lead pencils, costing at the works about three shillings and four pence per gross. For every hundredweight of paper it takes one pound of printing ink: and more than 3,000,000 blocks and engraved plates are used annually for illustrations. If we take into consideration all the various branches of commerce depending from and consequent upon the paper trade we arrive at an amazing number of people to whom it affords a means of livelihood and entitles paper to the rank of a "universal provider." Nor is it only for the requirements of trade, writing, printing, packing, wall covering, tobacco, etc., that paper is employed for, we have now paper chimneys which we were wont to build of bricks and of a height of as much as thrity yards and upwards. We here refer to such a chimney erected at Breslau and made from paper blocks compressed under high pressure and intercemented by means of a silicious mortar. It has been observed that paper pulp compressed resists fire, and as a result we find paper doors recommended where there is danger of fire. The tests made at Breslau on the above named paper chimney have given highly satisfactory results in respect of solidity, elasticity and incombustibility, while in point of cost it compares most favorably with brick constructions. Even gas retorts are being made of paper, but gas itself may some day find itself encroached upon by paper. We will in conclusion and *apropos* of gas, say a few words on the subject of *luminous paper*, which is, unquestionably one of the most striking inventions of the age. There is no particular novelty in its manufacture; it is made in the usual manner, and no mystery whatever exists in the after process. It is composed of.—

Water	10 parts.
Pulp	40 „
Phosphorescent powder ...	10 „
Gelatine	1 „
Bichromate of potash... ...	1 „

Thanks to this bichromate of potash it becomes waterproof; the phosphorescent powder, consisting of sulphates of lime, baryum and strontium furnishes luminous properties lasting for months in succession, and we have only to hang our walls with this luminous paper to strike a severe blow at gas, candles, lamps, etc.—*Paper Makers' Circular.*

BOMBAY MANGOS AND OTHERS.

BY DR. E. BONAVIA.

A short time ago I was given some real Bombay mangos which had just come from that place. I was asked whether I had ever tasted a *real* Bombay mango. They were yellow with a red cheek. Of course I do not know whether they were the best, or

only inferior Bombays. The presumption is they were the former, as no one in his senses would think of sending inferior Bombay mangos all the way from that capital. I confess I was disappointed. They were not bad, but stringy, and inferior in flavour to scores of varieties we have in Upper India. One has heard so much of Mazagons and Alphonses, that one may perhaps have learnt to look upon them with a sort of awe. The notion that Bombay's surpassed all the mangos of the rest of India may have been true in the days of Clive, when communication between the coast and the interior may have been difficult, owing to want of roads, and the presence of thugs, dacoits, tigers, &c. And it is not impossible that by repetition over a hundred years that they *were* the best, this notion may have stuck to them, and that everything else out of Bombay was *jungle-mango*. If our up-country Bombays were really orginally brought from that place, it would appear that the flavour and texture of the children have far surpassed those of their parents. Anyhow there are so many choice varieties now in cultivation up-country that they can hardly all have owed their origin to the Western Presidency. If the people of Bombay were made aware of the wealth of varieties which are to be had in the Upper Provinces, and of the superiority of many of them, it is almost certain that a brisk mango trade would result between Upper India and Bombay.

When pears are being sent to Covent Garden from the Cape in capital condition, and when both pears and apples are being sent to the Colonial Exhibition from Australia over 14,000 miles of sea it is a great pity that no one has thought of making some arrangement to send over to the Exhibition samples of the choicest mangos of India—fruits, which, in the estimation of many, are far superior to the pears and apples of any part of the world. The mango bears being plucked under-ripe, and by refrigeration, could easily be sent to England *tale quale*, and there ripened to perfection, within a week. Nay more, it could be sent to New York, a sea voyage of only six days further. The voyage from Melbourne to Colombo takes now about 19 days, and from Colombo to London the voyage is longer than from Bombay to London. So that mangos could be carried from Bombay to New York in a shorter time than apples and pears can be carried from Melbourne to London. Of course at these places, an Indian, up in the art of mango ripening, which is simple enough, might be employed to bring them to maturity after arrival. If England and America were made acquainted with the choice varieties of this unique fruit, there is no knowing what stimulus a trade in mangos between Bombay and those countries would give to their cultivationall over India. There are positively scores of superb varieties.

Leaving, however, foreign trade out of the question, there seems room for an extensive trade between Upper India and Bombay. Someone recently returned from Bombay, told me that mangos there were selling at R6 a dozen. It is true the octroi duties may be high in Bombay, and it may be true that high rent is paid for fruit stalls in the Crawford Market: still R6 a dozen for mangos in Bombay is an enormous price, when up-country the choicest, in favourable seasons, sell for 20 or 25 for *one rupee*. It would be interesting to have it settled once for all whether the "Lingra" of Benares, or the "Tikari" of Farukhabad, or a dozen of so-called Bombay mango varieties grown in these Provinces, are not infinitely superior both in flavour and texture to any *native* Bombay or Alphonse mangos. If not, those grown in Bombay must be simply *angelic* as many varieties grown in these Provinces are *simply perfect*. Alphonse De Candolle, in his *Origin of Cultivated Plants*, says that "in the new world the mango was first introduced into Brazil, for the seeds were brought thence to Barbadoes in the middle of the last century. In Jamaica it was introduced about the year 1782. It is cultivated at the present day in tropical Africa, and even in Mauritius and the Seychelles, where it has become to some extent naturalized in the woods..... It was not cultivated in Cayenne in the time of Aublet at the end of the 18th century, but now there are mangos of the finest kind in this colony. They are grafted, and it is observed that *their stones produce better fruit than that of the original stock.*"

If the latter statement be true, it should be written in *large letters* in every village and town in India, where mango *baghs* of the fine kinds exist. I have preached for many that it is a grave mistake to throw away the thousands of stones of superb mangos that are consumed every year. Natives still believe that there is no other way of obtaining good mango trees excepting by taking *grafts*. This is so, if the *identical* sort of mango fruit is wanted, but it does not at all follow that a stone of a good mango will not give a *better* fruit than that of its parent. A little reflection must teach them that all the choice varieties they now possess could not have come about except through the seed of interior sorts, and these again from sorts interior to them and so on until we reach the wild mango of the jungles. Very rarely new varieties of *any* sort of fruit can be raised in any part of the world, excepting by means of the seeds which may give an inferior, an equal, or a *better* variety. Anybody who came across a fine mango would do a good service if he either planted the stone himself, or gave it to some one who would plant it. The Canal Department and public gardens, and jail gardens might do a great deal in this way by letting it be known that they would be glad to collect seeds of fine mangos for sowing. If some of the trees turned out inferior kinds and not worth keeping, very little would be lost, as such trees might be sold for firewood, while the good ones might be propagated by grafting.

Although India has missed the opportunity this year of showing the world at the Colonial Exhibition what sort of a thing a good mango is, and how many scores of choice varieties she might send to London and new York, there will be yet another opportunity of doing so shortly. It is proposed to hold either next year, or the one after, an International Horticultural Exhibition in London, and under any circumstances *that* opportunity should not be again missed. The Maharaja of Durbhunga and the Maharaja of Benares, who are great collectors of choice mango trees from all parts of India, and many other Rajas, Nawabs, and native gentlemen could easily send a representative collection of one of the finest fruits in the world. And if the supply could be kept up, as is being now done with apples and pears from Australia, so much better. Already Jamaica sends mangos to New York, but an American in India who knows them, told me they are not good. No country for many years could compete with India for the supply of choice fruit. She has had centuries in which to perfect her mangos, and if they took the fancy of the English and American people, a good business might be made of it.

It is stated that "in London there are *restaurants* to-day, where over a thousand dinners daily are served, wholly of cereals, vegetables, and fruits:" the vegetarian mania is still on the increase. What would not a vegetarian give for a breakfast of iced mangos and toast? Those who have not tried it had better do so, and see how delicious and satisfactory it is. —*Pioneer.*—[In Ceylon, where grafting is practically unknown, a good proportion of the mangos, are excellent.—Ed.]

A CONTEMPORARY notices that in the agricultural class book for use in schools about to be revised by Mr. Robertson, there is a chapter on insectivorous birds which that able ornithologist, Mr. W. Davison, of Shoreham, has contributed. The birds described in the work are figured in colors on separate charts to be used to illustrate the book. The ignorance of natural history among school-going children of the present day is profound, and some satisfaction is felt in learning that at last the Educational Department is alive to the importance of the subject. It is not only those who are trained to agriculture who should distinguish one bird from another, and be able to tell the proclivities of each, but young children generally should acquire early a taste for such knowledge, which is both elevating and moralizing.—*Indian Agriculturist.*

Correspondence.

To the Editor of the "Ceylon Observer."

NEW TEA ROLLERS.

Maskeliya, 22nd Jan.

"Mercy o'me what a multitude are here—
They grow still too, from all parts they are coming."
Shakspeare, Henry viii.

DEAR SIR,—The divine William is ever equal to the occasion, and on reading recently "Notes and Comments" the quotation heading this rushed through my brain.

But I do not think B——'s roller has continuity of roll, as however good it is, I don't think the inventor even claims that as one of its merits, as a certain break most occur between discharging and filling. Another new roller does its work continuously without the smallest iota of a break until all available leaf is finished. B——'s does not do so, the seller's to the contrary notwithstanding.—Yours,

THE MORE THE MERRIER.

TEA IN HAPUTALE: WELL DONE.

DEAR SIR,—I have no permission to use names, but I think an extract from a report of a well-known Colombo tea-taster and broker will show that the Kandapola side will prove second to no district in the quality of its tea, which may be of interest to some of your readers:—"I must congratulate you on the stride made in the manufacture. No. 1 is really a handsome tea, full of golden tips, very brght, good aroma &c. &c., may safely value it at 2s per lb. and No. 2, pekoe souchong leaf, bright flavory clean brisk liquor, value 1s 2d to 1s 3d per lb."

This is promising. I may add the break was a small one, but No. 1 was 4-5ths of the whole, and the plucking was an usual one. The proprietor will soon have near a hundred acres of the same jât to pluck from.—Yours, PLANTER.

THE DHOLL PLANT.

The Colombo School of Agriculture, 1st Feb. 1887.

DEAR SIR,—I have learnt with great pleasure that some of our goyas have made arrangements for cultivating dholl extensively and with a view to giving them an idea of how the cultivation can be best carried on, I send you for publication the following particulars about the plant. I may also mention here that this letter has already appeared in Sinhalese in the "Dinakaraprakashaya," a leading native newspaper:—

The dholl plant or rata-tora of the Sinhalese is not very uncommon in some parts of the island, although it is very seldom cultivated by our goyas. The botanical name of the plant is *Cajanus Indicus* and the common English name is Indian peas or dholl. The following account of this plant appears in the "Catalogue of the most interesting forest trees" &c. prepared by Mr. D. Morris, M.A., Assistant Director of the Royal Botanic Gardens, Ceylon:—"There are two varieties of this species. Both are cultivated in various parts of the tropics for the sake of their seed or pulse. In India the pulse is called dhal or dhol and forms a large part of the food of all classes of natives. In the West Indies the seeds are called Pigeon Peas and are highly esteemed as food. Horses and cattle are very fond of the young branches and leaves, either in a fresh or dried state. There are few tropical plants so valuable. It grows luxuriantly in the parched Savannah and mountain declivity, as well as in the more fertile and seasonable districts."

Dholl is a most nutritious and agreeable food and the seeds are said to contain more nutritious matter, bulk for bulk than meat. The seeds are also said to possess the property of counteracting fever and I have the authority of the Chairman of the Agricultural Association of Ceylon for this statement. In one of his letters addressed to the Colombo School of Agriculture, he had stated this fact and asked for a supply of dholl seeds so that he may distribute them among the inhabitants of those districts of the island which are subject to frequent attacks of fever. A large quantity of dholl has been grown in the Agricultural School compound. It takes about six months for the plant to grow and flower. The cultivation of dholl is carried on to such a large extent in India that a large quantity of the decorticated seed is also exported annually. The decorticated seeds which are sold in our boutiques under the name of "parippu" are generally dholl. The "parippu" is a Tamil name for any kind of decorticated grain, such as dholl, gram, &c. The roots and the seeds of dholl are used medicinally by the Sinhalese and it appears that the few plants which are to be found in some parts of the island are also chiefly grown for this purpose. It can be readily seen that dholl is a most suitable food for those who never take any kind of meat either by habit or by principle.

On the occasion of the prize distribution at the School of Agriculture by H. E. the Governor, I heard Mr. A. M. Ferguson, C. M. G., speaking about dholl cultivation and alluding to the "grand physique of the men of Northern India as a result of living on dholl porridge, dholl being largely cultivated in that part of India." Dholl will grow in almost any soil, cowdung is a good manure for the plant. A top dressing of lime will be found most beneficial for obtaining a heavy crop. I here describe for the information of our goyas the method in which this plant is cultivated in India and the seeds prepared for the market. First of all, the land is prepared just as our goyas prepare their lands for sowing gingelly, kurakkan &c., and the seeds are sown broadcast—about five seers of seeds are required for an acre. If the land is hard and unfertile it should be loosened either by ploughing or by digging and manured. In about three days the seeds will germinate. The plants are very tender when young. After the plants have grown for about six months, they blossom and when the pods get quite dry the trees are cut down to within a foot of the ground and carried to a suitable place where the grain is thrashed out with the aid of cattle. The seeds are afterwards soaked in cold water for a whole night and dried in the hot sun, which cause the testa or the husk to split and the cotyledons to separate. The husks are very easily separated by means of winnows. Dholl can be cooked just as the natives cook green gram or mun-eta. A little ghee added when cooked will make it an excellent curry. Excellent soup can also be prepared from the seeds.

The stumps which are left shoot up again and give a second crop. After the second crop is gathered the plants are pulled up by the roots and some other kind of vegetable is grown on the land, or it is allowed to lie fallow for a few months and dholl seeds sown again.

As dholl is such a nutritious article of food and is so easily grown as the above account shows, I hope that our goyas would be induced to take up the cultivation of this valuable food-plant in every part of the island.—I remain, yours faithfully,

H. D. LEWIS.

[The writer of this interesting and useful communication is Assistant Master of the Agricultural School, Colombo.—ED.]

COCONUTS.—A Coconut plantation in the West Indies, well established and in full bearing (say at the end of eight years), with sixty trees to the acre, may, says Mr. Morris, in his annual report on the public gardens of Jamaica, be safely assumed to be of the annual value of £10 per acre. The expense of maintaining a Coconut plantation, when once established, is practically nothing; hence the thousands of acres of land bordering the sea-coast of our West India possessions are capable of immense development.—*Gardeners' Chronicle.*

TEA AVERAGES.

The following are some of the averages realised during the month, according to the circular of Messrs. Walker, Lambe & Co., our list for December, 1885, ranged from 1s ½d to 2s per lb.

Garden	Broken Pekoe	Pekoe	Souchong and Pekoe Souchong	Broken Tea	Average Price
Budderpore, Cachar ...	...	10½d	7¼d to 8d	...	8½d
Chatali, Sylhet	...	9¾d	7¾d	9½d	9d

SIR M. E. GRANT DUFF'S REVIEW MINUTE.*

In a Minute written on the principle of the paper before us there was sure to be plenty of reference to Sir M. Grant Duff's favourite tastes and studies, and readers of his former publications would expect a great deal in it on the subject of botany. This part of the "Review Minute" is exceedingly interesting. The hilly country surrounding Ootacamund, the Simla of Madras, its alternative capital, is especially favourable to the cultivation of the new and now very numerous plants introduced of late years into India. South America sends most of them, and, as is beginning to be known in this country, almost all the recent additions to the pharmacopœia come from South America. It is now long since the cinchona began to be cultivated on the Neilgherries, and Sir M. Grant Duff speaks strongly of the success of the Government officials both in raising the tree and extracting the healing alkaloids from the bark. There is, however, some mystery about the matter. The price of quinine has not fallen in Europe nearly to the extent which might be expected from the great quantity of bark added by Ceylon, India, and the Dutch colonies to the old supplies from South America. There is probably some commercial reason for this unsatisfactory phenomenon.* It appears, however, from this Minute that the Madras official quinologists have been highly successful in producing a preparation of the inferior alkaloids of cinchona which is an energetic febrifuge and extremely cheap. It may be suspected of not being very palatable, but the extraordinary numbers of the vast Indian populations who suffer from ague would not reject even the most nauseous medicine if the reward of swallowing it were a cure. Another South American plant, producing a medicine of which the extreme value is beginning to be recognized in England, the coca, grows readily on the Madras hills, and so do various new food plants, also of South American origin. Among industrial importations, there are the two species of rhus which produce the Japan lacquer and the Japan wax, and the quillaia, or vegetable soap, from Chili. It would appear, moreover, that some curious experiments are being tried on the Neilgherry Hills not only in respect of new trees and plants and new modes of cultivation but in regard to new methods of making hitherto useless vegetable productions available for food. The silo appears to have a considerable future before it in India. A mischievous weed, the *bidens glabra*, which overruns the slopes of the Neilgherries, is found, after being treated in a silo, to be devoured greedily by cattle; and Sir M. Grant Duff tells us that the Madras Commander-in-Chief (presumably Sir Frederick Roberts) was of opinion that the prickly pear, the most intractable of vegetables to all outward appearance, can by treatment in the silo be made most acceptable to animals.—*London Times.*

* "Review Minute." By his Excellency the Right Hon. the Governor. Madras, Printed by R. Hill, at the Government Press, 1886.

* The phenomenon exists only in the imagination of the writer. Quinine has gone down about two-thirds in price, since Ceylon flooded the bark market.—Ed.

Tobacco Culture.—We are reminded by Mr. Worthington Smith (prophet of evil!) that it is quite within the bounds of possibility that living Tobacco plants may, in this country, fall a prey to the Potato fungus—Peronospora infestans. It has been recorded in England amongst the Nicotianeæ. A New Palm.—Professor Sargent has recently detected a new Palm in Florida, not only new as a species, but sufficiently distinct to constitute a new genus. Dr. Wendland proposing to call the plant provisionally Pseudo-Phœnix Sargentii. The trunk is 10-12 inches in diameter [near the base ?], and 20-25 feet in height. The leaves are 4-5 feet long, pinnately divided; pinnæ lanceolate, 12-16 inches long. No flowers, and only immature fruit was found, so that the plant cannot be fully described. At present only six individuals have been found. We extract these particulars from the *Botanical Gazette*, vol. xi., No. 11.—*Gardeners' Chronicle.*

"Bouquets under water" reads a little far-fetched, but the following description of the process from *Vick's Magazine*, by which a boquet of flowers can be preserved fresh for a long time may prove interesting to our readers:—"A vessel of water is required, the vessel should be large enough to allow the submersion in it of a plate or dish holding the bouquet to be preserved, and a bell glass, to cover the bouquet. The dish or plate should contain no moss or other material; the water should be limpid and quite pure. Place the plate at the bottom of the water, and on the plate, submerging it, place the bouquet, which is maintained in an up-right position by a weighed base previously attached to it. This being done, the bouquet is covered with the bell-glass, the rim of which ought to fit exactly to the flat part of the plate; the bell-glass should be entirely filled with water,

and without the least air-bubble. Then all are raised together, plate, bouquet, and bell-glass filled with water, and placed on a table, carefully wiping the exterior, but leaving on the plate, around the base of the bell-glass, a little provision of water which prevents the entrance of air. The flowers in this condition will be preserved in all their freshness for several weeks, and their beauty is increased by a great number of bubbles of gas produced by the respiration of the leaves, and which attach themselves to the petals appearing like pearls. The edge of the plate and the water that it contains should be concealed by a light bed of moss in which are set some other flowers. In the evening by artificial light, a bouquet thus arranged produces a charming effect."—*Indian Agriculturist.*

FAIR PAY FOR OCEAN MAIL SERVICE.—Although Congress failed to make fair provision for American vessels carrying freight mails, it is interesting to know that the business men of this city are in favour of fair play for ocean mail service. The following is a memorial sent to Congress on the question:—"It is applying the same principle to carrying the mails between the United States and neighbouring countries that is applied to our coastwise steamship lines and to our entire postal system, and which has given other nations the world's trade. Steamships build up their respective countries just as trunk lines of rail road do their respective termini. We have only about 6 per cent of the Spanish-American trade, which for contiguity and natural laws of trade would, with proper steam communication, naturally come to us. We are now carrying only 14 61-100 per cent of our own products, against 75 per cent in 1859. Our country needs an outlet for her products. The last steamer in the South American line took out merchandise manufactured in twenty-six different States. This is no party question. It is business common sense that if we would obtain our share of the world's trade, we must do as our competitors, do to obtain it. A cry of 'anti-subsidy' cannot fairly be applied to a proposition to pay American steamers a fair price for a necessary service. The same cry, if heeded, would stop three-quarters of the mail routes in the United States." This memorial was signed by the leading business men of New York, and particularly by houses interested in foreign trade. The number included eight bank presidents and 189 prominent importing and manufacturing firms.—*American Exporter.*

THE WORLD'S SUGAR PRODUCTION.—The statistics of the world's production of sugar show that there is a steady and large annual increase. The amount of cane sugar produced in the season of 1885-6 was 2,905,000 tons, an increase of 733,000 tons over that of 1884-5 and 1,078,583 tons over that of 1875-6. Cuba led the list with 600,000 tons this season, which was a falling off of 27,000 tons from the year before and 61,058 tons less than in 1875-6. There was also a decrease in the product of Java, the next greatest source of supply, of 60,000 tons from the yield of 1884-5. But in the production of almost all other cane growing countries there has been, as shown by the totals, a marked advance. The yield of beet-root sugar (2,014,000 this season) has fallen off 501,000 tons from the last annual report, but comparison with the statistics of 1875-6 show a growth of 702,689 tons in ten years. These reports do not recognize glucose and grape sugar, or sorghum sugar or maple sugar, and, are evidently made up from the basis of of commercial statistics concerning the sugar that has entered the market. Beyond this there are vast quantities of cane sugar produced for domestic use in all tropical countries and consumed by the producers and their immediate neighbours, which do not enter into the computation. The most notable increase in any country is in the beet root sugar yield of Russia, which has grown from 222,000 tons in the season of 1875-6 and 386,000 tons in 1884-5 up to 525,000 tons in 1885-6.—*American Exporter.*

FORESTRY AND BOTANY IN CEYLON, are thus noticed in an article on *Indian Forestry* by Surgeon-General Elward Balfour:—Ceylon has been equally progressive and though not politically forming part of British India, it may be mentioned, as it has a Forest Department of its own, and its Flora and Timber trees have been well described by Dr. Thwaites and Mr. W. Ferguson. In climate and flora it assimilates with the Peninsula. Dr. Balfour adds:—It is 50 years since Indian Forestry had a beginning, in the nomination of Dr. Gibson to the superintendence of the Bombay forests, and there is now needed from them one book bringing their knowledge of the forests and their trees up to the present time, and another as a handbook of Indian Forestry, arranged in parts, to admit of the region of British India being worthily described. The information in Drs. Stewart and Cleghorn's works on the trees of the Punjab Himalaya; in Stewart and Brandis' *Forest Flora of N.-W. and Central India*; in Mr. Kurz's volumes on the trees of Burma; in Mr. Gamble's *Trees of India;* in the third edition of Surgeon-General Balfour's *Timber Trees of India and of Eastern and Southern Asia;* and in Colonel Beddome's *Flora Sylvatica*, need all to be brought together in compact volumes. The financial results from establishing a Forest Department in India justify liberality in making its trees and forests better known. Its revenue has been continuously on the increase. Twenty years ago, in 1867-68, the gross receipts were stated at £334,000, but in 1883-84 they amounted to £1,052,190, and the clear profit in that year was £403,815.

The SWALLOW'S nest has always been a delicacy highly prized by the Chinese; but from an interesting report recently submitted by Mr. Portman, in charge of the Andamanese it appears that the high estimation in which these nests are held is not confined to the Celestials. It is not generally known that the Government derive a revenue from this source, of which they have a monopoly, as we learn that Mr. Portman was directed to "take charge of the monopoly of edible birds-nests and trepang," and he now furnishes some interesting particulars on the subject not generally known. The nests are as a rule found in caves, and as many as four crops may be gathered in a year, although three only were gathered by Mr. Portman. The birds begin to build in February, and the nests can be collected up to June, after which the birds are allowed to build for breeding. Each collection takes about a month's time, and the swallows rebuild in six weeks or so. The collections averaged about 52 lb of nests each. It is a regular industry in the Andamans, and many caves are known to the people of the islands. The Chinese obtain the most highly-prized nests, however, from Borneo, where they are also found in caves in the interior of the island in crystalline limestone rocks. Mr. Portman thinks that when the interior of the Andamans is explored, similar caves will be found, as this crystalline formation is common throughout these islands. There are many theories as to the composition of the nests, one being that the glutinous matter is extracted by the swallows from a species of sea weed somewhat similar to Iceland moss; another, that it is secreted from the throat of the bird; but Mr. Portman is unable to give any opinion in the matter. There are three kinds of nests found in the markets. The most highly prized are pure white, and fetch from R110 to 150 per viss of 3½ lb; another is slightly discoloured, and fetches from R100 to 140 per viss; the third is more discoloured and dirty, fetching from R75 to 115 per viss. The refuse also sells at from R5 to 15 per seer. The financial result of the edible birds-nest industry for the past season, shows a net profit of R4,000 paid into the treasury; the total expenditure having been R791. The manner of cooking these nests is thus described by Mr. Portman:—"They are first soaked in cold water for two hours, when they swell up and become soft. They are then easily picked to pieces and cleaned. After this they are boiled in clear chicken broth until dissolved, a process occupying about two hours longer. The usual allowance is one nest (value one rupee) to a tea-cupful of soup. Any clear soup may be used." Mr. Portman adds that the nest is absolutely tasteless and flavourless, and he has not found that it is particularly strengthening or useful in any way. We therefore conclude that it is not at all likely to become a favourite dish with Europeans.—*Indian Agriculturist.*

COLLYER, DAVIES & CO.'S REPORT ON FIBRES, FOR 1ST JANUARY, 1887.

The introduction of new or little known fibres has made but small progress during the past year; causes, however, are at work which will probably lead to an important increase in this department within a comparatively short period. Further improvements have been made in machinery for extracting, which can now be had to suit the requirements of any locality at very moderate prices. The greatest practical difficulty seems to be the necessity in most cases of cultivating the plants required for treatment; generally speaking, the plants are too widely separated when growing wild for economical extraction on a large scale. As the average yield of fibre is only about three to five per cent of the weight of the green material when cut, the carriage of the latter to the machines is in many cases too costly, and therefore the concentration becomes a necessity. The most promising varieties of plants for cultivation are as follows:—

Rhea or Ramie (*Urtica Nivea, Tenacissima &c.*)—The China Grass of commerce, for textile uses, grows, or can be grown in most subtropical and warm temperate climates where there is sufficient rainfall. Value of China Grass £36 to £38 per ton.

Moorva (*Sansaviera Zeylanica, &c.*)—For fine twines for netting and cordage. This plant is also very widely distributed in Asia, Africa and West Indies, of several varieties. Value £25 to £35 per ton.

Wild Pine Apple (*Bromelia Silvestris, &c.*)—The varieties growing in West Indies and Central America yield a remarkably good fibre for cordage, and some of the edible kinds yield a fibre adapted for textiles. Sooner or later pine apple fibre will become an article of considerable importance. Good samples have also been received from Southern India. Value £20 per ton and upwards.

Calotropis Gigantea (or *Mudar*) yields a fine fibre, but it is very difficult of extraction. The flocs (or seed covering in the pod) when gathered at maturity is in good demand. Value, when free from seed, about 6d per lb.

Manila Hemp.—This improtant staple has been in steady demand throughout the year. Opening prices in January were—for good roping £31 10s to £32, fair £29 10s. Market opened dull, and values declined during February and March to £28 to £29 for good and £25 10s to £26 for fair. In April and till about the middle of May prices advanced to £31 10s to £32 for good and £30 to £31 for fair, but fell away again towards end of the month, and in June quotations fell to £29 10s to £30 10s for good and £28 to £28 10s for fair. The world's consumption January to June was fully equal to the production, say about 200,000 bales, London stocks falling in the same period from 18,686 bales on 1st January to 15,285 bales on 1st July. From July to December inclusive fluctuations have been small, rarely exceeding 10s to 20s per ton, and close at £32 10s for good and £30 10s to £31 for fair, with a firmer tendency.

The fluctuations in arrival values have been much more important, this hemp being a favourite medium for speculative operations. Shipments to United Kingdom to 13th December, 162,000 bales, against 177,000 last year; to United States to 13th December, 161,000 bales, against 190,000 last year.

Consumption for 12 months 174,000 bales.

Sisal Hemp (Mexico). This hemp has shown a greater change in value than any other fibre during 1886. Prices were unduly depressed for a considerable time, and continued to decline until the middle of March, when London value was £17 5s. to £17 10s. per ton; from this date prices gradually advanced till end of June, being then £18 10s to £19.

In July, owing to the largely increased consumption in America, where, by improved processes of manufacture, this fibre is now used instead of the finer and more expensive kinds of Manila hemp, prices rapidly advanced £3 to £4 per ton, and this advance, with a few unimportant fluctuations, has been maintained and increased, the price in December, £27 to £27 10s being the highest of the year.

Stock on 1st June, 1886, were 5,300 bales.
" 1st Dec., " " 1,470 "

New Zealand Hemp.—There has been much less variation in the price of this hemp than might have been expected from the advance in Sisal. Import restricted by the high cost production—the year opened with small stocks, 142 tons against 583 tons in previous year, following a reduced consumption in 1885 of 700 tons against 1000 tons in 1884. Value in January of fair to good £20 to £24, and common £18 10s. to £19 10s., prices fluctuated very slightly during the year, closing about £1 higher, consumption for 11 months estimated at about 545 tons. Stock on 1st December about 44 tons against 157 tons last year. Consumption in 1886, 565 tons.

Mauritius Hemp.—The supply during the year has been fairly regular without any great fluctation in prices closing with a firmer tendency. Stocks small good white about £28, fair £26 17s., common £21.

East India Hemp.—Calcutta Sunn.—Supplies have been very small, and prices high all through the year until December, when the new crop arrived in bulk. Shipments being ample, and quality unsatisfactory, prices have receded to about £17 15s, and still lower prices are probable.

Godavery Hemp of good quality has been in steady demand at full prices, closing at £25 to £27 per ton.

Gopaulpore Hemp.—Supplies have been fair, and prices well maintained. New crop offering at £19 to arrive.

Coconada Hemp.—Very little change during the year Prices about £17 to £18 per ton.

Consumption of all kinds of east India hemp in 1886, 1,826 tons.

Jute.—The year opened with stocks on spot and afloat to the United Kingdom of 92,000 tons against 119,300 in 1884, and with a dull and drooping tendency, prices ranging from £11 to £12 15s for medium to £13 10s to £15 10s for fine; but shortly after market improved, owing to greater firmness in Calcutta, fully 10s per ton, and remained fairly steady with slight fluctuations till May, when unremunerative trade led to the closing of several factories—and with increasing stocks prices fell fully 10s per ton, and continued weak during July and until the latter end of August, when a slight improvement took place, which was maintainsd during September and October. Prices were rather easier in November; but during first half of December, market became firmer, and closes with a better prospect. Stocks here and afloat on 1st December, 78,880 tons of jute and 2,110 tons of cuttings.—Collyer, Davies & Co., Fibre and Colonial Brokers, 141, Fenchurch Street, London.

CORAL FISHING.

Though Naples, or at least Torre del Greco, is one of the great centres of the coral trade, the material found in the gulf is both small in quantity and poor in quality. They are submarine rocks, well known to the fishermen, though they are laid down on no chart, where a peace or two may almost always be found; but they are so few, and their yield is so precarious and meagre, that by a private agreement among the boat-owners each of them is only fished once in every three years. There can be little doubt that other and more fruitful fishing-grounds are still undiscovered. In the opinion of many who ought to be well informed, wherever a rock rises above the sediment which forms the ground of a great part of the bay at a depth of about three hudred feet or more from the surface, the chances are that coral will be found upon it. The discovery of such banks has hitherto been almost entirely the work of chance. When a deep-sea fisher found a branch among the refuse of his nets, he gave information to the proper authorities, and received a reward proportionate to the value of his find. It was thus that the great bank of Sciacca, on the coast of Sicily, was discovered, of which we shall have to speak further on. But, though new fishing-grounds may be found in the Bay of Naples

itself, it is not likely that they will have any great importance.

The value of coral depends on its colour and its size. The white or rose-tinted variety stands highest in popular esteem, perhaps chiefly because it is the rarest. It is mostly found in the Straits of Messina, and on some parts of the African and Sardinian coasts. The bright red coral, in which the polyps are still living when it is fished up, stands next in value. Dead coral has a duller tint, and is consequently sold at a lower price. Two entirely different substances bear the name of black coral. One of them is not, properly speaking, coral at all, and it is commercially worthless, as it breaks into flakes instead of yielding to the knife, though it is often sold as a costly curiosity to foreigners. The other is the common red coral which has undergone a sea change, probably through the decomposition of the living beings that once built and inhabited it. It is not much admired in Europe, but in India it commands high prices, so that large quantities of it are exported every year. These are the four important distinctions of colour, though they of course include intermediate tints which rank according to their clearness and brilliancy.

The size is a still more important matter. The thickness of the stem of the coral plant—we use the commercial and entirely unscientific expression—determines its price, and many a branch of red coral is valued more highly on account of its thickness than a smaller piece of the choicer rose colour. The reason for this is clear. A large straight piece of material affords an opportunity to the artificer; a crooked one, if it is only bulky enough, can at least be turned into large beads; mere points and fragments can only be used for smaller ones, or made into those horns which are said to be invaluable against the evil eye, but which do not command a high price in the market, perhaps because it is overstocked.

The coral fishery of Naples has now for the most part, fallen into the hands of a few wealthy firms. Formerly fishermen would club together and try their fortune on co-operative principles, but this system has almost entirely died out. A few single *padroni* still remain, but their exertions are entirely confined to the gulf. They are usually men of experience who can decide how the net is to be laid and drawn, and who hold the guiding rope in their own hands. The boat and the nets are theirs, and they pay their subordinates a fixed sum to serve under them for one or two days. The whole yield, under these circumstances, of course belongs to the padrone. The larger firms could make an end of these boatmen easily enough, but it is not worth their while to do so. The yield of the gulf is comparatively small, and houses that possess from ten to thirty large boats of their own find it more advantageous to purchase the rough material from the local fishermen than to crush them by a cruel and irresistible competition, as they train the men, who are afterwards employed in expeditions to a distance.

The instrument with which the coral is taken consists of two strong beams of hard wood, which are fastened together in the form of a cross by metal claspings, to which a weight is added. Strong hempen nets are fastened to the arms. When a bank is reached this primitive instrument is lowered, and moved up and down against the submarine rocks by means of a capstan turned by the whole of the boat's crew, except the padrone, who directs the movement of the apparatus by means of a second rope which is attached to the chief one some feet above the point where the latter is secured to the centre of the cross. The coral branches are caught in the meshes of the nets, and remain hanging in them. Those that are broken off by the wood work and are usually lost. In some places, especially on the cost of Sardinia, the end of the arms is surmounted by a circle of curved iron teeth, like those of a garden rake, but larger and stronger, below which open nets are suspended. In this case the beams are nearly double the length of those generally used by the largest boats, as they often measure six or seven meters—that is, nearly eight yards from end to end. It is only by this means that coral can be obtained from the lower surfaces of shelving rocks; but the teeth are apt to fracture the stems in such a way as to render them almost worthless; and so this form of the instrument is rarely used where the other can be employed.

The banks, or rather rocks, that are most frequently visited lie at a depth of from 250 to 450 feet below the surface of the water; it is very rarely that an attempt is made to reach those which are lower than 600 feet. Indeed, it lies in the very nature of the case that, even if they exist, they should remain unknown, and that, if they were known, they would hardly repay the cost of fishing while it is conducted on the present system. They are scattered all along the coasts of the Mediterranean, sometimes close to the shore, and sometimes at twenty-four, or even thirty hours' hard rowing from it. At many stations there is a small local fishery; but the bulk of the trade, at least in Italy, is in the hands of large firms, which, for the most part, have their centres in Genoa, Leghorn, or the Bay of Naples. These firms both supply and equip the boats, which, according to their size, are manned by five or ten fishermen. In addition to these a padrone is alloted to each, who exercises large disciplinary powers. He is a man of knowledge and experience, and usually receives a a percentage on the value of the season's take, as well as his regular pay. The selection of the crew of his boat is often left entirely to him; he is always consulted with respect to it, and enjoys a right of veto. The men are hired for the season, by agreement, for from sixty to seventy francs a month, a large part of which is usually paid beforehand, and their food, which is of the coarsest kind. As a rule, the season lasts from April to the end of September, but it depends greatly on the weather, as fishing is impossible in mist or when the sea is high.

The labour is exceedingly hard. At dawn the padrone calls his men and, after a short prayer, the net is lowered; from then till sunset the work continues almost without interruption. The exertion required to let down and wind up the net under a blazing summer sun is extreme, and it has to be done on ship-biscuit of the coarsest kind, and water that on the more distant stations has often become foul by long keeping. In the evening a sort of soup is made. Garlic and peperoni, the pungent fruit of a southern plant, are boiled in water; olive-oil is added, and this is poured over biscuits which have been broken and placed in the dish. For months this diet is hardly varied, and yet the men retain their good spirits. After the evening meal has been taken, they indulge in guitar-playing and singing, and on the more frequented banks the boats answer and vie with each other.

In 1878 the discovery of the Sciacca bank, which lies at a considerable distance off the southern coast of Sicily, roughly speaking between Girgenti and the island of Pantellaria, caused a crisis in the coral trade. At one time nearly a thousand boats might be found fishing there, and seeming to form a city in the midst of the sea. Each of these is said to have taken between one and two hundredweight of coral a day. It is certain that within three years 88,000 German centners were taken from this bank alone. A great part of this coral was dead, and much of it was of the black colour that only finds purchasers in the East. The large firms did everything in their power to prevent the market being overflooded. Many of them still retain hundreds and some thousands of cases which have never been placed in the hands of the artificers. Still the price fell, and it is only at a considerable sacrifice that the greater houses still keep their boats at sea and the workshops open; but they know that, if they let them fall, the fate of their old competitors in Marseilles awaits them, for both the fishing for coral and its treatment by the artificers depend upon traditious which, when they have once been lost, it is difficult to revive. One of the matters of general interest which the bank of Sciacca placed clearly before those who were interested in it from other than a mercantile point of view was the fact that not only were dead and live coral there found side by side, but that in many cases the latter was growl

ing on the former. Signor Lo Bianco spent several days on one of the boats for the purpose of inquiring into this and other scientific matters. Few men possess a keener eye for such sides of nature, or have enjoyed so good an opportunity of training and regulating it as his connexion with the Zoological station at Naples has afforded him. In his opinion the original bank was submerged by volcanic action, and the mud killed the mature polyps. The germs and larval forms, which still existed in the water, settled upon such branches of dead coral as still rose above the sediment, and so began life anew. If he is right, the Sciacca is a kind of submarine Herculaneum. There is not likely to be any immediate improvement in the coral trade. As soon as prices rise, the large firms will be tempted to sell a part at least of the stock they have hitherto reserved in the hope of better times. If he depression lasts, they may be compelled to do so, which would lead to a further fall. This can have but a small interest for the general public, but the sight of the boats whose crews sail or row for long distances without the aid of a compass, guided only by the stars or the glimpse of some distant headland, and in their fishing employ instruments which are said to have been hardly modified since the days of the first Roman Emperors, may suggest a summer afternoon reverie.—*Saturday Review.*

ANOTHER INSECT SCOURGE.

The following has been addressed to the editor of *The Argus*:—

Sir,—I desire to call attention to a species of coccus known as dorthesia. This destructive pest was first observed in the island of Bourbon. Thence it spread to Mauritius, about 25 years since. In Mauritius it destroyed the orange and lemon trees, many of the ornamental shrubs and acacias, and wrecked most of the beautiful plantations and shrubberies. At Port Louis it still exists in loathsome masses on the handsome Talipot palms.

About 12 years ago in was noticed for the first time in the Botanical-gardens, Cape Town, and most probably arrived there from Mauritius with plants sent to the Botanical-gardens. During the first summer it spread about three miles into the suburbs along the railway. Its fearfully destructive character now became evident, for the orange trees, the Australian wattles, the pittosporums, and the blackwoods became loaded with this disgusting parasite, and the trees slowly but surely succumbed to its attacks.

Its vast powers of increase and its peculiar structure rendered all attempts to check its progress unavailing. The adult female dorthesia is about one-third of an inch long, and is furnished with a pair of white fluted wings, similar in form to those of the cicada. Underneath these wings the body appears to be one mass of ova, comprising hundreds of individuals. Syringing, &c., failed to reach this ova, and although the adult dorthesia was sometimes reached and killed, the young escaped, and they are so light that a breeze scatters them far and wide.

All trees of the orange kind, such as lemon, citron, shaddock, &c., proved especially suitable food for the dorthesia, and once a tree became infested no amount of syringing or washing prevented its destruction. The disastrous results of its arrival at the Cape are all too evident.

Formerly in Cape Town itself, and throughout the suburbs, the orange tree lent a charm to the gardens that no other tree could give, and in the Western Province orange-growing form a most important source of wealth, many farmers netting several hundreds a year from their orange groves. Some of these groves, planted by the Huguenots and their descendants, were of great age, and besides being profitable, were objects of great beauty. Those of the Pearl, French Hock, and Wagenmaker's Valley were especially famous.

To-day this is all changed, and except for a few dead stumps these fragrant groves and this valuable asset in the country's wealth have disappeared.

Not so the dorthesia; it is still advancing steadily, and leaving destruction in its wake, and will continue to do so as long as suitable food is within reach. This plague appears to enjoy a wide range of food, for I have seen medlars, pear trees, oaks, quinces, and many other trees smothered with it. It crowds the stems and leaf-ribs of the pittosporum, the wattles, the Cape plumbago, and the pomegranate. Strawberry plants become so covered that the fruit cannot be eaten. French beans and many vegetables also suffer from its ravages, besides roses and many garden flowers. Vines are slightly affected.

Now, sir, this dorthesia has appeared in Melbourne. Yesterday, at Mr. Guilfoyle's request, I accompanied him to the Customhouse, and indentified the coccus covering the two pittosporums at the entrance as dorthesia. I wrote some weeks ago to the Agricultural department, urging that every precaution should be taken to prevent its introduction, as there was great risk of its being brought from Mauritius.

As it is already here, and it has proved so destructive elsewhere, I think it the duty of the authorities and of the public to use the most strenuous efforts to cope with it before the advent of warm weather. Every particle of vegetation affected by this scourge should be destroyed by burning. It is also desirable that a short bill should be introduced to deal with this and similar noxious insects that may reach these shores.

The shrubs of Melbourne are beautified by trees and shrubs that are particularly liable to attack, and the total extermination of the orange, pittosporum, wattle, and other trees is certain to ensue in a very short period, unless the dorthesia is stamped out.

—I am, &c. E. J. DUNN.

Referring to Mr. Dunn's letter Mr. A. N. Pearson, the Government agricultural chemist, who has had much experience as an entomologist, writes:—

"Some cuttings of the pittosporum trees in front of the Custom-house were shown to me about a month ago by a gentleman who was experimenting with some fluid which he hoped would kill certain insects that were found on the plant, and I was asked by the secretary of agriculture to state whether or not the insects were dead. I had not previously seen these insects. They were, however, of the coccus family and from the description given in Mr. Dunn's letter I should say they were the dorthesia he speaks of. There seems to be some mistake, however, in Mr. Dunn's description. The mature females of all the coccidæ, so far as I know, are wingless; the males have wings similar to those of the cicadas (the insects commonly called locusts); but in Victoria the body of the female becomes a mass of eggs in nearly all cases, little remaining of the original insect beyond a mere shell or skin covering the eggs beneath. In the dorthesia known in England, however, the mother does not become so completely absorbed into her offspring as is case with most of the other members of the family. All members of the family of the coccidæ which are likely to visit the shores of Australia may, with very little risk of error, be set down as noxious and warranting immediate destruction, even at the cost of some-what drastic measures. All who have anything to do with orchards know what a pest the scale insect is; and many insects commonly called "blights" are members of the coccus family. I have not heard of this particular dorthesia before; but species of dorthesia are known in England, and one member of the coccidæ family, if I remember rightly, was the cause of the destruction some years ago of all the orange trees in one of the Azores, where the growth of oranges was the main occupation of the inhabitants. The surest way of destroying these insects is to burn the branches on which they are found, and I learnt this evening that the two pitto-sporum trees in front of the custom-house, on which these insects had been found, were saturated with kerosene and completely burnt, so that unless the dorthesia has spread from those two trees it no longer exists in Melbourne. The insect which was shown to me was boat-shaped, varying in size from a microscopic object to one-third of an inch in length, dirty grey on the back, red under

neath, with little nearly black legs, almost hidden under the body. The whole insect is covered over with a thick cottony excretion. It adheres to the younger branches and twigs, from which it sucks the juice. I think that from this rough description anyone else who should happen to meet with the pest may be able to recognise it. With regard to Mr. Dunn's suggestion that a short bill should be introduced for dealing with the introduction of noxious insects, were a Government entomologist appointed, as suggested in the articles on "Economic Entomology" which you published, it could be his duty to attend to the inspection of all plants and seeds passed through the Custom-house. But any action in this direction on the part of Victoria would be of little use unless there were united action by all the colonies. The matter is undoubtedly one of great importance.

A TRIP TO CHILAW.

The bank *pongol* holidays with two other additional days, enabled me last month to visit Chilaw where I have some precious possessions. We left by the morning coach to Negombo, a road in which there is nothing particular to note, save a coconut tree in bearing, the trunk of which has grown in the shape of the letter O, and a double-headed arecanut tree, both on the roadside near about the town. An engraving of this extraordinary coconut tree appeared in the "Ceylon Miscellany," which has ceased to exist, not for want of supporters but for want of contributors. Such has been the fate of every ephemeral production in Ceylon that depended upon unpaid help from the public.*

The road to Chilaw is lined by teak and Banyan trees, and is kept in good order; we skirted the canal as far as Madampe.

All round the town of Chilaw, tobacco was being transplanted from nurseries into gardens. This plant is cultivated, first by heavily manuring the ground, and then watering it twice a day during the dry months of the year. It is harvested about April and when cured becomes a valuable commodity, 50 leaves of the first quality being worth from R4 to R5. The leaf is exceedingly brittle when green and cracks on a slight touch, which is, therefore, carefully guarded against and the roots are so sensitive that if they encounter a stone or a stump, the whole tree withers and die.

The cattle here are miserably lean, there being no pasturage; but the coconut trees in this district are *par excellence* the best in the island, both from their size as well as their fertility, although I was told that some years ago *thousands* of trees were killed by drought.

The friend who accompanied me is a coconut planter of the Colombo district, who grew quite enthusiastic on the subject, comparing the worst Chilaw tree with the best in his plantation.

There is plenty of water communication inland, and splendid opportunities for boating and sailing &c. An adventurous proctor was about to order an English boat from Colombo for his own use.

NEPHTHYTIS LIBERICA.—At present this rare Aroid is somewhat attractive in the Aroid-house at Kew. The heads of bright yellow fruits—each of which is about the size and shape of a small Coffee berry—are borne on erect scapes nearly as long as the petioles of the triangularly sagittate green leaves. The species was introduced from Liberia half-a-dozen years ago.—*Gardeners' Chronicle.*

THE "PIONEER" ON THE CEYLON TEA INDUSTRY.—Returns for 1886 published in last mail's *Economist* show that tea is rapidly taking the place of coffee as the main export staple of Ceylon. Since the appearance of the leaf fungus the cultivation of coffee has steadily declined, and last year the exports fell by over 90,000 cwts. On the other hand the exports of tea rose last year by over three million pounds, or more than 50 per cent., and an equal proportionate increase is estimated for the current commercial year. These facts are of considerable interest to Indian teagrowers. The Ceylon exports are, of course, at present a mere fraction of the amount shipped annually from Calcutta; but when we remember that the Ceylon trade is in its infancy compared with the Indian, that the former's annual advance is at the rate of 50 per cent while for years the latter has been creeping on with 7 or 8 per cent, and that the natural advantages of Ceylon enable it to produce tea of a stated quality more cheaply than can be done on the Indian plantations, there is abundant reason for believing that in ten years or so Ceylon will prove a serious competitor to India in the European market.

WATTLE AND TANNIN.—Some few months ago we mentioned the discovery, by Messrs. Borrow and Haycraft, of South Australia, of a method of extracting the tannin principle not alone from the wattle-tree bark, but also from the leaves, twigs, and small branches of 2 in. diameter. The cultivation of the wattle is now a recognised industry in that colony, and also in Victoria, fully 10,000 tons of the dried bark being annually exported from Adelaide to Europe. In another column we give an account of the process of manufacture, as reported in the *Register*. It is interesting for the success of the process is so complete that there is no doubt it will ultimately develop an extensive export trade of a purely Australian product. Of the two sorts of wattle commonly used for tanning purposes, the *Acacia pycnantha* will grow on the poorest soil, sandy or stony land, that is fit for nothing else, but the black wattle (*A. decurrens*) requires a deep rich soil. This latter species contains 30 per cent to 40 per cent of tanage in the dried bark, and 1½lb. of this bark is equal to tanning 1 lb. of leather, whilst it requires but 1 lb. pound of bark oak for the same purpose. One ton of black wattle bark will tan from twenty-five to thirty hides, and it has been found best suited for tanning sole leather and other heavy goods. The disadvantage of this bark is that it gives a red colour to the leather, which is not the case with leather made by the use of oak bark' myrabolans, valonia, and sumach, &c. The leather is quite as good and durable as when oak bark is used. The mature bark of our golden wattle yields about 30 per cent of catechu (tannic principal), about one-half of which is mimosa-tannic acid. The fresh leaves contain only 5 per cent of tanage, and when well dried give from 10 per cent to fifteen per cent. It has been estimated that the waste in stripping a wattle forest amounts to four times the quantity obtained, for in stripping as now practised the bark is only taken from the trunk and a few of the main branches. The *Register* calculates that at this rate this waste if converted into "tanage" would represent some 5000 to 6000 tons, worth five or six times the same weight of wattle-bark. "Tanage" is the name given by the manufacturers to their new product, so as to distinguish it from similar products known to tanners as "cutch" catechu, &c. Being a new industry, it is necessary first of all to find an outlet for the product, and the makers have discovered that in the tanners' business there is as much conservatism as in other trades. In the colonies the tanners are used to wattle-bark, and it is within the mark to say that it will be exceedingly difficult to induce them to give up their prejudices and adopt the extract. In Europe, however, the tanners are acquainted with a hundred or so of materials for tanning leather, and there will be no difficulty in inducing them to adopt another—especially since the imports of oakbark, hemlock-spruce, &c., are decreasing, and those of gambir, terra japonica, sumach, cutch, &c., do not increase, whilst the demand has more than doubled with the past few years. In 1823 a fluid extract of black wattle (Acacia decurrens) was sent to England, and was sold at £50 per ton.—*Queenslander.*

ALCOHOL FROM SWEET POTATOES.—French chemists have been at work in the French Antilles making a series of successful experiments, showing that the sweet potato can be made to yield nearly four gallons of alcohol to 225 pounds of sweet potatoes.—*Oil, Paint and Drug Reporter.*

* Yes, but where were our correspondent's eyes when he failed to admire the many beautiful reaches on the road to Negombo, with coconut palms and other trees meeting overhead. There are also cinnamon gardens, rivers, pretty native cottages, &c.—ED.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, January 20th, 1887.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White, per cwt.	Slightly softish to good hard bright	£6 a £7 5s
Yellow	Do. drossy & dark ditto	£4 10s a £6
CINCHONA BARK—Crown per lb.	Renewed	1s a 3s
	Medium to fine Quill	1s 4d a 2s 6d
	Spoke shavings	6d a 1s 2d
	Branch	2d a 6d
Red	Renewed	3d a 2s 6d
	Medium to good Quill	6d a 2s 6d
	Spoke shavings	3d a 7d
	Branch	2d a 4d
	Twig	1d
CARDAMOMS Malabar	Clipped, bold, bright, fine	2s a 3s 1d
per lb. and Ceylon	Middling, stalky & lean	3d a 1s 11d
Aleppee	Fair to fine plump clipped	1s 3d a 2s 3d
Tellicherry	Good to fine	1s 6d a 2s 2d
	Brownish	6d a 1s 3d
Mangalore	Good & fine, washed, bgt.	1s 4d a 3s 4d
Long Ceylon	Middling to good	8d a 1s 4d

THE TEA MARKET FOR 1886.

We devote large space in our present issue to the elaborate review of the course of the British market for teas during the past year. The year was notable for the collapse of fine China teas, notwithstanding an improvement on the past season which is described as "vast." This seems to establish the fact that, even with the most careful preparation possible, China teas cannot compete in intrinsic value with those from India and especially those the produce of Ceylon. The figures for consumption now that, they are brought up to the end of 1886, prove more strongly than ever the large and increasing extent to which Indian teas are superseding those from China in public favour and in the markets, while Ceylon teas, so far as the comparatively small quantity yet produced shews, are ahead of all in the market. Looking, however, at the figures for total consumption in Britain, they are not so encouraging as could be wished. From 139½ millions of pounds in 1874, there was an advance to 174 millions in 1883, but the average for the succeeding three years has but slightly advanced. The highest figure ever attained was 175,203,000 in 1885, but the quantity recorded against 1886, shews only 174,665,000. Owing no doubt to the prevailing depression, the consumption of tea in Britain has been nearly stationary for four years. If war can be averted and trade improves, we may expect to see an increased demand. The great facts for planters in India and Ceylon are that whereas the percentage which their teas bore to the whole consumption in 1874 was only 12¾ it rose to 42¾ in 1886, and that in the 5 years between 1882 and 1886, while China shewed a decrease of 11 per cent, Indian and Ceylon increased by 48 per cent. The actual figures will give a more vivid idea of the great and rapid increase the consumption of Indian kinds, viz. from 17¾ millions of pounds in 1874 to 74,665,000 in 1886. This process seems likely to proceed at an increased ratio, so that before a total consumption of 200,000,000 lb. is attained one-half will be Indian and Ceylon. The deliveries of Indian teas (excluding Ceylon) are now up to an average of 7 millions per mensem. The average for Ceylon was a little over half-a-million for 1886, but the actual deliveries had increased from 285,000 in January, to 471,000 in December, the highest figure yet, 818,000 having been attained in August. There can be little doubt, we think, that for 1887 the average monthly deliveries of Ceylon tea will rise to 750,000 lb. The prices for our teas have, we regret to notice, decreased from 1s 2¾d and 1s 3¼d to 1s 1d; but the latter figure will pay well and with increasing care in preparation here and increasing prosperity at home we may hope for keener competition and higher prices for our teas, which now take the highest position in Britain and are finding favour on the Continent of Europe. They will ultimately make their way in America.

STENNING INSIKPP & CO.'S INDIAN & CEYLON TEA MARKET REVIEW FOR 1886.

LONDON:—29, MINCING LANE, Jan. 1887.

THE COURSE OF THE MARKET.—The steady tone that prevailed at the closing sales of 1885 soon gave place to dulness and lower values. Common kinds attracted some attention for a time, but prices fell again in April and medium sorts likewise showed a decline. Broken Pekoes had been difficult to sell even at very low prices since the beginning of the year, but in May their position improved. Just prior to the arrival of the New Crop, fine Teas, being scarce, commanded more money, whilst low and common grades went weaker. New Darjeelings proved of poor quality and obtained low prices; a parcel here and there having flavour sold well, but Ceylon Teas again affected the value of Indian growths. Late in August, owing to some improvement in quality, more attention was given to New Indians, and also to Teas for price at a slight advance, which was maintained for a short time, but on heavy arrivals of poor quality taking place at end of September, a decided fall occurred, and only very low prices for all but fine and finest could be obtained. October opened with a steadier feeling, but inferior Teas being offered, the month closed with a further fall, whilst good liquoring Tea from Assam sold at high rates. Heavy auctions then occurred, and values, chiefly for Broken kinds, again fell, whilst former prices were with some difficulty obtained for the finer grades. Afterwards, for a time, less pressure to sell was shown, but towards the close of business for the year considerable sales took place, and with the exception of common to medium whole leaf, which sold firmly, all Teas marked a giving way, Broken Pekoes being quoted at a decided fall from the highest point.

Present Prices are much below those ruling at end of 1885: common to the extent of about 3d per lb.; medium, about 4d; fine and finest, a little below to par.

The season has been generally unfavourable for the grower, except in the case of some Assam Gardens, which were able to produce a fair quantity of desirable liquoring tea, but in other gardens in this district, as well as in Cachar and Sylhet, the mistake has, apparently, been made of aiming too much at quantity, notwithstanding the repeated warnings from this side. In our Annual Review of 1885, and again in our Circular of 25th March, 1886, we particularly drew attention to this point, viz.: "Season 1886 87. A word of caution to planters at this time may not be out of place, and we would urge, as we have often done before, the advisability of adhering to *a moderately fine system of plucking*. The comparatively high prices that have ruled for the commoner classes throughout the past season (*i. e.* 1885-86) have been mainly due to better quality, the result of a careful method of plucking, and not so much to short supply. Moreover, it is probable that the improved position of common China Congou will lead to a large export from that quarter next season, in which case common grades of Indian "if of poor quality resulting from coarse plucking, will only realize low prices." Not only as production increases will it be more than ever necessary to avoid coarse plucking, that is, producing inferior Teas, as buyers here find much difficulty in disposing of them, but Ceylon as a competitor can no longer be ignored.

FIGURES.—In no previous season has the consumption responded so slowly to the fall in values; the low prices ruling in September failed to influence the Deliveries in October, and it was not until the following month that any expansion could be said to have taken place. Current low values should cause a great increase in consumption, and Indian Teas being now so much cheaper than China, the latter should be largely supplanted, unless it be possible to sell them at still lower than present prices. So largely has the use of Teas other than China increased that their consumption in November amounted to 7,965,000 lb., against 12,035,000 lb. (including 4,250,000 lb. taken for export) of China.

The quantity shipped on Garden Account shows a slight increase over that of last year. The same causes as last season have again been in operation, namely, the low exchange, the low average selling price in Calcutta, and the increasing attention paid by buyers in London to successive complete Garden Invoices.

The quantities compare as follows :—

	July to December.			
	1886.	1885.	1884.	1883.
	Packages.	Packages.	Packages.	Packages.
On Garden Account..	271,374	226,972	192,183	160,394
On Purchase Account..	198,983 or 57½ per cent on Garden Account.	170,260 or 57 per cent.	212,566 or 47½ per cent.	233,525 or 40¾ per cent.

QUALITY FROM THE DIFFERENT DISTRICTS.

ASSAM.—The improved standard of quality noted last seasou has been fully sustained, and the high averages, together with a fairly good, and in some instances, large yield must have amply repaid managers for their skill and labour.

CACHAR.—The quality has not been good, and has shown a falling off from the moderate standard of last sea on, and some of the well known marks have not attained such a high standard. The inducement held out by the market for common grades in 1885-86 has in many quarters been too strong to be resisted. Where teas have had quality, good prices were readily obtainable.

SYLHET.—The slight improvement noted a year ago has not been maintained; it is to be hoped that the rapidly increasing supplies from this district will soon show good quality, when a ready sale may be looked for.

DARJEELING AND TERAI.—We have again to record a disappointing season, so far, for these growths; very few invoices have afforded any real quality, and the good prices realized ought to stimulate growers to do their utmost to produce teas with flavour. Dull or thin flavourless Darjeeling teas invariably meet with very poor support.

DOOARS.—With the largely increasing yield in this district, it is surprising that excepting on one or two gardens, that so few good liquoring teas are manufactured: the promise of a few years ago of fine quality has not been borne out.

CHITTAGONG has produced some excellent teas, and the very satisfactory prices obtained should be an encouragement to persevere in keeping up a good standard.

KANGRA VALLEY AND KUMAON.—Almost all the tea from these districts has been of indifferent character, owing, we believe, to an unfavourable manufacturing season.

DEHRA DOON.—Very few teas have come forward, and these were perhaps as good as are possible to be made in this district.

NEILGHERRY.—Fewer flavoury Teas have been received this season, and prices, consequently, have not been so good.

TRAVANCORE.—Judging from a few small invoices. there seems no reason why this district should not turn out very good Tea. A few such have sold well at very satisfactory prices; the character of the Teas much resembles Ceylon makes.

JAVA.—In the early part of the year arrivals were large, and the quality being quite up to the average, the Teas found ready buyers, Lately, the low prices of Indian have checked Imports. 57,423 packages have been offered during the 12 months.

SORTING.—As a rule four, or at most five, breaks in an invoice are all that are really needed, viz.: Orange Pekoe or Broken Orange Pekoe, Pekoe, Broken Pekoe, Broken Tea, and Pekoe Souchong, with an occasional lot of Fannings and Dust. Such an assortment should be practicable if the leaf be plucked moderately fine. When a garden is producing but a small quantity,, there should be as few different kinds as possible, with a view to avoiding small or non-sampling breaks.

With the yearly increasing quantities at auction the necessity of making larger breaks becomes greater, in order to diminish the number of samples, often more than 300, to be tasted each sale day before 12 o'clock, and so enable buyers to give proper attention to the Teas, and thus ensure a full competition for them. This cannot be the case when Teas go to auction hastily valued or perhaps untasted, and to obviate this, in several instances lately, invoices arriving by the same ship from the same garden have been bulked together here, thereby reducing the number of breaks, and also effecting a saving in time, trouble and to some extent in expense, to all concerned. As time goes on this course will no doubt be more generally adopted, and buyers will be enabled to pay fuller attention to the Teas when offered in large and attractive breaks.

BULKING IN INDIA.—Whilst this operation has on the whole been well carried out with an equal quantity of Tea packed in each chest, cases have occurred in which these all-important conditions have not been fulfilled, thus causing much dissatisfaction to the buyers. Owing to this the Wholesale Tea Dealers' Association have threatened after the present season only to buy teas weighed gross and tare as formerly. This will not only cause delay in selling, but expense to growers, besides necessitating the additional cost of, and risk of damage by, bulking here. It is to be hoped that the Association may be induced to reconsider and modify their intention, as much disappointment will otherwise be caused to those growers who are successfully carrying out the conditions by which separate weights and bulking here are avoided.

Unless the teas are *thoroughly bulked* and an *equal quantity packed in each chest of the break*, an extra expense of *not less than 1s 4d per chest* will be incurred, which has to come out of the Planter's pocket.

WEIGHING NET.—This system has made fair progress, but there is still a want of accuracy in some quarters, the variation often much exceeding the limit of 2 lb. either way, *i. e.* above or below.

WEIGHING INDIAN TEA.—The following are the amended regulations which came into force November, 1885.

The weight of Indian Tea for duty may, if desired by the Importers, be ascertained under the following regulations :—

1.—The packages on arrival to be weighed to ascertain the gross weight of each package.

2.—The importers to give with each entry a statement that the Teas in each break have been bulked in India, and that the chests of each break contain even net weights.

3.—In order to test the accuracy of this statement, 10 per cent. of each break to be turned out and weighed net, but in no case are less than 3 chests to be turned out.

4.—If the variation in weight of the test packages, from each other, be found to exceed 2 lb., the whole parcel is to be tared. For instance, if the test packages weigh net 79, 80 and 81 lb. respectively, the variations would not exceed two pounds, but if one package be found to weigh 79 lb., and any other 82 lb. or more, then the whole break to be tared; unless the importer and surveyor consider that an everage tare can equitably be given, in which case the tarers must not vary more than two pounds, as in the case of net weights.

5.—Duty is to be charged on the average weight of the packages weighed net, provided that, when the average of the packages weighed net amounts to so many pounds and a half or more, the half or more will be charged as a full pound; when the fraction is less than a half, it may be disregarded.

6.—All Indian Teas bulked in this country are to be weighed gross, and each chest tared.

MARKS ON CHESTS.—Nothing is wanted, or is of any service here beyond (1st) garden mark, (2nd) description of Tea, (3rd) garden numbers, and (4th) bulked (if such be the case). Gross, tare or net, are not of the least use, and should be discontinued.

SMALL BREAKS.—Under eight chests or eight half-chests, or twenty boxes, are called "small breaks," and in order to save the time of the majority of buyers such breaks, although catalogued, are passed over until the conclusion of the day's auctions.

SIZE OF BREAKS.—Progress can be reported on this head; but as quantities increase the number of chests should be larger, buyers here paying greater attention to large breaks.

WEIGHT OF PACKAGES.—When a gross weight of 129 lb. is exceeded there is an additional charge of 5d per chest up to 159 lb.; the following scale of charges fully explains this and deserves attention.

Management rate, per package, subject to 5 per cent discount at Warehouses other than those at the Docks:—

Gross 160 to 199 lb. 2s 9d; 130 to 159 lb. 2s 3d; 90 to 129 lb. 1s 10d; 80 to 89 lb. 1s 8d; 60 to 79 lb 1s 5d; 45 to 59 lb. 1s 2d; 35 to 44 lb. 1s; 17 to 34 lb. 7d; under 16 lb. 4d.

HOME CONSUMPTION OF INDIAN, CEYLON AND CHINA.

	Indian and Ceylon.	China.	Total.	Percentage of Indian and Ceylon.
1886..	74,665,000	100,000,000	174,665,000	42¾
1885..	68,894,000	106,309,000	175,203,000	39⅓
1884..	63,038,000	106,918,000	169,956,000	37
1883..	59,097,000	114,953,000	174,050,000	34
1882..	50,497,000	115,569,000	166,066,000	30½
1881..	48,836,000	112,156,000	160,992,000	30⅓
1880..	43,807,000	111,307,000	155,114,000	28¼
1879..	35,243,000	125,576,000	160,819,000	22
1878..	36,776,000	120,192,000	156,968,000	23½
1877..	28,013,000	123,012,000	151,025,000	18⅔
1876..	26,735,000	126,004,000	152,739,000	17½
1875..	23,275,000	126,508,000	149,783,000	15½
1874..	17,756,000	121,622,000	139,378,000	12¾

Compared with 1882 (4 years ago), the consumption of China Tea has *decreased* fully 11 per cent whereas that of Indian and Ceylon has *increased* close upon 48 per cent

The total quantity of tea, Indian and Ceylon, offered at Auction, was during :—

	1886. Chests.	1885. Chests.	1884. Chests.
January to March... ...	245,441	261,645	221,010
April to June	156,447	99,558	142,583
July to September... ...	220,919	179,860	162,947
October to December ...	325,513	282,785	242,802
	948,320	823,848	769,342

The total quantity of tea, Indian and Ceylon, offered at Auction was, during :—

	1883. Chests.	1882. Chests.	1881. Chests.
January to March	199,671	151,347	127,532
April to June	136,984	112,356	80,052
July to September... ...	148,160	149,948	125,187
October to December ...	245,759	205,828	160,710
	730,574	619,479	538,481

CEYLON.

The year commenced with good quality on offer, bringing high rates; afterwards, arrivals being poor, the enquiry fell off and prices showed in favour of buyers, and it was not until the middle of the year that any decided improvement in quality took place when values soon became better and the Tea continued in demand to the close of business for the year. It is satisfactory to note that growers in Ceylon have not, as a rule, been led away to go in for quantity we think a steady adherence to the principle of moderately fine plucking throughout the Season, with the Tea packed in not more than four or five breaks or less if the out-turn is small, will prove the most profitable course for growers. The quality, owing we believe to unavoidable circumstances, has not been so uniformly good as during 1885. The Teas find favour amongst buyers and a large and increasing quantity is consumed without any mixture of other growths. For some time past Ceylon Teas have been taken or the Continent, a very satisfactory feature in the development of the Trade. The quantities offered and the average price throughout the year have been as follows—

1886 ... 101,145 Pkgs. Avr. 1s 1d. per lb.
1885 ... 58,921 „ „ 1s 3¼d „
1884 ... 15,701 „ „ 1s 2¾d. „ (1st August to 31st December only).

We would direct attention to the remarks on the 1st and 2nd pages under the heads of Sorting, Bulking, Weighing, Marks, and Size of Breaks, &c.

JANUARY.—The quality was good and in some cases very fine; prices for all makes were maintained at a high level until the end of the month, when, the selection being poor, Teas were less inquired for.

Public Sales contained 4,472 packages, against 2,364 in 1885.

FEBRUARY.—Commenced with a better inquiry, as the quality showed better, although poor invoices continued to be represented. Desirable Teas were supported at previous prices.

Public Sales contained 5,361 packages, against 2,456 in 1885.

MARCH.—The quality throughout was disappointing and except for common grades, values, in sympathy with Indian makes, were not so firm.

Public Sales contained 7,789 packages, against 3,114 in 1885.

APRIL.—The quality continued unattractive, and prices, especially for the higher grades, went decidedly in favour of buyers, Broken Pekoe being especially depressed.

Public Sales contained 4,677 packages, against 3,865 in 1885.

MAY.—Arrivals were heavy and a few invoices of attractive quality commanded attention at an advance, but inferior Teas were irregular at lower prices.

Public Sales contained 12,329 packages, against 3,871 in 1885.

JUNE.—The large offerings contained but a small proportion of desirable Teas, and consequently the averages obtained were low.

Public Sales contained 11,264 packages, against 5,901 in 1885.

JULY.—Towards the end of the month better liquoring Teas appeared, which attracted attention at firmer rates, especially for the higher grades.

Public Sales contained 11,743 packages, against 7,673 in 1885.

AUGUST.—The improvement in quality continued, and prices further hardened all round, Broken Pekoes commanding a decided advance. Inferior Teas were difficult to sell at low and irregular quotations.

Public Sales contained 15,884 packages, against 7,642 in 1885.

SEPTEMBER.—The position as regards both quality and demand remained unchanged throughout the month.

Public Sales contained 10,529 packages, against 7,522 in 1885.

OCTOBER.—Imports showed a falling off, but the offerings contained some choice liquoring Teas, which commanded very full rates. Teas without point were slow of sale.

Public Sales contained 6,616 packages, against 4,134 in 1885.

NOVEMBER.—The selection was satisfactory, and Teas found a ready sale at prices which compared favourably with Indian growths; common kinds, however, were a little affected by cheapness of Indian.

Public Sales contained 6,689 packages gainst 5,511 in 1885.

DECEMBER.—The quality continued to show improvement and high prices were obtained. The figures to end of November excited attention by reason of the great advance in consumption.

Public Sales contained 6,077 packages, against 4,868 in 1885.

CEYLON TEA.

	1886 Import	1886 Delivery	1886 Stock	1885 Import	1885 Delivery

PLANTING IN FIJI.

LEVUKA, Dec. 10th.—The weather of this year has been very remarkable. The first three months furnished three hurricanes. The next six threatened the islands with all the evils of a severe drought, and the last quarter promises to be unpleasantly remarkable for its rainfall. Over all the group heavy rains have been general, and the prospect is still very watery. In some parts more than enough has already fallen, and evil effects are following. Especially has this been felt at Taviuni. While from other parts of the group complaints were heard of the long spell of too fine weather which followed the hurricane, Taviuni continued to receive more than its average rainfall. Latterly, to this had been added an equal share of the copious general downpour, and the island has been deluged. The growth of jungle and weeds has been something extraordinary, but the root crops, yams, kumalas, &c., have rotted in the ground, and there is a scarcity of these kinds of food which will yet be more severely felt before it is relieved. From the above and other causes the cane on the Holmhurst estate has suffered severely, and the yield of sugar will be very poor. The mill commenced working late, and it is now continuing in a spasmodic fashion, crushing a few hours a day, as the labourers engaged are not sufficient to get cane to the rollers in quantity sufficient to keep them in full work. A considerable acreage has been planted up. It is reported that when crushing is over all but very few of the European *employés* will be discharged until next season for the purpose of reducing working expenses. At Selia Levu there is a large acreage of splendid cane to be crushed; but here, also, they are very backward, through the delay caused by substituting water for steam power. At Mango the rainfall has been heavy, but it has done only good. It has given a wonderful impetus to the growing crops and coconuts but as a matter of course the sudden excess of moisture reduced the density of the cane ready for the rollers, and after a few weeks's crushing it was considered advisable to stop the mill for a while. From the other parts of the Lau province the reports are to the effect that the country is looking splendid, and there is the promise of a heavy coconut crop for next season. At Ba and Ra, which are two of the driest districts in the colony, the heavy rains did not set in until the crushing was nearly over. The yield rom the New Zealand Association Company's Raiawai Estate in the first-named district has largely exceeded all expectations. This was set at 1,200 tons. Already 600 tons have been shipped away. A fortnight ago 1,200 tons were ready for shipment, and it was expected that the general yield would not be far short of 2,000 tons. The average of the cane crop has been light, not more than 38 tons to the acre; but it is the splendid density which has given the high return, and it is said that the average output has been at the rate of one ton of sugar to eight tons of cane. On this point millers are always very reticent, but the statement will bear a liberal discount, and then be a good one. At any rate there is no doubt that the returns are very satisfactory and prospects most encouraging.

Another step is to be taken which will have the effect of putting labour matters on a better footing. Legislation on this general subject ranged under three heads—Fijian, Indian, and Polynesian. The Ordinances have to a large extent been of a tentative character, and have been so multiplied by amending Ordinance and Ordinances to amend the amending Ordinances, that their name is legion. There are between 15 and 20 different laws in force affecting the relations of master and indentured servant, and it was found that to keep the run of them it would be necessary to retain standing counsel, not for, but on each estate. With a view to remedy this, the Hon. John Hill gave notice of his intention, at the last meeting of the Legislative Council, to move for the codifying of these numerous enactments, but withdrew the notice on being informed that the Attorney-General was already half way through the work.—*Argus.*

THE TEA MARKET: POSITION OF CEYLON ESTATES AND DISTRICTS.

We do not know why the returns should differ go greatly, but appended to the interesting annual review by Messrs. Wilson, Smithett & Co., we find the Board of Trade figures for Home consumption of tea, and we are glad to notice that they are far more encouraging than those we quoted from Messrs. Stenning, Inskipp & Co.'s Report. The quantities now given are:—

1884 .. 176,000,000 lb.
1885 .. 182,456,000 ,,
1886 .. 178,894,000 ,,

The average for the three years is thus 179,000,000 lb. These are the deliveries for Home consumption. For export they have been:—

1884 .. 44,611,000 lb.
1885 .. 42,036,000 ,,
1886 .. 44,413,000 ,,

The average export has, therefore, been almost exactly 44 millions of pounds, which added to the average for Home consumption give an average of total deliveries equal to 223 millions of pounds. The stock of all kinds at the end of 1886 was 109,727,000 pounds, of which 1,660,460 were Ceyon teas.

Messrs. Wilson, Smithett append to their review details, (which we shall reprint tomorrow,) in which Ceylon estates are ranged according to the average prices of their teas in 1886. Blackstone, owing to Mr. Barber's fine plucking, hard-rolling and generally careful manufacture, stands first with an average of 1s 9¼d for 20,000 lb. Agarsland, where also much importance is attached to hard-rolling, comes close behind with 12,000 lb. at 1s 9d. Loolcondura, many will be surprised to hear, who know how fine the plucking is, stands only third, with 34,000 lb. at 1s 6½d. The vast majority of the estates range over 1s and prices between that sum and 1s 2¾d, "sundry marks" realizing an average of 1s 0½d for 650,000 lb. The largest quantity against any name is opposite KAW, (three estates besides large quantities of purchased leaf,) the figures being 300,000 lb. at 1s 3¼d. This is a result of which the Manager, Mr. Megginson, may

well be proud. The next highest figures for quantity are opposite Vellaioya, 187,500 at 1s. Then we get 154,000 for Dunedin at 1s 1¼d and exactly the same quantity for Kandaloya at 1s 0½d. Mariawatte sold 137,000 lb. at an average of 1s 2¾d, Dewalakanda 136,000 at 1s 1d, and Imboolpittiya 135,000 at 1s 2d, Hope 100,000 at 1s 0¼d, Campden Hill 102,000 at 1s 0¾d and Windsor Forest 100,000 at 1s 3d. Gallamudena sold 92,000 at the fine average of 1s 3¼d, and Elston 76,000 at 1s 2d.

Messrs. Wilson, Smithett & Co. have also attempted to range the various tea producing districts, according to the averages realized by their produce. In this list (from which are excluded 650,000 lb. as "untraceable,") the comparatively young district of Bogawantalawa takes first rank with 76,000 lb. at about 1s 4d; Punduloya comes next with 54,000 at 1s 3d, while Ambagamuwa with Lower Dikoya, shows 1,130,000 at 1s 2d. Maskeliya will be put on her mettle to find herself No. 10, sharing the average of 1s 1½d with Upper Dikoya, Dimbula and Dolosbage. Badulla and Haputale begin well with 1s 2d, the same figure being against Hewahette, while Kadugannawa shows 1s 1⅞d. As the years advance it is more than probable that the relative rank of districts may be altered, but as a first attempt to classify, the list is interesting and useful.

We have no doubt planters and others interested will have criticisms to offer, when we publish the full details.

Wilson, Smithett & Co's Ceylon Tea Memmoranda for 1886.)

London, January 21st 1887.

Although the average price realised for Ceylon Tea, which we estimate at 1s 1¼d during the past year as against 1s 3½d for 1885, shows a considerable decline, yet those interested in the industry may well be congratulated on the firm hold the article has now obtained upon popular favor. The Colonial and Indian Exhibition afforded an excellent opportunity for bringing Ceylon Tea more prominently under public notice, and it is now readily admitted that the public were thus enabled to taste and appreciate the delicious flavor of absolutely pure Ceylon Tea—the majority of them, undoubtedly for the first time. This gave a great impetus to the demand for the article, and a glance at our table of Deliveries on the last page, will show how well this demand has been maintained. But that the article may not fall in the estimation of consumers, we trust that some means may be found to stop the wholesale traffic in spurious Ceylon Tea which many small and unscrupulous dealers do not hesitate to promote. The names of sundry "crack" gardens are pirated in the most shameless fashion to further the sale of the commonest China Tea, and we think it is worthy of the consideration of the Planters' Association in Ceylon to try and devise some measures to counteract this.

Complaints of loss in weight continue to be frequent; in order to avoid this, care should be taken at the factory to fill every package in a break with exactly the same amount of Tea—nominally a certain number of full pounds, but actually a ¼ lb. more to allow for any evaporation that may take place, and in order to ensure the scale being well turned. If this be carefully done the importer can guarantee that every package in each break is of an equal net weight and he will enter the goods at the warehouse for, "net-weighment;" this means that 10 per cent. only of each break will be turned out to test the accuracy of the merchant's statement, and on this proving correct the invoice weights are accepted, are so entered in the books of the warehouse, and cannot be delivered except at these weights. Should, however, a majority of the 10 per cent., in proportion to the size of the parcel, prove the given weights to vary, the whole of the invoice will be turned out, and the *tares* taken; in this process weight may be easily lost, for, should the package scale an ounce over a certain number of pounds, an extra pound is counted, and thus almost a pound a package may be lost; it is also advisable so to arrange that the weights of every chest, lead-lining, &c. may be equal and just under a certain number of pounds. We may observe that there are also frequent occurrences of gain in weight, however, and this suggests the enquiry whether planters have their scales tested and adjusted, a precaution which is continually being taken, under the superintendence of the Customs, at the London warehouse, and which would be still more necessary in a climate like that of Ceylon. In conclusion, we give an instance where a loss of nearly 2lb. a package is made under the system of "average taring." Suppose the gross weight of a chest to be 1 cwt. 20 lb. 15 oz. and the tare 19lb. 1 oz. the net weight will then actually be 113 lb. 14 oz.; the warehouse weights, will stand—gross 1 cwt. 20lb. (for in weighing gross the importer is not credited with the odd ounces) and tare 20lb., giving the net weight as 112lb. thus leaving an actual loss of 1 lb. 14 oz.

A great many "Factory Bulked" Teas still arrive in a condition requiring re-bulking here. We only advocate factory-bulking on estates where ample space is available. Machine-packed invoices from Kintyre have come under our notice where the appearance, size and color of the leaf was perfectly even, and bearing unmistakeable evidence that a thoroughly even pressure had been exerted in the process of filling.

Invoices have been much more satisfactorily graded of late. Small parcels are now frequently sent home in an unassorted shape, instead of being split up into several small breaks. We do not, however, advocate the wholesale manufacture of unassorted Teas on large yielding estates, but we think that the proportion of Broken Pekoe should be comparatively small, and that of the thickest and finest description.

Summary of Ceylon Tea sold at public auction in London between January 1st and December 31st, 1886. Estimated amount in lb. and average prices realised:—

TEA MACHINERY AND PATENTS.

Of course no man whose rights are invaded or his interests injured should be debarred from his legal remedy, but one is naturally inclined to ask what patents are good for and the investigations on

which patents are granted, if they leave the door for litigation as wide open as ever. The process with regard to tea rollers has been curious, if the facts as we apprehend them are correct. Messrs. Kinmond and Jackson were rival inventors in India and the High Court of Calcutta decided that Mr. Jackson had invaded Mr. Kinmond's patent. Mr Jackson compromised the matter with Mr. Kinmond by a money payment, and went ahead, until he gave tea planters the "Excelsior" roller. Then by a kind of poetic justice Mr. Jackson had to take action against invasion of his patent rights, being in this case successful. Then, we are told that Mr. Thompson's "most peculiar" Challenge Roller embodied a principle which Mr. Kindmond invented but did not patent here. What Mr. Thompson took over from Mr. Kinmond, Mr. Barber transferred from Mr. Thompson's Challenge, and challenges Mr. Thompson to follow up his advertisement by an action. Like a man who was recently shot dead in America, Mr. Thompson has "made no remark." While Mr. Jackson was prosecuting an invader of his rights, Messrs. Law and Davidson actually obtained a patent for a new roller and as proof of their good faith the fact is mentioned that they requested Mr. Jackson's agents to manufacture their machines They found they had gone into the lion's den, for *they* also are to be prosecuted for invading Mr. Jackson's patent. Finally and lastly Mr. Kinmond has again, in defiance of the proverb that "a rolling stone gathers no moss" gone in for another roller, which we trust will not generate such fearful heat as his former machine did, when we witnessed its performances on Dunedin. There is a full but not quite accurate description of the new Kinmond roller in the local "Times." We have been told that there is incorrectness in the addition of the words "or rolling surface" to the following passage :—

It seems to differ from the present Jackson's roller principally in the motion imparted to both upper and under rolling surfaces. This motion is not transverse, but rotatory, the pressure being obtained, as in Jackson's, by means of a loose weight in the upper jacket.

We are also told that ignorance of engineering principles is evident in the following passage :—

One would suppose that, when full power was applied, the rolling surfaces would move out at a greater rate than there was any necessity for, since a reduction in power to half still generates sufficient pace to give the leaf a good roll.

The errors in the local "Times" description do not of course affect the merits of Kinmond's new roller, regarding which our contemporary has been told that

The patentees are sanguine that they have hit upon a roller destined to eclipse all others at present in use here or elsewhere, and this can only be proved by time and experiment. We believe Mr. Hardengue is about to erect another of these machines on some estate in Dikoya, [one being at work on Lebanon.—Ed. C. O,] the name of which has not reached us, placing it alongside another of Jackson's rollers. The fact seems to us to be that Messrs. Marshall & Sons, the makers of Mr. Jackson's machines, and Messrs. Robey & Co., the makers of Mr. Kinmond's machines, compete keenly with one another, and the latter are anxious to show that they can turn out as well devised and well executed machines as the first-named firm have undoubtedly done. Of Mr. Jackson's machines tea planters in Ceylon have now had a lengthened experience in practical working, and, if the patentees of the Kinmond-Richardson intend to beat either the Excelsior, or the Universal rollers in public estimation, they have a task indeed before them.

So far for the contest as between the giants. As to the case of Jackson against Law and Davidson we are assured that the defendants feel assured they can successfully resist the claim made. It is added that Mr. Jackson must inevitably bring a fellow case against the patentees of the Kinmond-Richardson roller, as it appears to embody the very feature Messrs. Law and Davidson are accused of taking over, but which accusation they hold is groundless. Such seem to be the facts and while we, on behalf of the public appreciate the ingenuity devoted to improved tea machinery, by so many ingenious men, we can only trust that the right may prevail and that good profits to patentees and manufacturers may be found to be compatible with moderate prices.

CEYLON PLANTERS' ASSOCIATION: CINCHONA STATISTICS OF JAVA.

Planters' Association of Ceylon,
Kandy, 8th February, 1887.

The Editors, the "Ceylon Observer," Colombo.

Sirs,—I beg to enclose for publication, and to invite attention to, copy of further letters received from Government on the subject of Cinchona Statistics and Cultivation in Java. I am, sirs, yours faithfully,

A. PHILIP, Secretary.

Colonial Secretary's Office,
Colombo, 20th Jan. 1887.

The Secretary Planters' Association, Kandy.

Sir,—With reference to my letter of the 13th ult., I am directed by the Governor to forward for your information the annexed copy of a letter from the Governor General of the Netherlands India.—I am, &c,

(Signed) H. C. P. Bell,
for Colonial Secretary.

Batavia, 14th Dec. 1886

No. 24, Enclosure 1.

To His Excellency the Governor of Ceylon.

Sir,—With reference to your Excellency's letter of the 26th August last, I beg to enclose a report on cinchona cultivation in Java, which, whilst treating upon the different questions put by your Excellency contains some further informations regarding cinchona planting in these parts, which I venture to believe will likewise prove of interest.—I have, &c.,

(Signed) C. Van Rees.
Governor General of Netherlands India.

Report on Cinchona Cultivation in Java.

I.—Which kinds of cinchona appear to have the best chance of success and which descriptions are chiefly grown? For cinchona cultivation only the following species deserve consideration:—

(a) *C. Ledgeriana.*—In regard to type, this species stands foremost as it contains the highest proportion of quinine (ripe barks contain from 6 to 12 per cent quinine) and in the bark of which no cinchonidine or even traces of it are to be found. In comparison with the *C. Succirubra* the *C. Ledgeriana* is of an extremely slow growth and therefore more particularly adopted to fertile and specially to virgin forests' soils. The altitude at which *C. Ledgeriana* is being cultivated with success, varies from 3,500 to 5,000 Rhynland feet above the sea level. An elevation of some 4,000 feet is deemed the most favourable to cultivation, unless in very moist climates in which at an altitude of about 3,500 feet the growth is strongest.

(B) *C. Succirubra* from which highly valuable barks, best fitted for chemists' purposes are obtained. The ripe barks only contain a limited proportion of quinine, averaging about 1 per cent against 4 per cent of cinchonidine. These barks, therefore, are not so much used for sulphate of quinine manufacture, unless the McIvor process has been adopted, by which a new bark containing from 1½ to 4½ per cent quinine is generated. McIvor's method, however, is gradually finding more and more antagonists, and does not answer expectations because: 1stly, its application (partial stripping of the tree) requires a good deal of labor and most minute superintendence; 2ndly, it is highly injurious to the development of the tree; 3rdly, mossing the partially stripped tree attracts all kind of insects causing much damage and sometimes the trees to die,

The value of succirubra barks is not determined by the proportion of alkaloids they contain, but exclusively by their outward appearance. Undamaged thick quill barks, doubly rolled, if possible 1 meter in length, of a silver-white colour and covered with all kinds of moss and inside of a dark-red colour deemed the best. It requires from 15 to 20 years to obtain such barks and this leads to the conclusion that they will always command good prices on the European markets. It is true that their quill-barks of less length and also root-bark of C. Succirubra yield an article still highly valued by druggists, but it is obvious that owing to the rapid growth of the C. Succirubra the market will soon get overstocked with inferior bark of this kind.

(C) *Hybrids of C. Ledgeriana and C. Succirubra.*—These hybrids differ from C. Ledgeriana by their growth, which, if not fully equal to that of C. Succirubra, at least comes very near to it. Among these hybrids, some specimens may be found containing 10 per cent quinine with more or less cinchonidine. Great extension is given to the cultivation of these hybrids and there is good reason for it as they yield an important quantity of bark for the manufacturers' market within a comparatively short time. And if it might appear that owing to their composition they were less fit for manufacturing purposes, they will always prove valuable to chemists.

II. What is the area under cinchona cultivation and the average production of bark per acre?—No accurate information is to be obtained as to the acreage of cinchona. At all events the number of cinchona plantations is not likely to increase, confidence in cinchona cultivation being shaken by the constant fall in prices. Existing plantations, however, will scarcely fail to bring all the land granted in hereditary lease under cultivation. According to incomplete and rather untrustworthy information supplied by planters the yield of private plantations in Java for 1883, 1884 and 1885 is set down at 379,728, 667,894 and 659,492 *Amsterdam* pounds respectively. (125 Amsterdam lb. equal to 136 lb. English.) The Government plantations extend over about 1,000 Bahoes or about 1,750 acres, and now yield a product of nearly 500,000 *Amsterdam* lb., which may be gradually increased to about one million, without any noteworthy extension of the present acreage but merely by the high culture being resorted to. As to the yield per bahoe or per acre the following remarks in regard to the cultivation of both C. Ledgeriana and C. Succiruba may prove of use:—The price of manufacturer's barks is determined by the yield in quinine. Barks containing 1 per cent quinine (calculated for air dried bark) yield 1·346 per cent sulphate of quinine. The accessory alkaloids being of but little value are left out of account. In the trade the price of manufacturers' bark is calculated per unit viz., per pound and per cent of sulphate of quinine, which may be extracted therefrom. If that unit (as according to the latest market reports) be *c.* 0·15, barks with 1 per cent quinine will realize 1 x 1,346 x 0,15 *c* 0·20 per pound or half kilogram. Now *c* 0·20 per half kilogram is already very near to the limit at which bark can be supplied to home markets as it covers the cost of harvesting, drying, packing, shipping and sale in *Europe*, or in one word, the expenses of laying out plantation, however, of management, taxes and keeping up the estate in general, are left out of account. It is evident that with a rising market inferior barks may cover the collecting expenses, whereas they will be left on the plantations on prices falling, and this will make it clear that the production per bahoe or per acre is chiefly governed by the market value or the price per unit assumed. If it falls, the yield decreases, whereas on its rising crops at once become more plentiful. This also shows that there is no very marked difference between barks for the manufacture of sulphate of quinine and those for chemists' use. For if the latter are no more up to the mark owing to superabundant production, they may still be perfectly suited for wholesale manufacture of sulphate of quinine, as for instance damaged succirubra quill barks of unequal lengths without lichens and without silver white colour containing about 1½ to 2 per cent. quinine and succirubra root, bark yielding 1 per cent quinine. As to barks for the druggists' market their production per bahoe or per acre is determined by constantly increasing requirements. With a falling market the collection of branches, twigs and of the upper parts of the stem does not cover cost. These will, therefore, be abandoned on the plantations and only the finer barks selected for shipment. The following figures may be considered as minima of production:—Virgin soils subjected to high culture may yield per bahoe in Ledgeriana bark, after 3 years 300 lb. averaging ½ per cent in Quinine yield.

„	4	400	„	„	2	„ „
„	5	500	„	„	2½	„ „
„	6	600	„	„	3	„ „
„	7	700	„	„	3½	„ „
„	8	800	„	„	4	„ „
„	9	900	„	„	4½	„ „
„	0	1000	„	„	5	„ „

per acre (taking the acre at 6-10ths of a bahoe) after from 3 to 10 years 180 to 600 lb, averaging from 1½ to 5 per cent quinine, such productions may be obtained merely by clearing and thinning out no more than absolutely necessary without injury to the density of the plantations which, after felling and uprooting still may yield a return of at least 4,000 lb. per bahoe or 2,400 per acre containing 5 per cent quinine after ten years. It is to be observed that no accurate information is to be obtained as to the production of Ledgeriana bark, the collection of twig barks having considerably decreased under the influence of low prices, whereas felling type Ledgeriana plantations on the Government estate is still out of the question. It is even more difficult to procure information as to the return per bahoe or per acre of succirubra barks. Production is entirely ruled by the magnitude of supplies to home markets and in connection herewith by the increasing difficulty in meeting requirements. In addition to this the price of the unit for manufacturers bark has also to be taken into consideration, because as stated above, in certain cases, also a portion of succirubra barks is also taken for making sulphate of quinine. A couple of years ago the yield of succirubra plantations after the third year already was not an unimportant one. Actually harvesting has been postponed till the 5th or 6th year and even then the crop is a small one. Under favourable circumstances the following figures may be assumed as minima of succirubra production:—

After	the	5th	year	300	Amsterdam	lb. per bahoe
„		6th	„	400	„	„ „
„		7th	„	500	„	„ „
„		8th	„	600	„	„ „
„		9th	„	700	„	„ „
„		10th	„	800	„	„ „

or after from 5 to 10 years from 180 to 480 lb. per acre and this result may be secured merely by uprooting stiled and not sufficiently developed trees. The object is to retain robust trees in order to obtain those thick and long quill barks of a fine appearance which are always in such good request. The production to be obtained by felling plantation from 15 to 20 years old is not to be stated with accuracy but may be safely set down at 5,000 lb. per bahoe or 3,000 per acre. Planting hybrids of C. Ledgeriana and C. Succirubra has only been recently introduced and therefore no figures of production can be given.

III.—Is the yearly product regularly exported or stored in anticipation of an improved demand?—As far as known it is customary in *Java* immediately to ship off the bark to *Europe* and have it sold as quickly as possible.

IV. What will be the quantities for export during the next years?—The crop at the Government plantation is estimated at fully 450,000 lb. in 1886, 500,000 lb. in 1887 and 550,000 in 1888. It is very difficult to frame an estimate of private production, but it may be safely assumed as constantly increasing. The course adopted at the Government estate of promoting as much as possible the growth of robust cinchona trees, by the application of

high culture is universally imitated. Much importance is attached to obtaining dense plantation so as to check weeds as much as possible. To secure this end the trees are planted at very small distances into the unbroken soil 4 × 4. Rhynland feet may be taken as minimum distance. The plantations having densely grown up, thinning out is commenced with by uprooting stifled trees and trees about to be stifled, or merely by cutting twigs if it might appear that the open space left by the tree being felled would be too large. "Early, frequent and moderate harvesting" may be taken as a rule. This mode of working has proved in the long run to be the most profitable one to planters, because it requires but little care in keeping up plantations and leaves the trees to develop powerfully and undisturbedly. On production falling off by thinning out, felling of the whole plantation will have to be resorted do. Barks are generally sun-dried, owing, however, to the damp climate in which estates are situated, drying kilns are gradually getting into use.

GUM LEAVES FOR DISEASED FOWLS.—A correspondent writes to the *Town and Country Journal* that there is a remedy for the ills of the poultry-yard always at hand in the gum trees around it. He says:—"For diarrhœa, dysentery, and cholera in fowls, get a quantity of eucalyptus leaves (white or blue gum; I have used both) Dry the leaves sufficiently to make them brittle, crush, and make into pills with the aid of a little bread or dough. Put as much of the powder (*i. e.*, crushed or powdered leaves) as you can lift with a shilling into each pill. Give one to each fowl affected, and if necessary repeat the dose next day. I have not had a single death amongst my fowls since I used the foregoing remedy. I lost seventeen in two days with cholera, and the four I saved out of the twenty-one I had, could not stand when I gave them the pills. They are now fine healthy birds. I have recommended the remedy to several people, and in no case has there been a single failure. I lost at the same time a collection of Australian parrots from the same complaint, and it was by observing a flock of parrots on the white gum tree that I found out the remedy. I have not lost a single parrot since. I give any parrot ailing a little powdered leaf in a tube, inserting one end into the throat of the bird, and blowing the powder into it. Put a few leaves into the cage for them to eat. Finally I may add that I have taken a large pill, composed of the blue gum for a very severe attack of dysentery, which proved effectual, and the best remedy I have ever used. I have been a severe sufferer. I think the eucalyptus is Nature's remedy for the foregoing complaints, and is worth trying."—*Queenslander.*

AGRICULTURE AND PLANTING IN KWALA LUMPUR AND KLANG—Quite close to the town lies the property of the "Selangor Sago and Paddy Company," a block of land six thousand acres in extent; the land appears to be suitable in every respect for the cultivation proposed, but it is no secret that the estate has been dreadfully mismanaged, and that its prospects are not very bright. Arab gentlemen in general have many admirable characteristics, but they have yet to make their mark as successful managing directors of public companies. There appears to be a good deal of young sago on this plantation, but I saw no paddy. Another enterprise under native management is the plantation of about a thousand acres belonging to the Datu Dagang who conducts his business on truly oriental and patriarchal principles. He has attracted some hundreds of Javanese to settle on his land by offering them each a house and a plot of land plus forty dollars per annum in hard cash, in return for which they have to plant up his estate, all crops, except those grown in their own vegetable gardens, being the property of the Datu; the system seems to work very well, the Javanese, who did not appear to me to be working any harder than was good for them, are quite contented, and as for the Datu, although he does not expect to see any speedy return for his money, as he thinks it will pay best to principally plant fruit trees which will have to be in the ground for some years before they bear a crop, yet he is convinced that in the long run it will become a very valuable property, and says that if he does not live to get his money back, it will make a very good provision for his children. I greatly regret that I had not time to visit Mr. Stephenson's pepper plantation which has frequently been described to me as being a very successful and profitable enterprise; I rode over Mr. J. G. Davidson's gambier plantation, about which, however, it is difficult to say anything of much value, as the plants are very young and the place is terribly overgrown with lalang and weeds of all kinds, but for plants less than a year old, grown under such circumstances they looked very well; and clearing for pepper planting is in progress on this estate. I forgot to mention that there is a steam saw mill a little way out of Klang, belonging to the ubiquitous firm of Hill and Rathbone. The revenue for the district of Klang during the first half year of 1885 was $62,803, and since then the duties on oil, rice, and tobacco have been abolished, in spite of which judicious concessions the revenue for the first six months of the present year was $78,736 or an increase of $15,935, a most gratifying result which clearly shows what progress the country is making. Mr. Turney, like Mr. Syers, has acquired the art of managing the natives and getting them to do what is wanted of them without any bother or trouble. —*Straits Times.*

CEYLON TEA ADVERTISING.—A planter writes: —"I send you a circular being distributed in Aberdeen. The "*unwashed Mongolian*" is very fetching!" The main parts of the circular are as follows:—

CEYLON TEA! CEYLON TEA!! CEYLON TEA!!!—Having just arrived from Ceylon, where I was for several years superintending the cultivation and manufacturing of Tea, I have decided to open a business solely for the sale of *Pure Ceylon Tea*, importing it direct from the factories, so as to enable me to put before the public the pure article at lowest possible price. In Ceylon, Tea grows from an elevation a little above sea level up to 6,000 feet, and according to the height where the leaf is grown and manufactured so is its strength and flavour. Knowing the altitude of most of the estates in the island, I will be able to buy Teas so as to make a blend comprising both Strength and Flavour. CEYLON.—In the minds of the British public, the name has been chiefly associated with the production of Coffee, but now that Coffee in many districts has almost entirely collapsed the Planters have turned their attention to the cultivation of Tea, and, with their characterstic perseverance, are turning out an article, such as their Coffee was, *The Finest in the World.*

All Ceylon Teas are cultivated and manufactured under personal European supervision, and with the highest-class machinery to be had, packed on and shipped direct from the estates, which insures consumers getting the pure, clean article. China and Japan Teas are mostly cultivated in small patches by peasantry, who gather the leaves and prepare the Tea in their huts in a very unfastidious manner. Petty dealers hawk the country, buying up these small quantities, and selling to larger dealers, who manipulate and sell to merchants. Did the people thoroughly understand the difference between British-grown Tea —such as Ceylon and that of China or Japan, it is certain that those who could get the pure, clean machine-prepared leaf, which is turned out from the Planters' factory, would never touch the far from pure article prepared by the hands and feet of the unwashed Mongolian. Ceylon Tea is the most economical (in so far that one pound will go as far as 1½ pounds of China), Pure, Wholesome, and Pleasant. Purchasers are cautioned to see that they get the genuine article. Every lb. sold by me is guaranteed PURE CEYLON TEA.

The outside pages of the circular show a very fair engraving of "a Ceylon Tea Estate and Factory" and "The Interior of a Ceylon Tea Factory."

MANILA NEWS.

(*Translated for the Straits Times.*)

The devising of a machine for preparing Manila hemp, which has fruitlessly been exercising the wits of successive inventors, has apparently been solved by Don Abelardo Cuesta. The invention since it was first hit upon, has been improved upon materially, and is based on a principle which only needs to be fully applied to command success. To admit of the Philippines progressing satisfactorily, the present method of preparing hemp must be discontinued within a few years. It is destructive to the article under notice, and turns out an unsightly product. In these days of machinery to economise labour, it is certainly high time to improve the preparation of hemp, which, hitherto, has not shared in the march of industrial advancement.

The *Comercio* quotes from a Cuban newspaper a paragraph announcing that a scientific trial was about to be made there of an apparatus invented by Senor Aycart, who, so it is said, has solved the tough problem of perpetual motion, which has hitherto defied the ingenuity of many aspirants for inventive fame. It is said the invention took forty years to reach perfection, and can develop power equivalent to that of ten horses. The simpleness of its construction and mechanism is wonderful &c., &c. The etceteras cannot fail to strike one as evidences of mistrust. The discovery of perpetual motion would indeed be a wonder. It would prove to be the most thoroughgoing revolution ever carried out. The world would become in that case quite transformed. Businesses now yielding high profits would prove ruinous altogether. Others now unprofitable would turn out to be inexhaustible mines of wealth. Probably, however, this invention will go the way of all previous attempts to solve this knotty problem.

COMMERICAL SULPHATE OF QUININE.

It appears to be the fate of pharmacists that they should occasionally be startled into wakefulness regarding the purity of the drugs they handle. Fortunately the rude awakening seldom proceeds from without, it generally being the case that dwellers within the camp cause the commotion. Quite recently we have had a case in point in reference to the quality of European sulphate of quinine. Dr. de Vrij, the veteran quinologist, in a paper published in this Journal (May 1, page 378), stated that the quinine sulphate prepared by English, Dutch, French, and German manufacturers contained cinchonidine sulphate varying in extent from 4·73 to 12·448 per cent. In this respect English quinine was placed in a bad position undoubtedly, but in respect of the fact that our home-made quinine contains much less water than that which comes from the Continent, its actual quinine content is greater than that of any other production. So far we take Dr. de Vrij's figures as they are given, for it is not our object in this note either to contradict or to defend them. A few days after the publication of the paper in question, Dr. de Vrij gave a *résumé* of it before the Paris Pharmaceutical Society (*The Chemist and Druggist*, May 8, p. 404), and, as a result thereof, the Society at a subsequent meeting appointed a committee to experiment with the Codex test, which was impugned, and to check as far as possible Dr. de Vrij's alarming statements. The French Codex text is a modification of Kerner's test, a modification in so far as the exact temperature at which the test is to be performed has been unintentioonally omitted. This test of Kerner's is an old one, comparatively, and has been adopted in the German as well as in the French Pharmacopœia, and with, slight modifications in the United States Pharmacopœia. Its application is simple; 2 grammes of the quinine under examination are agitated and macerated in 20 c.c. of distilled water at 15° C. for half-an-hour; 5 c.c. of the solution are then filtered off and cautiously mixed with 7. c.c. of 10 per cent solution of ammonia, when a clear solution should be obtained. The principle of the test is also simple; firstly, the sulphate of quinine alone gives a precipitate soluble in excess of ammonia, or, more correctly speaking, in the ammonia and ammonium sulphate which is formed, and no other salt of quinine responds to the test. Secondly, cinchonidine sulphate—the body which the test is mainly designed to detect—is about six times more soluble in plain water than is quinine sulphate, consequently a small proportion is made apparent, and its hydrate, or ammonia precipitate, is quite insoluble in excess of the re-agent; therefore by suitable means the insoluble alkaloid may be separated, weighed, and the percentage of cinchonidine so determined approximately. The French committee, in addition to working with this test, repeated the polariscopic test used by Dr. de Vrij, with the result, as stated in our last week's issue, that they reported through their convener, M. Jungfleisch, that commercial quinine sulphate contains 8, 10, 12, and sometimes as much as 16 per cent of sulphate of cinchonidine. They also corroborate Dr. de Vrij in his statement that the light or bulky quinines contain most cinchonidine.

These facts are by no means new, and have been pointed out repeatedly by quinologists. Our own Pharmacopœia permits 5 per cent of impurity in sulphate of quinine, and gives an excellent test whereby that, or less or larger, amount may be detected and separated. Absolute purity, though obtainable, is not advisable or practicable, owing to the cost of producing a salt of the kind.

In the the course of his statement before the Paris Society, Dr. de Vrij mentioned another simple test, which is due to him, and which may be readily applied according to Mr. David Howard's modification. It is as follows:—Dissolve 10 parts of quinine sulphate in 9 parts of acid, sulph. dil. B.P., and 15 parts of water. Allow the acid and sulphate of quinine to crystalise and drain off the mother liquor; wash the crystals with a little water, and then shake the liquor with ether and ammonia. It is necessary to keep in mind when applying these tests that cinchonidine will be found; it is only as to its amount that a question arises, and on this point we have sufficient faith in our manufacturers to feel that retailers will be satisfied. —*Chemist and Druggist.*

SOME FACTS ABOUT TODDY.

The correspondent who has been supplying us with accounts of the peculiar temperance movement in this Presidency sends the following facts about toddy from Gujerat:—

Toddy comes from nearly every kind of palm tree, and is simply the extracted juice or sap. In these districts it is chiefly derived from the coconut, date, and brab palms. The coconut is supposed to yield the best, but is usually tapped only every second year. The fruit and flower stalk is first well bruised and then cut, and the toddy exudes freely. The same process is carried on with respect to the brab tree also. As to the date tree, an incision is deeply cut into the trunk of the tree close into the tuft of leaves at the top, from whence the juice flows. Fastened to the top are small earthen chatties or jars to hold the liquid. These are usually emptied morning and evening. The usual yield from a brab tree is from sixty to one hundred and twenty gallons. It seems almost incredible that such a large amount of liquid should flow through the trunk of one of these trees, and that after all this has been taken away, the tree should seem to thrive as well as if it had not been touched. The fruit of the brab tree is a glutinous substance of little or no value. The date tree in this country yields no marketable fruit. The coconut is very valuable, even if it yields no toddy, on account of the fruit.

The men who collect the toddy are called Bundaries. The same man however, will not usually tap, or collect from different kinds of trees. Besides this, each caste, if they may be called castes, has a different manner of climbing the tree. The coconut bundarie, for instance, has notches cut in the tree from bottom to top, to assist him in his ascent. With a strap around his body and the tree he fearlessly walks up the most slender and lofty, apparently as easily as

up a ladder. While in Rangoon a few years ago, we watched one climb a tree growing out of the base of the great Pagoda and leaning for over the edge, so that had he made a slip he would have fallen hundreds of feet to the bottom of a precipice. His danger almost caused our blood to chill, and for days the sight was deeply impressed on our minds. The risk was exceedingly great for the small amount of value received in the little toddy procured. The date tree climbers have no need of notches as the cast off branches of the tree leave it sufficiently rough to hold their feet. But we have often wondered how one could possibly reach the little chattie fastened many feet high in the green top of the smooth barked brab tree. We have been in this country over ten years, and only the other day was our curiosity on this matter satisfied. It was simplicity itself, yet very curious. The bundarie takes a small coil of rope the strands of which are not much thicker than rope yarn, and makes it into a short loop of many strands. This is not more than eighteen inches long. In this loop he places his ankles. It serves to hold his feet together as he places them against the trunk of the tree. A similar loop, a little longer, he places around the tree and around each wrist. The arrangement allows him the fullest use of his hands, and enables him to firmly hold the tree. Thus he is equipped for a journey to the top of the tallest and smoothest. As he ascends he appears like a huge frog springing up the tree. To descend, he has only to loosen his grip, and he comes sliding rapidly to bottom. His feet are worn thick and hard in great ridges. Of course their knives and other implements, and a large chattie, are fastened to a strap around their waist.

This toddy, fresh from the tree, has a sweet, pleasant, and slightly aromatic taste. It is said to be healthful and non-intoxicating. It soon ferments, however, when it becomes slightly intoxicating. Most of the natives prefer the fermented toddy, but even this is so little impregnated with alcohol that it takes from a quarter to half a gallon to make a man top-heavy. If it were not for the formation of an appetite, that toddy cannot satisfy, and the waste of money in its use, there could be little said against it; but these are sufficient reasons, we think, for any people to wholly abstain from this the least harmful of intoxicants.—*Madras Mail.*

SUGAR-PLANTING IN FIJI.

The New Zealand Sugar Company's new mill on the Ba River made its first start on Monday, the 12th inst. The concern is an offshoot from the Colonial Sugar Refining Company, which has its Fijian headquarters at Nausori, on the Rewa River. But in the Ba venture there is also a large amount of New Zealand capital invested by shareholders having an interest in it alone. The prosecution of this enterprise has opened up for cane culture one of the most important districts of the colony. The river itself, the mouth of which is on Viti Levu, about 80 miles from Levuka and 120 from Suva, is the second largest in the group. It is inferior only to the Rewa, and it has the advantage of greater depth. At half-tide the passage is open for craft ranging up to 80 tons, and once over the flats the river offers an open course for 15 miles. The stream holds its way between banks of rich chocolate soil rising from 7 ft. to 10 ft. above ordinary level, and on either hand stretches back rich country.

The attraction of soil and easy means of water transit were not overlooked in the earlier settlement of the country. In the days when cotton was more largely grown the river banks were dotted with the homesteads of pioneer planters. Cultivation was carried on with vigour and perseverance, and the Ba was one of the busiest centres of European population outside of Levuka. But the settlers seemed to have failed to agree with the natives. The mutual relations were always those of an armed truce, often breaking out into open hostilities, and, with the Kai Colo especially, there was carried on a constant war of reprisals. The two saddest results of this were the murder of Messrs. Spires and M'Intosh in 1871, and the massacre of the Burns family, father, mother and childern, and labourers, in 1873. This led to the interposition of the Government forces between the settlers and the mountaineers. But as the former had long been in violent opposition to the authorities constituted under King Cakobau, they hotly resented this interference. One by one the settlers succumbed to the influence of the cotton failure, and the cultivators dwindled to a few, who still clung to the old location.

Upon this state of things the New Zealand Company broke in during 1883 by purchasing the Rarawai plantation. The purchase of other contiguous blocks followed, until about 3,000 acres were available for immediate cultivation. There are now about 1,500 acres under crop, and the cane, young and old, has a splendid appearance. About half the above acreage is ready for crushing, and it is expected to put through 1,000 acres this season.

The Ba flats are more open for cultivation than the Rewa lands, and because of the rainfall being much lighter the tillage must be more thorough and systematic. Steam and gang ploughs have been employed, and the land has been thoroughly subsoiled, so that the cane may strike deep into the moisture. But it is recognised that recourse must eventually be had to irrigation, and a scheme has been already plotted, the cost of which, it is said, will approach £25,000. Until recently the labourers employed on the estate numbered about 450 coolies and nearly 200 Polynesians. To these 500 more coolies have recently been added. Fijians are only employed as casuals. It is intended to add to this crushing and manufacturing power as cultivation increases. The buildings at headquarters form quite a small town in themselves, and there are besides many blocks erected for working convenience in other parts of the estate. Land transit, as regards the carriage of cane to the mill, is provided for by about 15 miles of tramway, and for water transit the company has its large iron punts and a powerful steamer of 80 tons.

Good as the harvest promises to be throughout the colony, grave doubts are entertained as to the richness of the reward, and in view of the low prices ruling the market, one of the largest planters and millowners, Mr. Jas. Muray, of the Navua Company, has written to a local paper sketching future prospects in very dreary tints. It is the effect of beet competition that he dreads; and until this shall have been placed on a different footing he anticipates anything but profitable results from the manufacture of cane sugar. Nevertheless, it is significant that the Ba enterprise has been entered upon chiefly by the old established Sugar Refining Company, whose experience has been gathered in other than Fijian fields, and after it had spent over a quarter of a million of money in testing the capabilities of the colony. Had the result been other than encouraging it is scarcely likely that it would have so largely increased its investment.—*Australasian.*

PLANTERS AND COOLIE BROKERS.

In Deli, Chinese craft and persistent combination have once more scored a remarkable triumph over European disregard of the axiom that "Union is strength." For a long while, coolie brokers in the Straits, as is the way with monopolists, had taken advantage of their position as such, to exact higher and higher commissions on concluding labour contracts with planters in that colony, until their exactions so outwent all bounds that the planters, losing patience, determined in 1885 to free themselves from such galling thraldom, when the broker charge on each coolie delivered rose in amount to $60 and even more, of which the labourer only got one half. The planters formed a ring and decided upon giving no more than $50 as advance on each coolie. The brokers here, being taken quite aback by this unlooked for show of that unity which alone gives strength, dissembled, and made believe to assent to the new arrangement

The planters in bringing the brokers to put up with a fixed maximum amount for coolies engaged through them, met with cordial co-operation from the Protector of Chinese in the Straits, on that official finding that it was indeed high time to check the rapacity of the Chinese recruiters. The Protector in an annual report announced his readiness to back up employers against the exorbitant demands of the brokers, but he warned the planters that it was only by the closest co-operation, and the strictest observance of the agreement come to, that they could make head against the crafty Chinese who earn a living by the coolie trade. In Deli, too, there was no lack of voices raised to urge the planters to stick together and present an unbroken front to the brokers as their only chance of bearing up against them, and that, rather than yield, they should strive to bring about direct immigration from China. It was too evident that the powerful brokers' ring would never rest until it had brought the planters upon their knees, unless the latter remained firm and united. As usual, European disunion proved no match for Chinese craftiness and artfulness. The final result was a call for a meeting of planters in Deli to be held on the 14th instant. The object of holding the meeting was to register submission to the demands of the brokers.

That is the outcome of a contest begun with such a flourish of trumpets and determination never to give way to rapacious monopolists. The planters had, however, no other alternative. Those among them who had made up their minds to resist, were boycotted by the brokers, and could get no coolies. Their less scrupulous fellows got as many as they wanted. No doubt self-preservation prompted them to this step. Still had they stood out unitedly and braved the wrath of the brokers, the triumph of the monopolists might have been less assured. As Lord Randolph Churchill puts it they "have chucked up the sponge," for the same reason that brought on the break down here of every combination among European firms to check adulteration and fraud among Asiatic dealers. The lesson, hard as it is, will doubtless be thrown away and prove barren of beneficial results.—*Straits Times.*

DELI NEWS.

(*Translated for the Straits Times.*)

The Deli *Courant* in its retrospect for 1886, calls attention to the striking circumstance of that colony's steady prosperity throughout last year. Elsewhere in Netherlands India, in Java especially, the past year has proved to be a period of unbroken disaster and adversity to the commercial and planting interests. In Deli, on the contrary tobacco cultivation spread wellbeing and contentment abundantly. Although the crop of 1885 estimated at 125,000 bales did not prove superior to preceding ones in unusual fineness of quality, and though there was no immediate prospect of prices rising, confidence in the future of Sumatra tobacco continued as great as ever both among planters and cigar makers. Prices, especially for the finer and better cured kind, rose materially. But, far too much of inferior qualities have been brought to market to arouse complaint in Holland and Germany. The best testimony to the indispensableness of Sumatra leaf notwithstanding this drawback, arises from the fact of the average prices continuing so high in 1886. Satisfactory as is the outlook, far-seeing people find ample grounds for uneasiness in the distant future. The principle that the price of every article hangs upon the supply, works undeviatingly enough to admit of the anticipation that, as soon as the supply of leaf tobacco exceeds the demand, prices will assuredly fall. At present, Deli has no formidable competitor in the European market. The yield of tobacco from other districts under cultivation brought forward during the year, did not turn out encouraging enough to justify basing any alarming forecast of the future upon the result of experimental planting there. A better outcome befell a consignment of tobacco from North Borneo where, by last advices, this satisfactory result had led to a larger area of land being put under crop with the utmost vigour. Next season, that colony will probably yield a larger quantity of tobacco. Another quarter where competition looms in the distance is the island of Bacham in the Moluccas. Trial planting there has resulted satisfactorily, judging from the samples produced. These circumstances prove that the success attending tobacco growing in Deli, has stirred up competing enterprise in the same direction elsewhere. Deli planters have every reason to keep awake and look out sharp. They would do well not to depend upon the high reputation of their produce, but to strain every nerve to improve still more both the quantity and the quality of the outturn they send to market. On the spot, high expectations are entertained regarding this year's crop. Its outturn is estimated at about 140,000 bales. Should the rainy season not set in too early and damage the crop, which usually looks its best in June and July the quantity may prove to be 15,000 bales more. From the coast estates, the information to hand is less satisfactory. On the average, the results attained there have fallen far below the mark. New comers in that quarter have still to plod along to reach the goal. To them, the struggle is the harder from too many of them starting rashly with an insufficient command of capital. It is very doubtful whether these pioneers can stand one or two more bad seasons. Other articles of produce have not come under cultivation in any way worth particular mention. Several planters did not experiment with coffee, cocoa, and rameh but their praiseworthy efforts did not result in proving that any of these articles would thrive there. Their cultivation indeed cannot make any appreciable headway owing to scarcity of labour. Even for the tobacco estates, it was hard to get labourers throughout the year. Towards the close of the year it became almost impossible to secure the required number of Chinese coolies from the Straits. As matters now stand unless a remedy for this evil be found, resort will be had to foul means to get hold of labourers at any cost as used to be the case in bygone years. Javanese coolies were obtainable in sufficient numbers, the only objection to them being their unsatisfactory quality. Trade and navigation during 1886 were brisk and lively enough. The chief port, Labuan by name, lies under the disadvantage of an inadequate supply of good drinking water. The Government looks upon the privations of the unfortunate inhabitants with indifference, although the Sultan of Deli had offered to meet the want in some measure by sinking artesian wells at his own expense.

The beaconing of the entrances into that port underwent no improvement. Communication on land was materially facilitated by the opening of the first section of the Deli Railway, which has indeed been worked at a high profit.

A meeting of planters was announced to be held on the 14th January to take into consideration the difficulties in the way of engaging coolies in the Straits, at rates fixed by the Deli planters mutually. The Straits coolie brokers refuse to abide by these rates.

PLANTS THAT EAT.

Among the many rare and interesting plants forming the collection in the Botanical Garden at Washington U. S. there has recently been got together an almost complete set of insectivorous plants, so called from their being so constructed as to attract insects, capture them in various ways and feed upon them. A few of these plants have been gathered from their native habitats in the swamps of North Carolina and California, and others have been sent from India, Australia and Madagascar. Perhaps the best known of the group, and certainly the most wonderful plant in the whole vegetable kingdom, is *Dionæa muscipula*, commonly known as Venus Flytrap. The leaves vary from one to six inches long, and at the extremities are placed two blades or claspers, the shape of which may be said to resemble two hands placed together between the palms and the wrists, and the fingers held backward. The palms of the hands represent the inner walls of the trap, while the fingers represent

the marginal hair or teeth. On the inner walls of these claspers there are placed six irritable hairs, any one of which receiving the slightest touch from an insect is sufficient to bring the two blades together with such rapidity as to preclude any possiblity of the fly escaping. A correct idea of how the trap closes on its victim may be obtained by bringing the two hands rapidly together, the fingers of the one being firmly pressed between those of the other. This plant readily discriminates between animal and other matter; thus, if a small stone or piece of wood be dropped into the trap it will instantly close, but as soon as it has found out its mistake, and it only takes a few minutes, it begins to unfold its trap and the piece of wood or stone falls out. On the other hand, should a piece of beef or a bluebottle fly be placed in it, it will remain firmly closed until every particle of organic matter is absorbed through the leaf. It will then unfold itself and is ready for another meal.

Next in interest comes Sarracenia purpurea. This species is popularly and most appropriately called "The Vegetable Whisky Shop," as it captures its victims by intoxication. Here is a most excellent theme for temperance advocates. The entire shop is shaped after the manner of a house, with the entrance projecting a little over the rim. Half way round the brim of the cavity there are an immense number of honey glands, which the influence of the sun brings into active operation. This sweet secretion acts as a lure to passing insects, and they are pretty sure, should they come within its influence, to alight on the outside edge and tap the nectar. They however, remain there but a brief period, as there is something more substantial inside the cavity in the shape of an intoxicating liquid, which is distilled by the plant. The way down to this beverage is straight, there is no crossing over, as the entrance is paved with innumerable fine hairs all pointing to the bottom, and should the fly walk crooked, its feet become entangled in them. When the fly has had its first nip, it does not stop and fly right out, as it could do, but indulges until it is more than "half seas over"; it then come staggering up, and reaches that portion where the hairs begin; here its progress outward is stopped owing to the points of the hairs being placed against it. The fly is now in a pitiable plight; it attempts to use its wings, but in doing so, only hastens its own destruction. It inevitably reaches the bottom, gets immersed in the liquid and dies drunk.

Another species of the last-mentioned genus, *Sarracenia psittacina*, also distils an intoxicant of its own; but owing to the peculiarly complicated formation of the entrance to its inner parts, it excludes the great majority of insects and admits but a select few. In Europe it is known as the "city club insecticide." The individual pitchers somewhat resemble an inverted parrot's bill, with a narrow leaf-like expansion running along the top. The color is light green, beautifully shaded with crimson. The inside of the pitcher is divided into three parts, the first, nearest the entrance, is studded with minute honey glands, and is called the attractive surface; a little further down the inside, very minute hairs are situated, with their extremities all pointing to the other chamber. This is the conducting surface. Lastly, the small hairs give place to the longer ones, amid which are placed secreting pores, which give forth the intoxicating nectar; this is termed the detentive surface. When the pitcher has caught a sufficient number of insects the nectar gives place to a substance which has been ascertained to be identical with gastric juice in its constituents. This is evidently to enable the plant more readily to digest its food.

Another species which, were it plentiful, would prove a boon and a blessing to man, is *Drosera dichotoma*, the mosquito catcher. It grows about one foot high, and as its specific name implies, the leaves, after *reaching* a certain height, bifurcate into long narrow spathes, which are densely covered with club tipped, rose colored hairs, each of which is coated with a bright gummy substance. This during sunshine, gives to the plant a most magnificent appearance. This curious plant would seem to have great attractions for the mosquito, for if a plant be placed in a room where they abound, all of the troublesome pests, will in a brief period, be in its deadly embrace, at first struggling to disentangle a leg or wing, anon finding itself more and more within its toils. It is most interesting to watch the method by which it secures its prey. Immediately the fly alights on the leaf, it may be that only one of its six legs stick to the sweet, viscid substance at the extremity of the hairs, but in struggling to free itself it invariably touches with its legs or wings, the contiguous hairs, and is immediately fixed. The hairs meantime are not idle; being sensitive, they slowly but surely curl round and draw their victim on the very centre of the leaf, thus bringing it into contact with the very short hairs which are placed there in order to facilitate the process of sucking the life blood from the body. This interesting plant is besides a few others, very difficult to cultivate. Even after imitating nature as closely as possible, the plants thrive but indifferently.—*Washington Co. N. Y. Mail and Express.*

THE RAISING OF PLANTS FROM SEED.

Mr. J. Hart, Superintendent of the Government Cinchona Plantations, writing in the *West Indian Field*, says:—

When a seed is sown, certain chemical changes have to take place before it can develope its parts and grow. The agencies which bring about this change are heat and moisture. A certain proportion of moisture must be absorbed, but not too much, or the result is, that unless it belongs to aquatic or semi-aquatic orders, the seed will speedily perish. Great care is therefore necessary—especially with the smaller and more delicate seeds—to place them in soil which contains a suitable amount of moisture. If the seeds are known to be such as soon lose their vitality or have been kept so long that it is evident a loss of growing power has taken place, a more delicate system of treatment is required than for those which are known to be fresh and recently matured. The best practice with such, is first of all to place them in earth which contains only a very small, or scarcely perceptible quantity of moisture, and to let them remain in it until they commence to show that a sufficient amount has been absorbed to give rise to the act. or process of germination. When this is seen by examination to have taken place water may then be given in daily increasing quantities until the plants are sufficiently strong to stand the application of water in larger quantities.

As a rule seeds should only be covered with earth to the depth represented by the average diameter of the particular kind sown, but many seeds possess a vital principle so strong, that to scatter them on the surface of the soil is sufficient to ensure a speedy development of their germinating powers. Some have the power of burying themselves in the earth by an inherent property possessed either by themselves, or the plant producing them; a familiar instance being that of the earthnut or Pindar, Arachis, hypogea, many others could also be mentioned, but this instance is sufficient to call to miud the peculiar properties possessed by some plants to further the reproduction of the species, and to maintain themselves in the "battle for life."

The covering of soil serves the purpose of surrounding the seed with an equable but slightly varying temperature, provides for the absorption of the necessary moisture, and preserves them against the effect of light and too rapid evaporation, all of which have prejudicial effects upon germination; but is not essentially necessary to allow the process of germination to take place, as can be shown by keeping seeds by other means in a state, in which the conditions supplied by the soil are fairly represented, if such are provided germination takes place in most instances, very freely. An opinion is sometimes entertained that seeds should be deeply buried, that they may have a good hold of the ground, but this is quite unneces-

sary, and even injurious, for the root, of its own power, plunges itself downwards, and the stem progresses upwards from a common starting point, which is the seed itself, hence the result of burying a seed too deeply is, to cover a portion of the lower part of stem of the plant, which we know from experience to be inimical to its future welfare.

Some objection may be taken to this, when taking into account the germination of the Leguminosæ and other plants which raise their cotyledons or seed-leaves about the ground, but such will be found to be groundless, when it is considered, that although the seed-leaves are raised above the surface, they are so raised from the exact spot at which germination took place, and it is at this point that the differentiation between stem and root commences.

Seeds germinate also very unwillingly and slowly if buried too deep, for it is necessary that a certain communication with the atmosphere should be provided, if the process is to be maintained in healthy state, they are known to possess a large proportion of carbon, in proportion to their weight, than any other part of a plant, while they remain charged to a full extent with this element, they are not in position to put forth their dormant germinative powers. To rid themselves of this principal, a supply of oxygen is necessary to convert the carbon into carbonic acid, and thus enable the seed to grow, the necessary amount of oxygen being principally obtained from water, and the surrounding atmosphere.

There are noticeable instances, especially in the tropics, of seeds taking a very long time to germinate, and these are mostly found to possess a very hard outer coating, which requires to be partially removed to procure speedy germination. In a natural state this is accomplished, by various agencies, but principally by the action of water, which softens it and enables the embryo to attract a proportion to itself sufficient for the purpose, development. It is well however, when seeds of this kind are to be raised, to use artificial means to allow of this absorption of moisture by the inner portion of the seed and this may usually be accomplished by removing a part of the *testa* or outer covering with a knife or file. During my experience in Jamaica I had certain native seeds under my care, which were sown in the usual way, but after waiting for some twelve months, they had failed to germinate and I determined to try the process of removing a portion of their outer covering. I found on tryiug to cut it, that it resisted the efforts of a strong knife, and I therefore procured a file and with it removed a suitable portion taking care not to cut deep enough to injure the dormant embryo. Though it had laid in moist earth for the many previous months without growing, in about fourteen days after the operation they had developed into plants. In numerous instances since, I have followed the same practice and with similar results. When seeds are sown thickly the plants are apt to become "drawn." In their search for light, the plants have a tendency to unduly develope their stem in a perpendicular direction, instead of becoming sturdy and strong, and the same action takes place when seeds are sown in an unduly shaded position. In such cases they are rendered very susceptible to the attacks of Microscopic Fungii, and are also very easily injured when water is applied, unless the process is conducted with the greatest care. It is always best therefore if the room can be spared, to sow the seed very thinly, so as to avert these contingent disadvantages, but in case we are restricted in regard to room they may be thickly sown if, as soon as they are large enough to handle, the plants are 'pricked off' into other soil at wider distances apart. 'Pricking off' consists in carefully raising the plants, one by one, by placing a small stick or other instrument beneath the roots, carefully raising them, and then dibbling them into holes at proper distances, shading them for a few days until they recover from the check due to the transplanting.

Seedlings should always be 'pricked off' at some stage or other, and not left to develope themselves in the original seed bed until large enough for final potting or transplanting, for if this operation is performed they will become much more sturdy, and more easily lifted, than if left with their roots straggling and intertwining in their first position—until required to be placed in their permanent quarters. The operation tends to develop a larger quantity of fibrous roots, than would otherwise be the case, and these are the feeders which supply nutriment to plants in greater proportion, than the single and larger roots which would be developed if the operation was not performed. In British nurseries where plants have to be kept in large quantities from year to year, it is the practice to regularly transplant at certain intervals —dependent upon the nature of the plant—all kinds of trees, shrubs, and herbaceous plants, and this is done, so that the loss of plants consequent upon removal may be reduced to a minimum. That it does retard and prevent growth is well understood, and is an advantage in the cultivation of certain classes of plants and fruit trees; but when planted in their permanent quarters it has, otherwise, no prejudicial effect. Cultivators, therefore, need not fear periodic transplanting, if the operation is performed with care, and with sufficient frequency, as it will enable them to maintain a stock of young plants such as oranges, etc., until times when the ground they are intended to permanently occupy is fully prepared for them. If the system of frequent transplanting when in their younger stage of growth, be followed with such plants as the orange, they can be finally planted with greater disregard for seasons, than could possibly be the case, when other systems are followed.

Although it is the general nature of a seed to reproduce the species to which it belongs, it cannot be relied upon in ordinary cases, to renew a particular variety, yet there is always a tendency to produce a plant more like the parent, than any other form of the species. For instance the seed of a Number Eleven Mango cannot always be relied to produce a Number Eleven, but it will produce a mango of some kind. The special property of producing a particular variety is confined to leaf buds, and seems to be owing to the seed not being specially organised after the exact plan of the branch on which it grew, but merely possessing the elements of such organisation. Hence cultivators should not rely upon seeds for the production of special varieties, but should have recourse to the simple operations of budding and grafting, or propagation by cuttings if they wish to perpetuate any special variety.—*Planter and Farmer.*

THE USE OF LIME IN AGRICULTURE.

During the past week the Government agricultural chemist has suggested that the market gardeners about Caulfield, Brighton and that neighbourhood, who have for many years past been in the habit of applying to their land heavy dressings of stable manure, might find it advantageous to stop the supply of manure for some years, and use instead a small quantity of lime. He bases his suggestion on the fact that the soils of many of the market gardens have, owing to the practice of heavy manuring, accumulated a great amount of fertile material during the past years, and that if the fertile ingredients could by any means be rendered more accessible to the plants it might be unnecessary for some time to add to the store already accumulated. Lime, it is known, possesses the power of liberating the ingredients locked up in the soil and rendering them available for the immediate use of plants. Hence it may be supposed that if lime were added in a suitable manner to these soils, now so rich in manurial matter, a sufficient amount could be set free year by year to serve for the growth of crops without a further use of fresh manure.

There is undoubtedly reason in the suggestion; and if good crops can be grown for a period without the heavy cost of manuring, and without injury to the soil, the gain will be very great. Nevertheless the abundant use of manure is such an old established practice amongst the market gardeners of Victoria, especially amongst those who cultivate the naturally poor sandy soils lying to the south of Melbourne, the

it has come to be regarded amongst them as a cardinal necessity of successful cultivation, and the proposal that they should use no manure at all for a time will doubtless seem to some a very striking and radical change, and its very novelty might deter them from putting it to a practical test. It may be useful, therefore, to look more closely into the proposal.

The use of lime for agricultural purposes is no new thing. It is as old as the history of agriculture itself. The beneficial effects of lime when applied to certain soils were known centuries before the nature of its action was understood. Indeed it is only within the last half century that men have learnt why the addition of lime is frequently of so great advantage. In all the old civilised countries, and now in many parts of America, lime is regularly added to certain kinds of soils. In England it has passed into a saying—too general, no doubt, as such sayings usually are—that "the use of lime is the foundation of good husbandry." In Victoria, where many, probably the majority, of the cultivators of the soil have commenced their work without the advantage of the many sound traditions founded on generations of experience which serve as a guide to farming men in the old world, and have had to take things as they found them and work out methods of practice for themselves, it is not surprising that the proper use of lime, and indeed the rational use of all manures, should not have been clearly understood.

Lime, when applied to the soil, has a fourfold action. Firstly, it serves, like all other manures, as food for the plants themselves; secondly, it alters the texture of the soils, stiffening sandy ones,* and loosening clays; thirdly, it assists in the decomposition of the soils, more especially of the vegetable accumulations contained in them, and thereby sets free and accessible to plants those substances needful for vegetable growth; and fourthly, it neutralises the acidity of sour soils, and renders them sweet and healthy. We may still add a fifth benefit which results from the use of lime, namely, that it discourages the growth of many kinds of weeds, and drives away several injurious grubs, notably the wire worm

As regards the necessity of lime as a plant food, it is only necessary to point to the many instances of soils poor in lime being of very low fertility, and the good effects obtained in such cases by the addition of manures containing lime. For purely manurial purposes the most usual way of applying lime is in the form of gypsum, or sulphate of lime. Some comparative experiments conducted by Ville, in France, gave the following results:—

	Wheat. Bushels per acre.	Beetroot. Tons per acre.	Potatoes. Tons per acre.
Without lime	41	18¾	8 1-5th
With lime (gypsum)	43	20¾	11 1-7th

In another case clover was experimented upon by a German experimenter, Körte. The clover was top dressed with gypsum; and in this case the effect varied considerably according to the time at which the dressing was applied, this variation being of course due to the effects of the season. The yield from each small experimental plot was as follows:—

The undressed plot yielded	100 lb.
The plot dressed on the 30th March yielded	132 lb.
The plot dressed on the 13th April yielded	140 lb.
The plot dressed on the 27th April yielded	156 lb.

Of the effect of lime in the form of gypsum on peas and beans there are several recorded instances; with weak and sickly plants people have described its action as simply "magical;" such effects being produced, however, as it is necessary to bear in mind, only in such soils as are absolutely deficient in lime. It has also been observed that lime, in its action simply as a manure, hastens the development of crops and brings them to early maturity.

As regards the action of lime on the texture of soils, it is to be remarked that whilst slaked lime or marl may always be added with good results to clay soils, it must be used spoaringly and with caution to light sandy ones. Five, ten, and even twenty tons to the acre, may be worked into a clay field; the clay will be loosened, and be less liable to harden during droughts, and its fertile qualities improved. But such a quantity added to a sandy soil would be likely to have disastrous results, rendering it so light and porous* that it would retain no moisture. But small doses of lime may be applied to light soils with advantage, the effect being frequently to bind them together.

It is the third and fourth effects, above mentioned, of the use of lime with which we are most concerned at present. Sandy soils, such as those at Caulfield and Brighton, contain in their natural condition only a small proportion of vegetable detritus, or, as it is called, humous matter; and as they are light and porous, their fertility is readily washed away by the rain, after they have been cleared of their native protection of verdure. But their condition becomes entirely changed after several years of cultivation with heavy manuring. The composition of stable or farmyard manure is very variable, but a good sample may be taken to contain 70 per cent moisture, 25 per cent vegetable matter without nitrogen, 3 per cent sand and other useless mineral matter, and 2 per cent of useful fertilising ingredients. The moisture of course counts for nothing, and has little effect one way or another upon the manure beyond increasing its weight. The really valuable substance for which the farmer or gardener pays when he buys farm yard manure is the 2 per cent of fertilising matter. The 25 per cent of nonfertilising vegetable matter is not, however, to be left out of account in calculating the value of the manure, for it has this effect, that it locks up that 2 per cent of really valuable fertilising matter so that the plants cannot get at it. And until the vegetable matter of the manure is decomposed and the fertilising matters liberated, the buyer of farmyard and stable manure can get no return for his outlay, he, in fact, locks up his capital in the manure; and it takes a long time for the decomposition of the manure to take place, so that for the first year, not more than 1-10th to 1-5th of the total value of the manure can be realised. The remaining 4-5ths becomes stored up in the soil, except what is washed out by the rain.

So far, therefore, it may be considered that this vegetable matter contained in the manure is not only useless, but absolutely disadvantageous, since it prevents the farmer from gaining a full return for his capital laid out. But it is not altogether useless, for this vegetable substance is not readily washed away by the rain; if it were so then the 4-5ths of unused fertilising ingredients would be wholly lost; but inasmuch as they are locked up in the vegetable matter, which in its turn is not readily washed out by the rain, then they also for the most part are retained in the soil. It results therefore, that after several years of heavy dressings of farmyard or stable manure, a soil accumulates a large quantity of vegetable, or as it is called, organic matter, together with its contained fertile ingredients. And the soil especially if it be a sandy one, is greatly benefitted by this accumulation, since it is prevented from having its fertility washed away with the drainage waters.

This accumulation in time becomes very great. Lawes and Gilbert, to whose work we have had occasion of late to make frequent reference, found that a plot of land on which they grew wheat for 40 years consecutively, and which they manured every year with 14 tons of farmyard manure, had accumulated 5000 lb. nitrogen to the acre, a result very noteworthy when it is borne in mind that wheat is very exhausting to the nitrogen of the soil.

But there is a degree beyond which this accumulation cannot be allowed to proceed without injury to the condition of the soil. For the organic matter in the soil after a time generates vegetable acids which render the land sour, and everyone knows that a sour soil, will not grow satisfactory crops. When this stage has been reached it is absolutely necessary to add lime.

If then a certain amount of lime is added, it will sweeten the soil, and it will do no more. But if still more lime be added, it will set those fertile ingredients free for the nourishment of the crops. In other words, the lime renders active those substances which hitherto

* Is this a fact?—Ed.

* Entirely inconsistent with the previous statement about stiffening.—Ed.

were lying latent; it puts into circulation the capital which had been lying idle.

It needs no illustration, however, to show that the continued use or lime on this principle would sooner or later exhaust the soil unless more manure were added. Indeed, it is an old saying that lime "enriches the father and impoverishes the son." There seems no reason to suppose, however, that it could not be safely used until the crops grown under its influence began to indicate that the surplus of the soil's accumulation was at an end, and that a further continuance of this treatment would be drawing upon the soil's necessary fertility. When that stage was reached, the use of lime—always in moderation—need not necessarily be discontinued—but stable manure should also be used. Or the use of the lime could be discontinued, and artificial manures, with occasional applications of stable manure, substituted.

We have thus presented the theory of the use of lime, and of its application to soils rich in accumulated manures. The general theory is reasonable enough, and will, we should think, commend itself. But its successful application in practice depends no doubt upon a variety of conditions. Fortunately, we are not altogether in the dark in the matter; for the action of lime in a manner similar to that suggested has we learn been already tried by a market gardener at Balaclava, and the results, we are given to understand, are very favorable, there being a marked superiority in the vegetables grown with lime as compared with those growing in an adjoining plot in the same garden, and which have been treated with the usual heavy dressing of manure.

It will be readily understood, from what we above stated, that lime will have a similar action upon stable manure that it has upon a soil rich in manurial accumulations. It does, in fact, liberate and render immediately accessible to plants much of the remaining 4-5ths of fertile matter which we stated could not, under ordinary conditions, be used for some years. Hence, when lime is used together with stable manure a much smaller quantity of the latter is required than when lime is not used. So that in any case the judicious use of lime is likely to prove very profitable to those concerned. And we would suggest that some market gardeners, whose ground has been heavily manured for years, should grow some vegetables on, say three adjoining plots, treating one with a small quantity of lime only, another with lime and a small quantity of stable manure, and the third with stable manure only. It is necessary to point out that much depends upon the proper application of the lime, and as this is a matter of importance, we will recur to it in a subsequent issue.—*Melbourne Leader.*

BORNEO TOBACCO.—Shareholders in the Chinese Sabah Land Farming Company will feel interested in the following extract from the November number of *Tobacco*:—On Thursday, October 14, there was great excitement in the narrow footway called Fenchurch Buildings, which connects Fenchurch St. and Leadenhall St. At No. 8—the smartest house in the passage—is the firm of Messrs. Horatio N. Davis and Co., who, a year or two since, removed from their old quarters at 107, Fenchurch St. The firm was founded in 1722, and are the oldest tobacco-brokers. In the capacity of tobacco-brokers for the British North Borneo Company, they had offered for sale by public tender the first shipment of tobacco to England from that colony. The tobacco was divided into two lots, *i.e.*, 35 bales 1884 crop and 293 bales 1885 crop. On the day of the sale and the three preceding days, samples of the tobacco, together with cigars made from the several marks were on view. They were keenly examined by experts of London; Liverpool, the tobacco centres of the Continent, and even the United States. Opinion agreed that the tobacco was equal in all respects to the valuable cigar tobacco produced in the neighbouring island of Sumatra. At two o'clock the tenders were opened and the 'winners' announced. So great was the excitement that the presence of the police was required. The bulk of the tenderers were present, and some were full of confidence. One was so full that he had gone to the expense of reprinting the marks of tobacco, so that he might be ready to sell immediately he was announced as the happy man. When the tenders were opened, Messrs. J. Siemssen and Co. were found to be the highest for the 293 bales, and Messrs. G. W. Brangwin and Co. for the 35 bales. Dutch firms had been confident that no English house would be in a position to secure the tender, and it is, therefore, satisfactory to see that they are beaten in London in price for the description of tobacco in which they thought they had a monopoly.—*Straits Times.*

THE KINMOND-RICHARDSON ROLLER.—When we touched on this subject the other day, we did so with diffidence, and would not have done so at all but that we desired to give our planting readers information concerning this new roller which claims to eclipse even Jackson's machine. We seem likely in the not distant future to witness a veritable war of tea-roller patents, an Armageddon, which, if it should establish who has a right to a particular contrivance, will not be without its uses. But as the remarks we made the other day regarding the Kinmond-Richardson roller appear in one or two respects to be inaccurate, we are desirous of correcting the mistakes. We learn, from a letter received from Mr. J. C. Kinmond for publication, that "although he assisted in the design and construction of the roller," as stated by us, he in no way introduces it to the Ceylon public. "Messrs. Robey & Co. finance make and sell the Machines," we understand from Mr. Kinmond, and his visit to the island is not connected with the introduction of the roller in any way. In regard to the statement made by us, on the authority of a correspondent, that it took 50 per cent. less power to drive one of these machines than one of Jackson's of equal capacity—a statement for which we were unable to account except on the supposition the new machine was lighter and more simply geared—Mr. Kinmond says that the rollers are about equal weight, and adds "that the only reason why the Kinmond-Richardson can be driven with so little motive power is that the motive power is applied direct to roll the leaf with the minimum of loss in friction." We certainly should like to see one of these machines at work, for ocular demonstration is very much more satisfactory than any other, and we are anxious to see a roller which professes to work with less friction and with half the motive power required for the Excelsior. Mr. Kinmond's letter, explaining the difficulty we had in accounting for this we think it better not to publish, for such facts as he has to give us, other than the correction of the mistake we fell into, come with better grace from one unconnected with the machine in any way. We have seen a woodcut of the roller together with the explanatory letter press. Its most noticeable feature appears to be the circular motion of the lower rolling surface which has a hitching action between each stroke of the upper plate, the necessary pressure for the roll being obtained by means of a weight in the upper rolling surface adjusted by a screw as in Jackson's. The whole business of and interest in the roller belongs to Messrs. Robey & Co. of Lincoln who intend to push its sale in India and Ceylon.—Local "Times." [If the latter statement is correct the reticence and diffidence of Messrs. Robey & Co's local Agent are quite phenomenal. He does not seem to have been our contemporary's informant, or so many inaccuracies regarding the new roller would not have required correction amongst others from Mr. Kinmond, whose repudiation of direct interest in his own child is what Mr. Thompson would term "most peculiar." The *Observer* we may venture to assert, is read by the vast majority of the planters of Ceylon, but neither in person, by letter nor by advertisement has any communication been made to our office, by an Agent said to have come hither for the express purpose of pushing the sale of a machine used only by planters. The Agent is probably waiting until trial has established the merits of the new competitor for the favour of tea manufacturers.— a wise resolve.—ED.]

Correspondence.

To the Editor of the "Ceylon Observer."

THE SILO PROCESS APPLIED TO THE COARSE PATANA GRASSES OF CEYLON.

Feb. 5th 1887.

Sir,—In reading your report of Sir E. M. Grant Duff's "Review Minute" I noticed that he speaks of a weed "bidens glabra" which after treatment in the silo is suitable for feeding cattle. Would it be possible to convert our coarse patana grass into nourishing food by silo? We are surrounded by patana grass here, but of so coarse and rank a nature, that except after a burn—when the young shoots first appear, our cattle can scarcely find pasturage on a run of several acres, and in the dry weather get to resemble the thin and ill-favored kind of Pharoh's vision. If by means of ensilage they can be made "fat, flushed and well favored," I think it would pay well the trouble of making silos. Probably the idea has been already mooted or is not feasible, but as I am rather a recent importation and have only lately entered upon the pleasure and privilege of studying such subjects under the able guidance of such aids to knowledge as the *Tropical Agriculturist*, I must plead my rawness as an excuse for troubling you.—Yours, GREEN HORN.

[This is a good idea which ought to be practically tested. The question has a strong bearing on the subject of milk giving cattle, treated of in our editorial columns today.—Ed]

PUTUPAULA TEA.

Putupaula, Kalutara, 6th Feb. 1887.

Dear Sir,—In your paragraph relating to Ceylon tea sales you mention Putupaula as coming after Lindula in its average of only 1s 4d.

Kindly allow me to say the Putupaula teas were a complete break including dust and the exact average was 1s 5d.26.—Yours obediently,

H. A. TIPPLE.

[We give the teas and the prices just as they are reported.—Ed.]

DELICATE AND HARDY VARIETIES OF INDIGENOUS TEA.

"Sana" estate, Ratnapura, 8th Feb. 1887.

Dear Observer,—I send today something to show what this side can produce in the way of my dark-leaved indigenous. You will observe the difference between the ordinary delicate, too delicate for *very high*, and also too delicate against low-country spiders, &c., "Singlo," while my dark-leaved indigenous is hardy enough to defy these natural causes. I believe mine (and crossed, perhaps, with Assam Hybrid) will be "the jat of the future?" With salaams.—Yours truly, Wm. G. SANDISON.

P. S.—I think you will find one of the leaves quite a foot long.

[We are simply at a loss for superlatives wherewith to describe the tea leaves Mr. Sandison has sent us. If the English language permitted of such a form, we should say they were the most *magnificentest* we have ever seen, especially those of the dark and hardy variety. The leaves can be seen at our office.—Ed.]

RUNG OR RINGED.

10th February, 1887.

Dear Sir,—In your para anent the ringing of the gum trees on the Udapussellewa road your correspondent uses the word 'rung' as the past tense of ring. Ought it not to be ringed?'

AN INQUIRER.

[We should think so. In Australia they always say "ringed" in regard to a process at the desolating effects of which lovers of forest trees have *wrung* their hands. It is at marriages that hands get *ringed*.—Ed.]

MR. JAMES SINCLAIR AND CINCHONA STATISTICS.

Bearwell, Talawakele.

Dear Sir,—The letter appearing in your columns from the Chairman of the Maskeliya Planters' Association, disavowing non-compliance with the desire for cinchona statistics, also Mr. Wickham's letter in the local "Times" and other circumstances compel me as the originator of the idea, to ask space for the following. At the last meeting of our local Association it was stated that several District Associations, including the Committee of the Parent body, had refused to co-operate with us in collecting these. I forget who was responsible for this statement, but had the Secretary or late Chairman, who should have known the facts, not acquiesced in allowing these to gain currency uncontradicted, my action at the meeting would have been different, for I should not have allowed the matter to drop; I only did so under the impression that several Associations had declined to assist us, nor would I have accepted the decision of the Central Committee, for I intended to have brought it before the general meeting next week. I am throwing no blame on our Secretary, I dare say he was so pre-occupied thinking how best to dispose of his repleted treasury, that he did not hear all that passed. It now appears that the Badulla Association is the only one that stops the way, but surely the men of Uva will reconsider the matter! I happen to know that their present worthy Chairman was not averse to co-operation, but even if they refuse, sufficiently accurate figures for our purpose could be got even from Badulla.

With reference to Mr. Wickham's opinion that it would be impracticable to get accurate figures, I must repeat I do not see where the difficulty lies. It is different to five or six years ago, when there were thousands of acres only just laid out in cinchona, and whether these would reach a harvestable age or not, no one could say. Now we know better what we are doing, there is but little under three years, we are more accustomed to such estimates and could, I am sure, give fairly accurate figures of the total quantity now growing. I do not think it of vital importance that a correct estimate of the output for the next three years should be arrived at, so much depends on the ruling prices and the death-rate (some years being more disastrous than others in the latter respect) but most people have intentions on the subject of the quantity they will harvest during the period proposed, therefore if they gave in their return to that effect, it would be sufficient for our purpose. What in my opinion is of vital importance, is to have some idea whether we have at this moment growing in Ceylon 40 million or 200 million pounds. Could we as we stand, disprove that either figure is not within ten million pounds of the total? I say, no. It is the feeling that Ceylon may ship *more* this season than last and that she will for an indefinite period yearly increase the output, which keeps prices so low. The statistics I propose, although I am well aware that only an approximate estimate can be procured, would suffice to dispel the existing uncertainty in London, and also tend to cause those who could do so, to hold off the market, knowing that later on better prices would be going, and thus give a

better chance to those who must perforce continue harvesting. I am too late for a resolution on he subject for the coming meeting, but I hope he matter may not be allowed to fall to the ground, for apart from every other reason, it will be a little ungracious to Government, to say nothing of the Java Association, whom we asked to procure information for us.—Yours faithfully,

JAMES SINCLAIR.

[The conditions of cinchona cultivation are such that only a very distant approximation can be obtained and we believe the compiler of the Ceylon Handbook will come as near the mark as is possible. It would be to the interest of planters, no doubt, that a low estimate should be given, but all who have travelled and used their eyes must feel that there is much cinchona culture still in Ceylon.—Ed.]

PETROLEUM AS FUEL.

Colombo, Iron Works, 14th February 1887.

Dear Sir,—The question of petroleum as a fuel for use on tea estates is one which from time to time has engaged the attention of your correspondents. As the day cannot be very far off when firewood will be at a premium in Ceylon, there will be room for some other fuel and realizing this fact we have for a considerable time been collecting what reliable data we could get regarding petroleum fuel and the appliances for using it. In August last year our Mr. Frank Walker, accompanied by Mr. J. L. Shand, inspected a boiler fitted with a patent liquid fuel apparatus for the consumption of petroleum. It is claimed for this fuel that a ton of crude petroleum will get up as much steam as 2½ tons of coal and there is no smoke dust or stoking. The apparatus can readily be put into existing furnaces and taken out if the oil should run out of stock. There is no doubt about the working and getting up steam, and so far as Ceylon is concerned the whole question hinges on the price of the unrefined oil in Colombo.

Now this question of price is our difficulty and we fear that for the present all thought of using this liquid fuel in our tea factories must be abandoned.

The nearest oil wells are in Burmah and we have for some time been in correspondence with the proprietors of these wells regarding the importation of the crude oil into Ceylon.

The result of our enquiries is that we estimate the *cost* of this oil at R120 per ton (say 6 casks of about 40 gallons each to the ton) delivered in Colombo. Coal costs say R24 per ton and 2½ tons coal costing R60 are required to develop as much steam as one ton crude oil costing R120. That is to say, the oil is just double the price of coal. The oil is cheap enough at Rangoon where it only costs 25 cts. per gallon. The charges to Colombo double the original cost. The casks cost R1 each and we cannot get a freight quotation by steamer under R3.50 per cask.

With regard to the method of using oil as fuel and the results to be obtained from it as compared with coal the following extracts from a letter from the Rangoon Oil Company may be of interest to your readers:—

"We may say that we use steam injectors and we have also recently made trial of a series of of troughs placed one above another in the flue of the boiler. The oil runs first into the top trough and overflows into the second and so on according to the number of troughs used. This latter plan has an advantage over the steam injector in as much as it is necessary to get up steam on the boiler before the injector can be used. With regard to results as compared with coal there seems to be a great difference of opinion and probably very much depends upon the kind of work which has to be done. We notice from the report of a lecture delivered at Bombay by a Mr. F. Wallace that the heat producing power of a pound of coal compared with a pound of petroleum is roughly as 12 to 19, but that experiments conducted on a large scale have given results much more favourable to petroleum. He adds that a good ordinary boiler such as may be found in many of the mills in Bombay will evaporate 6½ pounds of water per pound of coal burnt and taking this as a basis of comparison, results have been obtained from petroleum as follows:—

		lb.
By Richard at the Cotton Mills in Tiflis, Caucasus		10.83
,, Nobel Bras at Baku		14.
,, Government Exporters at Moscow		14.
,, Karl Ludig at Baku		16.
,, Brandt on Locomotives, Baku ..		16.
,, Hydon at Woolwich Arsenal		19.5

He takes the average at 16 lb. or 146 per cent. beyond the effect of coal."

The patentee of the apparatus inspected by Mr. J. L. Shand and Mr. F. Walker states that "weight for weight or bulk for bulk, the liquid fuel will do from twice to two and-a-half times the work of coal." Any way we regret to say our enquiries have satisfied us that nothing can be done at present in this colony with petroleum as a substitute for firewood, but it is impossible to say what changes may be brought about in the course of a few years. The fuel is cheap enough at the seat of its production, the mechanical appliances for using it are satisfactory and the only question now remaining to be solved is how to overcome the difficulty and cost of transport.—We are, dear sir, yours faithfully,

JOHN WALKER & Co.

A Forage Plant.—The eastern districts of the Cape are indebted to Mr. J. B. Hellier, who brought with him from Cape Town a plant of a recently-introduced cactus from Mauritius, which is like the ordinary prickly pear in appearance, except for the important difference that it has not a single thorn or hair upon it. It is used in Mauritius as a forage plant, and it is expected that it will prove a most valuable boon to colonial farmers, as furnishing food for their stock in the dry season without the hindrance of damaging the mouths of the cattle as the prickly pear does.—*Colonies and India.* [Might be found useful in the north and east of Ceylon?—Ed.]

The British Borneo Trading & Planting Co. (Ltd.) is being circulated privately for subscription at the present time. It has a capital of £100,000 in £1 shares. Of these the present issue is £30,000. The Company has been formed for the purpose of carrying on the business of merchants, agents, and planters, in and with British North Borneo, and of acquiring a concession of 20,000 acres of land granted by the Government of that territory, and conveniently situated in the neighbourhood of Sandakan. It is proposed to carry on trading and planting, the profits of the company being derived from the following sources, viz:—The sale of the timber, forest and other produce on its estates, and the cultivation and sale of agricultural produce. Advances to natives or planters for agricultural purposes, and purchase and sale of the produce. The business of land agents, acquiring building land, advances on property, erecting houses, &c. From royalties on fibre machines, for which the Company have made arrangements with Mr. Death for the exclusive rights to use and let on royalty in the territory his patent fibre extracting machine. The payment to be made for the concession and the rights over Death's machine has been fixed at £3,500 in cash, £1,500 fully paid ordinary shares, and £10,000 in fully paid deferred shares. The *concessionaire* is Mr. J. J. Dunn.—*L. & C. Express.*

The Phylloxera Pest in France.—The average yield of the French vintage for the four years from 1875 to 1878, inclusive, was 1,275,000,000 gallons. The last three vintages have decreased at a greater rate than 100,000,000 gallons per year, and now it is reported that in the vintage of 1886 more than one-fifth of the yield was produced from dry raisins and dregs of the first and second press. Although it is beginning to be the fashion to ascribe this decrease chiefly to mildew and other causes, the presence of the phylloxera must be regarded as one of its principal causes. After a variety of researches only one method has been found to effectually kill this insect, and that is by inundation, begun in November and continued for forty days. The vineyard on which this experiment was tried was one of the first to be attacked. In 1867 the wine produced was 925 hectolitres; in 1868, 40; in 1869, 35; in 1870, the first year of submersion, 120 hectolitres. Since that year the quantity produced has gradually increased, until it has nearly reached its normal figure, and the vines have regained their vigour. The commission appointed in France, which publish every year such a heavy report, have chiefly studied methods for killing the insect underground, and but little practical benefit has attended their action. Had they directed their energies to a policy of extermination above ground very different results might have been attained.—*Colonies and India.*

A Tour through the Brazilian Coffee Districts.—By permission of Messrs. Behrens & Landsberg, the following interesting Santos report, dated 1st September, was reprinted in Messrs. Carey & Browne's weekly circular of the 24th October.—We have lately visited Campinas and around as far as Sao Carlos do Pinhal and Belem do Descalvado. The impression received on the spot may interest our friends. Brazil is an undeveloped mine of wealth, and, whatever may have been said or written against it, there are many bright highlights perceptible. The labour question is by far more serious than we dreamt of. It should not be lost sight of, being a great factor in the reckonings with coffee for the next six years. There are yet vast territories suitable for the cultivation of coffee; but without hands to harvest it, it is no use thinking of extension. Even with improved machinery, which replaces a great deal of manual labour, we have seen planters in despair, unable to get hands for gathering in the crop, although offering higher wages —and this with a medium of 1886-87 crop, which in all likelihood will not prove beyond 2,000,000 bags. Of course, as long as there are no statistical bureaux, all crop-estimates must be more or less guesswork. The balance of the 1885-86 crop left in the interior has surely been over-estimated; wherever we came, no more old coffee was to be seen. What is wanted here are hands! Many attemps have been made to attract colonists, but, we are afraid, without the proper understanding of the situation. Planters offer colonists, a neatly built house and garden, against which they have to engage themselves to work for 3,000 reis per day as long as planters require their labour for the harvest. Germans, in fact the Saxon race, are the preferred colonists. Now, considering that Brazil wants colonists who stay, found a home, marry and intermarry—unlike the Latin race, which comes here to earn a scanty amount in order to retire on rice and corn to their mountains—this does not seem to us to be the way to persuade Germans, Scandinavians, or Crofters. Unfortunately, the large landowners here are disinclined to selling land, which must sooner or later not only prove shortsightedness but to their detriment. Looking at the States—Canada and Australia—where land is given to colonists, it is evident that some inducement must be held out to get out of the dilemma. Church marriage being too expensive, civil-marriage, so far illegal, ought to be recognised at once. Not until such radical changes are made, and only then, will the labour problem have a chance of being solved. If not enforced, we may see in the next future crop yields go down for a time. The 1886-87 crop has suffered from two causes—from frost in some parts, from drought in others. We have seen plantations where two to three feet of the branches have died off, and to recoup such damage, means one to two years. The incessant rains during the last month produce another anxiety; plenty of coffee on the terreiros is mildewing and much under the trees is washed away."—*Grocer.*

Manuring Cinchonas.—From the Madras Government we have received the following correspondence. Messrs. Arbuthnot and Co., addressed Government on 2nd December 1886, thus:—

We have the honor to acknowledge with thanks receipt of the Director's very interesting report on the Government Cinchona Plantations for 1885-86, furnished us in accordance with G. O., dated 20th November 1886, No. 7,034. 2. We observe that the experiments in manuring cinchonas in order to ascertain the effect upon the alkaloids were on a very small scale, and that the Government, in its order of 15th instant, express the desire that investigations should be continued with trees of other varieties. 3. We venture to suggest that experiments should be conducted upon a far larger number of trees, and if no selection of any particular varieties is to be made for the purpose that it shall include *C. Succirubra* and *C. Robusta*. We propose ourselves to experiment upon *C. Ledgeriana*, both with cattle and other manures. 4. It occurs to us that since the date of the Director's report further experiments in manuring may have been conducted and the results ascertained and if so, we should be very glad to receive particulars. We may mention that mainly influenced by the advices of the Director's letter of 9th November 1885 to the Collector of Malabar, we have abstained from manuring our cinchonas (though recommended by planters to do so), as according to that letter experiments made up to that date had shown that the yield of alkaloids per pound of bark was *not* increased by manuring. 5. We therefore have the honor to request that Government will obtain from the Director or the Quinologist, as the case may be, and communicate to us the expression of his opinion whether, taking into consideration the views held in November of last year, and the result of the experiments conducted in the past season, he would recommend manuring of cinchonas from a commercial point fo view, and if so, whether cattle or artificial manure would be the more beneficial. If he be of opinion that the latter is the more desirable, we should be glad to know his views as to what components would be the best. Possibly the investigations of the Government Quinologist into the inorganic constituents of cinchona bark may have arrived at a sufficiently forward stage to indicate the class of manure that would have the greatest effect in increasing the quantity of alkaloids.

Dr. M. A. Lawson replied as follows:—

I am at the present time carrying on the extended experiments as to the value of different kinds of manure, and the first harvesting of the manured plots will take place next April, after which the bark will be analysed and any information will then be communicated to you. 2, Mr. Hooper's report on the inorganic constituents of cinchona bark, printed in G.O. No. 1,032, of the 24th November 1886, is the first of a series of analyses which he is engaged upon the result of which will be communicated to Government in due course.

We are surprised that after the results obtained by MacIver and noticed by Broughton any doubt of the effect of manuring should be entertained, although we can well understand hesitation to apply manure to a production the market value of which has gone so low. Those who manure now, however, may have their reward a few years hence. We should suppose that a very large proportion of the bark sent from Ceylon was from trees growing amongst coffee and so manured equally with the primary cultivation.

THE ANALYST'S REPORT OF PRODUCE.

We have received a copy of the annual report of the public analyst for the parish of Kensington (Mr. Charles E.Cassal, F. I. C., F. C. S.), which contains some interesting information, and from it we extract the following :—During the year ended March 25, 1886, a total of 524 samples of food were submitted for analysis by the inspectors appointed under the Act. Two out of the three samples of China tea were of very inferior quality, containing exhausted leaves. The adulterated samples of cocoa examined contained added starch and cane sugar, as follows :—

Added starch, per cent.	Cane sugar, per cent.
At least	At least
55	30
50	30 (2 samples)
40	35
40	30 (2 samples)
40	25
35	30
25	30
20	16 (labelled "Epps' Cocoa ")
15	20

Of the 44 samples of coffee there were 75 per cent genuine, and 25 per cent adulterated. Of the 11 adulterated samples one contained at least 45 per cent of chicory, one 20 per cent, and nine 5 per cent. The black pepper, of which 27 samples were examined, showed the proportion of 22·2 per cent genuine, and 77·7 per cent adulterated. Samples of genuine commercial black pepper should not yield more than 5 or 5·5 per cent of total mineral matter. Any sample yielding more than 7 per cent must be considered within the meaning of the Act.—*Home and Colonial Mail.*

MANUFACTURE OF LIME JUICE IN TRINIDAD.

REPORT OF CONSUL TOWLER.—The lime tree grows wild in Trinidad, and when I came here three years ago, the fruit was not exported. I recommended a gentleman of enterprising disposition to ship a few barrels of limes to America as an experiment. The fruit decayed in the transit, and the attempt was a failure. Another plan was resorted to, namely, the neutralization of the acid juice with chalk ; but this plan has been abandoned, and the expressed juice itself is now exported either in the simple state as obtained by pressure, or after evaporation to about one-tenth its volume. The simple juice finds a market in America, and the condensed juice in England.

CULTIVATION OF THE LIME.—There are only two parties here on this island that cultivate the lime for exportation. From one of these I have received the following information:—Lime trees grow and bear in any soil, but the better the soil the larger the fruit. They are planted from 12 to 16 feet apart. When young they have to be pruned and trained to assume the shape of an umbrella. When about to form a lime plantation it is best to form a nursery a year beforehand, and then to transplant the young trees, pulling them up from the soil, cutting off the end of the pivot root, and then placing them in the ground where they are to grow. A lime tree yields on an average 10 gallons of juice. The fruit is allowed to drop off, and is then collected and conveyed to the works, where, the limes are passed first through the cutter which rips them open, and then through rollers and the press to separate the juice. These cutters, rollers and press are constructed in a very simple and primitive way, and admit of very great improvement. The juice is then, as before remarked, exported either in this condition or it is condensed by boiling. A barrel of limes yields 7 gallons of juice.

COST OF JUICE.

	Cents.
The cost of collecting a barrel of limes is...	10
Carting a barrel to the works	3
Cutting and pressing	3
Cost per barrel	16

The cost of lime juice, including packages, should not exceed 12 cents per gallon ; lime juice is generally sold at a price varying from 36 cents to 60 cents per gallon.

The essential oil of limes is extracted from the rind before crushing by grating on rasps with the hands ; the oil thus extracted is called the hand made-oil, which is obtained from the crushed limes and by distillation. A hundered gallons of juice will yield by distillation about three quarts of the esssential oil. This branch of industry is capable of great expansion by means of capital and intelligence : the soil is always ready to do its duty.—*Oil, Paint and Drug Reporter.*

CLIMATE AND VEGETATION.

Many of our readers will recall with pleasure the interesting series of articles published in this journal on the climate and vegetation of the Riviera, and on horticulture as practised by Dr. Bennet at Mentone. Those articles form part of Dr. Bennet's delightful book, *Winter and Spring on the Shores of the Mediterranean.* Of the general correctness of Dr. Bennet's views there can be no doubt, and it is certain that for the physician's purposes an investigation into the effects of climatal changes on plants at various stages of their growth affords more trustworthy information than the mere study of thermometric records. Mr. Charles Roberts, to whom we owe various interesting and useful publications relating to "phenology," is following up this question of the combined and continuous effect of various meteorological factors on plant life. "A meteorological instrument," he says, "records a momentary atmospheric condition. A plant does this, and much more ; it records the current conditions, and sums up or registers all the past meteorological and geological conditions to which it has been exposed. Phenologists cannot accept mere inferences, however probable they may appear to be, and nothing short of simultaneous records will satisfy them."

Pursuing these ideas, Mr. Roberts selects for observation in the Riviera the plants mentioned in the accompanying list:—

"The plants and trees included in the schedule are well known in our winter health resorts, and require not botanical skill for their identification ; but observations should not be recorded when there is any doubt on this head. The plants are arranged in three groups, to indicate roughly the chief varieties of climate of the Mediterranean basin. The first group indicates a hot, arid, sandy or rocky soil, and a dry, sunny atmosphere, like those of the south-east coast of Spain, Upper Egypt, and the borders of the African Desert. The second group characterises the colder and damper climate and soil of the Riviera, Southern Italy, Sicily, Malta, Algeria, and Lower Egypt ; and the third group the still colder and damper climates of the Italian lakes, the West Coast of France, Spain and Portugal, end the South of England. This last group brings the ordinary climate of England into relation with that of the Mediterranean, and will connect this schedule with the one which I have specially prepared for differentiating local climates in the British Isles.

"It would be desirable to make concurrent observations on the maximum and minimum shade-temperature at each station (by means of verified registering thermometers, exposed in Stevenson's stands), to ascertain the extreme range of temperature, and the lowest which each plant will survive. We know, for instance, that the Lemon tree is killed by a temperature of 24° Fahr., and the Orange by 21° Fahr.; while the Olive tree will bear 16° Fahr., although its young shoots are killed by a temperature no lower than 25° Fahr. ; and we gather from these facts that, at stations where these trees flourish, the temperature never falls so low as these figures indicate, even for a night or two, during many consecutive years. As observations on the rainfall cannot be carried on all the year, the relative dampness or dryness of different stations cannot be determined

by the rain-gauge; and we must rely on the known habits of plants, in their relation to moisture of air and soil, to help us in this respect. Any one who has passed quickly between Nice, Palermo, and Algiers, cannot but have noticed the difference in the general aspect of the vegetation at each place; its greater activity at the latter station indicating a greater amount of moisture in the air and soil than at Nice, while Palermo holds an intermediate position.

"The following observations should be recorded of each plant in the list. Does the plant or tree grow at the station? Is it protected from the cold, sun, or wind? Does it blossom? and at what date does the first blossom appear? Do its fruit or seeds ripen and at what date do they arrive at maturity? With respect to the deciduous trees (Pomegranate, Vine, Fig, Almonds, and Horse Chestnut), at what date do the leaves open (first leaf-surface visible); the first blossoms open; and the first fruit or seeds ripen?

(1) Carob or Locust-Bean (Ceratonia Siliqua)
Prickly Pear or Indian Fig (Cactus Opuntia)
American Aloe (Agave Americana)
Date Palm (Phœnix dactylifera)
(2) Pomegranate (Punica Granatum)
Banana (Musa sapientum)
Lemom tree (Citrus Limonum)
Sweet Orange (C. aurantium)
Olive (Olea europæa)
Australian Blue Gum tree (Eucalyptus globulus)
Bamboo (Bambusa vulgaris?)
Dwarf European Palm (Chamærops humilis)
Oleander (Nerium Oleander)
(3) Magnolia (M. Grandiflora)
Camellia (C. japonica)
Myrtle (Myrtus communis)
Vine (Vitis vinifera)
Common Fig (Ficus carica)
Adam's Needle (Yucca gloriosa)
Almond (Amygdalus communis)
Horse Chestnut (Æsculus hippocastanum)

"By means of simultaneous observation on these plants, or a small number of them, it will be easy to lay down on a map isopheual lines similar to, but by no means identical with, the isothermal lines laid down by meteorologists; and thus produce a diagrammatic representation of correspouding climates, and the difference of one station from another."

Following up this subject Mr. Roberts discusses, in the *Transactions of the Sanitary Institute of Great Britain*, the evidence afforded by plants as to the relative degree of purity of the air in large towns, and he gives a diagram representing a series of squares one within the other. Thus, in his illustration it is shown that in the outermost square the Larch, the Scotch, Fir, and the Heather, will grow and lichens may be found on the trees. In the succeeding square, supposed to represent a more deteriorated atmospheric state, the plants included in the outer square will not grow, but the Sycamore, the Horse Chestnut, the Yew, the Deodar, the Arbutus, the Laurustinus, and various fruit trees will still thrive, which they will not do in the next square, and so on, till we come to the central space, in which—doleful spot—no plants at all are mentioned; but even here Poa annua, and Polygonum aviculare, and Docks will grow, as every one who will visit the courts and alleys of London can see for himself.

Some quarter of a century ago and more there was a tradition that evergreens would not grow in London, and, therefore, the squares were planted with Privets, and Lilacs, the deplorable aspect of which in the winter months was but too familiar. People are beginning to find out, however, that many evergreens do relatively well in the most confined places, especially those with thick leathery leaves like the Holly or Yucca, and which are well provided with chlorophyll and consequently proportionately vigorous. Conifers, as a rule, do not do well in such places, indeed one of the best rough tests of the purity of the air may be obtained by the observation of the common Arbor-vitæ, Thuia or Biota orientalis. If the reader will wend his way from the suburbs, say at a distance of 4 or 5 miles from the Thames on either side towards the banks of the river, he will have ample opportunity of noting how the lower branches of this shrub gradually become denuded of leaves, till at length the wretched plant resembles a disorganised Birch-broom with a few loaves at the top, and then it disappears entirely. Much to our surprise, however, we know of cases in which Pinus excelsa grows in localities where the Biota will no longer do so.

As a matter of practice much depends upon the care bestowed by those in charge. Frequent cleansing with a syringe or garden-engine will enable plants to grow in the most unlikely places, and in the cases we have in view this demands so little time and attention that we can but press it on the attention of the Society over which Lord Brabazon presides. We know from our own experience of a garden where Roses had long since ceased to blow, but where now not only a large assortment of choice evergreens may be found, but where also an occasional Moss Rose may now be plucked; and this we attribute, not to any improvement in the atmosphere, which is probably more smoky if not fouler than formerly, but to increased attention to syringing.

It is obvious that the sources of fallacy and exception are so numerous that it will be long before we can speak with any degree of statistical precision. Such an amount of precision is, however, quite within the bounds of probability, and it must be attained by extended comparative observations on plants under all conditions and circumstances, such as Mr. Roberts advocates from the point of view of hygiene.—*Gardeners' Chronicle.*

THE PROCESS OF LIMING.

No. II.

Last week we drew attention to the many good effects which may result from the proper application of lime to the soil, and recommended the more extended use of this material in Victorian agriculture. It is well to bear in mind, however, that these good effects are to be expected only from the proper use of lime. When used improperly there may, on the one hand, be no results whatever, either good or bad, in which case the time and labor and money spent will have been thrown away; or, on the other hand, the soil may receive absolute injury, the rectification of which will involve a further expenditure of labor.

There is one case in which lime may always be used without fear of injury, in which, indeed, it must be used if the soil is to be brought into a thoroughly healthy condition. We refer to the case of the land being sour. There is no doubt that very many, probably the majority, of Victorian soils are sour. Most newly cleared lands are sour, and it is a frequent custom to let such lands remain for a year or more uncultivated, in order to sweeten. The sweetening could be effected at once by a dressing of lime. When these newly cleared lands are exceptionally rich, their fertility may be, and indeed often is, such as to mask the effects of their sourness, and abundant crops can be obtained, even though the soil has not been sweetened. But where the soil is of poor or only medium quality, it is useless to expect large returns without the use of lime.

We may here remark that it is often regarded as unnecessary to add lime to soils in limestone country. Yet several instances are known of soils actually resting on a limestone bed which yet are almost destitute of lime; and in many other cases the amount of lime is so small that it is not sufficient to neutralise the natural sourness of the soil. The reason for this apparently contradictory condition of things is not far to seek. The lime is washed away from the surface by the rain, and either runs off with the drainage waters, or forms a layer at the bottom of the soil. Sometimes this layer forms a hardened cake, and is then one of the many forms of "hard pan," being then known as a lime pan. In these cases of limeless soils in limestone country subsoil ploughing should be resorted to; or if the limestone is too deep, then trenches may be dug along the fields and the limestone or marl thrown up from these and spread over the surface.

Every farmer may find out for himself if his land is sour or not in a very simple manner. There can be purchased of all chemists, for a few pence, some small slips of blue paper, called "blue litmus paper." This paper is turned red by acids, so that if a small quantity of a damp, sour soil be pressed with the finger and thumb against a slip of this blue paper, wherever the soil touches the paper it will produce a red color, and if this red color remains after the paper has been exposed to the air for a few minutes, it is a sure sign that the soil needs lime. If the soil is very sour it will produce a bright red color, but if it be only slightly sour it will cause only a bluish pink or purple color; and by this means a rough idea of the amount of lime required can be formed. For a purple color only two or three hundredweights of lime to the acre may be necessary; but for a bright red, half a ton or a ton may be required; it being always borne in mind, however, that a strong clay soil will require, and can bear, a heavier dressing than a loose sandy one.

Liming will do no good if the soil contains sufficient lime already. And here again is a case in which the farmer can apply a simple test sufficient for most purposes. If vinegar be poured on to a piece of limestone or a piece of old lime, it will cause a bubbling up or effervescence similar to, but less than, that which takes place when water is poured on a mixture of carbonate of soda and tartaric acid, or when carbonate of soda is put into a mixture of vinegar and water, as is sometimes done for making a cheap drink in the bush. If then a little soil be placed in a tumbler or wine glass, and sufficient water be poured on to cover the soil and to allow all the bubbles of air to rise out of it, and if then vinegar be poured into the glass, those soils which contain lime will bubble up; and the more lime there is the more will be the bubbling up. If this effervescence should occur, it may be certain that it would be a waste of money to add lime to such a soil. But, if this effervescence should not take place, and if also it has been found that the soil is not sour, then the only way to ascertain whether the soil is deficient in lime or not is by having it analysed.

Liming may injure the soil in three ways—first, by rendering it too open and loose, so that it will retain no moisture; secondly, by forming a mortar, and so hardening the land that neither water nor roots can penetrate it; and thirdly, by exhausting the land. But all these dangers can be readily avoided. As pointed out previously, lime should be used very sparingly on light, sandy or gravelly soils. If it is found necessary to add it to such soils, then it should be put on in the form of a compost of one part of lime with six or eight of fine earth, the compost being allowed to stand some time before using; or, if marl can be had readily, the lime may be put on as marl, about half a ton or a ton to the acre. Or, if the sand rests on a clay subsoil, then the clay may be dug up in trenches, as is done in the fen country in England, and spread over the soil, the clay being afterwards ploughed in, and then the lime sprinkled over the surface; or, if neither marl nor clay can be had, then an abundance of vegetable matter should be given in the form of farm yard or stable manure, or in the form of green crops, particularly root crops, ploughed in the lime being added afterwards. All sandy soils, it should be borne in mind, are greatly improved by an admixture of clay, and it is exceedingly likely that a process of claying, similar to that adopted in the fens in England, would greatly improve the sandy soils lying to the south-east of Melbourne.

The setting of the lime into a mortar can only take place in heavy wet soils, and it may be taken as a general rule that all wet clay soils and swamps should be drained and ploughed before they are limed. But at the same time no fear may be entertained of the hardening of the land unless very heavy dressings of lime, such as 20 and 30 tons to the acre are used.

We have, on a previous occasion, referred to the exhausting action of lime. It is this very quality, however, which, when rightly applied, renders the use of lime so specially advantageous in many cases. The lime liberates for the immediate use of plants the various ingredients of the soil and manures which are ordinarily locked up in an inaccessible form, and by so doing it greatly increases the returns. In fact it enables the farmer to turn over his capital quickly. But if he thereby gets more out of his soil, he must return more to it in the form of manure. Exhaustive farming in any case is bad; it is just as bad to exhaust a naturally fertile soil as to exhaust one rendered fertile by lime. The object of the farmer in any case should be to improve the land if it be poor, or to maintain it at a good level if it be rich. And the preventive of the exhausting action of lime is just the same as the preventive of the exhaustion of a good soil, namely the proper use of manures.

The forms in which lime may be used are marl, crushed limestone shells, and shell sand, and quick and slacked lime. All the forms are best strewn, over the surface, the more evenly the better, the dressing being put on some months before seed time. Quicklime acts most rapidly, slacked lime the next, shells and shell sand the next, and crushed limestone and marl act the most slowly. Limestone, shells, and shell sand may be converted into quicklime by burning; but it is generally most convenient to buy quicklime of the lime burners. Quicklime is only used for sweetening heavy and very sour lands, such as recently drained swamps. Of all forms of lime, the slacked lime is the most useful; it is made by the farmer himself, by sprinkling quicklime with water, when the lime becomes hot, gives off steam, and if good, falls into an exceedingly fine powder. If it does not fall into this powder, either the lime is not good, and is of less value, or too much water has been added, with the result of causing the lime to chill. The great point to be aimed at is to get the lime into this fine powder, for it is then much more effective in its action, and a small quantity of it goes a great way.

We last week referred to the action of lime in increasing the immediate effectiveness of stable and farm yard manure. It is well to bear in mind, however, that the lime should not be mixed with the decomposing manure heap; but should only be mixed with it in the form of a compost immediately before using. If mixed with the decomposing manure heap, it causes the escape of ammonia, and thus a valuable part of the manure is lost.

The action of shell sand on the soil may be seen, near many of the fresh water lakes of Victoria, as for instance along the margin of Lake Corangamite, where fine shells blown up yearly by the winds and strewn over the ground, induce a surprising degree of fertility. Similar cases are known in almost all countries. An instructive case may be quoted which occurred in France, where a sandy soil, similarly composed, was every other year laid an inch thick over land which produced only a threefold crop of rye, and caused it to yield an eightfold crop of wheat for several years; but—and this is the point to be borne in mind—after 40 years of this treatment, without any other manure being added, the land would produce only a fourfold crop of wheat.—*Leader.*

AGRICULTURE IN ECUADOR.

Consul Beach, of Guayaquil, says that Ecuador covers an area of 150,000 square miles, and has a soil and climate scarcely equalled by any other country in the world. About one-fourth of the extent is of tide water level, and the remaining three-fourths of various altitudes embracing hills, mountains, and mountain valleys, the highest altitude being that of Chimborazo, 21,220 feet. There are about twenty mountain summits that are more than 10,000 feet in height. The great difference in altitude will serve as an explanation of the wide diversity of climate and variety of soil productions, both of which are much greater than would be conidered possible in the equatorial region. The mountains, though all of volcanic orgin, are yet somewhat varied in their elements, but each has the characteristic of quite

rapid decomposition, which decomposition provides a soil more or less fertile for all of the mountain surfaces, and affords abundant material to be carried down by the streams to the mountain valleys, and to the level lands adjacent, to the numerous rivers in the lower sections. Ecuador, on both sides of the Andes, abounds in rivers and smaller streams, which greatly enhance the productions of the country, and the rivers themselves provide a water communication with the markets. The climate is exceedingly diversified, having the wide range from an average temperature of 75° Fahrenheit on the Pacific Coast and upper tributaries of the Amazon to that of the summits of the Andean range, where there is perpetual snow and ice. Between these extremes there are all the degrees of variation from the tropical to the arctic. The difference of temperature resulting from the difference of altitude permits the growing in Ecuador of nearly all the fruits and varieties of grain and vegetables grown in all other parts of the world. Everything pertaining to the tropics is produced in profusion, and in addition, wheat, oats, barley, apples, pears, peaches, cherries, strawberries, and vegetables of every kind. Consul Beach says that Ecuador has many natural advantages that might be rendered a great blessing, but the people appear to be wanting in the main essentials of industrial progress, and the country makes but trifling advancement, as may be seen by an examination of the agricultural implements now in use. The implements of most varied uses is the *Machete*, a heavy blade about two inches in width, two feet long, with a handle about five inches long. Most of the blades are straight, but some of them have a slight upward curve. A field is prepared for rice by cutting down all the weeds and bushes with a machete; an opening for the seed is then made with a broad-ended bar, and the seed dropped in. When the rice comes up, the grass and weeds between the rows are cut with machetes, which operation is repeated at intervals. For Indian corn and sugar cane the land is prepared in the same manner, and the planting and cultivating is performed with the same tools, and in the same manner as previously described. The rice is cut with sheath knives, and the corn and cane with machetes. The rice, after being cut and cured, is first trodden out by peons or labourers, and then put into large wooden mortars, and milled by the use of large wooden pounders wielded by peons. Ploughing is done in the interior, for grain and potatoes, with ploughs made by pointing round sticks with iron—these implements being very similar to those in use in many parts of Italy. There are no harrows, field rollers, cultivators, reaping and mowing machines, drills or horse rakes. In the cultivation of potatoes and other vegetables large hoes are used. Timber-cutting and hewing are done with broad axes, and the timber sold is drawn to the rivers by oxen, having yokes strapped to their horns, and a pole strapped to the yoke. Chains are not used, the logs being attached to the ox-pole by raw hides. The small wood, from three inches in diameter downwards, is cut with machetes. On the plantation no saws are used, but the tools chiefly in use are machetes, hoes, iron-pointed stick ploughs, bars (wedge-shaped at one end), sheath knives, and broad axes.—*Journal of the Society of Arts.*

FORESTRY.

A Select Committee of the House of Commons was appointed on Friday, May 15th, "to consider whether, by the establishment of a Forest School, or otherwise, our woodlands could be rendered more remunerative."

The committee held three meetings, with Sir John Lubbock as chairman. The following draft report was agreed to on July 24th:—"Your Committee are of opinion that at this late period of the session it will not be in their power to conclude their investigation; they have therefore agreed to report the evidence already taken to the House, and to recommend that a Committee on the same subject should be appointed in the next session of Parliament." The evidence has now been printed and issued to the public. The first witness examined was Mr. William G. Pedder, head of the Revenue Department of the India-office. The forest organisation in India, he said, originated in 1846; and in 1863, further steps were taken to secure the scientific training of Indian forest officials. Last year the gross revenue had risen to nearly £1,000,000, and the net revenue to nearly £400,000. But the improvement which has taken place in the forests was a much more important element than the mere increase of net revenue. The forests were in course of being so completely destroyed in the various parts of India that the duty of the Forest Department had been rather to conserve them. He thought that, by the improvement of the education of our forest officials, we might produce somewhat similar improvements in England to those which have resulted in India. Forest schools existed in Germany, France, Russia, Italy, and Switzerland. Believing there might be some improvements effected in training the forest officials, we requested the French Government to send over an experienced officer to examine and report upon the state of the English woodlands, and the authorities sent over Professor Boppe, who made a tour of inspection of some of our forests, accompanied by Colonel Pearson, then forest officer at Nancy, and some of the students. He made a report, which witness handed in. In this report the Inspector of French Forests says that were it only for the purpose of replanting the five or six millions of moor and waste land which cover one-third of the Highlands, he should consider there was a sufficient reason for the formation of a Forest School. He recommended that a National Forest School be founded in Great Britain, and that Professorships of Sylviculture be instituted at Cooper's Hill and at Edinburgh. Mr. Pedder expressed an opinion that in twenty or thirty years hence, when the result of what is now done has become apparent the net returns of the revenue from the Indian forests, will become very much larger. The Indian Government established their school at Dehra Dun because it was desirable that officers, even of the lower grade, should have some special training. It had only been established for five years, so that they could not tell yet what the result of it might be. There was nothing of the same kind in Great Britain at present. At Kew there was a magnificent school of botany, but not of forestry. He belived the establishment in England of a similar school to that of Dehra Dun would be advantageous.

Colonel James Michael, who was at the inception of the Forest Service in India, said he concurred with the foregoing evidence. He thought the management of our woodlands, in England, might be improved, and that a forest school in this country would have very beneficial effects. There was a good deal of land in England and Scotland which would bear planting. Timber in this country would always pay for its carriage.

Dr. Hugh Cleghorn, who was for twelve years conservator of the Madras forests, said he also concurred in Mr. Pedder's view. It was unquestionable that, if we had more trained officials, our woodlands would be rendered more remunerative; and it was marvellous that we should not at an earlier date have begun to adopt some means to preserve them. The establishment of a Forest School in each of the three kingdoms would be a great advantage to this country. The supplies of timber coming from abroad were rapidly diminishing, and it was of great consequence that we should endeavour to increase our own production. There were many places in this country exceedingly suitable for planting, but it would be necessary to exclude sheep for perhaps thirty years.

Colonel Pearson, who represented the Indian Government for eleven years at the Forest School at Nancy, said he had the general charge of the forest students, and had been through most of the principal French forests. He had also been through the British forests with the French professors. Several English colonists had applied to him for officials to take the management of forests, and, being unable to find any qualified Englishmen; he had been obliged to recommend French officials. The school at Nancy was an admirable one, and had done great service by instructing a very able body of men, who were now carrying on good work in India. He was in favour of supplementing the general education given in this country by giving a special

forest education in some convenient place, where there should be a museum supplied, with an instructor in forestry, who might give lectures on the subject, and conduct the pupils from time to time into difficult forests with the view of enforcing the instruction of the lecture-room. A forest school might be set up in this country for an expenditure of £600, per annum in salaries. He did not know one mature forest in England or Scotland at present, and, therefore, for an important part of the instruction relating to the removal of the crop, the students would have to go abroad. It would be desirable to interest in this subject persons concerned in the education of land agents. We should suffer in the future if this matter were not taken up now. He would give three courses—elementary, for the wood manager; more advanced for the land agent; and a higher course for the man who wanted a thorough education but for the complete course men ought to go to the Continent. There was one spot in the Forest of Dean especially suitable for instruction; but neither there nor in the New Forest could anything be shown regarding the management of conifers.

MR W. T. Thiselton Dyer, Assistant Director of the Royal Gardens, Kew, said Kew performed, to a large extent, the part of a botanical authority to the Government, and when the Colonies applied for information, the Government sent to Kew for assistance. It had been found impossible to recommend to the Colonial-office properly qualified persons either to report upon or to manage colonial woods. Apart from the trained officials of the Indian Forest Department, it was practically impossible to meet the requirements of the Colonies; and that department had only spared men temporarily, which had caused great inconvenience. A good many of our Colonies had now come to that state of things that there will probably be a demand for persons who understood the management of forests. He would make the demand for India a kind of nucleus of a school which should be utilised for the education of such gentlemen as wished to undertake colonial service, and for the instruction of land agents and persons competent to give advice as to our own woods.

Mr. Julian C. Rogers, secretary to the Surveyors' Institute, said he agreed with the previous witnesses as to the general advisableness of instituting a Forest School, both for this country and for the Colonies.

The report of M. Boppe on a visit to the English and Scotch Forests, by the professors and students from Nancy Forest School (see *Journal*, vol. xxx. p. 772) is printed as an appendix to the report of the committee.—*Journal of the Society of Arts.*

CINCHONA STATISTICS.

From the following documents it would appear that the number of cinchona trees of all ages planted on 21,000 acres of private land in Java, is thirty millions, or close on 24,000 per acre. It will be a good many years yet before the bark from these will closely affect the markets.

Colonial Secretray's Office, Colombo, 12th Feb. 1887.

The Honorary Secretary, Planters' Association, Dimbula.

SIR,—With reference to your letter of the 7th July last, I am directed to transmit to you the enclosed copy of a letter from the British Consul at Batavia,—I am, sir, your obdt, servant.

H. C. P. BELL,
for Colonial Secretary.

No. 18. British Consulate, Batavia 18th Jan. 1887.

Sir,—I beg to acknowledge receipt of your despatch of the 24th August last handing me copy of a letter received by you from the Secretary of the Dimbula Planters' Association, asking for information regarding the cinchona cultivation of Java, on receipt of which I addressed the Planters Association here on the subject and have only just now received its reply, which accounts for the delay which has occurred in my forwarding you the information. According to the estimate of the Association, the area privately planted is 21,000 acres; the number of trees planted 30,000,000, (of which 14.000,009 C. succirubra;) and the crop for 1887 1,433.250 lb.; and I believe these figures may be taken as practically correct, or as nearly so, as it is possible to come. The average proportion of sulphate extracted from the bark is estimated by the Association to be about 3 per cent. At the end of September 1886, the statistics of the Government estates were as follows.—

Plants in the nurseries { 1,249,000 Ledgeriana
560.000 Succirubra

Plants in open ground { 755,700 Ledgeriana
74,000 Calisaya & Hasskarliana
556,000 Succirubra and Calloptera
234.000 Officinalis
8,000 Lancifolia

In 1883, the last year for which returns are available of the area of land planted by the Government it was 1,778 acres.

CINCHONA STATISTICS.

Years.	Government crop.	Private crop.	Amount realized for Govt. crop.	Plants in Nurseries.	Plants in open ground.
	lb.	lb.	£.		
1881 ..	179,520	25,290	18,204	736,600	2,036,480
1882 ..	275,264	35,259	28,036	1,205,800	2,099,400
1883 ..	453.424	172,733	28,915	1,533,000	1,966,500
1884 ..	380,800	275,762	30,000	1,516,500	1,753,900
1885 ..	458,728	—	—	1,390,000	1,567,000

Trusting the above information may prove of use to the planters of your island.—I am, &c.,

(Signed) N. W. NEILL,
H. B. M.'s Consul.

MANURES AND MANURING.—It is well to bear in mind that no cast iron rule can be laid down on the subject, different factors having to be considered before it can be settled what manure is best. It has been truly said that "the essential ingredients that must come from the soil are potash, lime, magnesia, iron, phosphoric acid, sulphuric acid, a small amount of chlorine, perhaps a minute quantity of silica, and, finally, considerable nitrogen. Consequently, in order that plants may grow and thrive, they must have at the disposal of their roots in the soil a sufficient quantity of each of these ingredients of their food. If any one of the more important constituents—potash, lime, phosphoric acid, or nitrogen—be deficient, the whole plant suffers."—*Planter and Farmer.*

WE note in the Batavia *Handelsblad* of the 11th January that a concession, formerly held by the Kali Anam Company at Langkat on the East coast of Sumatra, comprising about 26,600 acres of jungle land, has been taken over by Mr. O. Eckels, owner of the Mabar tobacco estate in Deli, and Baron P. de Lapeyrie agent for the firm of Decauville in Netherlands India and the Straits Settlements. These gentlemen intend to start a company with a capital of $60,000 or so, half of which has already been taken up, in order, on a large scale, to set about growing pepper, cubebs, nipah, and India Rubber. The market value of these products has risen high enough of late to warrant confidence in this first experimental venture in that line set on foot by a European settled in Sumatra. The land formerly owned by the Kali Anam Company, is especially suitable for pepper growing. At the head of this enterprise, which will bear the name of the "Sumatra Pepper Company," Baron P. de Lapeyrie will be put in the capacity of manager. The head quarters of the company will be at Tanjong Robia between Sunghy Tungkan and Sunghy Halaban. The promoters of this novel enterprise deserve every success. They intend to turn Siamese laborers to account, above all, for pepper cultivation. Siam is certainly a new quarter upon which to indent for plantation coolies in this part of the world. We are informed that the concessionaries will begin work in May next, and as this will be the first European enterprise of the kind in Sumatra, we wish the Baron and his partner every success.—*Straits Times.*

CEYLON UPCOUNTRY PLANTING REPORT.

THE WELCOME RAIN—COFFEE BLOSSOMS AND CROP PROSPECTS—MR. COCHRAN'S ANALYSIS OF COCA LEAVES—FUNGUS IN TEA—THE SAU TREE.

14th Feb. 1887.

The welcome rain which we had last week has made us all jubilant. Even the depressed and despised coffee has responded to the genial showers, and it is quite a sight to see how the shuckest trees are putting on blossom. Where the bushes are in any kind of heart at all, be it native or otherwise, every branch and twig is full of spike, and in a few days more they will be clothed in a clustering magnificence of white. This promise, and the prospect of good prices, are stirring the inert native. The little patch of native coffee which still remains after the inroads of neglect, leaf disease and hug—a relic of an all but vanished past—is being seen to; the weeds are scuffled off, the jungle stuff cut down, and hopes built up, which are likely to be discounted to the wily Moorman at a ruinous rate, long before the harvest can be reaped. If the blossom will but set—and one that was out about a fortnight ago has already done so—those who have any coffee remaining, may have cause for satisfaction in that they spared it. We will be having erelong some man going in for a new clearing of Arabian coffee; as it is I have heard of an enquiry for Liberian plants so hopeful is the Ceylon planter, prepared even to double back if there seem but a possibility of success. From Mr. Michael Cochran, M. A., F. C. S., our local chemist, I have been favoured with a report of a chemical examination of coca leaves, which, as being interesting to the readers of the *Observer*, I now enclose. I was indebted to Mr. J. A. Ferdinandus, of the Royal Botanic Gardens, Peradeniya, for the sun-dried leaves which formed the basis of the report, and I would like when mentioning that gentleman's name, to bear my testimony to his unfailing courtesy, and his readiness to oblige on all occasions. Indeed this willingness to serve the public is the distinguishing feature of all the officials connected with the gardens. Mr. Cochran's report is a valuable and exhaustive one. Whether coca will yet be a much cultivated article in Ceylon remains to be seen: any how those who do try to grow it, will find that the harvest of leaves is very much increased if the plant be grown in the shade. In the open it is more apt to produce seed. As to the profitableness of the culture, there are many opinions current. But experience in the matter is very limited and while you hear a good deal which tends to its disadvantage, still there is an under current of belief in its future.

The dying out of tea trees, in threes, and fours, which is a common enough thing in most new clearings, is now traced to a fungus on the roots. After having destroyed the rootlets, it attacks the tap-root, and then, what before seemed a flourishing bush, withers and dies. I understand that it is not a thing likely to spread. The fungus is caused from the rotting of the soft wood jungle trees,* and with the decay of that useless stuff there will die out that which starts the fungus into life. The Sau tree, which is favourably regarded as a shade tree for tea, and a general opener of the soil, is being pretty extensively planted out in nurseries. I learn that there is a considerable demand for the seed at present, the dry weather we have come through lately, giving many the idea that a light flickering shade such as is thrown by the graceful foliage of the sau, would prove beneficial to the tea plant in the dry months, and not be altogether an objection in the rains. By and bye we will know more of this. PEPPERCORN.

* We were the first to notice it, and we have never traced the fatal fungus to any tree but one, a species of symplocos.—ED.

PLANTERS' ASSOCIATION OF CEYLON.

The following are extracts from the 33rd annual report for 1886-7 of the Ceylon Planters' Association read at the annual meeting on 17th February, 1887:—

PLANTING PRODUCTS.

2. *Coffee.*—The acreage under this product has been reduced during the past year, and, notwithstanding the satisfactory prices now obtainable, your Committee believes that in some localities a further area now under Coffee will in the coming year give place to tea.

The Exports for 1886 were 179,210 cwt. against 315,649 cwt. in 1885.

Tea.—Satisfactory progress in connection with this product, which is rapidly becoming the staple of the Island has to be recorded. The acreage under cultivation is constantly being extended both in supercession of other products and in fresh land. The season, so far, has not been altogether favourable to an abundant yield, as the excessive damp of the South-West Monsoon has been followed in many Districts by a failure of the North-East rains. The unaccountable fall in price which took place early in the year, was soon succeeded by a firm market. Further advances have been made in the improvement and cheapening of machinery, but in the latter respect much remains to be desired.

The Exports for 1886 were 7,849,888 lb. against 4,372,721 lb. in 1885.

Cinchona.—The same causes which led to the large export during 1885 have occasioned a similar export during 1886, and consequently prices have fallen to a barely profitable point. It is impossible to say for how many months this export may continue; but it is unlikely to be for long, and it is maintained entirely at the expense of the future. Your Committee while fully alive to the desirability of obtaining the statistics connected with the probable export of bark, as suggested by the Dimbula Planters' Association, has felt that it would not be possible, at the present moment, to obtain figures which would be even fairly reliable.

The exports for 1886 were 14,675,663 lb. against 13,736,171 lb. in 1885.

Cacoa.—This valuable product has asserted for itself a position of no mean importance among exports, while high and remunerative prices have been maintained. The increased production has been very marked during the past year, and bids fair in the current year to exceed that of any previous year. The "Helopeltis scare," is practically at an end, and the attention of those who have hitherto held aloof from cacoa cultivation is being drawn to it by the very encouraging results obtained on the older plantations. That its successful and profitable cultivation will be confined to certain localities is no doubt true, but your Committee believes that, with patience and perseverance, a larger acreage can be advantageously made available.

The exports for 1886 were 13,056 cwt. against 7,192 cwt. in 1885.

Minor Products.—Of these cardamoms remain the most important, and the crop for the past year has been an abundant one.

The exports for 1886 were 238,947 lb. against 184,142 lb in 1885.

Liberian Coffee—is at present the only other minor product deserving of notice, but it is being gradually cleared out to make way for tea, and may probably soon cease to be an article of export.

The exports for 1886 were 3,834 cwt. against 5,325 cwt. in 1885.

INDIAN AND CEYLON TEAS IN 1886.

The rapid advance in public favour made by Indian and Ceylon teas is the feature of the last year's trade. The *Grocer* commenting on this and the past and future of the trade generally, makes the following comments, which show a distinct prejudice, on the part of the writer, against Indian tea:—"Now, with reference to quality, we are sorry to see that it is being sacrificed in order to produce quantity. India says, 'The Grocer, can't do without us, therefore let us compete with China, produce the quantity, and knock down the price,' They have knocked down the price of the bulk of the Indian tea, and they are now on a level with China, viz. 6½d to 9d per lb.; but, after all this is done, what will be the result, and will Indian planters benefit themselves? We decidedly say, 'No.' The gardens may be, and we believe are, able to produce now even at present value, and still leave a profit, but there is a limit to their consumption, as the India teas are so raw and pungent that no retailer will keep his trade long if he uses only Indian tea—even now we believe it will be found that the home consumption of Indian and Ceylon tea is on a par with China congou, or say, half-and-half; and it is much to be feared that in time this striving to produce the quantity will have such an effect on Indian and Ceylon teas that the public will turn against them. The public like something pungent and flavoury, hence the reason of the ever-increasing demand for Indian teas instead of China teas, but if they are only to be given a bitter nauseous compound and no flavour (which the lower grades of Indian tea are quickly coming to,) there will soon be a reaction in favour of the more delicate and refreshing China growths, and which only require to be made properly to be appreciated." It then goes on to say—"Indian and Ceylon teas are fast becoming the principal market in the trade. Dealers will neglect China sales but the greatest attention has to be paid to Indian growths. As fast as they are bought they seem to be sold again in the country, and consumption goes on increasing yearly. As regards Indian tea, the results to the dealer cannot be so satisfactory as would be imagined, owing to their increase in consumption and favour with the public, for several reasons. Firstly, owing to high firing, the teas taste well on arrival, but if they are kept they soon lose their quality and freshness, and become coarse and bitter. . . The bulk of the teas that have come in this season consist of teas under 10d. per lb., and under the very heavy weight of sales each week prices have fallen 2d. to 3d. per lb. within the last two months for these grades; it can therefore be well understood that dealers must be left with some bad stock. All these teas have a good leaf and very fair liquor, consequently the increase in the deliveries of Indian tea for the last two or three months of the year has been very large, as they now can more than compete with the low China growths, and of course are taken in preference. When fair grades of Indian souchong and pekoe cost 9d to 1s. per lb. they could not be used so freely in cheap mixtures, but now that they are actually cheaper, than common China growths *price for price*, an enormous trade in them is the result, as they have more point and strength in a low-priced mixture." As regards Ceylon teas, they continue growing in great favour. The reasons for it are many, viz., that they have kept up their quality this season, which both India and China have failed to do; again, they draw a dark liquor, and possess a beautiful soft flavour, thus enabling them to be drunk alone without any mixing.—*The Grocer.*

COFFEE CURING.

Sir,—Mr. W.A. Lyrtle's rejoinder to Mr. Johnstone's letter in your paper, *re* the above subject, calls for a few remarks from one, who was a Ceylon, and is now an Indian coffee planter, of, I believe, of longer standing, and of greater experience in the "Spicy Isle" than Mr. Lyrtle's letter leads me to think he has gained there, Mr. W. A. L. writes about the exorbitant charges for curing on the part of the Colombo agents. Again he forgets, if ever he knew, that most estates were heavily mortgaged from their very earliest infancy to, or through their several agents, and that, consequently, the proverb of "charity begins at home" might have been not inaptly applied to the non-reduction of the agents' curing charges. I admit that when times were bad the big curing firms did not respond, as they should have done, to the proprietors of the vanishing coffee. It *is* possible to cure coffee at a lower rate than was usually charged in Ceylon by the big curing firms, who at the same time usually acted as financial agents to the estates whose coffee they cured. The ordinary rate was R2-4-0 per cwt. whilst Baker and Hall's rate was R1-12-0, still I maintain these prices offer no parallel. The big firms were mixed up in financial estate transactions, and the latter firm were merely curers *pur et simple*. Mr. W. A. L's. ideas about sending down coffee to the coast at a ton a cart; are absurd, in view of the state of the roads down the ghats. He evidently has just woke up from a dream of the Spicy Isle, and fancies that the peerless roads we had there are duplicated in this or any of Her Majesty's Dominions. There is *one* grain of wheat in W. A. L's letter and I would strongly advise my planting brethren to sift it for themselves, and this grain resolves itself into "when once the color is established in the bean, dry the latter no further, keep it turned over in the store daily till despatch." He is perfectly right when he says that long exposure will result in a loss of color; and with good sun, color, if there is *any* in the bean will come out in five days; but your correspondent does not say that leaf disease effects the color of the bean, as it undoubtedly does; or, did he reach Ceylon when leaf was at its height, and is the color of the bean, under these circumstances his *beau ideal* of what the color of a coffee bean should be?

SALAWAKIELLIE.

Sir,—For the information of your correspondent who replies to my letter on coffee curing I may state that I had ten years' experience in Ceylon, and though that may not seem much beside the assumed hoary antiquity of this veteran, yet I submit that it is long enough to enable one to understand what he writes about with reference to coffee. Will your correspondent kindly respond, and state how long his "standing" was? I do not see that the fact that our friend of the strange signature is "acquainted with Mr. Johnston" is made use of as an argument, or in support of an argument. I am glad that he supports my argument so well when he says "The latter firm (B and H) were merely curers *pur et simple*." Yes, *merely* so. Hence their success. As for the difficulty in sending a ton down the ghats, I maintain that it is an easy matter with the dry weather and dry roads during crop in India. In Ceylon this load is almost universal in rainy weather; so the advantage gained by the metal is counteracted by the weather, I may also inform the gentleman whose letter is under reply, that I have procured a cart from Ceylon, which, with the exception of extreme length of pole, forms a tremendously favourable contrast to the Mysore jimcrack affair. It is not because of inferiority of the roads but rather because of inferiority of carts that makes a ton seem a preposterous load. This leads me to point out that your correspondent, while admittiug the inferiority of the roads here, yet fails to notice what I said about the needlessness of sending coffee down the ghats. If leaf disease affects the colour of the bean then there was no call for Mr. Johnston's letter. I merely stated what I considered to be the extent of the planter's duty. I may now in addition state that good cultivation in an Indian climate seems to counteract to a great extent the evil effects of leaf-disease. *Hemileia vastatrix*, being a fungus, never ceased from its deadly ravages on the food cells of the leaves in the moist hot climate of Ceylon. In India the prolonged drought, as well as the sunless, ceaseless, drip of the monsoon,—checks the reproduction and activity of the pest, and gives the weary planter some respite, some breathing space to prolong the heavy fight. Your correspondent flippantly refers to mortgages, and admits he was not always used to "Mysore Curry." I

have had heavy and early acquaintance with the former, which makes me thankful if I can get the latter. W. A. Lyrtle.
—*Madras Mail.*

CHEMICAL EXAMINATION OF COCA LEAVES.

I have much pleasure in reporting to you the results of my first attempt at the chemical examination of the leaves of Coca Erythroxylon, which you were good enough to obtain for me. One portion of the sun-dried leaves yielded ·544 per cent of crude cocaine alkaloid; another smaller portion of the sample, which I treated with fully one and-a-half times the proportion of solvent used in the first case, yielded ·648 per cent of crude alkaloid. These results are good, but the total amount of alkaloid obtained from the quantities of leaves operated on seemed to me too small, viz., 4·2 and 2·6 grains respectively, to admit of an accurate determination of the pure alkaloid being made by the process followed. In assaying the leaves by this process, indeed, it is not customary to proceed further than the actual determination of the crude alkaloid. Determinations on the large scale shew the proportion of impurities (another alkaloid called hygrine and decomposition products,) which usually accompany the crude cocaine, and a corresponding deduction being made from the impure alkaloid obtained by assay, the difference is regarded as a close approximation to the amount of pure alkaloid. I should like to obtain a larger supply of leaves, both for the purpose of trying other methods of extracting the alkaloid, and also to determine for myself the amount of purified alkaloid obtainable from the crude alkaloid. I have before me two leading chemical journals, in both of which the process I used is given, yet the one authority states (giving instances from actual working) that the crude alkaloid usually contains from 20 to 25 per cent of impurities, while the other authority gives no examples, but states that the crude alkaloid "contains on an average 20 per cent of alkaloid with much impurity." The crude alkaloid which I obtained was a clear, almost colourless substance, resembling varnish, which by and bye crystallized, the crystals spreading out from star-shaped nuclei. The crystals even after long drying remained somewhat viscous to the touch. A small portion when laid upon the tongue and pressed against the roof of the mouth had a slightly bitter taste, and about a minute, there was experienced an increasing feeling of numbness. The effect, which was not very strong, but quite marked, passed completely away in a few minutes. A portion of the alkaloid obtained was dissolved in hydrochloric acid to a clear and neutral solution, and evaporated to the consistency of varnish. After standing for some time and being stirred it changed its physical condition to what looked like a moist nearly white amorphous powder, but, under the microscope, its structure was revealed as a mass of clear, but very minute, prismatic crystals. This is the cocaine hydrochlorate, the use of which as a local anæsthetic is now fairly established. A little of it placed upon the tongue soon produced a sensation (or want of sensation) resembling that of a painless blister. I dissolved the salt in water, adding a minute quantity of salicylic acid, to prevent the growth of low organisms in the solution. I have ent you a portion of this solution, which is clear and but slightly tinged with colour. A good way to test the effect of it on the mucous membrane of the mouth, is to put a drop of it on a small piece of blotting paper, which is then pressed between the tongue and the roof of the mouth. A comparatively short time ago, the crystallized hydrochlorate of cocaine was retailed in Colombo at R2·50 per grain, now it may be had for 25 cts. per grain.

As I have not in the course of my reading seen any analysis of the ash of coca leaves, I used a portion of the sample of leaves to make an analysis of the mineral ingredients left after burning the leaves. This is interesting, as showing the inorganic matter removed from the soil by a crop of coca leaves.

The sun-dried leaves gave off 10·8 per cent of moisture, when dried at 212° Fahr., and when burned, yielded fully 6 per cent of ash, including carbonic acid, which is not an ingredient of the leaf, but a product of combustion. The following are the detailed results:—

Composition of the ash of coca leaves.

Silica	3·06
Oxide of iron &c., ...	3·38
Lime	27·86
Magnesia	8·50
Sodium chloride	5·74
Postassium chloride ...	1·26
Potash...	13·94
Phosphoric acid	16.81
Sulphuric acid	4·61
Carbonic acid	14·84
	100·00

Since writing the above, I have come upon and interesting research into the composition of tea leaves, in the January number of the *Journal of the Chemical Society*, which, by analogy, may throw some light on the discrepancy of the two authorities referred to on the matter of the amount of pure cocaine obtainable from the crude alkaloid. O. Kellner has made systematic analyses of fresh tea leaves plucked from May to November, and it would appear from his tables of analyses that the amount of ethereal extract and of the alkaloid theine are variable, and in something like inverse proportion to each other. In May the amount of ethereal extract was 6·48 per cent. and the theine 2·85 per ct. calculated on the dry leaf, while, in November the figures were 22·19 and 1.00 respectively The constituents of the ash shew similar changes. The potash *e. g.* in May constitutes 49 06 per cent. of the ash, and it gradually decreases, till, at the end of November, it is only 17·31 per cent. Conversely the lime in May is 11·95 per cent. an at the end of November 30.46 per cent.

M. COCHRAN.

Colombo, 7th Feb. 1887.

Substitute for Coffee amongst the Natives.—A planter has sent us pods of a leguminous plant, asking,—"Have you heard of the new coffee that is now sold at the *kaddies* on the road side called *Toor atta*?" Having submitted the question to Mr. W. Ferguson, he writes:—These fruits (pods) are those of the *Sesbania Ægyptiaca Persona*. The plant is common about cooly lines all over Ceylon and has been grown in the island for several centuries. It is given as a native in Dr. Trimen's list, but though known to the Tamils as *Karum-chembai*, it has no Sinhalese name and it is not one of the Toras, (Cassias, or Cajanus). The leaves are used as poultices, and the wood makes excellent charcoal for gunpowder, but I do not believe the seeds are used for any purpose.* Those of a species of Cassia, had quite a run as a substitute for coffee sometime ago."

* Our correspondent distinctly states that they are now used as a substitute for coffee.—Ed.

INDIAN FIBRES SUITABLE FOR PAPER MAKING.

We have been favoured with a copy of the following official Report of a Conference held in the Commercial Room of the Imperial Indian Court of the Colonial and Indian Exhibition, 2nd July 1886.

Present:—Sir E. C. Buck, LL. D., Dr. G. Watt, C. I. E., Mr. John Wilson, Mr. F. G. Lloyd, Mr. E. H. Joynson, Mr. E. Bevan, Mr. Clayton Beadle, Mr. J. Buchanan, Mr. T. Christy, Mr. W. E. Death, Mr. F. P. Banlow, Mr. Routledge, Mr. Lascelles-Scott, Mr. B. Donkin, jun., and Mr. T. A. Archer.

On the tables were displayed, a large assortment of fibres suitable for paper-making, as also Indian power and hand manufactured papers. The following may be mentioned as the more important fibres shown:—

Pollinia eriopoda.	Rice straw and roots.
Saccharum Munja.	Dhup and other wild grasses.

Also bamboo half stuff and paper, prepared by Mr. Routledge, of Sunderland, and a number of the cheaper bark fibres of which those of *Bauhinia vahlii* were deemed the most hopeful. *Opuntia dillenii*, the cactus which has overrun large tracts of the drier regions of South India, was pronounced useless, but plantain fibre and half stuff was viewed as most hopeful. Jute waste and rags, and other waste materials used in India for paper-making, were also placed on the tables, but as these are articles of established trade they received only a passing remark.

It was admitted by the gentlemen present that paper might be made from almost anything; the question was one of price. It would never, for example, pay to cultivate any fibre for paper, and especially a fibre that required to be put through a preparatory process before being thrown into the paper-makers' vats.

Mr. Death said that, in his opinion, the most promising fibre in India for paper-making was the common edible plantain, but the great difficulty in utilizing it was the cost of carriage. What was therefore wanted was a machine that would strip the fibre on the spot, reducing the stems and leaf-stalks to a condition in which they would be baled economically. Experiments were being tried, with this object, in Costa Rica, and he expected to receive a report in a few days, which, he believed, would be favourable. He very kindly promised to communicate this for the information of Government in case it might be desired to have the same experiments repeated in India. Should his anticipations be realized he felt sure the fibre would come into general use in papermaking, and there was no doubt very good paper could be made from plantain stems, in fact this had been proved by practical test, and he would be glad to furnish samples of plantain paper.

D. Watt explained that this fibre had received considerable attention in India, and that the Bally Paper Mills showed in their case, samples of plantain paper. The difficulty that, in his opinion, would always stand in the way of a great development of plantain fibre was the collection of the stems. It was all very well to talk about a machine that could be used on the spot, but for whatever cost such a machine might be had, the owner of half a dozen plantain stems was not likely to purchase it. There are few plantations of plantains, and the supply would have ultimately to come from the hundred peasant homes within every square mile, since the plantain did not exist in sufficient abundance as a wild product in accessible regions.

It was stated to be indispensably necessary in a fibre intended for paper to reduce the bulk to a minimum so as to lessen the cost of freight to Europe, provided that this reduction did not entail any elaborate or costly process. Simple methods for doing so are known, such, for example, as beating to remove dirt, hydraulic baling of the fibre into conveniently sized packages.

It was urged that it was essential that information should be afforded respecting the quantity available and the probable cost of any proposed new fibre. Quantities of 10 tons were needed for reliable experiment, and the material sent should be as much freed as possible from all useless matter, provided the doing so did not increase the cost of the fibre too much.

Sir E. C. Buck suggested, that it would be well if the gentlemen present who were interested in paper making would go through the fibres shown in the Economic Court, and make a list of those which appeared most hopeful as future paper fibres, in order that samples of these might be sent from India beaten out and prepared in the desired manner. This proposition met with general approval, and it was again urged that to be useful to paper makers a fibre must be cheap, since all that the paper maker could pay for was waste from the fabric industries, or a fibre that, like esparto, might without any preparation be thrown direct into the vats. Esparto could be purchased at £4 a ton at the present moment in London, and wood pulp had so revolutionised the paper industry that, unless for special merit, the paper-maker could not pay more than £10 or £12 a ton.

The gentlemen present agreed that, while the *bhabar* and *munj* grasses were very good for paper it would never pay to import them in that condition, the more so since esparto was obtainable at a price far below what would be charged in freight alone from India. Unless these grasses could profitably be shipped in the form of half stuff they were out of the question. The only Indian fibres that seemed hopeful were bamboo, plantain, jute, and sunn waste, and the long stems of the *Bauhinia* creeper. Since the Conference perhaps some dozen paper-makers and textile manufacturers have asked and obtained samples of the last mentioned fibre, and it seems highly likely that as a direct outcome of the present Exhibition this creeper will come to be extensively used for a number of purposes. Everyone who has seen it has gone away pleased, and fortunately anticipating some such result; steps were taken to send to the Exhibition a large supply, and it has thus been possible to meet all demands for samples.

The practical result of the Conference may be briefly stated to be that fibres that are good enough for textiles are too good for paper-making. Bamboo has been tried, and may be viewed in as forward a position as it is possible to press a new material.* The gentlemen who attended the Conference agreed that the Government had best concentrate its energies on developing the plantain and *Bauhinia* fibres.

It was asked if the Government would grant any inducement to paper manufacturers who would be willing to undertake the necessary experiments, which, to be useful, must include technical trials as well as scientific analyses.

Sir E. C. Buck feared that there was no fund available for such purpose; but the fibres selected by any person desirous of experimenting, might be sent from India in the form of "stock," cleaned by the natives as near as possible in the desired manner.

After the usual acknowledgment to Sir E. C. Buck and Dr. Watt for the kind manner in which they had assisted at the Conference, the company separated. —*Planters' Gazette.*

THE VALUE OF MULCHING.

One of the greatest difficulties with which our New England farmers have to contend is the long and severe droughts with which our seasons are almost always accompanied, the cause being the peculiarities of our climate and the construction of our soils.

Water is continually passing from the soil into the atmosphere during the Summer months, either through vegetation, by the process of growth or through the soil, caused by the absorption of heat, which rapidly evaporates the moisture as it ascends to the surface through the capillary tubes of the earth.

The escape of moisture through vegetation, the intelligent cultivator would not check if he could, for upon this depends the quantity of our crops at harvest time. To prevent or check the escape of moisture on fallow lands, however, is one of the important labors of the agriculturist. This may be accomplished in two ways. One by repeatedly stirring the soil, by which means the continuity of the capillary tubes is served or bro-

*Young shoots and not well-grown stems being desiderated, we doubt if bamboo will ever be largely used for paper-making.—ED.

ken, so that the water does not ascend so rapidly to the surface. Another and more efficient method of preventing the escape of moisture is by mulching. This not only prevents evaporation, but also acts as a fertilizer to a certain extent.

When the ground is mulched the water ascends to the surface and brings with it fertilizing salts from, and even below, the subsoil. When the fallow is naked this water is, by the heat of the soil, converted into vapor before it reaches the surface, and the salts above referred to are left lower down in the soil, not infrequently below the reach of the plant-roots.

Mulching means shading, since both produce the same results. Evaporation progresses slowly where there is shade. The ground is kept cooler, and where such is not the case the intervening shade prevents evaporation. This latter is not so rapid on cloudy days as on bright ones, though there may be little or no difference in the temperature of the soil. Moisture accumulates under and about the stones, and we were once told that the stones drew water, but the truth is they prevent evaporation, or in other words, they mulch the ground.

The foliage of the trees in woods shades the ground, thus retarding evaporation, but the fallen leaves mulch the ground and retain the moisture; in such places the roots are found nearer the surface, and yet the foliage shows less effects of drought than the foliage of trees out in the open pasture, where the roots run deeper.

There are many crops grown which cannot be considered as mulching the ground, although they cover it, simply because they carry off more water by the way of their roots and leaves than would be evaporated from a naked fallow. Of such crops we may mention clover, grass and the cereals. On the other hand, corn, potatoes, tomatoes, squashes and the like act as mulches, because they shade the ground in the vicinity of their place of growth.

When corn first comes up it is cultivated and hoed to break the capillary tubes in the earth, so that evaporation may be checked, and the growing crop have the benefit of the moisture. When the corn has grown to a certain height, it then shades the ground, and in this way checks evaporation, preserving the moisture, to a certain extent, for its own growth. The same is true of potatoes and tomatoes, while squashes shade the ground more than any crop grown. They are perfect mulches. The roots of all these plants run out into the ground so shaded to obtain that moisture which their foliage retains for their use.

Great benefit is found from the practice of mulching in young orchards. The first season after setting out young trees is generally severe upon them. The young rootlets, not having secured good hold upon the soil, require the adoption of some means for retaining moisture in the soil. If not secured in some way, or applied by artificial means, many of the young trees are likely to die. The easiest way to effect this is to retain the moisture by mulching with matted hay, straw leaves or tan bark. These mulches will keep the ground moist and mellow. In the Fall they should be forked into the soil to prevent mice from harboring in them.

Continuous mulching is a great benefit to peach trees, resulting in finer and larger fruit than can be secured in any other way. Mulching currants tends to increase their size, while raspberries and blackberries should always be mulched. This latter process not only tends to supply moisture, but also assists in keeping down weeds. Through mulching, strawberries may be grown on much drier land than they would otherwise succeed in. In addition to keeping down the weeds, the fruit is kept clean and clear of grit, which latter is often thrown upon the fruit by rains.

There are some exceptions to the beneficial practice of mulching. Thus grape vines are considered better for not being mulched. The grape vine delights in a warm soil and the roots are generally very near the surface. While orchardists and raisers of small fruits are all agreed upon the value of mulching, yet, growers of grapes, as a rule, are equally certain that grapes do better if not mulched.

The question of mulching is an important one to farmers and of immense practical value. However, the science of evaporation, which embraces hte retention of moisture in the ground as well as the evaporation, of water through the foliage of plants, is one of the most interesting studies connected with the art of agriculture, and one which should be exprimented upon by every cultivator of the soil.—*American Cultivator.*

THE CULTIVATION AND MANUFACTURE OF SUGAR IN BRITISH GUIANA.

BY MR. B. HOWELL JONES.

The cultivation and manufacture of sugar occupied the attention of the early Dutch settlers in British Guiana, but the present system of cultivation of the low lands lying near the sea does not appear to have been adopted until the settlers found that the land in the interior was not so productive as the alluvial deposits on the sea border, as in the year 1756 the entry in the records of the Colony mentions that "the settlers, not finding the upper lands of the rivers so productive, are returning to the coast." It was, perhaps, as well for the Colony that the Dutch were the first settlers, as from the experience derived from the cultivation of the low-lying lands of Holland they were singularly adapted for establishing a similar system of drainage and navigation in a land of which a large portion lies some 3 feet below sea level; and the remains of old brick sluices and kokers tell us of the indomitable perseverance, courage, and knowledge they had in handling such difficult operations; and that they were right I think has been amply proved by the system having been carried on uninterruptedly since they established it. The cultivation of sugar did not absorb the whole attention of the population, as it does at present, until after the abolition of slavery, when the price of wages rose so considerably that it was found impossible to continue to cultivate cotton and coffee; these estates were consequently abandoned, whilst the sugar crop was reduced to one-half, and nearly all the estates changed hands. It was not until 25 years afterwards, with an importation of 45,000 immigrants from India, China, and Maderia, at an enormous cost to the planters, that the Colony once more regained its position as a sugar-producing country of any importance. The sugar estates are situated along the alluvial deposits bordering on the sea, and run in parallelograms at right angles, either from the sea or rivers, and extend four or five miles into the savanna which forms, in most instances, their other boundary. A line of dams is thrown up along the sea front, to protect it from incursions of the sea, and aback a line of dams to prevent inundation from the savanna, which in wet seasons gets flooded with rain water.

The estates are generally laid out with two centre-trenches, with a dam between them, known as the middle walk and middle-walk trenches, from which at right angles extend the cross canals which separate the fields from each other, and are used, as well as the middle-walk trenches, for the transportation of canes. At each side of the estate the side-line trenches, or main-drainage trenches are dug, and extend the full length of cultivation, and into these trenches the small open arterial drains, or small drains as they are generally called, discharge themselves. The main-drainage trenches either drain through sluices at low tide direct into the sea, when natural drainage is obtainable, or are united into one main trench, and artificial drainage by means of powerful pumps, is adopted. It is not the least important part of a planter's duties to see that both series of trenches, with their sluices, pumps, &c., are kept in thorough order, the importance of good drainage in a low-lying country such as British Guiana being a *sine quâ non.*

Keeping in mind the description, as just read, of how an estate is laid out, I will now describe the method adopted for planting and reaping a crop of canes. The cane plants, as a rule, are planted in rows running from cross canal to cross canal, and at right angles to the small or arterial drains of the field. I say as a rule, as in some instances, becoming rarer as time goes on, they are planted from middle-

walk trench to side-line, and parallel to small drains, and called Dutch rows—but this plan is not now generally adopted. The first operation when a field has to be planted is for the cane rows to be lined out, the distance apart depending on the opinion of the individual planter; but the plan generally in use is known as three by three—that is, pins are placed across the field 3 feet apart, the space next the middle-walk trench being left generally a foot wider, and is called the parapet. Then a cane row 3 feet wide is dug, a small portion of earth thrown out, the space carefully ploughed, and the earth levelled off—in fact, a seed bed is prepared. The next space is left untouched, then another cane row, and so on across the field, the space between the cane rows being known as the "bank." In the centre of these cane rows the plants are put in, sometimes a single row, sometimes a double row, the cane plant consisting of the last few joints of the cane, which is green and contains very little saccharine matter, or else they are shoots sprung from old cane stocks and known as "stumps," several of these shoots, with a portion of old cane from which they shoot, forming a stump. The plants are carefully selected and put into the ground at an angle of 45 degs., about 9 inches apart, care being taken that the eyes of the top are placed on the side, so that all spring; if otherwise, those placed below would not grow. In planting stumps care should be taken to see they are well and firmly set, all decayed matter having been first removed, so that no water lodges at their roots.

A field thus planted is left until the eyes spring, and the tender shoots are seen above the ground, which in fair weather takes place in nine to fourteen days. When fairly on their way the first weeding and moulding takes place, and the field generally cleaned up of all loose trash, pieces of cane, &c.: this, with the grass from the weeding, is placed tidily on one of the banks which for the time becomes the trash bank—the alternate bank, which is kept clean, being known as the clean bank. In moulding up the young shoots, the fine earth from the surface should be carefully spread over the head of the top, so as to protect it from the scorching influence of the sun. During the progress of the first weeding it is generally the custom—and I think advisable—to send in a gang of men, according to the quantity of work to be done, and carefully to put in new plants in place of any that may not have grown. This operation is called supplying. I think this should be done as early as possible; if not, the plants growing on either side, the new plants overshadow them, so much that they often die, or do not come away with the vigor desirable. As soon after the first weeding and moulding has been done it is desirable, if weather permits, to commence ploughing what is known as the clean bank; and often, when the first weeding has not been a heavy one, or if there has not been much trash left from the last crop of canes, both banks are ploughed together. This keeps down the grass, which in our climate is a serious matter, as it grows with wonderful rapidity, and would soon affect the growth of canes if left too long; and it is essential when canes are young to see they are kept from weeds. This work accomplished, manuring the young canes next occupies the attention, and this is done as soon as possible, generally six weeks or two months after planting. Various manures are used, according to the opinion of the manager of the estate, who judges what is required from the nature of the soil he has to contend with. Ammonia, nitrate of soda, Ohlendorff's guano, Lawes' cane manure, are all well known to us, besides many others made especially to meet the views of individuals; but, as a rule, mixed manures are shunned, except those that have stood a long test and have proved to be up to the standard at which they have been bought. With the assistance of chemists much has been learnt, and it may surprise some of my hearers to learn that on some estates an analysis has been made of the soil of every field, and in one instance that I know of an analysis of the first 3 feet has been taken, so as to arrive at the value of the subsoil. In a climate such as ours, with an excessive rainfall at one period and severe droughts with which we are periodically troubled with, the value of manure much depends on the season which follows its application.

A field cultivated up to this point, with both banks ploughed, drains well and neatly dug, and a vigorous growth of young cane, is a very pretty sight; and, a planter delights to show a fellow agriculturist a strip of young canes in this condition, or to hear from him the exclamation, "Ah! that's a fine young strip." Once a field is well established like this little more has to be done but to see it is kept clean, and it is not such an easy matter as an English agriculturist would imagine. At least one more weeding and moulding has to be done; sometimes a third is needed; but if not, and the canes are advanced enough, then the field has to be weeded and the canes trashed. Of course, the canes and the previous weedings have in a great measure kept down the grass, but care is needed to trash the cane, or, in other words, to pull off all dried leaves, and carefully pack them away on the trash bank. The cane stool must be freed from all rotten trash, and blighted canes picked out; this admits light and air to the canes, materially assisting their growth, and bringing the cane, with its crystallisable juice, to perfection. Care is required in trashing not in any way to injure the cane or to strip off those leaves which, from not being quite dry, might bleed the cane. The operation of trashing is generally performed three times, the last operation taking place a few weeks before the canes are cut; this not only assists in ripening the juice, but helps the cane cutter when cutting canes, they being always more ready and willing to cut when a field is well trashed and clean.

The age when canes come to maturity differs in Demerara according to season and locality; the average of a plant field such as I have described is about 14 months. On the river districts 15 and 16 months are often required to ripen canes; whilst on some of the coast lands 12 to 13 months often suffices, and I have known in dry seasons canes 10 and 11 months quite fit for the cutlass.

Such is briefly an account of cultivating a field of plant canes in British Guiana. I say plant canes, as that is the term generally used for canes grown on new land for first time; if planted on old land from which canes have been reaped they are termed replants. The second year of growth is termed 1st ratoons, the third 2nd ratoons, and so on until the field is again replenished. I have known fields to continue to yield well up to 25 years; but it is a question if any of the old stools remained, the supplies which from year to year have been put in having entirely supplanted them. As a rule, the stools are allowed to go on until they have become 4th ratoons when replanting takes place. The plant canes having been cut off and conveyed to mill by punts, a method hereafter to be described, it is necessary to prepare for the next crop, and as the cultivation is slightly different it will be found convenient to give and account of it here. The canes having been taken from the field, and the cane cutters, during the process of cutting, having removed the trash from the trash bank on to the clean bank, the trash is found lying loosely about the field and covering up the small drains. The first operation is to send in a gang of workers to clear up the field and to put straight the trash; this is called relieving, the workers taking the bands or leaves which form the head of the cane and tying round the trash, cleaning out all the drains, clearing the cane rows and weeding. Last year's clean bank now becomes the trash bank. The field is now left until the canes begin to spring; the first weeding and moulding is given as soon as they are established, and supplies put in where necessary. Sometimes during this last work the cane row is carefully ploughed, making it level and avoiding holes for water to lodge in. Then comes the working of the bank: sometimes it is ploughed as in plant canes; other times, especially if the land is stiff clay, or that the weather has been very heavy and canes suffering from over moisture, the bank is drilled, an operation which may be fitly termed surface drainage, and con-

sists in digging a drain, generally 2 feet wide by 1 foot deep, at right angles to the ordinary field drains. Some planters prefer 1 foot 6 inches by 1 foot 6 inches, but this is a matter of opinion, and the quality of the soil has to be considered: the earth which comes out of the drill is used for covering over the trash, which is allowed to rot under it. Should a field not require drilling, then as a rule the bank is ploughed as in plant canes, and the operation of burying trash on the other bank is usually carried out: this consists of turning in the trash with the fork or shovel. I may mention that all our ploughing is done with a four-pronged agricultural fork. The trash is completely buried, and allowed to rot. After whatever delving work has been done, weeding and moulding and weeding and trashing are carried on as in plant canes. In 2nd ratoons very similar work is done, only the trash is buried on the other bank to what it was last year, or the other bank is drilled; but, like everything else I know of in agriculture, no hard-and-fast rule can be laid down—so much depends on the soil and climatic influence, and in a tropical country with extremes of wet and heat, it is especially so.

We will now go back to the ripe cane field described as plants. We will imagine the arrow, or flower, of the cane blown. The cane cutter uses a sharp cutlass, or long knife, 20 to 22 inches long, cutting the cane as close to the ground as possible, with a clean cut, catches the cane by the middle, strikes off the upper leaves, which make the band mentioned when speaking of relieving, and with a second cut knocks off the top or plant. If the cane is too long the cane is then cut into two or three pieces, and put in bundles on the bank: these bundles are carried out to the cross-navigation trenches, or to the middle walk. Here they are picked up by the punt loaders, and put into punts. These punts are large flat-bottomed barges, 24 feet long by 8 feet wide and 3 feet deep, and, when full, contain about 3½ tons of cane, and are hauled by mules to the mill dock, to be dealt with in the factory. The foregoing does not pretend to be more than a general outline of cane cultivation in Demerara. Like everything in agriculture, opinions differ as to the best methods to employ to obtain the best results, and each may be right, as the position of estates, condition of soil, and effect of weather all have to be taken into consideration; but I venture to think that many agriculturists in England would be astonished to see the knowledge, care, and attention shown by the leading planters in British Guiana.

Manufacture.—The canes, once in the mill dock—and they are brought there as quickly as possible after cutting—are brought alongside the cane carrier, which consists of two endless bands joined together by cross-pieces of wood to form a table on which the canes rest, and are thus conveyed to the mill. The mills used by us are generally 3-roller mills, and vary in size from 5 feet by 24 inches to 6 feet 6 inches by 48 inches and the crushing varies, of course, considerably on different estates, and also according to the quality of cane which is being crushed, but I do not think more than 65 per cent is usually extracted. On some estates double crushing has been restored to—that is passing the canes through a second three-roller mill; and Mr. Russell's patent of maceration has also its strong advocates. This latter consists of passing the megass or crushed cane from the first mill through an iron chamber 30 feet long, the megass resting on an endless band of wire web: during its passage through, steam and hot water is turned on, and the megass absorbs as much as possible or whatever proportion is desired; it is then delivered into a second mill and re-pressed, of course the juice being of poorer quality than from first mill. By this method it is claimed as much as 77 per cent of original juice has been extracted. A five-roller mill, by McOnie, has recently been put up in the Colony, and the extraction hitherto recorded has been about 72 per cent, but it was during a season when canes contained a large percentage of woody fibre, and better results are expected. A large portion of the mills are now fitted with hydraulic power, which enables the planter to set his rolls as close as he likes, and to put on any pressure he may think desirable, and is a very great improvement on the old set screw, as, no matter what the feed is, an equal pressure is given to one cane as to a hundred, and thus a loss occasioned by an unjust or careless feed is avoided. The canes having been crushed, the megass passes away on a carrier, either to be burnt directly under the boilers, or is conveyed by trucks to the megass house, or logie, and there allowed to dry until fit for fuel.

The juice is first strained, then passed through a chamber where it is impregnated with sulphurous acid gas, which both bleaches and assists to coagulate some of the vegetable matter. It is then pumped into clarifiers, and milk of lime is added until nearly the neutral point is arrived at, a slight acid reaction with litmus paper being generally the point aimed at. Heat is turned on whilst the clarifier is being filled, and the temperature of the juice raised 190° to 200° F. When this point is reached the vegetable impurities have risen to the surface in form of a thick scum: this is carefully removed, and the clear liquor, which should be bright amber colour, is let down on to an open battery or into a triple effet which is gradually superseding and will in the future entirely take the place of the former; but whatever method is used the liquor is concentrated to the density required.

If the open battery or cropper wall, as it is called, is used, the liquor is passed from one trench to another as quickly as is consistent with the cleaning of the liquor, as, as the density increases, scum rises on the surface and has to be carefully brushed or skimmed off until it has had all the impurities removed; it is then gravitated, or pumped by a Monte-jus, into receivers, ready for crystallising in vacuum pan. Should the triple effet have been adopted the liquor from the clarifiers is run into open pans, or defecators, where it is quickly brought to the boiling point, and, as on the copper wall, the scum as it rises is removed; but concentration is not aimed at, and the liquor is run quickly into the triple effet, where the density is raised as required, and from there passed to the vacuum pan. Another method adopted when using the triple effet is to pass the liquor from the clarifiers straight into tripple effet, and when it is concentrated to run the syrup through bag filters to remove the impurities. Both methods have their advocates.

The syrup once in the vacuum pan is boiled *in vacuo*, as the name implies, at a low temperature, and gradually, grain is formed. More syrup is added until the pan is full of crystallised sugar; the pan is then struck out, the mass of hot sugar, with that portion of syrup not crystallised, or molasses, forming what is called the massecuite. This is either allowed to cool or is taken to the centrifugal machines. These machines consist of an inner case with sides of fine woven brass wire, or finely perforated copper, and an outer case of gun-metal; the inner basket is suspended from above on a spindle, which is made to revolve from 1,100 to 1,200 revolutions a minute. The centrifugal force thus set up, forces all the molasses and moisture from the massecuite into the outer casing, leaving the dry crystallised sugar on the inside of the basket. This is then taken out through an opening in the basket, and carried to sugar store, ready for packing into whatever packages it is considered most desirable.

We must go back a little in the process of manufacture, to where the scum is removed from the clarifiers, and from the copper wall. This is by no means wasted, but is received into tanks and brought to the boiling point: it is then allowed to gravitate through bag filters or is forced through filter presses of the Reaumur or Kroogs type, the clear liquor being either drawn straight into vacuum pans or used to mix with the molasses from the centrifugals to make a second quality of sugar. All the sugar which it pays to extract from the molasses having been taken out, the refuse is sent away to the distillery for making rum. This is briefly, and within the limit of the time alloted to me, a description of sugar cultivating and

manufacturing as carried out in Demerara. It may differ in details in the practice adopted on different estates, but it contains the general principles usually employed.

It has been said by people in England, and reported in the newspapers, that the reason why we do not succeed with sugar in the West Indies is that we do not employ the best means to extract the sugar from the cane, that our machinery is antiquated and not powerful enough—in fact, that we have stood still. Such, at all events, cannot be said of the planters of Demerara, unless, indeed, the English engineers have also stood still, as machinery of the newest design, without reference to cost, is, and has been for many years past, imported into the Colony from the best firms in England and America, and all that the planters and their agents can do is done to keep pace with the times. That this has been recognised is fully borne out by the constant visits of agents of engineering firms from England and the continental nations, and the adoption of their inventions, often the reverse of improvements, that have been palmed off on us.

I have been gibed at that we have not yet adopted "Diffusion," which, according to some, is to be the panacea of all our troubles. All I can say to that is, the matter is receiving the fullest attention and our leading proprietors will not spare their capital when they have before them such figures which will, warrant their destroying their present plant of machinery and in spending so large a sum of money. These have yet to be forthcoming, and it is as much the business of engineers who are connected with the sugar trade, and whose business is, according to their own showing, very bad, to try and obtain figures which would justify their making a diffusion plant, and, even if it does one-half that is claimed for it, orders would soon pour in. I will confess to one thing that we were, and still are, deficient in, and that is, employment of trained chemists in our works: it is fast being remedied, and men well trained, with a knowledge of sugar manufacturing, can now easily obtain employment with us—not boys from school and laboratory, but those who have made it a study, and will lay themselves out for original observation and research. I can only trust and hope that such improvements will be made as will enable us to fight with success against the odds of bounty-fed continental sugar, which the English Government unfairly assists under the taking garb of free trade.

USINE SUGAR.

The usine system of sugar production takes its name from the French word "usine," owing to the fact of the system having been first introduced and worked by the French in the Colonies of Martinique and Guadeloupe. The system owes its origin to the late M. Cail, head of the celebrated firm of Paris engineers, Messrs. Cail & Co. The essential feature of the system is the complete separation of the industry of cane growing from that of sugar manufacture; but the success of the system is more to be attributed to the fact that the usines which were established under the auspices of Messrs. Cail & Co. were supplied with the improved machinery which the development of the beet-sugar industry on the continent had brought about. Previous to the adoption of the usine system, the cultivation and the manufacture of the cane had been carried on generally on small estates making from 100 to 500 tons of sugar, the manufacture being of the simplest character. The canes were crushed by mills similar to those still employed, but in a rough-and ready manner, the extraction of juice being probably at least 10 per cent less than that now obtained, and the evaporation was conducted on what is known as the copper wall, *i.e.*, in open pans with a naked fire underneath. The concentrated cane juice was struck into shallow vessels called coolers, where crystallisation took place: from these coolers the sugar was dug out and placed in hogsheads, in which it remained until the greater part of the molasses was drained out; the hogsheads were then headed up and ready for shipment. There is no doubt that this process is one which fails to obtain as much sugar from the juice as can be obtained by more scientific means. At the same time, the process has much to recommend it when it is considered that a very small outlay of capital is required, and that it is so simple that there is no difficulty in working it with the ordinary uneducated black labour of the tropics.—*Colonies and India.*

Insects and Frost.—The writer of the interesting Agricultural Notes in the *Daily News* of Saturday last, referring to the weather, stated that frost was useful in keeping down insects, the larva perishing during prolonged frost. It would be useful to learn from some experienced entomologist how far that assertion is true [not true]. I am disposed to think it belongs to the category of popular errors, or, if not, needs more proof than has yet been given. The previous winter was decidedly a severe one, and we had much intense frost, and yet it will be remembered that rarely have queen or breeder wasps been more abundant than they were last spring, although most of them seem to have perished later. Then the writer specially mentions Daddy Long-legs as being more plentiful after a mild winter, and yet I never saw them so abundant as last autumn, indeed, it seemed as if the wasps had for the time been metamorphosed into these comparatively harmless insects. Is it not really the case, that whilst mild winters keep insects lively and thus exposes them to the attacks of birds, severe winters keep the larva not only quiescent, but also find it deeply buried? Has a severe frost, for instance, any destructive effect upon the eggs of insects deposited on trees or in wall crevices, or even in the soil?—and equally, does it really destroy comatose larva? Any entomological instructions to gardeners should make these matters clear. The recent frost, although at times intense, did not penetrate so deeply into the soil as in some previous years, because of the snow. With me, just now, insect larva is more in danger of destruction by drowning than by frost.—A. D.—*Gardeners' Chronicle.*

Quantity of Water per acre required to Irrigate Rice.—The *Indian Agriculturist* states:—A correspondent of one of the mofussil papers settles the question of the quantity of water required to raise a rice crop—a question to which Mr. C. Benson of the Madras Agricultural Department drew particular attention recently—in the following simple manner:—In your editorial notice of the report of the Madras Agricultural Department published in your issue of the 10th instant, you refer to "A suggestion made by Mr. Benson, Agricultural Reporter, that an elaborate series of expriments should be undertaken with the view of ascertaining the proper amount of irrigation required to raise a crop of rice." I beg to state that when I was in the Nizam's State between the years 1865-71 repairing tanks and cutting channels from rivers for the purpose of feeding these tanks, I found it necessary to ascertain first, before determining the bank sections, &c., what quantity of water the tank would be required to hold in order that it should be capable of irrigating the land under it. To enable me to obtain some correct and precise information for my own daily use, I invariably consulted the zemindar putwari and head ryot of every village I visited prior to commencing with the levelling and survey operations, and arrived at the following conclusions:—From a series of notes and observations I found that it took on an average about 72 days.

$$\left\{\frac{\text{Days}\quad \text{days}\quad \text{days}\quad \text{days}}{59 + 67 + 90 = 216} \quad \text{days.}\ 72\right\}$$

to raise one crop of rice; and that the land required as much water as would cover it all over to the depth of 1 inch, *i. e.*

$$72 \times 1 = \frac{72}{12} \; \frac{6}{3} = 2 \text{ yards,}$$

So, therefore, to irrigate one acre of land—namely, 4,840 square yards—a tank should hold—

$$4{,}840 \times 2 = 9{,}680 \text{ cubic yards of water.}$$

HOW TO MAKE POTASH.

Baron Ferd. Von Mueller, K.C.M.G., of Victoria, writes as follows how to make potash:—The wood, bark, branches, and foliage are burnt in pits sunk 3 feet or 4 feet in the ground; the incineration is continued until the pit is almost filled with ashes. Young branches and leaves are usually much richer in potash than the stem-wood, hence they should not be rejected. The ashes thus obtained are placed in tubs or casks on straw over a false bottom. Cold water, in moderate quantities, is poured over the ashes, and the first strong potash liquid removed for evaporation in flat iron vessels, while the weaker fluid is used for the lixiviation of fresh ashes. While the evaporation proceeds, fresh portions of strong liquid are added until the concentrated boiling fluid assumes a rather thick consistence. At last, with mild heat and final constant stirring, the whole is evaporated to dryness. This dried mass represents crude potash, more or less impure, according to the nature of the wood employed. A final heating in rough furnaces is needed to expel sulphur combinations, water, and empyreumatic substances; also, to decompose colouring principles. Thus pearlash is obtained. Pure carbonate of potassa in crude potash varies from 40 to 80 per cent. Experiments, so far as they were instituted in the laboratory, have given the following approximate result with respect to the contents of potash in some of our most common trees:—The woods of the casuarinas, or she-oaks, as well as that of the black or silver wattle, are somewhat richer than the wood of the British oak, but far richer than the ordinary pine woods. The stems of the Victorian blue gum and the so-called swamp tea-tree (*Melaleuca ericifolia*) yield about as much potash as European beech. The foliage of the blue gum proved particularly rich in this alkali, and as it is heavy and easily collected at the sawmills, it might be turned there to auxiliary profitable account, and, indeed, in many other spots of the ranges. In the Queensland coast country the mangrove could be made to yield potash in immense quantities, as it is richer in this alkali than almost any other native tree or shrub; and even if the mangrove were not used for the manufacture of potash, the ash being rich in this valuable fertilizer, could be easily and economically applied for manurial purposes. Of course, British woodmen are aware that it is hopeless to compete with the extensive mineral deposits in Germany whence most of the potash of commerce is now made.—*Journal of Forestry.*

THE NATIVES OF INDIA AND WILD BEASTS.

The *Journal of Forestry* contains an interesting article on the Indian Forest Survey, from which we take an extract:—The wild animals which inhabit the Indian forest afford excellent sport for those who have the time to engage in it, which the surveyors have not, for the outturn of good work of this sort is in direct proportion to the time spent on it, and arrears of surveying and mapping cannot be brought up by a stroke of genius; but to the unarmed native surveyor the presence of dangerous wild beasts in the forest in which he is called upon to work affords no attraction, and cases have occurred in which they have caused the most serious inconvenience. On one occasion a native surveyor, having seen a wild elephant, decamped and could not be persuaded to re-enter that part of the forest, while his accounts of the terrors of the locality spread among the other men, and for a long time the ground could not be surveyed. On another occasion three native surveyors having seen a tiger, climbed a rock and remained there all night. In the morning they managed to convey an appeal to the officer in charge to come to their relief, which he did, but without seeing anything of the tiger. This place was also in disfavour for some time afterwards. But a much worse case was that of the Jarhwal man-eater; this tiger had killed a very large number, some 300 or 400 it was said, of woodcutters within the area which had to be surveyed. The superintendent was aware that if he lost one of his men he would probably be obliged to abandon the work, and he took all means in his power to accomplish its destruction; but although the trail was twice followed, and the bodies of men who had been carried off were discovered, the tiger was not bagged. At last, as none of the survey party were touched, an idea gained ground among the men that the tiger bore them no ill-will, and they considered themselves perfectly safe if they could satisfy him of their identity, which they were content to do by carrying aloft in a cleft bamboo an old envelope from the superintendent's wastepaper basket! The natives present a strange mixture of bravery and cowardice; they do not hesitate to express fear when they feel it, and do not seem to think that to be afraid is anything to be ashamed of, but at the same time they frequently perform acts that appear recklessly brave. An old man of seventy, armed with a tulwar, has been seen hunting about in the tall grass for a wounded tiger which was lying concealed close by him, and he had ultimately to be forced into a position of safety on the back of an elephant. On another occasion a bear had taken up his quarters in a dense part of the forest, and had killed several bamboo-cutters who had unwittingly invaded his retreat; a man who had just been mauled by him insisted in joining a passing Englishman who sent in search of the bear, and could not be persuaded to keep behind the rifle, but advanced boldly into the beast's lair, anxious to take a leading part in the retribution which shortly overtook him. The servant of a noted sportsman in the North-Western Provinces once proposed to his master that he should walk past a dense piece of cover in which a wounded tiger was lying, in order that the animal might be induced to spring out into the open and thus afford a good shot!

THE TIMBER TREES OF CEYLON.

Under the title "*Timber Trees of Ceylon*, by Mudaliyar Mendis, with Notes on them by W. Ferguson, F.L.S.," a pamphlet of twenty-three pages has been issued from the *Ceylon Observer* press in Colombo. This little book is valuable as throwing some light not only on the botanical source of the trees, but on the character of the woods and the uses to which they are put in Ceylon. The timber trees of Ceylon are interesting in consequence of the general hardness of their woods and the fine colour of figure of many of them; but notwithstanding this, Ceylon woods, with the exception of a few such as ebony and calamander, [Surely satin wood ought to be added as far as Europe is concerned, while palmyra, halmilila, and several other Ceylon timbers are valued in India.—Ed.] are scarcely known out of their own country. Many of the species, however, are common to various parts of India. It is a fact that though most of the dependencies of the British Crown have at some time made a display of their timber resources by exhibiting large and striking slabs at some of the International exhibitions, the exhibits of Ceylon have always been of a more diminutive character. An excellent collection of Ceylon woods, however, was shown at the International Exhibition at South Kensington in 1862. It consisted of about 160 specimens each about 21 inches long, 3 inches wide, and 1 inch thick. They were all well seasoned and polished; but though well selected, and many of them finely-figured pieces, they were too narrow to give a good general idea of what the woods would be like in bulk. And here we may perhaps say a few words upon selecting and preparing woods for exhibition purposes. Dead wood should in all cases be rejected, and a fair average sample taken from properly-felled timber; the section should be cut in the case of large slabs through the centre of the tree, so as to show the sapwood as well as the heart-wood, so that the proportion of each may be seen at a glance; the bark should also be left on the edges. For small

and handy specimens where a large collection is got together, no size can be better than that adopted by the Indian Forest Department in the fine set of woods sent by them to the Paris Exhibition in 1878, a duplicate set of which is now in the Kew Museum. These measure 9 inches high by 6 inches wide and 2 inches thick: they lend themselves wonderfully well for any kind of arrangement. On a staging, for instance, they can be placed one above another without loss of space; and in the glazed cases of a museum, they suit almost any shelf; moreover, they are convenient for handling for examination. With regard to numbering, woods should always be *stamped* on the backs, and never on their faces. It often takes a considerable amount of planing to remove them. But to return to the Ceylon woods. In noticing the little work which has given rise to these remarks, a fitting opportunity seems also to occur to bring to more general notice some few of the most striking, or important out of the ninety-six different kinds mentioned in the book. [Then follow notices of our chief timbers.—ED.]

The few woods here indicated recommend themselves to notice on account of their fine colour or figure. From specimens of all of them contained in the Kew Museum, they would appear to be well worthy of a more extended application. They are referred to here as only a few instances of the general character of Cingalese woods which require to be more known to be appreciated.—*Journal of Forestry.*

MAIZE OIL.

A paper on this oil was read by Dr. C. O. Curtman before the Missouri State Pharmaceutical Association, in which we have further particulars. The oil is made largely by the Woodchande Milling Company, St. Louis. The amount of oil obtained by pressure from the embryo varies from 13 to 15 per cent. The following notes by Dr. Curtman, which we abstract from the Pharmaceutical Record, though agreeing generally with the conclusion of Mr. Shuttleworth (published in this Journal, p. 47 of current volume) differ in some respects, while fuller particulars are given on other points:—

The crude oil, as first expressed, is somewhat turbid and of a pale brownish yellow colour. It is easily rendered clear by filtration, or by letting it stand at rest for some weeks, and drawing off the clear oil on top from the impurities which have subsided.

Its average specific gravity is 0·916. The extremes, thus far observed, were 0·915 and 0·917. Maize oil has the peculiar flavour of freshly ground corn meal. This becomes fainter by age and may be removed to a considerable extent by rectification processes. Its taste is bland and of agreeable sweetness, with a bitterish after-taste, which increases somewhat with age, but may be entirely removed by purification. It does not very readily become rancid, when carefully kept, in this respect resembling benne oil. It does not dry like linseed oil. Portions left adhering to the outside of the vessel, from which it has been poured, have not become pasty nor rancid in twelve months.

In some of its general properties it stands intermediate between olive oil and oil of sweet almonds but approaches nearest to the olive oil. It contains a large proportion of olein, a compound of oleic acid and glycerine.

With Pontet's reagent (strong nitric acid in which a little mercury has been dissolved), it forms an abundance of elaidine, so as to become nearly as solid as olive oil. Treated with mercuric nitrate in the usual way, it yields a fine citrine ointment. With strong nitric acid it speedily turns a dark reddish brown, a reaction which is obtained still more rapidly and intensely by using a mixture of strong sulphuric and nitric acids. This reaction is, however, limited to a much paler colour after the oil has been rectified by treatment with sulphuric acid.

With alkaline dyes it saponifies promptly, forming a beautiful white soap, fully equal in appearance to the best Castile soap from olive oil. With aqua ammonia a liniment is formed, which remains sufficiently fluid at ordinary temperatures. Boiled with litharge the oil yields lead plaster and glycerine.

One of the most remarkable properties of the oil, by means of which it may be distinguished from similar oils, is its low congealing point. Olive oil begins to congeal and become turbid at + 10° C. (50° F.) Cotton seed oil at + 2° C. (+ 35 6 F). Oil of benne at—5° C. (+ 23° F.) Almond oil at—20° C. (—4° F.)

Maize oil is intermediate between the two last. It remains entirely clear down to—8° C (+ 17·6° F.); below that it begins to get slightly turbid, but is not, fully congealed at—10° C (+ 14° F.).

The properties above stated render it a valuable substitute for olive oil in pharmaceutical preparations. Its odour being but slight and not very penetrating, is easily overcome by essential oils, and on this account the oil may be used for toilet preparations.—*Chemist and Druggist.*

AN INTERESTING AGRICULTURAL EXPERIMENT.

Of the two explanations as to the meaning of the word "Dirt," the scientist's that it is "matter out of place" and the sharp child's that it is "mud with the wet squeezed out," the former is about to receive a practical exemplification, as far as Bombay is concerned in the proposed utilisation of the city sweepings for the manufacture of artificial manure. The invention is the idea of Dr. S. Cooke of the College of Science, Poona, who has secured a patent for his system. I have had an opportunity of inspecting the article which is put up in large or small blocks as desired. It is a grey porous substance somewhat resembling pumice-stone, but is much more friable; in fact one of its inventors claims is that it can be very easily reduced to powder and drilled into the ground with seed at the time of sowing. Dr. Cooke has a convincing proof of the efficacy of his invention in his garden. Five plots of ground of equal area have been planted with the same quantity of *nachnee*. The first plot has been left unmanured, with the result that the weeds have decidedly the upper hand. Plot 2 was dressed with wood ashes, the result not being very satisfactory. Plot 3 was fertilised by the ordinary process of rab, two experienced hill men coming especially to do the work. The result of this treatment of the soil was an average crop such as may be seen on the ordinary Hill Farm. Plot 4 was worked with partially burnt horse manure, the result being that too much heat was generated which destroyed part of the seed, leaving what did come up very good, however. Plot 5 was the patent fertiliser drilled in with the seed, and the result is simply astonishing. Whereas the average height of the plants on the other beds was about fourteen inches, and the colour of the stems varying from light to medium green, the stems and leaves in this plot were of the darkest and richest green and of a height of about two feet with magnificent heads of seed. As far as can be judged from an experimental growth under favourable conditions, the result is most conclusive, and there should be, if not "millions," at least "thousands" in the invention. As regards the manufacture on a large scale of this fertilizer, it is to be encouraged irrespective of its agricultural aspect, because it furnishes a means of solving what is becoming daily a most serious problem: namely, the disposal of street sweepings which in large cities and even in small towns in hot climates necessitates much thought and care, to render the operation of removal harmless and unnoticeable, a result not yet obtained in Bombay, where the Municipality have to grapple with the serious problem of removing the enormous quantity of nearly 400 tons daily. Eight hundred cubic yards of refuse are daily carted from Bombay, and the question is coming prominently forward, "What are we going to do with it?" At this moment Dr. Cooke comes to the front and proposes that a company be formed to take over the entire sweepings and convert them into a useful and powerful agent for good. The company, if formed, would thus stand in that are

but enviable position of Public Benefactors, while at the same time having the monopoly of a very money-making speculation. The method of manufacture and the results of the experimental crops have been seen by most of the principal Revenue and Forest officials, and both the simplicity of the former operation and the results of the latter have drawn forth the unqualified approval of the many experienced gentlemen who have visited the scene of operations. For the manufacture is required a furnace for reducing the sweepings to ashes, a kiln for obtaining lime, and a mill for roughly grinding bones.

The three materials thus obtained are then put into pits in layers of ashes, lime and bones, water is then poured into the pit, and layers of fresh material introduced as the contents sink, and in about two weeks the result is a pasty mass, consisting almost entirely of salts best adapted for replacing the productive power of poor soils. By mixing charcoal with the raw materials a fertilizer can be produced especially adapted for gardens. As a proof of the commercial success of an undertaking of this kind it is known that the sweepings of Manchester, Birmingham, and other towns in England are readily disposed of at prices varying from £4 to £6 a ton. Chemical Manure is exported in enormous quantities from Liverpool at £12 10 a ton. Taking into consideration the cheapness of the raw materials here, a company should make a large profit at R20 per ton, and above all it would be a great blessing to Bombay to have the mass of refuse innocently converted into a harmless inodorous compound instead of being a source of danger and unpleasantness to every one.—*Times of India.*

[Worthy the attention of the Colombo Municipality, the great desideratum being the removal of sweepings and sewage in a form useful and innoxious.—ED.]

NOTES ON TEA.

[By PERCY SWINBURNE, late of Sylhet, Cachar, and Assam.]

Manufacture—Withering.—The old method of withering was to spread the leaf 2 to 3 inches thick on a machan, and to turn it over several times during the night to prevent its heating too much. In wet and cold weather it was placed in small quantities at one time, on a machan, over the firing dhools, where the heat quickly softened and prepared it for rolling. But now great improvements have been made in the factory buildings and accommodation. It is generally recognised that the leaf must be thinly spread out, and the withering process most carefully conducted to turn out good tea. Withering sheds admitting air and light freely, and fitted with tier upon tier of bamboo trays, are made. Large pucka iron roofed tea houses are fitted with lofts for withering, and arrangements are made for regulating the heat and admitting or shutting out the air.

Natural withering, as generally understood, means that the leaf is placed in open or closed houses in which the draught of air may be regulated; while artificial withering includes the use of heated air, or of machinery.

A large proportion of the best tea which is sent to the market is now made from artificially withered leaf, that is to say, from leaf which has been withered by heated air. The lofts of the pucka tea houses are heated by the sun, to a temperature of over 100 degrees, and are often intolerably and suffocatingly warm. In dull and wet weather also, the temperature in these places is still considerably higher than that of the surrounding atmosphere as they are heated by Siroccos or other firing machines, the chimneys of which pass through them.

There has for a long time been a strong prejudice against artificial withering. Closed hot houses were used because the withering, under favourable circumstances, is always supposed to give the best results.

In natural withering, the faster the process the better the results, so we may conclude that perfect withering would consist in removing all superfluous water from the leaf instantaneously, without disturbing the oils, juices, &c., while sufficient heat was applied to reduce the fibre to the soft condition required for rolling.

A series of careful experiments have been made in a small house heated by smoke flues, with one maund of leaf spread on about 15 square feet to a pound. It was found still, that the faster the operation the better the result. That the greater the heat, the thinner the leaf must be spread, and the more care and nicety required.

The finest tea was made from leaf withered in 3 hours, at a temperature of 140 degrees. The tea was on several occasions carefully assorted, and true samples of the bulk were sent down to Calcutta to be valued, and the quality of the liquor as well as the appearance were pronounced excellent. The average valuations were about 14 annas, and the leaf was good, but not finer than that plucked on most estates, in Darjeeling, or Sylhet, or Cachar, being two leaves and a bud. The market at the time was depressed, and the average price of the teas of the districts named was, at that time, between 9 and 10 annas.

In 1883 the entire crop of the Kamagar Estate, Sylhet, just under 900 mds. was withered in hot-houses, heated by smoke flues, and realised 11 annas per lb. average. The houses were "kutchee" ones built of bamboo and plastered ekur. They were 14 feet high in the roof, 7 feet high walls, breadth 20 feet. Two four-feet wide, passages and 4 rows of chalnies 3 feet wide.

The pipes were 9 inches in diameter, and $\frac{1}{8}$ inch thick, and ran along both sides of the house underneath the outer row of chalnies. The heat was much greater near the furnaces than at a distance from them, and the house gets thoroughly heated for a distance of about 15 to 20 feet only from the furnace.

The heat is also uneven, and the greater it is the more difficult it becomes to equalize the withering. The leaf must be thinly spread and carefully watched. One part of the house withers much more quickly than another, and if the leaf is left for an hour only, after it has reached the right stage, much quality is lost.

These houses, defective as they are, are preferred to those of the old style.

When the men have learnt how to arrange the leaf, and work the fires, the rolling can be commenced at 5 A. M., every day, in all weathers.

The leaf does not turn red unless it is bruised in some way during the withering process, and its juices become exposed to the air. This may happen from the leaf being gathered up a second time, and removed from one place to another.

If it is once established beyond dispute that the best tea can be made from artificially withered leaf, there should be no difficulty in making a hot chamber in which the leaf could be very thinly spread out and the heat equalized and regulated, and the moisture removed.

One of the great disadvantages of open houses is that the damp cold air which checks the withering is admitted, as well as the warm air which favours it. Withered leaf absorbs moisture, and is refreshed by it—as a bouquet of faded flowers is revived by sprinkled water. But when the leaf has withered a second time, it loses its freshness, and when the flowers have again faded, they begin to give out an offensive smell; the first stages of decomposition having set in in both cases. Leaf which has once lost its volatile freshness and delicacy, never recovers it, and can never be converted into fine tea.

The fine qualities in the leaf may be chemically altered in the hot withering process, but they are not lost altogether as is proved by the quality of the tea produced by it.

In the same way, however, as the flavour of the tea is affected by different firing processes, so it is probably also affected by the degree of the heat applied in the withering, as well as by the manner in which it is applied.

Good tea can be made of leaf which is carefully withered, rolled, fermented, and finally baked out; although strong, it is peculiar, and has not the delicate flavour and smell of tea, which is roasted over charcoal in the usual way, and this again is not so

aromatic in flavour as that which is dried by the rapid hot-air draught of the "Sirocco."

It would appear that the best withering would be accomplished by strong draughts of moderately warm and quite dry air passing over the whole surface of the leaf.

If the juices can be kept uninjured, the more the leaf is withered, the better the quality of the tea. The presence of water in the rolled leaf appears to affect the fermentation injuriously. It is not accurately known at present what chemical changes take place in the various systems of manufacture, but we know that we are more or less dependent on the weather, and that the changes which take place satisfactorily one day, will not do so on another, under apparently exactly the same condition. Lightly withered leaf makes tea without strength or body, and this is probably due to the presence of too much water in the rolled leaf which causes an injurious fermentation. On the other hand, over withering, or bad withering, by which the juice have been injured or destroyed have the same effect ond produce weak pale liquored tea.—*Planters' Gazette.*

TEA, COFFEE, AND CINCHONA INSECT PESTS.

The ravages of insects on tea, coffee, and cinchona p'ants of late years have been so widespread as to threaten serious consequences to those who own large plantations. It is, however, a curious fact that few have deemed the subject of sufficient importance to devote their time and attention to an intelligent investigation of these insect pests, their ways, habits, methods of attack, propagation, &c.; and it is therefore with sincere pleasure we have perused an interesting paper on pests of the homopterous family of Coccidæ, which attack tea, cinchona, and coffee plants, read by Mr. E. T. Atkinson, C. S., at a recent meeting of the Bengal Asiatic Society. Mr. Atkinson is not unknown in this branch of science, and his paper will doubtless give rise to a proper discussion of this subject. The author stated that he sought to give such an account of this important family of insects as will induce observers to take up its study seriously. He went on to say that it comprises those insects known as scale-insects, or gall-insects, which are so hurtful to the coffee, cinchona, tea, and fruit trees generally. Nothing of value has yet been written regarding the species of this family that occur in India, with the exception of the *Carteria lucca* that furnishes the lac and lac-dye which form such valuable articles of export form Calcutta. The family is distributed amongst the sub-families *Diaspia*, *Brachyscelina*, *Lecanina* and *Coccina*, of which some hundreds of species have been described, but very few of which are recorded from India. The larval form of these insects, he said, has six legs, many jointed antennæ and a rostrum, or sucking apparatus; the adult female as a rule has neither wings, legs, nor antennæ, but only a rostrum, while the adult male has two wings, legs, and antennæ, but no rostrum, or mouth. Their forms vary from flat to spherical, many are covered with a white farinose filamentary substance, others with a felted, waxy, nacreous, and even calcareous substance. All are minute, and require much care in their manipulation and preservation. The author disclaimed all idea of purely scientific aims in this popular introduction to the study of a much neglected group of great economical importance to residents in the East. His object was to collect facts on which hereafter to base a scientific examination of the species of these insects occurring in India.

After Mr. Atkinson's paper, the President of the Society brought to the notice of the meeting letters addressed to him by Mr. Green of Punduloya in Ceylon, regarding a new pest belonging to the Homopterous family *Coccidæ*, which is now committing great ravages on the coffee plantations there, and in some cases compelling the abandonment of its cultivation.

Mr. Green writes:—"I have been led to pay some attention to the Homoptera of Ceylon, chiefly by reason of the fearful destruction caused by many of their number to agricultural products. I am now sending you under separate cover a few specimens of these insects. The parcel contains:—

"(*a*) A glass tube with coffee leaves, on the under surface of which you will find a species of *Lecanium*. This has only lately appeared in Ceylon, but has already spread in an astonishing manner, and has caused inconceivable destruction in the coffee districts. It is entirely distinct from *L. coffeea* and *L. nigrum* noticed by Mr. Neitner in his pamphlet on 'The Coffee Tree and its Enemies.' Both these species I am familiarly acquainted with, though their ravages are now very slight compared to the work of the green insect now forwarded. I have not been able to obtain the male form, though both sexes of the other two are fairly common.

"(*b*) Cinchona twigs with a species of *Coccus*, lying apparently beneath the cuticle of the bark, which is raised in the form of small blisters. This is a most extraordinary insect, and with closely allied species, which are numerous on other plants, has considerably perplexed me, especially as to the nature of the integument which covers it. In the specimens from cinchona, this would seem to be actually the cuticle of the bark, many of the incipient cracks extending right across the integument of the insect. Those now sent are all females. The male form closely resembles those in the tube containing spirits of wine. The larvæ and pupa are very similar to the species found on tea-leaves. The adult female has neither legs, antennæ, nor eyes, the only external member being a fine sucking bristle (rostrum) which proceeds from a spot near the middle of the under surface. In the young all the members are complete.

"(*c*) *Loranthus* leaves with allied species of *Coccus* also apparently lying beneath the cuticle of the leaf; but on examining the integument under the microscope with transmitted light, one finds no traces of cellular formation, nor any stomata, all of which, however, are complete in the tissues of the leaf immediately below the insect. Adhering to this integument, or forming part of it, are always one or more of the characteristic scale of the *Coccidæ*, which would seem to be the cast skins of the insect. The young larva, after fixing itself to the leaf, soon exhibits the scaly covering on its posterior half, leaving the anterior part free. The scale is then shed, remaining in its place, and the insect lies freely beneath and loses all its external members, except the sucking bristle. The integument, under a high magnifying power, appears to be composed of an irregular network of sinuous, intersecting filaments, with no trace of cellular formation.

"(*d*) A tube containing both sexes of another species, affecting the leaves of the *Loranthus*. The integument of the female is continuous with the woolly covering of the leaf. The males are minute red flies with one pair of two-veined semi-hyaline wings, which at rest are folded straight down the back, completely overlapping each other; the antennæ are very long and setaceous; anal extremity without filaments, but with a long central point. Both the upper and the under surface of the head appear to be furnished with a pair of eyes, and I can find no ocelli. The lower pair of eyes correspond to what is described by Neitner in his *Pseudococus* as 'two black knobs resembling blunted mandibles, representing the external mouth.' These two spots are present in the males of all this family, and I cannot help thinking that they have been erroneously described as mandibles, the external mouth, in my opinion, being present only as a minute spot between the anterior pair of legs, in the same position in which it is situate in the female. [Mr. Green is right in regarding these knobs as other than mandibles; they are eyes] If the head of the insect be macerated in water and examined with transmitted light, all four spots appear as colourless globules with two concentric dark rings, an appearance which would be given by the cornea of the eye."

Unfortunately most of these specimens suffered so much from damp in transit that they were useless for examination. In a subsequent letter from Mr. Green

it is stated that "the green *Lecanium* has spread at an extraordinary rate, and we have in consequence been compelled to abandon a large acreage of coffee and replant the ground with tea. This species is vastly more destructive than anything of the kind that has previously been experienced. The ravages of *L. coffeea* were nothing in comparison. It is curious that though they have been increasing so rapidly, there has been apparently no generation of male insects."

The foregoing facts are of sufficient importance to owners of plantations to induce them to devote more attention to the subject than hitherto appears to have been done, and by investigation, to hit upon remedies in view to protecting their plantations from the ravages of these insect pests.—*Indian Agriculturist.*

THE CULTIVATION OF POTATOS ON THE NILGIRIS.

The cultivation of potatos on the Hills dates from the earliest settlement of Europeans. Analogy of climate suggested its introduction to the first settlers, and experimental efforts were crowned with uniform success, for it took kindly to the soil and became in time a valuable addition to the food production of the district. In the early days of European occupation Government were disposed to assist settlers of energy and enterprise with advances of money for general farming purposes, the acclimatization of new products being one of the most important. The Kaity valley and Kulhutti were originally selected for experiments with potatos, and to this day these places retain a reputation for growing the finest tubers in the greatest abundance. Thence are derived the best potatos locally consumed and despatched to the plains. Their elevation ranges above 6,000 feet, an altitude below which this vegetable will not thrive, though we are acquainted with two experiments at 3,000 and 4,000 feet in the extreme North and South of the Nilgiris which were not quite failures. Up to within the last fifteen or twenty years the cultivation had not gone beyond the range of experiment, but each year the limits were enlarged with satisfactory results. Since then the strides have been rapid, and now it is well established among the agricultural classes, who find in it a lucrative and permanent livelihood.

The extent of land under potatos is estimated at 1,000 acres, including large areas of semi-drained swamps within the town of Ootacamund. For these swamps growers pay at the high rate of twenty or twenty-five rupees an acre, and cultivate expensively. Though remunerative crops are obtained on such lands, without much trouble the quality of the outturn is inferior. The potato when boiled is found to be wet, hard and waxy. Grown on the hill sides in the favorite localities to which we have alluded they boil dry and mealy, and possess good keeping qualities.

Two crops are raised annually, if the season is favourable, the one sown in February and lifted in July, the other sown in August and lifted in December. Although the climate of the Nilgiris is admirably adapted for sowing and reaping throughout the year and thus securing a regular succession of new potatos, the natives adhere to the periods indicated and accordingly the market fluctuates considerably, ranging very high just before crop time, and falling below remunerative prices just after, when it is glutted. Indeed so great is the scarcity in the local market at times that it pays speculators to obtain a supply from Poona and Bangalore. The imported Poona and Bangalore potatos are inferior and innutritious, the eyes are deep set, and on arrival the sprouts are well advanced.

The mode of cultivation is simple. The soil is forked up before the frost sets in, in order that the sods may be thoroughly loosened and aerated by the action of the atmosphere. A week or so before planting it is pulverized and raked over, the furrows are drawn and the seed dropped, with a handful of manure for each to rest upon. Weeding is carefully attended to, and when the plants are six inches above the ground, the first hilling takes place followed by two or three similar processes before lifting. The yield averages two hundred maunds per acre, which at 8 annas a maund pays the rent of the land, cost of cultivation and a return of from 20 to 50 per cent on the capital outlay according to the character of the season.

All field operations for potatos are manual and therefore expensive. The plough is never used either in the preparation of the soil or in process of culture, probably because the implement does not turn up the soil sufficiently deep for a root crop.

The potato disease which prevailed in Europe with such virulence between 1875 and 1878 extended to this country and temporarily extinguished the cultivation in the swamp lands in and around Ootacamund. Crop after crop was so extensively affected that the produce was not worth the cost of lifting. Growers preferred to allow it to rot in the ground, rather than incur the expense of removal. In the garden assessed lands surrounding the villages of the Hill ryots, the disease prevailed in a milder form, and growers were kept in countenance by the high prices obtained for the partial outturn. Science in England exhausted itself in trying to find a remedy for the disease which amounted almost to a national disaster. In this country not an effort was made either of prevention or of cure. The swamps were allowed to lie fallow in order that the disease-spores might die out. As good seed as could be procured was purchased and sown, but beyond this nothing was done, and the disease was allowed to run its course, and, if possible, to exterminate itself, which as might have been expected it failed to do. The season in the current year, when perhaps the largest area ever put under the tuber was sown, has been most unfavorable. The incessant wet weather that prevailed during the most vigorous period of growth developing the disease afresh in its worst form. To save the affected crops, growers lift as soon as the tubers are of moderate size though immature. They are no sooner out of the ground than disease at once sets in and a few weeks suffice to render them fit to be consigned to the manure heap. It is unfortunate for this cultivation on the Hills, that the period when the disease is known to be most active is the period of sowing and reaping. This is in July and August when the spring crop is lifted and autumn crop sown. A change in the present system of cultivation would under these circumstances offer some prospect of minimising the effect of the disease. There is also in this country, to some degree an absence of that noticeable folly in England, so potent for the propagation of disease of trying to grow potatos of abnormal size, though it is encouraging to learn that Judges at Exhibitions and Agricultural Shows, at home are, by the awards recently made marking their appreciation of quality as distinguished from mere bulk. The features now commended at potato exhibitions are beauty of form, elegance of proportion, evenness, color, and markings, clearness of skin and polish, but above all, superiority as an article of diet in the matter of nutriment. These qualities are hardly yet brought home to the mind and experience of Indian growers, because the spirit of competition in agricultural produce is absent or awakened only at such long intervals that there is no sustained impulse given to improvement and the attainment of excellence. The opportunities for bringing together specimens of produce and comparing them one with the other are few and far between. The spirit of emulation is wanting, and year after year the dead level of mediocrity maintained with change, if at all, by way of retrogression and deterioration.

The most injurious practise in this husbandry on the Hills is that of cultivating, year after year, on the same soil, without an attempt at rotation. Mismanagement in this respect is universal. More remunerative crops would undoubtedly be obtained if alternated with other garden produce or with cereals. Until the ryot takes up potato cultivation more generally this can hardly be expected. Native speculators are not the class to look to for progress. As soon as the crop is ready to lift they dispose of it, and leave the rest to the dealer who removes,

it in carts and despatches it to meet a demand, at present in its infancy, either on the Railway or in some of the towns with a considerable European population. Natives are rapidly acquiring a taste for potatos, and as soon as they are cheap enough to become an article of daily consumption in every Hindu household the cultivation will reach proportions of great magnitude. There are hundreds of square miles of arable land that the hill tribes cannot profitably cultivate with their ordinary grains, but which put under this vegetable would maintain their owners in comfort. A rich soil is not indispensable, though liberal-treatment with manure, other circumstances being favorable, would be well rewarded. The English cultivator raises from three to four times the crop that the native in this country does, but the latter is well satisfied with present results, and so long as high prices are maintained he will not be disposed to tax the soil to its utmost limit of productiveness. Natives appreciate the potato as an article of food, but its prohibitive price interferes to prevent increase of consumption. A rupee a maund places it beyond the reach of all but the well-to-do. Should the price fall to a third of this figure, at which it will yet pay the grower well, a stimulus to production will be given that will treble and quadruple the extent of land brought under contribution.—*South of India Observer.*

KAURI RESIN.

The following paper was read by Mr. Gellatly, Curator of the Edinburgh Museum of Science, on January 13, at the last meeting of the Edinburgh Botanical Society:—

The Dammara australis which yields these Kauri resin is the largest of the New Zealand trees. It is confined to the northern portion of the North Island, and grows on all soils up to the height of 1500 feet, but is said to prefer the dry and sterile clays of the hilly districts. It reaches a height varying from 100 to 140 feet—some few growing as high as 170 feet or rather more. The tree is usually bare of branches for about 50 feet from the ground. A trunk has been occasionally but rarely seen as much as 35 feet in circumference. Laslett saw two exceptionally large trees—one at Wangaroa (a little to the northward of the Bay of Islands), that measured 48 feet in circumference at three feet from the ground, and another near Mercury Bay, which was 72 feet in circumference and 80 feet to the branches. As the tree, which is of slow growth, does not add more than an inch to its diameter in six or seven years, Mr. Laslett computed the ages of these two giants to be respectively about 1,300 and 2,000 years.

The timber is so useful that it is employed in the construction of most of the houses and for nearly all the boats in the North Island. There is a little difference of opinion about its quality. Mr. Laslett says that the timber is generally sound and free from defects common to many other descriptions of wood; that it shrinks very little and stands well after seasoning. Further, that it is remarkably solid, and may be considered one of the best woods for working that the carpenter can take in hand. Some of the colonists, however, state that it has a strong tendency to shrink and contract in length as well as in breadth, and that it often does this when freshly planed, no matter how well it is seasoned. It seems, however, to be unrivalled for the masts and spars of ships, possessing the requisite dimensions, lightness, elasticity and strength; and being more durable than any other Pine. Its specific gravity averages about ·530, somewhat less than the density of the timber of Pinus sylvestris brought from the Baltic ports.

The so-called Kauri gum—really a resin—exudes spontaneously from every part of the tree, and hardens upon the surface by exposure to the air, immense masses of the resin being often seen on old trees, suspended from the stem at the forked part of the branches. It is believed that the bark, branches, stumps, roots, and even the leaves of the Kauri Pine would yield a large amount of resin under proper management. When an incision is made in the bark of the Kauri tree the resin exudes freely, so that here, in the course of a few weeks, a large mass of half-dried resin will have accumulated. This new gum takes about three months to harden properly.

All except a very small portion of the Kauri resin so largely exported from New Zealand is however, dug out of the ground in a fossil or semi-fossil state, but there is not much of it found more than 10 inches below the surface; that is, it occurs in the present soil. Occasionally it is found at a depth of 3 feet, and it is fished up in bogs or swamps, as well as dug out of dry ground. The resin is found either in small detached lumps, or in considerable quantities deposited in one whole. When dug up its surface is found to be partially decayed, and this portion requires to be scraped off. It is curious that where the buried gum is obtained there are now no remains of Kauri trees except the resin itself. Nevertheless, it is believed that forests of this Pine must have formerly grown over the areas where it is found.

The only tools used in procuring the resin are a spear and a spade. The spear is a pointed steel rod, with which the digger pierces the ground, and by this means, after he becomes sufficiently expert, he can tell whether he is touching a stone or a piece of resin. If the latter, it is dug up with his spade. Between 1,000 and 2,000 Maories are usually engaged in digging for the resin, but although from habit and local experience they are more adroit at obtaining it than the settlers, they are said not to care for the work, and only continue at it when pressed by want. Many Europeans are also engaged; these, however, are chiefly men impatient of regular occupation—vagabonds, dare-devils, or persons fond of gipsy life. I see that an American Consul, in a report to his State Department, points out with manifest glee, that amongst this nomadic class are a number of the degenerated sons of the aristocracy of Great Britain.

A few years ago an industrious man could dig out about 2 cwt. per day; now he will hardly obtain one-third of that quantity in the same time. The total annual yield is, however, not yet falling off, owing to the additional number of diggers employed. This quantity is very large for a substance of this kind, amounting to fully 5,000 tons, of which 3,000 are sent to America, and 2,000 to England. The average value of the fossil resin is now about £60 per ton. There are several qualities of it, however, varying in price from £45 to £170 according to its purity. The resin obtained from growing trees of which, as already remarked, very little has yet been exported—is not worth more than £25 per ton.

Although many specimens of Kauri resin are as beautiful as amber, the Maories, notwithstanding that they have the artistic faculty in a high degree, do not appear to have ever applied the resin in any way as an ornament. As we see by objects handed down to us, amber for this purpose must have been highly prized by the ancient Greeks, the Romans, the Vikings or Norsemen, and the early Celts. The only uses the Maories have made of Kauri resin have been to kindle fires and as a masticatory. In recent years lockets, brooches, and other small ornaments have been made of it by settlers at Auckland and other places in the North Island. They have the serious drawback of being not nearly so hard as amber ornaments.

The important uses of Kauri resin are—first, in the making of varnishes; second, in the manufacture of linoleum—a floorcloth now largely made—in which this resin is advantageously mixed with common resin and oxidised linseed-oil; and, third, in the dressing of silk fabrics. [It is also used by dentists for taking moulds or casts.—Ed.]

Unfortunately it is yearly becoming more difficult to keep up the supply of this highly useful vegetable product. The resin first appeared in any quantity as an article of export from New Zealand about the year 1850. Mr. Reynolds, of Auckland, who has been engaged in collecting it for export for twenty years, estimates that the fossil Kauri resin will be completely exhausted in twenty years hence. Probably in the meantime the discovery in quantity of some equally valuable resin in another part of the world may render

this calculation to some extent inaccurate, but according to several authorities the supply cannot last much longer.

The recent gum is not so serviceable as the fossil kind, owing to its softness, though it has a more pleasant odour when heated. But neither can a long-continued supply of the new resin be hoped for. I hear from persons acquainted with the country, and I also see by remarks in papers published in the *Transactions of the New Zealand Institute*, that the existing forests of the Kauri Pine itself will more than likely be wholly cut down in another fifty years. —*Gardeners' Chronicle.*

KINMOND AND RICHARDSON'S PATENT MULTIPLE ACTION TEA ROLLING MACHINE.

This tea rolling machine differs from all other tea rolling machines in that at each stroke or revolution of the rolling surfaces the tea leaf is presented to the rolling surfaces at a different angle, and no two points in the upper rolling surface give the same rolling action to the leaf.

The under plate which turns on its centre, has a hitching action between each stroke of the upper plate, and so presents the leaf to the surface of the upper plate at a different angle each revolution. The action of the machine is simple, but the tea leaf when being rolled is subjected to a multiple action, the consequence of which variety of action is a harder twisted leaf, and a total absence of all flat leaves.

The machine has been made very strong, and the moving parts are few and simple. Owing to the direct application of the motive power, 3 H.-P. is sufficient to work the machine, and comparing this with other tea rolling machines, a saving in motive power of about 50 per cent has been effected.

The machine should be driven at a speed of 60 revolutions per minute, at which speed it will roll 12 maunds of green leaf per hour.

The belt pulley of the machine is 2 feet 6 inches diameter.

PRICE, £100.

Packing in cases for shipment, 5 per cent extra.

The lower plate can be supplied with its surface made of end wood, at an extra price of £15.

The above is the description given of the new roller by the manufacturers. As a general rule machinery in action comes short of promise, and we venture to doubt a performance equal to 960 lb. green leaf per hour. The testimony borne by Mr. Dickson of Lebanon is that the roller took in 400 lb. and finished that quantity in 40 minutes, the roll being as good, but no better than that obtained by Jackson's excelsior. When 960 lb. of green leaf per hour are rolled with a specially hard twist at an expenditure of force equal to only 3 horse-power, we shall be glad, in the interests of tea planters to record the fact.

A NEW USE FOR WOOD.—The application of wood for stuffing beds seems, at first sight, an anomaly, nevertheless, a patent exists which moreover appears to be quite practicable, for disintegrating the wood of various kinds of Pine, so that it becomes as light and elastic as hair. The resinous properties of the wood cause it to be very healthy, and to act as a preventive against vermin. It is producible at a price far below that possible for any other material, except straw and seaweed, in quantities as low as 4s. per cwt.—*Indian Gardener.*

THE COLLECTION OF MINOR FOREST PRODUCE.—The system inaugurated last year, in the South Canara District, of establishing depots at different points for the receipt and purchase, at certain fixed rates, of minor forest produce, such as myrabolams, wax, honey, &c., collected in the forests and brought to the depot, bids fair to become in time an extensive industry, as it has already developed to a considerable extent, so much so that it has been found necessary to employ an additional establishment of clerks to keep account of the quality of produce brought in by the gatherers. Satisfactory as the undertaking promises to be from a revenue point of view, it is also found to serve as a check on forest fires, the gatherers of such produce being naturally anxious to protect from fire, as much as possible, the trees from the produce of which they earn a livelihood. Wanton damage to trees, so common, is also to a great degree prevented. The system will probably be extended in time to other districts, the Conservator being anxious to do so.—*Madras Times.*

THE GERMAN COLONIAL VEREIN AND THE BINUE RIVER.—As is well known the Deutsche Colonial-Verein is at present taking active measures in the region of the rivers Niger and Benuë. It is proposed to establish a series of observation stations in this territory, as, for instance, at Timbuctoo and in the land behind Sierra Leone. There is no intention to establish stations on the Niger, but only on the Binuë so far as it is not under English protection, that is, east from Ibi and in the land south of the Upper Benuë, which is generally called Adamana. The Deutsche Colonial-Verein is said to take its stand upon the assumption that the Upper Benuë and Adamana must one day be a German colony, even if not so in mere name. The society cannot colonise itself, but it desires to take steps to further colonisation. In the Upper Benuë and Adamana lands many raw products very important for German industries are to be found, as palm oil, palm kernels, coconuts, sesame, earthnuts, ivory, caoutchouk, potash, tobacco, coffee, cocoa, vegetable ivory, black pepper, red pepper, cubebs, ginger, many valuable spices, dye-stuffs, woods, resins, as well as minerals and other useful products, and animals. The Colonial Verein has decided to forward Flegel the sum of 15,000 Mk. by the quickest means possible. The Africanische Gesellschaft has put its steamer "Heinrich Barth" at the disposal of the Colonial Verein for use on the Benuë. Herren Handert and Staudinger are to join Flegel's party in the place of two members who have returned to Europe invalided.—*Kuhlow's German Trade Review and Exporter.*

ROYAL GARDENS, KEW.—"It is proposed to issue from time to time, as an occasional publication, notes too detailed for the annual report, on economic products and plants to which the attention of the staff of the Royal Gardens has been drawn in the course of ordinary correspondence, or which have been made the subject of particular study at Kew. It is hoped that while these notes will serve the purpose of an expeditious mode of communication to the numerous correspondents of Kew in distant parts of the Empire, they may also be of service to members of the general public interested in planting or agricultural business in India and the colonies, W. T. Thiselton Dyer, Director." Such is the announcement which precedes the first *Bulletin of Miscellaneous Information.* By way of Illustration two subjects are mentioned in this *Bulletin*—Teff, and oil of Ben. Teff is a cereal largely grown in the mountains of Abyssinia, and is the produce of a grass, Eragrostis abyssinica. In answer to inquiries the Director publishes extracts from the works of Richard and Bruce giving particulars of the nature and mode of cultivation of the plant, and also extracts from correspondence with the Foreign office, various Consuls, &c. As a result of these inquiries seed have been sent to Kew and analyses made by Professor Church, who notes that the grain contains 8·2 per cent of albuminoids (flesh-forming food), and 68·1 per cent of starch (or force-producing food. Oil of Ben appears from documents before us to be a sort of Botanical "Mrs.'Arris." "El Ben," we are told, is the Arabic or Persian name for Moringa pterygosperma, but the oil prepared from the seed of this plant in the West Indies is of no value, perhaps on account of some defect in its preparation. The *Bulletin* before us affords an indication of one phase of work done at Kew, of which the general public knows little or nothing, but which, nevertheless, is of first-rate importance. In a subsequent issue it may be found desirable to curtail the space given to mere formal official correspondence,— *Gardeners' Chronicle.*

CASTOR-OIL mixed with an equal weight of tallow or other oil, is, according to the *Chemist* and *Druggist*, an excellent dressing for leather. Besides this, neither rats, cockroaches, nor other vermin will attack leather so prepared.—*Indian Gardener.*

SLOW TREE GROWTH.—At a recent meeting of the St. Louis Academy of Science, Dr. Englemann exhibited a section of the trunk of Juniperus californica, which was not quite 4 in. in diameter, and yet showed an unmistakeable age of 127 years, each ring being on an average about one-fifth of a line wide. The largest growth in ten years had been about 4 lines, the smallest during a similar period about 1 ½ line.—*Indian Gardener.*

TREE FUNGUS IN RUSSIA.—According to the *Bulletin* of the Society of Naturalists of Moscow, the hitherto unaccountable destruction of pine forests is caused by the ravages of a species of mushroom which takes growth on the surface of the wood, and afterwards penetrates and destroys the tree. Maps are given in which the path of the destroying fungus is traced through the pine woods of Russia.—*Journal of Forestry.*

BRITAIN'S FUTURE.—England is the largest importer of wood in Europe, requiring, 280,000,000 feet per annum more than she produces. Inasmuch as neither Canada nor the United States can much longer spare large quantities, and since no European country can now produce much more than is required for home consumption, while most of them are importers, Great Britain must ere long depend on her own resources. There are extensive tracts of land in Ireland and Scotland that might be profitably devoted to forest culture. —*Mississippi Valley Lumberman.*

THE WAGES OF HUMAN LABOUR IN JAPAN are far lower than we had any conception. The figures are given in an article in the *Journal of Forestry*, shewing why superior farm implements are not used. The writer states:—Farm labour is so cheap that it is practically impossible to overbid it with labour-saving marchiney. Male field hands work twelve hours per day, have five holidays in each month, and receive their food, lodging, and wages, ranging from 10 to 15 yen (£1 14s. to £2 10s.) per annum. Female labourers work the same hours, are not entitled to holidays, and receive, besides their food and lodging, about 7 yen (£1 4s.) per annum.

TAR IN THE POULTRY HOUSE.—Poultry breeders seem to have failed to discover the value of tar. It is very useful and valuable in many ways. Some breeders tar their poultry-yard fences, in preference to whitewashing them, though we do not like to see it done, for it gives the surroundings such a gloomy, and forbidden look. It undoubtedly contributes largely to the durability of the wood, protecting it from the ravages of storm and time. It is in the poultry house, however, that the value of tar is the greatest, for it conduces greatly towards healthfulness. When that scourge of the poultry man, chicken cholera, makes its appearance, we would advise, first, a thorough cleaning of the house; next, a generous application of Carolina tar on all the joints, cracks and crevices of the inside of the building, and then plenty of fresh whitewash properly applied. The tar absorbs or drives away the taint of disease, and makes the premises wholesome. The smell is not very offensive, in fact, many people like it, and it is directly the opposite of unhealthy. To vermin, lice, etc., the smell of tar is very repulsive and but few will remain after you have tarred the cracks, etc. A friend of ours in Maryland was once troubled with chicken cholera, and by adopting the above, in connection with removing affected fowls, he soon put a stop to its ravages. A small lump of tar in the drinking water supplied to the fowls will be found beneficial, provided it is the Carolina tar, which is very different.—*Poultry World.*

BAMBOO SEEDING.—Some bamboos of the *Katang* variety (*Bambusa arundinacea, Retz.*), having flowered in Ghazipore, N. W. Provinces, Mr. Nichols, C.S., had the seed collected for distribution. I venture to advise sowing in shallow pans or in seed beds under shelter. Transplant to a nursery bed when the seedlings are about two inches high. Again transplant when about seven inches high, and keep till finally located in a place where they can be frequently watered. The Katang likes a rather sandy alluvial soil, though it will do well on 'regur,' or black cotton soil. At Jubbulpore, where they are planted mostly for ornament, the plan which seems to have succeeded best of all was to plant in a circle as shown below, each dot representing a single seedling of, say, 1½ foot high. So far as I can see, there will probably be no chance of getting more seed for some forty years. This variety is believed to have a life period of about 55 years. It often attains the height of sixty feet under favourable circumstances. In 1836 Captain Sleeman recorded in this Society's Journal (Transactions, Vol. III) the flowering and death of all the bamboos in Dehra Doon, and states that it is a characteristic of the bamboo that all the produce of the same seed will run to seed and die in the same season without reference to the season in which they may have been transplanted from original stock. Dr. Brandis seems to confirm this in his *Forest Flora*, and says isolated clumps may be met occasionally; "but, as a rule, all clumps in one district come into flower simultaneously, a few clumps flowering in the previous and some in the succeeding years." So it is probable that there will be a widespread flowering next season.—*Pioneer.*

WOOD ASHES have long been known to possess peculiarly valuable qualities as a manure. In India large tracts of land, covered with grass and brushwood, are systematically set on fire for the ashes they yield. The following, however, which we quote from one of our American exchanges on this subject, will be read with interest:—"Among the most common and most valuable of special manures, I place wood ashes, says Prof. Kedzie. The amount of ash and its relative composition vary with the kind or part of vegetable burned, but we may safely take the ash of the body of a beech tree as representing the average composition of wood ashes. One bushel of ashes represents about two-and-a-half tons of dry body wood. Wood ashes contain all the required elements of plant nutrition except nitrogen. One hundred pounds of wood ashes contains 16 pounds of potash worth 80 cents, 3½ pounds soda worth 2 cents, 67 pounds of lime and magnesia worth 8 cents, and 5¼ pounds of phosphoric acid worth 26 cents. If we had to buy in market the cheapest form the manurial materials contained in 100 pounds of ashes, the cost would be $1·16. Can you afford to throw away such valuable materials, or sell them for sixpence a bushel to the soap-boiler? No argument is needed; here is the value and there is the selling price. Draw your own conclusions." The effect of a handful of wood ashes upon a withering plant is wonderful. We have ourselves often tried the experiment of resuscitating weak, unhealthy, and yellow-looking plants with the aid of wood ashes, and always with uniform and remarkable success.—*Indian Agriculturist.* [N.B.—That the ashes from tea furnaces ought to be carefully utlized.—ED.]

THE WOOD OF THE CASUARINA.—Mr. J. Steavenson Secretary of the Madras Agri-Horticultural Society, has written to the *Journal of Forestry* as follows:—There are to the north and south of Madras thousands of acres of sand-dunes which, within the last five-and-twenty years, I and others have covered with thriving forests of *Casuarina muricata*, Roxb. The tree in favourable parts of the sands grows to a noble size, and that very rapidly. I have many 40 to 60 inches in girth at 5 feet from the ground, and tapering up probably 90 or 100 feet as straight as, and very like a larch planted in 1871. A few trees are cut for poles, shed-building, rails, and such-like uses, but hundred of acres go down in a very immature state every year for firewood. The wood is very hard, of great density and specific gravity, and bears a great strain, but is so liable to warp, perhaps from ignorance of the proper method of seasoning it, that it is very little used for other purposes. I have seen the wood take a very high polish, and some good tables and other articles of furniture made of it. It appears to me absolutely sinful to waste the well-grown trees for firewood, and it has occurred to me that there might be a market for them at home for paving blocks, even if the wood will not season to prevent warping. The logs could, I believe, be profitably put on board ship at from £1 to £2 per ton. [But why not utilize them locally for the principal streets, of Madras.—ED.]

THE SAGO PALM.

Sago is nearly pure starch, obtained from various species of Indian Palms. In the Indian Archipelago it is procured from Sagus Rumphii, Sagus lævis, and Sagus genuina; on the Coromandel coast from Phœnix farinifera; in Ceylon from Corypha umbraculifera; and in Assam from Caryota urens. These trees are cut down, and from the pith filling their stems the sago is extracted. The pith is thoroughly washed, and from the washing, when allowed to rest, the fecula or starch subsides; this is the sago flour of commerce, of which large quantities are used in the manufacture of calico. When used as food it is granulated, and known as pearl sago. Tapioca is really sago in lumps,* and was so called merely because the French, who introduced it from India named it Sagou-tapioca. About eight thousand tons of sago are annually imported.

Sagus Rumphii is a small tree, comparatively speaking, not above 30 feet high. It is a native of the Indian Archipelago, particularly of Malacca, Borneo, Sumatra, Celebes, and the Moluccas. Before the tree has arrived at maturity the stem consists of a mere shell, about 2 inches thick, with a great mass of spongy pith, becoming gradually absorbed, and ultimately the stem remains hollow. At the time when the pith is fully developed, and before it has begun to diminish, which is indicated by the superior leaves being covered with a sort of farina or white dust, the tree is felled, and the trunk cut into lengths of 6 or 7 feet long, which are split to admit of the pith being more easily removed. The pith is in the state of a coarse powder, and is mixed with water in a trough having a sieve at one end; the water, loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. The water is then strained off, and the farina which is left may be dried into a kind of meal, or moulded into whatever shape may be desired. Sago, as it comes to this country, is prepared by forming the meal into a paste with water, and rubbing it into grains; it is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it, so as to give it a fine pearly lustre, and large quantities are also prepared at Singapore. It is said that a single tree will yield from 500 to 600 lb. of sago. Sago forms the principal food of the natives of the Moluccas. A decoction of sago fermented yields alcohol by distillation, and by ascescence it forms vinegar. The fruit of this Palm is the size of a hen's egg. The base of the leafstalks is covered with long fibrous filaments that serve to make cordage and sacking.—*Journal of Horticulture.*

TEA FIRING IN N. FORMOSA.

Each tea packing hong has a large firing room attached. Small hongs have 50 to 100 fires and large hongs have about 200 to 300 fires, and even more. The fire places are simply circular holes, about two feet in diameter, surrounded by brick facings. They are arranged in rows, and are not much more than eighteen inches above the floor of the room. The fire holes are apart about half a foot, and on the top of these circular holes or receptacles for live charcoal are placed the baskets containing tea. The fires are prepared in a simple way; a large pile of charcoal is lighted and allowed to burn till all the combustible matter contained therein has disappeared, and then the red hot particles are placed by the circular fire places. For several hours the fires are allowed to flare up and cast forth a flame and glow that few men can stand for any length of time. If you enter a large firing room at the time the fires are being lighted it is like going into an oven, and the return to the open air reminds you forcibly of the heated atmosphere of Montreal hotels, where inside the temperature is perhaps over 70°, and on going out of the front door suddenly find yourself in an atmosphere several degrees below zero. This is putting it very mildly, for in a room with 300 fires the heat is far more intense. It takes time for the fires to settle down, and the red hot charcoal has to be broken up with iron implements; the red heat has to penetrate to the very core of the charred branches or portions of trees, and when no smoke whatever issues from the fire holes, the firing men place on top of the embers a thick covering of ashes of paddy husk, which deadens and tempers the heat to such an extent that in the course of 12 or 15 hours from the time the blazing lumps of charcoal were placed in the fire holes it is safe to place the baskets containing tea leaves over them. The baskets are cylindrical in shape, about 2 feet in diameter and about 3 feet high; they are divided in two by a sieve partition and on top of this sieve the tea is placed. The teas brought down from the hills and tea districts have undergone the sun-drying and absorbing process, have been fired in an iron pan, have been twisted by hand after passing through the rapid frying process and on occasions are basket fired up-country. But the up-country process of preparation is insufficient to permit of the leaf being shipped away to a foreign country; it has, therefore, after you have purchased it, to be "cured" properly and finally at Twatutia. Every particle of moisture has to be extracted in the final process, previous to packing the leaf in lead-lined chests.—*Indian Tea Gazette.*

* No: it is the starch of *Cassava Manioc.*—ED.

GHAUT FORESTS OF THE NILGIRIS.

There can be no doubt that Castilloa elastica would thrive in the lower Ghaut valleys. The climate, soil, and general surroundings of the forest in which the caoutchouc tree is indigenous are exactly similar to that of the lower Ghaut range. The point, however, which nothing but experience on the spot can determine, is whether in this tract of teeming fertility and bewildering wealth of species it can so far intrude on the closely fitting vegetative economy as to conquer an independent position in the forest flora. Most probably it would require some artificial aid to maintain itself. Only to a limited extent could we afford the latter, for the same poisonous climate exists in the tracts, under discussion as in the tree's new world habitat. The region is permanently inhabited by aboriginal tribes, who sometimes settle down into villages in healthy localities; at other times retire to the most lonely and malarious portions of the belt were they seem to be dying out. They cannot be relied upon for general work, but abundant labour for a portion of the year may be procured. Villages with surplus labor exists on spurs of the Ghauts almost overhanging the low country in a cool and nonmalarious climate, two or three thousand feet above the sea. On such a spot the hut of the supervising officer could be erected and feverstricken coolies located for change of air. The whole forest region below is now pierced by easy Ghaut roads at intervals of about fifty miles and bridle-paths run up the accessible passes along which the produce of the hills is taken to the sea. In the lower Ghaut forests Castilloa elastica would find a habitat quite as suitable and unhealthy as its own in America, and with a little care and culture there is no doubt, it would yield at least twice the amount of rubber which it now produces in its normal state. Planters might do worse than turn their attention to this cultivation. In these tracts may be seen towering trees such as grow nowhere else between the two seas: ebony slowly rotting; cardamoms, gamboge, woodsoil, cinnamon oil, resins, gums, &c. going to waste and untouched. True it is difficult to work some parts of these belts; to drag heavy timber, slides would have to be constructed or elephants employed. Though the latter exist in large numbers in an unregenerate state on the spot, yet in most of the acclivities, no elephant could work on a crumbling foothold dropping down at an angle of 40°. We fail to see, however, why a portion of the evergreen forests should not be put in working order. If money for forest purposes is to continue as scarce as it has

been it should in preference be spent where it will yie'd the quickest return, *i. e.*, in a rational working of the Ghaut forests . . . Considering the inaccessibility and unhealthiness of the lower Ghaut forests, we have here a case of what is termed a 'providential adaptation of ways to means' in the fact that the locality is so well fitted to produce an article so necessary in the arts and of such a growing application as Caoutchouc. —*South of India Observer.*

RED SPIDER.

A Darjeeling correspondent writes, in the Cachar Notes, published in the *Englishman* of the 3rd instant:— "For the last fortnight we have had an almost incessant fall of rain, which, together with the cold, has brought on red spider in many gardens. However, the hot weather of the last few days may choke off this unpleasant little visitor." Now, this sentence represents the very opposite opinion to what Darjeeling tea-planters entertain on the subject. They credit the hot weather with bringing on the pest, and look hopefully to the heavy rain to clear it away. It says little for the devotion of tea planters to their business that they are still quite in the dark as to the nature and habits of the red spider, although they have for many years been suffering, and still continue to suffer, very highly from its ravages. They do not even seem to have arrived at unanimity in regard to the times and circumstances of its actual presence or absence,—primary facts which surely might be easily set at rest, and placed beyond doubt by the most ordinary care and observation. Can it be possible that the Cachar and Darjeeling men are both right, and that as regards the red spider, the atmospheric influences in these two districts produce diametrically opposite effects. It is a pity that the red spider nuisance is not properly and promptly taken up and thoroughly investigated by competent persons without further delay. Although planters themselves may not, perhaps, have the necessary leisure or scientific accomplishments, they might easily engage some one with both and at no very ruinous expenditure either, for if every planter whose property is affected subscribed even a rupee for the purpose, an ample fundwould be available. A few months ago, whilst they were probably suffering from the bad prices of last season, the tea boards and bigwigs at Home were going to have the chemistry of tea manufacture thoroughly enquired into; but the good prices this year seem to have evaporated their ardour. And so we go blundering on from year to year without understanding the first principles of an Industry, the magnitude and importance of which, though obviously great, would be immensely increased if we only understood and guided ourselves by its correct principles, as is done in every other important Industry except Tea. Red spider and fermentation are two of the most vitally important matters, regarding which information is wanted, but there are many others regarding which we are equally ignorant; and if a committee of investigation were once started, the width of their field of operations would be very great. Let me ask a simple question. I will suppose that a sample of tea having just the proper colour, strength, and flavour most approved by the brokers be sent to a tea planter, with instructions to make all his tea exactly like the sample, putting quantity entirely on one side for the occasion—is there a planter in India who could do this? And if not, who not? All trades and professions work by sample, and as we can get bread, beer, wine, food, and condiments of any and every sort made exactly to our taste, why not tea? I shall be glad, if some one who is competent to answer the question, will do so.—*Cor. Indian Daily News.*

WITHERING MACHINES: A REPLY.

To your Dehra Dun correspondent, as per *Indian Tea Gazette* of 21st July, which has just reached us. "When will a good Witherer be introduced?" he exclaims! And again—"Who will come to the front with a good Witherer"? I quite agree with all he says of the difficulties and the manifold conditions by present methods in getting fresh or wet leaf, quickly, equally, and properly withered during all kinds of weather, so that it will ferment well and equally, and on which depends the making of first-rate Tea. But, Sir, what surprises us most in our frequent intercourse with most Planters, their Agents, and Directors, is the ignorance of what is going on in the Tea industry throughout the world, and particularly of its latest economic inventions around them. Your correspondent cannot be, surely, a reader of your *Gazette* or an inquirer, otherwise he might have seen our advertisements there, and in many other papers, during more than 12 months, having an Indian circulation, that there is a Witherer in existence for which we claim, and can now prove beyond doubt, that the XL-ALL Tea Drying and Withering Machine is the *first* and *only perfect Witherer*, and, from actual results in Ceylon, withering and drying tea daily. But perhaps he is one of those thoughtful and far-seeing men who does not believe in fire heat, "*i.e.*" warm air, or hot if you choose, properly applied as a means of artificially and rapidly withering tea leaf: therefore we take an interest in him, as he speaks of a fortune certain to accrue to the inventor of such a Machine that will fulfil all the conditions, and which must necessarily apply fire-heated air. I need not mention how the prejudice against fire-heat for withering has arisen, as the haphazard system of withering over Dhols in wet or foggy weather is well known to almost every planter, and also the results obtained from it.

Some years ago I observed, by actual experiments with fire-heated air on fresh tea leaf in the country, though small, but sufficient to show when properly applied to the air and leaf together, that the after fermentation, so named, was quite equal to the best natural (tray) withering, and believing, as I do, that the after colouring of the roll is due to the oxidation of the taunin in the leaf, and not to fermentation, properly so called, I resolved to bide my time, until I could cautiously, step by step, design and carry out properly a Machine that would obviate the necessity of the tedious handling of Tea on trays, for either drying or withering, and giving greatest effect, together with simplicity, highest class workmanship, and cheapness. The XL-ALL Drier and Witherer is now complete, and together with a whole set of simple and economic Machines are now at work in Natal (XL-ALL and factory-shafting lately sent there) besides single Machines in nearly every district; also a whole set for every stage at Messrs. Jas. Brown & Co., Hatton, Dikoya, Ceylon, who have lately sent a report on the Withering and Drying by XL-ALL, together with samples of tea from the bulk and unassorted, just as it was dropped out of Machine.

Report says, actual results of first attempt, without practice, gave, as a self-acting Drier, 130 lb. dried perfectly in 20 minutes. All the samples are marked leaf *withered* (while in a wet state) and dried by XL-ALL, withering a maund each fill of Machine, in a few minutes. A note in Report states that we find that the leaf that was withered by Machine, and after rolling same by our Link and Lever Machine, *takes exactly the same time to ferment as leaf withered naturally by the ordinary means.* I now come to the report on the bulk and unassorted samples of this same tea by Messrs. Geo. White and Co. of London. "Ceylon tea, black Greyish curly, *bright infused leaf, brisk and pungent flavor*, prices up to 1-10d. per lb. in bond."

The point here in evidence of its being, as your correspondent, like many other unprejudiced and thoughtful planters ardently desire, is the character of all the 5 samples *Bright infused leaf;* there is also the verbal evidence of the taster of the Civil Service Stores, London, that he *never saw a more regular fermentation or a brighter liquor.* What does this show, but the most perfect withering (by fire heat) and more rapidly and without labor than anything else in existence. From the fact of 130 lb. dried in 20 minutes, and with practice, Messrs. Brown say, they

will be able shortly to declare better results; it shows by the character, brisk, and pungent flavor, a first-class Drying Machine. But they say as a Withering Machine alone it ought to take.

It enables planters to make first-class tea during any kind of weather, be it rain, fog, or sunshine, as air of any degree of heat can be used accordingly, and they can time the withering to the rolling, and save all chalonies, lofts, large sheds, their annual repairs, labor, and worry infinite.

It is a rapid Drying Machine one minute, and a splendid Withering Machine the next. Any degree of withering can be given to prevent frothing and loss of watery juice, particularly at the first of the Assam season; concentrates the mucilagenous matter in the leaf, and holds the roll; rolls up quicker, gives bright flowery or orange nibs, enhances the price of the tea.

I apologize for this long letter, but your correspondent's exclamation —"who will come to the front with a good Witherer," has prompted it; and as a duty to ourselves and the Tea industry, and but for that I would have remained quiescent until the promised still more surprising results, with the staff in thorough trim and practice in Ceylon, where my system of fresh leaf equalizing (making first-rate equalized Pekoe Souchong, or all the classes, without sifting or otherwise, and without broken tea and dust) is being carried out by my several inventions, and by instructions given during 12 months in our Works to a young Engineer who is now there.—Yours faithfully, JOHN GREIG, JR., For John Greig & Co.—*Indian Tea Gazette.*

[The surprising thing is that we, in Ceylon, know so little, in fact scarcely anything of what is said to be done amongst us.—ED.]

THE AUSTRALIAN BLUE GUMS

are rather inconsistently described in an article on firewood in the *South of India Observer*:—At the present selling price of grass land outside of Ootacamund, and considering the unique rapidity of the growth of the eucalyptus and the enormous proportions it attains, it is proved to demonstration that the great quantity of fuel yielded by an acre would amply recoup the outlay of a producer, even if the latter sold his wood at half the rate now charged by the Department for a thousand pounds. The Forest Department charges a seigniorage of R1-4-0 for this weight of wood delivered at the forest, and the average rate of cart hire to and from the latter is R1-8-0. Thus a cart load of wood deposited on a purchaser's premises costs R2-12-0 (more than half of which is for carriage) anything but a light price, we submit, when we take into consideration the excessive and necessary consumption of wood in this climate for domestic purposes more especially during the monsoon and frosty months. Moreover Government denies to the native town population the privilege of taking their wood out of the forests, which is conceded to villagers. A cheaper supply of fuel in a damp climate like ours to a scantily clad and badly housed native community would be of incalculable benefit indirectly. It would improve the health of the town, and lower the death rate, to say nothing of the mere comfort of domestic life. On Æsthetic and Agricultural grounds we deprecate the promiscuous cultivation of eucalyptus within the precincts of the cantonment. Viewed in the former light of the prim formal, stiff, sombre looking blue gum is anything but an embellishment to the lanscape, and when in addition, its towering height, effectually shuts out from view the pretty tasteful English dwellings which since recently adorn our Sanitarium we think any Æsthete will support our contention that the disfigurement in question should be removed or at least not permitted to be extended. Unless one strains one's sinews to clamber up Dodabet's summit it is impossible to get a view of Ooty, owing to this thick growth of eucalyptus, which envelope it on all sides, and the natural beauties of our pretty Sanitarium are effectually effaced by this giant of the Antipodes. If the cheapening of fuel should fail to demolish our urban forests, for we hold that the factors, which contribute to enhance the price of firewood are distance of the source of supply and cart hire, we should like to see a bye-law introduced prohibiting the planting of the tree within the limits of the cantonment, though such a bye law can only be justified except by a very liberal construction of the Sections of the Municipal Act. Agriculturally considered it is an indisputable fact, that eucalyptus dries up streams and springs, destroys pasture and generally impoverishes the soil and it has been observed, particularly in Australia, that grass and undergrowth perish beneath its baleful shade and no green thing grows therein. In a word the Ecuaylptus Globulus is so select in its habit that it will tolerate no rival in the vegetable world in its vicinity and thrives rankly in solitary luxuriance or exclusive community like Robinson Crusoe, Monarch of all it surveys.

OUTDOOR CULTIVATION OF THE STRAWBERRY.

There is no doubt that many Strawberry plantations are relied on annually for the crop, when it ought not to be counted on as profitable for more than two or three years. As the time will soon arrive when there will be abundance of runners, it will not be inopportune to give a few notes regarding the outdoor cultivation of the Strawberry. Many gardeners make their new Strawberry plantations in the autumn, others leave it until the spring; but we think a full crop ought to be procured the first season after planting. Therefore we will recommend the runners to be planted in their permanent quarters from the last week in July until the end of August. The sooner the runners are planted the stronger will be the plants, consequently there will be a larger crop of fruit. This system of Strawberry culture is well carried out by Mr. Douglas, Great Gearies, Ilford, and better results could not be obtained. Preparing the runners and preparing the ground for their reception ought to be attended to at about the same time, for as soon as the runners are well rooted they should be planted out.

PREPARING THE GROUND.—The ground should be well trenched to the depth of 30 inches, placing a good layer of decayed manure in the bottom of the trench, and another layer within a foot of the surface. If the subsoil is not in very good condition it must not be brought to the surface but be kept underneath. It must be well worked up with some manure. After the ground has settled down it will be ready for the prepared runners.

PREPARING THE RUNNERS.—As soon as runners are obtainable they should be layered into 60-size pots, filled with a compost of four parts loam and one part decayed manure. The loam should be well divided and the manure sifted. If it is not convenient to use small pots pieces of turf 4 inches square are good substitutes. Pinch the points off the runners before layering, as it will strengthen the remaining runners. Press the base of the runner on the surface of the soil or turf, and peg it in position. After being layered they must be kept well supplied with moisture. When well rooted sever them from the parent plants, stand them together in a sheltered place, and keep them well supplied with water. In a week they will be in good condition for planting out.

PLANTING OUT THE RUNNERS.—Two feet apart in the rows and the same between the rows is a good distance. To every plant give a good shovelful of soil, the same as was used for layering, only it may be in a slightly rougher state. Press the soil well round the roots, and form a shallow basin round them. Keep all runners removed as soon as they appear, and well water them every alternate night, or according to the weather. They will soon commence growing, when the Dutch hoe should be used frequently amongst them. As the season advances and the autumn rains come on discontinue watering.

AFTER-TREATMENT.—If the winter is likely to be severe mulch with some short dry manure. If it is likely to be an open winter do not mulch them, but use the Dutch hoe freely. After the fruit has set, and if it is dry weather, a good soaking of sewage or liquid manure should be given, afterwards well mulching them with long stable litter, which will soon become bleached and be a good protection for the fruit, otherwise

clean straw can be used. It will well repay the cultivator if time can be spared to support the fruit with Birch branches. This is the best protection from slugs, and the fruit is kept clean.

SECOND YEAR'S TREATMENT.—After the fruit is gathered and all runners taken off that are required, remove the runners that are left with the old mulching. Well hoe and clean the plantation, and give a thorough dressing of well-decayed manure. This is all the treatment they will require beyond hand-weeding and cutting off any runners which may appear until the fruiting period arrives, when the protection of the fruit must be seen to.

If a new plantation is made every year it will be much the best system, as then there will be a one-year and two-year-old plantation in full bearing; but the one-year-old plantation will produce much the finer fruit.

VARIETIES.—Most gardeners have their favourite sorts, but I give a short list for succession:—Vicomtesse Hericart de Thury, Keens' Seedling, Sir Joseph Paxton, President, Sir Charles Napier, British Queen (in some soils), Unser Fritz, Loxford Hall, Reedling, Frogmore, Late Pine, and Oxonian.—A. YOUNG.—*Journal of Horticulture.*

IN the production of Rose Blooms for Otto of Roses no less than 145 towns and villages are concerned. Under favourable circumstances 2,000 lb. of Rose leaves will yield 1 lb. of the otto, whereas at other times it will take no less than 5,000 lb. weight of leaves to produce the same quantity. The area required to grow the Rose trees to produce such innumerable quantities of flowers covers large tracts of country, and in order to save loss by evaporation after picking, small stills are erected in the open fields. It is the more necessary to have the apparatus close at hand, as all the flowers for the same reason are picked if possible before sunrise.—*Journal of Horticulture.*

WORMS ON LAWNS (*G. R.*).—There is no simpler remedy for expelling worms from lawns and borders than clear lime water. Get some lumps of lime fresh from the kiln and place them in water, stirring well, then allowing the lime to settle and the water become clear. If there is any sediment at the bottom of the vessel the water will be as strong as you can make it, and perfectly safe. About a pound of lime will suffice for ten gallons of water. It is best to apply it during mild showery weather, when the worms are near the surface. If there is no sediment at the bottom of the vessel the lime water will not be strong enough. An ounce of corrosive sublimate dissolved in a little boiling water, then mixed with forty gallons of clear water and applied through a rose, has also been found to expel worms from lawns. —*Journal of Horticulture.*

ALLEGED INSECTICIDE CHARACTER OF TOMATOES.—A curious statement, deserving the examination of botanists at home, comes from Cape Colony, where it is alleged that insects are observed to shun land on which tomatoes are grown; and the culture of the *Lycopersicon esculentum* is accordingly recommended in all cases where it is possible to grow it—under fruit trees, for instance, since the tomato will thrive in the shade of other trees, which few other plants will do—for the sake of the virtues attributed to it as a prophylactic against the inroads of insect pests. The popularity of the tomato as an esculent is sufficiently great to repay the trouble of planting on a large scale, even if its supposed virtues proved to be a myth; and any surplus supplies might easily be preserved in tins, and shipped to this country. It will be interesting to know whether the tomato has been observed to exercise any such effect on insects elsewhere—in Canada, for instance, where the fruit is so popular—or whether it is only in warmer climates, like that of the Cape, that its peculiar powers are brought into play. Much the same power was once attributed, we believe, to the common broad bean, but we are afraid this plant does not "live up to" its character.—*Colonies and India.*

EXISTENCE OF MANGANESE IN PLANTS.—Manganese is tolerably abundant in nature, large deposits of the oxide occurring in Scandinavia and elsewhere, but it is almost exclusively confined to the mineral kingdom. It is true that traces of manganese have been long known to exist in the vegetable tissues of a few plants, but whether accidental, or essential for the growth of certain species of plants, botanists could not tell. Professor Fluckiger, of Strassburg, has during the last few years brought forward additional evidence that manganese is widely distributed, as it is to be found in the ash of many plants belonging to different families, but the quantities are comparatively minute, and anything but uniform. From experiments made by Fluckiger in 1872, it transpired that manganese pervaded nearly every plant of the *zingiberaceæ*. This can be demonstrated in the case of cardamoms by fusing the ash of one seed or capsule with nitre and sodium carbonate when the distinct green re-action characteristic of manganese is observable. Recently the same investigator has shown that the genus *trapa* contains throughout many species a distinct quantity of manganese. The fruits of these plants give evidence of a liking for this metal, or at least they have peculiar susceptibility for its assimilation. From this predilection or affinity for manganese such plants are appropriately denominated *manganophagous* or more simply manganophile.—*Chemist and Druggist of Australasia.*

PLANTING EXPERIMENTS.—Mr. J. Aitken Middleton of Tinkong, wrote as to his experiments at Tipling:—"*Vanilla.*—I think I told you that I had planted it in virgin jungle with only the undergrowth cut down. It came on splendidly, but I regret to say that the squirrels took a liking to it and ate off the shoots as they came out. I have removed it to a more open space and have planted artificial shade over it, and I am glad to say it is now doing very well. Of course this transplanting has checked growth considerably, and will, I fear, cause delay in blossoming and fruiting, but I have little fear for it now. *Ceara Rubber.*—Last lot has germinated fairly well: after it is germinated it seems to have only one enemy namely, the mole-cricket. This fellow destroys them when they are 3 to 4 inches high. I had 40 plants destroyed in one night. The only tree that came to any size here (Tinkong), out of the very first lot of seed you sent me, has begun to flower. I regret to tell you, however, that during a thunderstorm some two nights ago the flowering branch was broken off. This branch I have cut in pieces and planted to see if they will grow. In March one of the trees planted at Tipling was blown down in a gale. I had it cut in pieces and planted at once, and am glad to say that all the cuttings are doing well. I should now be obliged by your giving me some information as to when, where, and how the trees ought to be tapped. *Divi-Divi.*—As I told you some time ago the tree grows very freely here. Nearly every seed you sent me has germinated. The few trees I have here have not grown much in length lately, but have thicked about the roots and have spread out on top. They seem to like the sun as all are turned towards the south and south-west. Two are specially noticeable in that way, being spread out like trained plum trees facing south-west; not a leaf on the other sides. There is no shade anywhere near them, so I cannot account for this way of growing. *Rhea.*—I regret having forgot to watch this plant at seeding time (end of April and May) as I wished to send you seed. I was busy with a lot of new machinery and building at the time, and the bungalow garden was rather neglected. I shall be very glad to send you a lot of cuttings if you wish them, and shall try and remember seed next year. *Vegetable Seeds.*—When distributing the seeds I should like you to send all "*Buists*" (American grown seed) if possible. I find they do best in Assam. For eleven years I have never had a failure with them, whereas, even the best English seeds have never been a *great* success either with self or neighbours. *Neem.*—This tree requires great care; I have been able to save three trees only, and would be glad of a few more seeds if you can spare them."—*Madras Mail.*

THE DROUGHT; NATIVE CATTLE AS DRAFT ANIMALS AND MILKERS.

Hapitigama Korale, 16th Feb. 1887.

We had a mere sprinkling of rain on the 9th and 10th; no sign of any since. The sun blazes and the wind blows, and everything is suffering more or less according to its nature; man, beast, and plant. After all we have no right to complain as it is the only weather we have to expect at this season, and though the heat and the cold, and the wind are disagreeable, I hear of no sickness out of the common, either on the estates or in the villages, and for certain kinds of work nothing could be better. Coconuts on dry gravelly ridges or sun-baked clay suffer sadly both in the loss of leaves and fruit, but we must, take the bite with the buffet and make the best of our situation.

In my own case my cattle are my greatest trouble, the herbage is utterly burned up and day by day they become more lean and wretched. With reference to your recent article on our breed of cattle, it does not appear to me that in the low-country anything would be gained by crossing the breed with anything larger or less hardy. The native breed is admirably suited to the country and the habits of the people. Left to shift for itself the Ceylonese bullock is supple and enterprising, he holds in contempt all ordinary fencing and ranges far in search of a succulent mouthful; cunning and watchful, he dashes off like the wind whenever he smells danger in his marauding expeditions. He has great strength in proportion to his size and weight, and when trained to work is patient and docile in the hands of those he knows. Indeed both his vices and his virtues suit him exactly to his lot in life, but when well fed and tended he becomes a very perfect animal and will accomplish a run of six miles in a light hackery, in three quarters of an hour. As the cows are never milked* the lacteal glands are never properly developed but get a young cow with her first calf, feed her well, and milk her dry twice a day, and she will give as good a return for the food she eats as any other breed.

Cattle keeping is not a paying business in Ceylon, either breeding or fattening, anything except milking cows, and draught bullocks' are kept at a loss. The value of an 18 months calf is R5 and if kept till it is three years old, a handsome young one may be as high as R15, but a quey of that age will not sell for more than seven or eight, and if you go to the cost and trouble of fattening a barren cow or a young bullock that proves unfit for draught the butchers will give no more than for a wild animal from the jungle. There are more or less cattle kept on most coconut estates, but I think most proprietors of experience will agree with me that they are kept without profit, if not at a loss when they pay a keeper. If the manure is conserved that is something, but manure of equal value may be bought for less than it costs. Where cattle are kept on an estate, however, there is some gain in the cost of weeding, because even rank grass is injurious to coconut trees and the cattle droppings are of some service to the soil. I pay my cattle-keeper R90 per annum and my returns, the milk and butter of the year, would be worth a like sum if there were a market, but as it is all consumed on the premises, that may be written off as balanced, then I have my bullocks for cart and hackery work and 20 cubic yards of manure worth R40 and I could sell three head annually for R30, so that I am a gainer of about R70. Mine, however, is a special case; none of my neighbours milk their cows and few of them turn their manure to good purpose, and as my chief profit is in the milk, theirs must be a loss. None but a Scotchman can make a good breakfast on milk parritch with milk, and only he who takes all the milk he can get from his cows, can make from R30 to R40 in a year from ghee prepared from his spare butter.

We, coconut planters, are fortunate in being outside the Medical Wants Ordinance and with no personal interest in railway extension. Of course, my sympathies are with my mountain brethren on both questions and were I a member of the Association, I would vote for the most violent and outspoken of the proposed notions on the medical question.

* Our Correspondent does not seem to have the fear of the "Examiner" and its Correspondents before his eyes. For asserting that the natives seldom milked their cattle, we were severely reprehended, but there is our Correspondent, with his long experience making the assertion in a stronger form.—Ed.

INTERESTING ADMINISTRATION REPORTS.

(*From Report of Assistant Government Agent Kegalle.*)

Coconuts and Plantains.—There is a considerable area under coconuts and plantains; indeed, there is a large export trade in the latter in the districts bordering on the railway, the quantity sent away from Rambukkana alone in 1885 being 561 tons. On the whole, there is an abundant supply of food for the people, and it is only in the case of the estates, and to some extent the floating bazaar population, that imported rice is used.

Cost of Production.—The cost of the production of rice is shown in the tabulated replies to the following series of questions. I have taken a pela (*i.e.*, about half an acre) as representing the extent owned by the ordinary villager:—

If hire of buffaloes and Government tax is included, the value of each day's labour comes to (from 3 to 6 cents!)

Notes.—(1) There is scarcely any sale for straw in the Four Korales and Lower Bulatgama, and only a very limited sale in the Three Korales, where a pela's production of straw can sometimes be sold for from R1·50 to R2.

Other Products.—*Tea.*—The cultivation of tea has increased on a large scale during the year. There are now over 100 estates in the District, and the out-turn during the year from them all must have been close upon a million pounds. Land is going up in value, and is being eagerly sought after by investors, and the average price has risen to £3, £4, and even £5 an acre.

There can be little doubt that the Kelani Valley is destined to become the finest tea district in the Island. The soil may not be so good as in some up-country places, but in point of climate for tea and cheapness of production it beats them all. It has a navigable river within easy distance of every estate, that only requires a little money spent on it to be suitable during a considerable portion of the year for steam traffic; it has an unlimited labour supply in the village population, who are readily taking to estate work; and it has extensive tracts of Government jungle suitable for cultivation. I annex a table of the average rainfall, and of the number of days in which rain fell during the year, that may be of interest as showing the suitability of the District in point of climate for the cultivation of tea:—

	Average of five years. Inches.	How many Days.
Kegalla	... 117 to 120	... 174
Ruanwella	... 130 to 187	... 149 to 160
Kitulgala	... 188 to 239	... 200 (about)
Yatiyantota	... 145 to 150	... 200 („)
Dehiowita	... 135 to 155	... 240 („)
Avisawella	... 125 to 168	... 164-228
Indurana	... 120 to 168	... 168-179
Rambukkana	... 72	... 175
Western Dolosbage	... 180	... 223
Panawal Korale	... 148 to 171	... 217 to 243

The lowest rainfall is at Rambukkana, but even here there are the compensating advantages of a heavy dew at nights during the dry season, and the rich loose soil of the Mahaoya valley.

Cacao.—The cultivation of cacao has not been on so large a scale as in former years. Much of that already grown is dying out. I do not think that the soil and wet climate of the Distict are particularly suited to it.

Cardamoms.—The cultivation of cardamoms has extended in every direction. The soil and climate of the Western Dolosbage range and in the Kelani Valley appear to be very well adapted to it.

CINCHONA.—There is a little cinchona still remaining in Western Dolosbage, but it will soon become, like coffee, a thing of the past.

Annatto, croton, rubber, African palm, coca erythroxylon, are being tried here and there, but these are as yet in the experimental stage only.

ARECANUTS.—The cultivation of the arecanut palm is perhaps the most important native industry in the district. The finest nuts are grown here, and they are produced in the largest quantity. It is estimated that there are over 120,000 acres in bearing of this product. The arecanut serves in place of money to the native. By its means he pays his road and paddy tax, and obtains his salt, tobacco, betel, dry fish, &c. It is therefore an index of the prosperity of the villagers, and I have made it my constant object to extend the area under its cultivation.

Experimental Gardens.—A number of experimental gardens were opened during the year at different points in the District, *i. e.*, at Kegalla and Ambuangala, and on a smaller scale at Rambukkana, Dehiowita, Pindeniya, and Ruanwella, and various products have been tried at each. We have some excellent Gansabhawa rules to compel people to plant up their gardens, and these have been put in force in every District, with the result that palms and plantains are now being extensively grown. I think myself that one of the chief objects in our experimental gardens should be to grow native products of really good kinds; and we shall, I believe, do far better work in improving what the natives have already, than in forcing them to grow new ones. Take plantains and papaws for instance. They cultivate in many cases the poorest kinds, because they cannot get at their hands the best. The native papaw is a wretched fruit, while the West Indian, which grows here even better is a delicious one, and some of the Straits plantains are as superior to the ordinary Ceylon kind as English hothouse grapes are to those of Jaffna. Cacao is the only European product that a native can grow round his house with a chance of its being remunerative, and for this we can only supply seeds, as it will seldom bear transplanting. Tea will not, I think, suit the ordinary villager, but it would be well to give him the chance of growing it, if he likes. With the exception of these two, I think, we should spend our money and energy on improving their palms, their breadfruits, yams, plantains, papaws, pepper, cardamoms, and, if possible, their cereals.

It is significant how seldom one sees young palms (except arecanuts, which are self-grown) of from two to three years old, and I myself believe that the fresh planting of these is becoming less and less and that when the old ones die or become exhausted the people will feel their loss very much. As it is, many have nothing in their gardens but a few old jack or worn-out coconut trees, and when their rice crop fails, they are often brought to the verge of starvation. We should, therefore, I think, apply our new and most useful Gansabhawa rules more in the direction of forcing them to replant their gardens and high lands, than in making them take to new and thereore distasteful products.

NEW PLOUGHS.—The new ploughs introduced by Mr. Green, the Director of Public Instruction, have been at work in this District during the year in several places. So far the results have been satisfactory. Wattagama Ratemahatmaya, of the Belia Korale, used the Sewdish plough on a field of his of three pelas. Last year the field gave ten amunams, equal to thirteen-fold; this year he cultivated half by using the Swedish plough and half by the native plough, and kept the accounts separate. Result:—By native plough thirteen-fold as before; by Swedish plough twenty-one-fold. The Otara Pattu Korála used the same plough on a field of three pelas, and the native plough on an adjoining portion of the same field of two pelas. Result:—With the native plough on the two pelas, crop six amunams, equal to twelve-fold; with Swedish plough on three pelas, crop fifteen amunams, two pelas and five kurunies, equal to twenty-one-fold, or much the same result as in Wattagama's experiment. The great objection to this plough is that it is too heavy for the buffaloes to work, but the same objection does not equally apply to Howard's new "Cingalee" plough, nineteen of which I have now at work in the District, and the result of which will be shown in this coming maha and yala crops.

MR. J. TYNDALL ON CEYLON TEA.

Your readers may care to peruse copy of a letter addressed by Mr. J. Tyndall in October last to Lord Randolph Churchill, and the reply thereto of the Private Secretary of His Lordship:—

"Thomanean, Milnathort, 5th October, 1886.—To the Right Hon'ble Lord Randolph Churchill, &c., &c., &c. My Lord,—In justice to the island of Ceylon, mention of which you make in your late comprehensive and significant speech delivered at Dartford on Saturday last, I would beg most respectfully to point out to you that in your reference to the rise in price in the value of the coffee produced in that island, and from which staple in former years the chief basis of its prosperity was derived, you made no allusion to the industry which is now rapidly becoming a more important industry—namely tea. The accession of the Conservative Government to power has had the most marked effect in the tea market. Ceylon produces a very high quality of tea, which is now forcing its way into the home market, and has especially taken hold of the Irish taste. The effect of Mr. Gladstone's Irish policy was such as to produce an utter demoralization of the tea market there. Dealers would neither give credit, nor hold stocks, and the result was a marked fall in Ceylon tea. Happily, now a rapid recovery under a more stable and firm Government is already perceptible. Having lived and labored for upwards of thirty years in Ceylon, I am naturally anxious that this new product, tea, which is bringing back prosperity to the island, should not be lost sight of by the Government even in these trying times, and I would beg to bring under your Lordship's notice that the rise of the tea industry in Ceylon is, I venture to pronounce, one of the most striking examples of the British planters' pluck; for, after being ruined by leaf-disease in coffee and again struck down by the failure of cinchona, disheartened but not dismayed, the same men have planted up the same land with tea, which, as far as human foresight will allow, now promises a great future, the export of tea having risen from nothing in 1878 to seven millions of pounds this year, and by 1890 will bring into the market 30 million of lb. per annum! Trust that your Lordship will pardon the liberty I have taken in thus bringing forward to your notice so striking an example of what certainly may be classed within the category of the satisfactory revival in trade referred to by you, I beg to subscribe myself your Lordship's Most Obedient Servant,—JOHN TYNDALL."

To the above the following reply was received:—

"Treasury Chambers, Whitehall, S. W., October 11. 1886. Dear sir,—Lord Randolph Churchill desires me to acknowledge with thanks the receipt of your letter of the 5th instant which he has read with great interest. —I am, dear Sir, yours faithfully,—FRANK D. THOMAS."—*London Cor.* Local "Times."

[The grand joke is that the accession of a Tory government, by giving peace to Ireland, (which it certainly has *not* done,) is the real cause of the great increase in the value of Ceylon tea! "Jack Tyndall" could never resist the chance of poking fun.—ED.]

COFFEE, CINCHONA, TEA, ETC., IN BADULLA.

(*Extracts from Badulla Planters' Association Annual Report.*)

COFFEE.—Your Committee are still able to state that notwithstanding the reports that coffee has more or less, in other districts, succumbed to the effects of leaf disease, bug and climatic influences, in many parts of Uva coffee is not only still vigorous and healthy, but during the current season is bearing a good crop with every promise of bearing a fairly good crop in the succeeding year. It is also a matter to be noted with regard to this product, that hitherto, coffee from this part of the island fetched a much lower price than that from other districts, but latterly the

prices obtained for Uva coffee have not only been equal to, but sometimes exceeded those obtained for coffee from the other districts. It is matter for satisfaction that the market for this product has improved so much lately.

LEAF-DISEASE BUG, &c.—It is satisfactory to note the past year has been one of comparative freedom from leaf disease, which seems to have run its course and while this is matter for thankfulness, your Committee cannot but view with concern the appearance of green bug, and it is with sincere regret and apprehension that your Committee have to report its general appearance in the district, and they would strongly urge every member of the Association to do all in his power to check this pest and would point out that while it is only here and there in small patches is the time for energetic action. Your Committee sincerely hope that our genial climate, good soil and vigorous coffee may render the attacks of this pest abortive.

CINCHONA.—Your Committee are glad to be able to report a considerable improvement in the condition of this product in the district. There is a marked decrease in canker, and Uva has proved itself to be probably better suited to the growth of this product than any other part of the island. It is to be hoped that the low prices at present ruling for bark will shortly improve. Some important information was elicited from a series of questions issued to members *re*-harvesting bark; a proposal to send a Commissioner to Java was also discussed but was not carried out. A request was made by the Dimbula Association to collect statistics of cinchona, with the probable yield for some years, but owing to the difficulty of getting reliable information on this subject this request was not acceded to.

TEA.—The growth of tea in these districts is matter for sincere congratulation, and there is no longer any doubt but that our estates are eminently suited to the growth of this product, while sales from the district in the London and local markets have been most encouraging.

COCOA AND CARDAMOMS.—These products have both proved a success in our district more particularly in Moneragalla, and are showing excellent results.

THE TEA ENTERPRISE.

AN 18 MONTHS' PRUNING, RECOMMENDED FOR CEYLON TEA —THE GREEN TEA TRADE WITH CENTRAL ASIA, PROBABLE CAUSE OF ITS DECLINE—LOCAL CONSUMPTION OF TEA IN INDIA, AND THE CHANCES OF GREATLY EXTENDING IT.

Yatiyantota.

DEAR SIR,—Having made more than one careful experiment I am now convinced that tea bushes in Ceylon will go on yielding large flushes for eighteen months (and even longer) without pruning if a light topping (that is cutting away crowsfeet, and any straggling shoots) be given in the meantime *and this latter operation scarcely interfere with the flush.*

It is absurd, therefore, to go on punishing our bushes unnecessarily by a heavy yearly pruning, especially when that is done at the expense of quality, and possibly the premature exhaustion of the plants for this constant cutting away all old wood, and forcing the roots to throw up a continual supply of new wood as well as young leaves must be very trying to the bushes in a forcing climate like Ceylon where the bushes have literally no rest.

The following is the system of pruning I would recommend Ceylon planters to adopt viz., prune half the estate in June and the remaining half in November; these halves would then be alternately pruned in November and June: for instance that pruned in June 1886 would be pruned again in November 1887, and the tea pruned in November 1886 would run to June 1888, thus the seasons for pruning would not be changed though each half would have a run of 18 months from pruning to pruning.

No set time can be given for the intermediate topping, as that would depend greatly on the style of plucking, soil and other circumstances and the Superintendent must use his own judgment as to the best time for giving this, which might be 8, 10, or 12 months after the pruning. Some patches where the soil was good, and plucking had been carefully performed might probably be left to run the full 18 months without topping with advantage, both as regards quality and quantity of leaf. True the experiments mentioned above were carried on at an elevation of only 600 feet and the plan might not, therefore, suit *all* elevation in Ceylon, but anyone doubting if it would suit his own particular totum could easily see for himself by lightly topping a piece of tea he was about to prune, and then wash the flush for the next six months.

The advantages to be gained by such a system of pruning apart from the health of the bushes are many and obvious:—

1st.—The quantity of new and inferior leaf would be much less in proportion to the good leaf.

2nd.—This leaf could be so evenly mixed with the good that no one break of tea would contain enough to materially interfere with the strength and quality of the tea, and hardly a break need be sent away without *some* new leaf in it; hence a uniform quality could be thoroughly maintained.

3rd.—The time for pruning being divided would enable us to estimate the labour force required with greater certainty, and avoid any *great* rush of leaf or any slack time. In short such a system of pruning would almost answer the purpose I had in view in recommending a portion of our leaf being turned into green tea.

Apropos of this and your foot-note to my letter of the 19th June regarding the decline of the green tea-trade with Central Asia, as I was one of the first who had a finger in the pie, I may be able to throw some light on this subject that will interest you and your readers, and, perhaps, be of use to those more directly concerned.

My own candid opinion is that the planters of Northern India have no one but themselves to blame for the decline of this very remunerative trade, in fact it was a clear case of "killing the goose," etc., etc.

We were on our last legs finding it almost impossible to sell black tea for cost of production (owing partly to the depression of trade and partly to our isolated position and heavy transport as compared with Assam and other more favoured tea district and still more to the cold climate, and consequent small yield per acre) when some wealthy Calcutta merchants made their appearance, and not only offered to buy up all our teas on the spot, but also gave us better prices than we could get for our black teas after hundreds of miles of transport, and lead-lined boxes had been added to the cost of production. But these welcome customers required us to make nothing but green tea, colour it well with soap-stone and pack in sacks which they themselves supplied.

Now when it is considered that this tea (packed in a manner in which Ceylon planters would hesitate to despatch parchment coffee) had to be conveyed over a long and tedious journey of upwards of 2,000 miles on the backs of camels, and was probably months before it reached its final distinction somewhere in the dominions of the Shah of Persia, I believe, it may well be imagined in what condition it reached the consumer's hands. But what was this to us; the Afghans would have nothing to say to our lead boxes, they were buying the tea with their eyes open and we ran no risk in making green tea as stamped agreements were drawn up at the begining of the season for the whole year's outturn. After samples had been sealed and price agreed upon, and so if they eventually lost heavily on their purchases that was their look out. You may call it short-sighted policy on our part, but the fact was we saw a way out of present difficulties and in the meantime the market for black tea might improve, at least that was my own opinion, and I don't suppose a dozen planters expected the trade to last more than two or three years, though as it went on year after year and the demand seemed to increase it really seemed as if we had established a permanent trade with Central Asia. Perhaps the people rather liked the musty flavour our teas must have had acquired by the time that reached them, never having tasted tea that was not musty

and after all the real cause of the decline may be found in the unsettled state of the country between Afghanistan and Persia, through which the tea had to pass owing to the action of Russia, and now I come to think of it I remember that our own little war with Cabul in 1878-98 nearly put a stop to the trade,the Afghans saying it was unsafe to try and pass through. This trade may, therefore, revive now that the Russian difficulty has been satisfactorily settled, but if it does I would strongly advise the planters interested to take care *of the goose*, and by sacrificing a fraction of their profits provide airtight and waterproof bags so as to insure their teas reaching the consumer's hands in good condition, and free from mildew and rot, and if they could send the tea in small air-tight packets (such as are now being sold in Ceylon) to suit the retail trade I am certain they would be gainers in the end.

Talking of small packets remind me of what a vast field for the profitable disposal of their teas the Indian planters are neglecting at their doors. If we deduct the teas consumed by the troops [and Europeans the consumption of tea in India is almost nil; yet the natives are fond of tea, and thousands of them would become habitual tea-drinkers if they could always procure it in a fresh state *and in suitable sized packets.*

At present it is only in certain large cities, that the natives can purchase tea at all, and then it is either of the coarsest description, (Bohea) in paper-packers and of course musty as souchong taken from a box that has probably lain open in the Buniah's shop for more than a month, and, which, besides being musty has become impregnated with the smell of fish and all the other various strong smelling articles with which the shop is filled. Besides these China tea (so called being sticks and bits of flat leaf) can be had in some of the principal towns in ¼ and ½ lb. packets which are retailed at the rate of one rupee per lb. If some of the managers and assistants of tea estates would only combine business with pleasure, especially those who are fond of shooting and devote some of their spare time to hawking tea about the country and introducing it into the bazaars of small native towns and outlying districts, I am convinced we should hear no more about the scare of overproduction for years to come. The people of India are capable of consuming every ounce of tea at present produced by India, and two trips which I made with the above object in view, convinced me that very little care and trouble on the part of the planters to introduce their tea would secure them a very extensive and profitable market.

As the *Observer* is a widely circulated paper, and anything appearing in its columns affecting the interests of Indian tea planters would probably find its way into the Indian papers, a short account of the two trips mentioned above and the experience gained by them (of which my subsequently leaving India prevented me reaping the benefit) might not be out of place here.

1st—Each trip occupied nearly four months,but as they were accomplished during the cold weather, when there is nothing to be done on a tea estate in India, it could hardly be considered that any time was lost, and as a good part of the journey lay through thinly populated districts swarming with game of every description. I was more than compensated for the loss of the usual cold weather leave which was usually spent on a shooting expedition, but now for the experience gained, and which may be useful to any enterprising planter who may wish to try the experiment.

(1)—I found it easy to dispose of ¼ and 1 lb. packets at a profitable rate, but 2 lb. packets could only be disposed of at a reduction in price, and 10 and 20 lb. boxes were almost unsaleable.

(2)—Rich and even middle class natives frequently bought the highest priced teas preferring to pay R2 per lb. for good B. P. to buying souchong at 12 annas or Bohea at 8 annas; this shows the great mistake planters make in thinking that natives are too poor or too stingy to buy anything but the cheapest tea, hence they usually reserve nothing, but the cheapest and worst teas for the local markets, and this is either sold loose or in rough paper packets. It is this mistaken idea of the planters that has kept back the local sale of tea in India more than anything else. They could sell their *finest teas* in the Indian bazaars for better prices than they can ever hope to get for them in London; only they must be packed to suit the trade, *i. e.*, in 1 and ½ and even ¼ lb. packets lined with lead tinfoils or other waterproof material.

(3)—Although a good quantity of tea can be sold to individual consumers the hawker has to look chiefly to small Bunnias of the native bazaars for the disposal of his tea, and with these it is often advisable to barter rather than stipulate for cash payments. As a case in point, I may mention that one of these bargained with me for 100 lb. tea at 15 annas per lb., but offered to take 600 lb. at R1 per lb., if I would take R150 cash and the balance of R450 in goods from his shop. To this I consented, and soon found myself the possessor of two guns, 100 cooly-blankets and other articles worth for more to me than R450, as I intended to take them to a district where such things are scarce and dear.

(4)—Many of these native tea-drinkers asked me for green tea, as they have a theory that green tea is less heating to the system than black tea. Some of them told me they drink tea regularly during the cold weather, but have to give it up in the hot weather as it is too heating, but if they could get green tea they would drink it all the year round. I cannot pretend to say how far this theory is founded on fact. Personally I prefer black tea to green in the hottest weather, but such being the belief of the natives of India, the planters of the North-Western Province, who cannot now sell their green tea to the Afghans, might take advantage of the native belief and drive a good trade in the plain of India, now that Asia seems closed against them.—Yours faithfully, OLD PLANTER.

THE *Society of Arts Journal* records the largest Vine in the World is one growing at Oys (Portugal), which has been in bearing since 1802. Its maximum yield was in 1864, in which year it produced a sufficient quantity of Grapes to make 750 litres (165 gals.) of wine; in 1874, 665 litres (146⅔ gals.); and in 1884, only 360 litres (79¼ gals.). It covers an area of 494 square metres (5315 square feet), and the stem at the base measures 2 metres in circumference.

EXTENSIVE TREE PLANTING IN MEXICO is now being undertaken by the Government, and a contract has been made with Mr. Oscar A. Droege to plant 2,000,000 trees in the valley of Mexico within four years. The respective numbers are—80,000 Ash, 35,000 Willows, 120,000 Poplars, 60,000 Eucalyptus Trees, 60,000 Trœnos japones, 60,000 Mountain Cypress Cedars, 60,000 Acacias, and 120,000 of miscellaneous varieties. The trees are to be in plantations of from 50,000 to 100,000 each. —*Journal of Horticulture.*

AN American paper gives the following upon Sunflowers as fuel. A correspondent having tried "turf," coal wood, and Sunflowers has settled upon the last named as the cheapest and best for treeless Dakota. He says: "I grow one acre of them every year, and have plenty of fuel for one stove the whole year round, and use some in another stove besides. I plant them in hills the same as corn (only three seeds to the hill), and cultivate same as corn. I cut them when the leader or top flower is ripe, and let them lay on the ground top for three days; in that time I cut off all the seed-heads, which are put into an open shed with a floor in it, the same as a corn-crib; the stalks are then hauled home and packed in a common shed with a good roof on. When cut in the right time the stalks when dry are as hard as oak, and make a good hot fire, while the seed-heads with seeds in make a better fire than the best hard coal. The seed being very rich in oil it will warm better and burn longer, bushel for bushel, than hard coal. The Sunflower is very hard on land. The piece of ground selected to plant on should be highly enriched with manures. In the great steppes (prairie region in the interior of Russia and in Tartary), where the winters are more severe than here in Dakota, the Sunflowers are, and have been for centuries past, the only kind of fuel used."—*Journal of Horticulture.*

THE RUBBER-TREE PLANTING INDUSTRY IN CEYLON.

The result of a considerable amount of inquiry into the present condition of the rubber industry in Ceylon has led us somewhat unwillingly to the conclusion that for a time at least, the pursuit may be considered to be in abeyance—if not altogether abandoned by the majority of the planters who were so keen about it a few years ago. There are, it is true, scattered over the island a great number of properties on which are now growing Indian rubber trees of various kinds, more especially the "Ceara" kind, and on the selected estates from which we have authentic returns we find an aggregate of 150 acres under this cultivation. But if every patch of rubber trees in the country were counted, a much greater area would be made up. Generally speaking the age of the trees under reference is from four to five years, and the growth would appear to be in nearly all cases satisfactory, say from 15 to 40 feet. From but one property is there any statement to the contrary, and here we find some five acres planted on poor soil at an elevation of only 30 feet above sea level. The growth is reported "poor and scanty." The lowness of elevation in this case has probably but little to do with the unsatisfactory growth of the tree, as is evidenced by the flourishing condition of specimens in Colombo at even less elevation than 30 feet above sea-level. The experiments that have hitherto been attempted in extracting the gum from the trees have so far resulted in disappointment. There is, however, a general concensus of opinion that the trees on which these experiments have been tried are too young to produce satisfactory results. Should such be the case it only requires time to effect a cure, and if the rubber can be grown in otherwise unprofitable portions of ground it would be well to continue cultivation with a view to paying results at some future day. There are one or two points which must be taken into consideration in noticing the experiments which have been made in tapping the young trees. As a rule the test has been so much per cooly at so much value. It must not be lost sight of that coolies unaccustomed to any particular kind of work - no matter what it may be—cannot do nearly so much in a day when new to the employment as they will after a time when they have got their hands accustomed to it. Moreover, in a new industry like that under reference, the master is no more acquainted with the proper *modus operandi* than the cooly, and is unable to task the coolies employed in the work.

The cultivation should not be condemned offhand, because the coolies employed in collecting are unable at first attempts to bring in more than ¼ to ½ lb. of rubber. Methods, no doubt, would be discovered after a time of causing the cuts or punctures in the bark to bleed more freely, in the same way as the natives induce the spathes of the jaggery (kittool) to give out a greater amount of palm juice than they would by a simple cut with a knife.

Though we cannot but take into account the exaggerated tone which pervades the whole of a letter we append which a native firm has received from Java, we may without fear of being misled take it for granted that the tapping of old trees may without harm be carried on from day to day for some months at a time, a process which, so far as we can learn, has never been attempted in Ceylon,—probably for want of some older trees on which to experiment. The result mentioned from Java of 25 lb. per three-year old tree in five months we look upon as altogether apochryphal, though it might be credible did the experience refer to large forest trees like our own *Ficus Elastica*. The fact mentioned by one writer of his collecting the rubber from the abrasions caused by blows of a heavy stick on the bark of the Ceara tree remind one of the traditions of the old Royal College boys in Colombo who used to break the bark of the protruding and tortuous roots of the common indigenous trees and wind off the rubber as it exuded from the abrasions until they got elastic balls nearly the size of those ordinarily used for cricket. It has been urged with some show of plausibility that our local Government should encourage the growth of this common wild India rubber on the otherwise profitless banks of the low-country rivers, in view of the possibility of its being able at some future date to issue licenses for the collection of the produce, or at any rate to create a value for land, which at present is altogether unproductive. One of the lessons learnt during the few years in which Ceara rubber has been established in the island, has caused an entire revolution in the make of rubber nurseries. When first introduced into the island the seeds were sold at so much a hundred—germinated seeds, or seeds with the ends filed to facilitate germination—and in spite of all precautions a very large proportion of the seeds were failures while in contradistinction to this experience the seeds o the Ceara falling naturally on the surface of the ground and left to their own sweet will, sprang up like weeds under the parent trees and became rather a nuisance than otherwise. Observation of this fact led nursery-makers to merely turn up and soften the soil, throwing the seed on the surface and just covering with dead leaves, and a sprinkling of soil sufficient to hide the seed from the direct rays of the sun. Under these conditions the seeds seldom fail to germinate quickly even after having been left for months, even years, without any special care being taken of them. Of the rubber creepers such as come under the variety *Landolphia*, we can get but little information from our planting correspondents: no results further than ascertaining the capability of a few localities for their growth have as yet been attainable, though we hope in a short time to be able to learn something more about them, especially from low, hot, moist districts. It is impossible to observe without regret the very prevalent disregard by the planters in Ceylon of what at one time, it was hoped would eventually prove a very lucrative industry, and the produce of which is becoming daily more valuable for a number of processes connected with electricity and telegraphy. The fact of the matter, no doubt, is that facility of production and resulting profits were at first so grossly exaggerated, that when actual results were ascertained by experiment on a fairly large scale, the disappointment was correspondingly great—and with rather unusual precipitancy discredit was thrown upon the whole concern, and it is no longer thought worthy of being followed up by cultivation on a large scale. However, we still hope at some future day to be able to number rubber amongst our valuable exports, though we must confess that at the present time there is not much to lend encouragement to our aspirations. We need hardly say that however pleased we may all be to welcome the enterprising—though somewhat exaggerating—gentleman from Java,

—see letter below—there is no chance of his receiving any remuneration for the time and trouble involved in a journey from Batavia to Ceylon for the purpose of teaching us the art of extracting the milk from the rubber tree.

We now proceed to reproduce some of the reports from different planting districts in the island, with which we have been favoured in answer to our enquiries, and first from Matale, we learn from the proprietor of Wiharagama estate as follows:—

Wiharagama estate has about 25 acres Ceara rubber and specimens of other varieties. Age seven to four years but principally four years old. No harvesting has been attempted as the trees for the most part are not considered old enough to tap without deterioration, and the older trees are not numerous enough to offer inducement for systematic tapping.

The Manager of Kandanuwara, in the same district, writes:—

Kandanuwara estate has nine acres or about 6,000 trees of Ceara India-rubber; growth in years equal five; in robust healthy condition and in a variety of soils. Milking was attempted in 1886 to the extent of about 20 lb and gave from ¼ to ½ lb per cooly, but my opinion is that at this early stage of its growth, whatever it may do later on, possibly nothing much greater, it does not pay to grow this variety for rubber. I am told Ceara rubber trees have been found suitable for cacao shade in Dumbara and I have planted cardamoms under them here, but have not found them by any means equal to the natural jungle shade.

We can vouch for the success of Ceara rubber shade for cacao in Dumbara, by what we saw on Pallekelly, where, we believe, Mr. Vollar has a high opinion of the tree, both for its rapid growth and favourable shade. Mr. Vollar had also made some highly successful experiments in harvesting rubber, to judge by the quantity he was able to gather off individual trees without giving much attention to the matter. The rapid growth of the Ceara tree in the Dumbara valley is very remarkable.

From Mr. Charles Gibbon of the Panwila district we have the following report, but Mr. Gibbon says valuable results should be got during the present month:—

Goonambil estate has some 15 acres of India-rubber Harvesting, tapping has been attempted on two or three occasions but the result as to quantity did not justify it being continued. The quality of rubber has been very good. Experiments will be made in January and February (which will be the best harvesting month probably,) and I will communicate them to you. Some of the trees are eight years old, but the larger proportion are half that age.

From Hantanne district, we learn that,—

Galoya estate has ten acres of Ceara trees of India rubber growth in years equal four years, but the cultivation has been abandoned and weeds allowed to grow. Some of the trees are very fine.

Farther south, we have reports as follows:—

Ambalawa, estate (in Dolosbage) has 30 to 40 acres of trees of India-rubber, growth in years equal from three to five years old; growth good. I have not tried any regular system of harvesting; have tapped several trees and found the quantity of rubber insufficient to pay cost of collecting.

Sanquhar estate, Pussellawa, has 11 acres clearing, and also about 500 trees planted here and there about the estate. The 11 acres is four years old having been planted in 1882, the other trees a year older. The trees in 11 acres are pretty regular, but have forked rather low. No harvesting has been done nor has any record been kept of any particular tree's growth.

Kanapediwatte estate, Pussellawa, has about three acres of India-rubber, three years old. No harvesting has been attempted owing to the failures of others in obtaining satisfactory results.

Our only report from the high districts, is from Mr. Mackie of Great Western, who wrote;—

We tried rubber-trees on the Rathnillokelly division of the group four years ago—elevation 4,000 to 4,200 ft.—only a few came up in the sheltered parts. Some are now 10 to 15 ft. high, but I cannot speak of them as a success. I do not know that the cultivation of this tree has been tried much above (say) Nawalapitiya on this side, at any rate I have not seen any save our own growing in this part of Dimbula.

Crossing to Uva, we learn from Mr. Hoseason that,—

Kottagodde estate has here and there trees of India-rubber, growth in four years, equal to 15 to 25 ft., but nothing has been done to them nor are they in any way cultivated, nor is any gum taken from them.

But the most complete report is that for which we are indebted to Mr. Philby of Cocoawatte estate, Lunugalla, as follows:—

Cocoawatte, 27th Nov. 1886.

To the Editor of the *Ceylon Observer*,

DEAR SIR,—I now send you a few remarks on the cultivation of rubber on above estate.

Extent.—I have 30 acres of Ceara rubber planted from three to five years old; the growth appears to be satisfactory and there is no appearance of disease.

Wintering.—The trees winter regularly every year about June and July, as all the leaves drop off and the tree looks as if it was dead, but in a very short time the young buds appear and the foliage becomes as luxuriant as ever.

Seed.—About the third year the trees begin to flower and bear heavy crops of seed, which drops on the ground when ripe and germinates readily.

Harvesting.—I have not yet arrived at any satisfactory process of extracting the rubber. I have succeeded in getting a quarter of a lb. per cooly but this will not pay. There is no doubt, that the rubber is there and the question is how to get it? Do the rubber gatherers of Brazil fell the trees before tapping them? From a tree which had been felled a fortnight or more I got two ounces of rubber in about a quarter of an hour. Passing it in the morning I knocked it about with a big stick and in the afternoon I found lumps of congealed milk where each blow had fallen and easily picked them off.

Enemies.—Pigs and porcupines are the chief enemies of the rubber tree and they are very fond of the potato-like bulbs at the end of the roots. However, they do not do much harm here and it takes a good deal to kill a rubber tree when once established.

I should very much like to know at what age it would be considered right to begin tapping and also any known process of extracting the rubber in paying quautities. I annex a table of measurements of trees from one to five years old, some are larger and some are smaller, but these figures represent a fair average of the growth on this estate.—Yours faithfully,

H. MONTAGUE PHILBY.

TABLE OF MEASUREMENTS OF RUBBER TREES.

1 Year Old.—18 feet high; 10 inches round base; 6½ inches round 6 feet from ground.

2 Years Old.—26 feet high; branched out 14 feet from ground; 22 inches round base; 14 inches round 6 feet above ground.

3 Years Old.—37 feet high; branched out 15 feet from ground; 30 inches round base; 24 inches round 6 feet from ground.

4 Years Old.—43 feet high; branched out 17 feet from ground; 42 inches round base; 25 inches round just under branches.

5 Years Old.—48 feet high; 45 inches round base; branched out 22 feet from ground; 33 inches round just under branches. H. M. P.

We are much obliged to Mr. Philby and think his trees on Cocoawatte must equal those we saw in Dumbara in size for age. As to the questions asked about Brazil and felling operations there, we shall have pleasure in sending Mr. Philby a copy of the second edition of our "Rubber Manual" now in the press, in which he will find the latest

available information from all parts of the world. Tapping and also felling and stripping are both practised in South America.

We now turn to the lowcountry of the Western Province and from Kelani Valley we have the following :—

From Manager Mahalla, Muraloya and Dambuloya. Those estates have neither acres nor trees of India-rubber. I may mention that there are two or three in Mahalla and Muraloya, but nothing is being done to them.

Pleasure Ground estate has 500 trees (? creepers) of Landolphia Kirkiei India-rubber, equal four years' growth. These are kept as show trees and are very large, the largest was somewhat destroyed in cutting thick stem for "Indian and Colonial Exhibition.' They are being kept to see if they will seed. [But why not send us measurements?—ED. C. O.]

More satisfactory is the following report of his experience at Heneratgoda and Mirigama by Mr. W. B. Lamont :—

Having reared about 100 plants of Ceara rubber up to their fifth year and having given a good deal of attention to them, I arrived through a long course of experiments at the following practical results. One half of the plants turn out useless, either from the inferior quality or small quantity of their yield; that all such trees should be eliminated as soon as their character is ascertained, and replaced by others; that no satisfactory result will follow any attempt to obtain produce before the tree is at least four years old; that no system of cutting or piercing the bark will give a satisfactory yield; that it is only in the dry season, when the tree is leafless, and the growth at a stand, that a satisfactory result can be obtained, in the way of harvesting. The plan of obtaining the rubber, that my experiments led up to, was, as soon as the leaves begin to fall, remove the outer bark in vertical strips of not more than two inches wide, and not less than four inches apart. The tender inner bark thus exposed to the sun breaks out, in something like running sores, from which the rubber slowly exudes and drips on the surface as fast as discharged. In this process, the strip of exposed bark is destroyed, but a vigorous tree working from both sides will close in on the bared part in the course of the year, if the width is not more than two inches. Ceara rubber planted at 100 trees per acre will, after the second year, require hardly any expense in cultivation, and for the harvesting I collected 30lb. last January and February, by one boy at 15 cents a day, or say, 23 cents per pound, the local value being about 80 cents. Supposing each tree equal to an average yield of one pound per annum, and allowing 30 cents for cultivation and collecting, 50 cents would remain as profit, or R50 per acre. It is well to have the plant in the island, but it is not likely to be largely planted so long as there are other products that pay better, or that are better understood, but a time may come when it will *kep a strait.*

"Fifty rupees an acre" is a return not to be despised: indeed we doubt if the average from coconuts for all cultivated plantations in the island is so good, and, therefore, there ought to be plenty of room for a systematic Ceara rubber industry in Ceylon; but what is the use of speaking of such returns as can be got here if we are to accept the statement of a Java planter (already referred to) conveyed to us by Messrs. J. P. William & Bros. as follows:—

The Editors Ceylon Observer.

Dear Sirs,—Many planters from different countries had written us from time to time enquiring as to the best mode of tapping the Ceara Rubber tree, and we are glad to place before the planting community the following letter sent us by a Ceara Rubber planter in Java, dated 30th November 1886. We shall be happy to give the name and address of the planter in question to gentlemen who may be willing to communicate with him. Newspapers please copy,—Yours obediently,

J. P. WILLIAM & BROS.
New Product Growers, Seedsmen, &c.,
7th Jan. 1887. Heneratgoda, Ceylon.

Letter referred to :—"From different papers I got the knowledge that the tapping of the Ceara Rubber tree (Manihot Glasioii) is very expensive and do not give much results. I now beg to inform you that by my manner of tapping even trees of nearly three years age by once carving, produce four till five ounces of guttah each, and this manipulation can be repeated every two days during five or six months without doing any harm to the carved tree, also supposing every tree is carved 15 days a month, about five months the production of every tree at the end of five months will be 300 ounces or 25 pounds. Besides that my manner is not expensive, and the production is of the first quality. If the different planters of the Ceara Rubber tree like to be acknowledged with my manner of tapping I am ready to go to Ceylon in order to show the manipulation if all costs of transport and staying will be paid by the planters, and a remuneration according to the number of trees of every plantation. As I do not know the planters of Ceara Rubber and their number at Ceylon I cannot apply to each of them directly, and therefore, call on your kind assistance in this affair being ready to part with you the remunerations the planters should like to give for my manner of carving and tapping the abovementioned trees. Hoping to be favoured with any answer of you."

Messrs. William Bros., had better tell their correspondent to patent his process for Ceylon and then come here and lease the Ceara rubber groves already fit for harvesting, while planting on his own account.

From the Southern Province we have two brief reports :—

Hurst-Pierpoint estate has five acres or 5,000 trees of India-rubber, equal four years old. Nothing has been done with them and no results can therefore be sent. Trees are growing on bad soil at an elevation of say 30 feet and are poor and scanty in growth.

In Udugama district Rubber cultivation has been dropped entirely. I asked some of the neighbours and no one seems to have carried on experiments since Mr. Dobree left the district, and I think he sent you the result and particulars of his experiment.

We trust the above recapitulation of the present stage of the Rubber Planting Industry in our midst will have one good effect, namely, in stirring up our planters to renewed interest in the subject, and to experiments with the trees already available.

JAVA AS A TEA COUNTRY.

Java was, and notwithstanding the very considerable ravages of leaf-disease, still is the second coffee country in the world. Before the sudden and mysterious outbreak of leaf-disease in 1869, Ceylon promised to run the great Dutch Colony rather hard for second place. As a tea country Ceylon is, already far ahead of Java, although in this enterprise, the latter had the start by a good many years. Our export of tea in the past year must have been close up to that of Java, while there can be no question that in 1887, we shall take rank as the fourth tea-producing country in the world, in the following order :—

1st China; 2nd India; 3rd Japan; 4th Ceylon; 5th Java.

From a summary of statistics of Java tea issued by Messrs. Gow, Wilson and Stanton, we observe that against our hundreds of plantations only thirty-three are shewn for all Java, a considerable proportion of which sent little or no tea into the London market. The leading estate is Mr. Kerk-

hoven's fine, model-property of Sinagar, which sent 9,526 chests and 17 boxes to London in 1886. Next comes Dramaga with 2,405 chests and 4,545 boxes. Nangoeng has opposite it 1,289 chests and 4,547 boxes, while Bagelen sent 4,711 chests and no boxes. The differences are curious. The total packages sent to London in 1886 consisted of 45,190 chests; 94 half-chests and 11,206 boxes. The contents seem to have been 3,946,000 pounds; the deliveries being 3,676,000 against 6,245,000 pounds Ceylon. The brokers seem to think that the jât of the tea grown, principally China, is responsible for the low value of Java tea, but we suspect soil, and even more than soil, manipulation must be at fault. In any case, the fact remains that, while considerable improvement in Java teas have taken place in recent years, their average price in the London market last year, was little more than two-thirds of our Ceylon average, 9¼d against 1s 1d, the figure for Java having gone down to 8¾d for the last half of the year. Whatever may be the case in Holland, and in such foreign countries as Persia, Java tea does not seem to be a favourite in England. From the circular, however, we learn, that in Ireland not merely Indian but Java tea is used, or was used to a considerable extent. The advice given to the Java planters to plant India tea has been largely anticipated, and no doubt there will be improvement in preparation and bulking, but all the evidence seems in favour of Ceylon not only keeping ahead of Java, as a tea country, but of speedily supplanting Japan as No. 3 and taking rank immediately after India. A very considerable proportion of the tea grown in China and Japan is locally consumed (although the quantity used in China has been greatly exaggerated); and we suppose some of the Java tea also is used in Java. India and Ceylon send all but fractional parts of their tea to the London market and the proportions of teas delivered in 1886 was as follows:—

China, Japan, &c. ..	142,547,000 lb.
India	68,420,000 ,,
Ceylon	6,245,000 ,,
Java	3,946,000 ,,
Total.. ..	220,880,000 lb.

We suspect that before this century is over the figures will be altered in some proportions like the following:—

India	150,000,000 lb.
China, Japan, &c. ...	75,000,000 ,,
Ceylon	50,000,000 ,,
Java	10,000,000 ,,
Total...	285,000,000 lb.

There is a very interesting coloured diagram showing the history of Java teas for the past seven years. From this we gather that Java pekoe, "tippy, with fair liquor," which began at 1s 6d and very nearly touched 1s 8d at the end of 1881, went down to 1s 4½d last year. "Pekoe medium" commencing at 1s 2d went down in 1881 below 11d; rose in 1882 to 1s 3¼d, and then, with some variations went steadily down to 9½d. "Pekoe souchong, medium to fair" was close on 1s 1d in 1880, was at 1s in 1882 and then went gradually down to 7¾d. Finally "souchong, medium to fair," commencing at 1s ended at 6½d. Except for the very highest quality the decrease has been striking, no doubt largely owing to the influence of Indian and Ceylon tea of better quality, or, at any rate, of more acceptable flavour, being obtainable at moderate prices. With special exceptions the Java teas are of poor average quality. A trial of the Australian market with those teas was such a dead failure, that we believe the experiment has never been repeated. No doubt the introduction of better jât and improved machinery will effect improvement in Java teas, but as a competitor in providing the world with tea, Ceylon seems to have little to fear from the Dutch colony. The following are the remarks of the brokers:—

Movements of Java Tea in London—in English pounds—during the past six years:—

	1881.	1882.	1883.
Imports	1,216,000	2,158,000	3,057,000
Deliveries	1,315,000	1,786,000	2,893,000
Stock	411,000	751,000	914,760
	1884.	1885.	1886.
Imports	3,586,000	3,344,000	3,946,000
Deliveries	3,709,000	3,537,000	3,676,000
Stock	875,560	676,000	944,000

Our diagram shows a marked increase in the arrivals of Java Tea in London during the second and third quarters of 1886. The above figures are interesting as showing a gradual development of the trade, the deliveries keeping pace pretty evenly with the arrivals.

The direct imports from Java to London during 1886 were the heaviest yet recorded. As large quantities have also been shipped from Java to other countries besides England, it is probable that the yield per acre during the past year shows an increase over recent seasons; it is to be hoped that growers have by this means been to some extent compensated for the low range of prices current.

The contraction in value of Java Tea, however, has not been so great as in Teas from some other places. Java Teas are consumed in so many different markets that the demand from one quarter or another will generally retard a serious and sudden decline in prices, when caused by a drop in similar grades of Teas from other countries. This cause has for some time past maintained the value of Java Pekoes at a comparatively higher range of prices than Indian growths; it has also frequently retarded,—and at a certain period checked—a decline in the value of Congous and Souchongs which might otherwise have been more pronounced.

The wide area over which Java Tea is distributed thus acts as a great and continuous safeguard.

The value of broken pekoes has been greatly interfered with by the unsettled state of affairs in Ireland, where they were at one time largely consumed, and this class of tea being taken in fewer foreign markets than whole leaf descriptions has probably suffered to as great an extent as Indian growths. Broken pekoes, however, are now becoming more used in some of the continental markets.

QUALITY.—Looking back over the past 12 months we note with some regret the poor average quality of a large proportion of the offerings; this is specially unfortunate at a time when a super-abundance of weak liquoring Teas had been arriving from other localities, and had already seriously depressed the market for the lower grades.

FUTURE PROSPECTS.—The brightest spot in the year is noticed in a few consignments which have stood out pre-eminently over the rest as being unquestionably grown from good Indian seed, and being manufactured with the greatest attention to quality, accompanied by skilled and careful manipulation. The future of the Java Tea trade must be largely influenced by the liquoring character of the Tea, and now that imports from India have so largely increased, and that there is every reason to anticipate a still greater addition to the Tea harvest in Ceylon, this matter of quality may become one of *vital* importance to proprietors of Tea Estates.

We would, therefore, again impress upon owners the advisability of planting good Indian seed, and neglecting no opportunity of utilising every appliance for efficient manufacture, and for greater economy, which the most recent scientific researches have placed within their reach.

Bulking in Java, has perhaps, shown some improvement during the past year, but still requires additional attention in many factories. The subject is of greater importance now than ever, as an additional charge has

been imposed for the performance of this operation in England.

Average Price.—The 56,490 packages of direct import sold in public auction during the year realized an average of 9¼d; the average for the 31,473 packages sold during the first six months of the year being 9¾d, and of the 25,017 packages sold during the last six months being 8¾d.

In 1885, 45,272 packages of Java Tea of direct import were printed for public auction; the equivalent in chests being 39,418. In 1886 the quantity had increased to 56,490 packages, the equivalent in chests being 48,038.

Imports and Delivering of Tea in London from 1st January to 31st December 1885 and 1886, with Stocks on 31st December in each year.

THE SENSITIVE PLANT.

The singular phenomenon exhibited by this well known exotic has long been the admiration of the curious, a puzzle to the botanist, and a standing marvel in the vegetable kingdom. The plant has the property of contracting certain parts of its structure when touched, and is not only sensible to the application of force, but appears to be influenced by the surrounding elements. Sudden degrees of heat or cold, steam from boiling water, sulpher-fumes, the odour of volatile liquids, in fact anything that affects the nerves of animals, appears also to affect the sensitive plant. It is in the highest degree a nervous subject, and, like that species of the genus *homo*, is in this country a thorough hothouse habitant. The subject of our present consideration was originally introduced from Brazil, and along with other varieties possessing the same faculty in different degrees, is common to other parts of South America. The stem of the plant is cylindrical, and of a green or purplish colour, with two spines at the base of each leaf, besides a few others scattered about the branches. The leaves are pinnatified, divided into pairs, supported on long footstalks, and each pinnule is furnished with fifteen or twenty pairs of oblong, narrow, and shining leaflets. From the base of the leaf-stalks proceed the peduncles or flower-stalks, each of which supports a bunch of very small white or fresh-coloured flowers. The seed-vessels are united in packets of twelve or fifteen each, and are edged with minute spines, each husk containing three little seeds.

Dr Hook, Dufay, Duhamel, and other naturalists, have studied this plant with equal attention, and from their observations we learn that it is difficult to touch a leaf of a healthy mimosa—under which name the sensitive plant is also known—even in the most delicate manner without causing it to close. The great nerve which passes along the centre of the leaf serves as a hinge for the sides to close upon, and this they do with great exactness, the two sides exactly opposing each other. If the pressure is made with considerable force, the opposite leaf of the same pair will be affected at the same time and moved in the same manner. Upon squeezing the leaf still harder, all the leaflets on the same side close immediately, as if resenting the affront. The effect may be even carried so far that the leaf-stalk will bend to the branch from which it issues, and the whole plant collect itself as it were into a bundle.

As soon as evening approaches, the sensitive plant begins to lower its leaves, till at length they rest upon the stem. With the morning light, they gradually re-open. When the leaves have even faded and turned yellow, the plant still continues this action, and retains its sensibility when agitated by external influences. A fine rain will not disturb the mimosa at all; but should the rain fall heavily, and be accompanied by wind, the plant becomes immediately affected. When irritated and made to close by force, the time necessary for the leaves to recover their usual position varies from ten to twenty minutes, according to the season and the hour of the day.

Though heat and cold contribute greatly towards its alternate motion, yet the plant is more sluggish in its movements and less sensitive in winter than in summer. After a branch has been separated from the shrub the leaves still retain their sensibility, and will shut on being touched. If the end of the detatched branch is kept in water, the leaves will continue to act for some time.

If the sensitive plant be plunged into cold water, the leaves will close, but will afterwards re-open; and if touched in this state, will again shut themselves, as if in the open air, but not so quickly. This experiment does not seem to injure the plant. If the extremity of a leaf exposed to the rays of the sun is burned with a lens or a match, it closes instantly; and at the same moment, not only the leaflet which is opposite to it follows its example, but all that are upon the same stalk. If a drop of sulphuric acid is placed upon a leaf so as to remain stationary, the plant is not immedittely affected; but when it begins to spread, the irritation is communicated from one leaflet to another, till the whole of them on the affected stalk are closed. Although a branch of this wonderful plant be cut through three-fourths of its diameter, yet the leaves belonging to it retain the same degree of sensibility, and open and shut with their usual freedom. The vapour of boiling water affects the leaves in the same manner as if they were burned, and for several hours they appear benumbed—in fact, seldom recovering during the remainder of the day.

These are some of the principal phenomena connected with this very singular plant. No doubt, other experiments have been made; but these will serve to show how much akin is the delicate organisation of this plant to that of the animal kingdom.

Many conjectures have been formed and many theories raised to account satisfactorily for the working of this exquisite machine; but the mainspring is still hidden, and has, as far as we know, eluded the search of the naturalist. It has been supposed by some that the mimosa is endued with a power of perception which actuates all its motions, and is the connecting link between the animal and vegetable kingdoms. But at least an equally rational theory is, that its movements are purely mechanical. To enter into a discussion as to the relative merits of these and other theories would exceed the limits of this article. We can only contemplate the plant as one of those natural wonders which add to our admiration of mother Nature and her products.—*Chambers' Journal.*

THE GOVERNMENT CINCHONA IN JAVA.

The report on the Government of Java's cinchona gardens in 1885 has been translated, and published in the January number of the *Tropical Agriculturist.* Although it has been so long delayed, it is well worth reading, and planters in this country will find that Mr. Van Romunde, the Director, has answered some questions which have been troubling them during the past year. In the matter of extensions the work done has principally consisted in replanting fields from which, as we some months ago recorded, the less valuable varieties

had been extirpated. The number of trees of all ages now existing in the various plantations is estimated at 1,567,000 as against 1,960,500 in 1883. The decrease is, we are told, more apparent than real, and is due to a careful census having been taken. It must, however, be borne in mind, that vast numbers of the trees existing in the former year have been uprooted, and that a large proportion of those that have taken their place, as yet are only a year or two old. The number of plants in the nurseries at the time of the report was 1,390,000, over a million being ledgers, and the greater part of these it was intended, to put out during the first quarter of 1886, so that a notable addition has been made ere now. Amongst them 35,000 are ledgers, grafted on succirubras. Besides these there were in the graft nurseries about the same number which would have been ready to put out at the end of last year. These grafts, which form one of the most interesting features of the Java Cinchona enterprise, have all been taken from the very richest trees known to exist, the bark of which has been analysed, and given in some cases over 13 per cent of quinine. The result of these experiments has not yet had time to fully develop itself. Two unfavorable features, are however, noticed, one being the tendency to early blossoming and seeding. We believe that the Madras Director is of opinion that this is not likely to harm the trees, but Mr. Van Romunde thinks that it "must undoubtedly have an unfavorable influence on the development of the plants." Efforts have been made to check this tendency, and by manuring and constantly turning up the soil, to force the trees to form leaves, and bring about a hardy growth. The other objection to the grafting process is that the succirubra stem appears to influence the bark of the ledger graft, and it was hoped that by selecting particularly pure trees the grafts would yield nearly as good a result as ledgers. The analyses of one of the parent trees was 10·79 of quinine out of 11·53 total alkaloids, cinchonidine being entirely absent; but a strip taken from the graft at five years old showed only 3·30 of quiuine and 1·40 of cinchonidine, this being the predominant succirubra alkaloid. Other experiments, however, show that the hardness of the succirubra stem is transmitted to the ledgers; at any rate the system will be carried on for some time longer.

The only new land that was opened was a few acres for grafted plants. The gardens appear to be worked on the best principles as understood in India and Ceylon; they are kept clean weeded, and are frequently dug over, while on the older fields deep draining has been carried out, and is found to act beneficially. Close planting has been adhered to as much as possible "not only for furthering the rapid formation of humus out of the fallen leaves, and thereby improving the soil chemically, but also to attain the maximum produce at the lowest possible up-keep. The beneficial influence of close planting for the development of cinchona is particularly noticeable on the replanted fields, where at first the growth of the plants was slow, and where it became rapid as soon as the surface became shaded by the branches and masses of leaves." This statement should be made a note of by planters in this country, amongst whom it is sometimes maintained that the wider apart cinchona is planted the better for its future prospects. In addition to the census, the growth of the trees was ascertained by actual measurements, and the average height of eight year old ledgers was found to be about 14 feet with a circumference of 10 inches; this result does not strike us as praticularly good, but we think that the year's growth in the nurseries is counted, which is not the custom elsewhere. The average height of six year old grafts is given as 12 feet 6 inches with a circumference of 10 inches. The gardens were subjected to attacks from *Helopeltis Antoni* and other insects, but the damage done was insignificant; the only remedy was to collect and destroy the pests. It was supposed at one time that the formation of alkaloids was increased by topping cinchona; but Mr. Van Romunde ascertained that this is not the case, and discontinued the practice. The yield of bark from the various plantations amounted to about half a million pounds; part was obtained by rooting out inferior varieties, but it was also found necessary to cut down a number of ledgers which had been shaved in 1884. It may be remembered by some of our readers that in reviewing an account given by Mr. Brady of his visit to Java, we mentioned that while in India it had not been found profitable to shave ledgers, the Dutch planters had been able to do so with excellent results. It would now seem that this writer's statement was erroneous, or that at least the process had not been long enough in vogue when he saw the plantations to prove its efficacy or the reverse. We now learn that the bad results of the shaving in 1884 became apparent in the second quarter of 1885 on three estates, where some 10,000 trees showed such signs of decay that they had to be rooted out. But on another of the estates, with more valuable ledgers, and where the trees had only been shaved once, the result was still more unfavorable; "the trees continued to droop for a long time, and during the long-continued rains the bark began in some few instances to rot." The prices realised for the shavings appear also to have been much inferior. In concluding his remarks under this head, the Director says "if the application of the MacIvor system, by which regular strips of bark were taken from the trees, has not in the long run answered expectations, the result of shaving off the bark have been so detrimental that its continuance is not to be depended on, so that there is nothing left for us to adopt but a systematic thinning out of the plantations, with a carefully limited lopping of the trees, and finally, complete uprooting."

The drying houses were found insufficient for the large amount of bark harvested, and enquiries were made as to how they could be improved. This is a matter that interests planters in India, and it may be mentioned that Davidson's "T" Sirocco was recommended as the most suitable machine for the purpose. We have some doubts on this subject; the largest size Sirocco costiug £90 f. o. b., in Liverpool, only takes about 400 lb. of leaf. In addition to this a building would have to be erected to hold it. The estates were worked at a profit of florins 224,187 (say rupees), but of course the harvest was unusually large owing to the uprooting which took place. No account is given of the amount of cinchona grown by private individuals, but we showed some time ago that the stories told in Ceylon of the existence of an enormous acreage under cultivation were unfounded. Mr. Van Romunde says that "the demand for waste land on lease for the purpose of cinchona cultivation continues to diminish, and little or nothing is heard of new undertakings. It is true that on existing estates the cultivation continues to be extended, but confidence in cinchona culture has felt such a shock by the steady fall in prices, that capital worth naming is not to be had for new undertakings of the kind." The Director, however, thinks that this want of confidence is not well grounded, and that there is no reason to fear that prices will cease to be remunerative. The most interesting result of the analyses made during 1885 has been noted above in connection with the question of grafting. With a view to save the cost of transport, experiments were made to obtain a coarse extract of the cinchona alkaloids. Some 6 per cent bark was selected for this purpose, and by means of boiling with lime and spirits of wine, a substance called *quinium* was produced, which was found to contain about 60 per cent. of alkaloids, with very little total loss from preparation. We have yet to learn if this will prove a commercial success. To sum up the information to be derived from this very able report we may say that it would not seem as if Indian planters need have any fear of Javan bark flooding the market in the same way as the Ceylon export has. The stamp bark from the Government estates will no doubt always command better prices than can be expected from the average run of the Indian exports, but the quantity sent is not likely to be very large, as large shipments are counted now-a-days. —*Madras Mail.*

THE JUNGLE PRODUCTS OF BORNEO.

Consul-General Leys, writing on the trade, commerce, and productions of North-West Borneo, says that the chief articles of jungle produce, in which a large export trade is carried on, are gutta-percha, india-rubber, rattans, and bird's nests. Gutta-percha is the inspissated juice of tall forest trees belonging to the natural order *Sapotaceæ*. Various kinds and qualities of gutta are afforded by various sapotaceous trees, but the pure red Bornean gutta is yielded by the species *Dichopsis gutta*. Other species of the genus *Dichopsis*, however, yield guttas, which, being of inferior quality, are frequently mixed by the native collectors with the more valuable red variety. This red variety is obtained from red and rough-stemmed trees, which are generally found growing among old jungle on hill-sides to a height of from 100 to 150 feet. The following is the method employed by the natives in collecting the raw product:—On finding a tree old enough to be cut, one having a diameter of about twelve inches, they fell it, cut off the top, and ring the bark at distances of about a foot. The sap for two or three days gradually drains away, and as it does so is collected in any convenient vessels, such as leaves, coconut-shells, &c., from which receptacles it is transferred to a pot and boiled for the space of half-an-hour with a little water. The milk is boiled to prevent it from hardening on exposure to the air, as if allowed to do so it becomes comparatively valueless. It is difficult to estimate the average yield of each tree, as the quantity varies according to the size of the tree and time of the year, the flow of sap being greatest when the tree is producing most leaves; but a small tree will generally yield a quarter of a picul,i the picul being equivalent to 133 lb. avoirdupois, while the largest may yield as much as three quarters of a picul each. The value of the red gutta varies, according to its purity, from 40 dollars to 80 dollars per picul. Another species of *Dichopsis* yields an inferior gutta of a white colour. This species has a smaller growth, attaining a height of from 50 to 60 feet, and a slightly different foliage. It yields proportionately less gutta, only about twenty-six pounds per tree. India-rubber, or caoutchouc, is obtained from three varieties of rough-stemmed woody climbers or *manungans*, which attain a length of over 100 feet, and a thickness of about eight inches. The juice is obtained in much the same way as gutta, and is prepared either by boiling like gutta, or by steeping in a solution of salt. The wasteful method of collecting guttas and rubbers has naturally caused an exhaustion of the supply from the more accessible districts; the rubber trees are not, however, so thoroughly exterminated as the gutta trees, owing to the greater tendency of the former to be reproduced from suckers, from cuttings of the stem taking root accidentally, and from the fruit which, being edible, is much sought after by monkeys, birds, wild pigs, &c. Rattans, or canes, are the stems of various species of *Calami*, which are found in profusion througout the whole of North-West Borneo. Birds' nests, well-known as the edible production of the Indian swallows, are found principally in the water-worn limestone and sandstone caves that exist in considerable numbers all over the districts of North-West Borneo. Consul-General Leys says, "although highly esteemed by the Chinese as a luxury in health, and as having curative qualities in sickness, I believe that these birds' nests have no more nutritive or medicinal value than so much wholesome isinglass, which substance they strongly resemble in every way. Many very absurd theories have been mooted as to the way in which the substance forming the nest is procured by the bird. I am strongly inclined to believe that it is formed from the saliva of the birds—an opinion founded chiefly on the fact that the saliva-producing glands are, during the nesting season, always immensly enlarged, and evidently in very unusual functional activity. When it is remembered that a viscid secretion usually found covering the inside of the mouth and the throat of birds—living as the swallow does, on small insects caught while on the wing—and that the nature of their food is peculiarly fitted to supply the substance of which the nest is chemically composed, and that the nest, though strong, is very small, thin, and light, such a theory is more probable than one would suppose." It appears from the import and export returns of Borneo for the year 1882, that the value of gutta-percha and indiarubber exported during that year amounted to £62,600, of rattans £24,500, and of birds' nests £10,000.—*Journal of the Society of Arts.*

SCIENTIFIC TEA MANUFACTURE.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

SIR,—One of those strange coincidences has occurred, by reason of which George Eliot was prompted to suggest that we might almost infer that at certain periods new thoughts float about in the world's atmosphere and are attracted by brains favourable to their reception in countries wide apart. The idea of withering tea by means of cool dry air, and of employing comparatively cool dry air for drying tea, may not be quite so novel as some interested are inclined to believe. The practical application of the idea is, however, distinctly a novelty, and all credit is due to those now attempting to introduce it to our factories. The coincidence I have referred to consists in the fact that two methods of arriving at the same end have been launched upon as at precisely the same time, one hailing from Boston, U.S.A., and the other from Glasgow. That from Boston comes to tea planters more by accident than intent; whereas that from Glasgow has been from its first conception devoted to tea manufacture before all things.

Mr. Jennings of Boston having found that the "hot-air methods and the drying kiln have been tried and given up as failures," that they "warped timber, made the grain of leather harsh and rough, spoiled the flavour of tea (!) and the colour of coffee, turned rice yellow, and failed to save the farmers' grain" in wet seasons, determined to discover a process which should meet the requirements of dryers of all such substances. He found the solution of his problem in a "Cool Dry-air Process." The name completely explains the principle of his system.

Mr. Jennings places the materials to be dried in a chamber, through which a current of moderately warm *dry* air is passed continuously, and he claims that "the test of experience shows that air so deprived of moisture acts as an absorbent in a manner that, without such a test, would have been deemed impossible." In the first instance, the current is drawn through a small furnace, in which it is heated to about 600 degrees Fahr. At this temperature the atmosphere is said to be without trace of vapour. This, I think, must depend upon whether the air has been passed through a sufficient body of live fire to ensure decomposition of the moisture, and upon this point I have no information at present as regards Mr. Jennings's system. After being heated, the desiccated air "is cooled by a vigorous circulation of external air," which lowers the temperature to between 80 degrees and 90 degrees, and in this condition the desiccated air is propelled by fans, driven by steam, through the drying chambers. Within these chambers the temperature is that of a hot summer's day, but the air is said to be so "greedy" of moisture that everything within its penetrative influence is desiccated. I must assume, as I do not know for a fact, that the "vigorous circulation of external air" is applied without its being allowed to mix or come into absolute contact with the heated air, otherwise the latter would naturally again commence absorbing moisture from the external air, and thus entail a waste. A machine erected on this principle is working at Messrs. Smith's extensive saw-mills, Commercial Road, Pimlico, and there the practical operation of the system has shown some results which are, if as reported, equally remarkable from a scientific as from a commercial point of view. I have seen it stated that at these saw-mills a package of wool 1 lb. in weight was saturated with water; it then weighed 3½ lb., and in this condition was placed in the dryingroom, and in twenty minutes the moisture was found to be almost wholly extracted. Timber, as everybody knows, takes

years to season, and it has a perfectly surprising power of absorbing and retaining moisture. Thus 44 cwt. 2qr. of birch were subjected to the test for ninety-four hours, and then examined, when it was found to be completely "seasoned, free from checking, rents, or warping, and it had given off in the operation 10 cwt. 2 qr. 24 lb. weight of water!" Wool so treated, even tested by the microscope, "shows no evidence of any change beyond the dryness of its substance, and this appears uniform throughout," "the fibre and cells seem to be unchanged; they are as close, but no closer, than before, and there is no perceptible shrinkage of dimension. Some lengths of ash gave still more striking results. Out of 47 cwt. 3 qr. no less than 21 cwt. 1 qr. of moisture was extracted; 22 cwt. of mahogany yielded 6 cwt. of moisture in ninty-six hours, whereas to obtain the same result by ordinary exposure would have taken years to accomplish. British oak is a very stubborn wood to season. Some logs, two inches thick, were finished in nine days, which by natural drying would have required three or four years. These effects were accomplished with a current of 6,200 cubic feet per minute; and the great lesson they teach is that all the mischiefs hitherto produced by drying systems accrued from the excessive heat. In this process the temperature never exceeds blood heat; and as a consequence, delicate fibres, fabrics and chemicals are uninjured. The industrial value of this important discovery can scarcely be over-estimated. A technical journal computes that in the matter of Indian tea alone cool-air drying would probably give it such an advantage as to increase its saleable value £200,000 a year." (!) So much for Mr. Jennings's process.

Coming now to the Glasgow one, introduced by Messrs. Main and Dick, the former of the well-known firm of A. and J. Main and Co., I cannot ask you for space in this, and the further communication I propose to send you next week, to do more than compare its *principles* with those of Mr. Jennings's system, leaving a description of the application of the principles to a future occasion. Mr. Main, your readers will remember, visited India during the Calcutta Exhibition, and during his visit travelled considerably among the Tea Gardens, with a view to obtaining a practical insight into the class of iron houses most suited to the wants af Planters, and also to inspect the various appliances used in tea manufacture, in the hope of being able to improve upon one or other of these. By conversation with planters he soon learned that in the matter of withering wet leaf in bad weather there was a field practically untouched by inventors. He claims now to have succeeded in the efforts he has been strenuously making since his return to provide the long-looked for withering appliance, and, whilst engaged upon his research in this direction, to have done even more than he had orginally sought to do, inasmuch as a modification of the principle he has adopted for withering, assisted by means of a different appliance and different temperature, has shown him that he can not only wither but "dry" tea also. From start to finish Mr. Main has consulted eminent chemists and practical planters, and has spared no pains or expense in prosecuting his experiments, which have been conducted over two years. His process is based upon thoroughly scientific grounds, and worked out on scientific principles, with every regard for obtainable scientific data; and it is indeed remarkable how identical the resulting principle is with that of Mr. Jennings, although it it true the method of desiccation varies. The point of difference may be briefly stated as follows:—Mr. Jennings desiccates his air by means of heat and then cools his air again; Mr. Main desiccates his air by means of an almost everlasting absorbant, and saves both the cooling process and certain other disadvantages.

In considering this matter of rapid and effectual withering and drying, it is as well to seek the fundamental principles. To solve the problem, Mr. Jennings and Mr. Main, if asked, would probably both refer us to *desiccated air*, but when asked how best to obtain desiccated air with which to conjure, Mr. Jennings would probably reply, by means of superheating it—I have not asked him—and Mr. Main would answer, by means of an absorbent—I have asked him and eangive his reasons. Possibly Mr. Jennings might be converted to Mr. Main's opinion were the latter's arguments brought to his attention; but that is surmise. Knowing Mr. Main, and being already acquainted with his interest in this subject, in my search after "more light," I brought Mr. Jenning's process to his notice, and it will afford some insight into the thorough and extremely careful manner in which he has conducted his labours if I give the gist of some of his comments upon Mr. Jenning's process as compared with his own. He forwarded me the subjoined table which shows the amount of moisture or water-vapour in the air, per 1,000 cubic feet, at the point of saturation, at various temperatures, and he tells me that from such facts as these he was led to wonder, how a delicate substance like tea, could ever be quickly or effectively dried during the rainy season, with so much moisture in the air. Finally he came to the conclusion that the whole of the difficulties of the process lay in the presence of the excessive moisture in the air—a fact already too well known to planters—and he then felt sure that the reason why so many failures had occurred in machines constructed for drying tea, lay in the fact that moist air—hot though it undeniably was—was used. As soon as he experimented with desiccated air, astounding results were obtained. In drying (not withering) he found that when employing desiccated air a large reduction in the temperature showed more effective results as regards the time occupied, than a high temperature showed when undesiccated air was used. Thus at a temperature of 200 degree Fahr. rolled leaf was perfectly dried in fifteen minutes! To practical planters it is unnecessary for me to draw any comparison from this. Mr. Main rightly refuses to express any opinion upon the quality of tea produced at a low temperature, as he is most careful in testing every detail before committing himself to any statement as to its value; and, as he says, the question of quality cannot be properly settled exeept by actual experiment with tea-leaf, which cannot be effected in this country. At the same time, if there be anything in the views I have previously expressed in your columns, I, for one, look forward to improved tea being produced, when rapid firing at low temperatures is introduced.

Having taken up so much of your space this week I will, with your permission, continue my remarks upon the *principles* of the new process next week.—
I am, &c.,
ARTEMUS.

PLANTING IN PERAK.

The great backbone of revenue and prosperity of the State has been tin, and this metal will probably continue for some years to be the chief attraction. Chinese have had almost a monopoly of this mining until a year or two ago, when one or two Europeans and European Oempanies came into the field. Generally speaking, as is commonly known, these companies have not been a success. They too frequently started with millstones, in the shape of large quantities of very expensive machinery, and European managers, assistants, engineers, &c., at salaries which only an El Dorado could pay, and still have something for a dividend. That money can be made at tin mining, and by Europeans, I feel convinced. The Chinaman has, of course, a great advantage in his store account, for he supplies everything to his coolies at an enormous profit to himself. Cases occur every month where a Chinaman is an apparent loser by working the tin, and his books will probably show a loss of $5,000 to $10,000 on a six months' working. In reality, however, he is a gainer probably to that extent, his store account having covered any deficiency, and likewise left him with a profit. Europeans cannot, of course, go into this system, but if they would be a little more ready to profit by the Chinaman's experience in actual mining I am convinced that much useful information could be gleaned; and most of these Chinese are ready at all times to give the intelligence. The idea seems to be to make a grand start; if they would be content with small beginnings and proceed slowly, only getting expensive machinery where such is shown to be an undoubted economy, I think there is money to be made. At present, this may be termed the only money-making concern in the country, but there is also rich agricultural land in many parts, the district for instance round Kwala Kangsa being of rich soil and suitable for the growth of many products. Arabian coffee and tea (Assam hybrid) are doing well on estates in both Perak and Sunghie Ujong, though at present the extent is not very great. Liberian coffee is also doing well in low countries. Sugar likewise, on the Shanghai Company's Gula estate on the banks of the Korean River, is doing well. About seven hundred acres are now under cultivation, and more is being got into order.—*London and China Express.*

PRODUCTION OF ALFA IN ALGERIA.

Consul General Playfair, in his last report issued at the commencement of the year, on the commerce and agriculture of Algeria, says that alfa is of great and increasing importance, both to Algeria and England, where nearly the whole of the exports are consigned, and he gives the following account of the plant taken from the report of a commission recently sent to the high plateaux by the Governor-General, to study the subject in the great upland plains where alone it is found. Alfa or halfa is a plant which is found in calcareous soil or silicious clay, but not in compact clay or pure sand, unless, at a short depth below them, silicious clay is found, or soil unimpregnated with sea salt. In the high plateaux of the south of Oran it is found in calcareous soil of the formation *cretacee superieure* (compact calcareous rock, in horizontal bands, the decomposition of which produces stones and finely powdered earth coloured dark red by the oxide of iron), and in sand mixed with clay or quaternary alluvium. The thin circular and shallow roots of the plant require air and a little moisture, thus the alfa is never found in the white sand near the *Chotts*, nor in the depressions of compact soil scattered about the high plateaux. The surface of the high plateaux in Oran may be compared to a carpet, the ground of which is alfa, picked out with innumerable ramifications of *sennara* and *artemisia*. The tuft of alfa presents at its base the appearance of a central axis around which at a short distance proceed horizontal ramifications. These spring up vertically and produce bunches of flowers, sheathed in narrow falling leaves. After the first year's growth, each ramification sends out from its base a shoot, which decends into the ground, producing a small root; other ramifications are then produced at the base of previous ones, and become rooted in their turn. The tuft thus increases from the centre to circumference, each addition being united to the central mass, but forming gradually its own root, so as to be able to live when the central part dies and disappears. It is only in the third year from the sprouting of the ramification that the flower appears to be developed. If the plant is allowed to grow unchecked, its flowers and leaves vegetate during the spring, they ripen in summer, and they commence to decompose from the points downwards, under the action of the autumnal rains, fading progressively during the winter. In proportion as the sap of spring developes new leaves, those of the previous year fall over inert and partly dried up without ceasing to adhere to the stem on which they continue to decompose during the following years. After several years the dead leaves form a thick central mass, impenetrable to the shoots at their base, and around this mass the new leaves pierce through, and the small roots continue to develop outside the circle. Alfa grows abundantly in Algeria, and a large population, both of Spaniards and Arabs, is engaged in collecting it. The workman generally twists round his hand, or round a small stick, the upper part of the leaves, which he tears out by a sudden jerk, and puts under his left arm, and this he continues to do until he has made a small sheaf which he ties up. A number of these small sheaves are made into a larger one, and these are placed upright to dry. To preserve this plant as much as possible, an ordinance of the Governor-General was published on the 13th March, 1884, prohibiting the collecting of it during a close period of about four months every year, varying according to the climatic conditions of the district where it occurs. A large quantity of the best alfa is exported to Spain, where it is mixed with the esparto grass of the country; the ordinary quality is almost all sent to England for the manufacture of paper. Of late the exportation has greatly diminished, owing partly to the competition in Spain, Morocco, and Tunis, but partly to its excessive price and the introduction of wood pulp in the paper trade. The extent over which the alfa is found in Algeria is about 4,441,000 acres, and it is estimated that upwards of 16,000,000 cwt. were collected during the year 1883.—*Journal of the Society of Arts.*

JAPANESE LABOUR IN THE SANDWICH ISLANDS.

The Planters of Hawaii are not unanimous as to the value of Japanese labour. Some appraise it very highly; others place it below that of Portuguese or Chinese. From the report presented at the Planters' Labour and Supply Association, we learn that on a majority of the estates where they were employed the Japanese had given satisfaction, though in a few cases their labour was rated very low. This is perhaps as much as could have been expected. It has been already pointed out in these coloumns that the Japanese who went to the Sandwich Islands were a very mixed lot. The first batch consisted of ex-soldiers, vagrants, needy fishermen, and, in general, persons not at all likely to settle down to steady work. Curiously enough fishermen, though capable of enduring hardship and toil of the severest description, frequently fail where persistent effort is required. Trained to a life of fitful exertion with intervals of almost absolute indolence, they find great difficulty in reconciling themselves to the monotony of unvaried labour. Even fishermen, however, would have answered the purpose of the Hawaiian planters better than ex-soldiers and vagrants who emigrated under the delusion that their sojourn in the sugar islands was to be a long spell of sun-basking, relieved by the business of eating and sleeping. It might have been foreseen that men of this class would not prove a success. But the task of selection,

difficult and invidious enough under any circumstances, was, we believe, complicated at the outset by unavoidable obstructions. The emigrants chosen later on were adapted to the duties awaiting them, and have given universal satisfaction. Accordingly we find that at the last annual meeting of the Planters' Labour and supply Association, the following resolution was adopted:—"That we heartily approve the acts of our Government and what they have accomplished since our last annual meeting in bringing and permitting labourers to come to these Islands, and that we urge upon our Government, by this resolution and otherwise, that they put forth like exertions for supplying labourers during the coming twelve months, not only in bringing in Portuguese and Japanese as heretofore, but permit the influx of free labour from all countries so far as it can be done without injury to other national interests." So far as the Japanese are concerned, despite the resolute attempts made some months ago to scare intending emigrants by fabricated or grossly exaggerated pictures of the hardships and cruelties their predecessors had undergone, we learn that when a notice inviting applications was recently issued in the prefectures of Yamaguchi and Hiroshima, no less than 1,400 applicants presented themselves during the course of the first two days. Nor is this to be wondered at. For certainly from a financial point of view, the record of the emigrants is well calculated to tempt their countrymen. The total number now in Hawaii is 1,780, of whom 845 arrived at the plantations on March 1st of this year, and 935 on August 1st. The savings of these people up to November 1st had exceeded $50,000, being an average of about $8·62 each per month, and this after paying for food, clothes, and other necessaries. They are apparently quite contented with their lot, and the nature of the letters they send to their friends in Japan may be gathered from the eagerness shown to follow their example. We learn that another batch will be sent to Hawai by the "City of Peking," on Janury 28th, and that it will consist of 650 men and 275 women. They will be accompanied by nine Japanese inspectors and interpreters, and by seven Japanese physicians, all of whom have been selected by Dr. Nagayo Sensai, Chief Director of the Sanitary Bureau. The salaries of the inspectors and interpreters vary from $150 to $33 per month, and the physicians will receive $108. These officials will also be furnished not only with passages to Honolulu, but also with return passages after three years. The Inspectors, who will be Hawaiian Government officials, are to be under the direction of Mr. Nahayama Jogô, who will be in direct communication with the Hawaiian Minister of the interior. The interpreters will also act officially in the Hawaiian courts in all cases where Japanese are concerned. —*Japan Weekly Mail.*

SERICULTURE IN INDIA.

At Calcutta, on the 18th December, there was a large gathering of ladies and gentlemen at the Dalhousie Institute, they having been invited by the Honorary Secretary to see a splendid collection of insects made by Mr. Mowis in Sikkim. The cases containing the collection had been laid out in the institute, and almost formed an exhibition of themselves, though they are intended for the Indo-Colonial Exhibition in London. Every class of insects was represented, and the gorgeous colours of some of the butterflies and beetles baffle description. Shortly after 9 o'clock, the Honorary Secretary introduced Mr. Mowis to the audience, and the lecture which followed was listened to with the utmost attention. Free from all technicalities and abounding in amusing stories out of the history of insect life, Mr. Mowis's comparisons of the different powers and faculties only to be met with in insects, made up a concise and able disquisition that kept his audience thoroughly interested. In addition to its interest as a lecture, there were facts made known of real importance and great practical value. We quote the part relating to silk and sericulture of India, and only wish we could give it *in extenso*. Describing the three great silk-producing families of moths, the lecturer said that, the first family contained all those cultivated and domesticated by men: secondly, those that are left to themselves to weave their silk in the jungle, and are called wild silk-worms; and thirdly, those silk-worms which spin a cocoon, but have no commercial value at present. In former years, he said, India had a very large silk industry, but owing to prevailing diseases of the silk-worms and years of drought, it is now scarcely one-hundredth part of what it once was. Government had made many efforts to revive it, and tried hard and incurred heavy expense to give a new impulse to this industry, but though land and labour is cheaper here than in any other part of the world, the lecturer was doubtful whether the mulberry silk will ever regain its former footing in India. It takes, we learn, three years to make a plantation fit to feed the worms to make good marketable silk, so that it is impossible to attempt any large scheme; but as the lecturer remarked, if we are unable to obtain the best silk except at a loss, get the next best that pays—and pays well. Therefore every encouragement should be given to the tusser industry in this country. Mr. Thomas Wardle has just reached this country, having been sent out by the Home Government to investigate our silk industries. He was the British delegate at the late Paris Exhibition, and has demonstrated the fact that tusser silk can now be reeled and spun, bleached, and dyed, in splendid colours, and be used in almost any material where formerly the best silks only were employed. A demand has, therefore, sprung up where there is at present but a limited supply. The tusser cocoons are found in every part of India, and the worms feed on almost every plant. They are very hardy, and little liable to disease, and if Government would only take the matter earnestly in hand, we should have a most extensive industry in the space of a very few years. This new industry would almost equal the waning cotton one, and prove much more remunerative, while giving employment to thousands of the poorer classes to whom this work would be particularly well suited, thus adding already to our revenues. Lakhs of rupees' worth of these cocoons are shipped home every year, taking up great space on board ship. These cocoons have to be reeled at home on spindles which cost £75 each, and by labourers who demand 20*s.* a week. The same result could be obtained here with labour at 5 rupees per month. The great drawback in all native-reeled silk has always been the unevenness and lumpiness of the thread, but with very little trouble, an improved reel could be introduced here, which would give all the desired evenness. The lecturer exhibited a model reel, which has been constructed by him, and which combined to a certain extent both the European and native methods, and still remained simple enough to suit unskilled labour. The cost of this reel is so low as to be within the reach of the poorest coolie of the country, and by a general adoption of such a reel or a similar one, Indian-reeled tusser silks could be laid down in the European markets at about 10*s.* per pound, and thus give 100 per cent profit on the outlay! In explaining this reel, it was shown that it reeled evenly, and distributed the silk regularly on the real, from which it can be removed by a very simple contrivance, without distributing the layers of the silk, which is very essential. It could be worked by hand or foot, and also be adapted to machinery; and any child could learn to work it in a short time. A case of sample silk was exhibited, which had been reeled on this model, and a small quantity was also reeled before the audience in the lecture hall.—*Statesman.*

PLANT-BEDS.

It is usual at this period of the year for planters of tobacco to be contemplating their arrangements for a supply of plants for the next crop. These arrangements must be concluded on, and the actual work done, between the 15th December and the 15th March. About a year ago we asked the attention of the readers of the *Planter* to the old and new

methods of managing plant-beds. The old method involved the burning of large surfaces of forest land at a heavy cost of labor and firewood, and then leaving the surfaces exposed to the ravages of the flies, which destroy the young plants. Every Spring since the settlement of America the cry, to a greater or less extent, comes up from the planter that his plants are seriously injured by the fly; and in our experience we have known the planting of crops to be entirely abandoned from this cause.

Thinking farmers have put their heads to work on this matter, and in the past four or five years they have one after another tried the plan of covering the beds with cloth, and always with success when the work was properly done. The methods pursued by different persons were, of course, in many cases different and more or less thoroughly executed. In this matter, as in all practical operations of the farm, careful execution always pays the best. The most usual method in the new plan is to *burn in the woods* about one-fourth of the surface what would be required if the beds are left uncovered, and to cover with thin and cheap cotton cloth. The bed is frequently square, or nearly so, and necessarily the cloth will *sag* in the centre unless supported in some way. It is also inconvenient for the cloth to be removed in mild weather to admit air, and moisture from dews and rains; and more than all, if not saturated with oil, or otherwise gummed over, to render it valueless for under-clothing, the first passing rogue will appropriate it. It is best, however, to use the cloth covering and take all such risks.

We wish now to suggest to our readers a plan which will save *burning* the bed, and also make the covering with cloth more convenient and efficient. Select a spot of naturally drained land—that is, a porous subsoil through which water will pass—and as near to your stables as possible, with a south or south-eastern exposure; dig a trench one foot deep, eight feet wide, and as long as may be needed, by one or more beds, to hold one-third more plants than will be required. This work should be done in a good spell of weather in January, or early in February. After the trench is dug, fill it with *fresh stable* manure to the depth of a foot after it is firmly tramped down. The haul from the forest fresh mold sufficient to cover the manure six inches, or even eight inches, deep. Rake out all roots, sticks, leaves and other coarse matter. Boards a foot in width are then placed edgewise all around the pit, supported on the inside with pegs driven into the ground, and the earth on the outside is then banked up to the top of the boards. The bed may be left open until the weather gets cold, or frosty, but before the job is completed eight-penny nails should be driven two feet apart near the top edge of the planks, and their heads left projecting about half the length of the nail, and to these are to be tied the strings which are to be attached to the cloth covering of the bed at distances on its edges corresponding with the nails. The knots in the tying should be such as can be easily unloosened when it is necessary to do so, for air or moisture to the plants. Care should be taken that the twine used for attaching the cover to the frame is well sewed on with a lap of several inches to prevent a tearing of the cloth, which would be the case if the fastening was confined to one point.

In a week or two after the bed has been completed, some of the grass seeds which may be in the mold which covers it will vegetate, and then the bed should be hand-raked to destroy this grass; a week or ten days later other seeds may vegetate, when another raking is necessary; and possibly then all seeds have felt the influence of the warmth generated by the underlying stable manure, and the tobacco seed may then be sown. Care is to be taken that the plants are not too much forced, and with this view air is to be admitted freely when necessary. If a bed so constructed does not get the required moisture from rain, it will be seen how convenient it is to water it, passing along the sides with a fine-nozzle watering-pot. If the plants should need any cleansing of spires of grass, it can be handily done from the sides without stepping on the bed; and so, when the plants are to be drawn, there is no occasion to place the foot on the bed and damage by bruising. As a substitute for the ashes which the plants get by the common method of burning, save up from house fires, dry, hard-wood ashes, and give the bed a liberal dressing, to be thoroughly raked in before the tobacco seed are sown, and the ashes will supply all the potash needed for the plants. After the plants are up they may be lightly dusted by the sweepings from the floor of the barn in which the previous crop was handled, and these dustings may be increased with the growth of the plants.

In this issue of the *Planter* will be seen an advertisement of the *U. S. Water-Proofing Fibre Company*, who claim to have the best material for covering tobacco and vegetable beds; and we see it recommended by our friend, Maj. Ragland, of Halifax, who is good authority with the tobacco planters of Virginia, and it is also much approved of by other planters of Virginia, North Carolina, and all the states where tobacco is grown.—*Southern Planter.*

THE ORGANIC ELEMENTS OF PLANTS: THE SOURCES OF CARBON.

By B. Puryear, ll.d., Professor of Chemistry in Richmond College.

All plants when perfectly deprived of moisture contain of Carbon about 50 per cent.

Oxygen	„	36	„
Hydrogen	„	6	„
Nitrogen	„	3	„
		95	

The remaining 5 per cent consists of ash (the inorganic part), which comes exclusively from the soil, and returns to the soil upon the decomposition of the plant. The amount of inorganic matter in plants is frequently less than 5 per cent, and as often more. We simply give 5 per cent as an average statement.

As the atmosphere is the primary source of all the organic elements of plants, it will be well, in considering the forms in which plants obtain their organic elements, to notice the composition of the atmosphere. 100 volumes of air contain

79·16	Nitrogen
20·80	Oxygen
·04	Carbonic Acid.
100	

The foregoing table is valuable, showing, at a glance, the relative volumes of the three gases which as a mechanical mixture constitute the atmosphere. There are always present in the atmosphere, however, in small and variable proportions, other gaseous substances, to which attention will be invited hereafter; but, for the present, it will be best to limit our attention to the three gases already mentioned, namely, nitrogen, oxygen, and carbonic acid, which exist in the atmosphere everywhere in the proportions given.

In what form and from what sources do plants obtain their carbon? Evidently, they do not get their carbon in the form of carbon. As an element, carbon does not exist in the atmosphere; and, for a reason as obvious, it cannot come as an element from the soil. Carbon is absolutely insoluble in water, and hence it cannot get into the circulation of the plant in a state of solution. Solids get into plants, but not as solids. The capillary tubes of plants are too small to allow the passage of any solid, however small. When a solid is dissolved it is no longer a solid; it is as liquid as the water, or other liquid, which has dissolved it. Potash, soda, lime, silica, all solids, are found in the ash of plants: they enter, however, not in the form of solids, but when, and only when, they have been dissolved by the water of the soil. Carbon, being entirely insoluble, cannot enter in this way. We are safe then in the conclusion that plants do not obtain their carbon, *as carbon*, either from the atmosphere or from the soil.

Dr. Priestley, the great discoverer of oxygen gas, afterwards made the equally important discovery that the leaves of plants have the power, under the influence of sunlight, of absorbing carbonic acid by their under surfaces, holding the carbon in the formation of vegetable compounds, and emitting from the upper surfaces the oxygen gas set free by the decomposition of the carbonic acid. The demonstration is so simple that anybody can repeat it. No cumbrous and complicated apparatus is required. A bell glass or candy jar and a bucket of water is all the apparatus needed for the splendid demonstration. We have our bell glass full of water, the rim dipping an inch or so beneath the surface of the water in the bucket. A blade of rapidly growing corn is bent over, and inserted into the bell glass. At once, bubbles of gas collect on the upper surface of the blade and rise through the water, displacing the water and driving it down into the bucket. In this way, we may collect, in a few minutes, enough of the gas for experiment. The gas is oxygen, for an extinguished taper containing the slightest spark, when introduced into the gas, flares up immediately. Now what has happened? To make the explanation perfectly clear, two preliminary explanations are required. (1.) Carbonic acid is a compound of carbon and oxygen, in the proportion of one atom of carbon to two atoms of oxygen. Hence it is written CO_2. (2.) Water, under ordinary pressure, absorbs its own volume of carbonic acid, so that all water contains this gas.

Under the influence of solar light, the under surface of the leaves have sucked in or absorbed the carbonic acid present in the water, the carbon has been held to form the vegetable skeleton, and the oxygen evolved from the upper leaf surfaces. And as carbonic acid contains its own volume of oxygen, the volume of oxygen evolved from the upper leaf surfaces is equal to the volume of carbonic acid absorbed by the under leaf surfaces.

We may vary the experiment as following:—Let us have a trough of water furnished with a shelf. On this shelf we place a pot containing a vigorous geranium. Let down a bell glass over the geranium pot, so that the water will be a little above the mouth of the bell glass. The air is confined. Water prevents the access of the outer air. Place the whole arrangement in the sunlight. In an hour or so, the air of the bell glass is found to be utterly destitute of carbonic acid.

There can be no mistake. Nothing is more easily detected in the atmosphere than carbonic acid (CO_2.) When lime water is exposed in an atmosphere containing carbonic acid, immediately a thin crust, resembling ice, begins to be formed on the surface of the water. This film or crust is carbonate of lime, formed by the combination of carbonic acid with lime. If touched with any acid it will effervesce, the effervescence being due to the liberation of carbonic acid.

The leaves of plants then suck in carbonic acid, decompose it, fixing the solid carbon in building up its compounds and evolving the oxygen gas. Now, the great proximate compounds of plants, as starch, sugar, gum, woody fibre, are simply carbon combined with the elements of water. All of them may be easily resolved into carbon and water. We are now prepared to understand how simply they are formed in the vegetable economy. They are all formed by the union of carbon, set free in the decomposition of carbonic acid, with the elements of water introduced from the earth by the roots of growing plants.

We consider then the carbonic acid of the atmosphere the primary source of all the carbon of plants. Plants sometimes grow under circumstances which utterly exclude any other source of supply.

If we plant a grain of wheat—the experiment has been tried—in pulverized silica, and keep it properly moistened with rain water, it will swell and sprout and germinate. A true stalk is formed, which grows enough to contain three times as much carbon as the planted grain. Whence this excess of carbon? Evidently and necessarily the carbonic acid of the atmosphere, for there was no carbon in any form in the artificial soil which grew the plant. We witness the same thing, on a larger scale, when clay, containing no carbon in any form, is dug up from great depths, and exposed to the atmosphere. Seeds are dropped upon the clay; they germinate and grow to a greater or less extent. The carbon obtained by vegetation growing under such circumstances must come exclusively from the atmosphere, for the soil contains none.

Let us consider how plants grow upon a purely mineral foundation. Consider an acre of granite. Granite is composed of three minerals: quartz, feldspar, and mica, and none of these minerals contain carbon. Seeds dropped by birds or wafted by the winds are deposited upon this acre of granite. Under the necessary conditions of warmth, moisture, and access of air they germinate, and develop into scant and stinted vegetation, which contains, say, three times as much carbon as the seeds which produced it. The atmosphere by its carbonic acid necessarily furnished the whole of this excess of carbon. But the vegetation of the second year will be more vigorous and heavy for two reasons. First, the roots have penetrated somewhat into the hard granite in search of food, and to a small extent have comminuted it, and this comminution will be still greater from the freezes of the coming winter. As the roots decay, water will fill up the little channels they made in the rock, and in freezing will expand and so split and peel off the surface of the granite. The vegetation of the first year will be mixed with this reduced and disintegrated granite, and now the process of soil formation begins. The crop of the second year will be more vigorous, having the advantage of pulverized mineral matter, from which it will more easily and abundantly obtain its mineral constituents, and the advantage also of rotting vegetation, which yields carbonic acid, to say nothing of the other products of its decomposition. Carbonic acid being freely absorbable by water is carried by the sap, as it ascends to the leaf where it is decomposed under the influence of sunlight, just the same as if it had been observed directly by the under surfaces of the leaf. The crop therefore gets a part of its carbon in the form of carbonic acid directly from the atmosphere by the agency of its leaves, and the remainder in the same form from the soil by the agency of the roots. But it is obvious that the carbon obtained by the second crop from the soil was obtained by the first crop from the atmosphere, so that the primary and original source of all the carbon of the plants is the atmosphere. By exact parity of reasoning we will be able, even when a century has elapsed, and a true soil has been formed on the underlying granite, to trace back all the carbon of each succeeding crop to the carbonic acid of the atmosphere as its primary source, though with each successive year, the amount obtained from the soil has been increasing, from the admixture with it of the dead vegetation of preceding years. Our conclusion then is that plants, as they grow under ordinary circumstances, obtain their carbon partly from the atmosphere and partly from the soil, but that the carbonic acid of the atmosphere is the primary and original source of supply.

The exhaustive experiments of Boussingault, conducted through a series of seven years, show that plants, as they ordinarily grow obtain $\frac{2}{3}$ of their carbon directly from the atmosphere, and $\frac{1}{3}$ from the soil. This experiment, perhaps unsuited for our pages is very simple, is easily understood, and irresistibly carries the foregoing conclusion.

If it be objected that the amount of carbonic acid in the atmosphere seems too small to furnish to all plants growing on the globe $\frac{2}{3}$ of their carbon, the objection will vanish as soon as we calculate the absolute weight of the carbonic acid of the entire atmosphere. The amount of carbonic acid in the atmosphere is exceedingly small; the amount of carbonic acid in the atmosphere is enormously large. A word explains the seeming contradiction; relatively small, absolutely large.

One hundred gallons of air contain 4-100 of a gallon of carbonic acid. One gallon of air then contains 1-2500 of a gallon of carbonic acid. But as carbonic acid is one and a half times as heavy as air, we

find the relative amount by weight of carbonic acid in the atmosphere by multiplying 1·2500 by 3·2 which gives three five-thousandths. We can now easily calculate the amount of carbonic acid in the atmosphere over an acre of land. An acre contains 6,272,640 square inches, and the weight of the atmosphere on a square inch is 15 lb. The product of 6,272,640 by 15 is 94,089,600, which expresses the weight in pounds of the atmosphere over an acre, and three five-thousandths of this product is 56,453 pounds or 28 tons, and this expresses the weight of the carbonic acid in the atmosphere resting upon an acre. But three-elevenths of the weight of carbonic acid is carbon, and three-elevenths of 27 tons is seven and seven-elevenths tons, the amount of carbon in the form of carbonic acid in the atmosphere of an acre's surface.

Now, the yield of an acre in dry vegetable matter may be put down at one and one-half tons, half of which (three-fourths of a ton) is carbon. An acre then demands per annum three-fourths of a ton of carbon and two-thirds of this, or one-half ton, must come from the atmosphere. The amount of carbon in the form of carbonic acid in the atmosphere of an acre is seven and seven-elevenths, say seven and one-half tons; the demand upon the atmosphere of an acre in vigorous vegetation is one-half ton. The supply is fifteen times the demand; and this would be the relative supply and demand if every acre of the earth's surface supported vegetation. But three-fourths of the earth's surface, and more, is covered with water, and vast areas are barren sands and burning deserts. Perhaps we shall not be very far from the truth, if we say that only one-hundredth part of the earth's surface supports vegetation. If this be so, then the supply of carbon is 1,500 times the annual demand.—*American Farmer.*

The British colonies include the richest and largest forests in the World, extending over millions of square acres. In India alone about 60,000 square miles are afforested, and the forests of Canada, Australia, New Zealand, and Cape Colony are second to none in size and the variety and value of their productions. The acreage under timber in France, Germany, and Great Britain is small and constantly decreasing. Of the 20,000,000 square acres of Scotland only about 700,000 to 800,000 acres are woodland.—*Journal of Horticulture.*

A Dressing for Peach and Nectarine Trees.—I have used the following composition for many years: it destroys all insects, mildew, and disease, &c., without injury to the birds in any way :—2 lb. of tobacco-powder, 1 lb. of flowers of sulpher, 1 oz. of nux vomica powder, 2 lb. of clay, ½ lb. of soft soap, with sufficient boiling water to make it the thickness of paint; well mix and stir up before using, then paint the Vines and trees all over.—Wm. Smythe, Basing Park, Alton, Hants.—*Gardeners' Chronicle.*

Wine-growing in Italy.—Italy, with an area of 296,322 square kilometres, and a population of 27½ millions, has 1,879,109 hectares (4,641,400acres) of vineyards, which produce annually 27,108,574 hectolitres (596,344,628 gallons) of wine, which, calculated at an average price of 25 lire per hectolitre (nearly 11 l. per gallon), would amount in value to 677,664,350 lire, or £27,106,574 sterling. In Europe, Italy ranks third in importance as a winegrowing country, following immediately after France and Spain.—*Journal of the Society of Arts.*

Cultivation of Flax in Russia.—The *Central Blatt fur Textile Industrie* reports that the complaints of the inferior quality and defective yield of Russian flax within the last few years, have led buyers in other countries to represent to their various Governments the advisability of stimulating domestic flax culture by means of subsidies. The sale of Russian flax has been to some extent prejudiced in foreign countries by the importations of Indian and Italian flax. Efforts are now being made, however, in Russia to place this important branch of national industry upon a better footing, by organised measures for promoting the improvement of the quality, and the general development of flax culture.—*Journal of the Society of Arts.*

The Select Committee of the House of Commons, appointed on the motion of Sir John Lubbock to inquire into the desirability of establishing a Forest School in England, recently took the evidence of Mr. W. G. Pedder, Revenue Secretary of the India Office, who stated that a Forestal Department was authorised in Bombay in 1846. About that time the revenue of the Indian forests was £40,080. Since then it had risen to a gross revenue of nearly £1,000,000, and a nett revenue of over £400,000, and that, he considered, was undoubtedly due to the increased education of forest officials. Instructors were obtained from France and Germany, but latterly chiefly from France, because it was found that the woodlands of England and Scotland were not so well managed as to enable the managers to give instruction.—*Journal of Horticulture.*

Earthworms—Mildew.—Earthworms in the pots are another troublesome pest, especially where the extra precaution has not been taken to grow the plants on boards or tiles throughout the summer. These disturb the roots and cause the flowers to be thin and weak. A good nob of fresh unslacked lime put into a two-gallon watering can and left to settle will make sufficient lime water for a good number of plants, which is the best thing to use to kill the worms in the pots. Mildew will appear more especially on high-fed plants. The best remedy is sulphur, which should be dusted over at the first sign of it. Some varieties seem more susceptible to this than others. Val d'Andorre of the Japanese, and Triomphe du Nord, and also Dick Turpin amongst the Pompons, are the only varieties that have given me any trouble this season.—*Journal of Horticulture.*

Sub-Tropical plants in Small Gardens.—These, of course, are named as best sites, but the owner of a small villa garden, who—as a matter of course—has no choice of sites, need not despair. If he only has shelter, he may, if so inclined, have a first-rate sub-tropical bed. Say, for instance, he has a large circular bed, and wishes it planted effectively after the sub-tropical fashion; here is the arrangement. In the middle plant a large clump of the hardy bamboo (*Bambusa Metake*), or else of New Zealand flax (*Phormium tenax*); then three plants, equal in size, of seedling *Acacia lophantha*; and next six plants of *Grevillea robusta*; the outer row of all being twelve plants of variegated abutilon; the edging to be the hardy variegated plantain lily (*Funkia ovata variegata*). All these plants can be bought at the prices usually paid for common geraniums, and are therefore within the reach of all. The bed can be filled out either with flowering or foliage plants; considering the position, we should advice the former, the kinds to be either geraniums or fuchsias, or both in mixture. Should foliage plants be preferred, variegated thyme, golden feather pyrethrum, or any of the mossy selection of sedums would be appropriate.—*Cassell's Popular Gardening.*

Acclimatisation of Chinese Plants in India.—We are informed that Monsieur Reynaud, Professor of Agrimony at Pondicherry, has raised some strong healthy plants from the seed of the Chinese "milk plant" (*de soya*). It is a native of Japan *Teou Tou*, The Chinese use it largely, expressing the milk, which is used in its liquid state, and is also manufactured into cheese; it has not yet however, found favour among Europeans, the flavour being unpleasant. The Chinese bamboo, Katang, has also been raised from seeds by M. Reynaud; this particular bamboo grows to an enormous size, and is valuable for a variety of purposes; all kinds of utensils are made of it—casks, tubs, buckets, troughs, &c. The Angola beans (*Cytisus Cazan*) sown a short time ago are thriving satisfactorily, and a good gathering is expected. They are by far the best beans for *haricot* and many other French dishes; a great recommendation is their easy digesting qualities and pleasant taste. The plant continues to bear for seven years, and is greatly prized in the Antilles for its economical usefulness; it requires little or no tending.—*Planters' Gazette.*

QUININE BARK.

6, MINCING LANE, LONDON, 31ST JAN. 1887.

GENTLEMEN,—At the commencement of the past year prices for both bark and sulphate of quinine had fallen to a point low beyond all previous precedent.

They were, however, nevertheless, doomed to suffer a still further and heavy fall in the course of the year. The fall cannot be put at less than 25 per cent on bark, and 20 per cent on quinine. This unparalleled depression has, on the one hand, been accompanied by a very extended consumption of quinine: and, on the other hand, the extremely unremunerative price of bark has not, so far, had the effect of at all diminishing our supply. On the contrary our receipts from Ceylon —at present the main source of our supply—were again larger than ever last year.

JANUARY.—The new year opened as the old one closed, with a quiet market at previous very moderate prices—4½d a 5d per unit—business limited.

FEBRUARY was without any improvement either in demand or value.

March witnessed a little more animation; volume of business somewhat large; previous prices firmly maintained.

April saw much the same condition of things. No diminution in the quantity of business accomplished, and, although with some little fluctuations, no quotable alteration in terms.

May was a bad month; the supply of Ceylon became very heavy; the demand fell off very much, and prices went down to 4d a 4½ d per unit.

June opened very heavily for South American Bark; but business to some extent was done in Ceylon upon previous terms.

July was a most unfavourable month for Importers, especially of the South American varieties, which were entirely neglected; rates for Ceylon also ruling decidedly in favour of the buyer.

August was without recovery in value; business to a tolerable extent accomplished.

September proved the worst month of the year, the unit having fallen to 3d; demand very slow.

October was, if anything, rather better in general tone, but without any quotable advance in currency. A fair amount of transactions.

November was decidedly better all round; manufacturers apparently operating with more confidence. Large business done, and prices quite ½d a 1d per unit higher.

December passed without any noticeable change: and so ended a year most discouraging to all concerned in the cultivation of and trade in Bark! As regards the supplies of last year, it will be observed that from Ceylon there has been again a considerable increase; the total receipts having reached 15,365,000 lb.

Against	11,678,360	„	in	1884-5
Against	11,500,000	„	in	1883-4
Against	7,000,000	„	in	1882-3
Against	3,100 000	„	in	1881-2
Against	1,200,000	„	in	1880-1

The supplies of Java Bark shew some, though not material, increase upon the receipts of the previous season.

In 1882	to	1883	they were	735,381 lb.
1883	to	1884	„	989,158 „
1884	to	1885	„	1,321,569 „
1885	to	1886	„	1,771,420 „

There has been some little augmentation of our supplies from South America; but it may nevertheless be assumed that, except in the case of Calisaya, actual cutting has altogether ceased, prices being so utterly unremunerative.

The following are the imports of the last six years:—

	South American.	Ceylon and India.	Total.
1881	pkgs. 99,970	15,390	115,360
1882	„ 95,940	21,630	117,570
1883	„ 53,780	31,330	85,110
1884	„ 21,075	37,300	58,375
1885	„ 5,290	50,410	55,700
1886	„ 10,500	59,700	70,200

Last year, contrary to the two preceding years, our deliveries fell just a little short of our receipts. The official dock and wharf returns of bark actually warehoused between the 1st January and the 31st December render the following:—

	landed pkgs.	delivered.		
1884	59,287	78,532	19,245	more dlvd. than imptd.
1885	55,343	74,094	18,751	do. do. do.
1886	70,195	68,986	1,209	less dlvd. than imported

The said docks and wharves return the stock of all sorts of medicinal bark, at the end of each of the last three years, as follows:—

1884	... ...	80,500	packages.
1885	... ...	62,117	„
1886	... (stock corrected)...	62,350	„

We commenced the past year with a steady market at the following prices for fine qualities, viz.:—

Calisaya Quill ...	(say 5 per cent. Bark)	2s 0d per lb.
New Granadian		2s 6d „ *
Soft Columbian		1s 6d „
Cuprea		1s 2d „
Carthagena		1s 3d „ †
Ceylon		0s 4½d a 0s 5d „ ‡

* Quite nominal, no supply. † Quite nominal, no supply. ‡ Per unit.

We closed the year at the following disastrously low quotations for fine qualities:—

Calisaya Quill ...	(say 5 per cent. Bark)	1s 6d per lb.
New Granadian		— „ *
Soft Columbian...		1s 2d „
Cuprea		0s 10d „
Carthagena		0s 11d „ †
Ceylon		0s 3½d „ ‡

* No quotation in the continued absence of supply. † Practically no supply. ‡ Per unit.

SULPHATE OF QUININE.—Low as were the prices at which we commenced the year, they continued to fall with scarcely any interruption for ten months: and although there was some little recovery in November and December, they closed at an average decline of 8d per oz. for the year. German Quinine has fluctuated more than that of any other country; speculation in that manufacture being the most rife. The consumption of Sulphate of Quinine must have been very large, especially in America.

Fluctuations were as follows:—

English—Highest—3s 2d per oz. in bulk.
Lowest 2s 4d per oz. in bulk

French—Highest—3s 0d per oz. in bulk.
Lowest 2s 2d per oz. in bulk.

German—Highest—2s 10d per oz. in bulk.
Lowest 1s 11d per oz. in bulk.

Italian—Highest—2s 9d per oz. in bulk.
Lowest 2s 0d per oz. in bulk.

The following table shews the fluctuations for the month—in bulk: 2d per oz. more in bottles:—

	English. per oz.	French. per oz.	German. per oz.	Italian. per oz.
January...	3 2	3	2 9 to 2 10	2 9
February	3 1	2 10 to 2 11	2 8 to 2 9	2 9
March ...	3 1 to 3	2 10	2 8 to 2 9	2 9
April ...	3	2 10	2 8 to 2 9	2 9
May ...	2 10	2 8	2 7½ to 2 6	2 7
June ...	2 10	2 8	2 5 to 2 3	2 4 to 2 3
July ...	2 10 to 2 8	2 8 to 2 4	2 3 to 2	2 3 to 2 1
August ...	2 8 to 2 6	2 3 to 2 4	2 1 to 2	2 1
September	2 1	2 2	2	2
October ...	2 4	2 2	1 11 to 2	2

TEA IN LONDON.

(*Special telegram for the "Observer"*)

This morning we received the following details in a telegram which was despatched from London yesterday at 3-35 p.m.:—

The quantity of Ceylon tea offered during the week was 2,741 packages, of which 2,199 sold at an average of thirteen pence. The tone of the market is duller.

To the above we add the following, for which we are indebted to a leading merchant:—

"I regret to say a telegram from London reports the tea market not so good; that quality is falling off, and that prices are down 1½d a lb.

"Probably teas are getting home from bushes pruned towards the end of last year."

Our correspondent may possibly be correct as to the cause of the falling off, but mere season, apart from pruning it would seem to affect the quality of tea, as was shewn in the quotations made by Mr. Cochran in his paper on Coca leaves and their alkaloids.

On turning to the paper referred to by Mr Cochran, we find that it is stated in the *Journal of the Chemical Society*, with reference to a paper on the Composition of Tea-leaves, by O. Kellner (*Landw. Versuchs-Stat.*, 1886, 370—380). "—The chief interest in this research lies in the fact that it is almost the only case in which an evergreen plant has been systematically examined throughout the year."

Then come the purely technical details of the drying and chemical treatment so as to obtain the proportions of theine, tannic acid, &c. We quote the conclusion of the paragraph:—

"The fluctuation in the percentage of water is less than that observed in leaves of deciduous trees; the percentage of ash lies between that found in the needles of pines and in ordinary leaves. It will be

* The imports from Ceylon in 1886 as in 1885 and 1884 contain many very large packages.

noticed that the non-albumonoid nitrogen is almost wholly absent during the later stages of growth, being found as theine. Connecting this with the fact that albumin has increased, and that no theine is found in the seeds, the author believes that positive proof is afforded that the alkaloid, like glutamine and asparagine, is a decomposition product of albumin, and is capable of again forming albumin.

"As regards the ash, we have here a regular increase, whilst in deciduous trees is found both diminution and increase."

Tables are given showing the constituents of the leaves gathered at different seasons of the year, from which we gather that the precentages in dry leaves vary largely at different dates. For instance, theine gave in May 2·85 and 2·80, going down steadily to 1 30 and 1·00 in November. Tannin, on the other hand, which showed only 9·67 and 8·3 in May rose to 11·34 and 12·16 in November. The amount of ash rose from 4·69 in May to 5·11 in September, going down to 5·00 in November. "Ethereal Extract," on which, probably, the aroma of tea chiefly depends, varied so enormously as from 6·42 in May to 2·19 in November. —The water in *fresh* leaves, went down from 76·83 in May to 59·43 in November. "Old leaves" (fresh) gave 60·03 of water, in May against 76·83 in young leaves (flush, of course). Theine in the old leaves was only 0·84 and tannin 11·11. Ash gave 5·14 and ethereal extract 14·18.

In 100 parts of ash, excluding carbonic acid, potash showed 49·06 in May, going gradually down to 17·31 in November. Lime, on the other hand, rose from 11·95 in May to 30·37 in November, Magnesia likewise rose from 8·69 in May to 17·99 in November. Soda went up from 1·07 in May to 2·76 in November. Peroxide of iron rose from 3·80 in May to 11·37 in November. On the other hand phosphoric acid sunk from 15·63 in May to 10·70 in November. Sulphuric acid varied only from 3·75 in May to 4·02 in November. Oxide of manganese, silica and chlorine, we need not quote. It is striking to note that the ash of old leaves in May gave only 14·20 potash against 49·06 in young; lime in old leaves was nearly double; magnesia more than double; peroxide of iron much more than double, but phosphoric acid only 10·64 against 16·67; sulphuric acid being 4·41 against 3·75.

It thus appears that in the two important constituents of potash and phosphoric acid, young leaves (of which we make tea) are far in advance of old leaves while the latter contain a far larger proportion of lime.

But the changes in the constituents of the young leaves from the hot summer month of May down to the winter month of November (the experiments having been, we presume, conducted in India), are the most interesting results. Of course the extremes of heat and cold in Ceylon are but slight as compared with India; but still they must be operative, and we cannot doubt that much of the tea now selling at low prices in London was most injuriously affected by the bitterly cold winds which swept over Ceylon in December.

LIFE IN NEW ZEALAND.

(By an ex-Ceylon Colonist)

South Riverton, 1st Jan. 1887.

This is a quiet spot in the very South of New Zealand where I have come from Invercargill to spend a holiday. I have now been pretty well all over the country and am quite a different man in health to what I was latterly in Ceylon. The question as to what one should eat and drink never troubles one here, the food being good and wholesome and stimulants not being required. No flannel belts now! You will be expecting an account of the country and my difficulty is where to begin. So for the moment I shall try to imagine myself in Ceylon and then write to you about the things a Ceylon man would like to know about.

CLIMATE.—For health the climate of New Zealand is very good. For comfort it is not so admirable, as taken all round it is much windier than the Old Country and in some places—notably the Canterbury Plains, hot winds come occasionally. It can be very dusty too in dry weather. There are great varieties of climate from wet Southland and Otago to dry Hawkes Bay in the North Island. Upon the whole it is warmer than the British Isles.

SOIL is generally of a light clayey appearance, and a stranger is astonished to see some of it yield 20 tons of potatoes to the acre, and 75 bushels of oats to the acre. But it varies very much in fertility. Hawkes Bay, the Canterbury Plains, the Taeri Plains near Dunedin and some of the Southland Province, are considered the crack districts, but there are many other places of smaller extent that can cope with them. There is plenty land yet to be taken up as good as any now in cultivation. The South Island has been most opened up, owing to the Maori troubles in the north, and were I coming here to farm I think I should select a spot in the North Island. Land can be got there now that will by-and-bye carry 10 sheep to the acre.

SCENERY.—The mountains and bays of the west coast in the South Island are magnificent, but as few people go there they are lost to view. There are some views of bold scenery about Dunedin, and lovely places of a quieter kind at Auckland, but altogether the inhabited parts of New Zealand are somewhat tame. As the country gets older, and English trees grow up it will look better. The bush has the same appearance all over the islands and it is so vast and dense that no pretty peeps of waterfalls and glades can be obtained as in Ceylon.

PLANTS &c.—Despite the great variety of plants there is monotony to the eye owing to the predominance of the Tea* tree so called, the fern, and in the South Island the Tussack grass. At the Bluff in Southland there is tea tree and fern, and at the north of the North Island there is tea tree and fern. The stunted-looking palm called the cabbage tree grows all over New Zealand, but in the north there are several other palms and the celebrated Kauri pine which does not grow in the south. If a railway is anywhere made through the densest bush, clover and English thistles at once spring up on its sides. I was astonished to discover in thick bush the homely old Musk which has found here a congenial home. Docks and sorrel abound, perhaps owing to careless farming.

FRUIT-GROWING IN KENT.—In consequence of the ruinously low prices obtained for last season's fruit crop, a large number of growers in Kent have grubbed their orchards. This has been done even in cases where the crop of 1886 was the most prolific on record, the growers stating that it would not be worth their while to grow fruit and sell it at the prices of last season, which, in hundreds of instances, did not pay the cost of picking and carriage.—*St. James's Budget.*

* Properly Ti.—ED.

CEYLON UPCOUNTRY PLANTING REPORT.

COFFEE CROPS IN THE KANDYAN DISTRICT—THE NEW TEA ROLLER OF KINMOND AND RICHARDSON—KANDY AGRI-HORTICULTURAL SHOW—SUCCESSFUL FLOATING OF A LOW COUNTRY TEA COMPANY—TEA CLEARINGS BURNT OFF ON SUNDAYS—CARDAMOM PLANTING—CHEAP LABOUR.

28th Feb. 1887.

In all the Kandyan districts and especially in Dumbara there has been a fine blossom on the coffee. It has been very magnificent in Dumbara, as much as eight cwt. an acre said to have been out. The rain which followed a few days later must have given it every chance to set, and although a set blossom in that part is not by any means a harbinger of a sure crop, still it is so far on the way. There is more blossom still to come, so that the trees will have enough to do to carry it.

The new roller of Kinmond and Richardson is doing gook work, I learned. One who has seen it at work speaks of it as "a stylish machine," being "neatly made, nicely fitted and very compact." He adds: "We put in 300lb. of leaf for a roll, although it will take up to 450lb. and the work was splendidly done. The leaf was well withered and the machine had every chance of showing what it could do, and I must say it proved to us all present that it was able to do good work."

At the Agri-Horticultural Show which is to be held in Kandy if each maker would forward a specimen roller there would be a fine opportunity for the public seeing the different machines, and especially if they were in motion, which ought to be arranged. A reward for the best tea rolled on the spot might well find a place in the prize list, and what would hinder the firing off of the samples in one of the driers which might be on exhibition? An opportunity would then be given of comparing the merits of the different makers, such as otherwise would be impossible. The made teas might also be judged. I incline to think, that for planters at any rate this part of the exhibition, if carried out, would be as popular as any and not without value in an educational light.

One of the lowcountry tea Companies—which was held to be bound to come to grief from the number of V. A.'s which had shares—is doing very well and full of much promise. It is said that they expect to declare a dividend of 20 per cent next year! Happy shareholders! If this fine return does come how these V. A.'s will open their eyes? As to the croakers who saw in the accumulated wisdom of the V. A.'s a source of danger which might wreck any enterprise, even the most promising, they may safely be left to come to a better state of mind, and recognize somehow that the Company has been mercifully preserved.

It is strange how such things at times come about. I know a tea clearing which was burnt off on a Sunday, the Sinhalese contractor deeming that a lucky day—and which immediately became the subject of prophecy. With a fine sense of justice, it was sure by those who took up their parable that the effect of this supposed breach of the fourth commandment, would bring with it disaster, not on the Sinhalese sinner nor on the European manager, but on the innocent proprietors in England, who had no say in the matter. The clearing would never thrive, it was said, and from its earliest date it inherited a curse. But like threatened men, who live long, cursed estates don't do badly, and the clearing in question can today be favourably compared with any I know. I am very glad it is so: otherwise one's sense of what is right would have been confused past all hope.

In a quiet way in different districts there is land being prepared for the planting of cardamoms during the next S.-W. monsoon. Those who pretend to know say "Now's the time," and hold out prospects of a good return.

Group of coolies are on the move, and kanganies seek employment for them at moderate advances. Many estates have men at the Coast recruiting and more are going. This is really the way to solve the labour difficulty, and not go on buying up gangs here at enhanced rates.

PEPPERCORN.

PEARL.

Pearl.—A peculiar product of certain marine and fresh water molluscs or shell fish. Most of the molluscous animals which are aquatic and reside in shells are provided with a fluid secretion with which they line their shells, and give to the otherwise harsh granular material, of which the shell is formed, a beautifully smooth surface, which prevents any unpleasant friction upon the extremely tender body of the animal. This secretion is evidently laid in extremely thin semi-transparent films, which, in consequence of such an arrangement, have generally a beautiful irridescence, and form in some species a sufficient thickness to be cut into useful and ornamental articles. The material itself in its hardened condition is called nacre by zoologists, and by dealers Mother-of-Pearl. Besides the pearly lining of the shells, detached and generally spherical or rounded portions of the nacre are often found on opening the shells, and there is great reason to suppose these are the result of accidental causes, such as the intrusion of a grain of sand or other substance, which, by irritating the tender body of the animal, obliges it in self-defence to cover the cause of offence, which it has is no power to remove; and as the secretion goes on regularly to supply the growth and wear of the shell, the included body constantly gets its share, and thereby continues to increase in size until it becomes a pearl. The Chinese avail themselves of the knowledge of this fact to compel one species of fresh-water mussel, Unio Hyria, to produce pearls. In order to do this, they keep the Unios in tanks, and insert between the sheil and the mantle of the animal either small leaden shot or little spherical pieces of mother-of-pearl. These are sure to receive regular coatings of the nacreous secretion; and after a time look like pearls formed under ordiuary circumstances. These curious people also practise another trick upon these animals; they insert small images of the Buddha stamped out of metal, which soon become coated with the pearl secretion, and are cemented by it to the shells; to those ignorant of its origin, the phenomenon is a supernatural testimony to the truth of Buddhism. Examples of these curiosities are to be found in many of our museums.

A plan of making pearls was suggested to the Swedish Government by Linnœus. It consisted in boring a small hole through the shell of the river mussel, and inserting a grain of sand, so as to afford a nucleus for a pearl. The plan at first succeeded sufficiently well to prove its practicability, and he was rewarded by a sum of money (£450) but it failed as a profitable speculation, and was abandoned.

The exact nature of the secretion has never been satisfactorily determined; it is, however, ascertained that it is deposited in thin films; which overlie each other irregularly, and to this peculiar disposition of the plates, the beautiful irridescence of common pearls is attributed. This formation was a great puzzle to the ancients, amongst whom they were highly prized. Dioscorides and Pliny mention the belief that they were drops of dew or rain which fell into the shells when opened by the animals, and were then altered by some power of the animal into pearls. This opinion which, obtained all over the east, is thus charmingly alluded to by Moore:—

"And precious the tear as that rain from the sky,
Which turns into pearls as it falls in the sea."

The most famous pearls are those from the east: the coast of Ceylon, or Taprobane as it was called by the Greeks, having from the earliest times been the chief locality for pearl fishing. They are, however, obtained now of nearly the same quality in other parts of the world, as Panama in South America, St. Magarita in the West Indies, the Coromandel Coast, the shores of the Sulu Islands, the Bahrim Islands, and the islands of Karak and Corgs in the Persian Gulf. The pearls of the Bahrim fishery are said to be even finer than those of Ceylon, and they form an important part of the trade of Bassora. These, and indeed all the foreign pearls used in jewellery, are produced by the pearl oyster. The shells of the molluscs which yield the Ceylon, Indian and Persian ones, are sometimes as much as a foot in diameter, and are usually about nine inches. Those of the New World, although the shells are smaller and thicker, are believed to be the same species. The chief locality of the Ceylon pearl fishery is a bank about 20 miles long, 10 or 12 miles from shore, opposite to the villages of Condatchy and Arippo on the northern coast. The season of the fishery lasts about three months, commencing at the beginning of February, and is carried on under Government regulations. The boats employed are open, and vary in size from 10 to 15 tons burden; they put out at night, usually at 10 o'clock, on a signal gun being fired from the fort of Arippo, and make for the Government guard vessel, which is moored on the bank, and serves the double purpose of a guard and a lighter-ship. The divers are under the direction of a manager, who is called the Adapanaar, and they are chiefly Tamils and Moors from India. For each diver there is provided a diving stone, weighing about 30 pounds, which is fastened to the end of a rope long enough to reach the bottom, and having a loop made for the man's foot; and in addition to this, a large network basket, in which to place the pearl oysters as he collects them. These are hung over the sides of the boat; and the diver placing his foot in the loop attached to the stone, liberates the coils of the rope, and with his net basket rapidly decends to the bottom.

To each boat there is usually allotted a crew of 13 men and 10 divers, 5 of whom are descending whilst the others are resting. This work is done very rapidly; for, notwithstanding the stories to the contrary, the best divers cannot remain longer than 80 seconds below, and few are able to exceed 60. The greatest depth they descend is 13 fathoms. When the diver gives the signal by pulling the rope, he is quickly hauled up with his net and its contents. Accidents rarely happen; and as the men are very superstitious, their safety is attributed to the incantations of their shark-charmers, performed at the commencement of the fishing. Sir E. Tennent, however, attributes the rarity of accidents from sharks, usually so abundant in tropical seas, to the bustle and to the excitement of the waters during the fishery frightening away the dreaded creatures. The divers are sometimes paid fixed wages: others agree for one-fourth of the produce. When a boat-load of oysters has been obtained, it returns to shore, and the cargo, sometimes amounting to 20,000 or 30,000 is landed and piled on the shore to die and putrefy, in order that the pearls may be easily found. The heaps are formed in small walled compartments, the wall surrounding each being about one or two feet in height. Several of these compartments surround a small central enclosure, in which is a bath, and they slope towards this bath, and are each connected with it by a small channel, so that any pearls washed out from the putrefying mass by the rain may be carried into the bath. When the animals in the shell are sufficiently decomposed, the washing commences, and great care is taken to watch for the loose pearls, which are always by far the most valuable; the shells are then examined, and if any attached pearls are seen, they are handed over to the clippers, who, with pinchers or hammer, skilfully remove them. Such pearls are used only for setting; whilst the former, being usually quite round, are drilled and strung and can be used for beads, &c. The workmen who are employed to drill the pearls, also round the irregular ones, and polish them with great skill. The method of holding the pearls during these operations is very curious; they make a number of holes of small depth in a piece of dry wood, and into these they fit the pearls, so that they are only partly below the surface of the wood, which they then place in water. As it soaks up the water and swells, the pearls become tightly fixed, and are then perforated, &c. These operations are all carried on, on the spot.

For many miles along the Condatchy shore, the accumulation of shells is enormous, and averages at least four feet in thickness. This is not to be wondered at, when it is remembered that this fishery has been in active operation for at least 2,000 years. The place itself is exceedingly barren and dreary, and, except during the fishing season, is almost deserted; but at that time it presents an exceeding animated spectacle; thousands of people of various countries and castes, are here drawn together, some for the fishery, others to buy pearls, and others to feed the multitude. They chiefly reside in tents so that it appears a vast encampment.

The pearls vary much in size; those as large as a pea, and of good colour and form, are the best, except unusually large specimens, which rarely occur, the most extraordinary one known being the pearl owned by the late Mr. Hope, which measured two inches in length, and four in circumference, and weighed 1,800 grains. The smaller ones are sorted into sizes, the very smallest being called seed-pearls. A considerable quantity of these last are sent to China, where they are said to be calcined, and use in Chinese pharmacy. Amongst the Romans the pearl was a great favorite, and enormous prices were paid for fine ones. One author gives the value of a string of pearls at 1,000,000 sesterees, or about £8,000 sterling. The single pearl which Cleopatra is said to have dissolved and swallowed was valued at £80,729, and one of the same value was cut into two pieces for earrings for the statue of Venus in the Pantheon at Rome. Coming to latter times, we read of a pearl, in Queen Elizabeth's reign, belonging to Sir Thomas Gresham, which was valued at £15,000 and which he is said to have treated after the fashion of Cleopatra; for he powdered it and drank it in a glass of wine to the health of the Queen, in order to astonish the ambassador of Spain, with whom he had laid a wager that he would give a more costly dinner than could the Spaniards.

During the occupation of Britain by the Romans this country became famous for its pearls, which were found in the fresh water mussel of our rivers. Generally the pearls of these molluscs are small, badly coloured, and often valueless; but occasionally they occur of such beauty as to rival those of the pearl oyster. Some years ago, in the Scotch rivers, the search for pearls was prosecuted vigorously, especially by a merchant named Unger, of Edinburgh, who had brought Scotch pearls into great repute. He collected specimens ranging, as was stated, from £5 to £90 each and formed a necklace said to be worth £350. In Scotch pearls of the highest quality, there is a pleasing pinkish tint, which is very permanent. The fishing for pearl mussels is by no means so dangerous or troublesome as for pearl oysters; usually they are found in the beds of streams, shallow enough to wade in, and so clear that they can see the bottom. If too deep to remove with the hand, they are easily captured by putting a stick between their gaping shells, which instantly close upon it, and can be drawn out with it. So profitable did this pursuit become, that a great many persons engaged in it.

Very fine river pearls, known on the continent as Bohemian pearls, are found in the rivers Moldan and Wottawa. There is also a fresh-water pearl fishery in Bavaria, where the river Iltz yields at times very fine specimens. Even the most inferior pearls can only be properly polished with pearl dust, and the inferior pearls are powdered for the purpose of polishing and rounding the finer ones.

False pearls are very admirable imitations, made by blowing very thin beads or bulbs of glass, and pouring into them a mixture of liquid ammonia, and the white matter from the scales of the Bleak and sometimes of the Roach and Dace. The proper way to prepare the

pearl-matter is first to remove the scale of the lower part of the fish; these must then be very carefully washed, after which they are put to soak in water, when the pearly film falls off and forms a sediment at the bottom of the vessel, which is removed and placed in liquid ammonia for future use. This pearl mixture, when of the best quality, is very costly, being as much as £4 or £5 per ounce. For use, it is diluted with ammonia, and injected into the glass beads, so as to thinly coat them inside; afterwards the better kinds have melted white wax poured in, which renders them more durable. The French and Germans produce in this way imitations of the finest oriental pearls of such beauty, that the most practised eye can hardly detect the difference. The bleak is procured in considerable quantities for this purpose from the Thames and other rivers in England.

The invention of artificial pearls is due to a Frenchman, named Jaquin, in the time of Catherine d'Medici, and the manufacture is now chiefly carried on in the department of the Seine, where great improvements have lately been made, especially in the art of giving the irregular forms of large pearls to the glass-bulbs, and thus increasing the resemblance, and in removing the glassy appearance caused by the exterior glass coating, by exposing it for a short period to the action of the vapour of hydrofluoric acid. Mucilage of fine gum-arabic is also used instead of wax, which increases the translucency, gives greater weight, and is not liable to melt with the heat of the wearer's body—a defect to which those filled with wax are very liable.

Roman pearls differ from other artificial pearls, by having the coating of pearly matter on the outside, to which it is attached by an adhesive substance. The art of making these was derived from the Chinese.

Mother-of-Pearl, the shells of the large bivalve mollusc, *Meleagrina margarifera*, which also produces the precious pearls.* These shells are collected in vast numbers in the tropical seas, chiefly on the coast of Ceylon, Manila, Cuba, Panama, and the South Sea Islands. Those from Panama are small and thick, and are known in commerce as "bullock" shells; those from Manila are finest in quality, often as much as a foot in diameter, round and flat. There are two varieties—the white or silver lipped and the black lipped. So enormous is the trade in these shells, that the imports of this country alone amounted to 3,000 tons per annum, the value of which is nearly £100,000. Although large quantities of these shells are consumed in inlaying fancy wood-work, papier-mache and in making knife-handles and other small ornamental objects, by far the greater portion is required for making buttons, chiefly in Birmingham.—*The British North Borneo Herald.*

To the Editor of the "British North Borneo Herald."

Sir,—Without wishing any criticism to be implied on the Early Notices of North Borneo and Sulu from Chinese Sources which were printed in your issue of the 1st instant, I should like to remark that I was especially struck by the weight of the pearl mentioned in the following passage:—"In the year 1421 (A.D. is supposed to be understood) the mother of the Eastern King (King of Sulu) sent to Court a brother of her late husband, called Paduka Suli; he presented as tribute a large pearl weighing more than *seven taels*." Now seven Chinese taels are equal 4,137 2/5 grains Troy, which if valued at the present valuation of pearls, presuming the pearl in question to have been of the first quality, would give the grand sum of £41,374. In the estimation of the Chinese it may have possessed a still higher value, seeing the fabulous prices they sometimes put on pearls. That which Julius Cæsar presented to the mother of Marcus Brutus was valued at £48,417 10s; and the one which Cleopatra, in her desire to expend in one feast a larger sum than Mark Anthony had done in his most sumptuous feasts, swallowed with a draught of vinegar; cost about £30,729 35s 4d. The pearl obtained by Philip II of Spain in 1587 from the island of Margarita off the Columbian Coast which weighed 250 carats or 800 grains was valued at $150,000.

To those celebrated pearls just noted must now be added (if credence is to be placed in the Early Notices of Borneo and Sulu from Chinese Sources) the above remarkable one presented by a Queen of Sulu to the Hông-Te of the Kingdom.—Yours, &c. Chin-Chu.

* This is a curious error. Mother-o'-pearl is procured chiefly from large shells of quite a different species.—Ed.

NOTES AND QUERIES.

Green Tea.—"C" is right in saying that more green tea is sold in this country than in Europe. The reason for its popularity here is, no doubt, as a recent English writer has observed, in a great measure due to our intercourse with Japan, where green tea alone is manufactured. In the making of tea, as in everything which this curious people do, the Japanese have a way of their own. It would startle an Assam planter to see them in picking time squatting down before the trees and stripping the branches of the leaves, instead of scientifically selecting only the young, undeveloped leaf, the first leaf below that, and half the second, from which would be evolved respectively "Broken Tips" or "Orange Pekoe," "Pekoe" and "Souchong." Any one accustomed to the elaborate machines for "rolling" and "firing" the leaves which are in use on European plantations might be amused at the Japanese method, where the workers roll and squeeze and twist the leaves in their hands on parchment stretched over a charcoal fire. Very fine teas are, nevertheless, manufactured by the Japanese, and in the celebrated district of Uji rumour tells of tea worth $16 per pound, though it is not definitely stated whether that price has ever actually been paid for it. Moreover, in the case of teas intended for export, only so much work is done upon them as will enable them to be sent to the "tea-firing godown" of Yokohama, where they are worked up for the market before being shipped. As is now well known, the difference between green tea and black lies in the fact that in the former fermentation has been arrested by "firing," the color of the leaf being in this way partially preserved and fixed; with the latter, by a much longer process, fermentation up to a certain point is permitted, and the leaves are not "fired" until they have become oxidized by exposure to the air. In Japan the leaves, after being picked and "whithered" by a short exposure, are fired in the way described above sufficiently to stop fermentation, and in this partially-cured state are sent to the European tea merchants, by whom they are again "fired." In the "godowns" of Yokohama hundreds of women can be seen at work turning the leaves over and over and round and round in large basins built over a charcoal fire. The coloring or "painting" is also done at this period by means of a spoonful of indigo and powdered soapstone put into each basin, and thus disseminated through its contents. But in Japan tea is not grown for export only, but is the chief article of home consumption; and these domestic teas as procured in the country are probably the only samples of unadulterated green tea which foreigners are likely to meet with. They produce a beverage which is refreshing, quite harmless, and which, notwithstanding the way in which it is prepared, can, after only a short residence in the country, be readily distinguished from hot water.—*American Cultivator.*

A new "everlasting" Wood Pavement has been brought out in France. The wood blocks are boiled in a solution of sulphate of copper, sulphate of zinc and chloride of sodium, mixed with a heavy mineral oil, linseed oil and tallow. The blocks are afterward compressed to about one-tenth their original volume. In this state they are said to practically defy wear and tear.—*Journal of Forestry.* [Our Municipal Councillors ought to "put their heads together" in order to supply wooden pavement to some of the principal streets of Colombo.—Ed.]

Fifteen years ago, the net forest revenue of British India was £50,000. Now it is £100,000. Forest culture has brought about the change.—*Journal of Forestry.*

FRATER'S PATENT DUPLEX TEA ROLLER.

Writing from Aberdeen under date 1st February, Mr. Frater says :—"I am sending you by this mail a set of three photos of my Tea Roller, made at home. The first consignment was shipped about a month ago to Messrs. Brown, Rae & Co., Hatton, and a second lot is being pushed rapidly on. No. 1 card shows the machine with gear to drive by belts; No. 2 showing the machine without driving gear; No. 3 showing the machine open. This last photo shows the entire principle of the machine, which (as, of course, you know) is 3 discs, the centre one going the opposite way to that of the two outer. The machine should really be called the 'Duplex' Tea Roller. You will see from the photos that the design is thoroughly substantial throughout. The cylinder is of cast-iron, lined with brass, and the discs the same. On the faces of the latter are fixed teakwood battens. The pressure is applied to the leaf by means of a worm screw and quadrant lever fixed to outer discs. The machines now being sent out are a great improvement on those of the same made in Ceylon. I have bestowed a great deal of thought on them, and, having the advantage of fine machinery here for their manufacture, I hope to have a share of Ceylon's demand. . . . Ceylon tea is rapidly getting into favour in the north here, and is well advertised in the newspapers and shop-windows. China tea will soon have no place at all !"—The photographs referred to are now for inspection at our office.

THE PLANTING "MOLESWORTH*."

"The Planter's Note-book" which is intended for the pocket of the tropical planter is a start in the right direction. The model on which the lines are laid, of this new venture of the *Observer* Press, and from which it takes part of its name—'The Planting Molesworth"—is so good. and so likely to lead to good, that I am reminded of the Scotch proverb, "He'll shoot higher that shoots at the moon, than he that shoots at the midden, e'en though he may miss the mark"

For a first, or even a second or third edition of a "Planting Molesworth" to attain to the excellence of the famous original, although not a hopeless aim, is certainly a high end: and it is manifestly clear that the publishers, Messrs. A. M. & J. Ferguson, intend to put "their best foot foremost," and do all in their power to make "The Planter's Note-book" a grand success, when they have taken the engineering "Molesworth" as their model, and invited comparison by adopting its name.

The planters will have to remember, however, that ere this—the latest heir of a noble name—can resemble even in part the high qualities of its eminent predecessor, their help will be needed; for the practical information which must be supplied to bring this desirable likeness out, is to be found, not so much at [illegible] office of the compilers, as in the field and fact[illegible], and among the every-day work of an estate. [illegible]lready it is pleasing to see, that suggestions are appearing in the *Observer* columns, by selecting and adopting the best of which the value of the next edition of the "Planting Molesworth" will be materially increased.

As to the present edition, the title-page gives a fair idea of the comprehensiveness of the public catered for. It runs as follows:—"The Planters' Note-book with every-day information for the tea planter, and also for planters of coffee, cinchona, cacao, rubber, cardamoms, coconuts, cinnamon &c., with useful hints on machinery, buildings, &c., also manuscript note-book for field and factory or store." And in the 52 pages of letter-press with which the "note-book" opens, the grower of any of the above products will find in a highly-condensed form, figures and facts to refresh the memory of the old hand, or to guide the ways of the beginner. As an example take: "Cardamoms 100 lb. green—about 24 lb. dry.

Per Day:

A cooly can cut about 12 lb. Malabar
" pick " 18 " Mysore
" clip " 5 " Dry Malabar

Average cost of production 35 to 40 cents per lb. Frieght and home charges 3d to 4d per lb. Chests could contain 100 lb. nett."

Now this information useful as far as it goes is not all which might be given under the heading of cardamoms. The cost of planting and curing, and the best methods of carrying out the latter, not to mention aught else might well have been added.

Indeed the leading fault of this first edition is its want of plan. Why was the cost of work in planting cacao given, and similar information in regard to cardamoms withheld? Why are we told how to cure coffee, and not a word given about the manner of curing tea? In compiling a book of this kind there ought to have been prepared first of all a carefully drawn up series of questions on the points where the culture of all Eastern products touch, and then after that queries on the special ones. By this means there would have been less chance of such omissions as I have referred to. This was more especially called for as "The Planting Molesworth" aims at supplying a general want in the East, a tropical planter's *vade mecum*, in fact.

The information under the heading of "tea" is very full and of an exceedingly varied character. You can learn all about tea seed, the average task of a cooly at the different works in a tea garden, the cost of opening, detailed price of curing: facts and figure regarding choolas, hoop iron, bins, firewood, tea-boxes, tea lead, solder, nails &c., &c. But comprehensive as the list is there is much a-wanting, and which ought to find a place in a future edition. There should for example be a series of tea-house notes, regarding the manipulation and curing, and also guides to tea-tasting.

It is a very easy matter, however, to go on suggesting, and in works of this kind one is apt to overlook and undervalue the really useful and comprehensive nature of the information which is already supplied. But I have no desire to do this, for I feel sure that to all planters experienced or inexperienced alike, "The Planter's Notebook" will commend itself, by its own inherent worth. It will afterwards become more and more precious, as the blank pages get filled with "tips" and "wrinkles" supplied by neighbours or worked out and discovered by the individual writer. As it is, the practical knowledge which has been compressed into the 52 pages of letter-press, would if written out in long-hand have more than filled the whole note-book had it all been available, and anyone who had been in possession of such a note-book would have been inclined to look upon it as invaluable. Such a source of information could only have been in the hands of the experienced, whereas a beginner can now leap as it were into the wisdom of the tried, and save himself a world of worry by a reference to the notes in "The Planting Molesworth."

In the preface the publishers "apologize for the rather rough appearance of the blank paper and binding as arranged by native workmen," but although we live in a refined age, and even wish one's attention drawn to these defects, I feel inclined to say "no

* Tropical Planters' Note-book, published by A. M. & J. Ferguson, Colombo, 1887.

need for any apology." There is, however, a want of a pencil, or a place to hold one, which is somewhat noticeable. I don't know that there is any need to add more on this new venture. The publishers seem to have somewhat lacked confidence in it when the introductory note was being drawn up, for they say "In now issuing the little work we are conscious of many imperfections—to be remedied *perhaps* in a second edition should such be called for." I have a great deal more faith in its future than that; for, although to Mr. R. B. Arthur of Dikoya has been awarded the honour of suggesting the work, I incline to dispute his right as it has been a pet project of mine for a long time, and early in May last year I suggested in your own columns that in the series of planting manuals issued by the *Observer* press there was an unoccupied niche for "a Planting Molesworth." "He kens his ain groats amang other folks' kail" you will be inclined to say after this little bit of purely personal matter. PEPPERCORN.

[To "Peppercorn" certainly belongs the suggestion of the title "Planting *Molesworth*", and we are sorry to find we omitted to make acknowledgement for this and aid generally.—ED.]

GRASS UNDER TREES.—When difficulty is experienced in keeping grass green under trees in open woods, particularly pine woods where the shade is continuous the year round, sow a little nitrate of soda occasionally throughout the growing season when the weather is moist. This will bring a fine crop of verdure pleasing to the eye and agreeable to cattle.—*Journal of Forestry.* [A hint for owners of coconut plantations?—ED.]

LIQUID MANURE.—To prepare a strong liquid manure, fill a tub with water, into which throw fresh cow manure, pigeon's or fowl's manure, guano, bone-dust, &c., either one or more of these matters may be used. The vessel should not be covered, but the air should have free access to the liquid. It should also be stirred up from time to time. As soon as fermentation sets in, it is ready for use. It should be poured through a sieve into the watering can, and applied to the plants in the morning or evening. It is advisable to dilute this with water if it should be too concentrated, as then it is injurious. Experience and observation of its effects will soon teach whether it is too strong or not. —*Rural Australian.*

PADDY CULTIVATION IN THE GALLE DISTRICT.—Some time ago we mentioned that Mr. William Jansz obtained some seed paddy from Batticaloa with the object of improving the cultivation of the grain in the Southern Province. The result of his experiment has just been communicated to us. In November last one bushel was sown in a field at Halpatotte near Baddegamma, under the supervision of Mr. L. Christie, the Superintendent of Gordon tea estate. The land selected was not very advantageous. A crop had been taken from it scarcely six weeks before, and there was no time for it to be fallow. In addition to this, there were other adverse circumstances. A portion of the crop was destroyed by cattle, and the seed which had been sent from Batticaloa had got mixed, as when a portion of the paddy had ripened, it was observed that a second and more luxuriant crop was coming up. It was decided not to cut the first crop with the view of preserving the second, with the result that the former, as also a third crop, were wasted, showing that three kinds of seed maturing in three periods had got intermixed. The second crop yielded 11½ bushels to one bushel, while not one of the neighbouring fields sown with ordinary grain gave half the quantity. Mr. Jansz is now assured that but for the adverse circumstances above referred to, he would have obtained 25 to 30 bushels to the bushel. The experiment was closely watched by the Sinhalese agriculturists of the neighbourhood, who were very doubtful of its success and did not therefore care to try it on their own account. They have now spontaneously come forward in praise of the new cultivation, as several letters addressed to Mr. Jansz in Sinhalese will show. We may add that the paddy thus grown has no beard like the ordinary Sinhalese paddy. It closely resembles the grain imported from Rangoon and Chittagong, and its increased cultivation will, no doubt, tend to benefit a large section of the native population in the South. Mr. Elliott, the experienced Government Agent of this Province, was the first to recognize the utility and encourage the adoption of Mr. Jansz's scheme. He at once ordered a supply of the seed to be distributed amongst some of the District Mudaliyars, and the result of the trials made by them will, no doubt, be reported in due course. In the present instance Mr. Jansz was careful to avoid high manuring, only the ordinary methods of cultivating the grain were adopted.

PREPARATION OF PARCHMENT COFFEE IN EUROPE. —We quote as follows from the *Singapore Free Press*:—38, Mincing Lane, E. C., 13th Nov. 1886.—Dear Sir,—Referring to the conversation I have had the pleasure of having with you a few days ago, there are two bonded wharves in London where suitable machinery has been put up for peeling and sizing coffee in parchment, viz., "Red Lion Wharf" and "Metropolitan Wharf." I have had several opportunities of seeing coffee worked at both places, and have no hesitation in saying that both do their work exceedingly well. In addition to the experiments I mentioned to you, where E. Indian coffee has realized 4s to 5s per cwt. nett more, when prepared in London, Costa Rica, New Grenada, and Guatemala, from 8s to 12s per cwt more, I have had a parcel of Liberian imported in parchment from Johore treated at Red Lion Wharf and the result has been a pale yellowish coffee much better looking than the ordinary dull brown and greenish Liberian and I have sold the same in public auction at 57s 6d for the large size and 52s 6d for the bulk, instead of 49s to 50s the price of ordinary Liberian. I would not, however, recommend sending Liberian in parchment to be worked in London, as the parchment is very coarse and heavy and there must be a much greater loss from the weight of the parchment, than with the Ceylon Liberian, for instance. For plantation coffee, such as is exhibited from the Perak Experimental Hills, some of which appears to have suffered from damp or in preparation, I cannot help thinking that it would be of great advantage to send the parchment to London. I assume, of course, that the coffee has been picked at the right time, that it has been pulped at once and carefully, and that the clean parchment has been properly dried; those conditions are absolutely necessary, and, if they are observed, I have little doubt that the parchment will have been found to have preserved the colour and quality of the berry in a remarkable manner, and that the result will prove to be very satisfactory to the planter. The extra freight to be paid on the parchment may perhaps be 1s per cwt. whilst the coffee will probably realise 6s or more in excess of what it would have done otherwise. I may add that the whole of the plantation Java crop (from 250 to 300,000 bags) comes now to Holland regularly in parchment; some of our Dutch friends have tried London lately with a few parcels of parchment and have expressed themselves as highly pleased with the way their coffee has been treated. Should you wish to see the working of coffee, I shall be happy to arrange to take you to one of the wharves on any day which may suit you. I should have been glad to have sent you a copy of one of my reports on coffee, but the report belongs to the Royal Commissioners and the Society of Arts, and, until it has been published by them, I am precluded from making any use of it. I remain &c., H. PASTEUR,

F. A. Swettenham, Esq.

Correspondence.

To the Editor of the "Ceylon Observer"

ELECTRICITY FOR TEA MACHINERY.

SIR,—With reference to Mr. Grigg's letter of October 25th upon the above subject, I should like to give with your permission, some practical information concerning the transmission of power by means of electricity. It is a most interesting question and when thoroughly understood, will, I have no doubt, be of the greatest importance to employers of machine-power within reasonable distance of water-power.

Until recently, one of the chief stumbling blocks to the employment of electricity was the difficulty of obtaining a cheap and efficient electric motor for converting the electric current into mechanical power; this has now been entirely overcome and motors can easily be obtained having an efficiency of at least 80 per cent and higher according to their power. The dynamo for generating the electricity has also been considerably improved especially as regards regulation, and, therefore, this part of the question may be dismissed as having been practically solved.

The remaining question now is that occasioned by the wires conveying the electric current, this unfortunately is the prohibitive factor where power has to be conveyed over great distances. Of course where waterpower is used, this loss does not matter so much if there is an abundance, as the working cost is in no way increased, though the first cost is owing to a larger generating machine being required. It is impossible to give a fixed rule for determining the loss of power per mile in the conductors, because this is dependent upon their size and, therefore, cost. It is a question for the employer of the power to decide according to the circumstances of the case, weather he increases the first cost of the conductors and therefore decreases the loss of power or the converse.

Now as regards the first cost, I will give some figures showing the approximate cost of an electrical plant (in London packed) for transmitting 10 horsepower 1, 2, 3 and 4 miles. The plant includes the generating dynamo, motor and necessary length of copper conducting wire:—

Distance in miles.	Loss in the conductors.	Approx. power required at generator.	Cost of conductor.	Cost of plant including conductors.	Weight of motor.
	Per cent.	H. P.	£	£	lb.
1	15	16	32	320	550
2	30	18	64	350	
3	30	18	158	435	
4	40	20	200	480	

Added to this must be added the loss in the motor say 15 per cent and also that of the generating dynamo say 10 per cent.

The figures given in the column of "loss in conductors" may be very considerably reduced by using currents of much greater tension, but as these become dangerous I have not thought it worth while to go into that part of the question, seeing that what is required is a practical solution of the problem for employers of motive power not having any special knowledge of electricity.

Among the important advantages that electricity offers as a motive power is that the current can be used for lighting any buildings on the estate when not used for the machinery. As an example the above would work 10 arc lamps of 2,000 candle-power each or 90 incandescent lamps of 20 candle-power each, and finally store the electricity in accumulators when not required either for lighting or power.

The maintenance of the plant when once erected would be very small indeed. I do not think that the damp climate would affect the dynamos as suggested by Mr. Griggs as the wires are made of copper and covered with insulating material.

Apologizing for the length of the letter,—Yours &c.,

F. GEERE HOWARD, Electrical Engineer.

36 Cleveland Street, London W.

ABRUS PRECATORIOUS.

Minuwangoda, 21st Feb. 1887.

SIR,—While perusing the current number of the *T. A.* today, I came across that the seeds of the *Abrus Precatorious* are an official drug recently introduced to Ceylon and America.

The *Abrus Precatorious* called *olinda* in Sinhalese is a creeper which I have seen growing abundantly in the low-country. The leaves have a peculiar sweet taste and the seeds are scarlet with black spots. The seed of this may be collected if there is any market value. Kindly, Mr. Editor, see whether there is any market value for it, if so, it will become a good minor industry for the poor interior goyas—and perhaps it may be cultivated to a large extent with profit.—Yours faithfully,

W. A. D. S.

The *American Grocer* says, that a French savant claims to have discovered in cotton-tree seed a nutritious matter, presenting some most remarkable features in its composition. An analysis of the seed of Cotton trees, of which several varieties are cultivated in Bolivia, shows that this is the richest of all known grains in nitrogenous substances. He is convinced that Cotton-tree seed will make a flour destined to take an important place as a food for man.

AN American paper has apparently become very philosophical, and puts forward the following remarkable observation:—"A life devoted to the extermination of cockroaches is nobler spent than a life devoted to the gathering of Orchids." This will perhaps prove an alarming discovery to some similarly thoughtful readers, but we do not anticipate that many will be induced thereby to undertake the "nobler" employment.—*Journal of Horticulture.*

NOVEL METHOD OF POULTRY RAISING.—A French correspondent of the *Phenix Agriculturist* gives the following novel methods with poultry in one of the departments of France. He says:— The farmers in the department of the Tarn raise large quantities of fowls which they sell at considerable profit in the neighboring towns. Their hens are carefully chosen with special reference to their laying qualities, for long before artificial hatching was generally practiced, these managing people had found a way to hatch chickens without hens. One turkey hen can cover thirty eggs and can be made to hatch three sets of eggs the same season. But if she can hatch three sets of eggs she cannot raise three sets of chickens at the same time. To obviate this difficulty a fat capon is shut in a basket with four or five little chickens, the baskets covered with a cloth and placed in a dark spot from twenty-four to forty-eight hours, according to the tractability of the capon. When turned out with his chickens and others added, for he can take care of twenty-five, he is a better nurse and provider than the hen herself. He is larger and covers them better, is stronger and better able to defend them against birds of prey and other enemies. —*Southern Planter.*

SCIENTIFIC NOTES.—The deepest boring yet made is at the village of Sc ladebach, Prussia. It has been made by the Government to test for the presence of coal and was bored with diamond drills. Its depth is 4500 feet, its breadth at the bottom two inches, and at the top 11 inches. It has occupied 3½ years to bore, and cost a little over £10000. The temperature at the bottom is 118° Fah.—*Southern Planter.*

SUBSTITUTES FOR BOXWOOD.—Sir Villiers Lister calls attent on to the following passage in Mr H Romilly s "We tern Pacific and New Gui ea" (Mu ray , p. 136. "The Trisbands.....are exceedi gly rich islands, and produce various sorts of woo i not met wi h elsewh re, unless perhaps it be on the mainland of New Guinea. There is an extremely hard white-wood which I have never seen except from the Trisbands. It looks a most like ivory when polished, and should be of service for cabinet-making."—*Journal of the Society of Arts.*

FENCE POSTS.—A writer in *The Maine Farmer* thus expresses himse'f in regard to setting fence posts:—It has commonly been stated that posts set top end in the ground would last longer th n when set with the butt end down. We recently had occasion to remove a fence which had been set eighteen years, and to our surprise the posts set top down were still sound and strong, while many of those set the reverse were rotted entirely off. We have before found evidences of the greater durability of posts set in this way. If general experience corroborates our own, it is a matter well worthy of wide attention.—*Indian Gardener.*

THE PLANTING MOLESWORTH.—This, the latest addition to the long list of useful publications issued by Messrs. A. M. & J. Ferguson f r the tropical plant r, is not the least valuable. Whether to the old experienced planter or to the tyro, the planting Molesworth will be very handy owing to the many useful tables it contains, and to its size permitting of insertion in the pocket and ready reference. Whether for factory or field work, the little volume will afford all young planters more instruction than years of practice, and every Superintendent would do well to provide his Assistant or Conductor with a copy of this handy and useful compilation. As is to be expected, the bulk of the "Notes" relate to tea. We leave the criticism of the figures to those most competent to deal with them—pra tical tea planters. All tea planters are not necessarily engineers, although many engineers are tea planters, and the "Memoranda for the economical working of Machinery" will be specially useful for those, and their name is Legion, who have to work machinery, the deterioration of which is generally due more to ignorance in working it than to inevitable wear and tear. There are a few hints on coffee, which will not be found to be new to those actually engaged in the culture of the old king. We believe there are at present no new hands on coffee plantations, tea estates absorbing all the new arrivals. Cinchona, cocoa, cardamoms, castor oil, coconuts and cinnamon receive as scant attention as coffee. Strange, that with the exception of tea, all the principal products of the Island, like its name and its capital, begin with a C. We have not the space to comment critically on all this useful little book contains; but we may remark that cinnamon must be giving little or no returns to those engaged in its cultivation, for, according to the information supplied by an "old Planter," the yield of an acre is a bale of 100 lb., which at present market rates=R28. The cost of weeding an acre per annum is R10. Pruning R6. The cost of cutting and peeling is not given, but averages, with Cangany's wages, about R16 per bale, total R32, shewing a loss of R4 per acre, without taking into consideration the cost of supervision, transport, buildings &c., and yet many are still engaged in its cultivation, and make a profit out of it too! How is this managed? Those whose cinnamon fetches R28 per bale do not cultivate it, and gradual extinction of these places is going on, while those who cultivate their estates and pay particular attention to manufacture, manage to nett something more than R28 for a bale of their cinnamon; but the profit, if any, is cut very fine now-a-days.—Local "Examiner."

PRODUCTION OF CREAM OF TARTAR AT MESSINA.—According to the annual report of the Chamber of Commerce of Messina, it will be seen that a marked increase in the exports of cream of tartar from that port has taken place during the last three years, being as follows:—1883, 3,500,000 kilogs.; 1884, 4,155,671 kilogs.; 1885, 5,721,597 kilogs.—*Journal of the Society of Arts.*

EXPORTATION OF FOWLS FROM ITALY.—Formerly the greater part of the fowls sent to Marseilles was furnished by Gascony and Languedoc; now Italy supplies the greatest number, and chiefly Lombardy. Italian fowls also are sent to Spain. Every Friday a specially constructed live poultry truck arrives at the Marseilles railway station. It is of similar dimensions to an ordinary covered goods truck, and contains about 3,000 fowls in 108 hencoops. The truck consists of nine tiers of cages, twelve to each tier, and each capable of holding thirty fowls. Being well ventilated and kept scrupulously clean, and supplied with an abundance of fresh water and millet-seed, the fowls from Milan and even Venice, arrive at Marseilles in the best possible condition of health, and large numbers are likewise forwarded to Spain —*Journal of the Society of Arts.*

THERE has been a coffee famine in Rangoon in the past few weeks, occasioned, it is supposed, by the large quantities sent upcountry for the troops. Anyhow, says a correspondent, the price for several days rose from one rupee per viss (3⅓ lb.) to R2·4 and R2·8 per viss. And yet excellent coffee grows in the vicinity of the town, and the climate of most of the Lower Burma stations seems excellently adapted for the production of any quantity. It is strange that in a large city like this, with so many stores where every description of English and Indian supplies can generally be got, they allow themselves to run out of an article in such general use with all classes of the community. Yet such has been the case in Rangoon with coffee.—*Madras Times.*

USES OF HOPS.—The hop is not only known as an ingredient in beer-brewing. Its tender tops serve the Belgians for asparagus, an infusion of its flowers yields a well-known yellow dye for wool, its stalks yield a flax that in Sweden is woven into cloth, and a bag of hops is often used in medicine to allay inflammation. The strong bitter odour of the ripened bloom has a strangely exhilarating effect in cases of despondency, and the dried hop itself has curious sleep-beguiling properties occasionally taken advantage of in critical cases. When the Prince of Wales was so seriously ill at Sandringham, a pillow of hops was used for him to sleep on. When his great grandfather George III. lay sick almost to death in 1787, a hop pillow was also used. And in each case the recovery is claimed as a triumph for the *Humlus lupulus.*—*Leisure Hour.*

THE FLORA OF AUSTRALIA.—Baron F. Von Müller, K. C. M. G., has just completed and issued under the auspices of the Victorian Government a second supplement to his Systematic Census of Australian Plants. From the information now published it appears that while the known plants of Australia and Tasmania are about 9,000, they occur in the following proportions in the respective colonies: Western Australia, 3,455; Queesland, 3,457; New South Wales, 3,154; Northern Australia, 1,829; Victoria, 1,820; South Australia, 1,816, and Tasmania, 1,016. The progress of Botanical discovery in Australia within the last quarter of a century has been very marked, says the *Colonies and India*, and the Colonies are mainly indebted to Baron Von Müller for this result. At the beginning of the century (1805) Robert Brown, who may be styled the father of Australian Botany, returned to England with between 3,000 and 4,000 species of plants, and these in subsequent years he described in his "Prodromus Flora Novæ Hollandiæ et Insulæ Van Diemen." Since Brown's work no systematic addition was made to his labours until Baron F. Von Müller, considering that the time had arrived for the publication of a general flora of Australia, prepared in conjunction with Bentham, the seven volumes of the "Flora Australiensis."—*Indian Gardener.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, February 3rd, 1887.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.

COCONUT CULTIVATION AND IRRIGATION.

We have received through Mr. W. H. Wright some particulars of a very interesting experiment made by Mr. Akbar in irrigating coconut-palms on an extensive scale. Mr. Akbar is proprietor of the Siramgapata and Tuisava estates, covering 614 acres in the Katukenda division of the Negombo district, Alutkuru-korale. His average yearly crop has been from 900,000 to 1,000,000 nuts. On this property he has expended about £1,000 in machinery, chiefly powerful force-pumps, with some 15,000 feet of cast-iron piping, 4 inches diameter, besides 12,000 feet of other spouting. The property being some 150 feet above the Maha-oya, which forms its boundary, the water of the river is pumped up and distributed in channels among the coconut-palms, with a result which, after personal inspection, has astonished so old a cultivator and planter as Mr. Wright is himself. During the first day's work some 20 acres of very dry land were irrigated, and the effect on the drooping palm-trees was almost immediate and very striking. The coconut-palm is a very thirsty plant, and has the faculty of very quickly appropriating liquid brought within its reach, so that, on this occasion, it seemed to drink up the irrigating water at once. Mr. Wright has no doubt that the experiment will prove a thorough financial success in giving bigger crops of nuts, steadily, season by season, while maintaining the trees in full vigour.

Mr. Akbar also shows an example of capacity and enterprise, we learn, by manufacturing his own oil and coir, while, we suppose, he is the first Ceylonese to lead the way with an experiment on an extensive scale, such as above-described, in irrigating coconut land with river water, drawn and distributed by force-pumps.

As regards coconut cultivation generally, Mr. W. H. Wright is now experimenting on his own account in the Mirigama valley, and he is likely to show what can be done through manuring and high cultivation. Although a comparatively dry region, Mr. Wright says, the palms flourish in the good deep soil, sending their tap-roots far down. By judicious clearing of his land, leaving the large trees for shade for a year or two, by making large holes and burning *debris* to ashes therein, he is also able to plant his coconuts at almost any time of the year with satisfactory results. As to what may be done by manuring, Mr. Wright has already proved in his garden at "Wilhelmsruhe," Turret Road, where by careful planting, good soil and manuring, he has succeeded *in bringing coconut-palms into bearing, in three years!* Six to eight years have been considered the minimum hitherto under the most favourable circumstances, and, of course, an exceptional garden experiment cannot be taken to regulate a plantation. But it is evident that, granted good soil and careful planting with the means and opportunity for manuring, there is no reason why coconuts should not begin to repay in crops after five and six years. This, in fact, is the term given by Mr. D. Morris for bringing coconut plantations into bearing on the littoral of the West Indian islands, where, Mr. Morris says, there is great scope for the extension of the cultivation with the prospect of a clear return of £5 or £6 per acre per annum. In the favourite Madampe district, in Ceylon, where coconuts are being widely planted, seven to eight years is the term allowed for trees to come into bearing, and, meantime, a European gentleman who has gone in for coconut cultivation there, gets a fair return by cultivating plantains between his young coconuts.

TEA SEASONS IN INDIA AND CEYLON.

Although here in Ceylon, within 7° of the equator, we have no winter such as the Darjiling and Assam tea planters experience in 20° farther north; yet, as our readers are aware, there are two periods of the year, when, over a large portion of Ceylon growth is checked, and flushing,—though it never entirely ceases,—is considerably diminished. One of such periods extends from January to March and is distinguished, especially in the hill country by cold temperature at night and in the mornings and by north-east winds which are occasionally parching. Such winds have been especially prevalent from December of last year until now. This period is, so far, our winter,—from about the middle of December to the end of March,—although when rain falls freely, as it sometimes does in January, tea is harvested in quantity in this season. Then a second check to the luxuriant growth of tea occurs, on places exposed to the full force of the South-West monsoon, in the months of June and July. The rain alone, which falls so copiously in those two months would promote, rather than check growth, but for the fact that it is attended by chilling winds and obscuring cloud. Some hold the opinion that pruning ought to be performed in those months,—months in which our neighbours in India pluck their heaviest crops of leaf.

Looking over the series of valuable tables which Mr. Sumner Hogarth has placed at our disposal, we find that in the large proportion of Indian tea districts, December, January and February are blank months, while March and April do not count for much. The tea harvest extends from May to November, the bulk being gathered in the five months, June to October. In the richest bearing district, Luckimpur, the bulk is really gathered in three months, July to September; 40 per cent of the whole being on some estates gathered in August and September. We have often remarked how tolerant tea is of heavy rain, how it rejoices in moisture and now we find that the tea harvest is synchronous with the rainy season and not only so, but as a very general rule the quantity of tea gathered is, month by month, in proportion to the rain which falls. August is, we believe, the hottest month in Assam and it is one of the rainiest. The absence of strong cold wind is doubtless the great reason for overflowing crop in the rainy months. There is the inconvenience that the conditions most favourable for growth should be the least favourable for withering, and no doubt this is the reason why artificial heat is so much resorted to and good "withering" machines so much desiderated. In most parts of the tea districts of India some seventy per cent or more of the rainfall occurs in the four months, June to September, and about a similar proportion of the crop is harvested in those months. As was the case formerly with our coffee planters who had a rush of work in crop time and then a lull, so it seems to be with the tea planters of India. For the five months, June to October, they must often be driven to their wits' end to secure the harvest, while December to April are comparatively, holidays. Here in Cey-

lon there is no absolute cessation of growth and consequently no intermission of work. Only twice a year, in most years, will there be less to do—in the dry North-East and the wet South-West months,—and the question may be raised, whether both planters and plants might not be benefited were "flush" allowed to pass into "bangy leaf" during one month of each monsoon.

In a future issue we shall compare Ceylon figures with Indian, on this interesting subject.

WONDERFUL DISCOVERIES: INDIARUBBER IN WOUNDS.

The medical journals for the past ten years have given accounts of wonderful discoveries in surgical science, and of their application in practice—the filling of large, deep wounds with sponge, and the organization and assimilation of the latter; skin-grafting, bone-grafting, and the successful adjustment and regrowth of fingers. Recently two other wonderful discoveries have been reported. One is the organization of rubber within the animal tissues; the other, the organization of blood-clots, their formation into new tissue, and the application of them to the surer and better healing of surgical wounds. As to the first, it appears that Professor Vanlair, of France, had, in a certain case, inserted a drainage-tube, of ordinary gray vulcanized rubber, one and one-fourth inches in length and one-fifth in diameter, and that this, at the end of seven months, seemed to have undergone partial absorption. But, on examining it with a microscope, it was found that the substance of the rubber had become truly organized; that the lower end of the tube had become fully assimilated to the surrounding tissue, and had wholly lost its original form; that the part of the tube next above this had lost its original shapeless appearance, and had acquired a complex structure, showing fine connecting tissue fibres with cells of various forms between them, and very numerous capillary blood-vessels.

Says the *Medical Record*:—"That Indiarubber can thus become organized is the more remarkable when we consider that it is a pure vegetable exudation, devoid of all structure, and seemingly more calculated to act as a foreign body and so prevent the union of the wounded surfaces, than to undergo organization to and become thus and integral part of the animal tissue."—*Companion.*

COFFEE IN THE STRAITS.

A French newspaper, the *Univers Commercial*, thus sets forth the advantages of Johore and Singapore, for coffee growing:—Judging from the latest and most trustworthy advices in coffee estates in all lands where the article is grown, there prevails a disease which, according to many is nothing more or less than the blight which seizes upon the vine plant. It bears the name of *Hemileia Vestatrix*. Ceylon, where formerly coffee was largely cultivated, grows now but little. The plantations in British India are in danger of going the same way. Those in Java are also imperiled, and the Brazilian ones fare no better. We must draw attention to the circumstance that it is only the Arabian variety which becomes stricken in this fashion. But another kind, called Liberian, brought from the west coast of Africa, which, in the fertile soil of Brazil, reaches sometimes the height of forty feet, does withstand the disease, at least so it is reported. Mr. L. E. Chassereau one of the most experienced planters in the East Indies writes as follows regarding this subject: Now that coffee growing has in general fallen off in consequence of this disease, which has gained a firm foothold in all lands producing that article, it would be worth while to set up a company for starting large plantations of Liberian Coffee in the island of Singapore and in the State of Johore. These plantations are expected to take up 3,000 hectares (about 7,500 acres.) An undertaking like this may be successfully set on foot in the abovementioned countries where coolie labour never falls short of the demand. The climate of Singapore and that of the whole Malay Peninsula, as well as the composition of the soil, are admirably adapted to the coffee tree. In time of drought Arabian coffee trees lie under a serious disadvantage owing to their roots not going down deep enough. The roots of the Liberian variety, on the contrary, strike out so vigorously that they easily find their way to a great depth in search of the moisture they need. A plantation taking in 1,000 hectares would require a capital of about 900,000 francs. It is undoubtedly pretty well known that the production of coffee which begins when the tree attains its third year of of growth, reaches its utmost limit in the sixth year. But, so says Mr. L. E. Chasseriau, a plantation of the above mentioned acreage at that period represents a value amounting to a couple of millions of francs. The island of Singapore is one of the healthiest spots on the globe. The larger of the plantations could be utilised as a nursery of young planters who, in two or three years, would lay in a stock of experience and knowledge sufficient to admit of their setting up for themselves in this difficult line of business. These young planters would do well in that case to betake themselves to Cochin China, Cambodia, Annam, and Tonquin. In these countries both climate and temperature are highly suitable for the coffee plant. France, which has extensive colonies in that quarter of the world, might materially profit by this advice from Mr. L. E. Chasseriau. In Tonquin and the other countries named, coffee might flourish free from leaf disease.

TEA IN FIJI.—The reports for tea from the plantations still continue very encouraging, and the reports of exports upon the product could not well be more favourable. One sample of flowery orange pekoe is marked as worth from 7s to 8s per lb. in London.—*Cor., Sydney Morning Herald*, Jan. 4th.

J. K. ARMSBY ON COFFEE.—The following characteristic paragraph is from the *American Grocer*: Mr. J. K. Armsby has been looking into the coffee question. This is what he finds:—

Coffees are just humping themselves; you could not keep them down with a pile-driver. Arbuckle, who has been on the bear side and has been trying to sit on our boys who have been on the other side, has paid for his mistake and has confessed his sins, and is now singing just as high notes in the coffee chorus as anybody. They think that the market is going up because the crop is short, but while the stock is short now, yet the crop was reported a large one, and that is what fooled Arbuckle. He couldn't tell what had become of the coffee, but the writer has found out. Al. Whyland knew all the time, but he kept the thing quiet, but last week he sent a can of his Momaja coffee, and the secret was out. The blarmed stuff is so good that everybody takes three cups instead of one, and are drinking it three times a day. Nobody wants tea—everybody wants Momaja. Look at the tea market, and then at coffee! What makes the difference? Momaja. Oh, Whyland is a twister! If he has a customer come in that is a little hard bitted he gives him a dose of Natrolithic Water to take the old brown taste out of his mouth and then gives him a cup of Momaja, and the fellow wants to buy everything in sight.

PREPARATION OF HIDES IN SOUTH AMERICA.

A Buenos Ayres newspaper calls the attention of stock breeders to the fact that the hides of cattle in many cases lose a great part of their value on account of the careless way in which they are stripped from the slaughtered animal. Calf skins and sheep pelts are often reduced one-half in value by being gashed and improperly stretched. When a hide is stripped off, it should be stretched at once and pegged out to dry, with the flesh side upward. If it is rolled up, thrown into a heap, and left to dry in that shape, it is so mean looking that a buyer will only offer half its real value. A few hints as to taking off a hide will be useful. The skin is slit from the chin down the brisket in a straight line to the tail; it is then cut round each hoof, the hind legs are slit behind over the gambrel, but the front ones are slit up in front over the knees. This leaves the skin in a good shape for finishing the leather. The head and legs are first carefully skinned, taking care to avoid cutting the skin. The skin is then easily drawn off, by taking hold of it firmly and pulling it steadily. It is then spread out evenly on a floor, and sprinkled with fine salt. If there is but one, it is best to take it out as soon as the salt has taken, and dry at once in a cool shady place. If there are more than one, then they are laid upon each other, and salted freely, and afterwards thoroughly dried. If the skins are to be kept, they should be closely watched for moths or grubs.—*Journal of the Society of Arts.*

WILD MANGOES.

(BY C. MARIES.)

The *jungli âm*, which is the original stock of all our fine mangoes, is not often met with in its native habitat, and less frequently in fruit. I have just received a few fine specimens of several varieties of jungli mangoes. From the fruits, it appears they vary quite as much as our cultivated ones; and as to shape, they are the exact counterpart in miniature of many of our best varieties. My specimens came from the Kangra valley, and were collected by a gentleman much interested in the fruit. I once saw the true *jungli* mango in the Dooars, and again afterwards growing at an elevation of about 2,000 feet in Sikkim. It is very unlike the cultivated sort, having generally a straight trunk, whitish, smooth bark, and thin leaves, forming a fine, round-headed tree. The fruit rarely weighs 2 oz.; often only 1 oz. The common country mango called "Beju" or "Desi," in Tirhoot, is really an inferior kind of cultivated mango, and not the proper wild mango of the forests.

Wild mangoes are found from India through Malay to Manillâ and some of the Pacific islands, and it is not really known if there is more than one species. The wild and cultivated sorts are so widely different in shape of fruit, that they could almost be called distinct species, but every intermediate connecting stage may be found to bring them under one head. The flowers of the wild and cultivated mango are exactly the same in structure, except that in the wild one there are often more stamens fertile.

It may not be known to most people that generally in a mango flower there is only one stamen out of the lot fertile; this one is curved round just over the pistil in a peculiar way, to facilitate the fertilization. The so called "nak," or nose of the mango, is the place the pistil adhered to in the flower. All this can be plainly seen with a moderately powerful reading glass or lens when the mangoes are in flower.

PROTECTING MANGO FRUIT.

A very good way to protect mangoes from the attacks of birds and insects is, get a lot of very finely-woven, round bamboo baskets made, say 4 inches wide at top, 5 inches at the bottom, and as long as may be required for the fruit; see that there is not room for a fly to get in through the basket-work. Then put the mango inside as it hangs on the tree, push a long thin peg through the top of the basket by the side of the stalk of the fruit on one side, and another similar peg on the other side, and the mango will hold the basket up itself; then tie a little calico over the top of the basket, taking care not to tie the mango stalk, and also to completely shut up the top of the basket. The mango stalk must be quite free, because when the fruit is ripe, or nearly so, it will fall of its own accord, and will be found to be just fit to gather. If a net be suspended under the tree, then all danger of bruising the fruit will be avoided. Then shake the tree to gather only the ripe ones. These should be kept on a "machan" for a few days till quite ripe, as all mangoes improve by keeping a little, and should never be eaten perfectly fresh from the tree.—*Indian Agriculturist.*

LICHENS INJURIOUS TO FRUIT TREES.

The following from the American *Gardeners' Monthly* has a bearing on the treatment of tea bushes infested with lichens. Rubbing off the foreign growth is no doubt expensive, but it certainly must be beneficial:—A New Jersey correspondent says: "Will you please give me the name of the inclosed moss, which I find growing in company with unlimited quantities of lichen on a lot of old cedars on the river bank in front of my cottage. As these trees, knarled and twisted as they are, are very necessary to me, I have amused myself for a week past, scraping the lichen off.

"I know that the lichen is not regarded among botanists as a true parasite but as an epiphyte. But I am satisfied from my own observations the past week, that the lichen is almost as deadly in its embraces as the mistletoe or the fabled Upas tree itself—though possibly longer about it.

"Small limbs, twigs, and sometimes the entire tree, if fairly girdled with the lichen, are dead in most cases or dying. The lichen has a strong affinity for moisture and very retentive thereof—trees on the river bank, more or less damp from exhalations from the river, have much lichen upon them—while the same tree (cedars) a hundred yards back have little or none.

"On lifting a piece of lichen from the tree I find the spot beneath invariably damp or even wet and the bark discolored, and generally more or less rotten or doted, penetrating in some cases to the wood. 'Tis, in my opinion, this wetting process that destroys the twig, limb or tree. But whether the lichen does it with 'malice prepense,' as a lawyer would put it, I am not botanist enough to determine.

"Will you please enlighten me on this point, for I am not a little interested in the lichen."

[The old gardeners—whose practice was often better than their reasonings—always insisted on the advantages of scraping lichens from the bark of fruit trees. But modern gardeners teach that if fruit trees are properly cared for they will throw off lichens themselves. In other words, the existence of lichens is a sign of bad health. Scraping the bark or any other thing that "injures or closes the pores," as these good people say, is regarded as an evil. We have, however, seen so much good result from slitting the bark of hide-bound trees,—lime washing those covered by lichen or moss,—and soap cleaning trees that were even in fair health, that, though our natural tendencies are with scientific progress, we are compelled to admit that the practice is good, and therefore to believe that mosses and lichens may have, as our correspondent believes, some injurious tendency, quite aside from the general belief that they feed wholly on dead bark or other meterial.—ED. G. M.]

HOW TO CLEAN A BOOK WITHOUT INJURY.

An adept in the art of washing or cleansing dirty books sends to the *Publishers' Circular* a few plain directions to be followed by those who wish to cleanse their soiled volumes. The amateur book cleanser had better begin to practise on some worthless volume until he acquires the necessary skill. All traces of lime, acid, etc. used in the cleaning process must be removed from the book, else in time it may be entirely destroyed.

The first thing to be done in a book that wants washing is to cut the stitches and separate the work into sheets. Then a glance may be taken for the separation of those leaves or sheets which have stains of ink or oil. The dirty leaves are now placed in a bath composed of a quarter of a pound of chloride of lime and the same quantity of soda to about a quart of water. These are left to soak until the paper has regained its proper tint. The pages are now lifted out tenderly into a second bath of cold, if possible running water, where they are left at least six hours. This removes all traces of lime. The paper, when thoroughly dried by exposure, must be dipped into a third bath of size and water, and again laid out to dry. This restores the consistency of the paper. Pressure between printers' glazed boards will then restore smoothness to the leaves.

The toning of the washed leaves in accordance with the rest of the book is a delicate process, which requires some experience. Some shag tobacco steeped in hot water will usually give the necessary coloring matter, and a bath in this liquid, the necessary tone.

The process described above may do for water stains; but if the pages are dirtied by grease, oil, coffee, candle drippings, or ink, different treatment will be required. Dilute spirit of salt with five times its bulk of water, and let the oil-stained pages lie in the liquid for four minutes, not longer, then remove and wash, as before, in cold water. To remove ink, a solution of oxalic, citric, or tartaric acid should be used, but care must be taken in the washing and sizing. If the grease is a spot in the middle of a page, place between two sheets of blotting paper or cover it with powdered French chalk (the blotting paper is preferable), and pass a hot iron over the place. This will melt the grease, which is immediately soaked up by the chalk or paper.

For dirty finger marks, the following is recommended:—Cover the mark with a piece of clean, yellow soap for two or three hours, then wash with a sponge and hot water, and dip the page in weak acid and water. Give another bath of hot water and then thoroughly cleanse with cold water.

To remove ink stains: Dip the page in a strong solution of oxalic acid, then in a solution of one part hydrochloric acid and six parts of water, after which bathe in cold water and allow to dry slowly. Vellum covers which require cleaning may be made almost equal to new by washing with weak salts of lemon; or, if not much soiled, warm soap and water. Grease may be removed from the covers of bound books by scraping a little pipe clay, French chalk or magnesia over the place, and then ironing with an iron not too hot, else it will discolor the leather.—*Chambers' Journal.*

SUGAR-REFINING BY ELECTRICITY.

In the March *Sugar Cane*, page 116, we called attention to a Company which had just been started in New York for refining sugar by electricity; and we also gave a report, taken from a contemporary, of some sugars which had arrived in this country, and which, it was stated, had been refined by this process. We gave the account as a curiosity—no more believing it, than if we had been told that some one had arrived in Liverpool that morning having left New York the previous day in a balloon.

Experiments with this new process have continued to be made, with results, as reported, which are simply astounding.

Within the last few days we have seen Mr. Robertson, of Liverpool, who is interested in this company, and represents it in England. No one, we think, can converse with this gentleman, without being persuaded that he most thoroughly believes in this invention, and that it really does what is reported of it.

He told us that a gentleman in New York, in order to test the matter, had 3 cwt. of raw sugar taken to the inventor's room, for the purpose of being refined; he satisfied himself that there was no other sugar in the room except that which he had brought with him, and that there was no way by which the sugar could be replaced, except through the door, which he had securely fastened and sealed upon leaving. Within two hours he re-entered the room—during his absence the raw sugar had been passed through the machine by the inventor, and converted into refined sugar, the weight returned being within 1 per cent of the saccharine contents of the raw sugar.

An experiment upon a much larger scale has within the past three weeks been made under conditions set forth in Mr. Robertson's Circular, dated July 17, which we give at page 439, together with the report of the five gentlemen who were selected to certify to its genuineness; we notice that two out of the five gentlemen are the president and vice-president of the company. Assuming, as we do, that all is perfectly square, we think the company would have done better to have obtained the services of five well-known gentlemen who were perfectly disinterested.

The quantity of raw sugar to be refined was 80 bags—producing 40 barrels of refined sugar of "12 different sizes, from the finest granulated up to about the size of a small bird's egg;" the time occupied in the process was seven hours. These gentlemen did not witness the operation itself, but they conclude their report as follows:—"We have no reason whatever to doubt that the aforesaid refined sugar was produced by the said (Professor) Friend by his said process on the said 14th July from the aforesaid raw sugar."

The conclusion that one is driven to, with this information before us, is, that it is either a great fact or it is a great fraud. The company are about starting some works to refine, by this process, 500 tons per day. We shall therefore know in a little while which of these conclusions is the correct one.

If it is a fact, it means that we are on the eve of a revolution in sugar refining, without a parallel in its history; it means that planters in all parts of the world can, if they choose, and have the capital, refine their own sugars on the spot. It opens up besides, a market for refined sugar with millions of people in India, who, from religious belief, are now debarred from its use on account of the animal charcoal employed in refining under the old system.

The particulars of the invention may be stated to be as follows:—

"The process is an electro-chemical one which is worked by a machine, automatic in its action to a very great extent. Boiling and animal charcoal are entirely dispensed with. No syrups nor soft sugars of different grades are produced, the entire product being hard sugars in whatever forms of sizes which may be desirable to produce, that is, from finest powdered up to and including cut and pressed loaf. One valuable feature in this mode of manufacture is, that all the saccharine matter in raw sugar, whether crystallisable or uncrystallisable, under the old system of boiling and filtering, is by this system rendered into hard sugar, with a small fraction of a loss,—less than one per cent of the whole quantity. The cost of refining by this process is 2s. 4d. per ton (2d. per cwt.), and the time occupied not more than four hours."

By the favour of Mr. Robertson we have been furnished with samples of sugar refined by this process, and which are at our office, 57, Market-street, Manchester, for inspection.—*Sugar Cane.*

SUGARCANE CULTIVATION IN INDIA.

[The natives of Ceylon might take profitable hints from this article.—ED.]

The following extract from a letter received from Mr. Burrows, of Behea, has been courteously placed at our disposal by the Director of Agriculture, Bengal, and we publish it, as it will be found very useful at the present time:—

The usual Indian method of cane culture may be called *broadcast* as opposed to *planting*, as the term is understood by European and American planters. The difference in results may be approximately obtained by asking any ryot the difference in produce between *cheetwa* and *roap dhan* (broadcast and planted.)

The root of the sugarcane is a small collection of thin fibres or rootlets, there is no tap root. On these

depend the health and vigour of the plant with its long succulent stem and succession of long broad leaves; it should, therefore, be placed in the best possible condition to enable it effectually to meet the heavy demand on it.

By the native method the root is on or near the surface of the ground. The field gets 12 or 14 surface ploughings giving a seed bed only four or five inches deep. The little manure (if any is given) is scattered irregularly over the surface, a plough goes round the field in a continually decreasing circle, and the cuttings are dropped into the shallow track so made. There may be a little manure where they fall, or there may not be any. The cuttings are covered with about three inches of earth by a piece of wood drawn over the surface, a man or two standing on it, each supporting himself by holding the tail of the bullock in front of him. This surface covering soon dries; the surface is then loosened a little by the hoe, the roots being carefully avoided. A little manure may now be placed round each plant by hand, and water is let on till the field is sumberged or water-logged, thus sealing up the roots from air in plastic clay or loam compressed by the downward course of the water, and hardening as it dries. As the hoe avoids the roots, the compression of the soil around them increases just where it should be most friable. The hoeing is repeated about three times, followed by a *melwanee* watering, that is, till the ground is water-logged each time. When the plants reach a certain height, and the leaves begin to shade the field, hoeing is stopped, and as they grow, being close together with no regularity, a thick jungle is the result excluding sun and free circulation of air. Considering the nature of the plant and the work its root has to do, this treatment of it is most irrational

In Mauritius, West Indies, and other places where cane cultivation is under European supervision, the cuttings or seedlings are laid at least nine inches under the surface of the ground, either in carefully-made rectangular oblong holes in rows three and-a-half or four feet apart, or in continuous channels or furrows made by hoe; or double mould board plough, the bottom being flat, and eight or nine inches wide, that is, wide enough to receive three cuttings placed some distance from each other. A field planted in this way will take as many cuttings as are usually put in by the native method. The space between the rows need not be ploughed, only cleaned of weeds by hoe, these are left on the ground, and are covered by the earth from the channels or holes.

Previous to planting the cuttings, manure in proper quantity is spread over the bottom of the channels and mixed with a little earth. On, or in this, the cuttings are laid end to end either in single, double, or triple rows as the width of the bottom may allow, and covered by hand with about three inches of earth. The "hole" system is used in Mauritius, the ground is hilly and undulating, rain is frequent, and each hole retains what may fall into it. In India where irrigation is necessary, the channel or deep furrow method is best. After some days the surface of the soil in the bottom of the channels is loosened by hand. This may be done by women or children, whereas the hoeing of the ryot's field has to be done by men. If water is now necessary, a little is allowed to flow from one end of the channel to the other, and then shut off. As the plants rise, more earth is filled in around them with a little manure where it may be needed; the loosening of the surface, watering and filling in is repeated till the channel is filled; after which, as the plants grow, the earth is drawn from the spaces between the rows and heaped round the roots till a ridge is formed at least nine inches high over the original surface. Subsequent irrigation is given in the hollows between the ridges, the water not being allowed to reach the top of the ridges by four or five inches, which are thus left friable, and open for the action of the air and expansion of the roots.

Our ryots have for years seen and acknowledge the considerable economy of labour, water, and manure in this method as compared with their own. They have also seen the common *mongoo* cane in the district so improved that they had to be assured it was nothing else, yet none of them have had the enterprise to adopt it, though several among them have been at work on the cane fields of the West Indies and Mauritius, and know the method and its results.

Cane culture should be more of the nature of garden than field cultivation, and if done with a reasonable consideration of the nature and necessities of the plant, a third of the land, now yearly devoted to cane, could be put under other crops with no falling off in the weight of sugar produced.

The industry, as a whole, and in its details, from the preparation of the land till the crude produce is ready for the market, is in a very backward and wasteful condition; there is no reason except the inertia of the ryot why this should be so. This might be overcome, and a better rut opened out by some sustained effort on the part of Government, probably a graduated set of prizes for the best cane fields cultivated with reference to the nature and requirements of the plant. We know by experience they understand what this means when explained to them terms with which they are familiar. —*Indian Agriculturist.*

SOURCES OF SALTPETRE.

BY C. G. WARNFORD LOCK.

Whilst every miner is attracted by mineral veins which promise to yield metals, the majority overlook a class of earthy products which, nevertheless, possess considerable commercial value. Foremost amongst these is saltpetre, or potassium nitrate. The following notes on this useful salt have been collected by the writer at various times, and in various localities, and will probably be interesting to many readers of the *Journal*, as accessible information on the subject is not abundant, and some of the deposits alluded to, seem worthy of better development. The generally accepted conditions necessary for the formation of saltpetre are (1) the presence of decaying organic matter, whose decomposition affords a supply of nitrogen; (2) access of atmosperic air to oxidise the nitrogen into nitric acid; (3) sufficient potash in an available form (such as wood ashes or decomposed felspathic rocks) for the nitric acid to combine with as fast as it is liberated. Given these conditions, the formation of the salt will take place in very varied situations, being most commonly observed in countries where a tropical climate favours the decomposition of organic matters.

With this introduction, we may proceed to indicate the chief localities of production.

India.—Some saltpetre is obtained from the slimy mud deposited by the River Ganges during the flood season. Analysis of a nitrous earth from Tirhut, in Bengal, gave 8·3 per cent of potassium nitrate, and 3·7 of calcium nitrate, or 12 per cent of total nitrates. The soil around old buildings in the Punjaub is very productive of nitre, which appears as an efflorescence, not to be confounded with the sodium sulphate crust occurring on the *reh*, or barren lands. The deposit is scraped up as often as it is renewed, and submitted to simple treatment for the separation of the nitre from the accompanying dirt by the agency of water and filtration. A small spade is used in collecting the earth, which is taken off to a depth of one or two inches, and piled in heaps two to four feet high, where it is left without taking harm till an opportunity arises for transporting it to a spot where water and fuel are available. In the upper part of the Punjaub, the extraction process is conducted in a series of wide-mouthed earthen pots, with an aperture in the base, supported on earthenware stands, so as to admit of placing cups beneath the pots. On the bottom of each pot is spread a bed of straw, covered with a layer of wood ashes; above this, the nitrous earth is added till it reaches nearly to the top of the pot. Then water is applied till all soluble salts contained in the earth have been dissolved and carried in solutions into the cups below. The straw bed acts mechanically as a filter to hold back insoluble matters; the wood ashes act chemically, affording potash in an available form, so that any calcium

nitrate present may be converted into potassium nitrate, the nitric acid in the calcium nitrate exchanging bases with the carbonic acid united to the potash in the wood ashes. The very weak nitrous solution thus obtained is used instead of fresh water for washing through the contents of another series of pots, and thus becomes gradually charged with saltpetre to the extent of 2 or 3 per cent. The next process is the removal of the water and crystallisation of the salt. This is conducted in elliptical iron dishes, measuring one or two feet across and six to nine inches deep, heated from beneath; as evaporation proceeds, fresh liquor is added, during a period of twelve to eighteen hours. The scum which rises is skimmed off, and at a certain point of concentration the crude potassium nitrate, with accompanying saline impurities, is abundantly precipitated. This product in some districts is termed *dhouah*, and contains 45 to 70 per cent of potassium nitrate. The small pans used in the Upper Punjaub give 8 to 16 lb. of crude nitre per shift of thirty to thirty-six hours. Over 4,000 pans are kept working in the Punjaub, paying an annual tax of two rupees. In addition, there are over a dozen large shallow basins, called *agar*, where sun-heat is utilised for evaporation; these pay eight rupees yearly.

In the different districts, slight modifications of the process described above are in vogue. Thus, in Mooltan, the liquor, after twenty to twenty-four hours boiling, is often run into a vat to cool for a night, and next morning the crystals are raked out and washed in a woollen cloth, being then tied up in it, and exposed to the sun till the moisture has been dissipated. Sometimes the filter is made on the ground in an inclined situation being formed with mud walls lined with stiff clay on three sides, the remaining sides being left open for escape of the liquid, but provided with reeds or closely-woven grass mats, with or without a bamboo false bottom; the liquid passes into a reservoir made of pucka masonry. In Guzerat, the nitrous solution is passed through a cloth filter; it is evaporated to about one-fourth its bulk, and on cooling affords an impure crystalline product (*dhouah*) worth about three rupees per maund (say, 8s. per cwt.). When re-dissolved, filtered, and re-crystallised, forming *kalmee*, it is worth eight rupees per maund. The following table of the average cost per ton of Indian saltpetre is instructive:—

	£	s.	d.
Prime cost of crude material at the factory	4	2	0
Salaries, bags, packing, &c.	1	14	2
Freights and expenses from factory to Bombay	5	17	3
Interest on outlay at 9 per cent	0	13	8
Government license	0	2	7
Insurance at 7 per cent	0	17	1
	13	6	9
Profit per ton	1	0.	3

Selling price at a brisk demand at Bombay £14 7 0

Indian exports of saltpetre reach something like 25,000 tons annually, with a value of over half a million sterling.

Ceylon.—The nitrates of potash and lime are of frequent occurrence in Ceylon. Some thirty places might be enumerated where saltpetre is produced and has been prepared for market. The formation of the mineral is apparently confined to caves in dolomitic rocks, the felspar in which contributes the potash base. The caves are generally remote from inhabited places, being situated in desolate and not easily accessible regions. Future explorations in the interior will probably add to the number already known. While some of the caves are the resort of vast numbers of bats, whose dung accumulates in them, others are quite untenanted.

An analysis of the most productive nitre rock near Doombera, in an unfrequented cave, showed 2·4 per cent potassium nitrate, and 0·7 per cent of magnesium nitrate. The nitre earth from the great cave in Lower Ouva, near Wellaway, yields 3·5 per cent of calcium nitrate, and 3·3 of potassium nitrate. The nitre crop is harvested during six months of the year by chipping off the incrusted portions of the walls of the caverns; the fragments are reduced to powder, mixed with an equal portion of wood ashes, and dosed with water. The potassium nitrate present, as well as that produced from other nitrates by the action of the wood ashes, is dissolved by the water, and the solution is evaporated first in pits exposed to the sun's rays, and then to the crystallising point in fire-heated pans.

Burma.—Some of the caves contain accumulations of nitrous earth, and the preparation of the salt is carried on extensively between Pugan and Ava, on the Irawadi.

Thibet.—In the government of Rudokh, saltpetre is obtained by digging up the soil, which is put into brass vessels, and treated with hot water. The solution thus formed is decanted into another vessel, and there allowed to cool, that the nitre may crystallise out. By the crude native method, no man can prepare a sheep load (say 20 lb.) in three weeks.

Sumatra.—The nitre caves in the county of Caltown, near the land of the Duni river, are filled with nests of innumerable birds of the swallow kind, which abound the more the further the caves are penetrated. It is their dung, forming a deposit in many places 4 to 15 feet thick, which forms the saltpetre. A cubic foot of this earth, on boiling, will afford something like 8 lb. of nitre.—*Journal of the Society of Arts.*

AGRICULTURE IN JAPAN.

Field farming in Japan is unknown, the tillage being really gardening, but of the most thorough character. Consul-General Van Buren says that fully one-half of the population are farmers, and of the day labourer or coolie class a large number is employed in the cultivation of the soil. The average size of the garden farms is about half an acre. The fee simple of the soil, formerly in the feudal lord, is now held by the farmer. The area under cultivation has been extended fully one-fifth within the past ten years. The Japanese Archipelago extends north and south through fifteen degrees of latitude, and the cultivated areas are at all altitudes, from the sea level to 10,000 feet above, with the climate of the temperate or sub-tropical zones. Of the 50,000,000 acres of tillable land, a little less than one-fourth, or about 12,000,000 acres, are under cultivation. This is owing to the absence of good roads and proper means of transportation; most of the carrying in the farming districts is done upon the backs of men and animals. Rice is the staple product of the country, growing in all districts of the empire; about 6,800,000 acres, or more than half of all the area under tillage, is, during the summer, devoted to its cultivation. Wheat is grown in all parts of the empire, and it is estimated that the yield averages twenty bushels to the acre. It is mostly eaten in the form of cakes, cooked without any process of fermentation. The wheat flour is ground in a small stone mill, and is bolted by hand in a small box about two feet wide and three feet long. The uplands are preferred for wheat growing, and the soil is thoroughly dug up and pulverised with a long bladed mattock. It is then divided into small plots, each of which is then furrowed by the same instrument into rows, three or four inches deep and twelve or fifteen inches apart. Into these furrows, ashes and a thoroughly decomposed compost is scattered, and in October, seed is dropped by hand, about one to one bushel and a quarter to the acre, and covered by the mattock to the depth of about one inch and a half. The ground is turned up two or three times a month, and liquid manure is applied three or four times during the winter and spring to the roots. In the autumn some hardy vegetables are planted between the rows of wheat. The wheat ripens in May, and is cut by a knife and bound into small bundles, which are either hung up on trees or bamboo poles, or laid on hard ground to dry, when it is carried to the farmhouse, where it is thrashed.

The threshing process consists of first pulling off all the kernels of grain and the husks by means of a row of iron teeth, long and saw-like, closely set in a stick of wood. Between these teeth a few heads of wheat are rapidly drawn, tearing off the kernels and their coverings. The grain is separated by threshing on mats with a flail, and the chaff is separated by one person slowly pouring the grain from a scoop-shaped basket held four or five feet from the ground, while another person stirs the air with a large fan. The wheat is then put into straw sacks and carried either on hand-carts or on the backs of horses to market. Barley is a much more important product than wheat, and is more universally eaten; and it is also used for making *saki*, a liquor largely consumed in Japan. That which is made into flour is ground and bolted in the same manner as wheat, and is also cooked without fermentation. The mode of cultivation, harvesting, and threshing are the same as with wheat. The sugar of Japan is made from that species of the sorghum plant known as the Chinese sorghum. It grows luxuriantly in the southern parts of the empire. For three or four hundred years the processes of granulating and refining sugars have been known and practised. Sorghum is grown from cuttings and not from seed. In September selected stalks are cut and buried in trenches a foot deep. Through the winter, from each joint of the stalks sprouts shoot out, and in the spring these joints are cut off and set out in rows fifteen or eighteen inches apart, and about the same distance from each other in the rows. The ground has previously been dug up and pulverised by a long-bladed mattock. The fertilisers used are ashes, fish, decomposed hay, straw, and seaweed, and the plants are thoroughly hoed and irrigated. In October and November the leaves are stripped off, and the stalks are then cut, and the hard outer covering removed; the remaining portion is then ground between rollers of stone on hard wood. The cane juice is then boiled in iron kettles till the granulation takes place, when it is placed in bags and pressed dry, the expressed syrup being used as molasses. Dry, upland soils are required for the successful growth of the cane, and the expenditure in labour and fertilisers is greater than for any other crop. Tobacco is also an important product, about 90,000,000 pounds being produced in one year, and amounting in value to £1,500,000. It is grown on uplands, and the seed is planted at the end of March, or begining of April, in rows about 15 inches apart. In September the lower leaves are picked, at the begining of October the middle ones, and the upper ones at the end of October. The leaves so picked are dried and packed in small bales. Beans, peas, and other leguminous plants are extensively cultivated in Japan, and Consul van Buren says that there is probably no country in the world where this class of food-plants enters so largely in the diet of a people as in Japan. The cultivation of tea is one of the most important branches of Japanese agriculture, the total production for the year 1880 amounting to as much as 90,000,000 pounds. As regards textile fabrics, silk is the most important, the mulberry tree growing on nearly all parts of the islands south of Yesso. The principal provinces in which it is cultivated are Iwate, Miyagi, Yamagata, Fukushima, Gunba, Tochigi, Chiba, Iberaki, Kanagawa, Nagano, Yamanashi, Shidyuoka, Gifu, Ishikawa, Shiga, and Kioto Fu. The variety of the mulberry most in use is the *Morus nigra*, and it grows from five to ten feet in height. Hemp is grown on the lower and richer soils, in drills sixteen inches apart. It is sown in March or April, and receives the same careful garden tillage as all other products of the soil in Japan. The soil is carefully prepared by the small Chinese plough, or the long-bladed mattock, and well manured in the drills where the seed is sown. During the summer it is frequently hoed, and fertilisers are applied to the root of the plants. All hemp lands are flooded three or four times in the season, from the irrigating ditches. The stalk, usually ready for harvest in August, grows from four to seven feet high, and is pulled and spread on the ground, where it is allowed to rot, and the fibre is easily separated. This is done by beating with a bamboo stick. The resinous substance is removed by hand-scraping, with a sharp-edged bamboo knife, and the fibre is of great length, strength, and lustre. Flax is not grown in the country. Consul van Buren says he cannot render too warm a tribute to the thoroughness of the present tillage by the Japanese farmers, the value of which is proved by its immense results. When the mattock or broad-edged pick is alone used, the whole surface of the ground is dug up and turned over to the depth of eight to ten inches, and then the whole of the soil is pulverised and raked over, until not a lump of earth is left. When the small Chinese plough is used, the soil is ploughed and re-ploughed from four to eight times.—*Journal of the Society of Arts.*

Manures for Vines and Peaches.—For Vines and Peach trees I mix the following materials in the following proportions:—4 bushels of fresh lime, 10 bushels of good fresh soot, 20 bushels of wood ashes, 2 cwt. of guano, or 6 cwt. of night-soil. Put water on the lime to slack it, then carefully mix all the materials well together, and as soon as it has got well heated, turn it over three or four times, when it is fit for use. Put the mixture about 1 inch thick all over the Vine borders, both inside and out, and then lightly fork it in. After this operation give the inside a good watering with diluted liquid manure. I give my Vine borders a dressing every year with this manure as soon as the Grapes are cut, and have used this first-class fertiliser for many years with the best results. It destroys insects in the soil and prevents mildew.—W. Smythe, Basing Park.—*Gardeners' Chronicle.*

Non-Germination of Seeds.—The seedsmen of the present are beginning to realise that if they would have their trade grow, they must supply their customers with fresh seed, without any attempt to get rid of the old stock by mixing with the new. Hence, *now*, the fault of non-germination is the purchaser's more commonly than the seedsman's. It is a great mistake to cover small seeds too deeply, and to sow in ground but freshly broken up, or too loose open will largely promote failure. Ground sufficiently firm to retain an even moisture, is a condition of the first importance, for open ground may contain just sufficient moisture to start the seed, and then for want of it to let it perish. Very light and open soil should be trodden down firmly with the foot and raked level, before and after sowing the seed.—*Rural Australian.*

Hot Water as an Insecticide.—Hot water is a clean, safe, and effective means of destroying green fly on pot plants. To the amateur whose stock of plants might be small, or who might not have accommodation for fumigating, it would be found a convenient remedy. There is a margin of many degrees between the lowest temprature that will destroy this insect, and the highest that a plant will stand with impunity. 130 degrees is a good medium, or as hot as the hand can be held in two seconds. The plant should be plunged into and withdrawn from the water instantaneously. The smaller body and more delicate skin of the insect is more quickly acted upon than that of the plant. Should anyone be afraid to employ the remedy, let him, if he has several plants effected, try it on one first, and the next day, when he sees that it has suffered no injury, he will have no misgivings about treating the rest in the same way.—*Rural Australian.*

Dr. Watt, writing in *Nature*, says that Manipur is a small valley surrounded by mountain ranges, and in this valley the rainfall was found to be only about 39 inches; but seventeen miles off, in the mountains which formed the north-east ranges, the rainfall was as much as 120 inches, and towards the Naga country to the north it became greater and greater in certain limited tracts. In the Khasia Hills 600 inches might fall in one place, and twenty miles off only 50 inches. Nothing in Manipur struck Dr. Watt so much, as a botanist, as the remarkable transitions of vegetation in that small region. Dr. Watt gathered twelve or more species of Oaks, many of which were new to science, and ten or

twelve species of Rhododendrons, in Manipur alone. The Rhododendron Falconeri found in the Naga Hills by Sir Joseph Hooker is nowhere met with in the immense tract between the Naga Hills and Sikkim. This and the epiphytic R. Dalhousiæ, which grows on a hill thirty miles north of Darjeeling, Dr. Watt found in the Naga Hills at an altitude of 6000 to 8000 feet, but these Rhododendrons never occur in Sikkim below 10,000 to 13,000 feet. There were many instances of plants falling in their altitude as the traveller passed to the east and south-east from Sikkim, until at Moulmein a Rhododendron was found growing near the sea—a circumstance which was not met with in any other part of Asia.—*Gardeners' Chronicle.*

FORMATION OF DEW.—From a paper read before the American Association for the Advancement of Science, in August, 1886, by Prof. H. E. Alvord, on the "Formation of Dew," we learn that the facts established by repeated observations are, that the lower stratum of air rapidly increases in cold as we descend towards the ground, until checked by the radiation of heat stored up there during the day. The height of this critical stratum, where the two temperatures just counteract each other, varies under different conditions. On bare soil it is usually very near the surface, and even may be slightly below it. Grass or other thick growths of vegetation behaves like the soil in retaining a considerable degree of heat in the air entangled among its foliage, so that its presence restrains the cold stratum of air at a still greater height. There is, therefore, on the occasions when dew is formed most copiously a stratum of air of markedly low temperature lying close down to the surface of the ground, with its lower limit sharply defined, but above gradually increasing in heat. Above this stratum is the comparatively warm atmosphere, bearing watery vapour; below it a thin layer of air supplied with heat and moisture from the soil. The result is the formation of dew by condensation of watery vapour within the cold stratum. Most of the moisture seen upon many plants in the morning, in the course of a season, is transpired by the plants themselves, and this transpiration is sufficient in quantity to supply an appreciable portion of the atmospheric vapour subsequently deposited as dew.—*Gardeners' Chronicle.*

AN EASY METHOD OF MEASURING THE HEIGHT OF A GROWING TREE.—Several methods of measuring growing trees have appeared in your columns at various times, but all requiring a more or less complicated calculation, and consequently can only be worked out by those who have a fairly good education, and in some cases, probably, expensive instruments. An accurate measurement may be quickly taken without either, as any one may make all necessary apparatus in a very short time, and at a cost of not more than sixpence. Take a straight piece of common slater's lath, say, for convenience in measuring, 10 feet long, plane smooth, and mark it in feet and inches; also a small piece of board, half an inch thick and 6 inches square will do very well (it must be perfectly square); draw a line diagonally across one side of the board, and on the other side screw two square staples sufficiently large to admit the lath to slide closely through; these must be exactly opposite each other. At from 5 feet to 6 inches above bore holes in the lath to admit a peg to hold the board in position, to suit the height of different persons (a stout wire nail makes a good peg); a yard of fine string, with a loop at one end and small weight at the other for a plumb-line, and that is all that is required. To measure the tree put the peg in a hole to suit your height, slide the board on to the lath to the peg, and hang the plumb-line on the peg, then walk to a distance from the tree, so that when holding the lath perfectly upright, which the plumb-line will show on looking up the diagonal line across the board it is exactly straight to the top of the tree, the corner of the board nearest you will be exactly the same distance from the tree that the tree is high from that level, which can at once be measured by the 10 feet lath; add to that the height the board was from the ground, and you have the exact height of the tree. It is simply two sides of a square which must be equal This can be done by any one, and certainly will not take five minutes.—THOS. WOODFORD, The Nurseries, Atherstone. [This method is accurate enough if the ground be level, but it sometimes happens that it is not so, or the base line is inaccessible, owing to water or other trees or objects of some kind. ED. *Gardeners' Chronicle.*]

FRUIT TREES CANKERING (*An Old Gardener*).—While it is not wise to be prejudiced against what you call "new notions," we think you are right in considering that the truth of the "insect theory" is not yet established beyond dispute. But this is not such a "new notion" as you appear to imagine. We have heard of it years ago, and seen the insects alluded to after the canker appeared, not before. Insects cause ulceration, as in the case of the Aphis lanigera, or American blight, but that is not canker as the term is generally understood. The following remarks cited from the "Cottage Gardener's Dictionary" are pertinent to your inquiry, and we have not a doubt there is a considerable amount of truth in them:—"This disease is accompanied by different symptoms, according to the species of the tree which it infects. In some of those whose true sap contains a considerable quantity of free acid, as in the genus Pyrus, it is rarely accompanied by any discharge. To this dry form of the disease it would be well to confine the term *canker*. In other trees, with sap abounding in astringent or gummy constituents, it is usually attended by a discharge. In such instances it might strictly be designated *ulcer*. This disease has a considerable resemblance to the tendency to ossification, which appears in most aged animals, arising from their marked tendency to secrete the calcareous saline compounds that chiefly constitute their skeletons. The consequence is an enlargement of the joints and ossification of the circulatory vessels and other parts—phenomena very analogous to those attending the cankering of trees. As in animals, this tendency is general throughout their system; but, as is observed by Mr. Knight, 'like the mortification in the limbs of elderly people,' it may be determined, as to its point of attack, by the irritability of that part of the system. This disease commences with an enlargement of the vessels of the bark of a branch or of the stem. This swelling invariably attends the disease when it attacks the Apple tree. In the Pear, the enlargement is less, yet is always present. In the Elm and the Oak sometimes no swelling occurs; and in the Peach we do not recollect to have seen any. The swelling is soon communicated to the wood, which, if laid open to view on its first appearance by the removal of the bark, exhibits no marks of disease beyond the mere unnatural enlargement. In the course of a few years, less in number in proportion to the advanced age of the tree and the unfavourable circumstances under which it is vegetating, the swelling is greatly increased in size, and the alburnum has become extensively dead; the bark above it cracks, rises in discoloured scales, and decays even more rapidly than the wood beneath. If the canker is upon at moderately sized branch, the decay soon completely encircles it, extending through the whole alburnum and bark. The circulation of the sap being thus entirely prevented, all the parts above the disease perish. Trees injudiciously pruned, or growing upon an ungenial soil, are more frequently attacked than those which are advancing under contrary circumstances. The soil has a very considerable influence in inducing the disease. If the subsoil be an irony gravel, or if it is not well drained, the canker is almost certain to make its appearance amongst the trees they sustain, however young and vigorous they were when first planted. All these facts before us unite in assuring us that the canker arises from the tree's weakness, from a deficiency in its vital energy, and consequent inability to imbibe and elaborate the nourishment necessary to sustain its frame in vigour, and much less to supply the healthy development of new parts. It is quite true that over-luxuriant trees are particularly liable to this disease; but over-luxuriance is really a demonstration that the tree does not digest and secrete its juices healthily." We do not consider that canker arises from either weakness or exuberance only, but both are contributory causes, and when they exist remedial measures should be adopted accordingly. —*Journal of Horticulture.*

INDIAN AND CEYLON TEA STATISTICS.

Messrs. Gow, Wilson & Stanton's Circular which we publish below, goes largely over the same ground as, and puts forward many of the conclusions arrived at in Messrs. Stenning, Innskip & Co.'s, which we lately dealt with. On the one hand, we see, that the deliveries of Indian and Ceylon teas had increased by more than fourteen millions of pounds in five years. On the other large imports, and, unfortunately, the inferior quality of some of the tea had sent down prices to an unprecedented extent. The fall in prices would be alarming, but for the reflection that low prices have always led to largely increased consumption, and that a subsequent reaction to higher prices has not lowered deliveries. If, therefore, the prices of last year were the lowest ever reached, comfort is to be derived from the fact that never were the deliveries of Indian and Ceylon kindslarger. Ceylon contributed a considerable proportion of the increase of thirteen millions of Indian kinds imported in 1886 over 1885, and it is time that Ceylon teas were separately dealt with, rather than included in the Statistics of Indian teas. They stand apart as much as Java, and in a far more favourable position.

Nevertheless, for ALL the producing countries, the figures showing exports and transhipments to places on the Continent of Europe and elsewhere, are very interesting and suggestive. Of the estimated deliveries equal to seven millions of pounds per mensem in 1887, we may take it for granted that over 10, probably 12 per cent will be Ceylon teas, which, although they also have gone down in value, still continue to hold the first place in the London market, as they will in other markets, when their quality becomes known in such markets. It is satisfactory to learn that, in the face of largely increasing production especially in Ceylon, not only is home consumption increasing, but also deliveries for export; it is well to observe the advice tendered to us to pay attention to new markets and to the sustaining of quality. In the latter respect however, we are far more dependent on *seasonal* influences,—the effect of local weather,—than our friends at home, may be ready to admit. Certain it is that never were science, skill and care more fully applied to the preparation of tea in India and Ceylon, and yet at this moment, lowered prices are attributed to a falling-off in quality! The great hope of the Indian and Ceylon tea-producer as regards "new markets" must be based on the United States and Canada, while a steady increase in consumption of good teas in Britain may be anticipated.

INDIAN TEA STATISTICS.

LONDON, E.C., 11th Feb. 1887.

The lower quotations chronicled last year were not confined to the grades shown in the accompanying diagram; they extended to all descriptions except the finest Pekoes and Broken Pekoes. The supply of these kinds was unusually limited; hence they alone have maintained their values. The fall in prices was heaviest during the last few months of the year, and had the effect of raising the deliveries for the last quarter to the highest figure ever yet reached.

Without giving a detailed review of the many variations in price which have occurred, and which are common to most seasons, there are a few points which render the year 1886 remarkable, and which from their importance deserve more than passing comment.

The first of these is the increase of over 13 million pounds in the arrivals from India.

The second, the unusually large proportion of inferior liquoring Teas contained in the Indian crop.

The third is the rapid increase in the imports from Ceylon.

These three causes have resulted in a serious depreciation in the value of Tea generally—particularly the lower grades—and in an unusually heavy accumulation of stock at the close of the year.

The pressure of the increasing imports from Ceylon was first seriously felt about May to July, when arrivals from Ceylon were heaviest, and the trade was at its slackest point,—a position which may be intensified during the coming season. These unusual arrivals thus exercised considerable influence and temporarily depreciated values.

The Indian crop then beginning to arrive proved most disappointing in quality, and thus caused a demand for the few finer descriptions. The crop soon assumed larger proportions than the trade could absorb, and prices generally commenced to recede. The flood of common teas, of which the arrivals chiefly consisted, also told seriously upon the market, and during the last quarter of the year quotations for the lower descriptions fell to a point never previously reached. Although this reduction in values soon caused an increase in the deliveries of Indian and Ceylon teas and lifted them higher during the last quarter than any previous record—as depicted on the chart—the drop occurred too near the close of the year to prevent an accumulation of stock, nearly 9 millions in excess of that on 31st December, 1885.

	1883.	1884.	1885.	1886.
a Imports of Indian and Ceylon tea	61,667,000	67,152,000	66,863,000	83,460,000
b Delivery of Indian and Ceylon tea	59,096,000	64,217,000	68,895,000	74,665,000
Stock of Indian and Ceylon tea	24,116 000	27,076 000	25,780,000	34,548,000

a Import of Indian Tea 1885, 67,160,000 1886, 76,585,000. Import of Ceylon Tea 1885 3,703,000; 1886; 6,875,000.

b Delivery of Indian Tea 1885, 65,678,000; 1886 68,420,000. Delivery of Ceylon Tea 1885, 3,218,000 1886., 6,245,000.

The Home consumption of Indian and Ceylon Tea has increased from 38 per cent of the whole in 1885 to nearly 42 per cent in 1886; still the Home consumption of all tea was less than in 1885—hence the increase in these sorts was gained entirely at the expense of China Tea, the Home consumption of which fell 9 million pounds during the year.

Home Consumption.	1882.	1883.	1884.
China Tea, &c.....	114,461,000	111,685,000	110,843,000
Indian and Ceylon Tea.....	50,497,000	59,096,000	64.217,000
All Tea.....	164,958,000	170,781,000	175,060,000

	1885.	1886.
China Tea, &c.....	113,514,000	104,226,000
Indian & Ceylon Tea.....	68,895,000	74.665,000
All Tea	182,409 000	178,891.000

EXPORT.—One effect of the low range of prices has been to draw the attention of various foreign markets to the lower grades of whole leaf Indian Tea. The export of these has been large, and shows distinct signs of extension. Another and very important cause of this export demand is to be found in the larger size of breaks arrived during the present season,—a matter which is of great importance to shippers. It is probable that the small breaks into which Indian Tea was until very recently divided, had much to do with the slow progress of the export trade in previous years. The exact quantity of Indian Tea exported cannot be

ascertained, as Indian Tea is included with China in the export figures published by the Customs Authorities. The separation of the descriptions might be an advantage to the trade.

PROSPECTS OF INDIAN TEA TO END OF JUNE.—Having now considered the subjects of both Home consumption and export, let us glance at the probable position of the Indian Tea trade during the next six months.

The amount of the Indian crop available for London is generally estimated at about 75,000,000 lb. Of this amount 52,500,000 had arrived to 31st December, thus leaving 22,500,000 lb. to come forward. Estimating the arrivals from Ceylon to the end of June as 6,000,000 lb., we get a total import of 28,500,000 lb. This quantity added to the stock on 31st December of 34,500,000, gives us a total of 63,000,000 lb. to deal with. Calculating the deliveries of Indian and Ceylon Tea at as high a figure as 7,000,000 lb. per month —which the lower range of prices may warrant us in doing—we get a total delivery of 42 000,000 lb. for the six months, thus leaving a stock at the end of June of 21,000,000 lb.—as against 18,345,000 lb. at the same time last year.

However, as the December stock would thus be reduced by nearly 14,000,000 lbs., there is ample ground for the hope of some re-action from the unsatisfactory averages now being obtained. Periods of the most rapid increase in the consumption of Indian tea have usually been the effect of low prices; but after prices had again advanced, deliveries have seldom materially receded, and even then have soon re-attained the higher rate.

NEW MARKETS.—Still, looking at deliveries even in the most favorable light it is more than doubtful whether they can long keep pace with the rapid increases taking place in production not only in India, but especially in Ceylon,—unless indeed new outlets can speedily be found, or existing foreign markets can be considerably extended.

CONSULAR REPORTS.—The published Consular Reports contain information of a specially useful character to those interested in the development of an export Tea trade. In addition to instancing various foreign markets recently opened, or largely extended for Tea, they throw much light upon the condition of British enterprise in many important localities as compared with more pushing commercial nations on the Continent. It may be mentioned that for every *one* British commercial traveller in the Levant, there are *twenty* representatives of Mercantile Houses owned by two only out of the many foreign nations competing against us.

The subject of New Markets is of great importance to us, as a nation bestowing considerable attention upon the cultivation of Tea. We therefore append a table showing the quantity of Tea exported from England to various countries during recent years.

Table showing the average amount of Tea in pounds exported from Great Britain to the following countries during 1882-83, and 1884-85:—

Countries	Average Exports during 1882 & 1883 lb.	1884 & 1885 lb.
Germany	17,671,000	17,879,000
Canada	6,231,000	8,229,000
United States	1,301,000	3,775,000
Holland	3,373,000	3,422,000
Russia	3,361,000	2,517,000
Turkey	579,000	991,000
Denmark	813,000	791 000
Newfoundland	844,000	771,000
Chile	607,000	744,000
Channel Islands	612.000	664.000
Morocco	444,000	643,000
Portugal	589,000	631,000
France	616,000	542,000
Brazil	406,000	393,000
Victoria	21,000	235,000
Belgium	(no returns) 1885	207,000
Argentine Republic ...	275,000	195,000
Gibraltar	150,000	144,000
Cape of Good Hope ...	114,000	141.000
Austrian Territories ...	162,000	120,000
Malta and Gozo	106,000	100,000
British West Indies ...	98,000	93,000
Natal	122,000	87,000
Uruguay	84,000	77,000
Peru	58,000	60,000
Spain	48,000	49,000
Egypt	34,000	43,000
Bolivia	29,000	40,000
Roumania	36,000	28,000
Azores	14,000	22,000
Bermuda	19,000	15,000
Maderia	13,000	13,000
St. Helena	14,000	12,000
Danish West Indies ...	7,000	4,000
British Guiana	5,000	4,000

It is necessary to mention that only a small portion of the large amount exported to Germany is consumed in that country, the greater part being re-exported. In addition to the above exports from Great Britain large quantities of tea are transhipped to various places. In 1885 the principal transhipments were as follows:—

United States...	6,012,000
Germany..	2,380,000
Holland	895,000
Russia	262,000
Turkish Dominions	225,000
British North America ...	138,000
Argentine Republic	685.000
Austrian Territories	89,000
Uruguay	78,000
Norway	91,000

Cannot Indian and Ceylon tea be introduced in some of these numerous markets? There is a large field for enterprise in the extensive markets of the United States of America, where some 70 million pounds of tea are annually consumed; and there, the proportion of Indian and Ceylon tea used is at present infinitesimal.

In order more fully to elucidate this important subject, we intend issuing in a circular upon Ceylon tea, a list giving the quantity of tea consumed in various countries—together with the different rates of duty charged upon the article.

PRODUCTION.—In view of the rapidly increasing imports we venture again to draw attention to the subject of "Plucking," upon which we have frequently commented on former occasions; we would strongly urge the advisability of pursuing a medium course, and above all, of avoiding the dangerous policy of flooding the market with an enormous quantity of inferior liquoring tea. The great point to be aimed at in the future is *quality* not *quantity*. The need for utilizing every facility for improvement in manufacture, and for systematic economy is becoming more urgent every year.

BONDED WAREHOUSE RETURNS do not unfortunately show the movements in the different grades of Indian Tea; this is a matter in which we believe an alteration would be of advantage to the trade, as it would often be useful to know in what particular sorts the deliveries were most extensive.

GOW, WILSON & STANTON,
Tea Brokers, 13, Rood Lane, London, E. C.

PLANTING IN NETHERLANDS INDIA TOBACCO.

(Translated for the *Straits Times*.)

In Java, encouraging signs are not wanting, evidencing a determination on the part of the interests suffering from the prevalent depression, to put their shoulders to the wheel, and help themselves in place of relying upon the aid of the Government, which indeed shows no disposition to move out of old fashioned grooves. The planters there who have already taken the pioneer lead to protect themselves more than once have again bestirred themselves to set an example to their fellow colonists. The *Java Bode* says that, with a rare spirit of co-operation, they recently decided upon setting up experimental stations for the behoof of sugar growers. Now they have laid the foundations of another station of the kind for the cultivation of hill produce articles. There is every prospect of the scheme coming to maturity. Under influence of the thought that the only way for Java planters to carry on the struggle for existence with any hope of success in the future

would be for them to take every advantage of scientific improvements in the direction of reducing the cost of production, the members of a planting association in the Preanger Regencies, have taken the first step for the purpose, by sending round to their fellow planters a circular requesting their cooperation in gaining the desirable end in view. The Government has also been applied to for part of the money required in the shape of a subsidy.

A gentleman named Carst who intends starting a tobacco estate in Cotie on the East Coast of Borneo, writes to a Batavia journal pointing out that the British North Borneo Company has committed a blunder in failing to forward its tobacco to Amsterdam or Rotterdam instead of to London. In these Dutch cities, there is better chance of securing higher prices, owing to the greater demand for the article, in consequence of the hundreds of dealers from Germany and America, who carry on a brisk competition there. At London, adequate competition is wanting from so few dealers having the means to travel there for the purpose of buying tobacco. In fact, the consumption of tobacco is so limited in Britain that the latter country has no chance of becoming a market or emporium for leaf, coming up to the kinds produced in British North Borneo.

MANURING FRUIT TREES.

We have often noticed great waste of material and labour expended on fruit trees, and because no visible reward—by finer or more abundant produce—was experienced, the practice of surface-dressing was denounced as useless, and then abandoned. But the mistake was in the application of the manure, the feeding roots being far distant from the stems of the trees, and I need not say that these roots had no assistance rendered them whatever. In a large West of England orchard which we visited during last summer, manure in abundance was placed over the hard dry surface, in circular form 1½ foot wide, by the trunks of the large trees. The advice was copied from some horticultural journal, but certainly not to the letter, and it is because such work is often performed in such an unintelligent manner that the instructions so well given have been treated with contempt. Often manures scientifically prepared to meet the wants of fruit trees, vegetables, and flowers are denounced as being worthless because they have been misapplied.

Vines are frequently victims to barbarous treatment in the manner indicated. Borders which may have been well prepared with the best of material are long since vacated by the feeding roots, which may have gone out into the vegetable quarters, or into a hard road if such were near by. Cultivators may sometimes be seen treating such borders to their annual dose, or biennial supply of choice manure, solid and liquid, and at the same time all was waste—none could reach the feeders. The Vines gradually failed, disease became prevalent, and failure was certain. We have more than one such case in our mind's eye at present, where valuable applications are given which is utter waste. The hint given regarding the renovation of the Madresfield Vines may be taken by many who have long been helping (in vain) the roots of their Vines. Trace the feeders to their utmost limit, and good service may be then done by feeding them where they can consume their food.

Shrivelling is much complained of this season (we have a little of it), but attribute it to absence of moisture at the roots, or to a dry, hot atmosphere, or both at the same time. Our shrivelling is easily accounted for. The roots of some two Vines had grown up into the surfacing of manure in the inside border, and when damping the house was discontinued these roots were dried up.—Caledonian.—*Gardeners' Chronicle.*

CULTIVATION OF CHAVICA BETEL.

BY MR. S. RAMASAWMI IYAH OF CHINGLEPUT.

(*From Journal of the Agricultural Students' Association, Saidapet, Madras.*)

I purpose to give you a detailed report on the cultivation of Chavica Betle as practised in this part of the District (Chingleput). The subject is one of much interest, and it is hoped that it will secure the attention it deserves.

Varieties.—There are two important varities, *viz.*, the white, and the black. The former is sub-divided into "Karpuram" and "Goulipathrum," whereas the latter, into "Kammaram" and "Kalizeru."

Karpuram.—Small, fine, and agreeable to the taste.

Goulipathrum.—Large, thick, agreeable to the taste, and aromatic.

Kammaram.—Large, thick, pungent, and aromatic.

Kalizeru.—Small, not very thick, and bitter to the taste.

Extent.—The white variety is cultivated largely in this District to the extent of 1,842 acres, whereas the latter occupies only 398 acres.

Selection of land.—Red loams and clayey soils are best fitted. Sandy soils are objectionable. As a rule, the land selected should contain a fair amount of organic matter. The crop requires a very copious supply of water, and, therefore, it is desirable that the land be freely irrigable by gravitation.

Preparation of land.—Land which has recently been cropped with paddy is fallowed for three months. In the beginning of June, straight furrows are made by a plough 6 feet apart. Trenches are then dug in the field (1 foot 3 inches deep by 2 feet broad) along the furrows. The soil removed from the trenches is heaped in the interspaces, leaving a margin of 9 inches on either side, to a height of 1 foot. The length of these trenches depends upon the extent of the field: the trenches referred to throughout my report were 280 feet in length.

Agathi Planting.—As a rule, the betle crop is planted along with Agathi albiflora. The advantages of growing them together are as follows:—1.—that the gardener may have free and full control over each plant. 2.—that the creeper may be trained on the agathi plant. 3.—that the creeper may be protected from high winds. The method of sowing the seeds of the agathi is as follows:—Seeds are placed in water; those that float are rejected, and those that sink are taken for sowing. About 54 Madras measures of seed are necessary for sowing an acre. Under favourable circumstances and careful management a less quantity may suffice. Four rows of agathi seeds are sown on either side of the trenches, 4 inches apart between the rows and 9 inches in the rows. By the end of a week after sowing, the whole field is covered with young agathi plants in regular drills. These plants require no shade when they are young, but regular watering is necessary. When the whole field is well covered and the plants attain to a height of 7 feet to 9 feet, preparations are made to plant betle creepers.

Fences.—Fences are absolutely necessary for this crop. There are two fences, *i. e.*, the outer and the inner. The outer is generally a live fence while the inner is a dead fence.

Planting plantain shoots.—Plantain shoots are planted at the rate of 200 to an acre. The plantain requires no cultivation besides what is usually done for the betle crop.

Selection of Betle creepers.—Creepers (with leaves) specially selected, are the tops of healthy plants whose leaves possess superior qualities. Each of these tops, or creepers, must contain 9 nodes; 150 bundles to an acre are required.

When planted.—In the beginning of December, when sufficient shade is afforded by the Agathi plants, the creepers are planted.

How planted.—The creepers are arranged in sets of two each. Two such sets are placed horizontally opposite to each other in the soil between every two Agathi plants of the second row. Puddle taken from

the trenches, is then placed over the creepers so as to cover the cut surfaces but no manure is applied Three months after planting, *i.e.*, in the beginning of March the creepers strike root, when new leaves appear on the main stems. These, as they grow, are fastened to the agathi plant.

Irrigation.—As a rule, these betle fields are irrigated from tanks and but seldom or never from wells. Water is distributed in the trenches by gravitation. When the trenches are full, a cooly is employed to throw water on the ridges. Regular watering is usually necessary for the betle crop throughout its duration of growth. It may be remarked that the trenches are always filled with water which becomes stagnant and ultimately a nursery for injurious insects that feed upon the plants. Excess of water turns the plants pale in colour, and weakens them.

Diseases of the plant.—The betle leaf gets blanched and sickly, if deprived of light. When the evaporation is impeded, they suffer, while on the other hand when it is excessive, leaves dry and fall off. *Rot*, a disease in which the lower branches begin to decompose, is also seen when there is no free circulation of air. A *fungus*, characterised by small bundles of white globules, is also seen among them. It first attacks the roots and then the stem. The plant attacked by it, turns yellow, and the leaves fall off; the section of an internode exhibits a dark ring around the pith, and ultimately becomes rotten. When plants are affected in the abovementioned ways, the agathi plants are stripped off their leaves and the diseased plants are removed.

"Serva" operation.—In the beginning af April, the operation of arbouring the stems of Agathi plants known in Tamil as "serva" operation takes place. This is as follows:— A plant in the first row along the margin is tied up with the corresponding one in the adjacent row on the same ridge. When the whole field has thus been dealt with, a pair of agathi on the ridge is fastened to the opposite pair on the other. Bamboos are at the same time placed all along the interior angle formed by the junction of two pairs of agathi, facing the trenches. 600 bamboos of 2 inches in diameter, on the average, are required to each acre. This operation engages the labour of 50 men to complete an acre in a day.

Harvesting leaves.—No leaves are plucked until the plants are about 6 months old from the time of planting. The gardener never plucks leaves from the main creeper, but removes them from the branches. From the beginning of June, 25 bundles of 400 leaves each, may be collected from an acre per day till the first pruning takes place. The plants are afforded 3 months' rest between the successive prunings.

Pruning operation.—When the creepers reach the full height of the agathi plants, the ties are removed, and the whole creeper is shortened to 3 feet and the ties are replaced. The fibre used in binding is obtained from the stem of Cypress bulbosa.

Manure required.—At each time of pruning or *lowering*, 50 cart loads of compost are required for each acre.

Labour required.—One cooly takes 10 minutes to do all the manipulations necessary for one creeper. As there are 560 creepers in a ridge he will take 96 hours to finish the work. Considering that 8 hours= 1 working day, a ridge will be finished in 12 days by a cooly, in other words, 12 coolies are required to finish a ridge in one day or 300 coolies to an acre in a day.

Duration of growth.—Under favourable circumstances and good management, the crop will live for a period of not less than 6 years.

Labour difficulty.—The chief difficulty which the cultivator experiences in the cultivation of this crop is securing a sufficient number of coolies at the proper time, notwithstanding the enormous expense that he is prepared to incur.

PRODUCTS OF DOMINICA.

CACAO.

Dominica ought to make a fine display of cacao, as on its increased cultivation unquestionably rests, in no small degree, the future prosperity of the island. Two or three specimens will only show that cacao can be produced here, but a large variety of exhibits—say specimens from thirty or forty of the principal growers—will give visitors to the Exhibition some idea of the island's capabilities in regard to this staple.

The following are the classes under which our cacao and its products can be sent:—

1. Dominica plantation cacao—fermented.
2. Dominica plantation cacao—fermented and clayed.
3. Dominica settlers' cacao.
4. Prepared cacao.
5. Chocolate.

Three quarts of cacao should be sent, put up neatly in shallow boxes about 14 inches square, but two pounds of prepared cacao and chocolate will be sufficient.

The plantation cacao should of course have the name of the estate and the exhibitor as well as the ordinary marks that are placed on the bags before they are sent to the market. The cacao can easily be "clayed" by rubbing over the beans finely-powdered red earth or clay as soon as the fermentation (or "sweating") is completed. Clayed cacao fetches a better price than the ordinary article and it is usually bought by the French for their celebrated chocolate. In some instances red ochre is substituted for clay, and we know of an instance where it was so employed in this island.

Settlers' cacao forms the greater part of our crops; it is the cacao purchased by the merchants from the peasant proprietors, and unfortunately it is to this imperfectly fermented and sometimes unripe article that we owe the prevailing low prices for the Dominica cacao. To our merchants we must turn for representation in this class, and we sincerely trust that each cacao broker will send on a sample of "settler's cacao" with the name of the firm and the usual mark. This will really be an important exhibit, for if it be demonstrated to the trade that we have plantation and settlers' cacao, it will at once cause extra scrutiny amongst buyers, and raise the price of the former article to the great "benefit of all concerned."

Our prepared cacao and chocolate will also make important exhibits; and it would be a good commercial speculation for one of our merchants to consign these articles in quantity to the Executive Commissioner for the use of the refreshment bars and pavilions in the Exhibition grounds. A cup of pure Dominica cocoa or chocolate will be a surprising treat to those accustomed to the villainous decoctions usually sold in such places, and it cannot but tend to draw attention to our island.

COFFEE.

Under this head we make the following divisions:—

1. Arabian or "creole" plantation coffee.
2. Arabian or "creole" settlers' coffee.
3. Mocha coffee.
4. Liberian coffee.

Years ago Dominica was one of the chief coffee producing countries in the Western Hemisphere, and capital enterprise alone are wanting to make its name known again in the great markets. Liberian coffee grows well in the lowlands; and, in spite of the "white fly" blight, the so called "creole" variety gives remunerative crops in lands situated over 1000 feet above the sea. It is to be hoped, therefore, that there will be a good coffee exhibit at the forthcoming exhibition. Three quarts of each kind of coffee is the minimum quantity required, and the exhibit should be packed in flat boxes about 14 inches square, and about 1½ inch deep. The labels should have the name of the exhibitor and the estate.

We may here impress on every exhibitor to attend carefully to neatness in getting up his exhibit, for any article will look much better in a tastily made box than it would in a rough receptacle hastily knocked up out of an old packing case. Mr. Jemmott, the carpenter, made the most of the boxes sent to the Demerara exhibition, and the neatness of the Dominica exhibits at that show was the subject of much public and private commendation. Two shillings each were charged for the boxes.

SPICES.

We can send eight kinds of spices as will be seen by the following enumeration:—

1. Nutmegs.
2. Mace.
3. Cloves.
4. Cinnamon.
5. Ginger—*a*. Unscraped.
   b. Scraped and cleaned.
6. Vanilla.
7. Black-pepper.
8. Pimento.

Thus we see we have nearly all the known spices growing in the island, and this will be a most important fact to impress on the visitors to the exhibition—for the bulk of the spices used come from the East Indies, and therefore they cost more to place in the English and American markets. Nutmegs have done much to help on the prosperity of Grenada, and it is to be hoped that in a few years the same thing may be said of Dominica. Already two of our planters have commenced the cultivation in real earnest, and other doubtless will soon follow in their wake.

Pimento, allspice, or Jamacia pepper, is the fruit of our "Bois d'Inde" picked green and dried in the sun. It is a very important article of export from Jamaica.

OTHER FOOD PRODUCTS.

Of these we have a large variety, and possibly our readers will be able to add to the following, fifteen classes which we have made in the division:—

1. Farine manioc.
2. Farine starch.
3. Arrowroot.
4. Tous-les-mois.
5. Plantain starch.
6. Yam starch.
7. Tania starch.
8. Bread-fruit starch.
9. Sweet-potato starch.
10. Tapioca starch.
11. Plantain meal.
12. Dried sliced plantain.
13. Rice.
14. Dried peppers (or capsicum) whole.
15. Ground peppers. (or Cayenne pepper).

Most of the above articles can be exhibited by the ladies, and we take this opportunity of pointing out that the sterner sex are not expected to carry off all the honours. The Exhibition Committee will be very glad to receive all the help the ladies can give in making the Dominica Court at the Exhibition worthy of the island, and their Honorary Secretary will only be too happy to assist *all* intending exhibitors to the best of his ability.

We may remark that the true Cayenne pepper is made from the bird pepper—a common Dominica wayside plant of two kinds. One kind bears small round red berries, and the other has elongated pyramidal ones.

Three quarts is the quantity fixed on for the meals and starches, and the article may be exhibited in boxes similar to those described above. It will be as well to line the boxes with blue or white paper.—H. A. A. N.—*Dominica Dial.*

CINCHONA IN MEXICO.

Notwithstanding the discouraging state of the Cinchona market fresh competitors in the industry are entering the field, and the latest of these is the Mexican Government. Cinchona was first introduced in Mexico by the Emperor Maximilian, in 1866, upon the advice of Mr. Maury, a scientist and lieutenant in the United States Navy, who had been making a tour through the South American Andes, and was struck with the climatic similarity of those regions to certain parts of Mexico. The Emperor Maximilian applied for cinchona seed to Mr. Waltham, who had introduced the plant in the East Indies, and received from him a supply of three different species, together with instructions regarding the treatment of the seed. By the Emperor's orders the seeds were handed to the Geographical and Statistical Society of Mexico, who in turn, commissioned a Mr. Jose Apolinar Nieto, of Cordoba, to plant them, and supplied him with the necessary funds for the experiments. A German named Finck, carried on an experiment with some seed of the *C. condaminea* variety, which planted and produced good seed at the end of four years. He afterwards planted a number of seedlings on an estate at a height of between 1,800 and 2,000 feet above the sea-level. But the mean temperature of these plantations, 75° F. was found too warm, and the plants did not succeed, although they attained a height of thirteen to sixteen feet. In 1873 only 115 of the trees survived. Dr. Finck, notwithstanding this disappointing result, remained a firm believer in the feasibility of successful cinchona-growing in Mexico. In 1874 he made a fresh attempt, this time on a "rancho" about 2,900 feet above sea-level, and had the satisfaction to see his efforts crowned with complete success and to find other planters following his example. At present 12,000 trees are flourishing on Dr. Finck's plantation, and it is said that the total number on the plantations around Cordoba is nearly 20,000. A great many varieties have in course of time sprung up from the original three species, and the alkaloidal percentage of the Mexican cinchona is equal to that of the best Bolivian bark. Nevertheless it would seem that for the next few years, at any rate, there is no probability of cinchona being exported from Mexico. All the bark which is grown in the republic is consumed in the country, local wholesale druggists buying it at prices ranging from 56½c. to 75c. (2s. 4d. to 3s. 1d.) per lb. It is not, therefore, worth the while of growers to export their cinchona to markets where, most likely, it would realize less than at home. Foreign cinchona has to pay an import duty of about 2d. per lb. in Mexico, and quinine about 1½d. per oz., while the shipping and carrying expenses are very heavy.—Local "Times."

RHEA IN MEXICO.

I notice from time to time an expression of opinion by correspondents in your columns to the effect that, successful as tea has become, Ceylon planters will do well to see that they be not again caught, as was the case with coffee, with all their eggs in one basket. With this in mind and remembering the nature of your climate in the low country, and in mid-region between it and the hill-ranges, I have lately been taking notes in regard to the growth of the rhea plant, from which is made the well-known and valuable China grass, as well as of its manufacture into a great variety of fabrics. There is a Rhea Manufacturing Company in London with a factory on the River Lea, and a large extent of land in the Madras territory, where the plant is being grown and treated for handy shipment. During the currency of the Colonial Exhibition, I had frequent opportunities of examining the beautiful fibres and cloths shown by the Company in the Indian Court. They have already indeed manufacturers to take up the article, but what is wanted is a larger supply, for there is very little doubt that many thousands of tons of the prepared fibre would be taken at paying prices. Having had, whilst in India, some experience in the growth of the rhea plant, I do not hesitate to say that it is most readily cultivatable in a moderately good and light soil, in a climate such as exists in the Ceylon maritime districts, and, even as high up as Gampola and Kadugannawa. In many parts of India it is successfully grown, but hitherto the difficulty has been in separating the fine long fibres from the woody stalk, covered as it is with resinous matter. This, the Company declare, can be easily and economically carried out by adopting a very simple process which they have patented. They are prepared to enter into engagements with any persons who will grow the plant and supply them with the fibre in the raw state under their patent. In placing before you, for the information of your readers, a few extracts from the Company's lately published pamphlet, I have in view the possibility that the cultivation may find someone willing to give it a trial on a small scale in some moderately

moist district, Saffragam, Kurunegala, the Kelani Valley, Kalutara, Galle, Matara, and doubtless other localities would be suitable. The pamphlet in question says:—"The Rhea Manufacturing Company will supply seeds and plants and cuttings, and will either buy the crop, or, in certain cases, accept drafts against consignments intended for treatment and sell them to the best advantage of the consignor. The Rhea Manufacturing Company is prepared to consider propositions for its sole agency in such of the British Colonies and dependencies as are not already occupied by its licensees; the principal duties of such agents being to facilitate the cultivation of rhea by even the smallest landholder. The patent processes of M. Favier and Professors Frémy and Urbain, of which this Company holds the exclusive rights, render it possible to convert into "ribbons" on the ground where grown the whole crop so soon as cut. As this is done without breaking or bearing the stems, all the "nature" and valuable qualities of the fibre are preserved. The preparation of the raw material so obtained is completed at the Company's extensive works on the River Lea, near London. Growers, therefore, dealing with the Rhea Manufacturing Company, Limited, will produce at the smallest cost, and will receive the highest market rates. Rhea varies in its yield and quality according to the latitude in which it is grown, the land in which it is planted, the time of year in which it is cut, the rain-fall of the locality or facility obtainable for artificial irrigation. A consideration of paramount importance is that the outlay, diligence and care indispensable for a rhea plantation *cease* (so far as the area planted is concerned) with the end of the second year. After the second year the agriculturist has an increasing and perpetual income and a minimum expenditure. Rhea is an evergreen, and once properly planted fills every vacant spot of ground, leaving no room for weeds. The normal crops really begin only after the second year of planting; from that time the crops obtainable throughout India and latitudes from 0° to 20° may be calculated as from 3 to 6 per annum, each crop giving in the third year about 200,000 stems per acre. This number, however, as well as the weight of each stem and of the fibre in each stem, will vary according to the conditions mentioned above. Taking an average of four crops a year or 800,000 stems per acre per year, and 10 green stems (stripped off their leaves and with the tops cut off) to the pound, and taking it also that the ribbons, when decorticated, will weigh one-tenth of the gross weight of the green stem (stripped off its leaves and minus its top) the 800,000 green stems will weigh 80,000 lb. and should yield 8,000 lb. of dry ribbons. Assuming the selling price of these ribbons to be £10 per ton on the ground there would be in the first and second years enough tops for the nursery, plants for transplanting, and stems cut for ribbons to cover all costs incurred except the original outlay for preparing the ground and purchase of plants. According to the statements of the manager of the Company it will require about two millions of matured stems to yield a ton of marketable fibre worth £30. The preparation of the ribbons for working into the fibre is, I am assured, of the simplest and most inexpensive kind, by a patented process which the Company will place at the disposal of anyone working them. I furnish these outlines in the belief that someone or more with spare land on his hand may care to try this new cultivation.—Local "Times."

BRITISH NORTH BORNEO: ITS PEOPLE AND PRODUCTIONS.

The island of Borneo and the surrounding seas are exceptionally rich in natural products, many of which, are, as yet hardly, if at all, collected or utilized. The main reason why these resources have been so little taken advantage of hitherto, is, that matters have been in such a disorganized and anarchial state, that it was impossible to store up the slightest wealth, without some one more powerful than the possessor coming and seizing it, by force of arms, if need be. It was useless, therefore, up to quite lately, for any one to attempt to do more than provide for his immediate wants, and so much has this grown to be a habit, added to the natural laziness of the Malay character, that the bulk of the people simply have, even now, no thought for the morrow. A remarkable illustration of this is found in the undoubted fact, that it has been known that Bajau boats having brought some "find" of a rather higher importance than usual to market, and bartered it for the only article they attach any value to, rice, have afterwards thrown the greater part of the remainder into the sea, rather than be at the trouble of taking it about with them. It will thus be understood that the people of these parts have come to regard it as but a natural state of affairs that they should be surrounded by wild produce of a valuable character, which they have only to stretch out their arms to gather, and, in fact, as a Bank upon which they simply have to draw, whenever the need arises.

Sea Produce.—Bêche-de-mer, scientific name, *Holothuria*, or Sea-cucumber: Malay, *trepang*: Bajau, *bart*. These repulsive looking echinoderms occur in quantities all round the coast, and are collected principally by the Bajaus, or sea-gipsies, who cure and dry them, and bring them to market, where they are bought by Chinese traders, and sent ultimately to China, where they are much appreciated, being used principally to make soup of. They vary considerably in price. Some of them have no value at all, and go uncollected; others fetch as much as $25 a picul, but the usual price is from $10 to $15 per picul. Along our own coast they are rather fully collected, but amongst the islands, and on the coast line down to the south there are immense quantities left undisturbed from year to year. The exports of this curious produce during the years 1882, 1883, and 1884, were valued at $6,739, $9,057 and 7,373 respectively.

Keema is a large mollusc, resembling an enormous cockle or clam. Their shells may occasionally be seen in museums in England, and are much used in France as vessels for Holy Water at the entrances to churches; these shells are sometimes found six feet in width, and the natives aver that they grow very much larger, and state that on the coast of Tawi-Tawi, there is one as big "as a house." It may be mentioned, however, that fifteen feet broad for a Bajau house, would be quite a respectable size. *Keema* is usually found on a coral bottom, and it requires the keen and practised eye of a Bajau, to distinguish between them and the surrounding lumps of coral, &c., they usually present the appearance of an indigo-blue streak, the partly opened mouth being all that is visible, the shell being too much covered by sea-weed, anemonies, &c., to be seen, and when the Bajau distinguishes one from amongst the quantities of other creatures and colours, with which the bottom abounds, he thrusts a three-pronged spear into the aperture, whereupon the two shells close with a firm grasp, which enables the fisherman to bring it to the top without further trouble. The price of *Keema* is usually so low, that it is despised by the gatherers, though however low the price might be, $2 to $3 a day, could always be earned by collecting it. During the war between France and China the prices of *Keema* rose considerably, owing, I was told, to its being more easily prepared for culinary purposes than *trepang*, and therefore more adapted for soldiers on the march. There are places on the coast where boat loads can be got in a very few days, and its collection was being largely expanded, when the end of the war came, and prices showed a disposition to fall.

Agar-agar, an edible sea-weed grows freely enough in many places at the bottom of the sea, and is to be had for the collecting.

Mother-of-Pearl Shell is the produce of a very large oyster, known locally as *tepai*. Beds of this oyster are found in the seas all the way from Borneo to Australia, more or less; they would seem to terminate, however, about Lat. 6, North. There is a tradition of a large bed being situated outside Balhalla, somewhere between the islands of Nunuyan and

Taganac, and in confirmation of his report, occasional single specimens have been obtained. A bed also exists, without much doubt, on the 'Rene" shoal off Tambesan, but the mouth of Darvel Bay has to be crossed to the southwards before ground is reached, where they are constantly found. Information apparently trustworthy has been received of an important bed, extending from Port Elphinstone to some sixty miles to the southward, called the Ada Bank, so named after the wife of Mr. Pryer, the Resident of the East Coast. Shells from this bank are sent in occasionally, and some pearls are said to have been found. The price of shell is usually about $45 a picul. Exports hitherto in this article have principally been composed of a few shells that have, from time to time, found their way over from the Sooloo islands to Sandakan.

Pearls.—These are found in the above-mentioned mother-of-pearl or tepai oysters. Hitherto but very few have been found on our own coast, and those which are offered for sale in our market have come principally from the islands of Tawi-Tawi, Skobong, Ubian, &c., in the Sooloo Archipelago. Pearls of very high price are not unfrequently to be bought in Sandakan. The largest one that has been seen was valued at $8,000. The diving powers of the people who bring up these shells is something extraordinary, and is probably not to be exceeded anywhere in the world; without any stone or weight they turn over on the surface of the water and swim down head foremost to the bottom, collect shells, and bring them up, each one weighing six or seven catties. In this manner they will descend to an ascertained depth of twelve fathoms, and claim to be able to go down much greater depths. In waters much infested by sharks, a sort of plough shaped trawl, here called "badjer" is used.

Seed-pearls.—These are found in a thin flat pinkish-shelled oyster, known locally as *Selisiep*, which occurs usually in shallow water on the mud at the mouth of rivers. This oyster is somewhat peculiar in character, the water in which alone it can thrive must be slightly brackish, as it cannot live in entirely salt water, while on the other hand, an admixture of too much fresh water kills it at once. There used to be large beds of it in Sandakan and Lakuk Bays, but very heavy rains in the year 1879, so thoroughly destroyed the oysters, that they have never properly recovered yet, (December, 1885.) On several occasions it has been said that the oyster was beginning to be found again, and that minute pearls were forming in them, but rains always came at the critical moment and destroyed them. In Maroap Bay, a certain amount of collecting has been in progress for the past two years, and there are places in Darvel Bay, where these oysters are abundant, but other natural produce, more easily collected, is so plentiful in its neighbourhood, that they are never touched. Seed-pearl collecting is great fun. It is always necessary for several boats to rendezvous, at the same time and place for the purpose of frightening away the crocodiles and sharks, and for the same reason, as much shouting and splashing about as possible, is indulged in. The consequence is that there are rarely less than from twenty to thirty persons in the water at one time, all diving, splashing, laughing and shouting at once, and rarely bringing up less than three to four shells at a dive, whilst extra yells from all hands salute a rather larger find than usual. The mode of obtaining the pearls is by opening the oysters and throwing their contents into some vessel, and there leaving them to decompose, stirring them up daily during the process, until at last the liquid putridity being poured off, the pearls are found at the bottom. Very few of them are large enough to be of any value individually, but they are sent to China where they are pounded up and made into powder and there swallowed by ladies who desire to improve their complexion, at least so we are told. Another and rather larger kind of oyster known as *beloong*, found in somewhat deeper water than *selisiep*, also always contains seed-pearls. Exports 1882 $71, 1883 $106, and 1884 $2,401.

Tortoise Shell.—The name applied to this article of commerce is somewhat of a misnomer, as it is supplied by a turtle; these turtles are fairly common in our seas, and are usually obtained by means of spearing as they lie asleep on the surface of the water. It is averred that the turtle-egg collectors, if they find a lay of eggs, less than one hundred and thirty in number, return to that spot twelve nights afterwards when the same turtle comes again, and, being secured, is always found to be of a good kind. (The ordinary turtle is not interfered with.) The usual price of tortoise shell is about $6 to $12 for the produce of one turtle, but occasionally, single shells are valued at extraordinarily high prices. Some short time since one was secured by Panglima Ypel, which was said to have been sold for $500, and more recently, we have heard that $2,000 was asked for a single specimen brought to Sandakan. No people but Chinese, would pay such prices for such an article.

Turtle Eggs.—Some of the sandy shores of the islands about the East Coast, abound with turtle eggs, which are collected by boats which go in search of them, and quite a large trade is the result, baskets' full always being exposed for sale during the season in the shops at Sandakan. The island of Bergoan is the one most favoured by the turtles, and the season is during the continuance of the southern monsoon, viz., fron April to October.

Sharks' Fins.—Sharks abound in these seas, and are caught chiefly by the Bajaus, in a variety of ways, sometimes by hook and line, sometimes in *keelongs* (fish-stakes or fish-weirs they would be better known as in England), and sometimes by spearing, but by none of these methods can the very largest be captured, and they sometimes are seen of immense size. A Bajau boat however rarely returns from a trip of any duration, without bringing a bunch of tails and fins, usually cut off from fish four to seven feet in length. The quantity in the sea may be described as inexhaustible, and the larger our sea-population grows the more sharks fins are likely to be brought to market. Our sharks are, to a certain extent, dangerous, but not so very much so; an occasional mother-of-pearl shell diver is carried off, but otherwise accidents happening to persons going into the sea are rarely heard of, not by any means so often, as from crocodiles up the rivers. I have seen a canoe pass over the spot, where, a few minutes before, the two back fins of a shark had been visible, and between which the canoe (a very small one) could almost have been placed lengthways. A crocodile of similar size (if such a thing were possible) would almost certainly have tried to upset it, or at any rate knock the man overboard. The trade in sharks' fins, like most of the other articles hitherto mentioned, is carried on exclusively with China. Prices range from $8 to $25 a picul, and Exports were in 1882 $837, 1883 $1,105, and 1884 $1,516.

Sponges.—These are frequently washed ashore all along our coast line, wherever there exists much coral. I have seen one or two pretty fair specimens, but if sponges of any real value could be obtained by systematic searching or by a slight amount of culture, remains yet to be seen.

Edible Oysters.—In some places these abound to such an extent, that there are as many lying on the rocky shores as there are stones, and at first sight it is difficult to distinguish one from the other, boat loads could be obtained without any trouble. They are very good eating and quite innoxious so long, that is as the *rock* variety is procured. There is another kind found adhering in masses to the roots and branches of the mangrove trees, which ought to be carefully avoided, for, if eaten, this oyster occasionally produces an attack very much resembling colic, and even more dangerous. When dried, however, its harmful qualities are, I believe, to some extent destroyed. It is expected that a certain amount of export business will in time be developed in both these kinds of oysters.

Fish.—Nowhere in the world, probably, is there such a quantity and variety of good eatable fish, Eswarming in the seas, as off the ast Coast of North

Borneo. This is mainly owing to the wide extent of shallow seas (up to one hundred and fifty fathoms in depth) and to the numerous islands. Various of these fish resemble cod, rock-cod huge perch, whiting, herrings, &c., *menungin* is like haddock; *pila-pila*, soles; *ikan-mirah* red garnet; *ikan-parey* is a general term for all sorts of flat fish, skate, flounders, &c.; *ikan-tumbun* is nothing other than sardines; *ikan-blannak*, mullet. A large silvery-scaled fish has the appearance of salmon, but there the resemblance ceases. A great variety of others have no synotypes, in our English waters, but are excellent eating. Several methods are employed in their capture. *Keelong*, (fishstakes); hook and line; *scrambau*, (dip-net.) nets; casting-nets; spearing with and without torches, and *bubut* (a sort of trap sunk in the water) are the principal. Of these *keelong* fishing is the favourite when it is intended to take away a quantity. The principal, upon which the *keelong* is designed, is that of the wire mouse-trap, which being once entered it is impossible afterwards to escape out of. A fence, or barrier, extends from the shore to the required distance out at sea; the fish encountering this, skirt along it, and thus find their way through two outer chambers, till in time, they arrive in the end compartment. When once the fish have gone into the first chamber, there remains little chance of escape for them, the sides being curled inwards in a heart-shape at its entrance, so that though very easy to pass in by, it is a difficult matter to return. The compartment at the end is usually round, and about seven to nine feet across. The *keelong* is made of split bamboo, driven into the sand, and lashed together by split rattans. The total length of the split bamboo, at the end of the *keelong* being usually from twelve to fifteen feet. Low tide is naturally the time the fish are captured, a canoe paddling up from the shore frightens as many as possible from the first and second chambers into the end one, the narrow entrance or door-way into which is then closed altogether for the time by men who descend into the water, and put through the catching operations, with some little assistance from above. A curious sight may be seen when all is ready by anyone getting upon the slender scaffolding which surrounds and surmounts the end chamber, the water below being thick with fish of all sorts and sizes. The next proceeding is to lash a loose piece of *keelong* or bamboo-matting stick or screen kept for the purpose to the inside of the chamber (most of these operations, it will be understood being conducted under water), and being unfolded gradually, the fish are driven into a central fold of it till there is almost a solid heap of them. A basket is then let down from the scaffolding on top, and the fish are simply bailed out by the basketful and thrown into the canoe alongside. Many of the fish manage to get by or under the loose piece of *keelong*, as it is being folded around them, and this process has to be repeated three or even four times before all are taken, and even then there are frequently one or two so large that they cannot be got with the basket, and have to be speared. From three to five piculs of fish is not an uncommon take from one *keelong* a day; and four *keelongs* have been known to yield nearly thirty piculs a day between them for a week together. There is an absence of mental strain or physical exertion in working a *keelong*, which much commends it to the Malay character, for, as soon as the fish are caught, they are taken to market and sold in one lot to the stall-keepers, and there remains nothing else to be done during the rest of the day. This industry is capable of being indefinitely increased. If our population were larger and more pressed for means of subsistence, the fishermen would make larger and deeper *keelongs*, and would no doubt catch many more fish and a large export trade in salted fish would soon be inaugurated. In the south of Borneo, and in Java, there is a large inland population, salt fish being one of their staple articles of consumption, and their own seas being unable to supply all they want they would come to us for the balance.

Keelongs are a sure method for capturing crocodiles, should one appear in the neighbourhood of a *keelong*, it is certain to be found inside it during the course of the next day or two. No matter how large they happen to be, they but very rarely succeed in forcing their way through the fencing, as the bamboo is very tough and yielding, and, owing to its being partly curled round, the creature cannot exert its full strength. When once caught, they are easily despatched by a rifle shot through the head, fired from the scaffolding above. The next most important method of catching fish, in any quantity, is by seining. This mode hitherto on our coast can scarcely be described as successful, the takes, by its means, not affording an adequate return for the capital invested in the seine and the labour involved. Seining has been principally practised by Chinese fishermen from Hongkong, and there is no charge to be brought against them for lack of energy, but it has been almost painful to notice the disappointing results they have brought to market after a hard day's toil, with expensive apparatus as compared with the boat loads of fish brought in by Sooloo men who have simply bailed them out of their *keelongs*, the construction of which costs but little money. The Chinese however are very loth to adopt new ideas, and sooner than practice what is clearly the best mode of obtaining a good catch in these waters, they give up the whole thing in disgust and return to Hongkong. Far too many young fish are captured in the seine, a matter which will require legislature in the future. All the other methods, by which fish are caught, may be described, as hand-to-mouth, ones, or at all events, suitable for the supply of the local market only. Hook-and-line fishing, is, perhaps the principal. When owing to want of rain, the water is very clear, the fish avoid the *keelongs*, and the supply in the market falls short, a canoe with two men, lying inside the harbour, can always capture from sixty to eighty catties of fish, in a few hours, which being in request, they can easily obtain $3 or $4 for, in the market. *Scrambau*, or dip-net fishing sometimes results in large takes, but it is only had recourse to in the off season: it is usually over twenty feet in width and is managed by a man sitting in an elevated position, who when he sees a shoal of fish passing over the net, lifts it and captures them. The fish thus caught are nearly always mullet; eighty catties a day is by no means an unusual take. The casting net is usually employed as a means for providing fish for single households. The correct way of handling it is a small art soon acquired, and it affords good amusement when fishing for shrimps and *ikan tumbun* (sardines.) These latter fish are very abundant in the Omaddal district, shoals of enormous size being always visible. The spearing of fish is practised from boats when opportunities offer; large skate and other flat fish which have a habit of sleeping on the surface being frequently taken by this means, and at night a bright light, either carried by hand or in a canoe attracts fish which are then easily speared, but no great quantity is taken in this way. Up to the present time the export of salt fish, has been very small, the upcountry demand being large enough to take all that is salted, but with an increased population, and cheaper labour a very large and important business may be expected.—*North Borneo Herald.*

CUTTING BACK PEACH TREES.—A "Maryland correspondent" says: "Some weeks since a very intelligent gardener insisted with me that cutting back budded peach trees was one source of weakened power that led to disease. The budded peach is, as you know, operated on near the ground. The next winter or spring the plant, perhaps four or five feet high, is cut down to the bud. Numerous sprouts come, and one only left to form the tree. This check, he says, affects the constitution of the tree. The seedling tree is not cut back, and for this reason it is always a healthier tree. Is there anything in this doctrine?" [We think there is a little theoretically—but practically it is we think so little of an injury as not to interfere seriously with the health. But it is worthy further thought.—ED.—*Gardeners' Monthly.*

CONSUMPTION OF TEA.

Those who are afraid of tea being overdone, may derive encouragement from the fact that in the seventeen years between 1870 and 1885, the consumption in Britain has increased by 60½ millions of lb., or by about one-half of what the consumption in 1870 was. The average rate of increase per annum was very nearly 3½ millions of pounds, a rate which, if peace is preserved and prosperity prevails, is likely largely to increase with the increase of population. There is every reason to believe that the present depression in India and Ceylon tea is only temporary.

PLANTING IN DELI.

(*Translated for the Straits Times.*)

A novelty in the commercial line is coming into vogue in Deli. Efforts are being made by certain parties there to buy up cover-leaf tobacco on the spot by Europeans. Their intention is to secure all the leaf available, so that none can be sent to the Amsterdam market. The local *Courant* is dead against the continuance of this practice, on the ground of its trenching on the virtual monopoly of the Amsterdam tobacco dealers which, so far, has worked advantageously in the interest of planters, importers, and traders generally. The rise of Deli as a tobacco producer, and the high position taken up in the market by that article, are said to be mainly due to the present state of things in this regard. The novelty, if allowed free play, will result in Sumatra tobacco being forwarded direct to smaller markets in different parts of the globe instead of to one central market at Amsterdam, where the multitude of dealers congregating in the busy season, ensure competition resulting in higher prices than can be secured under other circumstances.

Tobacco growing in Deli bids fair to distance that branch of cultivation as carried on in Java, owing to the crushing fiscal burdens weighing upon growers in the latter. To bolster up the failing revenue, a license tax has been imposed in Java, which has proved so heavy and oppressive as to be intolerable to the long suffering Javanese. The land tax is pitilessly exacted from the latter in spite of the circumstance that their means of meeting it are crippled by the price of rice falling 25 to 30 per cent. To make both ends meet, they had to set about growing tobacco. When ripe they gathered and cured the tobacco at home for sale in the neighbourhood. The money earned thereby, however small, proved welcome additions to the budget of the overburdened cultivators. Nowadays they have to take out licenses before they can plant tobacco at all. The bother and expense of taking out licenses have turned out so great as to deter the simple villagers from growing any more tobacco. No wonder the license tax has become hateful, detested, and vexatious.

The Battaks go on merrily burning down tobacco storehouses on estates. Sometimes they act on one pretence and sometimes on another. In one instance incendiarism was resorted to for the purpose of recovering alive a Battak killed by a certain headman. The authorities are too busily engaged in other matters to admit of their grappling firmly with this evil, no matter how hard it may prove upon the planters.

FISH-BREEDING: THE HISTORY OF HOWIETOUN.

The History of Howietoun. Part I. By Sir J. Ramsay Gibson Maitland, Bart. (Stirling, N. B. : J. R. Guy. Secretary Howietoun Fishery 1887.)

In view of the recent successful introduction of trout ova to the Nuwara Eliya Lake, our readers will be interested in the following extract from a review in *Nature* :—

Probably every one at all interested in fish-breeding has heard the name of Howietoun, and a great many people, especially in Scotland, have some knowledge of the character of the establishment and the operations there carried on. Occasional paragraphs in scientific periodicals, as well as in daily papers, announce some experiment in the artificial stocking of home waters with some kinds of trout or with salmon fry, or some successful exportation of salmonoid ova to America or to the colonies at the Antipodes. The name of Sir James Maitland or of Howietoun very often occurs in such announcements. Those who have given attention to the subject will find much to interest them in the account of the development of his fish-farm, and in the description of its present condition, which Sir James Maitland is now placing before the public. * * * *

In Chapter III. an elaborate account is given of the methods of packing ova. The first operation is to transfer the ova which are to be packed from the *grilles* to peach netting stretched on square wooden frames. This step is carried out in a specially constructed sink, through which water is kept running. The ova are emptied from the *grille* into a wooden box, from which they pass into a leaden basin with a narrow bottom. One of the frames is then floated in the sink, and a glass measure containing 1,100 eggs is used to measure the eggs from the basin on to the frame. The frames are placed in the packing-room in piles, one pile for each box. Next morning the frames are examined, so that any egg with an ill-developed embryo may be picked out. Then a square of swan's-down, contained in a special tray, is placed over the eggs on the frame, and, the two being suddenly reversed, the eggs rest on the swan's-down without altering their relative position; thus each egg lies separately on the swan's-down. The frame is removed, and the square of swan's-down with its burden placed in one of the travelling trays. Above the eggs is next placed a square of felted moss (*Sphagnum*). Above the moss is placed another layer of swan's-down carrying layer of eggs, and then another layer of moss, and so on, till the travelling, tray is filled. The bottom of the travelling-tray is made of perforated zinc, and before any eggs are placed in it, the bottom is coverved with a thin layer of moss. The eggs thus rest on swan's-down, and are covered with felted moss, a layer of which also forms the lowest and uppermost layer of the tray when full. For journeys to the Continent or America, unbleached lino is substituted for the swan's-down, because swan's-down retains so much carbonic acid that advanced embryos are asphyxiated. For the Antipodes, an extra precaution has to be taken: a thin layer of moss is inserted between the layer of unbleached linen and the eggs, so that the latter are in contact with the moss above and below. The travelling-tray is 10 inches square and 2½ inches deep. The trays packed in an inner box only ⅜ inch larger than themselves, and this is placed in an outer box 4 inches deeper and 3 inches wider than the inner. Between the two is a layer of sawdust. The outer box or case measures 1 foot 4 inches square, by 1 foot 10 inches deep. This is the method of packing for short journeys within the United Kingdom. The boxes for foreign consignments are larger, and oblong in shape; there is a sawdust space as in the boxes already described, but the trays are separated by meaus of charred fillets, so that an air-space surrounds each tray: above the pile of trays is a large ice-tray, which occupies the whole of the top of the box. Ova can be safely kept in one of these boxes during a period of sixty days.

COFFEE-CROP PROSPECTS—We hear that in consequence of the showers we mentioned a fortnight ago in the Ouchterlony Valley and Gudalur, there is now a fine display of vigorous blossom which, with a continuation of a favourable weather, should resu in large crops.—*S. I. Observer.*

BRAZILIAN RUBBER EXPORTS—during 1886 (according to the *American Grocer)* were 28,457,299 pounds, of which 17,411,662 pounds were to the United States and 11,045,637 pounds to Europe. The stock in Brazil, Jan. 1st 1886, was 2,435,400 pounds, and at the close of the year, Dec. 31st 1886, 1,541,375 pounds.

THE RECENT "PEPPERETTE" disclosures, which prove that a great deal of what is commonly called pepper is really ground olive stones, will not surprise people acquainted with the tasteless powder usually to be found in restaurant pepper-casters. The only way to defend oneself against the adulteration of coffee is to grind it oneself, and the same applies to pepper.—*Globe.*

TEA: BONDED GOODS.—The monthly account of the quantities of bonded goods remaining in the Customs and Excise warehouses of the United Kingdom on January 31st as published in the B. Bill of Entry, shows a stock of tea amounting to 109,386,375lb., against 108,154,004lb. in 1886 and 116,310,677lb. in 1885; cocoa, 8,931,998lb., against 6,164,303lb. in 1886 and 6,875,895 in 1885; coffee, 283,327 cwt., against 312,735cwt. and 372,523cwt. respectively.

GOLD IN BORNEO.—We have been shewn by Hadji Brahim a sample of coarse gold from the Bole river got a short distance above its junction with the Segama river, one piece is half quartz, and evidently not travelled from the matrix. In the opinion of the diggers in Sandakan the quartz reefs containing the gold are not far to seek. The dry weather and the search of experienced miners will doubtless bring them to light.—*British North Borneo Herald.*

VANILLA CULTIVATION.—Mr. W. H. Wright's culture of Vanilla—an orchid be it remembered—is likely to be most successful. On his two brickwork circles of trellis work at Wilhelmsruhe, Mr. Wright has up to date artificially fertilised no less than 3,000 flowers. He is also trying experiments with gum arabic and with ants in modes of fructification. It must be remembered that to Mr. Wright—in the old Peradeniya days of 30 years ago—belongs the credit of being perhaps the first in Ceylon to cultivate Vanilla for the European market. Some pods sent by Mr. Wright to an Exhibition in Sir Henry Ward's time were valued at 5 guineas the pound. A portion of the same Vanilla was sold at that rate in London through Messrs. Baring Brothers.' On that occasion the Committee, (Messrs. Rawdon-Power, Layard, &c.) red-tape-like, decided that Mr. Wright's small assortment could not be sent on. So also said other big-wig officials when applied to. Mr. Wright asked to see the Governor. Mr. John Bailey and others in attendance said: "Impossible—Sir Henry is deeply engaged with the mail." But Mr. Wright persisted and finally got an interview, with the result that like the hearty, manly English gentleman he was, Sir Henry entered into the Peradeniya Assistant's experiment with the greatest interest. "Stop the mail" was the Governor's cry;—but it was too late. "Well then prepare a runner express at once" was the order and all this for Mr. Wright's Vanilla! No wonder though Sir Henry Ward endeared himself at every turn in his Government of Ceylon.—Mr. Wright's experiment at Wilhelmsruhe is merely preliminary to cultivation at Mirigame where about 10 acres are being devoted to Vanilla.—Dr. Trimen has pronounced Mr. Wright's garden Vanilla the finest he has ever seen.

COFFEE AND CAFFEINE.—Some interesting experiments have recently been made by Dr. B. H. Paul and Mr. A. J. Cowuley on coffee berries in the unroasted state, and the results as published by them have revealed several important facts hitherto imperfectly understood or erroneously recorded in chemical literature. Many varieties of raw coffee, it is well-known, come into our markets, and their value varies so greatly that it is natural to suppose that their quality, so far as caffeine content is concerned, may vary proportionately, and a semblance of reality is given to this supposition by the published data, which put down the percentage of caffeine in raw coffee as from a fraction of 1 per cent. to as much as 3·64 per cent. Dr. Paul and his coadjutor have examined altogether about a dozen different kinds of coffee, and find that, instead of the percentage of alkaloid being variable, it is wonderfully constant; for example, Ceorg coffee beans yielded 1·1 per cent. (the minimum), while the maximum, 1·38 per cent., was shown by Liberian coffee, the variety which has been found to withstand climatic influences under which all others succumb. Continued experiments corroborate the first results, and it is fairly established that pure coffee may be judged by the amount of caffeine which it contains, about 1·3 per cent. being taken as the standard for roasted coffee. Consequently, the fraudulent sale of mixtures of coffee with chicory or other less valuable substances is now rendered easy of detection by Paul and Cownley's discovery, and they have rendered important service to chemical analyses by it. Another statement which they appear to have disproved is that caffeine is volatilised from coffee beans during the roasting process, for they find that the roasted beans contain proportionately the same amount of alkaloid as the raw beans.—*Chemist and Druggist.*

COFFEE IN AFRICA.—A planter writes:—"Have you seen the annexed from the 'Free Church of Scotland Monthly Record' for January *re* coffee planting in Central Africa. I remember going in company with the late Professor Balfour of Edinburgh, through the Edinburgh Botanic Gardens, and if I mistake not seeing the very coffee trees from which the seed sent out was derived, and at that time they had a quantity of white bug, the common white coffee bug of Ceylon, on them. No attempt had been made to take off the bug, though I daresay there being only one or two trees, it might easily have been done:—'2. African Missionary Coffee:—We have received from Mr. Ewring, Secretary of the African Lake Company, a sample of coffee drawn from the Company's first shipment of African coffee. Its history is noteworthy. Of three plants sent out to Shire Hills from the Edinburgh Botanic Gardens one survived. That plant has, in eight years, by the careful culture of the Messrs. Moir,' (sons of the well known Dr. Moir of Edinburgh) 'and their assistants, produced seventy bags of many hundredweights, of the finest coffee. The culture is a commercial success, and should result in time in the covering of all the hills and plateaus around the lakes with the best foe of the slave trade and substitute for fast disappearing ivory.' *Note.*—I fear, however, they are reckoning without another foe viz. leaf-disease. It will, indeed, be strange if this coffee should be without it." [Africa is, of course, the home of coffee: and in Abyssinia on the east, as in Liberia on the west, and no doubt in other parts, the shrub or trees can be found growing wild. But to get over the difficulties of securing steady labour, *transport* &c., will take many years, and it will be long before an appreciable effect is made on the exports and world's supply. Taking coffee plants from Edinburgh to Africa seems like taking coals to Newcastle.—ED.]

Mexican Ixtle.—The United States Consul of Mexico writes that the ixtle fibre, which comes from the lechuguilla, is becoming more widely known in Europe and America. It is used largely in the manufacture of brushes, sacks, mats, ropes, cordage, ladies' corsets, carpets and coarse cloths. It is also employed with success in the fabrication of imitation Brussels carpet, and in the imitation of hog bristles for brushes. Ixtle is exported from Mexico only as raw fibre. There are no factories in Mexico for the manufacture of goods from the fibre. The fibre is extracted from the lechuguilla plant, which grows wild in certain mountainous regions.—*Bradstreet's.*

Ceylon Pepper.—Pepper has been one of the oldest of Ceylon exports; the Dutch paid attention to it, but since then, it has become of little importance, save in its growth by natives for consumption in their local markets. Among "new products," however, which have of late years been claiming the attention of European planters is pepper, and we are glad to learn that a favorable report has been obtained on the North-Matale-grown article which has been valued in quantity at 8d to 8½d per lb. The report goes on to say:—"It is highly charged with the natural oil, *i. e.* pepperine, on which account it would be valuable for mixing purposes." Seeing that the treatment of the product in preparation, in the case referred to, was that of beginners, the report should, we think, be considered eminently satisfactory.

Tea at High Elevation in Ceylon.—The actual yield last year of six different estates of varying altitude from 4,200 to 6,700 ft. The yield of each field had throughout the year been kept separate, so that only the results of tea five years and upwards was taken. The highest yield from a 20 acre field was 631 lb. and the altitude almost as high as any others 5,800 ft. The lowest was 320 lb. and the altitude 4,960ft. All the tea was grown on old coffee land, though the coffee was not very old and not a bit worn out when removed to make way for the new product and realized good prices in London, none selling under an average of 1s 2¼d so that the financial results were capital. The real significance of this result can only be understood when I say that three-fourths the land likely to be in tea two years from now will be old coffee-land and very much more than half will be over 3,500 ft. altitude.—*Cor.—Indian Planters' Gazette.* Feb. 22nd.

The Samples of Cinnabar found up the Segama river in the vicinity of Pulo Itok Batu, mentioned in a previous number as having been sent home for assay have proved to be of a most satisfactory character. Messrs. Johnstone and Mathey report the average assay of the two samples to be 53 per cent, one sample averaging considerably better than the other at 75 per cent. This assay is decisive as to the fact of the Segama country containing payable Cinnabar lodes and a systematic search for the lodes should be set on foot. There are Sarawak men engaged in digging for gold in the Segama, men who have also worked for Cinnabar at Sarawak. These men should be only too glad to prospect for the sake of the Government reward. Mr. Sun Kuong Lung on being shown samples of Cinnabar at a meeting of the Gold Committee on the 27th January at once recognized them as identical with stones he had got in washing in the Bole river, but not knowing their value had thrown them away. Some of his coolies also indentified the samples. As those assayed came out of the main river some considerable distance above the junction with the Bole, it is evident the Bole deposits are distinct from these found in the main Segama.—*North Borneo Herald.*

Potatoe Disease.—Some highly interesting experiments have recently been made by Messrs. Jensen and Nobbe to protest potatoes from disease. The main thing in the system experimented upon is to earth the stalks as high as possible. Mr. Nobbe has constructed and used a special plough for the purpose; and he reports that all his experimental fields were free from disease, although the lattor prevailed in the district. The experiments were continued for three years, and in all cases the potatoes were free from disease. It was found, however, that the total yield of the protected crops was less than those which were unprotected in the above manner. It is thought that the loss is due to the injury caused to the leaves and stalks by ploughing.—*Australasian.*

Snake Poison.—A German chemist has been experimenting with snake poisons, and the following are the the conclusions he has arrived at:—In the Indian cobra the venom is not due to living germs, as some people have stated: nor even the so-called "cobric acid." All the alkaloids are entirely absent from the venom. The "cobric acid" crystals are in reality composed of sulphate of lime. Mr. Wolfenden says that the poisonous properties of the snake poison are due to its proteid constituents as follows—Globulin, which is always present, and kills by causing asphyxia; syntonin, very similar in its action to globulin, but less intense, and serum albanum, also poisonous, which produces paralysis. Again, in the venom of the Indian viper, Mr. Wolfenden found no germs, toxic acids, nor alkaloids, only three of the proteids above mentioned.—*Australasian.*

Sawdust.—Some of our best cultivators have lately been advocating the use of this for propagating, and it possesses all the qualities claimed for it, but, as a rule, I think it rather light and open for some things rooting freely when used by itself. When, however, a half-and-half mixture of it and sea or silver sand is made up, cuttings in it then root both quicker and better. Further, as the time is now upon us when our fresh Cauliflower, Cabbage, &c., will be planted out, and will offer tempting meals to snails, many will be at their wit's end as to how to prevent loss, and I may tell them that nothing proves a safer remedy than sawdust. If a good handful is placed around the stem of each plant it acts as a mulching to the roots in dry weather, and whether wet or dry a snail will hardly ever attempt a passage across its surface.—G. D. in *The Garden.*

Getting Rid of Stumps.—The *Scientific American*, gives the following important information to those who desire to get rid of stumps on their farms:—"In the autumn or early winter bore a hole one or two inches in diameter according to the girth of the stump, and about eight inches deep. Put into it one or two ounces of saltpetre, fill the hole with water, and plug it close. In the ensuing spring take out the plug, and pour in about a gill of kerosene oil and ignite it. The stump will smulder away to the very extremity of the roots, without blazing, leaving nothing but ashes.—*Rural Australian.*

Fish Farming is an industry that will yet find scope in Queensland. A great success has been realised with carp, perch, tench and other British and Continental fresh water fishes in Lake Wendouree, on Ballarat, Victoria; and an example furnished us Queenslanders to go and do likewise. Very deep tanks or waterholes are not best adapted for fish of this description. Water three feet deep, if shaded and permanent, is better than if ten feet in depth. We have very little confidence in the success of the experiment of letting fish—carp, perch, etc., loose in the Gold Creek Reservoir for that very reason. The best carp ponds in the old country are very little more than two feet deep; and there are plenty of fish farms now in America where the water is always shallow and often warm. There is no reason whatever—save lack of enterprise—to hinder Queensland becoming well stocked with this welcome addition to her bill of fare. Farmers, gardeners, and squatters could easily farm their own fish.—*Planter and Farmer*

THE USE OF THE ORANGE.

(Translated from the French of Louis Figuer.)

The orange is extensively cultivated in order to extract from its flowers and leaves the essential oil which they contain. In the south of Italy, about Sorren o, whole forests of oranges exist, the fruit of which is carefully harvested, of which Lamartine sings:—

"On the Sonorous Shore where the sea of Sorrento
At the foot of the Orange unrolls its blue wave."

The orange sometimes attains great age and dimensions. In the orangery of Versailles a magnificent bitter orange (C. Bigaradier) familiarly called the "Great Constable," is known to be 450 years old. Its trunk is 30 inches in circumference. It was planted in 1421 by the gardener of the Queen of Navarre. The orange tree at the Convent of St. Sabina, at Rome, dates from the year 1200. It is about 33 feet in height. At Nice, there was in 1789, a tree which usually bore upwards of 5000 oranges, was more than fifty feet high, with a trunk which it took two men to grasp.

The substance to which odoriferous plants owe the qualities which render them so useful at the toilets' is a volatile oil. It happens sometimes that distinct oils exist in the same plant. The orange furnishe, an example. The essence drawn from the flowers of the orange is very different to that furnished by the leaves, and the latter differs from that furnished by the fruit. The mode of extracting these essences varies according to their nature and condition. Some of them may be extracted by simple pressure. But the greater part of the essences are obtained by distillation but even this practice is being sup erseded. The essential oils obtained by distillation dissolve readily in fatty oils or alcohol, but very imperfectly in water. The condensed water, however, which passes over with the oil is a true watery solution of the essences, in fact, orange flower water. A large proportion of the essences used by the perfumer are not made by distillation at all, they are extracted from plants by the agency of fat.

At the season when the flowers are in bloom, clarified fat, generally lard, is "melted in a water bath," such as a "double glue-pot," and as many flowers, such as jasmine, orange or rose, are put into it. These are allowed to remain commingled about 24 hours, at a temperature just sufficient to keep the fat liqu d; the fat is then strained off. It is strongly scented; the flowers have lost their perfume. The same fat is melted again and further flowers are added. The process is repeated in all "seven times," and is then very highly scented, and is ready for use or exportation as pomade: to obtain the spirituous essence or tincture, suitable as a perfume for the handkerchief, the pomade is macerated in spirits of wine, which dissolves the greater portion of its perfumed oil, what remains, however, is sufficient to render the grease a rich pomatum for the hair. —*Rural Australian.*

ORANGE AND LEMON CULTIVATION IN SICILY.

Consul Woodcock, of Catania, states that oranges and lemons are designated, in Sicily, *marina* and *montano*, the former growing in the lower altitudes near the sea, and the latter on the mountains. The montano, or mountain fruit, is the choicest, and commands the best prices in the market, but the crop is not so sure, owing to the frost. The marina orchards bear more abundantly, and the crop is more certain. In commencing an orange or lemon orchard, the following is the method adopted:—First, the seed of the bitter orange is planted, and when the young plants are a year old, they are transplanted. When they have grown to be about one inch in diameter, that is, when they have attained the age of three to four years, they are again transplanted, and placed in the orchard where they are intended to remain. The tops of the young trees are then cut off about four feet above the ground, and when they have taken firm root, the best varieties of the orange and lemon are budded upon the stock. Two buds are generally inserted, and upon opposite sides of the plant. From these buds, branches shoot out, and when a quarter of an inch in thickness, become of a reddish colour. The distance to be maintained between the lemon trees in the orchards depends upon the situation of the ground, and conditions of soil and climate; usually it varies from thirteen to nineteen feet. When the soil is loose, rich, and easily cultivated, the lemon trees are planted at least nineteen feet apart, as they will then grow luxuriantly and attain considerable size. The distance maintained between the orange trees is from thirteen to fourteen feet, and this varies in accordance with the situation and quality of the soil, as in the case of the lemon. The ground in the orchards between the trees is always cultivated, and great care is taken to keep it scrupulously clean. The soil is worked at least five times a year, commencing in March and ending in October. When the trees are young and small it is not considered necessary to work the soil, as it is believed that the vegetable growth protects the young plants from the too powerful rays of the sun. The annual cost of cultivation in the best orchards per hectare (the hectare being equivalent to 2·47 acres) is estimated at about £30, but where extraodinary outlays are necessary, such, for instance, as is incurred when there are streets running through the orchards, as is often the case in the lava covered soil of Sicily, or through the necessity of obtaining steam power for irrigation, the cost per annum is sometimes as much as £80 per hectare. On the average, a lemon tree produces in Sicily one thousand lemons annually, and an orange tree six hundred oranges, and cases have been known where trees have produced ten times this amount of fruit. The trees are subject to various diseases. A parasite growth of a fungus nature frequently apppears upon the bark, and the lemon tree is more subject to this thanthe orange. This growth, after a heavy rain, or after being soaked in water, can be removed by scraping. The fruit of both the orange and lemon tree is also sometimes injured by a small insect which makes its appearance at the beginning of summer, and commences its work of devastation by depositing its eggs in the fruit itself, and these develop into grubs, which entirely destroy it. As a preventative, tar water and water slightly tinctured with kerosene, are used to wash the leaves and fruit, and soda ash is also frequently employed. In picking the fruit for exportation, which is usually done by hand in the month of November, the greatest care is taken to avoid bruising or injuring it in any way by rough handling, and it is then placed very gently in baskets lined with cloth. The stem is left on the fruit, cutting it about a quarter of an inch from the surface of the fruit. Before placing the fruit in the boxes, all insects and other injurious matter are removed. The boxes generally used are capable of holding from two hundred and fifty to three hundred and sixty oranges or lemons, and are made with a partition in the centre. They are lined with common silk paper, and each orange or lemon is encased in the same kind of paper before being placed in them. The boxes are not made air tight, but interstices are left between the boards for ventilation. Lemons gathered in the month of November, and thus packed, are supposed to keep without spoiling for six months, but oranges will not keep so long.—*Journal of the Society of Arts.*

QUESTIONS IN AGRICULTURE.

BY PROFESSOR JOHN SCOTT.

[We commend this valuable epitome of soil science to the attention of our readers.—ED.]

I.—SOILS.

1. Explain the origin and formation of soils.
2. Name the chief elements of plant growth found in all fertile soils,

3. In what respects do soil and subsoil differ?
4. Explain the following terms:—Weathering, Denudation. Alluvium, Drift, Nitrification.
5. Give a brief statement of the physical properties of soils.
6. What are the physical properties of (*a*) clay soils, (*b*) chalk soils, (*c*) sandy soils, (*d*) peat soils?
7. How is fertility of soil influenced by (1) mechanical texture, (2) climate and local conditions?
8. What practically determines fertility of soil?
9. Distinguish (1) between a *barren* soil and a soil *exhausted* and (2) between *natural* and *acquired* fertility.
10. How are soils classified?
11. What soils and conditions of soils possess the power of capillary attraction in the highest degree; and what is its importance as regards drainage, the retention of moisture, and the supply of that moisture, to the growing plants?
12. State some of the principal causes of infertility in soils.
13. Is there a ready test for ascertaining the presence of injurious constituents in soils?
14. Give instructions for a rough mechanical analysis of a soil.
15. What is meant by exhaustion of soil, and what causes it?
16. Mention (*a*) the surface distribution, and (*b*) the agricultural characters of (1) silurian, (2) old and new Red Sandstone, and (3) Greensand soils.

ANSWERS.

I.—Soils.

1. The mineral and organic matters forming the crust of the earth are the origin of all soils. The inorganic or mineral portion of the soil is derived from the crumbling down of the solid rocks, by the natural process of weathering or disintegration, which is favoured by warmth, and the presence of moisture and organic matter. All rocks, however, are not acted upon with the same ease: but the hardest of them are surely though slowly crumbling into dust under the mighty but invisible agency of the carbonic acid and oxygen of the air. The union of decaying vegetable matter in the soil with the oxygen of the air also helps to promote the decomposition of rocks,—as do frosts, rain, wind, and other kindred forces. These disintegrating agents are further aided by the root-growth of plants, by the burrowing of worms and other earth-dwelling creatures, and in no small degree by the acids generated by organic decay. The organic portion of the soil is derived from the remains of plants and of animals and insects of various kinds. In some cases the soils are purely organic in their origin. These are both plant and animal formations—the former comprising vegetable mould and peat mosses; the latter, beds of chalk and limestone, &c.

2. The inorganic or mineral constituents found in all fertile soils are—silica, alumina, calcic carbonate, potash, soda, magnesia, phosphoric acid, sulphuric acid, chlorine, and oxide of iron. The first three—sand, clay, lime—represent perhaps 90 per cent or more of the substance of most soils. The others vary from a mere trace to at most 2 per cent. The organic matter is formed of C. H. O., and a series of organic acids—humic, ulmic, geic. Sandy soils are generally deficient in this ingredient. Cold clays are also poor in organic matter. In fertile loams it is more abundant; and in peaty soils it is usually in excess. Altogether the organic matter in soil varies from 1 to upwards of 90 per cent.

3. In a majority of cases the *soil* is merely rotted *subsoil*, and differs from the latter chiefly in the greater amount of oraganic matter it contains, end in being less compact, and darker in colour.

4. "Weathering" is the term used to denote the natural disintegration or breaking up of rocks as explained in answer to the first question. "Denudation" is the wasting or carrying away of soils from the place of their original formation by rainfall or surface water. "Alluvium" is soil deposit which has been transported from higher to lower levels by the agencies of rivers or tides. "Drift" or *boulder clay* is a wide-spread surface detritus of the different formations, which is attributed to glacial action. "Nitrification" is the oxidation of nitrogenous bodies in soil—humus and ammonia—and their conversion into nitric acid.

5. The physical properties of soils which may be supposed to exert a greater or less influence on fertility have been well stated by Schubler as follows:—(1) The weight of the soil, its specific gravity as well as the absolute weight of a given bulk in a dry and moist state. (2) Its power of containing water, according to its weight and bulk. (3) The firmness and consistence of a soil in its dry and in its moist state. (4) Its different capability of becoming dry on exposure to the air. (5) Its diminution in bulk on drying. (6) Its absorption of humidity from the atmosphere, (7) Its absorption of oxygen from the atmosphere. (8) Its power of retaining heat. (9) Its capability of becoming more or less warmer by the sun's rays. (10) Its capability of developing heat on being moistened. (11) Its electric polarity and capability of conducting electricity.

6. A clay soil differs from all others by being tough, wet, and cold. In wet winter weather it sticks to the plough, like mortar, and in dry summer weather it is hard and cloddy, and the surface covered with chinks or cracks. A sandy soil is subject to defects of an opposite description. A chalky or calcareous soil contains a great deal of carbonate of lime and when wet is of a soapy nature, but is marked by the freedom with which it admits of natural drainage, and warm and productive though white in colour. A peat soil if light and spongy in texture, dark in colour, and very absorbent and retentive of both heat and moisture.

7. Mechanical texture influences fertility of soil in a great degree for the conditions of air moisture, and warmth which are essential to the development of the changes which occur in the process of germination, have little or nothing to do with the chemical qualities of the soil, but are all dependent upon its mechanical relations. This influence is not confined to the first stage of vegetation. Climate also exercises a great influence on fertility, and disregard of local conditions sometimes leads to very erroneous estimates of the value of soils which may be similar in composition, and texture.

8. Fertility of soil is practically determined by the *minimum* of any one essential ingredient and not by the maximum of the others, but intrinsic value depends on the depth of the soil; its mechanical texture, situation, altitude, and sorroundings, quite as much as on its chemical composition.

9. The difference between an *exhausted* soil and a *barren* soil is this: the former will recover its fertility or be renovated by nature in the course of time if, meanwhile nothing more is carried away from it; whereas a barren soil will continue barren, if the operating causes remain as before. A soil which has once been fertile can never be completely exhausted by the cultivator, and the deeper the soil the more superficial will have been its partial exhaustion. The distinction between *natural* and *acquired* fertility is that the former is a permanent quality and the latter is not. An examination of the soil and subsoil is the only reliable test. The appearance of the crops on arable land is often very misleading, and even in the case of grass land the herbage is not altogether a criterion of the quality of the soil; if the herbage is poor it may be the result of years of bad management; while, on the other hand, a splendid pasture may owe more to good farming than to the natural fertility of the soil.

10.—Soils are usually arranged in four classes—clay, sandy, calcareous, and organic soils—according to the dominant ingredient. A soil consisting of nearly equal parts of sand and clay is termed a *loam*; if two parts sand and one part clay, a *sandy loam*; and if two parts clay and one part sand, a *clay loam*. A soil consisting of nearly equal parts of clay and lime is termed a *marl*; if two of clay to one of lime, it is a *clay marl*: and if two of lime to one of clay, it is a *calcareous marl*.

11.—The soils which have their particles in the

finest state of sub-division possess the power of capillary attraction in the greatest degree. Its importance to plant growth in dry seasons and on dry soils can scarcely be over-estimated. It will be referred to again in connection with land drainage.

12. As regards the principal causes of infertility in soils the following are the conclusions arrived at under this head by the late Dr. Voelcker as set forth in his paper on the subject in the *Journal* of the Royal Agricultural Society:—Soil appear to be barren or more or less unproductive—*(a)* When they contain something inimical to vegetation. *(b)* When they are deficient in one or more important constituents which enter into the organisation of the living plant, *(c)* When they contain too large a preponderance even of a valuable ingredient, such as organic matter, sand, lime, and even clay. *(d)* When there is but a thin layer of soil resting on the bare rock. *(e)* When the land is thin, and rests on an impervious and very thick, clay subsoil, or on subsoils containing something injurious to vegetation. *(f)* When they are badly drained. *(g)* When they are affected by a bad climate. The soil constituents which are injurious to vegetation briefly are—(*a*) Superabundance of organic(humic) acids. (b) Sulphate of iron (green vitriol), even when present in the soil in small quantities. *(c)* Sulphate of iron (iron pyrites), and especially finely-divided black sulphide of iron which in the smallest proportion, is most pernicious to plants. *(d)* Abundance of protoxide of iron, and absence of peroxide, indicating a bad physical condition of the land, *(e)* Chloride of sodium (common salt) in proportions of 1-10th per cent and upwards. *(f)* Nitrates, and all soluble saline matter, in quantities exceeding small fractions of 1 per cent of the whole mass of soil.

13. The presence of injurious constituents in soils can be readily ascertained by bringing a strip of litmus-paper in contact with wet soil. If the blue colour of the test paper turns rapidly red, the soil is certain to contain something injurious to plant life. All good and fertile soils either have no effect upon red or blue litmus-paper, or show a slight alkaline reaction; that is to say, in wet condition they restore the blue colour to reddened litmus paper.

14. Put a given quantity of soil into a large glass jar of water; then shake well, and allow to stand. The ingredients settle and the following order, and their proportions can then be estimated:—(1) Sand or gravel; (2) clay; (3) organic matter.

15. A soil is said to be exhausted for a particular crop when it will no longer grow that crop —or, practically speaking, will no longer grow enough of the crop to afford the cultivator a profit. This can only be brought about by a continued course of cropping without manuring. But when a soil will no longer grow a certain crop, it may still have all the elements requisite for the growth of some other crop.

16. The silurian soils are for the most part high-lying, cold, and poor. Where limestone predominates the soil is better, but as a whole they are deficient in lime. Even where the soil is naturally good on the formation, the climate and position are generally unfavourable for the cultivation of wheat and the higher vegetables. Finger-and-toe in turnips and louping-ill in sheep are very prevalent diseases on these soils. The old red sandstone furnishes some of our best soils, but these, too, are generally deficient in lime. The old red-sandstone formation may be called the home of the Hereford breed of cattle, and of the old Ryland breed of sheep. The new red sandstone soils are light and moderately fertile. The greensands are light soils of great adaptability and productiveness. Want of space prevents a full reply to this and some of the other questions, but discussion is invited.—*Scottish Agricultural Gazette.*

WHITEWASH.—The following recipe for whitewashing has been found by experience to answer on wood, brick, and stone, nearly as well as oil paint, and is much cheaper: Recipe.—Shake half a bushel of unslacked lime with boiling water, keeping it covered during the process. Strain it and add a peck of salt, dissolved in warm water; three pounds of ground rice put in boiling water, and boiled to a thin paste; half a pound of powdered Spanish whiting, and a pound of clear glue, dissolved in warm water; mix these well together, and let the mixture stand for several days. Keep the wash thus prepared in a kettle on portable furnace, and when used put it on as hot as possible, with painters, or whitewash brushes. —*Rural Australian.*—[This whitewash might be useful in adding to the amount of light in the interior of tea houses.—ED.]

WOOD PULP FOR MAKING BARRELS.—The latest novelty in the application of wood pulp comes to us from America, namely, for making barrels for holding both solids and liquids. The following account of this manufacture is given in a recently issued report from America:—"Wood pulp, so conspicuous of late years as a material for the manufacture of paper, has been found to afford one of the best means of making light, cheap, and durable barrels, adapted for all purposes for which these useful packages are demanded. The barrel is made in one piece of coarse wood pulp, subjected to a pressure of 400 tons. The heads are made in the same way, giving a degree of compac ness of grain that is sufficient for every use. When the barrels are put together they are very light, very strong, and very satisfactory in every way. Two kinds of barrels are made—one for fruit, flour, and other dry substances; the other for oil, lard, beef, pork, and liquids of all kinds. These latter are made impervious to the infiltration of oil and other liquids by a simple process. The flour barrels are so strong that when filled they can be dropped from a waggon without injury, and fruit packed in them keeps a long while, being excluded from all contact with the air. These packages can be made for half the cost of ordinary barrels."—*Indian Gardner.*—[If cheap barrels, why not cheap tea boxes? Wood not suitable for cuting into dials could he converted into pulp and then solidified.—ED.]

THE DRYING UP OF RIVERS.—Though the belief that forests increase the rainfall has been given up everywhere, except in Forestry Conventions, there is still a clinging to the belief that they regulate the flow of springs. It would be of great value to hydraulic science if some exact facts and figures could be given—facts collected by men trained in geological observation. Unfortunately, the only "science" that we have in the matter is furnished by "some of the oldest inhabitants" in various places, whose verdant memories tell them that "something has gone wrong since they were boys." It is pitiable to see a government report on American forestry sent forth with such "facts" and quoted abroad as if it were the work of an intelligent investigation of the facts involved. If we were to take the views of the "oldest inhabitants' on many other questions, besides those on forestry the only wonder would be that the world altogether had not come to an end long ago. Some of the "younger inhabitants" have, however, some tales to tell. Only "six years ago" an "intelligent" observer at Berlin, New Hampshire, had an "unfailing brook that ran three hundred gallons an hour." Now it is "cut short in summer and in winter by drouth." Another specimen is this: "At Richmond, New Hampshire, in 1865, there was water power for four saw mills all the year. Now the water has wholly disappeared." Now, everyone conversant with geology knows that these things are liable to occur anywhere, even in countries that never had a tree at all. The writer knows of a tract of country in which every well went dry last year, and numberless springs failed. But it was not referred to the cutting away of forests, but to a huge railroad which cut off all the supplies from the spring. Now nature herself often does just what this railroad did, opens new avenues under ground for the hidden streams, and turns them away in other directions. It would be very important to ascertain just what influence forests have on our water supplies, but to give in a government document mere street corner gossip as forest science is putting science in a degrading shape.—*Gardeners' Monthly.*

THE MADRAS AGRI-HORTICULTURAL SOCIETY

is the subject of correspondence, for a copy of which we are indebted to the Madras Government. It will be seen that in the fifty years of its existence the Society has done a large amount of good and useful work:—

Read—the following letter from Joseph Steavenson, Esq., Honorary Secretary, Agri-Horticultural Society, Madras, to the Chief Secretary to Government, dated 16th October 1886, No, 1781:—

With reference to the Proceedings of Government, dated 22nd September 1886, No. 5589, I have the honor, by desire of the Committee of the Agri-Horticultural Society of Madras, to report for the information of the Right Honorable the Governor in Council and of the Government of India, as follows.

The facts set forth in the last triennial report to Government, dated 12th January 1883, No. 28, being true now as then, the Committee think that as this report must necessarily contain much repetition, I cannot do better, for the sake of brevity and convenience, than follow the form then used.

2. Since the report above referred to, which related to the period 1879 to 1882, inclusive, the Society so far from relaxing its efforts to carry out its self-imposed task has materially increased them, as appears from its enhanced receipts in all branches, and more especially from its growing correspondence. The letters recorded in the office books, which may be taken as a fair criterion of the Society's business, have increased from 955 in 1877, when the present Honorary Secretary took charge, to 1,734 in 1885, and promise a still higher increase in the current year.

3. During the years 1883, 1884, and 1885 the Society has introduced, experimented with or distributed large numbers of the plants referred to and particularised in paragraph 2 of the last special report, including many interesting for their curious, ornamental, botanical or economic value, and amongst them two which call for special mention, namely, *Cyphomandra betacea* and *Erythroxylon coca*. Seed of *Cyphomandra betacea*," the tree Tomato," was received from Mr. Morris of Kew, then head of the Botanical Department, Jamaica, and the plant has been established amongst the society's correspondents on the hills and plateaus of Southern India. *Erythroxylon coca* was largely propagated from a single specimen in the gardens as soon as the merits of *Cocaine* attracted public attention, and has been widely distributed amongst planters and others in various parts of the country.

4. The extensive growing and distribution, of fibre plants, valuable timber and fruit trees, rubber, drug and tan producers has continued and increased. In 1883-85 the Society raised and sent out 117,640 rooted plants of *Fourcroya gigantea* alone for fibre-growing experiments.

5. Besides specimens of new and rare plants for garden cultivation, large numbers of young trees and other plants of indigenous or established kinds have been supplied to Municipal Commissions, Local Fund Boards, and other authorities for plantation, avenue and hedging purposes, being often sent long distances where facilities of rail or water carriage sufficiently reduced the cost of convevance.

6. The implements mentioned in paragraph 3 of the last report continue to be distributed; gardeners are obtained for members of the Society and others in Madras and elsewhere, while boys trained in the gardens easily find places; and the services of the Superintendent have several times been lent to lay out the grounds of public institutions in Madras.

7. The magnificent botanical collection belonging to the Society continues to be added to by the liberality of correspondents in many parts of the world, and by the Society's own collectors. The scientifically-arranged botanical garden is in good order and is largely resorted to by students and others.

8. The efforts of the Society to diffuse information have been sustained, the correspondence, as stated above, having largely increased and the monthly proceedings of the committee conti uing to be regularly printed and more and more widely distributed to members, to the press, to kindred societies and bodies, and to persons interested in the various subjects to which they refer.

9. In 1884 a complete and useful list of plants to be found in the gardens and neighbourhood was compiled by the superintendent of the gardens, printed and largely circulated.

10. The Society's library has, with the assistance of a liberal grant from Government, been much improved by the addition of many valuable works of reference, and is consulted by visitors, who are freely admitted, whether members of the Society or not.

11. The gardens are open to the public from sunrise to sunset; botanical specimens are given whenever asked, to local professors and lecturers and to scientific visitors; and the library and botanical garden are believed to be of great service to the students of the various botanical classes.

12. The Society continues to act and be largely employed as an agency through which persons at a distance obtain supplies of fruit, avenue, shade and other trees, plants and seeds; and annually obtains and forwards to all parts of India, and often abroad, large numbers of grafted mango and other trees and seeds of useful plants, such as *Inga dulcis*, casuarina, cotton, tobacco, senna, forage plants, fibres and cereals. In the last number of the "Journal of the Agricultural and Horticultural Society of India," page 325, it is stated by Mr. Maries, a recognised authority on the mango, that "The 'grafts' made by the Madras Horticultural Society are the best I have seen in this country."

13. The Society is often honored by references from Government and the Board of Revenue for information on horticultural and kindred subjects, and is frequently able to be of use, to Commissioners, Collectors, and other authorities in this presidency and distant provinces.

14. On 15th July 1885 the Society completed the fiftieth year of its labours; and to quote from the last annual report——"The half century nobody familiar with the Society's gardens and their very great wealth in exotic plants collected from every quarter of the globe would suggest has been spent in sloth. Horticulturists in Madras are apt to forget, and those who are not horticulturists are probably ignorant, that for many, possibly most, of their handsomest herbaceous plants, trees and shrubs they are indebted to the Agri-Horticultural Society; and that for that reason, as well as others, the Society deserves their support in both subscriptions and contributions. Observers, not scientific botanists, are now so accustomed to the great variety of vegetable life which beautifies Madras and its suburbs, and makes gardens and roadsides interesting, that the time, labor, and money expended in their collection from every country within the tropics, and many without, escape their memories, as do the nursing and propagation by skilled hands in, and liberal distribution from, the Society's gardens. Many of the most useful and commonest plants of the hedgerow now annually sowing themselves and reproducing their kind in spite of never-ceasing cropping and browsing by voracious goats and their hungry owners, but for the Society and its correspondents, would not have wandered here from their distant homes in other parts of India, in Africa, America, or Australia. The Committee think that the past and present members of the Society may look around and congratulate themselves that their first fifty years of association have been well spent."

15. The monthly proceedings of the Committee, which are regularly forwarded to several departments of Government, detail the more important work done; the whole work of each year is briefly stated in the reports annually laid before the general meeting of the Society, the last three of which are submitted herewith.

16. The following table shows the income and expenditure of the Society since the last triennial report to

Government up to the end of last year :—

Years.	Monthly allowance from Government.	Special grant from Government for prizes for special products.	Extra allowance from Government.	Grant from Government to buy botanical books for the library.	Members' subscription.		Sale of seeds, plants, &c.		Total receipts.		Total expenses.	
	R.	R.	R.	R.	R.	A. P.	R.	A. P.	R.	A. P.	R.	A. P.
1883	3,000	500	500	...	2,383	8 0	9,189	14 7	15,573	6 7	14,484	11 2
1884	3,000	500	500	1,000	2,371	7 8	8,636	0 0	16,007	7 8	15,361	11 1
1885	3,000	500	500	...	2,590	0 0	10,901	1 7	17,491	1 7	17,627	7 7

17. The Society continues to have the benefit of the long experience of the Honorary Secretary who has managed its affairs since 1877, and has now, in addition, the able assistance, as Superintendent of the gardens, of a professional gardener who was sent out to Government from Kew in 1870 to conduct experiments in the cultivation of cotton in the Central Provinces; and the Committee believes that its usefulness and the importance and extent of its work is limited only by the funds at its disposal and the small amount of time which the Honorary Secretary is able to devote to it from his other duties.

READ—the following letter from J. Grose, Esq., Acting Director of Revenue Settlement and Agriculture, to the Secretary to Government, Revenue Department, dated Madras, 8th December 1886, No. 2291 :—

With reference to G.O., dated 20th November last, No. 7036, I have the honor to state that the Agri-Horticultural Society of Madras have, on all occasions on which they have been applied to, readily favored this department with their co-operation, and that this department has, whenever possible, freely utilised their services in the matter of procuring, raising, and distributing seeds and plants of great economic value. Besides supplying seeds of *Reana luxurians*, *Divi divi*, and of varieties of well-known foreign tobacco, the Committee of the Society have procured shoots of the edible Cactus from Malta, planted them first in their own gardens, and distributed them to the districts after they had become well established. The Society has also furnished valuable information and suggestions to this department on the subject of grafting the edible Cactus on the common variety and on that of indigenous salt plants for the reclamation of salt soils.

2. All that is stated in the report as to the utility of the Society to the general public of this presidency seems to me well warranted.

ORDER—dated 22nd December 1886, No. 1119, Revenue. The report read above, together with the letter from the Acting Director of Revenue Settlement and Agriculture, will be forwarded for the information of the Government of India with reference to their letter, No 711—1201-A (Revenue and Agricultural Department) of 9th September 1886. Copies of the Society's annual reports for the years 1882—85 will be transmitted at the same time.

2. Throughout the period under review the Society has been in receipt of a contribution of R4,000 from Provincial funds, the former grant-in-aid of R3,500 having been increased by R500 under G.O., dated 8th March 1883, No. 538, Financial. It is satisfactory to learn from paragraph 16 of the report that the receipts of the Society from other sources have also increased considerably during the same period.

The ratio between the amount of the grant-in-aid and the total income of the Society is considerably less than the maximum prescribed by the Government of India in their resolution, No. 7—274-278, of 17th September 1879. In recognition of the flattering testimony borne by the Kew authorities to the good work of the Society, a special grant of R1,000 was, in G.O., dated 16th September 1884, No. 1045 Financial, made to their funds. This sum has been utilised for the provision of a botanical library, which, it is stated, is freely and widely consulted.

3. In his letter read with the above, the Director of Revenue Settlement and Agriculture bears testimony both to the general public utility of the Society and its ready co-operation with the Agricultural Department. Government note with satisfaction that the Society's library and botanical collections are extensively utilised by students and lecturers, and are thus the means of diffusing a knowledge of botany throughout Southern India. Altogether, the period under review seems to have been one of increased activity and usefulness, and Government desire to place on record their sense of obligation to the Honorary Secretary and the members of the Committee, to whose exertions this desirable result is mainly due.

TOMATOES.—An American contemporary states that during the past season there were put up 48,508,248 cans of Tomatoes in the United States, being one-third less than the pack of 1883, the decrease in acreage being heaviest in the eastern States. It is said that a farmer in Salem Country, New Jersey, last season raised 83 tons of Tomatoes on 6 acres of land. The crop was sold in the canning establishment for 7 dollars (nearly 30s.) per ton.—*Journal of Horticulture.*

FORESTS AND RAINFALL.—Prof. Cleveland Abbe in a recent lecture before the Franklin Institute of Philadelphia, attacked the "popular error" that forests had any influence on rainfall. He showed that in eastern Pennsylvania during the past one hundred years there had been a slight increase in rainfall, though the forests had almost wholly disappeared. He explained that the increases or decreases in earth elevations influenced the annual rainfall, and not forests. It is too bad, however, to charge this error to the "popular" side. It is an error propagated by so-called men of science, and has been a pet theme with many a science association,—and it has been the work chiefly of this magazine to show that there was no foundation for the notion that was worthy of the name of science. We have protested against the error with considerable earnestness, because of its injurious influence on practical forestry. It has led to the waste of hundreds of thousand of dollars in fruitless "commissions" and legislative blundering, and prevented the forestry question from standing on its profit and loss foundation, as a commercial undertaking should be—which by this time might have led to profitable results.—*Gardeners' Monthly and Horticulturist.* [This comes to us from the United States. It is common sense and truth. Rain depends on trade-winds, monsoons and mountains. Forests are the effect not the cause of rain.—ED,]

RED SEEDS: ABRUS PRECATORIUS.

A writer in *Science Gossip* gives some very interesting information concerning a plant very common in the neighbourhood of Townsville (Queensland, and in Colombo.—ED.) and which will be readily recognised from his description. He makes a mistake in saying that the root of the abrus precatorius is poisonous. It has a decided flavour of liquorice, and may be unwholesome if any great quantity be chewed; but practically speaking it is not injurious to the human subject:—"Those who have visited the Indian and Colonial Exhibition, or, as it is barbarously called, the Colinderies, will no doubt have noticed in a number of different courts, a curious pea-like seed of a light red colour with a black patch; in our court I noticed a number of caps and ornaments made entirely out of the seed of mimosa glauca and this red seed, which has for its scientific name that of abrus precatorius. But this is not the only name which will be found in the different specimens; some have the name of reglion sauvage, cascarella, jequirity seed, suabre's-eyes—and in fact the names are legion, but they are all applied to the one seed, abrus precatorius, called precatorius because it is much used for Roman Catholic rosaries in some parts of the world. This seed is that of a plant which once had the name for curing certain diseases of the eye, but there is not much foundation for this reputation. The plant is a deciduous climber, and has pea-like flowers of a reddish-purple. A specimen two years old may be seen at Kew, but it has not yet flowered. On chewing the leaves, which are composite and much like those of the acacia, a sweetish liquorice taste will be noticed; it is in fact called the wild liquorice, but must not be confounded in any way with the liquorice plant (Glycyrrhiza) of the British Pharmacopœia, though they both belong to the same group of plants. Curiously, the root of this plant is poisonous and has often been used by the convicts in Mauritius, both by rubbing it on their eyes and chewing it, to induce illness. Another most interesting fact about this plant—or rather the seed—is that the natives of the country in which it lives found out that all the seeds weighed precisely the same (about five grains, I should say), so, as they had no other standard weights, they instituted these seeds as a standard weight, and called each seed in their own language a carat: and this carat is in fact the origin of our carat weight of gold. This fact alone made the seed one of interest to me, and, combining it with the fact, that it belongs to one of, if not the most important order of plants of economic value, makes me think that there may be others like myself, who, ignorant of the above facts, will be glad to know them. —*Townsville Herald.*

JAFFNA CIGARS.

Somehow the trade in Jaffna cigars has received an additional *stimulus* lately, so that the business in the Cigar Boutiques is unusually brisk as one could see on passing One cause is said to be the short production of those varieties of Jaffna Tobacco which chiefly enter into the making of what is called a real "Jaffna." During the month of December 1885, the weather appears to have been rather unfavourable to the lives of the young plants which were then being removed from the nurseries and transplanted in beds. Some thousands of young plants transplanted during a day were found the next morning withered and dried—not indeed by the heat of the Sun's rays; but by some unknown cause. Some few who have tried in various ways to trace the cause of this wholesale destruction seem to have discovered a small worm, which they call "Uluvan" literally *the plougher*, which gnaws away the plant at its root—a single worm going through a whole bed of plants during a night. In this way were the nurseries so thoroughly exhausted, that plantations were not as fully planted as usual. This accounts for the comparative shortness of the Tobacco crop of this year. But the *whole* Tobacco has not suffered so much, as it is usually grown on higher ground and in harder soil than the one in which the Cigar-Tobacco is cultivated. Good prices are now realized by Cigar Boutiques as well as by the hawkers of what are called *street cigars*. But there is yet a good deal that can be done to stimulate the trade and make the Jaffna Cigars the real luxury they ought to be, if properly made and tastefully served up. What are Cigarettes as compared with a good genuine Jaffna Cigar? Of course the dealers in Cigars should first have a taste themselves before they can provide for the taste of others. But they generally calculate on deriving their customers from the general population rather than from the upper classes or even the middle class.

Of Cigars there are 4 sizes.

The 1st size,	12	pkts.	to a lb sells for	10	cts.	the pkt.
2nd do	16	do	do	6	„	
3rd do	24	do	do	5	„	
4th do	30	do	do	4	„	

The price per thousand is as follows:—

1st size	R7	50	per thousand
2nd do	6	00	do
3rd do	5	00	do
4th do	3	75	do

Of course there is an allowance or abatement or discount or whatever you may call it to those who buy Boxes or in wholesale, as it were.

The *Street Cigars* do not come under any of the above rates, they being made of Tobacco of inferior kinds: and generally they have no fixed prices; but they sell for whatever they can get, whether it be high or low. Most of the cigars selling in Colombo are of the *Street Cigar* kind, and they serve in general to bring Jaffna cigars into disrepute. The real Jaffna cigars could be had only at about 10 principal boutiques in Colombo, not any where else. These boutiques profess to supply Negombo, Kaltura, Kandy, Ratnapura, Chilaw, Puttalam and Anuradhapura; but in none of these places is a real "Jaffna" to be had "for love or for money." Another fact in connection with Jaffna cigars deserves to be noted. Each of the 10 Cigar boutiques of Colombo employs about 150 men in Jaffna in the manufacture of the cigars: and about as many more are hawking cigars in and around Colombo. Including the growers of Tobacco, every boutique may be said to maintain about a thousand families, being altogether ten thousand families depending on the trade in Jaffna cigars. *Com.*—"Ceylon Patriot."

SUGAR SOILS IN BRITISH BURMAH.

Dr. Romanis says:—

"These soils are evidently produced by the decomposition of granite or some other primitive rock. In the sample of E I found fragments of decomposing felspar, the constituent of granite that supplies potash to the soil. There is no doubt that this is the secret of the fertility of these soils. Another thing is that soluble potash is higher than usual. They will yield several crops before they show signs of exhaustion."

Canes had been cut on the land from which soil selections were made, the juice tested, and the amount of kyantaga (gur) obtained had been ascertained with the following results:—

Name of soil.		Percentage of sugar in juice according to saccharometer.	Percentage of coarse sugar (gur) in juice according to experiment.
Bilni vallye	A	25·71	15·27
	B	20·00	12·52
	E	25·71	15·27
	D	22·85	14·31
	C	...	...Not cultivated.
	H	22·85	14·31
Thébyu valley	K	27·14	17·00
	M	...	...Not cultivated.

The percentage of juice was, however, taken from the different places at different times and there was a month's interval between the testing of H and that of K. The cultivators themselves stated that the

best kyantaga (gur) was produced by soils A and E' then by H, then D and K, and finally B. They stated that the kyantaga (gur) of B was bad owing to the land being flooded, and that the sugar of K would improve as the land was regularly cultivated year after year.

Comparing the result of the soil analyses with those of the testings of the juice and kyantaga (gur) Dr. Romanis remarks:—

"The order of the productiveness seems to be that of the amount of phosphoric acid the soil contains. Leaving K out of account, as it was more mature when cut, it will be observed that the sugar obtained is very nearly proportional to the percentage of phosphoric acid. According to Ville the phosphate of lime is the predominant constituent in sugar manure, but he gives no experiments to prove it. H is the third in order of phosphoric acid and third in order of productiveness. The great excess of potash cannot be utilized by the plant for want of a sufficient proportion of phosphoric acid. K, according to the natives, comes after D; but D is new land and, therefore, for a year or two many yield good crops; but, if the analysis fairly represents its composition, it cannot last long.

"H is no doubt beginning to be exhausted of its soluble ingredients. What is extracted by hydrochloric acid does exactly correspond to what the plant can extract from the soil. I should say it wants a fallow or change of crop.

"The soil should not deteriorate if nothing is removed from it but pure sugar, the constituents of which are entirely obtained from the air. If the crushed canes are restored to the land in any form, there is no loss, or very little, of mineral matter."

SHALL WE GROW MILLET.

My success with millet has been so marked that I have practically abandoned my meadows as a source of hay supply, and with millet in place of oats, and clover in rotation, depend upon these for my forage; and after ten years' or more experience, have I never been without an ample hay supply. I am, taking one year with another, convinced that oats never paid me as well as the same land would in either corn or millet. Possibly I may yet go to speculating in Bohemain oats, not in feeding them, but raising them to sell to neighbours who go crazy over oats worth (?) ten dollars per bushel. Mem.: Who ever heard of a farmer selling his crop of Bohemain oats for $400 per acre?

For several years I sowed Hungarian grass, but became convinced that German millet was far superior, and now sow it exclusively. Some winters I have fed no other hay, but usually feed clover and cornstalks along with it; but, so far as I can see, I would quite as soon take exclusively millet; for winters I have fed nothing else, not even grain, until the cows began to calve in the spring. No one could ask for stock to do better than did mine on thin, early-cut millet.

The chief objections to millet are that it is thought to be a great exhauster of land, and that it is a hard crop to cure. It is probably more taxing on land than timothy; for millet, besides its great mass of foliage, develops at least forty bushels of grain to the acre. Now millet is what is known as a gross feeder, and needs to be sown on soil filled with vegetable matter, and will attain its greatest perfection on fresh turned clover sod, or a crop of fallow corn, or decayed sod.

Millet should not be allowed to mature its seed to obtain best results as a hay supply; and in avoiding this a great draft upon the soil is prevented; for, if cut just as the heads are developed, and the seeds are forming, the final demand upon fertility to mature this heavy crop of grain is avoided. And I now place millet, when sown in its proper rotation, as one of the medium crops in its demand for fertility. Then its growth is remarkable. In favorable seasons it is ready to cut in seventy days from sowing, and therefore does not "draw" upon the soil like corn, oats, or wheat, that need far longer time, and must of necessity develop their grain.

As a crop to precede wheat, it has no superior; for its dense growth completely shades the soil. It is, therefore, a cleaning crop. And, lastly, it leaves the land mellow, and exceedingly easy fitted for wheat. In fact, with the improved spring harrows, it is often quite as well to prepare the land for wheat without ploughing; but usually it is better to invert the soil, and plough under the great mass of roots and stubble, that upon an acre must aggregate tons in weight, and must, therefore, have a great fertilizing value. Wheat upon millet-stubble often shows superior growth, possibly from the fact that the dense shade during the hot months increases the nitrification of the surface soil.

Millet delights in a dryish summer, and only needs an occasional shower to give it luxurious growth. Last season my millet only had what could be called two rains upon it, and yet its growth was astonishing—nearly six feet in height for the entire fields, and yielded at least four and a half tons of cured hay per acre. This season we have had rains and rains, and invervals of cold cloudy weather, and the yield will not probably exceed three tons per acre the smallest crop in years.

Millet is a tropical plant in its nature, and should not be sown until the hot June days guarantee high and somewhat uniform temperature. This year's seeding chanced to be followed by ten days of cold, rainy weather, and as a result, the millet did not come up evenly; part was, as afterwards proved, drowned out. On the 6th day of July a small field was sown, and, when the fields were cut last week, this piece, sown twenty-five days after the others, was in many respects the finest millet.

In sowing millet a full bushel per acre should be used. Then the hay is fine and choice; and if cut just as the heads are all out in bloom, and cured in the cock—the larger the better—and then stored in the big bay of the barn, it will come down upon the floor in the winter bright and green, and with that attractive fragrance that will cause cattle to eat it in preference to any other hay that may at the time be placed before them.

For years I have fed my work-team upon early-cut millet—not all they would eat, but in proper amounts, and have never noticed any ill effects; but on the contrary, have regarded it as a most excellent ration. For milch-cows it has no superior as a hay ration. With a proper feeding of milk-feed, the March and April messes of milk will fully equal to June flow maintained from the pastures, and in texture and quality leaves nothing to be desired.

The question is, with the advent of ensilage and the demonstrated great growth of German millet, can farmers afford to feed hay grown upon high-priced land, when from a half ton to a ton of inferior hay is the average? But, on the contrary, are not the profits to be rather found in cropping for abundant rations, and thus securing them at the lowest possible cost?—JASON JONES *in the National Stockman.*

THE BANANA.

TO THE EDITOR OF "THE AUSTRALASIAN."

Sir,—"A species of the genus musa, a tropical tree clearly allied to the plantain. The fruit is 5in. or 6in. long, and 1 in. thick, grown in clusters, is very nutritious, and, in some parts, forms a most important article of food," so says the *Standard Pronouncing Dictionary.* Few colonists now but have seen and tasted the banana, and I have, no doubt, endorse the pithy description given of it of being nutritious. The trade between the colonies and the islands is perhaps more than the generality of your readers is aware of; the S. S. "Rockton," having on board 19,000 bunches in one trip to Sydney. This is a larger cargo than is usually brought, but the average will certainly be not less than 9,000, and as there are steamers to New Zealand, Sydney, and Melbourne constantly running and bringing them up there must be, in any case, as many as 366,000 bunches of bananas exported from Fiji every year to Australia and New Zealand, for I am told that quant

ities find their way to Brisbane, although bananas grow there. I have counted as many as 370 of the fruit on one bunch, quite a load for two men to carry on a pole. A Suva paper of last year writing of a Fiji plantation, of 80 acres, the property of Messrs. Armstrong and Huon, part of the article, writing of the culture of the banana, says: — "The superiority of the fruit is attributed to careful cultivation, deep digging, constant weeding, and attention to and careful stripping of each bunch when ready to burst from the blossom, as this exposes the young fruit to the sun, and, besides assisting its development, deprives a grub which infests these plants, and is otherwise the cause of the destruction of thousands of bunches, of a lurking place." To keep these 80 acres in order is the work of 30 Polynesians and two Europeans. How the banana known as the sugar banana got to the South Seas is, perhaps, not generally known, so that I have much pleasure in giving the incident as it occurred.

Many years ago (in 1838) the Rev. Jno. Williams, who was then a missionary in the South Seas, as an agent to the London Missionary Society, left Raiatea, one of the Society Group, for England for the purpose of collecting money to purchase a vessel for missionary purposes, instead of chartering small craft, hitherto done by the Society, to visit the various stations in the South Pacific.

On Mr. Williams's arrival in England he was selected by the Society to travel through England with another Missionary as a deputation to address meetings and collect funds on behalf of the London Missionary Society. Of the great success attending their labours history has already made public, in the shape of a very readable book, entitled *South Sea Missionary Enterprises*. The vessel was purchased principally by the contributions of Sunday-school children, who were limited to penny subscriptions, and she was known as the "Camden" brig, lying in the London Docks. A thorough overhaul was made, and alterations to suit the extra number she had to carry out, as a staff of young men had expressed their intention of accompanying Mr. Williams as missionaries to the Pacific.

The movements of Mr. Williams in England had been watched with great interest by men generally outside the influence of the London Missionary Society. At an interview he had with the Corporation of the City of London, he so convinced them that religion and commerce should go hand in hand that they unanimously voted him £500, on behalf of the Society he represented—a thing unheard of previously. Others, too, took a deep interest in what was being done, and one, probably His Grace the Duke of Devonshire, at Chatsworth, more than the rest.

When Mr. Williams went to England his son John, then a youth of 14, accompanied him, whom the Duke took charge of while Mr. Williams was making the tour of the British Isles. The youth was taken by the Duke to Chatsworth, and these were to be considered the youth's head-quarters. The change was remarkable, from the modest dwelling of the South Sea Islands to one of England's stately mansions. Every comfort was provided for him, and youths about his own age invited to meet him. After a pleasant stay of some months the time came for young Williams to take his departure, and prepare for the voyage. In conversation with the Duke the youth had thoroughly discussed South Pacific topics- the character of the soil, climate, &c, and had given His Grace an idea of what plants were likely to grow of those in the conservatories, the conversation leading to good results. The day before young Williams left Chatsworth the Duke called his manager, then Joseph Paxton (afterwards knighted), and asked him what he thought he had in the conservatory that would benefit the South Sea Islands. After a careful survey Mr. Paxton said he thought he had found a plant that might be of use, and he suggested two of the Musa Cavendishii, or the sugar banana.

The little plants were placed carefuly in a glass case by the Duke assisted by young Williams, the manager (Mr. Joseph Paxton), and the head gardener, Mr. Donald (now the Superintendent of the gardens at Hampton Court). I particularly mention this then small event, but now attended by large results.

The case was shipped on board the "Camden," and, after a long passage of eight months, arrived at Apia Upolu—the Navigator Islands (or Samoa). Here the plants fell into good hands, those of the Rev. Mr. Mills, agent to the London Missionary Society at Apia. On the case being opened, one of the little plants was dead, and the other in a weakly state; grave doubts were manifested that it also might not survive. However, by the care and attention bestowed upon it, and the reviving effects of the Samoan soil, the watchers were soon rewarded; vigorous life set in, and from the Chatsworth plant all the bananas of that description came which now spread over the north and south Pacific.

J. L. E.

THE ECONOMIC RESOURCES OF INDIA.

BY DR. GEORGE WATT, C.I.E.

From lectures delivered before the Society of Arts which we should gladly quote in full, did our space permit, we take the following extracts:—

THE IMPERFECTLY KNOWN, OR MINOR PRODUCTS OF INDIA.

There are food grains that loudly call for more thorough investigation and more extended cultivation. Dyes, tans, and fibres, which betoken fortunes to the industrious persons who will carry to a practical issue the initial experiments necessary to successful introduction. There are minerals and ores in sufficient abundance to admit of profitable competition with the supplies poured in from foreign countries. But above all, there are the thousand and one little insignificant things lying at our feet which, in the hands of the technical expert, will each come to meet a distinct market. To Government, these unimportant industries offer naturally a great attraction, for, without capital and without expensive plant, the poorer natives can participate in the trade done in them. But it would be hopeless to attempt to enumerate, even by name, the multitude of natural or wild products in which trade might be done. Seeds which will yet have a commercial value as ornaments or buttons. Fibres which are likely to be used as useful and cheap substitutes for whalebone and bristles. Palm spathes, which may come into use as natural surgical splints, or be employed as simple mechanical filters. The fibrovascular frameworks of cucurbitaceous fruits, which constitute admirable bath-room sponges. Small pieces of *solah* pith to displace patent corn-plasters, or to be used in place of wax in the preparation of microscopic sections. The employment of pith instead of cork for many purposes, such as for floats to fishing nets. Fungi and pith utilised as substitutes for felt in the manufacture of at least certain parts of hats. The indefinite series of uses to which the bamboo is put in all Asiatic countries, but of which Europe is ignorant. Indeed, the application of the bamboo to European wants seems so natural, that it is impossible to avoid the surprise that in an age of keen competition for novelties, this has not been done long ago. The bamboo is eminently suitable for many details in household fittings. The thicker joints make quaint umbrella stands; the better qualities are so hard that they are used by the natives of India as swords and knives, and these would make admirable and clean paper knives, cheese and butter knives, and, cut up into smaller pieces, might, with great advantage, be employed as pegs by cabinet-makers and shoe-makers. The gums and resins which have each their peculiar properties—properties far better known to the simple and primitive aboriginal inhabitants of the wild forest tracts than to the professional experts of Europe, who often value samples according to a crude standpoint, viz., the colour, appearance, and condition of package demanded by the trade. This standpoint is conservative to established brands, but precludes the possibility of the properties of new products being in-

vestigated. The practice of the simple *Santal* in mending his iron cooking pot by means of the *sal* resin (the resin of *Shorea robusta*) suggests a use for that, at present, valueless substance, as it indicates also a personal acquaintance with its properties. It is not at all improbable that the properties of this and many other little-known gums and resins will commend themselves in the future to persons who may be in search of substances with properties we have not as yet been educated to require. The useless hog-gum (the gum of *Cochlospermum Gossypium*), consigned falsely as tragacanth, has been accidentally discovered by the bookbinder to be invaluable for marbling purposes, and the gum of *Sterculia urens* has been found to restore to tasar silk the lusture removed from it during an improved process of reeling that fibre. Practically, the one requirement for gum in Europe is a strong and useful adhesive mucilage, and although with care in selection and packing, India might easily come to play a much more important part in this trade than it has done in the past, India has, at the same time, gums and resins which possess distinctive properties, each one of which finds in India a market in meeting the demands of some indigenous industry. But I have said enough to indicate the long category of the unimportant products of India. The bulk of these products are, however, unimportant only in a European sense. The people of India are indeed children of nature; they are perhaps far more dependent upon nature than any other community in the same condition of civilisation. Natural or wild products not only form the bulk of their ornaments and their children's toys, but there are few people in India who are not dependent, to a large extent, for food on the plants climbing the village hedgerows, or floating over the tanks which their ancestors excavated. They are herbalists, and their medicinal plants are all gathered from the neighbouring jungles. To the people of India, therefore, the products I have, from a comparison with the trade done in the staples of India's foreign commerce, designated as unimportant, are by no means so. The diffusion of definite and accurate information regarding these substances will, in some instances, extend their use from one province to another, and in others create a foreign demand for them. Indeed, so important are these minor products to the people of India, that they may be said to give the finishing touches to the story of India's productive resources. They not only enter into the everyday domestic life of the people, but, in many instances give that charm to the handicrafts of India which western skill has vainly tried to imitate. Given the raw product which imparts the actual tinctorial principle, and the European dyer fails to produce the desired result because he has overlooked the laborious and apparently meaningless combinations which centuries have taught the Indian dyer to employ. The use of soap in washing the fabric in one case, and the employment of saponaceous nuts for that purpose in another, have as much to do with the beautiful and permanent colours produced as have the complex series of vegetable and mineral mordants.

CLASS III.—FIBRES.

At this late hour it would be useless to attempt to deal with cotton, jute, silk, and wool. There is so much to say under each of these subjects, that it would take hours to deal with them satisfactorily. I cannot, however, pass from the subject of cotton without reminding you that the great cotton mills of Bombay have already given promise that each year the Indian mills will more and more meet the Indian market, until they begin to materially affect the immense import trade in British cotton goods. The imports of cotton goods into India were last year valued at £24,282,628, a large enough trade to invite competition in every direction. The British manufacturer has not so much to fear, however, from native enterprise, at least for some years to come, as from British. Just as happened with the jute trade of Dundee, Englishmen with their capital and machinery may remove to India to manufacture from Indian cotton the peculiar goods required by the people of India. When this is done, there will be a saving in time and of freight charges and agency. The raw cotton, instead of bearing freight to England, and the goods freight back again to India, together with the charges for agencies and brokerages which these transactions necessitate, would be produced and manufactured on the spot, and go direct into consumption. I have endeavoured to show that the difference between the cost of Indian and English labour is not so great as is commonly supposed. The advantage is, however, in favour of the mill-owner in India, and the disadvantage against the hand-loom weaver. To put this matter clearer, the cheapness of Indian labour is not sufficient to enable the hand-loom weaver to hold his own against the power-loom manufacturers; but Indian labour is cheaper than English, and this cheapness is another advantage which the mill-owner in India has over the British manufacturer.

There is no more hopeful future for India than the opening out not of cotton mills only, but of factories of every description. It is impossible for India to stand still. Each year will see her becoming more and more a manufacturing country. The world has, however, grown tired of using cotton, jute, silk, and wool. A distinct demand has arisen for new fibres, and India possesses at least 300 fibres, few of which have as yet received even a passing consideration. At the late Colonial and Indian Exhibition the largest and most complete display of the fibres of India ever shown was placed before the public. These fibres attracted very considerable attention, and experts from all parts of the world were afforded every possible facility in examining them. It will be enough to allude to three of these fibres.

1. *Sida rhombifolia.*—This beautiful silvery white fibre is obtained from the above-named plant—a member of the mallow family. Botanically *Sida* may be said to be allied to jute, and the fibre it affords, in many respects, resembles jute. It may be grown on the same fields, and by the same cultivators. It can therefore be produced at about the same price, for the fibre may be separated from the stems by the same simple process, namely, by retting and washing in water. The only factor that might conduce to make it more expensive than jute is the fact that, in its wild state, it does not attain the same length of stem as the cultivated jute; but *Sida* has not been cultivated as yet, and there is no knowing but that it may even exceed jute in its yield of fibre per acre. It may be accepted, however, that *Sida* fibre is, like jute, a cheap fibre, and one that might be produced with great ease in immense quantities, the supply being as constant as that of jute. Its claims for superiority over jute are very considerable. The fibre is not half as thick as jute, and it is of a much purer quality, and can therefore be spun into finer yarns than jute, and thus come into textile purposes which jute has totally failed to reach. It can take colour with great ease. In fact, *Sida* fibre has been much admired by all the manufacturers who have examined it. It is now being experimented with on both flax and jute machinery; and I am hopeful that, as one of the tangible outcomes of the late Exhibition, this fibre will, in a very few years, come to hold a distinct place amongst the fibres exported from India.

2. *Bauhinia Vahlii.*—This extensive climber belongs to the family of the pea. It abounds throughout all the warm lower mountainous tracts, being the most abundant climber in the mountainous forest of the great tableland of India, and crossing the Gangetic basin, it occurs again in all the forests which skirt the foot of the Himalaya. Mr. Routledge, of Sunderland was, I believe, the first person who within the past few years drew prominent attention to the fibre derived from this plant. Long before even Mr. Routledge's attention was directed to it, however, the late Dr. Forbes Royle spoke highly of it under its vernacular name, and specimens were exhibited at the Great International Exhibition of 1851. The fibre is universally used by the natives of India for the purpose of ropemaking, and it stands high in

their esteem. Mr. Routledge has urged its use in the paper trade; but although the plant is sufficiently abundant to warrant the idea that it might even pay to be thrown into the paper-makers' vat, it seems to possess such merits as a possible textile fibre, that it is more likely to find a much higher place than Mr. Routledge designed for it. The *malu* fibre may be gathered in immense lengths, for the plant is one of those gigantic climbers which, by means of its tendrils, extends its long arms from tree to tree, binding the forest into great clumps. It is, indeed, a source of greatest annoyance to the forester, for it not only injures his trees, but has such a vitality that it is next to impossible to exterminate the plant, and a few months after it has been cut to the ground, its long elegant pendant boughs laden with its great clusters of white flowers, are seen waving in defiance from the topmost branches of the trees. A very large and practically inexhaustible supply might be drawn from the forests of India, but I have no confidence in a large industry depending upon a wild plant. The wide area over which it would have to be collected, and the complete control which the owners of the forests could exercise over the buyer, would be dangerous to success; therefore a tract of country, say twenty miles, of the practically useless stony hill sides would have to be purchased and systematically planted. A forest is not necessary for the plants to climb on; they would trail over the ground and form with each other great clumps. From such a plantation a nucleus of supply could be drawn and depended upon, which would have a good moral effect upon the persons bringing to the planter supplies from the wild source. In this way it is possible to procure a constant supply, and if this can but be secured, the fibre possesses in itself such high merit that it will soon make itself known in the textile world. It is one of the few vegetable fibres that will stand to be dyed, bleached. and worked up along with wool, a property which speaks volumes in itself.

3. *Caloptris gigantea*.—The world has heard so much of the *madar* fibres that it may be viewed as, preaumptuous on my part to desire to go back upon the unfavourable verdicts which experts have passed upon them. It is well known that the stems of this plant afford one of the strongest and finest of vegetable fibres, and one of the most beautiful. The great difficulty is to separate this fibre from the stems, and, indeed, so great is this difficulty that the idea has practically been abandoned. My friend Mr. Cross, by nitrating *madar* fibre, has, however, produced a substance which can with difficulty be detected from silk. It has all the gloss and softness of silk, and would seem so valuable that, in this state, it could well afford to bear an expensive process of separation.

I desire your attention not so much, however, to the possibilities of *madar* bark fibre as to the floss found attached to the seeds. This has been pronounced too short and too light to be worked on machinery. But I have begun to suspect that we can correct these defects to a large extent. The plant is wild along country roadsides in India, luxuriating on every bit of waste sterile land. No person, as far as I am aware, has thought of cultivating it. An important Lancashire spinner has assured me that, even in its present state, he can use any amount of the fibre; all he requires is a uniform and steady supply. We have agreed that this can never be secured from a wild plant which has to be collected by wandering along miles of roadsides. Through the kindness and co-operation of a missionary friend, however, I am at present having a few acres of inferior land cultivated with *madar*, and we are hopeful of being able to prove to the poor Santals of Bengal that this crop would pay them far more than some of the things they and their forefathers have been in the habit of growing. If this can be done, uniformity and continuance in supply may not only be secured, but it may be confidently hoped that, with careful selection of seed, after a few years, we may educate the plant into becoming obedient to man's skill. Our cultivated *madar* may yield a floss that will have none of the defects complained of. If this can be done, I am satisfied my friend will do it, for I know of no more careful and painstaking person in India than the gentleman who has most generously undertaken to pioneer the introduction of this new annual crop.

Class IV.—The Oils and Oil-seeds.

But I have already trespassed too far upon your time. There is much that one might say about the existing crops and the possible new crops of India, that one scarce knows where to begin or what to say first. Speaking of the oil-seeds, however, the greatest possible interest was taken at the late Exhibition in the white form of linseed sent from the Central Provinces. Were it possibe to develop this form to the exclusion of the red, a large trade would be done in it. The greatest danger to the Indian oil-seed trade is the difficulty to induce the people to discontinue their practice of adulteration, or to persuade them to be more careful in rooting up different crops growing in the same field. A comparatively small percentage of rape-seed mixed with the linseed renders it completely useless as a drying oil. Speaking of the rape-seed trade, on the other hand, few persons seem to be aware that there is, practically, no mustard grown in India. The so-called mustard exported from India is in some cases better qualities of rape, or in others the Indian mustard—the small black and pitted seeds of *Brassica juncea*. It seems desirable that this fact should be made more generally known, for should demand arise for *Brassica alba* or *B. nigra*—the true white and black mustards, these might easily enough be substituted for the white and black forms of *B. campestris* or rape seed, which seem to find a market as inferior mustard.—*Journal of the Society of Arts*

THE TESTS ON QUININE SULPHATE.

Although some of the facts to which I propose to refer in connection with this subject do not in themselves possess any great novelty, the special attention they have lately received in various quarters gives them a new interest at the present moment.

Among all the salts of cinchona alkaloids quinine sulphate is undoubtedly the most important in every respect, and therefore especial attention should be given to the means of ascertaining its purity. Quite lately it has been contended, that in regard to this character it is the duty of the pharmacist to enforce upon the manufacturer very stringent demands, and from an ethical point of view nothing can be said to the contrary, especially if it should be decided upon therapeutical grounds that it is desirable to use quinine sulphate in a state of absolute chemical purity. But that is a point to be determined by medical authority, and for the present it will suffice to consider what is to be understood by the term purity in this case as a matter of practical pharmacy. In doing so it will be important to bear in mind that however much we may be in a position at the present time to define the particulars which are evidence of the purity of quinine sulphate, it must be admitted that in regard to this salt the term purity has hitherto had only a relative application. With our present knowledge of the various alkaloids occurring in the material which is the source of quinine, it may be taken for granted that quinine sulphate is not likely to be naturally contaminated with cinchonine sulphate, or, indeed, with any other cinchonine salt as an accidental admixture, and hence, for practical purposes, this impurity may be to a great extent left out of consideration. For various other reasons, true quinidine sulphate may also be disregarded in this respect as being an unlikely admixture, and, in a general way, attention may be confined almost entirely to cinchonidine sulphate as being the impurity most frequently present in commercial quinine sulphate. The intrinsic value of the cinchonidine salt is very much less than that of quinine sulphate. Consequently from this point of view alone independently of therapeutic value, it is very

important to ascertain the presence and amount of this impurity in the quinine sulphate of commerce.

When we call to mind the fact that cinchonidine is almost always associated with quinine in the bark from which quinine sulphate is manufactured, and also the fact that up to the year 1844 cinchonidine was not known as an independent substance distinct from quinine, it will be evident that there is, on these grounds alone, very good reason for believing that prior to the date mentioned the article known as quinine sulphate was really a mixture of the sulphates of quinine and cinchonidine. It would be possible to mention in support of this view many circumstances recorded by trustworthy observers, but I will merely refer to the fact lately made known by Dr. deVrij that the quinine sulphate originally manufactured by Pelletier contained a considerable amount of cinchonidine.

Winckler's identification of cinchonidine, in 1844, was coincident with the introduction of bark from New Grenada, to supply the place of the Bolivian bark that had been previously used for the manufacture of quinine, and the fact that this New Grenada bark contained a much larger amount of cinchonidine than Bolivian bark was, no doubt, the circumstance which led to the identification of the alkaloid. Unfortunately, Winckler gave it the name of "quinidine," and very shortly afterwards the sulphate of this alkaloid was met with in commerce under the name of "quinidine." At the 1851 Exhibition it was shown by Zimmer, of Frankfort, and a prize was then awarded to his firm for its production in a separate form. Probably it had been used long before as an adulterant of quinine sulphate, and as the methods of testing the purity of quinine sulphate in use at that time were not calculated to detect the presence of the cinchonidine salt, there is also a probability that it was often present to a considerable amount in commercial quinine sulphate as an accidental and to a large extent quite unrecognized impurity, originating from the material used. The literature of that period indeed furnishes abundant evidence of this, and several new methods of testing were then suggested for the detection of cinchonidine. None of them, however, were thoroughly effectual, and the official tests given in the various pharamacopœias were all of such a nature that a considerable amount of cinchonidine salt would pass unrecognized. That has, indeed, been the case up to the present time.

It is evident, therefore, that the presence of cinchonidine sulphate in commercial quinine sulphate cannot be regarded as a matter of any novelty, either as an unrecognized accident before 1844, or as a well understood fact since that time; but that, on the contrary, it was a natural consequence of the association of cinchonidine with quinine in all the varieties of material employed for the manufacture of quinine sulphate. The question as to the purity of this salt, apart from actual falsification, has therefore always been a question as to the actual amount of cinchonidine it contained. It is mainly in regard to this particular point that the value and efficiency of the tests applied for ascertaining the purity of quinine sulphate require to be considered, and it is now just ten years ago that I pointed out the defective nature of the test prescribed in the British pharmacopœia of 1867. I then showed that by the application of the Pharmacopœia test a sample of quinine sulphate containing at least 10 or 15 per cent of cinchonidine sulpate could not be distinguished from one of absolute purity, or containing no more than one per cent, and that while there were some manufacturers who supplied the article in a comparatively high state of purity, that obtained from other sources often contained a large amount of the cinchonidine salt. The existence, even in the past, of such differences in the quality of a medicinal agent so important as quinine sulphate, and the possibility of their recurrence, should certainly induced pharamacists to give attention to this matter, and to verify the quality of their supplies by careful examination, not only for the sake of their own protection, but also for the purpose of enabling them to furnish a personal guarantee as to the purity of this article.

The methods of testing quinine sulphate for ascertaining its purity and detecting the presence of salts of the other cinchona alkaloids are for the most part based upon the relative solubility of those alkaloids in ether or in ammonia, and partly, also, upon the relative solubility of the neutral sulphates of those alkaloids in water. As already mentioned, the problem to be solved, under ordinary conditions, is a simple one, and it may be stated in these terms: What is the amount of cinchonidine sulphate present, The ether test was first applied for this purpose in 1852. It consisted in shaking a weighed quantity of the sulphate in question with ether and ammonia in a test tube, and if the alkaloid set free by the ammonia was completely dissolved by the ether, forming a clear solution, the sulphate was considered to be free from objectionable impurity. But the ether test thus applied is not sufficiently delicate for the purpose required. Freshly precipitated quinine dissolves readily in a very small proportion of ether, and the solution remains quite clear if the evaporation of the ether be prevented. Cinchonidine is also soluble in ether, but to a very much smaller extent. Thus, for example, 10 grains of quinine sulphate treated in this way, with 1 drachm of ether and some ammonia, will give a clear solution; but 1 grain of cinchonidine sulpate gives a very different result when so treated, a large portion of the alkaloid remaining undissolved by the ether. The actual limit of solubility of cinchonidine in ether is reached when the sulphate is in the propotion of about half a grain to the fluid drachm of ether. Hence it might be expected, that when this test is applied to a sample of quinine sulphate containing 10 per cent of cinchonidine sulphate, the presence of this impurity would be ascertainable. That is not the case however. When such a sample is tested in this away, the whole of the alkaloid is dissolved, forming a clear solution, and there is no indication of the presence of cinchonidine. The fact is, that an ether solution of quinine dissolves more cinchonidine than an equal volume of ether does. The practical result is that the ether test applied in the manner just described will not in any case indicate the presence of cinchonidine unless its amount is upwards of 10 per cent at least.

It was partly in this respect that the ether test as prescribed in the British Pharmacopœia, 1867, the French Codex, 1866, and the United States Pharmacopœia, 1870, was defective. In each case also there was the further mistake of directing too large a proportion of ether to be used. Half an ounce of ether, the quantity to be used, according to the B. P., with 10 grains of the quinine sulphate to be tested, is capable of dissolving 2 grains of cinchonidine, and the 5 grams of ether to be used with half a gram of the salt according to the Codex, is sufficient to dissolve 0·0386 gram of cinchonidine, these quantities corresponding in one case to about 20 per cent, and the other to 13 per cent of cinchonidine sulphate that would escape recognition by the test. So far, therefore, as those official standards were concerned, it is again evident that the purity of quinine sulphate must be regarded as having had up to within a very recent period only a relative significance.

In the German Pharmacopœia of 1872 Kerner's test was adopted, and it has since been adopted in the United States Pharmacopœia of 1880. It is based upon the fact that quinine is much more soluble in ammonia solution than any other cinchona alkaloid. When a cold saturated solution of neutral quinine sulphate, containing only from 1-700th to 1-800th of its weight of the salt, is mixed with ammonia solution, the alkaloid precipitated in the first instance is readily dissolved again by adding more of the ammonia solution. If a volume equal to that of the quinine sulphate solution be added the mixture becomes quite clear. When, however, a saturated solution of cinchonidine sulphate is treated in the

same manner the result is very different, because cinchonidine is so very much less soluble in ammonia solution than quinine. Here then is a means of distinguishing between these two alkaloids, and the further difference existing between the sulphates of these alkaloids, in their solubility in water at the normal temperature, admits of this means of distinction being applied as a test for the presence of cinchonidine sulphate in quinine sulphate. The way in which this is done may be explained most readily by taking as an example the case of quinine sulphate containing 10 per cent of the cinchonidine salt, and applying the test as directed in the German Pharmacopœia.

One gram of such a salt will contain 0·99 gram quinine sulphate, and 0·01 gram of cinchonidine salt.

The first step is to separate the two sulphates by means of their very different solubility in water.

For this purpose the sample to be tested is shaken with ten times its weight of cold water, and if the two sulphates were taken up in proportion to their respective solubility in water, the cinchonidine sulphate dissolved would be seven times as much as the quinine sulphate, since cinchonidine sulphate is soluble in about 100 parts of water; while quinine sulphate requires about 700 parts for solution.* That is the assumption upon which Kerner's test was founded, and if it were correct, the solution obtained by shaking 1 gram of quinine sulphate containing 10 per cent cinchonidine sulphate with 10 c. c. of water would contain 0·0143 gram quinine sulphate and 0·1 gram of cinchonidine sulphate. If such a solution were really obtained under the conditions mentioned, Kerner's test would be a very delicate one. But that is not the case. The solution of the sulphates is not determined altogether by their respective solubility, and for various, reasons it does not take place at the normal temperature in these proportions so readily as might be expected. The consequence is that in applying this test to quinine sulphate containing cinchonidine sulphate only a portion of the latter salt is dissolved, and the portion which is not dissolved escapes detection. This fact was pointed out by me ten years ago, in the paper which I read at one of these evening meetings; but as the test is described in the German and the United States Pharmacopœias it has not received sufficient attention. Practically considered, the result is that Kerner's test is not much better than the other test already described, although it would be a very delicate one if rightly applied.

It is altogether useless to apply so delicate a test for cinchonidine, unless in making the solution to which ammonia is applied that alkaloid is really dissolved out of the sample to be tested. This is not done when cold water is used. Whether it be due to the slow action of cold water upon cinchonidine sulphate, or to the existence of a double salt, the result is the same, part of the cinchonidine remaining undissolved and thus escaping notice. I may here mention that I think there is some reason for believing part of the cinchonidine may be present in a free state, as it frequently happens that quinine sulphate has a decided alkaline reaction. If this be the case the insufficiency of Kerner's test in such a case would be quite intelligible.

The same test is adopted in the French Codex, and the conditions I have shown to be necessary are to some extent provided for by a slight modification intended to meet the difficulty that has just been mentioned. That consists in warming the mixture of quinine sulphate and water by immersing the tube in warm water, and then cooling the solution to a temperature of 15° C. before adding ammonia to the filtered liquid. It has been found, however, that mere warming is insufficient to ensure the solution of all the cinchonidine salt that may be present in a sample of quinine sulphate, and that consequently the application of the test in this way cannot be relied upon to afford trustworthy indications of the purity of quinine sulphate. For that purpose it is essential that the quinine sulphate tested should either be dissolved in boiling water, or at least heated to the boiling point with nearly enough water to dissolve it at that temperature. It is only in this way that the whole of the cinchonidine sulphate can be dissolved and brought into a condition to be recognizable on the subsequent addition of ammonia.* The Commission appointed by the Pharmaceutical Society of Paris to inquire into this subject has, after some months of investigation, also arrived at the same result, and therefore recommended that the mixture of quinine sulphate and water should be heated to the temperature of 60° C. But that is not sufficient to ensure the detection of all the cinchonidine salt that may be present, nor do I think that it is in any case, from an analytical point of view, a mode of procedure sufficiently precise to furnish trustworthy results as to the actual amount of cinchonidine sulphate. For various reasons, economical or therapeutical, it may be advisable or expedient to recognize a certain limitation of the purity to be demanded in quinine sulphate; but that would be most appropriately done by specifying the amount of cinchonidine salt that is to be allowable. Such a practical regulation of the matter does not, however, constitute any reason for making analytical methods less precise and analytical results less accurate than is consistent with the knowledge at our command. Any test that provides for overlooking some portion of a substance to be detected must be distrusted as unsafe.

In the present British Pharmacopœia the facts that I have previously pointed out have now been taken cognizance of and in accordance with them an improved modification of the ether test is adopted for the testing of quinine sulphate. Here the impossibility of obtaining correct results when operating directly upon the sulphate to be tested is overcome by having recourse in the first instance to a fractional solution of the salt by heating it with water to the boiling point, and then, after cooling and recrystallization of the quinine sulphate, applying the ether test to the cold mother liquor. By this means the greater part, if not all of the cinchonidine salt will be dissolved, while the proportion of quinine sulphate remaining associated with it in solution will be so minimized as to admit of the presence of cinchonidine being detected by the formation of a crystalline deposit either immediately or after the lapse of some hours.

Taking a sample containing 10 per cent of cinchonidine, boiling 10 grains of it with 5 fluid drachms of water, then cooling to 60° F., and filtering, such a solution is obtained. To get a good result the solution should be evaporated to about one-fifth its volume before being shaken with ether and ammonia, and then the presence of cinchonidine will be distinctly indicated. Even 1 per cent of cinchonidine sulphate can be detected in this way with certainty,† and it is very easy to tell whether any sample of quinine sulphate comes within the limit of purity fixed by the Pharmacopœia of "not much more than 5 per cent."

In regard to the testing of quinine sulphate the British Pharmacopœia is now decidedly in advance of other pharmacopœias. The ether test as there

* The solubility of neutral quinine sulphate is given somewhat differently by authorities, and it is not always quite the same for different samples. Taking the range of variation above-mentioned the quantities contained in 10 c. c. of the solution will be as follows—

For a solubility of 1 part in	10 c. c. of the solution will contain gram
700 parts of water at 60° F.	·0143
755 " "	·0132
800 " "	·0125

* Even then more than one recrystallization will generally be requisite.

† When the amount of cinchonidine is small it is requisite to leave the closed tube for twelve hours or longer for the formation of the crystals to take place.

applied is more to be relied upon than Kerner's ammonia test, even when a boiling temperature is applied in making the solution, because the manipulation is more simple, and the cinchonidine can be actually weighed instead of being estimated from the quantity of ammonia solution required to dissolve it. There are also possible sources of error in the ammonia test which do not apply in the other case. Perhaps the best testimony to the excellence of the modified ether test is, however, to be found in the circumstance that very shortly after the reading of my paper here it was adopted and specially recommended by so high an authority on this subject as Dr. Hesse, who published with that object a paper in the *Archiv der Pharmacie*' describing a mode of applying this test which has been commonly referred to since as Dr. Hesse's test.

But to return to the test of the British Pharmacopœi. So far as concerns the details hithero mentioned the principles to be observed are correctly applied; but I think it is unfortunate that the addition of acid should have been directed in making the solution, for except in so far as perfect neutralization is concerned, every drop of acid added proportionately invalidates the result by introducing into the mother liquor so much the more quinine, and thus, for the reason already mentioned, reducing the delicacy of the test for cinchonidine. Another objectionable feature of this test is the treatment of such a large volume of liquid with ether and ammonia. Five ounces of the solution will dissolve at least half an ounce of ether before there is any separation of ether to dissolve the alkaloid, and in that way a liquid will be produced which is itself a solvent of cinchonidine to such an extent as to interfere with the indications of its presence. The proper mode of operating would be to evaporate the mother liquor of the crystallization to a small bulk before treating it with ether and ammonia, and then the result of the test would be much more distinct and accurate.

2. Determination of Caffeine.

The method adopted for this purpose, and described in the *Pharmaceutical Journal* a few weeks ago, by myself and Mr. Cowuley, has since then been applied to the examination of a number of different samples of coffee from various sources, and we have found that in accordance with the view we then suggested as being probable, the amount of caffeine in coffee berries is a tolerably constant quantity. For the samples examined, we are indebted to the kindness of Messrs. Patry and Pasteur, who very obligingly provided us with material representing the produce of different countries where coffee is grown upon the large scale. In these further analyses, for carrying out which I am indebted to Mr. Cowuley, the coffee berries have first been dried at 212° F., since it was found very difficult to reduce them to powder when in the air-dried condition. The figures in the following table, therefore, apply to the dried raw berries, and the results previously published, have been corrected so as to allow for the amount of moisture in the berries.

Kinds of coffee.	Moisture per cent.	Caffeine. Berries dried at 212° F. per cent.	Air dried berries. per cent.
Coorg	8·0	1·20	1·10
Guatemala ...	8·6	1·29	1·18
Travancore ...	10·0	1·29	1·16
Liberian	8·0	1·30	1·20
Liberian	8·0	1·39	1·28
Rio	9·1	1·20	—
Santos Brazil.	9·0	1·29	—
Manila	6·6	1·20	—
Ceylon	6·2	1·24	—
Perak	7·3	1·22	—
Costa Rica ...	7·2	1·24	—
Pale Jamaica..	8·7	1·21	—
Mysore	8·0	1·28	—
Jamaica.....	9·0	1·23	—

It is evident from the results quoted in this table that the discordant statements hitherto published in reference to the amount of caffeine in coffee must be ascribed to defective methods of analysis, and that, in reality, the determination of the amount of caffeine in a sample of coffee by the method we have described would be one of the most conclusive data to rely upon in any question as to the adulteration of coffee.

3. Cocaine Hydrochlorate.

In a recent number of 'Ephemeris,' Dr. Squibb has put forward a statement in reference to the condition in which this salt should be employed in medicine and pharmacy, that may be considered rather remarkable as coming from him. He proposes that the cocaine as extracted from the coca leaves should be converted into hydrochlorate, and that this salt should be reduced to a dry state by evaporating the solution with constant stirring until a granular crystalline mass remains. Such a product would probably always contain a certain proportion of uncrystallizable material, which Dr. quibb thinks is physiologically equal to the crystallizable portion, and he recommends that the whole should be mixed together for use in medicine, because the separation of the uncrystallizable portion would entail considerable loss. Having lately had occasion to operate upon a large quantity of crude cocaine, as it is now imported from South America, my experience of this article has led me to disagree with the opinion expressed by Dr. Squibb, as to the propriety of allowing uncrystallizable hydrochlorate to be mixed with the crystallizable salt. I find that there is no difficulty in obtaining the salt in a finely crystalline condition, quite colourless and quite free from odour. It is, indeed, produced in this condition by several manufacturers, and for many of the purposes to which it is applied this appears to be the only suitable form of the salt.—*Pharmaceutical Journal.*

DISCUSSION.

Coffee Husks and Catha Edulis.

Mr. Allen said he had been entrusted by Mr. Redhouse with two specimens. That gentleman had for many years resided in Turkey and other parts of the East, and he had continually evinced his desire to improve their knowledge of eastern Materia Medica. A short time ago Mr. Redhouse wrote to his friend the Consul at Jedda, with regard to coffee and another matter, and in reply he had received a letter from the Consul in which occurred the following passage:—

"I send you by this mail per sample post, a bag containing a small quantity of the dried 'gisher' or shell of the coffee berry, so largely consumed both here and in the Yemen for coffee. Also, by same means, a quantity of the dried 'quat' so much chewed in the Yemen. This last has been forwarded to me by our Vice-Consul at Hodeidah, who says:—'In Yemen they always chew gat green and fresh, but whenever they proceed to the Hedjaz for Haj, or go to some other place where gat is not obtainable, they do not fail to provide themselves with a quantity of the gat herb previously dried. The Arabs of the Yemen never make nor have made a decoction from gat to drink.'"

So far as he (Mr. Allen) could find there was no record of the coffee husks being used as a beverage. It was a singular thing that the Arabs should discard the seeds altogether, and use only the husk for drink. There was no aroma in the husks. He found that the "kat" had been described in an interesting paper by Mr. Hanbury, in the *Pharmaceutical Journal*, [1], xii., p. 269. The "kat" was really the *Catha edulis*. The top shoots were probably cut off in a fresh state and brought to the market. They were very eagerly bought by the natives, both rich and poor. The men went into the bazaars or exchanges, and drank water and energetically chewed the herb, and thus got into a pleasant state of exhilaration. It would be interesting to ascertain whether these leaves contained an alkaloid or glucoside. In most text-books it was stated that the *Catha edulis* was used for making a drinking decoction as well as for chewing, but in the consul's letter it was distinctly stated that the Arabs do not make decoction from it. He had found in the text-books mention made of a coffee which was

made from the external parts of the berry. This was called Sultan's coffee and was never imported into the West.

Poison Cabinet.

Mr. Abbot exhibited a model of poison cabinet, which he said was of American invention. Its working was partly mechanical and partly electrical. The cabinet was so constructed that only one bottle could be out of place at one time, and the first bottle taken out must be restored to the shelf before another bottle could be removed. The invention, he said, had been recently perfected and patented in America.

Mr. Passmore asked wherein this cabinet differed from one brought forward by Mr. Young, of Warrington, at least fifteen years ago, and described in one of the early volumes of the present series of the *Pharmaceutical Journal.** That appeared to be practically the same invention as the present cabinet.

Mr. Abbott said that he had not heard of the invention to which Mr. Passmore referred. American patents were not granted until the patent authorities had thoroughly investigated whether the invention had been in any degree anticipated, and if it had been so anticipated a patent was refused. He would make it his business to see whether the invention of fifteen years ago was similar to the present one. Of course, it was possible that this idea had been anticipated.

Specimens Exhibited.

Dr. Paul called attention to a sample of margosa oil recently brought to England from Bombay, and sent for examination by Mr. Charles Christy. It was remarkable for being exceedingly bitter. The soil was obtained from the seeds of the nim tree (*Azadirachta indica*) one of the drugs of the Indian Pharmacopœia, and was valued as an anthelmintic.

Mr. Holmes said that the remarks made by Mr. Allen suggested some important points. The physiological action of coffee undoubtedly differs from that of tea in several points, yet the value of these beverages is generally attributed to the caffeine they contain. He believed that the leaves of *Catha edulis* had been examined by Professor Schorlemmer, but he had not been able to procure a copy of his paper on the subject. He had been informed, however, that caffeine had not been found in the leaves, and the exhilarating properties of the leaves must therefore be due to some other principle. If this were the case with *Catha edulis*, the cause of the differences between coffee and tea appeared to him to be worthy of further investigation. With respect to the margosa oil, it possessed a remarkable alliaceous odour which he had not observed in the bark of the tree, specimens of which were in the collection of Hindoo Materia Medica in the Museum of the Society. In reference to the specimens which he had placed before the meeting, the tree trunks at the back were those of cinchona tree, from Ceylon, principally *Cinchona officinalis*, *Cinchona succirubra* and a cinchona hybrid, apparently between the *C. officinalis* and *C. succirubra*. Some of the specimens showed that bark had been renewed by shaving it off instead of removing alternate strips.

NILGIRI BEES AND CURIOUS LEAVES.

A meeting of the Nilgiri Natural History Society was held in the Herbarium, on Monday last, March 7th, Mr. Lawson, President, in the chair. Mr. F. D. Short of Vercaud, was elected a member of the Society.

Mr. L. Morgan sent a paper to be read on "the Bees of the Nilgiris." It showed that there are three distinct honey producing Aphideæ on these hills, *Apis dorsata*, *A Indica*, and *A Florea*. The first is the largest and fiercest. Its hives are found in crevices of precipitous rocks, and in trees, particularly the kil, and always well protected from wind and damp. The shape of the comb is semi-circular, one and a half to two feet in diameter, and about two inches in thickness. The average yield of honey is from 15 to 30 pounds from each hive. These bees were numerous last year on account of the strobilanthus in flower. Their honey is dark, golden-brown, and peculiar in taste. The *Apis Indica* is the commonest Indian bee. It is very difficult to hive, always preferring natural holes in trees, and they invariably consume all the honey they gather. Their hives are kept very clean, and they are very cautious in selecting the site, as they have many enemies to contend with in the mice, rats, honey-bazzard and even the jackal and sloth bear. The *Apis Florea* is found in the lower valleys especially about Badaga cultivation, with their hives usually in some thorny bush. The hive is elongated and surmounted by a dome containing all the honey about 2 to 3 pounds. They never stay long in one place but keep moving about according to the flowering season.

Mr. D. Hooper next read a paper entitled "an examination of the leaves of Gymnema Sylvestre." These leaves when chewed have the peculiar property of destroying the taste of sugar and all saccharine substances. On taking some powdered sugar after masticating a leaf or two it appears to be as tasteless as sand in the mouth. A chemical examination was made of these leaves to ascertain the constituent to which this peculiar property was due. The paper gave the result of this examination, describing the different principles and their manner of extraction. The leaf was found to contain chlorophyll and two acid resins soluble in ether. An organic acid allied chrysophanic acid and containing the anti-saccharine property was discovered and named by Mr. Hooper, *Gymnemic Acid*. Other principles of the leaf were tartaric acid, a neutral bitter principle, gum, glucose, carbohydrate, cellulose, pararabin, and oxalate of calcium. The last was in the form of crystals in the leaf, known to botanists as conglomerate raphides.

Votes of thanks were passed to the authors for their papers and the meeting terminated.—*Nilgiri Express.*

AGRICULTURAL ENTERPRISE.

To the Editor of the "Bombay Gazette."

Sir,—I see that the question has been raised in Madras whether the example to agriculturists of successful private enterprise is more potent than that of Government farms. I confess that I do not see much analogy between the two, as the object of each is entirely different. That of the latter should be the encouragement of agricultural improvement by the economical expenditure of capital and of practical skill, and in such an institution one of the last considerations should be that which is essentially the first object of private enterprise, viz., profit. A Government farm should be an example farm, it is true, in the sense of being an experimental one, but as encouragement to capitalists to put their money in the land instead of underground, I would prefer the example of a successful private undertaking carried out on conditions open to all possessing a fair amount of capital and energy.

Allow me, therefore, again to ask for space for a short account of Mr. Bomanji A. Dalal's Farm (near Bahadarpur), the prospects of which have improved since my last visit, a short notice of which you were good enough to publish two years ago. The farm covers 3,500 acres, 1,300 of which are this year under cultivation. Of these, 400 are under wheat; 300 under tur (with rice as a first crop); 150 under winter jowari; a small area under oil, gram, and tobacco; and the remaining 300 acres under a mixed crop of a somewhat unusual kind, viz., rice and cotton. This I have never seen elsewhere, but it appears that the "besur" soil here is so rich that cotton sown alone runs to wood and leaf. Whether an exhausting crop such as rice should be used with cotton appears doubtful, but it is not easy to suggest a substitute which would be harvested early enough not to interfere with the growth of the more important crop.

Pharm. Journ., [3], vol. i., p. 870.

Four years ago Rustumpura contained only a single family, cultivating about twenty acres; it has now a population of nearly 500, attracted here by the liberal terms offered by the proprietor. A school and a post-office have already been established. The water-supply is not good as yet, but Mr. Bomanji has spent a good round sum on the village, well, and tank, and hopes for sympathy and assistance from the local board. The food grains produced on the farm are not more than sufficient for the consumption of the colony, and exports are confined to cotton and oil seeds. The station of Bahadarpur is only six miles distant, but the road is very bad, and even more disheartening than the road, is the transit duly taken by His Highness the Guicowar on all produce carried by his own railway! It is melancholy to see agricultural enterprise and every branch of trade handicapped by these obnoxious duties, and the policy is as short-sighted and suicidal as it is barbarous. I rode this morning over a very large extent of waste land belonging to His Highness, still nearer to the railway than Rustumpura, and with equally good soil. A few roads, a few wells, and the abolition of these duties would soon turn this bare plain into a valuable cotton-producing and revenue-paying district.

Mr. Bomanji has found time for a few experiments, having given some attention to Nankin cotton, linseed, safflower, and white wheat. With tobacco he has done well, and his crop of red "hansotia" wheat looks excellent. Mr. Bomanji himself is an Honorary Magistrate, a member of the Local Board, and a most hospitable gentleman, very well worthy of the success which, I feel sure, you, sir, will join me in hoping is before him.—G. F. S.

THE MANUFACTURE OF SCENT.

This is the time of year most perfect on the Reviera: the sky is serenely blue, the sea rolls lazily as if overburdened with warmth, the scent of the orange-blossom still lingers undisturbed by wind upon terraced hills, the air is gently bracing, and everyone is in a good humour.

With the advent of the new year, the wild flowers begin to bloom, violets coming first in great abundance, soon followed by hyacinths, blue-bells, narcissus, and all their sister train of light and colour; but in February the aspect is changed, the mistral sweeps along the land, curling over the olive leaves, till the country becomes silver-grey instead of sombre-green, driving clouds of dust before it, and penetrating everywhere like a thorough scavenger. A period of restlessness then commences; the invalid loses ground, and is weary of the proximity of the sea, from which there is only one escape to a quiet, old-fashioned Provençal town called Grasse, lying under the shelter of the Basses Alps, with fresh, invigorating air, and having for its chief attraction the important business of manufacturing scent. The position is very pleasant, at an elevation, of 1,100 ft. on the side of a mountain guarding off the North, and about ten miles by rail behind Cannes, so that there is a full Southern aspect which tempers the atmosphere, and renders possible a great cultivation of flowers. Owing to the height, the wild flowers are a little later than those of the true Riviera; but acres of violets are privately grown, with innumerable beds of hyacinths, jonquils, and narcissus; while long before it is necessary to leave, the May blooms upon the hedges, and the tender Star of Bethlehem brightly gleams everywhere, in pleasant contrast to the green of spring. During this season the factories work to their full extent, though the treatment is so slow, and in some instances requires such constant repetition, that flowers are only received twice a week. If, however, one should happen to visit a factory on a receiving-day, one will find the floors of the reception-rooms covered, perhaps, with a mass of violets, upon which probably recline two or three young ladies, enjoying the perfume and delighting in the reality of an imaginative dream. Every flower, before arriving at the perfumery, is removed from its stem, when, according to its nature, it undergoes one of the three processes,—distillation, submersion in hot grease, or absorption by cold grease, all utensils used in the manufacture being made of copper.

The first is the costly but ordinary method of the retort, placed over a small furnace, carrying the vapour as it condenses into a receiver, with glass tubes on the outside to catch the essential oil. Verbina, geranium, and lavender are treated in this way. The second is very curious, and seemingly, ought to be disastrous. Flowers in certain proportions are flung into good-sized kettles of hot pork and beef-grease, kept warm by placing the vessels in boiling water; they are well stirred together, and left still hot for twelve hours, after which the mixture is heavily pressed. The flowers are then thrown away, and the operation is repeated with fresh ones, until the liquid grease is sufficiently charged with odour, when it is placed in a cold receiver half-full of spirits of wine, which in a few days becomes impregnated with the perfume, and is drawn off for sale. If the grease is not subjected to the spirits of wine on the premises, it is sold in its congealed state to the London scent-makers, who treat it at their leisure. Roses, orange-blossoms, and violets are some of those requiring this method. The third, to the eyes of a novice, does not appear so hopelessly destructive or so wilfully barbarous; yet the sacrifice of beauty is the same. A layer of olive-oil or cold grease, carefully prepared, is placed upon a frame, the flowers being dotted over it face downward, and remaining for twenty-four or thirty hours. The process is very tedious, requiring to be repeated with the same grease many times, after which the perfume is absorbed by spirits of wine, as in the previous manner. The delicate scents can only be caught in this way,—will only give out, so to speak, their exact selves according to Nature. It is no extraction, but literal absorption, the catching of sweetness freely imparted to the fresh air of native hill-sides. Jessamine, tube-rose, jonquil, and others not of tough formation, must be submitted to this treatment. The industry is of great value; there are upwards of fifty perfumeries; and though the London market is the best outlet, yet their products are being gradually shipped to almost all parts of the world. There is no toil about the work, no grinding poverty no din or rattle of machinery, no emaciated children everything is quiet and peaceful; in fact, if it would not be a paradox, one might call life in these factories the Nirvana of labour. The manufacture being a very profitable one, the perfumers are naturally the men of the place, and besides possessing good means, are large owners of property at Cannes and Nice, as well as at Grasse.—*Spectator.*

QUEENSLAND SUGAR-GROWERS are by no means so depressed as might have been supposed at the prospect opening out before them. A splendid growing season, with a slightly better price for their sugar than was previously calculated upon, has cheered them considerably; and, but for the fact that the labour difficulty remains unremedied, and that operations on the plantations are either brought to a standstill or reduced to a minimum, there would be little in connection with sugar to grumble about. Beet sugar growers have more reason to feel concerned at their prospects than have growers of the sugar-cane. Fruit-preserving and jam-making are the stars of hope for the sugar manufacturer; and here it is that beet sugar is a miserable failure. It is not generally known that beetroot sugar decomposes fruit, while cane sugar preserves it. Those who contemplate the making of preserves should take this fact into account, for it will prove a false economy to use beet sugar for that purpose. Out of this fact arises the query: Can a sugar that decomposes fruit be properly nourishing to the human frame? Value is not by any means in proportion to price. For saccharine and preserving properties, if cane sugar stands at 100 per cent, beet sugar is no higher than 65 or 70, and if cane sugar is worth 3d. per pound, beet sugar, notwithstanding its bright and granular appearance, is not worth more than 2d. The fight between these powerful rivals is resulting in favour of Nature's best article—cane sugar; and a few years will probably be efficient to establish the cane sugar industry on a better and more satisfactory basis than it has ever before rested upon.—*Queenslander.*

Ginger-beer Powders.—Mix ½ oz. of bruised ginger, ¾ oz. cream of tartar, and 4 drops of essence of lemon with as much powdered sugar as will make the packet a presentable size. Direct that the powder be added to 1 gallon of boiling water, containing 1 lb. of lump sugar. When nearly cold float a piece of toast on the liquid, on which place 2 or 3 tablespoonfuls of good yeast, and set in a moderately warm place to ferment for a day or two; strain and bottle.—*Chemist and Druggist*

Preservation of Flowers.—The *Chronique Industrielle* states that flowers may be preserved, with all their brilliancy and freshness, in the following way:—In a well-corked bottle, dissolve six drachms of coarsely cracked, clear gum copal, mixed with the same weight of broken glass, in 15½ ounces (by weight) of pure ractified sulphuric ether. Soak the flowers in this mixture, take them out slowly, and expose them to the air for ten minutes; then immerse them anew, and again expose them to the action of the air. Repeat this operation four or five times. The flowers thus treated will keep for a long time if care be taken not to handle them too much.—*Journ. Royal Micros. Soc.*

The Saltpetre Solution is a well-known remedy for the cut worm; but not everybody knows how to apply it. We therefore give in the following method of a correspondent of the *New England Homestead*, even if a little out of season. We might forget, you know. One year ago I had a patch of beans entirely destroyed by cut worms. I planted it over; as soon as they came up, the worms began again. I dissolved half a pound of saltpetre in three pints of water, mixed that thoroughly with one-half bushel of dry ashes, and I sprinkled the ashes on the beans just as there was a shower coming up, and the rain washed the ashes all off into the ground. I had no more trouble with the worms, but had a good crop of beans.—*Southern Planter.*

Pepper Adulteration.—A. Hilger, in the *Archiv. der Pharmacie*, states that adulteration of ground pepper by means of broken pepper has lately been very frequent. A sample of broken pepper was taken, and on careful inspection was found to contain an admixture of broken pericarps of chillies. The microscope proved that pressed seeds of the oil palm (*Elaeis guinensis*, Jacq.) were also present. Complete analysis showed the so-called "broken pepper" to consist of.—

	Per Cent.
Shells of pepper	50
Flour of oil-palm seeds	30
Dust of pepper	15
Mineral substances	4
Pericarps of chillies	1

—*Chemist and Druggist.*

Peach Growing in America.—As to pruning, let them alone the first year. Cut the lower limbs off the second year, but not too much. Cut more in the third year, and then direct the form of the tree; but avoid, in all stages of tree, too much pruning. Let them grow low; don't let the limbs crowd and press each other; keep the tree erect, or inclining a little to the south; don't let the sun shine on the bodies. Use judgment in pruning. Some trees require it often; other sorts hardly at all. Prune in latter part of May or June. Don't cut your trees in winter or fall; it is ruinous to them, and there can be no necessity for it. Save the soap-suds after clothes washing, and wash down the bodies of your trees, young and old, or get some other wash—carbolic soap, or something else. Rub some axle-grease on the bodies of your young trees in the fall, to prevent hares and mice from girdling them in the winter. For the first time in my memory, the hares were very destructive to young trees in this section during the last winter. I had a lot of young apple trees, one and two years from the nursery, and saw, on the 1st of December, that something was biting them; three were already girdled. I gave a man a box of axle-grease, and had him rub it on with his hands, the whole lot, from the roots to the limbs, and they were not touched afterwards, while hundreds were destroyed at other places where they were not thus treated. This is the first time that such a thing has occurred here that I know of, but it may not be the last.—*Southern Planter.*

Cement Wash.—Take of fresh cement three parts, clear sand one part, and mix them thoroughly with fresh water. This will give a grey or granite colour, dark or light, according to the colour of the cement. If a brick colour is desired, add enough venetian red to the mixture to produce that colour. The cement, sand, and colouring matter must be mixed together. If white is desired, the walls, when new, should receive two coats of cement wash, and then whitewash. After the work has received the first coat, a single coat every three or four years will be sufficient. It is best to thoroughly dampen the wall with clean fresh water, and follow immediately after with the cement wash. This course will prevent the bricks from absorbing the water from wash too quickly, and will give time for the cement to set. Care must be taken to keep all the ingredients of the cement wash well stirred during the application of it. The mixture must be made as thick as it will admit of to be conveniently put on with a whitewash brush. —*Rural Australian.*

The Future of the Date Palm in India. By E. Bonavia, M. D., Brigade-Surgeon I. M. D. (Thacker, Spink, and Co., Calcutta.) A considerable experience and study of the date palm has convinced Dr. Bonavia that it is the best of all trees, "either for fuel or as a help in times of famine," in India, and he has done well in giving his views to the public on the subject in this small volume. He has been at considerable pains to collect information through Government and private sources, and gives some general rules for the cultivation of the date palm in India, "and a scheme for extensive date-planting in tracts where its presence in large numbers would be most desirable." There are, as he points out, two objections to the planting of date palms—viz., dampness of the atmosphere and soil during ripening time, and the depredations of wasps. To meet the first objection he contends that, as he proposes the date palm as a protection against the failure of ordinary crops through scarcity of rain, consequently at the season when the dates would be most wanted the dampness would not arise to ruin it. As to the wasps, he thinks that there would be no difficulty in contriving a wasp-trap which would capture the bulk of them. As to the financial question, he says, "Any expenditure on such a scheme, which would at the outside be only required for ten or fifteen years, would be capital well invested. Not only would the foundations of an alternative ample supply of food be laid, but means would be provided of pushing population into tracts of country which are now lying waste for want of labour, and sufficient labour will not come without the fruit of some tree which requires little labour and a minimum of water.—*Home News.*

Ginger.—As a rule, spices grow above ground, but this is not the case with ginger. This product is a root, and grows beneath the surface. It is one of the most valuable spices, and its uses are more numerous and varied than anyone of the others. Ginger was first found near the Red Sea, and very early found its way to Greece and Rome. Like many other commodities, it was first used as a medicine, and held in high esteem. Soon after the discovery of America the plant was transferred from Asia to the West Indies and the tropical regions of the Spanish possessions of the new world. It is now cultivated as an article of commerce in Cochin, Bengal, Africa and Jamaica. It can probably be successfully cultivated wherever the coffee tree grows luxuriantly. The ginger of Jamaica has gained so high a reputation that the impression is made on many credulous minds that more ginger is grown, cultivated and exported from that island than from any other part of the world. In 1876 there were exported from Jamaica more than 1,600,000 pounds, valued at $144,000, or nine cents per pound; but the reports of exports vary so greatly that it is not easy to believe them correct. In 1867 the exports of ginger from Jamaica were reported at 1,728,675 pounds; in 1872, five years later, they fell off to 599,786 pounds, and then four years later, 1879, they again run up to 1,603,764 pounds.—*Grocer and Canner.*

THE OFFICIAL CALABAR BEAN is the seed of *Physostigma venenosum*, a large perennial climber found near the mouth of the Niger Old Calabar, and in Western Tropical Africa generally. Lagos and Gambia, for example, contributed specimens to the Colonial and Indian Exhibition. The plant has also been successfully cultivated in Ceylon, [By the Messrs. Frasers, near Matale.—ED. C. O.] and good specimens of the seed from that island were shown at the exhibition, and are now deposited in the Pharmaceutical Museum. —*Chemist and Druggist.*

TEA CULTIVATION IN CEYLON.—We are indebted to Mr. Rutherford for the ready transfer to us of the returns he has been getting of the tea acreages in the several districts with a view to arriving at the total planted in 1886. These returns will be carefully compared with those furnished for our Directoy. Meantime we may mention that Mr. Rutherford makes out 152,000 acres under tea at the end of 1886, and although our information is not yet forward sufficiently to enable us to check these, yet we believe, the total is very close on the actual state of the case.

NORTH QUEENSLAND.—After an interview with a journalist, who is also a planter of considerable experience in India, we were gratified in finding that our convictions with reference to the adaptability of the Johnstone River country for the cultivation of tea, cocoa, and rice were substantially confirmed. In India land suitable for rice does not favour the tea plant, for the latter is best on hill sides, where the drainage is good; and the same is equally true of the *theobroma cacao.* The Johnstone soil is unsurpassed for fertility anywhere, and the climate is sufficiently moist for tea wherever the land is high enough to allow of good drainage. The swampy portions would grow rice to perfection, and the back country rising about Herberton into a lower temperature would be the very thing for cinchona. The sugar industry there is working with fewer hitches than elsewhere, and so far as that district is concerned it would be, comparatively speaking, an easier matter to bring in a satisfactory substitute for it than in any other agricultural district in the North. All that streteh of country including Port Douglas, Cairns, the Johnstone River, and back to Herberton is included in the above remarks, and has a great agricultural future before it.—*Queenslander.*

VINE DISEASES.—The various diseases which affect vines, formed the subject of conferences held in last October in Florence, where an exhibition was also given of anticryptogamic and insecticide apparatus for combating those diseases. Mr. Consul-General Colnaghi sends a short summary of the conferences. The diseases discussed were *Peronospora Viticola* (a mildew; *Anthracnosis* (Black rot); *Mal Nero* (Black sickness); and decay of the roots. The characteristics of these are generally known. In the first case, milk of lime and unwashed sulphur have proved successful antidotes, but those remedies containng sulphate of copper have been found most efficacious —the latter having drawbacks owing to its deleterious effect on the fruit. In the second case, the preventive used with most success has been the treating of the branches and stems of the plants with acidulated sulphate of iron. For the third disease there are not yet any known remedies, nor has the cause of the malady been ascertained with certainty. Cutting away and precautions against humidity of soil are recommended. The fourth disease is not peculiar to the vine, and may be produced by a variety of causes, among which are: stagnant humidity in the soil, want of proper aëration, damage produced by frost, and parasites. As a remedy, the causes indicated must be removed, and the decayed parts of the plant destroyed. It is proposed to renew the conferenee this year, at which reports will be presented on various experimental tests. (Miscellaneous Series, 1887, No. 27.)—*Chamber of Commerce Journal.*

SARSAPARILLA —A short time ago a correspondent wanted to know about the cultivation of this product the notes from a reliable source may be of service. In cultivation, the plant is reproduced from the vine or stem, which is lifted clear from the ground. The soil is then loosened, the vine is buried slightly into it, roots freely, and forms new stock with new roots. Were the plant once established in open scrub land, its nature and habits induee us to believe that it could be made a valuable produet with comparatively little trouble. It is also propagated from the seed which fall around the parent plant in great numbers when they fall in loose and rieh soil. This seed is enclosed in a fruit or globose envelope, which hangs in branches from the vine like grapes. Each berry eneloses a pit of the size of a pea. It turns black upon falling and its envelope is red. Each plant bears twice a year Sarsaparilla can also be made to root by cuttings. This method is more prompt than by the seed. According to the trials which have been made with it, the roots by this method attain full size in two years; by the seed three years are necessary. Sarsaparilla, cultivated with skill, would give a yield of twice what it does in its wild state. It is estimated that if on the space of an acre, one had a thousand plants, whether from seed, from cuttings,or from sprouts the result would be from four to six thousand lb. of dry sarsaparilla, of the quality most esteemed in eommerce. When the roots are ripe they are dug and exposed to the sun until they are quite dry; in some cases the roots are washed before drying. They are then tied up in bundles, weighing from 12 to 20 lb. each, for export. The bundles of South America are packed in bales weighing from 80 to 100 lb. or more, and imperfectly covered with skins. In the interior of the bundles are often found roots of inferior quality, rhizomes with adherent stems, stones, chunks of wood, &c. The roots are furnished with a few rootlets. The general color of the roots is dirty grayish or reddish brown. The cortex is very mealy, and the meditullium or central cord is thinner than in the Jamaica sort.

CHEAPER CHARGES ON TEA.—We learn that the Indian Tea Districts' Association are carrying on an animated correspondence with the representatives in this country of the great steamship lines running between Calcutta and London, and also with the associated inland companies, with a view to the obtaining of a reasonable reduction of the rates of freight hitherto charged on tea. We hear also that the question of cheaper rates for storing and warehousing teas in bond is also under the consideration of the Association.—*H. & C. Mail.*

M. PAUL BERT ON TONQUIN INDUSTRIES: BANANAS.—M. Paul Bert, late Resident-General of Tonquin, forwarded to the Minister of Commerce and Industry the following letter, which he had addressed to the Chambers of Commerce at Mines and Clermont-Ferrand, on the advantages offered by the preserving of bananas in Annam :— HANOI, 22nd September, 1886.—Annam produces in abundance the best bananas; it is said that in quality those of Singapore are much inferior to them. At Singapore there are a large number of houses engaged in the preserving and sale of bananas for export. I think it right to bring this fact to your notice as your town possesses a large number of well known fruit preserving establishments with a large connection. I think that at least one of them might work the bananas of Annam. I would do all in my power to assist in its establishment.—*Hongkong Daily Press.* [If really the preserving of bananas for export is a paying industry at Singapore, it surely ought to pay in Colombo. The fruits split in two, lengthways, could be spread on mats and dried by solar heat, under protection of wire netting. Or they could be baked and packed in jars or tins, like figs. The Dutch preserved plaintains by solar heat and many Ceylon children in school in England were made happy by a present of a tin of preserved plantains from the Rev. Mr. Thurstan's Industrial School. The latter were, we think baked and a little white sugar scattered over the layers,—ED.]

COCONUT PEARLS.

A trade journal appearing in Java, gives the following particulars regarding a peculiar kind of pearl found in this part of the world :—It is well known that pearls have been met with within oysters and mussels. Sometimes even trees yield pearls. In the Proceedings of the Boston Society of Natural History, there is a paper by Mr. J. Bacon regarding a kind of pearls often found within cocoanuts. The specimens shown have been bought at Singapore. They are said to be so rare in the East Indies as to be highly prized by the native rajahs, and worn by them as precious stones. Mr. Bacon himself possessed a small pearl of this sort. It is said that, when allowed to grow, they will reach the size of cherries. This pearl resembles the common variety in smoothness, whiteness, and scant lustre of surface. It is harder than it, and almost as hard as feldspar or opal. The common pearl varies in hardness, but is never harder than feldspar. The coconut pearl consists of carbonate of lime, with very few organic substances remaining after treatment with acid solutions. This organic matter is insoluble, shows no trace of vegetable substances after microscopical examination, and seems to be akin to albumen in structure. In the common pearl there is also found an albuminous substance, but the latter remains unchanged in appearance and lustre even after the calcareous constituent parts have been dissolved away. In other respects, microscopical research has brought out the fact that the coconut pearl is formed of concentric layers without any nucleus. The whole mass is made up of layers of fine crystalline fibres. Professor Bleekrode, in commenting on the former in a Dutch scientific periodical says that Rumphius, the famous botanist, had in his *Herbarium Amboinense* given full particulars of this petrifaction in the coconut. Rumphius has even illustrated his account of it by accompanying drawings of the two forms in which this kind of pearl is met with—pear-shaped and round, either of uniform appearance or with red edges. Hardly one in a thousand coconuts on the average displays this strange peculiarity. The formation of the latter is always a remarkable phenomenon hard to account for from the water in the nuts generally lacking the chemical substances favouring abnormal growth of the kind. Rumphius states for a fact that coconuts from Macassar yield more pearls than those from other places. This scientist, in 1682, sent, as present to the Grand Duke of Tuscany, a ring in which a coconut pearl had been set. Similar pearl-like formations are met with in other East Indian fruits, such as the waringin, the pomegranate, and the kechubong.—*Straits Times.*

[During our fifty years' residence in Ceylon we have never heard of any such concretion in the coconut. If any of our readers have been more fortunate, we shall be glad to hear from them. There is the story of the Sinhalese King who, to try a sage, asked him if there was any water which did not contain fish. The sage replied "none." The King triumphantly ordered a coconut to be split, when lo! out jumped a fish! The pearl story seems as probable. But if, as is stated, Rumphius described, figured, and sent as a present a coconut pearl, scepticism must give way. Who will refer to Rumphius for us?—Ed.]

PEARLS AND PEARLING LIFE.

Pearls and Pearling Life. By Edwin W. Streeter, f. r. g. s. (London : George Bell and Sons, 1886.)

The book before us, according to the preface, and as far as we are aware, is the only work in the English language which is entirely devoted to the history of pearls. The introductory chapter is immediately followed by one which gives a brief historical account of pearls in connection with India, China, Persia, Palestine, Egypt, Ancient Greece and Italy, and Europe in the Middle Ages. This is succeeded by a *resume* of the ancient ideas respecting the origin and supposed medicinal qualities of pearls, and by a few words on "breeding" pearls. The next chapter treats of the different kinds of pearl-forming mollusks, both marine and fluviatile. The writer then gives an account of the true mother-of-pearl shell, describing its geographical distribution, the different varieties, its structure, the parasites found within the shells, and their external enemies, their method of getting rid of extraneous substances (stones, small shells, &c.) accidentally introduced within the valves of the shell, and the uses to which the mother-of-pearl is put. The sixth chapter, although headed "The Origin and Formation of Pearls," also refers to the different kinds, such as *bouton* pearls, *baroque* pearls, and *coq de perle*, the mode of life of the oyster, the positions in which pearls are found, &c. It also treats of the qualities which regulate the value of pearls. The next chapter gives a short account of the Sooloo Archipelago, the natives as pearl divers, and their method of dredging. Then follows a good description of the fisheries of North-West-Australia and Torres Strait, and this is succeeded by an interesting chapter entitled "Pearling Life at the Present Day," which is practically descriptive of pearling expeditions made by Mr. Streeter's vessel, the *Sree Pas Sair*, from Singapore to the North-West Australian coast and the Sooloo Archipelago. Chapter XI. is devoted to a condensed account of the pearl-fisheries of Ceylon and Southern India, and this is followed by a *resume* of what is known respecting the fisheries in the Persian Gulf, the Red Sea, on the west coast of North America, and at the West Indies. Pearls produced by shells which inhabit the rivers and lakes of Great Britain and foreign countries are described in Chapter XIV., and the artificial production of pearls by the Chinese is also here referred to. The different kinds of coloured pearls, and the mollusks which produce them, are then treated of. In the succeeding chapter the most famous pearls of both ancient and modern times are recounted, and the immense sums at which some of them were valued are stated. Chapter XVII. gives the history of the remarkable cluster of pearls known as "the great Southern Cross pearl," which was exhibited in the West Australian Court of the Colonial and Indian Exhibition, and valued by the owners at 10,000*l*. The next and concluding chapter is devoted to the value of pearls, and shows how their worth has varied in this country at different periods from 1671 to the present time.

A map is then introduced showing the principal pearling regions. In an appendix, the works bearing on the subject which have been consulted by the author are enumerated, and a full index completes the volume.

Mr. Streeter has brought together a large amount of information which will be of interest to the general reader, for whom especially, and not for the scientific, the work has been written. The most original material is comprised in the part extending from the seventh to the tenth chapter. The chapter devoted to the Sooloo Archipelago contains some details which, although interesting in themselves, are rather foreign to the subject of the work.

The same observation applies to the account of the constellation *Crux Australis*, or Southern Cross, introduced in the seventeenth chapter.

As far as we have noticed, the various opinions and statements set forth in the work are mostly accurate. It may, however, be questioned whether "there is perhaps no instinct implanted in the human breast more powerful than the of love admiration," for is not that of self-preservation supposed to reign supreme? We would point out that the term *Lamellibranchiata* is now superseded by that of *Pelecypoda*, and with good and sufficient reasons is adopted in the latest and best manuals on conchology. The bathymetrical range of bivalves far exceeds the stated limit—200 fathoms—specimens having been obtained by the *Challenger* and other deep-sea exploring expeditions in depths ranging as low down as 2900 fathoms.

The book is printed in good legible type upon toned paper, but the pictorial portion mars the rest. The plates illustrating the *Malleus*, the *Meleagrina*, the *Unio*, the *Pinna*, the *Strombus*, and the *Turbinella* are simply execrable. They are printed upon a fearful black ground (one almost expects to see "Sacred to the memory of," &c.), inclosed by a thin white line with ornamental corners, and seem to us to have a most common appearance. We cannot see one redeeming feature in them, the drawing and colouring of the shells being equally bad. If another edition is called, for, fresh and accurate illustrations should be provided. E. A. S. —*Nature*

[The pearl shells are beautifully engraved in Tennent's Natural History of Ceylon.—Ed.]

INDIAN TEA AND TEA COMPANIES.

We reproduce from the Calcutta Commercial Correspondence of the *Pioneer*, a series of summary reports on a long array of Tea Companies. The experience of the past year, in the case of our Indian neighbours, cannot fail to be full of interest and instruction to Ceylon planters. The profits made in some cases must be considered exceedingly good: indeed, fair, if not handsome, dividends are the rule; but there are some exceptions; and we may be thankful in Ceylon, although we have drawbacks—as the present droughty season shows—that it is almost impossible for us to have to chronicle such an experience as that of the Holta Tea Garden where 30,000 lb. of tea were lost in one hailstorm! We quote as follows:—

Tea.—The report of the Directors of the Bolasun Tea Company discloses an outturn of 1,054 maunds against an estimate of 1,000 maunds, which sold at an average of As. 10-8 68 per lb. against As. 13 9 per lb. in 1885. The gross revenue was R56,552 and the expenditure R42,287, leaving a profit on the working of R14,265, and after one or two small adjustments the amount at credit of Profit and Loss is R14,122 A dividend of 5 per cent. has been declared, and it is now proposed to pay a final dividend of 2 per cent. and carry R122 forward. The dividend last year was 10 per cent. The estimates for 1887 provide for 1,000 maunds of fine tea at a local cost of R27,500.

The report of the Managing Agents of the Goomtee Tea Company shows that the outturn was 862½ maunds against an estimate of 750 maunds, the average price realised being nearly 8 annas per lb Last season the outturn was 700 maunds and the average price As. 11-2 per lb. The revenue account shows receipt of R34,516 and an expenditure of R30,577, leaving a profit on the season's work of R3,939, but the loss of a shipment of tea in 1885 fell to be adjusted in these accounts, and the result is a credit balance at profit and loss of R1,207, which is too small for division.

The estimates for 1887 provide for an outturn of 750 maunds at a total expenditure of R30,000 Last season the dividend paid was 13 per cent.

The report of the Managing Agents of the Hopetown Tea Company shows an outturn of 621 maunds against an estimate of 500 maunds, and an outturn in 1885 of 435 maunds. The average price realised was, however, As. 9-5½ against As. 13-2 per lb. last year. The revenue account shows receipts of R29,982 and an expenditure of R31,684, resulting in a loss of R1,702 on the season's working. The amount at debit of Profit and Loss is R1,113. This coming season the Manager hopes to make 650 maunds of good tea.

The report of the Managing Agents of the Indian Terai Company shows that the outturn was 140,010 lb., being 24,010 lb. in excess of the estimates and 22,120 lb. more tea than was made in 1885. The gross average price, however, was As. 8-1 per lb. as against As 10-9 for the crop of 1885. The receipts for the year were R69,375 and the expenditure R53,014 leaving a profit on the operations of R16,361, and the net balance at Profit and Loss is R16,599. A dividend of 5 per cent. was paid in September, and it is now proposed to pay a final dividend of 5 per cent. and to carry R1,599 forward. The dividend last season was 17 per cent. The estimates for the current year are for 132,000 lb. at an expenditure of R52,503.

The report of the Managing Agents of the Kornaful Association shows that the outturn was 3,948 maunds, or 198 maunds more than estimated, and 166 maunds in excess of 1885. The average price obtained was As 10-1 per lb. against As. 11-4 obtained in 1885. The revenue account shows receipts of R1,99,328 and an expenditure of R1,42,848, leaving a profit of R56,480; this amount is reduced by payment of interest, commission, and sundry instalments for new cultivation and machinery to R29,135 as the net profit for the year, and adding the amount brought forward from 1885, the balance at credit of Profit and Loss is R44 672. This sum the Managing Agents recommend should be carried forward as in the present position of the Company it would not be desirable to declare a dividend, though if sufficient capital were subscribed to pay off the Company's debt, a dividend might be paid out of the accumulated profits. This subject will be discussed at the general meeting on 9th proximo. The estimates for the current season provide for an outturn of 3,920 maunds at an expenditure of R1,73,000 The report of the Directors of the Teesta Valley Tea Company shows that the outturn was 1,716 maunds, against an estimate of 1,500 maunds and an outturn in 1885 of 1,523 maunds. The average price realised was As. 9-3 per lb. net, against As 11-10 in 1885. The revenue account shows receipts for R86,112 and an expenditure of R66,013, leaving a profit for the season of R20,099. But the loss on a shipment made in 1885 reduces this amount to R17,552. An *ad interim* dividend of 5 per cent. has already exhausted R16,000 and the balance of R1,552 will be carried forward. For 1887 the estimated outturn is 1,800 maunds at an expenditure of R63,000. Last season the dividend declared was 10 per cent. The report of the Directors of the Dehra Doon Tea Company shows that the outturn for 1886 was 384,492 lb., or 57,879 lb. more than in 1885,, the percentage of first-class teas being 51 against 45 in 1885. The revenue account shows receipts of R1,59,316 and an expenditure of R1,04,233, leaving a profit of R45,083 and adding the balance from 1885 the amount at credit of Profit and Loss is R47,087. A dividend of 5 per cent. is recommended, carrying forward a balance of R3,187. Prices have ruled unprecedentedly low, but the increased outturn and more economical working has admitted of the same dividend being paid. Messrs. Devenport and Co. have been confirmed as Secretaries to the Selim Tea Company on a salary of R500 a month, which is to include office allowance.

The report of the Managing Agents of the New Terai Association shows that the outturn in 1886 amounted to 183,130 lbs., or 23,130 lbs, in excess of the estimate and 17,045 lb. more than the crop of 1885. It was sold at an average of 9½ annas against As 11-11 per lb. in 1885, The revenue account shows receipts of R1,10,093 and expenditure of R68,516, leaving a profit of R41,577, and adding the amount brought forward from 1885, the sum at credit of Profit and Loss is R45,314. An *ad-interim*

dividend of 5 per cent, has already been paid, and a further dividend of 17½ per cent has been declared or 22½ per cent in all, leaving a balance of R1,814 to be carried forward, which will provide for the cost of a new Excelsior roller and meet the cost of improving the water-supply. The estimates for 1887 provide for an outturn of 2,100 maunds at an outlay of R74,000. The balance in the hands of the Managing Agents on the 31st December was R69,990, and bankers have been since appointed to the Company. The garden extends to 410 acres and the block stands at R1,83,015. The report is in the highest degree satisfactory, and Messrs. Schoene Kilburn & Co. are to be congratulated on these good results. The dividend last year was 20 per cent.

The report of the Managing Agents of the Ring Tong Tea Company for the season of 1886 shows that the estimated outturn of 1,200 maunds was exceeded by 127 maunds, but unfortunately the average price realised was only As. 9-9·14 per lb against As. 13-2 for the season of 1885. The revenue accounts shows receipts of R65,137 and expenditure of R63,963, leaving a profit of R1,174, which is reduced in the Profit and Loss account to R934, which will be carried forward. The dividend last season was 7 per cent. The estimates for the current season provide for an outturn of 1,200 maunds at a local expenditure of R37,000, which includes the upkeep of the 75 acres put out in 1884.

The report of the Managing Agents of the Singbulli and Murmah Tea Company shows that the outturn was 2,364 maunds against an estimate of 2,050 maunds, and 696 maunds in excess of the season of 1885. The quantity of the tea was, however, much below the average, selling at As. 9-6·65 against As. 13-9·95 in 1885. The revenue account shows receipts of R1,13,932 and expenditure of R91,256, leaving a profit on the season's operations of R22,676, and adding the balance from 1885 and some unclaimed dividends, the amount at credit of Profit and Loss is R23,420. An *ad interim* dividend of 5 per cent has already been declared, and it is now proposed to pay a final dividend of 2 per cent, making 7 per cent for the season, to transfer R2,000 to Reserve Fund and to carry the balance forward. The dividend last year was 9 per cent. The estimate for 1887 has been kept down to an outturn of 2,000 maunds, with a view to better quality, at an estimated local expenditure of R65,765. The area of the gardens is now 711 acres.

The report of the Directors of the Holta Tea Company shows that 121,000 lb. of tea were made against an estimate of 125,000 lb. A severe hail-storm on the 28th May destroyed not less than 30,000 lb. of tea, or the results would have been very different. The average price of tea has, however, been barely maintained; but, estimating the unsold portion of teas retained for retail trade, the average will be not less than As. 11-1¼ per lb. The local retail trade has continued to make steady progress, and is receiving the closest attention. The revenue account shows receipts of R85,217 and expenditure R68,383, resulting in a profit on the season of R16,835, and adding the balance brought forward from 1885 the amount at credit of Profit and Loss is R17,514. A dividend of 5 per cent is proposed, carrying forward R14. The heavy pruning necessitated by the hail-storm will not permit of a higher estimated crop than 20,000 lb. for 1887 at a local expenditure of R17,000. The dividend last year was 11 per cent.

The report of the Managing Agents of the Springside Tea Company shows that the outturn was 855½ maunds against 800½ maunds in 1885 and 780½ maunds in 1884. The average price realised was As. 10-8 per lb. against As. 13-8 in 1885, and As. 11-10 in 1884. The revenue during the past year was R45,634, and the expenditure R35,991, leaving a profit on the season's operations of R9,643, and adding R1,442 brought forward from 1885, the amount at credit of Profit and Loss is R11,085. An *ad-interim* dividend of 3 per cent. has already been paid, and a further dividend of 3 per cent is now recommended, carrying forward R1,005 to this year's accounts. Arrangements have been made to lease 49 acres of tea adjoining the Company's gardens. The estimates for the current year provide for an outturn of 1,000 maunds at an expenditure of R41,987, showing at an average of 10 annas per lb. a profit of £8,013. The area of the Company's gardens is 358½ acres.

The report of the Managing Agents of the Singell Tea Company shows that the outturn was 226,330 lb., against 202,970 lb. last season. The tea sold in Calcutta averaged. As. 8·81 per lb. and that in London As. 8·60 per lb. Last year the average was As. 11·01. The gross receipts were R1,24,073 and the expenditure R1,02,970, leaving a profit of R21,123, which is increased in the Profit and Loss account to R26,379, or equivalent to 4 per cent. on the capital. The dividend for 1885 was 5½ per cent. The estimates for the current season are for 2,900 to 2,950 maunds of ten-anna tea.

The report of the Managing Agents of the Teendarrea Company shows that the outturn was 74,756 lb. against 60,822 lb. in 1885. The tea sold in Calcutta realised an average of As. 7¼ per lb. and that in London As. 8¾. The average last year was As. 9¼. The gross receipts were R35,434 and the expenditure R32,950, leaving a profit of R2,484, and adding the balance from 1885, the amount of Profit and Loss is R3,022 or a little over 2 per cent. The dividend last year was 3 per cent. The estimates for 1887 are for an outturn of 1,000 maunds.

The report of the Directors of the Central Cachar Tea Company shows an outturn of 395,813 lb., which sold at As. 8-2⅛ per lb. against 296,562 lb. in 1885, which however sold at As. 10-4 per lb. The revenue account shows receipts of R2,03,785 expenditure of R1,69,085, leaving a profit on the working of R34,700, and adding the balance from 1885, the amount at credit of profit and Loss is R34,989. An *ad interim* dividend of 3 per cent has been declared, and it is proposed to carry forward the blance of R4,989. The estimates for the current year provide for an outturn of 432,000 lb. at an expenditure of R1,70,000. The estimates for the past season were for 400,000 lb. tea at an expenditure of R1,55,000. Last year the dividend was 5 per cent.

The report of the Directors of the Phœnix tea Company shows that the outturn was 327,513 lb against an estimate of 309,600 lb. and an outturn in 1885 of 279,670 lb.—being in fact the largest crop on record. The average price realised was As. 7-4 per lb. against As. 10-7 in 1885. The revenue account shows receipts of R1,51,362 and an expenditure including depreciation on machinery of R1,40,824, leaving a profit on the season of R10,538, and adding the balance brought forward from 1885, the amount at credit of Profit and Loss is R24,708, which would admit of a dividend of 4½ per cent but the report is silent on this point. The season's profit, it will be observed, is barely 2 per cent. The estimates for 1887 provide for an outturn of 330,400 lb. at a total cost of R1,35,700, or As. 6-7 per lb., so that, unless prices improve, the outlook is not very encouraging. This garden has paid no dividend now for two years.

Colonial Fruit.—At the meeting of the Royal Colonial Institute on February 8th, Mr. D. Morris, Assistant Director, Royal Gardens, Kew, read a paper on the fruit trade of this country, pointing out that the home country imports fruit from foreign countries to the extent of more than £7,500,000, much of which might as well be obtained from colonial sources. Mr. Morris then gave details at great length as to the present state of the fruit industry in the various British colonies. By means of special cool chambers for the storage of fruit on board ship the prospects of the trade in fresh tropical and subtropical fruits would be greatly improved.—*Gardeners' Chronicle.*

A Good Whitewash.—Gardeners more than most men, except builders, use whitewash—in pits, greenhouses, bothies, and the various structures found in gardens, both private and market. We give a recipe for whitewash, extracted from the pages of our contemporary, the *Irish Farm, Forest and Gardens*, of January 15:—"Get half a bushel of freshly burned

lime; slake it with boiling water: cover it during the process to keep in the steam. Strain the liquid through a fine sieve, and add to it 7 lb. of salt, previously well dissolved in warm water; 3 lb. of ground rice boiled to a thin paste and stirred in boiling hot; ½ lb of powdered Spanish whiting, and 1 lb. of clean glue which has been previously dissolved by soaking it well, and then hanging it over a slow fire in a small kettle within a large one filled with water. Add 5 gal. of hot water to the mixture. stir it well, and let it stand a few days covered from dirt. It must be put on quite hot. For this purpose it can be kept in a kettle on a portable furnace. A white-wash made after this fashion will last for years." Such a holdfast whitewash as these compounds would make might be entrusted to entomb insects and their eggs more effectually than that usually compounded from lime alone.—*Gardeners' Chronicle.*

MAURITIUS NEW INDUSTRIES.—Mr. Horne, the Director of the Public Forests and Gardens of the island, has furnished an elaborate report on the industries which it is desirable to foster in the present depressed state of the sugar trade. Mr. Horne does not doubt but that in the future, as in the past, the cultivation of the sugar-cane must be the principal occupation of the agriculturists of the island, but he points out that many other resources are open to them, and recommends, moreover, the appointment of an agricultural chemist to advise in matters connected with Sugar-cane growing and its management. Mr Horne suggests, in addition, the extended cultivation of coconut Palms, Cacao, or Chocolate, Coffee, Tea, Dates, oil-nuts, Elais, Betel-nuts, and other Palms, various cereals, starches, Indigo, Anatto, oil-seeds of various kinds Bananas, Pine-apples and other fruits, Ginger, spices, fibre-plants, Cotton, silk, indiarubber, Tobacco, dyewoods. and a variety of other plants and their products—a list which will give some idea of the resources that are open to the cultivator in the tropics if other circumstances be propitious. Cinchona does not prosper in the island.—*Gardeners' Chronicle.*

KEEPING POTATOES.—It may not be generally known that Potatoes can be kept sound and well-flavoured until next year's crop comes in. The following is the method (said to be a French one), which I closely followed with the best results:—A large boiler of water, the water being kept up to the boiling point. The potatoes when well washed (avoid breaking the skin if possible) are placed in small baskets or nets, which are then rapidly thrust under water and there retained for about four seconds. The tubers in each batch on being withdrawn are spread out on the flooring to dry; when dry they are stored away in a dry dark room as nearly air-tight as possible. The potatoes by this process will have lost all tendency to germination.—*Journal of Horticulture.*

CANKER IN FRUIT TREES.—To be brief, my opinion, and it is a firm one, is this—Gardeners, as a rule, spoil their fruit trees by too much kindness in two ways: first by digging and manuring annually; secondly, by a too frequent use of the knife, commonly called pruning, but which in many cases is simply cutting into some shape agreeable to the eye. This has more to do with canker than many will admit. The remedies used here were not in any way elaborate. Lifting and root-pruning were adopted in most cases, in others all cankered wood was cut out carefully, the latter and syringing with petroleum mixture being purely out of respect to Mr. Hiam's insect theory. Might I be allowed to "blow my horn" I would say that if given healthy trees to start with (healthy trees should have stock and scion of an equal growth without rupture or blister) a moderately firm soil with good drainage, the roots being kept to the surface by mulching, and I venture to predict that canker would be a thing of the past.—C. L. RITCHIE, *Redhills House, Belturbet, Cavan. Ireland.—Journal of Horticulture.*

THERE are hundreds of fruit trees affected with "what is known as canker," but which is really ulceration. This is caused by the punctures of insects. Some years ago I had more to do than was pleasant with a number of young Apple trees, not a dozen or two of a few varieties, but hundreds, covering many acres of ground, embracing all the most useful varieties in cultivation. The trees were planted for commercial purposes, and perhaps no better could be had. The soil, too, appeared of the best—a reddish brown, sound, yet free-working, loam, 18 inches or more deep, and naturally drained by the gravelly brash on which it rested. The proprietor of the trees felt certain they would eventually be very profitable. For a time they grew well, producing sturdy wood that was well ripened, but in the course of four or five years canker appeared on the branches. They were fine trees then, with heads 4 to 6 feet in diameter. They were pruned, the branches doctored with strong insecticides, the soil over the roots dressed with manure, but still the scourge spread. Some we dug up, root-pruned, and replanted, but the improvement resulting was only of a temporary character. It became evident a cure was impossible. The trees were ruined, and the land sold. It was purchased by a company for extracting the abundance of iron it contained. It was full of iron, which glistened in the stones excavated. The trees I had to remove, or at least the few considered worth removal. The worst cankered roots and branches were cut away, and the trees replanted in suitable soil. They were dressed with no insecticide, yet they "grew out of the canker," and have since borne many a good crop of fruit. It was an excess of iron in the soil, and not minute insects on the branches, that caused the destruction of that great and once healthy collection of young trees. It was a lesson never to be forgotten of the importance of making sure of the real condition of the soil and subsoil before planting fruit trees extensively.—[I wonder if there is much iron in the soil where canker in Cinchona was worst.—COR.] To return to the insects. There is only one way in which these, if they had "caused" the canker of the trees in their old position. did not injure those removed to the new—namely, being shaken off in transit, and I have yet to learn that fruit tree pests can be "shaken off" so easily. I have been managing and mis-managing fruit trees for nearly thirty years. and have been able to trace canker to other causes, but never satisfactorily to insects. I have seen them in cankered portions of apple tree wood under the microscope, as I have seen others marvellously like them in the decaying wood of a gate post; but as I was not able to regard the mites as the cause of the collapse of the post, I could not consistently regard them as the originators of canker in the tree. This is my response to Mr. Hiam's invitation, and his reply shall have my respectful consideration, as though at present I must dissent from his views, his researches are fully appreciated.—*Journal of Horticulture.*

EARLY BEARING COCONUTS.—Mr. W. H. Wright, with whom we communicated on the subject of our Veyangoda correspondent's letter, was good enough to call on us with the information that the trees in bearing in his garden could not have been more than a year old when he put them down three years ago. Four years is an exceptionally short time for coconuts to bear in especially in Colombo; but the late Mr. Nathaniel Cooke had a young Estate 3 or 4 miles from Chilaw, three years old, on which we saw more than one tree throwing out spathes. The trees were close to the huts of the Goiyas who were on the land, and had probably been watered in dry weather; but they proved the early age at which coconuts can be made to bear.—Local "Examiner."

THE VOLATILITY OF CAFFEINE.—Sir, I should feel indebted if you will correct the erroneous statements attributed to me in last week's issue concerning the presence of caffeine in the sublimate obtained in coffee roasting. The statement I made was that I had never failed to detect the presence of caffeine in these sublimates, thus showing that a loss took place. This you will find is diametrically opposed to the printed matter in the Journal.—WATSON WILL,—Ossory Villa, Ossory Road—*Pharmaceutical Journal.*

Correspondence.

To the Editor of the "Ceylon Observer."

COFFEE PROSPECTS IN BRAZIL.

The Scottish Trust and Loan Company of Ceylon, Limited, Ingram House, 165, Fenchurch Street, London, 2nd February 1887.

Dear Sir,—I enclose a Brazilian Coffee Circular, and you can polish up your French translating it. There is no doubt of a very short crop both in Brazil and Java, but whether Messrs. Berlas' ideas are correct or not I cannot say, but I am curious to learn your own and your planting correspondents' views as to the nature of the disease alluded to; and whether any such has been experienced in Ceylon.—Yours faithfully,

THOMAS DICKSON, *Managing Director.*

COFFEE.

(Translated for *Ceylon Observer*, from *Messrs. Berla & Co., Rio Janeiro & Santos.*)

The *Journal de Commercio* in its issue of January 8th, 1887, writes thus:—"It is generally known that a prolonged dronght and after that frosts and severe cold have done considerable damage to the coffee harvest of 1887-88. The information which we have collected with the greatest care will not allow us to estimate the coming harvest at more than 2½ to 2¾ millions of bags for Rio de Janeiro. If, later on, unforeseen circumstances oblige us to modify this estimate, we shall inform our readers.

The "*Etoile du Sud*" a commercial, financial and maritime review for the Empire of Brazil, writes on the same subject:—"The news which, so far, reaches us from all sides is unfavorable, hence we give with all reserve the information that has reached us up to the 31st December 1886. According to this the West and North of the province of San Paulo will not offer the third of last year's harvest, which was already reduced, since it will not yield, for the port of Rio only what we had foretold, namely 4 million bags.

"The region of Campinas is especially tried and in the western ports of the province where there is something to hope for, the plantations are all young.

The letters that reach us from Minas-Geraes also inform us that it is only the new coffee that gives any hope, the old, though very green and fine, has not blossomed.

"It is the same in the province of Rio Janeiro. For the sake of those of our readers who know the centres of production, we give the sources of our information; it comes from S. Simão, Cravinho, Ribeirao Preto, Campinas, Ipiabas, Miracema, Pindamonhangaba, Guaratingueta, Campo-Bello, Rezende, Rochedo, S. Joao Nepomuceno, Cataguazes, Providencia, Cantagallo, etc.

"As we said, we publish this with all reserve, for supposing it to be correct, it would allow us to estimate the coming crop at 2½ millions of bags for Rio and 1½ bags for Santos only. Our chief editor has started for the provinces of Rio and S. Paulo, and will soon verify all our information.

In the same journal is a letter from M. A. Glaziou, Director of the Imperial gardens, a botanist celebrated throughout the learned world, who for many years had occupied himself with the Brazilian flora and who anticipates preconise in this letter, a remedy for the coffee-leaf disease. The letter written in Portuguese is too long to reproduce and would interest only Brazilian planters, but it accompanied a paper on the coffee disease which, adds the "*Etoile du Sud*," seemed a serious threat when the first symptoms were noted, and which justly alarmed the centres of production in the province of Rio.

"I will give you an extract from this paper. M. Glaziou attributes the disease to a parasitic animal of the genus *Anguillula* which lodges itself in the hairy roots of the tree and there deposits its thousand of eggs. ..... It is owing to this scourge that the coffee tree fades, becomes yellow, loses its new leaves at the tips of the branches and lets its fruit drop, already dried (*atrophiés*) by the deviation of the sap which the organs of the nutrition had elaborated in the ground for the benefit of the normal life of the coffee-bush. Thus attacked, the tree soon dies, bequeathing (*léguant*) to the soil, the whole of the mischief, which caused its own ruin. From what precedes, it is evident that the mischief is really greater than is generally believed in Europe, and you know that since the publication of the *Journal de Commercio* telegraphic information has reduced the total crop 1887-88 in the two provinces of Rio and Santos to 3,500,000 bags.

"In communicating these facts to you, I have wished to put you on your guard against the manœuvres of those interested in the fall, and to enable you to base your operations on reliable documents. I hope they will be useful to you and remain.—Yours, &c., &c.,

J. B. Berla."

"*P. S.*—As we go to press, a telegram from Santos reduces that estimate to 1,250,000 bags."

PINEAPPLES IN BADULLA.

Badulla, 3rd March 1887.

Dear Sir,—In re Irvine and his theory of probabilities of fruit traffic from here by the long-waited-on railway, what think you of a pineapple weighing slightly over (eleven) 11 lb. which I had presented to me by one of our workmen last night? It was grown in a garden not far from Badulla: it smells deliciously as well as looks big. Is it out of the common?—Yours,

INQUIRER.

Unusually good we should say.—Ed.]

COCONUT AND ARECA CULTIVATION UNDER TANKS: A GOOD SUGGESTION.

March, 7th 1887.

Sir,—Referring to your article on coconut cultivation and irrigation, I must express surprise that no one has, as far as I am aware, planted coconuts under a Government tank. Mr. Akbar has to raise water from the Maha Oya at a great expense, both for plant and working, while in the other case almost the only cost would be the annual water-rate of one rupee per acre. The advantages would be:—

1st. Saving the expense of hand-watering the young plants; 2nd. Quicker arrival of the tree at maturity; 3rd. Larger crops.

I believe that under a tank in the Puttalam District there is a large quantity of land that has already been surveyed and only waits for purchasers. I presume that the purchase money for this land would as usual in such cases be payable in four annual instalments, *i. e.*, that the coconut trees would almost be in bearing before the whole of the purchase money would be paid.

The arecanut being a still more thirsty palm than the coconut, all that is said above applies with greater force to the cultivation of that tree.

E. H.

TEA FROM THE UVAH COMPANY'S ESTATES.

Glen Alpine, Badulla, 8th March 1887.

Dear Sir,—In your issue of 25th February last, under the heading "Ceylon Produce in the London Market," the following appears:—"Glen Alpine makes a great show with 25 packages orange pekoe and pekoe at 1s 5d, probably expressly prepared for the report of the Directors of the Ouvah Company and a sample of what the province may be expected to do shortly in the way of producing tea."

The small break of tea referred to was not "orange pekoe and pekoe" as described, but unassorted tea.

It was in no way "expressly prepared" but manufactured in the ordinary way, rolling being done by hand, and firing over choolas.

The Directors of this Company have never directly or indirectly, expressed a wish to have produce "expressly prepared" for any of their reports, and I cannot even guess your motive in assuming that they should have done so in this case. Kindly give this publicity in an early issue. —I am, dear sir yours faithfully,

JOHN RETTIE, *Manager.*

[For the description "orange pekoe and pekoe" —which led our paragraphist to suppose the parcel was specially prepared—not the *Observer* but Messrs. Wilson, Smithett & Co., are responsible, as Mr. Rettie can see on referring to their circular. We are very pleased to see unassorted teas from Uva ranking so high.—ED.]

CEYLON JUNGLE-FOWL REARED IN CAPTIVITY AT NUWARA ELIYA.

Galle, 11th March 1887.

DEAR SIR,—Referring to your enquiry in the *Observer* of the 8th March, I may mention that I saw atNuwara Eliya years ago in an aviary or large cage several jungle-fowl that had been hatched and reared by Mr. George Hawkins from eggs found in a nest in the jungle.

I was struck by this, because at the time the value in England was £50 per pair. I remember this was the statement of Dr. Buckland in a contribution to some periodical.

I refer, of course, to Stanleyii. There is a more beautiful species in South India, much more difficult to tame, of which I secured a male specimen; but it hurt itself in its struggles in the small cage in which I was obliged to put it whilst travelling, and died. It strongly suggested that our domestic fowls represent *two* species, one of which is our Stanleyii, if we except also the Rumkin fowls, of which a few years ago I had one specimen, and which we do not now see in domestication, though it originally existed in Ceylon, and appears to have been carried to the Cape. I have seen a large cock of this species near the Galle market, which was said to have come from the Cape; but this, perhaps, is only a variety of one of the species.—Yours truly,

N.

II.

DEAR SIR,—I am sorry that I cannot give you very recent information; but about a dozen years since there were specimens of the jungle-fowl of Ceylon living in the Zoological Gardens of London, and were in capital health, quite acclimatized. It is probable that they were the same taken home by Mr. Holdsworth, for he took every care possible to get them home alive. At that time living specimens were exceedingly rare and valuable in England.

I have kept them in an aviary with proper treatment and plenty of room. They, no doubt, would breed in confinement, as other jungle-fowl have done so.

ZOOZOO.

To another correspondent we are indebted for the following:—

"In the 'Life of Frank Buckland' there is a para. anent birds &c., in the Zoo in 1874, which runs as follows:—'Another very beautiful and interesting bird, in excellent health, is Stanley's jungle-fowl; its home is Ceylon; these birds are worth £50 per pair. A collector, who did not know their value, procured seven of them alive at Trincomalee, and had them cooked for dinner—rather an expensive feed, three-and-a-half pairs of fowl of the value of £175.' So, you see, one jungle fowl at least has gone 'home,' a fact which ought to answer your query of the other day."

A superior waterproof paper, transparent and impervious to grease, is made by saturating good paper with a liquid prepared by dissolving shellac at a moderate heat in a saturated solution of borax. Such a mixture may be colored by the addition of various aniline dyes.—*American Cultivator.*

THE CULTIVATION of the tea plant is being rapidly prosecuted in the Transcaspian Province. The chief experiments have been made on the estates of Messrs. Tchelokaieff, near Douchak, of the Brothers Barkalaieff, at New Sarakhs, and of M. Metodieff, near Zugdigi. So far those of Messrs. Barkalaieff have succeeded best. There are also tea plantations near Lake Van.—*British Trade Journal.*

AN EXAMPLE TO CEYLON.—Cannot the Ceylon Director of Public Instruction follow the example set in South Australia?:—

TREE PLANTING BY SCHOOL CHILDREN.—The Hon. Dr. Cockburn, having become impressed with the beneficial results likely to follow the planting of trees in the grounds of State schools, has caused to be issued a circular to Boards of Advice, which contains the following:—"The Minister wishes to bring under the notice of Boards of Advice the advantage of tree-planting in school grounds. The Minister has, with much satisfaction noted the efforts made by some of the Boards in this direction, and feels sure that the portion of their funds so expended could not have been better applied. With a view to promote a general interest in this subject, and as a means of imparting many useful lessons to the children, the Minister proposes to set apart a suitable day during the winter months to be devoted to the planting of trees around those schools where the ground has been properly prepared. No ordinary lessons would be given on this day, but the attention of the pupils would be directed to be benefits of forestry, and, when practicable, the trees would be planted by them under the superintendence of the teachers. The operations preliminary to planting, the process of planting, and the after growth of the trees so planted would afford an opportunity to those teachers able and willing to avail themselves of it to give a series of object lessons on forestry, which would be of lifelong value to the children and of ultimate benefit to the State."—*S. A. Register.*

SUGAR.—The Berlin *Deutsche Zucker Industrie* of the 4th instant recommends to the special attention of its readers a letter, which it publishes from a Java Sugar Planter. The writer urges that the German Government should invite representatives of all Sugar-producing countries to a Conference, for discussing a method for a general restriction of production. The Java Sugar planter is sanguine enough to believe that some practical plan would be the outcome of such a Conference, and he thinks that if the German Beet Sugar Association would take the matter in hand, the fall in prices would be arrested. Perhaps the best demonstration of the Utopian nature of such a scheme is to take a map of the world, and note in what diverse places and under what diverse conditions and interests Sugar is grown and manufactured. The false economical steps which have landed the Industry in the present crisis can never be remedied by the equally false economy of creating an artificial scarcity. There are mouths enough in the principal Beet Sugar countries to consume far more than all the so-called over-production which now weighs down the Sugar market. But the people who are willing and ready to eat it are prevented from doing so by the price being artificially raised by their governments. In this direction lies the remedy. Continental nations might enjoy the abundance which is at their doors by freeing Sugar from restrictive and prohibitory taxes; and there would then be no more talk of over-production or of impracticable and unnatural schemes for creating, in the midst of plenty, an artificial scarcity, for the fancied benefit of a few, while the many suffer.—*Produce Market's Review,*

SOME OF OUR COLONIAL WOODS.

BY ALLEN RANSOME.

Ceylon.

With the exception of satin wood, which is already well known in the English market, none of the timbers of Ceylon are likely to find a sale in this country, for although there are many varieties, which from their fine figure, and diversity of colour, are adapted for ornamental furniture and cabinet work, they are, generally speaking, of small growth, and are not found in sufficient quantities to be advantageously imported into England. Moreover, some of the larger descriptions of trees which are worked up by natives of the colony, contain a great quantity of very fine grit, which quickly blunts the tools, and would render them very costly to work at the high wages paid to our skilled workmen. For the reasons just mentioned, I do not propose to describe further such Ceylon timbers as were submitted for trial.

Victoria.

Blackwood (Acacia melanoxylon).—This wood is higly prized in the colony. Being close-grained, heavy, strong, and flexible, beautifully marked, and richly-coloured, it is much used by cabinet-makers, coach-builders, coopers, and by railway carriage and agricultural implement makers. Samples of both old and young trees were sent for trial; the former were made into joiners' specimens, the latter into casks. The figure of the old growth wood was very fine, and the surface left by the cutters all that could be desired. The casks also proved a complete success. It is stated that timber of from ten to twenty years' growth is the most suitable for coopers' work, and as the tree is readily propagated, the supply could be made to keep the pace with the demand for this purpose. Large quantities of this timber are found in Tasmania as well as Victoria. The wood, which seasons well, has already being imported into England in small quantities, and sold at the docks at from 2s. to 3s. per cubic foot, at which prices it would certainly be worth while to import it much more largely.

Blue Gum (Eucalyptus globulus).—This is a hard light-coloured timber of great strength, tenacity and durability. The tree, which is found in Tasmania as well as Victoria, attains a colossal size. By way of testing the samples sent, a sleeper was adzed and bored, and a panel planed. Both experiments proved very satisfactory, the latter especially so, as the wood was found to plane as well against the grain as with it. Being plentiful, it is largely used in the colony for beams and joists in buildings, and also for railway sleepers, piers, and bridges.

Red Gum (Eucalyptus rostrata).—This is a very hard, compact wood, of a reddish-brown colour, and is found throughout the colony, along river flats and open valleys. It is largely used for fencing posts, and is well adapted for engineering works and buildings when required to withstand a vertical pressure, although, on account of its short grain, it is not considered trustworthy to support a heavy transverse strain. It has the reputation of being the best of all the gums for railway sleepers, being almost indestructible in damp soil.

South Australia.

Blue Gum (Eucalyptus leucoxylon).—This wood, which is also found in the colony of Victoria, where it is known by the name of "iron bark," is considered one of the most valuable woods in the colony, the trees growing to a height of 100 ft., with an average diameter of 3½ ft. It possesses great strength and tenacity, and has a close and straight grain, on which account it is largely used by the coachmaker and wheelwright for shafts and spokes. It is also extensively used for railways sleepers and piles.

The experiments on this wood were in every case most satisfactory.

Western Australia.

Farrah (Eucalyptus marginata.)—This timber abounds in the south-Western portions of the colony, and the best grows on the iron-stone conglomerate hills, the finest quality being, as a rule, found at the highest elevations. Stems have been found measuring as much as 80 ft. to the first branch, with a circumstance of 32 ft., a height of 5 ft. from the ground.

Visitors to the Colonial Exhibition cannot fail to have observed a fine log of this timber, 5 ft. in diameter, which, with its polished end, of a deep claret colour, was quite a centre of attraction in the Western Australian Court.

The jarrah timber is hard, touch, and durable, and being proof against the ravages of the teredo, and white ant, it is highly esteemed for piles, dock-work, and ship-building purposes, as well as for railway sleepers and building constructions.

To retain the valuable properties of the jarrah requires a somewhat special process of seasoning; and it is above all important that it should not be felled during the rainy season.

The system of seasoning jarrah, which is found to give the best results, is as follows:—About four or five weeks before the tree is to be felled, it is girdled; thus effectually preventing any fresh sap from rising, and as the leaves continue to draw the sap out of the tree it becomes partially seasoned before it is cut down, as much as 3 lb. of water per cubic foot, being extracted from the standing log in this manner. When the leaves have withered the tree is felled, and at once removed to the saw mill, where it is converted into scantlings or boards of the sizes required, which are then stacked, and entirely covered with saw-dust until properly seasoned.

If not treated as above described, jarrah will remain imperfectly seasoned for many years, and if the heart is allowed to remain in the log, it cracks and splits to such an extent as to render it almost useless, while, on the other hand, if seasoned and converted in the above manner, it yields very sound boards and scantlings.

A portion of a jarrah pile which was taken out of Perth Bridge, over the River Swan, after having been for 35 years and 9 months between wind and water, was exhibited, and shows no sign of decay, nor trace of the ravages of the teredo; and a short piece of same wood, also exhibited, which has served as a tram-rail on the jetty at Bussleton for 42 years, shows how very little it has suffered from the constant wear of the wheels upon it during that period.

Jarrah is frequently very handsomely figured, being shaded, or mottled with dark waves and veins, and notwithstanding its density and hardness, it is easily worked by machinery. it takes a very fine polish, and might be used to advantage for shop front fittings counter-tops, and cabinet work. Its greatest uses, however, will undoubtedly be for sleepers and piles for harbour work, and as it can be imported and sold in this country for £6 per load of 50 cubic feet, it will probably, when better known, to a great extent supersede greenheart for dock gates, and other work for which the latter is now generally employed.

Karri (Eucaylptus diversicolor).—This timber also grows in great abundance in the south-west portion of Western Australia, and when sawn up and partially seasoned, so closely resembles jarrah in appearance, that anyone not conversant with both timbers, would find it difficult to tell them from one another, although in many points they differ materially. The karri grows to an enormous size, some trees being no less than 300 ft. in height by 60 ft. in circumference.

Energetic steps are now being taken to introduce both karri and jarrah largely into this country, and those interested in karri claim for it all the attributes and advantages of jarrah, and it must be admitted that it stands a great transverse strain than that wood; but while its suitability for internal work is well established, it is open to question whether it will last as long as jarrah in contact with the ground, or for marine structures.

Karri timber, in the shape of squared logs, flitches, and planks of various sizes, can now be bought at the docks at from £7 to £8 per load of 50 cubic feet.

Samples of both jarrah and karri timber, converted into straight and circular mouldings, matchboarding, spokes of wheels, and barrels are exhibited, and although both of these woods were readily worked by all the machines, the jarrah in every case left the cutters with a smoother surface than the karri.

The treatment above described for seasoning jarrah, is found advantageous in the case of karri, and it may be taken to apply to most, if not all, varieties of the eucalypti, in which our Australian colonies abound.

Tuart (*Eucalyptus gomphocephala*).—This is another valuable timber tree, found principally between the Bunbury and Busselton districts. It is of straight growth, and yields logs up to 46 ft. in length, by 24 in. to 30 in. square.

The wood is of a yellowish colour, hard, heavy, tough, strong, and of close texture, and for large scantlings, it will be found a most valuable wood, especially where great strength is needed. The tuart shrinks very little in seasoning, and does not split while undergoing that process. It also stands exposure to all vicissitudes of weather for a long time without being affected by it.

The experiments showed that this wood is well suited for wheel work, but its chief value would doubtless be for heavier purposes, such as the under framings for rolling stock, ship-building timber, piles for piers, and supports for bridges, and also as backing for armourplated ships, as no ordinary shock or rebound will cause it to split; and as it can be sold in this country at from £7 to £8 per load of 50 cubic feet, it is probable that it will frequently be used in place of teak.

Raspberry Jam Wood (*Acacia Acuminata*).—This is a dark, reddish-brown wood, close-grained, hard, and having a fragrant scent, from which it derives its name. The tree, which is small, abounds in extra tropic Western Australia; it is easily worked by machinery, and leaves the cutters with a very smooth surface; and as it takes a fine polish, and can be purchased in this country at the low price of 3s. 6d. per cubic foot, it should find a ready sale among cabinet makers and others interested in ornamental wood work.

Discussion.

Mr. D. Morris being called upon to speak on the woods of the West Indies, said Mr. Ransome had very properly confined his attention to the new woods brought forward at the Exhibition. The horse-flesh mahogany from the Bahamas was a very excellent wood, tough and enduring. The tree at the Exhibition was presented to Kew, and they were at first disinclined to take it, because they were unable to determine its botanical character; but on appealing to the Government of the Bahamas, some specimens were sent over to show that it was closely allied to the *bragiletto* wood, which was very highly esteemed in the West Indies, though it was only a small tree. The timber of British Honduras best known was mahogany, and the cedar used for cigar boxes. As in the Straits Settlements, most of the valuable timber within reach of the rivers was already cut down, but if railways were opened into the country a large quantity could be brought down. It would be useless to import any very heavy, tough kind of timber, as there would not be a sufficient demand to make it remunerative; there were excellent timbers in the West Indies which could be easily brought if the price offered would justify it. The paper was very valuable, as suggesting to Colonists what sort of timber to plant, in the manner pointed out by Sir Charles Mills. The yellow wood of the Cape, for instance, being applicable to so many purposes, should be developed; he had seen it growing in Saint Helena, and had introduced it into the West Indies, where it grew very well. The straight-grained cedar, which he had already referred to, was easily worked, and it might be grown in any part of the West Indies, at elevations of from 1,000 to 4,000 feet. In many of the Colonies there were extensive tracts, once occupied as sugar estates, which could very well now be planted with timber, such as the yellow wood or cedar; and there was no doubt the time was coming when reafforesting must occupy more attention in all the Colonies. The forests were cut down, and the land used for other purposes, and when it was exhausted by cultivation, it was often left to go to bush or jungle, when it would be much better to plant timber. In different parts of the world trees could be found adapted for any waste places, some for clay, others for rocky soil, and so on, and cedar, for instance, would grow well in a limestone soil. It often happened, too, owing to the change of climate arising from cultivation, that trees from elsewhere did better than those which were originally indigenous. Australian and Cape trees did better in the West Indies than those which originally grew there.

Mr. G. N. Hooper said, as a carriage-builder, he had not had much experience of these woods, but he left much indebted to Mr. Ransome and to the Society of Arts for initiating this discussion, which would tend more than anything else to achieve the result desired by the Colonies of finding a market for these timbers. There had been too much laxity in preparing some of the specimens sent to the Exhibition; for instance, he heard that those from Canada were collected in a short space of time, so that the necessary care could not be given to them. In 1862, being on the jury on the carriage department at the Exhibition, he had to examine woods sent for some of the Colonies, and published a list of those suitable for carriage purposes; but for twenty-five years nothing came of it. Meetings of this sort were a much more practical way of bringing the matter before manufacturers and those interested in the trade. Manufacturers required full information with regard to any new wood as to its qualities, and the proper method of seasoning, without which a good article might be unfairly condemned; they also required to know the price at which it could be delivered, and if the supply could be depended on, for it did not do to introduce a material and then have to use something else. Various new processes for seasoning timber were coming into use, and he had seen in America, at the Pullman works, a process which was then new to him, but which, he was told, was being introduced here. Large sheds were used, in which the timber was stacked and steamed for so many hours, after which it was exhausted by a fan, and hot air blown in. The result seemed very good, judging by the work turned out, which was first-rate, both in material and finish. The cold air system spoken of by Mr. Ransome seemed to succeed well, certainly, if the period of seasoning could be curtailed, it would lead to immense economy. He could bear testimony to the excellent quality of some of the woods at the Exhibition which were worked up. Those in the South African wagons were very fine, and the workmanship was also good, and he was informed that one of those wagons had been made by Kaffirs, under English superintendence. He would also draw attention to the excessive waste of timber in some of the Colonies. He had been painfully struck by it in Canada, some of the waste being accidental and some wilful, but the destruction of good material was most lamentable. Two Committees of the House of Commons discussed the question of founding schools of forestry, for up to the present young men trained for the Indian Forest Department had to go to France or Germany for instruction. Much good had already been done in India in this way, and there was no reason why equally good results should not follow in England and Scotland, and especially in the Colonies, from attention being paid to the forests. He thought there should be schools of three grades, one of the actual working men, one for the superintendents, and a high school for proprietors of forests and those who worked them commercially. It occurred to him that as all kinds of garden produce were improved by cultivation, so it must be with trees. Much of the timber in this country, oak, ash, and elm, was unsurpassed in quality, it being grown under conditions

of semi-cultivation, whereas, in a wild forest, for every fine tree there might be 50 or 100 very inferior. If partial cultivation had been so successful, more careful cultivation would be more entirely so. After all, the most important point was to encourage the growth and import of timber from our own Colonies, in preference to depending on foreign countries, as we now did so largely.

Tests of the Breaking Strains of some Colonial Wood.

Name of Wood.	Deflections at 2 cwt.	Deflections at 2 cwt. 1 qr.	Broke at
Billian, North Borneo (*a*) ...	¼″	5-16″	5 cwt. 96 lb.
Karri, Westernn Australia (*b*)	¼″	5-16″	4 cwt. 18 lb.
English Oak (*c*)	⅜″	7-16″	3 cwt. 95 lb.
Teak (*d*)	¼″	9-16″	3 cwt. 67 lb.
Yellow Deal (*e*)	⅜″	7-16″	3 cwt. 50 lb.
Russock (*f*)	⅜″	13-32″	3 cwt. 49 lb.
Mirabou (*g*)	⅜″	7-16″	3 cwt. 46 lb.
Jarrah (*g*)	½″	⅝″	3 cwt. 7 lb.
Kauri Pine (*h*)	½″	1″	2 cwt. 67½ lb.
Serayah (*i*)	⅝″	¾″	2 cwt. 55 lb.
Douglas Fir (*j*)	¾″	1″	2 cwt. 42 lb.
Best Pine (*k*)	1⅜″		2 cwt.

Remarks.—(*a*) Good breaks, 12″ long. (*b*) Very fibrous but somewhat short break. (*c*) Long fibrous break. (*d*) Short sudden break. (*e*) Good break, 6″ long. (*f*) Very fibrous break, 4″ long. (*g*) Good break, 7″ long. (*h*) Very short break. (*i*) Fibrous but somewhat short break. (*j*) Short break. (*k*) Very short.

All samples were sawn from plank, planed 1″ square. Bearings 2 ft. apart.—*Journal of the Society of Arts.*

PEPPER AND GAMBIER IN JOHORE.

The great industries of Johore are the growth of pepper and gambier, to which the Chinese cultivators direct their attention. Both these industries pay well, but the profits, as a rule, find their way back to Singapore, which had to make the advances in the first to the cultivators. Tapioca is also successfully grown, and a little tobacco. During the last few years Europeans have appeared on the scene, and have devoted their energies to growing coffee, both Arabica and Liberian, tea, cocoa, tapioca, and tobacco. The concessions granted by the Government were very liberal, and the industries went off with a big flourish of trumpets. Unfortunately all these ideas have been dissipated, and in consequence planting in Johore—like tin mining in Perak and Selangore—received a bad name. "Give a dog a bad name, and you may as well hang him;" others besides those who had essayed would have made a venture, but were less bold than the pioneers, and awaited results. Mistakes were made and heavy losses incurred, many people in China being involved to a considerable extent. Experience has now been gained, and I feel certain that money is to be made out of the European culture of both coffee (Liberian) and tea. But the errors of the past must be avoided. People are for the moment afraid of embarking anything, but when more results are obtained, say in one or two years' time, they will, I think, show that profits are to be obtained under judicious, proper, and experienced management. I have seen several gardens and estates, and the look convinced me that money can be made. Liberian coffee, on properly selected ground, may, I think, be now written down as a success. (The Sultan himself has an estate now seven years old, which must pay very handsomely, to judge by the berries one could see on the trees. His brother, Tunkoo Mahjid, also possesses an estate which pays well. If Malays, who are not as a rule given to over-exertion in matters of this sort, can obtain good results, Europeans should also be able to do so). Tea is hardly as advanced as coffee, and is still in a more or less experimental stage. Good samples have been forwarded home and been favourably received and reported on in the "Lane." An attempt is also being made to work the leaf up like a Formosa Oolong, so as to fit it for the American market, but complaint so far is that it is hardly pungent enough for the American taste, which requires something of an extraordinary strength, such as is provided by Formosa teas. A difficulty will also be experienced by the fact that tea grown tropically produces a larger leaf than that grown farther north, and consequently cannot be made to look, and roll up, so neatly as its present competitors in China and India. To reduce it to the standard demanded by the New York Produce Exchange it would have to be broken, which spoils the appearance even more. These are small difficulties, however, which further experience will probably overcome. Cocoa seems to do badly, and does not appear to be worth attention. Enormous care is required to get it over its critical stages, and when passed more or less successfully, the trees are poor, weedy, seedy, and undersized. It is not worth the attention of Europeans. Coffee (Liberian) and tea seem to be the products that will pay. The Arabica plant appears to be a failure, for though its cultivation has been pursued for some years on the slopes of Gunong Pûlai, nothing worth speaking of has yet been achieved, and the prospect for Arabica does not seem to hold out many inducements. Would-be planters had better turn their attention to Liberian, to tea or to pepper, the last of which is at present monopolised by the Chinese, but in which a good field exists. The present districts where European planting industries are carried on are Johore Bâhru, Tebrau, Batu Pahat, Pantie, Pûlai, Panggerang, and Puloh Kobob.—*London and China Express.*

PROSPECTS OF CINCHONA.

The Mannheim firm of quinine manufacturers, Messrs. Böhringer & Co., have recently issued a report on the cinchona trade of the past year, as well as a notice of the various alkaloids prepared by them from this bark. I have not succeeded in obtaining a copy of this document, and must, therefore, be content to give you the contents of a rather brief *resumé* which has appeared in a medical journal. The Messrs. Böhringer point out that, with regard to the trade in, and price of, quinine, the almost sole factor is the importation of cinchona. They believe that the consumption of quinine is steadily increasing, and is capable of enormous, extension, the chief reason for arriving at which conclusion is that this alkaloid is without a serious rival; for, although various substitutes have been brought forward from time to time, they have invariably been found to be devoid of some essential quality or too high in price. They go on to say that "the world's consumption of quinine was estimated at 3,510,000 oz. per annum in 1879, and afterwards at 4,237,000 oz., but it is probably much larger. At the conference of American wholesale druggists last year, the consumption of quinine in the United States, formerly estimated at 100,000 oz., was put down at 2,600,000 oz per annum, or about 1 oz. for every twenty-three inhabitants. The demand for quinine is certain to gradually increase in other feverstricken parts of the globe. A large outlet is particularly looked for in the rice-growing provinces of the Chinese Empire, where fever is never absent, and where quinine might advantageously supplant opium to a certain extent. Among the minor alkaloids of cinchona bark, cinchonine, cinchonidine, and quinine are still largely used in extra-European countries, although they have fallen out of use in Europe. Quinidine, the action of which most closely resembles that of quinine, occurs only in very small quantities in the present manufacturing barks, and its extraction no longer pays." I have since discussed the above statements with Dr. Paul, the cinchona analyst, and am bound to say that he does not by any means concur in the sanguine anticipations as to the future consumption of the alkaloids, nor as to its present use. In his opinion the

United States is the only country in which the consumption of the article has increased, and he freely admits that, owing to the opening up of new land in the Far West and on the banks of large rivers, where fever largely prevails, the consumption has gone up by leaps and bounds; and is now probably about three millions of ounces; but owing to improved drainage and other means of sanitation, he thinks that throughout Europe fever has declined; and added to which we must not ignore many new febrifuges which have come to the front of late years, though not permanently. Of course it is rather difficult to deal with general statements such as appear in the summary of the Mannheim report, and, until I succeed in obtaining a copy of the original document, I fear I cannot pretend to reconcile the conflicting opinions of the authorities I have quoted. Dr. Paul regards Ceylon soils, and, indeed, the generality of soils, as not capable of yielding cinchona of a high analysis for any length of time without the aid of manure, and he gave me to understand that he is now engaged in conducting a series of experiments with manured and unmanured barks for South American and other growers, the results of which I am to obtain when completed. Dr. Paul assures me there are very few barks from Ceylon which can compare in quinine analysis with the cultivated cinchonas from Bolivia, though the produce from Sir, Glenlyon, Amherst, and one or two other Ceylon estates, continues to hold a high place in public estimation. He assured me that the finest Bolivian barks seldom come on the open market, nearly all being disposed of privately to a few continental druggists, who give quite fancy prices for what they want. Another scare in the quinine market was recently created by an announcement in the *Lancet* of some very successful trials of a new substitute for the cinchona alkaloid in the form of *picrate of ammonia*, a combination of the alkaline base with *picric acid*. This has been largely tried, and the medical journal tells us that quinine is doomed! But we have heard this so frequently that I was led to institute enquiries as to the *cost* of the new fever remedy, when I learnt, as I fully expected, that the "new quinine" is nearly double the price of the old article; but then people declare that this is only a temporary dearness owing to the enormous demand for *picric acid* by the French Government, this same chemical entering into the composition of new war explosive of which large quantities are being produced in anticipation of an outbreak of hostilities.—*London Cor.* Local "Times."

DUTCH *V.* ENGLISH COLONISATION.

It is universally admitted that the two great colonising Powers of the world at the present day are Great Britain and Holland. I do not mean by this Powers whose sons and daughters go to swell the population of alien flags, as in this respect Germany can probably show an annual emigration to the United States equalling if not exceeding that of either of the Powers in question to their colonial possessions. But in acquiring and retaining colonies both the Dutch and ourselves now take the places once occupied by France and Spain, and it is curious to note the different ways in which we arrive at the one end of governing Asiatic, or other races, so as to combine fairness to them with advantage to the alien lords of the soil. Tersely put, the most striking difference to the chance visitor to Netherlands India is that, whereas British administration is almost needlessly unsympathetic with the Asiatic, and social amalgamation the exception rather than the rule, the Dutch system is that of living down to the Asiatic standard, and disclaiming, except for official purposes, that assumption of social superiority so characteristic of ourselves. In saying that our rule is unsympathetic I do not mean that it is intentionally unjust. We are apt, indeed, to push ideal justice on behalf of parties accused of crime to an extent which, to the Asiatic mind, savours of decided injustice to complainants. But though we are honestly credited with a desire to do absolute justice between man and man, it is felt that we do not make sufficient allowances for the utterly different modes of thought and reasoning which distinguish the governed from the governors. We insist, for instance, on an absolutely incomprehensible oath being taken in our courts, because British law provides it. We give prisoners the benefit of a doubt at our assizes, because a couple of Asiatic witnesses are utterly unable to detail—without serious discrepancies—certain minor matters bearing on the case. It is in vain to point out that perfect agreement on the part of Eastern witnesses, *i.e.*, the perfect agreement expected from educated European witnesses—is to the experienced magistrate or judge the surest sign of concocted testimony. And so with a vast number of other matters. We punish gambling in an open space of ground, where nobody is inconvenienced, as if it were a crime, and are powerless to deal with clubs (Chinese) started really for the express purpose. A newly arrived coolie, who has never seen a watertap before in his life, is arrested for "wasting water," while his slow mind is revolving the question how best to stop the running. We give a few months' (it may be weeks') imprisonment for crimes which, under native government, would ensure death or lengthened captivity. We are not saying that all this is wrong; we are merely putting the Asiatic point of view. Some of the matters complained of are doubtless more trifles, but they are deemed very irritating, and lend colour to the assertion that we are "unsympathetic" in our administration.

The Dutch, on the other hand, seem to us—especially as regards social matters—to go to the opposite extreme. Their municipal and conservancy rules are less harassing and the native scale of punishment is more closely followed than with us. In many cases this bears far more hardly on offenders than with us. But it is not so much the defendants as the complainants in our courts who criticise our administration, and compare it unfavourably with that of the Dutch possessions. And beyond all, the Dutch follow local customs to an extent which gains native good will, though holding out no example of a higher life. In fact in many of these matters, they leave the natives at precisely the same point as they find them. Slovenliness of dress, an absence of punctuality in small matters, a tendency to sleep much during the working hours of the day, and similar habits, proclaim to the native that the white man makes no affectation of superiority in those directions which supplied the basis of his former victories over indolent Asiatics. Another social custom—that of temporary marriages between Dutch and Javanese has immensely lowered the prestige of the former in native eyes. It is quite true that the latter regard the marriage tie from a different point of view to that held here, and that these *pro tem.* arrangements involve no local discredit to the woman. Sociologically there is much to be said for them, as worse results invariably follow the interning of large bodies of troops at Eastern stations. But the natural effect is to deprive European life of any claims to superior purity in the marriage relation, and morals are apt to run low.

On the other hand a non-interference policy of legislation as regards the Chinese population is bearing evil fruit. The secret societies throughout the Dutch territories are assuming a position which threaten danger to the Government, and the Java papers have, of late, drawn attention to the fact. It is becoming increasingly evident that unless some strong means be taken to regulate them, the eventual alternatives will be either suppression at the cost of probable bloodshed, or riots which may threaten the very existence of the Government itself. I would strongly advise the Dutch authorities to establish a "Protectorate" of Chinese and Registry of Secret Societies similar to that in force in the British Straits Settlements, and I concur with the Singapore Press in thinking that such a measure is probably the most prudent that could be taken. Even now the difficulties of bringing the societies under control would be a task of no small difficulty, but the difficulty will increase with each year if they be left unmolested. An additional argument is also found in the fact that other troubles exist at present in Java. Taxation has been pushed by the authorities to its utmost verge, and combined with bad crops and depreciated prices of produce, have produced consider

able disaffection in the native mind, which the authorities would do well to watch carefully. Not by shutting up newspapers which report any facts, but by meeting those facts where they are substantiated by properly devised measures.

Reverting to my original theme, it is not sufficient for the Dutch to say that in most instances the lower standard is sufficient for the natives, who are lazy and indolent, and do no more than they are obliged to do to obtain a subsistence. And it is to this level the Dutch bend rather than to elevate the natives not right up to the European standard, but at all events in that direction. It is what is demanded in the latter half of the nineteenth century from a nation which would maintain its *status*, and Holland may possibly be called on ere long to take considerable measures in Java to maintain its position.—*London and China Express.*

VEGETATION: NOTES OF A NATURALIST IN AUSTRALIA.

By Dr. J. E. Taylor, F. L. S., F. G. S, &c.,
Editor of "Science Gossip."

The most remarkable thing about the wild roses in Australia is that they are acquiring the same trick which the ancestors of the orange learned years ago, and transmitted to their descendants—that is to say, I found them many a time bearing flowers and fruit at the same time, and this was taking place in June and July, corresponding to December and January in England. Evidently the more equable climate has affected its habits in this respect. I observed also that its foliage was not dropped—at least, not to any remarkable degree. Is the wild rose making up its mind to become an evergreen shrub, or rather, to have descendants which shall be, like the orange tree? The degree to which plants and animals will alter their habits, and become modified in their structures, is only just being taken up by naturalists. Nowhere can this department of practical Darwinism be better studied than in Australia. I say practical, because there is a great deal, not only of knowledge, but possibly also of commercial benefit, to be gained by attending to these matters; and I hope that the scientific societies of your colonies will take up the subject. Let them put on accurate record the exact degree to which the imported animals and plants vary, as well as all the conditions under which the tendency to variation occurs. It strikes me that *variation* (due to ready *adaptation*) will be found very frequently to take place quicker than many geologists and naturalists have hitherto imagined. They have hypothetically formulated millions of years as necessary; but in most cases careful tabulation of observed facts will reveal to us how responsive many animal and vegetable organisms are to the conditions under which they leave. Look, for instance, how quickly the European deciduous trees imported to the Australia learned to adapt the time when their leaves should fall to your Australian winter. They made a muddle of it for a few years, and most of their leaves fell off during your summer; but this was because of that acquired ancestral experience we denominate *instinct*. Year by year this grew weaker in comparison with the newly-acquired *individual* experience with the new conditions of their leaves revealed to them. And now they are as well adapted to Australian seasons as if they had always been Australian trees.

Let it not be supposed that I have anything to say against the mere act of drawing upon the "Bank of Time" for due explanations of natural phenomena. Time by itself can do nothing at all—although people speak of its "tooth" growing and eating away rocks, &c. It is the number, intensity, &c., of the events which take place in time which makes the latter of value.

The Australian trees transplanted to India, California, and elsewhere have had to reverse the ancestral experience handed down to them from that of their northern representatives in the Indian botanic gardens all of their individual and infantine uncertainties in respect of the changed seasons have been duly chronicled.

Sydney and its suburbs are truly wonderful as regards the ease with which all warmth-loving forms of vegetation are induced to grow there. The old notion concerning the geographical distribution of plants seems to have been based on pretty much the same kind of principle as that of *classes* in English society—that all men "should be content with that station of life in which it had pleased Providence to place them!" It was imagined that the reason why certain animals and plants were found in certain places and not in others was that the localities where we found them were the *best* for them. This teleological conclusion barred out any further questioning.

For almost every Melbourne, Sydney, and Adelaide garden of any size (and indeed, of all size) demonstrates this. Each is a kind of "Noah's Ark," in which we find gathered together (as if, also, it was a kind of representative "Little room in Jerusalem") all the "tribes, families, and tongues" of the vegetable kingdom.

What is more to the point is—such plants are doing better than they would in their original homes. Every human colonist will recognise the importance of this fact, but the arm-chair naturalist, who is as much chocked when the wild roses out in Australia behave after the Darwinian fashion as he would be if he saw too much "white stocking" in the muddy streets of Paris, is unable to appreciate the point.

Thus, next to the oranges, lemons, and citrous (besides varieties of each) which grow hereabouts as if it were their natural home, we have loquats, bananas, peaches, plums, and a host of other fruit native to every part of the globe. They attain a larger size here than they do in their native *habitats*—a plain proof that the old teleological doctrine of their being found where it was best for them to grow is not correct. The loquat shrubs are especially numerous in all the gardens of the Sydney suburbs, and their fruit is extensively eaten—at which I was surprised, considering how abundant is the choice. Grenadines also are grown, and appear on every table dessert: but they were too much like coarse green gooseberries for me to try them more than once.

Driving out from Manly along the capitally-made and well-kept road which runs to Broken Bay, and more or less skirts the coast the entire distance, one sees much both to admire and study. Within a mile or two we get into the forest—and such a forest! I had not seen anything in all my Australian rambles to compare with it for number and variety of plants. The solemn monotony of the ubiquitous gumtrees has had to give way to the healthy survivals of even more remarkable types of the Australian flora. Banksias of several species, she-oaks or *casuarinas*, abundance of the native pine (*ferneléa*), numerous species of uncommon gumtrees, native cherrytrees (*exocarpus*), and a few solemn and stately and rare Australian palms formed the arboreal vegetation. The ground was occupied with a bush of myrtaceous plants (*melaleuca* chiefly), and thickets of ti-tree. In places it was quite ablaze with pink and scarlet *Epacrics*, and the wild indigo plant (*hardenbergia*) climbed and twisted its stems over and within the wiry bush vegetation, and flung its abounding spikes of brilliant purple flowers about with botanical recklessness. Here and there the tall, blackened stems of the grass-tree (*Xanthorea*) rose from amid the bush to the height of ten or a dozen feet, and their clusters of terminal foliage looked as if they had earned for the tree a very appropriate name.

In one of the many richly-clad dells leading to Broken Bay, I came across a sight which gladdened my eyes. It was what I may call a forest *Zamias*. They grew in numbers, and in places occupied the entire ground, in company with maiden hair and other ferns. I had never seen these plants growing in a state of nature before, and I examined them carefully. Some of them were bearing fruit, and the oldest of them had the turnip-shaped and scarred trunks (not much unlike pineapples). These remarkable plants may be regarded as intermediate in their botanical relationship between the ferns and the pines. I regarded them with unusual interest, for they are the southern survivors of a once cosmopolitan group of plants. As far back

as the beginning of the secondary period in Europe which cannot be much less than from 15 to 20 millions of years such yamias grew in England. They are among the most characteristic forms of the fossil flora of the Lias and the Oolitic formations; and in the celebrated "Dirt Bed" at Portland, in Dorsetshire, their scarred and dumpy stems (all petrified) are so common that the quarrymen call them "crow's nests." I have seen them in the fossil state, just as they grew years ago, many a time—now I was looking upon the lineal descendants of the same group in the uncleared part of an Australian forest. My readers will understand how in this way, many of the Australian plants possess an interest for the geologist second to those of no other country in the world, inasmuch as numbers of them are the survivors of a flora which has been crushed out of existence by new-comers, and whose remains are therefore only found in the fossil state in the old world.—*Australasian.*

ABOUT GREEN TEA.

To the large majority of modern English men and women green tea is probably little more than a name, calling up, it may be, vague visions of old-fashioned tea-parties and elderly ladies in turbans, and wheezy lap-dogs and card-tables. It is certainly true that in England the day of green tea, with its mysterious subdivisions, Twankay, Hyson-skin, Young Hyson, and Gunpowder, is over. Possibly it has succumbed tardily to the prejudice which in the last century denounced tea-drinking as a pernicious habit, leading inevitably to dram-drinking and to other ills more numerous and more deadly than those which Mr. Arthur Arnold attributes to tobacco. The effects of green tea upon the nerves are known to be more powerful than those of black tea, and for this reason it may have attracted to itself the bulk of the odium against tea-drinking, which has proved quite powerless to impair the influence of its sturdier brother. Another explanation for its decline in favour may be found in the fact that green tea is much more the subject of adulteration than black tea. The latter is by no means always above suspicion. We read of a horrible confection prepared out of the refuse of tea and the decayed leaves and twigs, which is pressed into moulds, and, with a little sheep or ox blood added to stiffen the mass and perhaps make it palatable, is sold as brick tea. It is some consolation to learn that this variety is chiefly consumed in Northern China and Thibet. Then, again, there is a highly-prized commodity known by the name—given to it with an admirable candour by the Chinese—of Lie-tea. This consists of the sweepings and dust of the tea warehouses, cemented together with rice-water and rolled into grains; and its peculiar mercantile value lies in a certain pliability whereby, at the will of the operator, it may be converted into either black or green tea, as may be required.

Nor are these the only ways in which the ingenuity of tea adulterators has shown itself; black lead, turmeric, and mica; leaves of the beech, elm, horse-chestnut, plane, willow, poplar, hawthorn, and sloe, with the humbler harvest of the hedgerow; all these and more have been freely spoken of in connection with black tea. But though black tea may have its foibles, green tea has long been the established and recognized medium for introducing into the human system such substances as Prussian blue, China clay, and talc. Adulteration is far more common in green than in black tea; in fact, it may almost be said that whereas adulteration in the latter case is exceptional, in the former it is universal, and that practically no samples of green tea are brought into the market which have not been artificially coloured. The blame for this (if blame there be) lies, in a great measure not with the manufacturers, but with the public. For some reason mankind, when they like green at all, have been found in all ages to like it greener than nature has made it. This being so, the tea manufacturer steps forward with his spoonful of indigo and soapstone, and supplies the deficiency. Tea which is not treated in this way would not be looked at by the dealers, who know the public and its tastes. After all, the adulteration is a very harmless one; even in the bad old days, when Prussian blue and sulphate of lime were used, it is questioned whether the minute quantity employed can have had any injurious effects upon tea-drinkers; and in the present day there is certainly nothing to be feared from the materials used in colouring the tea for the market.

The principal market for green tea is the United States. Having fallen rather into disrepute in the Old World, it has established itself in the New World, where it is largely consumed and known as "tea" simply, in contradistinction to "English breakfast tea," by which name the black teas are designated. The reason for its popularity is no doubt in a great measure due to the intercourse with Japan, where green tea alone is manufactured, and which every year sends enormous cargoes across the Pacific In the making of tea, as in everything which this curious people do, the Japanese have a way of their own. It would startle an Assam planter to see them in picking time squatting down before the trees and stripping the branches of the leaves, instead of scientifically selecting only the young undeveloped leaf, the first leaf below that, and half the second, from which would be evolved respectively "Orange Pekoe," "Pekoe," and "Souchong." Any one accustomed to the elaborate machines for "rolling" and "firing" the leaves, which are in use on European plantations, might be amused at the Japanese method, where the workers roll and squeeze and twist the leaves in their hands on a parchment stretched over a charcoal fire. Very fine teas are nevertheless manufactured by the Japanese, and in the celebrated district of Uji rumour tells of tea worth 16 dols. per pound, though it is not definitely stated whether that price has ever actually been paid for it. Moreover, in the case of teas intended for export, only so much work is done upon them as will enable them to be sent to the "tea-firing godowns" of Yokohama, where they are worked up for the market before being shipped.

As is now well known, the difference between green tea and black lies in the fact that in the former fermentation has been arrested by "firing," the colour of the leaf being in this way partially preserved and fixed with the latter by a much longer process; fermentation up to a certain point is permitted, and the leaves are not "fired" until they have become oxidized by exposure to the air. In Japan the leaves, after being picked and "withered" by a short exposure, and fired in the way described above sufficiently to stop fermentation, and in this partially cured state are sent to the European tea-merchants, by whom they are again "fired." In the "godowns" of Yokohama hundreds of women can be seen at work turning the leaves over and over and round and round in large basins built over a charcoal fire. The colouring or "painting" is also done at this period by means of a spoonful of indigo and powdered soapstone put into each basin, and thus disseminated through its contents. But in Japan tea is not grown for export only, but is the chief article of home consumption; and these domestic teas as procured in the country are probably the only samples of unadulterated green tea which Europeans are likely to meet with. They produce a beverage which is refreshing, quite harmless, and which, notwithstanding the way in which it is prepared, can after only a short residence in the country be readily distinguished from hot water. —*Lewis & Co.'s Tea Trade Circular.*

"A NEW INDUSTRY," the *Garden* says, "had just been started in East Kent—that of growing crops of lavender and peppermint for the purpose of extracting the oil and supplying it wholesale. A large breadth of land at Grove, near Canterbury, has been planted with lavender and peppermint by way of experiment, and the result has proved in every way satisfactory. It has, therefore, been determined to establish extensive works on the spot, in order to carry on the process of extracting the oil from these plants, neither of which, it is stated, has ever been cultivated before in Kent."—*Australasian.*

THE RELATION OF HEARTWOOD TO SAPWOOD.

It is a common and rather loosely held opinion that the formation of sapwood into heartwood in trees is not a gradual and concurrent process, but that it begins at a certain age in the same species invariably; modified only in a trifling degree by the differences of soil and climate as they may affect the growth of individuals. Thus the larch, for instance, must attain a certain age, no matter what the differences of soil and climate under which it is grown, before it begins to form heartwood. It matters not whether the growth be rapid or slow, heartwood must appear at or within a brief period of its arriving at a certain age, varying only in point of time in propotion to the difference of soil and climate as exerted on the individual during its period of growth. In a colloquial sense, it may be admitted there is a general foundation of accuracy in this commonly recognised opinion. No doubt the indivuals of a species, such as the larch, or any other grown in the same soil and other circumstances, on attaining a certain age will present relative proportions of heartwood to sapwood sufficiently close to establish the general conclusion. But this is merely stating in other words the fact that it takes so many years to bring the individuals of a particular species to maturity. What is really meant by the statement that heartwood begins to form at a certain age in any tree is simply that it has become visible, and presents a marketable quantity in relation to the sapwood out of which it is formed. But this is a totally different thing to what is implied by the statement, and also as to what really takes place in the growth of the tree. The formation of heartwood, like that of sapwood, begins with the birth of the tree. The exercise of the functions leading to the building up of sap and other vessels which form the structure of the newly-born plant, is the point at which the formation of sapwood and heartwood alike begin, and the processes go on concurrently season after season. Not perhaps with invariable results in even the individuals of the same species; certainly not in all species alike. Some species are slow to exhibit the same relative proportion of heartwood to sapwood that others do. And this may, as a general rule, be taken as an index of the longevity of a species; those, such as the oak, which are slow in forming heartwood being longer-lived than most of the species of coniferæ which form their heartwood more rapidly, or in other words, arrive at maturity earlier. But the process of the formation of heartwood goes on concurrently with that of sapwood from the first development of the plant from the seed, whether growth be slow or rapid, whether maturity be arrived at in a few years or after many years. Briefly, the conversion of sapwood into heartwood is accomplished by the thickening and indurating of the walls of the sap vessels, and by the deposition in them of the peculiar secrections of each species, such as gums, resins, etc., resulting from functional action, by which they eventually become filled up, and their original use as channels for the upward flow of the sap ceases. The time required to complete the process varies in different species, and even in individuals of the same species, according to circumstances already alluded to as affecting comparative rapidity of growth.—*Journal of Forestry.*

THE GROWTH OF LICORICE IN EUROPE:

ITS CULTIVATION IN SICILY.

Report by Consul Woodcock, Catania.

Licorice grows to the height of 2 or 3 feet. It bears a small yellow flower. Its leaves are pinnate. The roots grow from 6 to 20 feet in length.

The valley of the river Simeto (ancient Symæthus) in this consular district is rich in vegetation. Here not only all the cereals grow to perfection under the rude culture of the rustic Sicilian husbandman, but the wild plants with which the farmer has to contend, spring up spontaneously. Among the latter may be classed the licorice plant.

In response to a question asked of a Simento Valley farmer, if the licorice plant grew upon his farm, he replied, "God forbid, for of all wild vegetation it is the most difficult to subdue."

If any particle of the root is left in the ground, it grows and sends up shoots. It is not cultivated in this district; it grows in a wild state. In the fields where it grows are cultivated not only the various grains, such as wheat, oats, barley, &c., and vegetables, but also oranges, lemons, and the various other fruits of this climate. Of course this plant is injurious to the grains and fruits, but the thorough digging of the soil for the roots of the licorice is beneficial to the production of crops.

The agriculturist here uses the most rustic of implements. His plough is that of the old Romans, consisting of an iron point which simply scratches the soil without turning a furrow. In digging for the licorice root, the soil is thoroughly turned over, and is dug to the depth of from 1 to 3 feet.

There are two species of the licorice plant here. The one sends down a main root the depth of from 3 to 6 feet with but few lateral roots; the other does not sink so deep into the earth, but creeps beneath the surface a ta depth of from 6 inches to 2 feet.

The latter plant is most productive, and is the most highly prized.

Doubtless if the licorice plant were cultivated it would yield larger results. The people here think its culture will not pay, hence they are satisfied to collect it as produced by nature in its wild state. There is no use made of the stem except for fuel.

The licorice plant grows most luxuriantly in the valleys adjacent to streams of water. It is, however, found among the foot hills of the mountains, but here grows less luxuriantly. It requires a moist soil consisting of a clay loam. The climate must be warm, such as is adapted to the growth of oranges, lemons, and the other semi-tropical fruits. It cannot endure frosts or cold high altitudes.

The root continues to grow for four or five years, when it is considered in the best condition for gathering. The root will continue to grow for ten or twelve years longer, but it is not considered so rich in juce-yielding quality.

The crop is gathered from the same ground once in four or five years. On the average 100 pounds of the root produces 16 pounds of licorice paste. During the months of June, July, August and September, and the first part of October the root is not disturbed, for the reason that it is then in full vegetation, and for the further more important reason that the ground is dry and hard baked by the sun, and it is with much difficulty and great expense that it can then be dug.

As soon as the autumn rains set in, in sufficient quantity, to saturate the ground the root harvest commences.

During the months aforesaid the manufactories of licorice are idle, doing little or nothing in the way of manufacture. In Catania there are some seven manufactories of licorice, which employ from twenty to forty hands each, and are capable of manufacturing 750,000 pounds of the root. There is also a factory in Paterno; another in Caltogerone, and another in Terranova, in this district.

When the roots are taken from the earth they are bound in bundles, and upon the backs of mules transported from the fields to the factories. Here they lie in store for a time in a state of seasoning.

When the roots are sufficiently cured, men and women with hatchets, cut them in bits of from 3 to 6 inches in length. These are then plunged into a vat of water and thoroughly washed. They are then crushed in a mill of rude construction. It consists of two circular stones of lava. The one is in horizontal position; the other, perpendicular, rests upon it. Through the centre of the upper stone is an axle, to which is attached a mule, which revolves it slowly in a circle (cart-wheel

like) upon the lower stone. A workman with a wooden shovel is constantly employed in keeping the roots beneath the revolving stone. When the roots are sufficiently crushed they are placed with water in kettles and boiled for twenty-four hours. They are then removed from the kettles and placed beneath a screw-press, and all the juice is thoroughly squeezed out, which runs into a cistern beneath. This juice is pumped from the cistern and passed through a sieve into kettles and the boiling resumed. The sediment from the strainer is again pressed.

The contents of the boiling kettles is a second time filtered. When boiled to the proper consistency it is removed to a broad, shallow kettle over a slow fire, where workmen with spades continue to stir it until it becomes dense enough for paste. Then it is removed and placed in wooden moulds of the size they wish the cakes, or by workmen worked into little rolls or sticks. When cold and hard the cakes are wrapped in paper and boxes for export.

The little rolls or sticks of licorice are placed upon shelves to dry. When they become perfectly dry and hard they are packed in laurel leaves in boxes.

In preparing the root for market, women with knives scrape off the bark and then cut it into bits of one half inch or longer in length, as the purchaser may wish. These are then dried in the sun and placed in bags for export.

In response to my question a manufacturer answered that licorice paste may be adulterated with starch, rice flour, wheat flour, flour of the carraba (locust bean), or even wood ashes; but he expressed the opinion that the manufacturers of Catania could not be so recreant to honesty as to resort to these base methods.

The Chamber of Commerce of Catania report that in the year 1883, 440,920 pounds of the root were prepared by the manufacturers and exported to the United States, in value amounting to $11,580, and that 79,126 pounds of the root were manufactured and exported to France, in value amounting to $2,079, the total export for the year being 520,080 pounds of the root manufactured, valued at $13,659.

As shown by my records for the year 1884, there were exported to New York of licorice paste 112,746 pounds, valued at $14,965·85, and of the root 14,047 pounds, valued at $567·24; the total value of the article exported for the year being $15,533·09.—*Chemist and Druggist.*

AGRICULTURAL EXPERIMENTS AT SHIYALI.

The very interesting report by Mr. Krishnasawmy Mudaliyar, of Shiyali, recently published by the Madras Government, shows that that gentleman continues his public-spirited efforts to induce his fellow-countrymen to improve their agricultural methods. Mr. Krishnasawmy Mudaliyar engaged his labourers permanently, but the cultivation of rice on single crop land affords employment for only a portion of the year, so that it became necessary to introduce some crop which would allow of a more economical distribution of the work of men and cattle. The crop selected was sugar-cane, and, to begin with, an experiment was made with an acre and-a-half, which was planted in the season of 1882-83. A three-roller Beheea mill was purchased, and the canes, in due course, were cut and crushed. Owing to several causes, chief among which was deficient drainage, and want of experience in the process of crushing and converting into jaggery, the experiment was scarcely a success, although the rate of profit is said to have been a little above the average gained from rice cultivation. Mr. Krishnasawmy Mudaliyar accordingly determined to repeat the experiment, and this time he selected a larger area, with greater natural advantages for drainage and irrigation. The land was ploughed to a depth of five or six inches, and was manured with 175 cart-loads of farmyard manure. The planting out was completed by the middle of May, and, after a particularly fortunate season, the cutting and crushing were commenced in the following February. The average yield of stripped cane was a little over 16 tons per acre. This yield is poor compared with the 22½ tons which is the average yield for the Presidency as a whole, while in Lower Bengal, an acre of good land is said to yield 25 tons of stripped canes. The proportion of juice expressed to the cane crushed was about 50 per cent, and this again cannot be considered satisfactory as compared with the 64 per cent obtained at the Saidapet Farm. The proportion of jaggery obtained to cane crushed was 9¼ per cent which compares favourably with the Saidapet Farm results of only 8¼ per cent. The average yield for the Presidency, however, is believed to be about 10 per cent, and this is obtained with the native wooden mills, which are much inferior to the three roller iron mill used by Mr. Krishnasawmy Mudaliyar. It is only fair to mention that none of the canes of the best of the three varieties grown at Shiyali were crushed, as they were required for seed. When the results of the present season's crop are known, we may fairly expect a higher percentage of jaggery. We would suggest, as one means of improving the yield, a change in the manures used. An analysis of the juice of the sugar-cane shows that it consists very largely of potassic salts. It is obvious, therefore, that the manures to be used in sugar-cane cultivation are those which are rich in these salts. We would recommend Mr. Krishnasawmy Mudaliyar to make a few experiments with bone-dust and saltpetre. The latter might, with advantage, be used as a top-dressing. We would also commend to his notice the trench system of sugar-cane cultivation, which is followed in the West Indies, and which is the most economical both of water and manure. It has, we believe, been adopted with the best results by Messrs. Thomson and Mylne, of Beheea.

Turning now to the financial aspect of the experiment we find that the total cost of cultivation, including the subsequent manufacture of the cane into jaggery, was R136-5-3 per acre, while the value of the outturn is given as R168-12-0, leaving a net profit, after payment of all charges, of R31-11-0 per acre. We are not sure, however, whether the jaggery was actually sold for the amount stated above, or whether that is simply the value placed upon it by its owner. The point is an important one as hypothetical valuations are apt to be misleading. We observe that a few canes were sold for seed, and that the rate per acre realised from this source was R350, or more than double that obtained for jaggery, with the additional advantage of a saving of the expense of crushing and boiling. Here is indeed matter for the consideration of the political economist. The supply, compared with the demand, is practically unlimited. Yet custom, that element which so constantly disturbs economical theories in India, is stronger than the laws of supply and demand, and we find an article fetching in its raw state a price more than 100 per cent greater than that which can be obtained for it when manufactured. The profit yielded by 6 acres of sugar-cane was greater than the whole of the profit derived from 124 acres under rice crop in the same village. The season was particularly unfavourable for rice cultivation, and the conclusion to be drawn from these results is, not that rice is a worse crop than sugar-cane, but that the ryot would be well advised to cultivate more than one kind of product, and not place all his eggs in the same basket. It will frequently happen that one season is favourable for one kind of crop and unfavourable for others, and the farmer who would insure himself against risks of this nature should so distribute his capital and labour that failure in one direction will be compensated by success in another. Mr. Krishnasawmy Mudaliyar's example has already been followed to a considerable extent, and we consider that this fact affords the best possible evidence of the financial success of the experiment, for, opinions to the contrary notwithstanding, the ryot is very quick to appreciate what is likely to lead to his own advantage. The Board of Revenue, however, knows better than Mr. Krishnasawmy Mudaliyar, or the ryots who have followed his example, and it considers tha sugar-cane is quite unsuited to Tanjore. It appear

to have failed to grasp the object with which the cultivation of this crop was introduced, viz., to afford employment to men and cattle when they were not required for paddy cultivation. Sugar-cane, it is true, is a crop which takes from ten to fourteen months to mature, but it does not require labour throughout the period it is in the ground, as the Board seems to suppose. Nor should the suggestion of the Board to use copper instead of iron evaporators be accepted simply because the Coimbatore ryots consider the former superior. Messrs. Thomson and Mylne recommend pans made of sheet-iron, and their experience is quite as valuable as that of the Coimbatore ryots, and iron pans are much cheaper than those made of copper. The report concludes with a brief account of an experiment made to test the advantages of preparing rice land in the dry state, instead of on the usual puddle system. The experiment was successful, but the advantage was slight, and there are several obstacles to the general introduction of the new method.

We cannot close this notice without offering our congratulations to Mr. Krishnasawmy Mudaliyar upon the success which has attended his public spirited experiments. District Agricultural Associations rise and fall with the advent of each new Collector. They excite but little interest, and the ryots have little confidence in them. It is to gentlemen like Mr. Krishnasawmy Mudaliyar, then, that we must look for the spread of agricultural knowledge, and we wish him that success in the future which has so signally crowned his efforts in the past.—*Madras Mail.*

VEGETABLE PRODUCTS AND THEIR CULTIVATION.

If there were was one thing more than another which struck the thoughtful visitor to the Indo-Colonial Exhibition of last year, it was a feeling of surprise at the vast resources afforded by the vegetable kingdom. Even those more or less familiar with vegetable products of various kinds from different countries were compelled to own that they had never before so completely realized the immensity and diversity of the means at our command. At a time when botany, or one portion of it, is falling into disrepute, as witnessed by its recent partial exclusion from the curriculum of the Medical Schools and of the Universities, it is worth while calling to mind the fact that it is to botanists, and to systematic botanists in particular—to the very class whose labours just now are held in relatively little esteem—that we are indebted for a knowledge of these resources; not wholly, of course, but mainly so. Witness what was done for economic botany in the past by the Roxburghs, the Wallichs, the Wights, the Royles. Call to mind what has been done by the Hookers, father and son; by Lindley, by Ferdinand von Mueller, by Hanbury, by Markham, and many others that might be mentioned. Think what is being done now by Dyer, by Morris, by Watt, by Duthie: and it will be seen that the botanists of what is now called the old school have been the chief agents in bringing to light, identifying and developing, those products, the importance of which has been so forcibly brought home to us. Consider, too, for a moment on the one hand the depressed state of agriculture, and on the other the host of matters awaiting development, and for which development increased knowledge, botanical, chemical, and cultural, is demanded, and it will surely be seen that this is no time to depreciate the study of systematic botany. We cannot, however, stop to discuss this part of the question. It may aid others to do so, it may promote the extension of profitable knowledge, if we make passing allusion to some of the various conferences and lectures delivered relating to vegetable products, and which are the more or less direct outcome of the Exhibition. Reports on special subjects—such, for instance, as on fibres for textile purposes, for paper-making, and for mats, ropes, and basket-work, have appeared. During the discussions that took place many interesting facts came out on the uses of the products under notice; thus, on the question of vegetable fibres suitable for substitutes for silk, a sample of Jute was exhibited by Mr. Cross which had been subjected to a chemical process, the effect of which was to reduce the fibre to its ultimate fibrils, and at the same time to increase the durability of the substance. "This chemically treated Jute," it is stated, "was much admired, the more so as it was almost impossible to distinguish the fibre from Tasar silk."

Amongst substances suitable for paper-making the bark of Bauhinia Vahlii was considered the most hopeful, and it seems that since the Conference a number of paper makers and textile manufactures have applied for and obtained samples of the Bauhinia fibre; and it seems likely that, as a direct outcome of the recent Exhibition, this will become an important one for a number of applications.

On the subject of perfume-yielding oils, the otto of Ilang Ilang (Cananga odorata) is said to have been the first ever exhibited from India; while the tubers of Cyperus rotundus, and the oil prepared from them were pronounced quite new to Europe. The substance is said to be largely used in Upper India to perfume clothes, and an essential oil is prepared from the tubers.

Of oils suitable for candle and soap making, that from the seeds of the Mahwa (Bassia latifolia) was thought to be the most hopeful; it was stated to be harder than Cocoanut-oil—a fact, in the candle trade, that would make up for its slightly inferior quality: Messrs. Price & Co. report it to be worth £35 per ton. It is believed that is has never been, to any great extent at least, experimented with for the purpose of the European soap trade, although the people in Guzerat and other parts of India make soap largely of it. With reference to dye products, it is stated by Mr. Mu Rharji, that the Charila of the Punjaub (Parmelia Kamts-Chadalis) is employed in India to a considerable extent in calico printing, but with the object of imparting a peculiar perfume, and a very pale rose-tinge to the fabric.

Perhaps one of the most important of the Conferences was that on Tobacco and cigars. "Most of the samples of leaf exhibited were pronounced almost unsaleable from being packed too hard, having a bad smell, and being often perforated, and even broken, and indeed in many cases almost rotten, due to imperfect curing. . . . A few samples were, however, much admired, and one or two brokers were authorised by the manufacturers to take steps to procure large quantities if the price was found suitable." It was strongly urged that the leafstalks should be cut off at the base of the blade and never exported to England. It was pointed out that about 75 per cent of the Tobacco cut for the pipe is sold in the shape of shag at 3*d.* an ounce, retail. The manufacturer sells this at 3*s.* to 3*s.* 2*d.* a pound; so that, taking the average cost of Tobacco at 6*d.* and the duty at 3*s.* 6*d.*, the article is being sold at considerably below cost price. This is due to the fact that the raw Tobacco comes into manufacturer's hands in a dry state, and the profit is made on the increased weight due to moisture absorbed. A Tobacco must, to use the technical expression "drink well" to be profitable, but if the importer has to pay duty upon a heavy section of the parent stem dangling at the end of a long and heavy leafstalk it is impossible that he can make a profit. Indian native leaf is also very injuriously coated with sand and dirt, which, apart from the trouble of cleansing which this necessitates, greatly increases the duty by raising the weight. England is, one might almost say, well enough supplied with Tobacco without the aid of India, and with numerous disadvantages it is scarcely likely that India can take an important place in the supply of Tobacco unless radical improvements are effected. Tobacco on importation should contain not more than 10 per cent of water, for although the duty is raised when there is less than 10 per cent of water, it is not lowered when there is more. This is a most important consideration, and one that cannot be too forcibly urged, for, as has been stated, the profit in the Tobacco trade is due to water, but it is fatal if the importer has to pay duty on the latter.

Regarding Indian cigars, though there has been a considerable sale of Trichinopoly and Burmese cigars of late, it was stated at the Conference that they could never compete with those produced in the best cigar producing countries, and their only competition would be with those of British make. Indian cigars are described as being too hard filled and that instead of being packed in a bunch-like manner the filling of Indian cigars went through the entire length: this makes them heady and difficult to smoke. It was "urged that every consideration should be subordinated to the effect on duty, since it is the heavy import duty that kills the Indian cigar trade, and therefore light weight was of primary importance.

Since the Exhibition closed Mr. Morris, the energetic Assistant-Director of Kew, has read an elaborate paper on "Fruit as a Factor in Colonial Commerce." It occupies many closely printed columns of the *Colonies and India*. Its length, however, precludes us from reprinting a paper which is of the highest practical interest. It must suffice to say that Mr. Morris called attention to the possibilities of our colonial empire as a source of a large supply of fruit, illustrating his subject by reference to the display made in the colonial market throughout the whole duration of the Exhibition from various colonies, the most remote as well as the nearest. Mr. Morris shows how most of the fruit consumed in this country, that is not home-grown, is derived from foreign countries. The value of the fruit in round numbers is £8,000,000 sterling per annum. This might equally well be earned by our fellow-countrymen in the colonies, who are able to supply us with the fruits of tropical as well as of temperate regions. Mr. Morris alluded to the inter-colonial fruit trade, and to the supply of the American market from Jamaica and other West Indian Islands. Of Apples, the home country imports barrels to the value of £700,000 annually, the larger portion of which comes from the United States, Canada only supplying fruit to the value of £91,000 annually. Mr. Morris then passed in review the fruit-producing capabilities of the several colonies, and showed how much their resources might be increased by attention to fruit culture and exportation. Mr. Morris' labours for the development of so-called minor industries in Jamaica and elsewhere, as a means of alleviating the trade depression which prevails in some colonies are so well known and appreciated that his remaks were listened to with much attention; and as an illustration of the practical character of his address it may be mentioned that an important section of it was devoted to the proper means of packing and shipping.

Another exhaustive paper was read lately before the Society of Arts by Dr. George Watt on the "Economic Resources of India." Here, again, the importance of "minor" products was dealt with as only a botanist could deal with them. The paper is published in full in the *Journal of the Society of Arts* for February 18, to which we must refer the reader, merely saying that the greater part of the paper is taken up with the discussion of products, the European trade in which is capable of greater extension, or of products practically unknown in European commerce, but which promise to be of very considerable importance. The products are classed under the heads of foods, drugs, fibres, and oils. Dr. Watt's remarks illustrate forcibly the waste of resource that arises from imperfect appreciation and want of application of the knowledge acquired by the botanists.

Another paper of great interest in the same number of the *Journal of the Society of Arts* is that on Colonial Woods, by Mr. Ransome. Our readers will remember the magnificent samples of various kinds, many of which were alluded to in our reports at the time, and they will be glad to have in a convenient form the record of the experiments made by Mr. Ransome to test their value for different purposes. One great defect in the consideration of woods arises from their faulty or defective nomenclature. In many cases the botanical source is not known, in others the indiscriminate and most inappropriate application of such terms as Cedar, Cypress, Iron-wood, &c., is a real bar to knowledge.

We would not in any degree impute blame to the authors of the papers we have mentioned, that they did not specially treat their subjects from the point of view of cultivation; but we must point out here emphatically that this question of cultivation is all-important. Cultivation is imperative, if the resources we have alluded to are to be continuously developed; otherwise, we run the greatest risk of destroying what we ought to be propagating and developing. The necessity for cultivation is of course greater in some cases than in others—in many cases it is prospective rather than actual—but it is none the less imperative. The first thing is to know thoroughly, we mean not superficially, what our resources are, and this is work for the botanist; the next thing is to know how to develope them to the best advantage, this is the work of the cultivator, and he requires not only practical skill and experience, but extended knowledge of vegetable physiology, the conditions under which plants grow, and how they may be modified and adapted to suit our requirements. He must grow the best, and he must grow them in the best way. The merchants must do the rest.—*Gardeners' Chronicle.*

FRUIT AS A FACTOR IN COLONIAL COMMERCE.

One important result arising from the recent Colonial and Indian Exhibition is the great interest awakened in the possibilities of our Colonial Empire as a source of a large supply of fruit. In the Colonial Market attached to the Exhibition there was shown a succession of rich and rare fruits from all parts of Her Majesty's possessions. The Dominion of Canada and the West India Islands, Cape of Good Hope and Natal, the Australian Colonies and New Zealand, Fiji, Straits Settlements, Mauritius, Cyprus, and Malta, all were represented by produce in fruit, which, for diversity of form and of representative character, probably surpassed anything previously seen in these islands.

The shipments of fresh fruits from the southern hemisphere were, in many cases purely of an experimental character; but the results achieved were certainly striking and suggestive, and will doubtless lead to a trade in fruit between the Colonies and Mother Country of benefit alike to both producer and consumer. At the present time we import into this country raw and preserved fruit to a large amount annually. Most of this fruit is supplied to us by foreign countries. But within the area of the British dominions is included a fruit climate as extensive as the world itself. We have all the fruit climates of the north temperate and tropical regions, and we have also the fruit climates of the southern hemisphere, which latter can turn winter into summer, and supply fruit in abundance just at the time we want it most.

As compared with many subjects brought forward and discussed at meetings of the Royal Colonial Institute, the subject which I have the honour to bring before you to-night may seem at first sight of small importance. But having regard to the interest and charm which has always surrounded the subject of fruit, the mention of which "never fails to inspire thoughts of classic form, artistic hue, fragrant delight of palate, and healthful service to the body," and having regard also to the possible expansion and the development which the fruit trade, not only between the Mother Country and her Colonies, but also between the Colonies *inter se*, or between the Colonies and neighbouring States, is capable of attaining, there are few subjects that deserve more careful and exhaustive treatment at our hands.

The fruit trees that are now cultivated in England and yield such stores of luscious food have travelled here during the slow progress of centuries from Eastern countries; and, after improving them by scientific culture and skill, we have sent them forth like our sons, to people the orchards of the South. From these sunny lands, where our sons and daughters have

made their homes, we shall draw the future supply of fruit in quantity and quality probably exceeding that of any fruit industry that the world has ever seen.

I believe it is Leigh Hunt who has drawn attention to the beauty as well as the agreeableness of a well-arranged group of fruit. He says:—"Here are the round piled-up oranges deepening almost into red, and heavy with juice; the apple with its brown red cheek as if it had slept in the sun; the pear swelling downwards and provocative of a huge bite in the side; thronging grapes, like so many tight little bags of wine; the peach, whose handsome leathern coat strips off so finely; the pearly or ruby-like currants, heaped in light long baskets; the red little mouthfuls of strawberries, ditto; the larger purple ones of plums; cherries, whose old comparison with lips is better than anything new; mulberries dark and rich with juice, fit to grow over what Homer calls the deep black-watered fountains; the swelling pomp of melons; the rough inexorable-looking coconut, milky at heart; the elaborate elegance of walnuts; the quaint cashew-nut; almonds, figs, raisins—in short,

'Whatever Earth, all-bearing mother, yields,
Rough or smooth rind, or bearded husk or shell.'"

It will not do however, to spend time over the mere question of beauty or attractiveness in fruit. We have to-night to discuss the practical and economic aspects of fruit and to express sympathy with a young industry which will afford such a confederation of interests as will be mutually beneficial to our Colonies and ourselves.

In spite of a fairly large home industry in the cultivation of fruit, and to which we are naturally prepared to give due sympathy and support, the fact is established that we are very far from supplying our wants. Whether we wish it or not, we are compelled to import annually fruit raw and preserved, as will be shown below, to the value of nearly eight millions sterling. There is, I believe, plenty of room for an extension of fruit industries in the United Kingdom, if only in apples alone; and farmers would do well to turn their attention to the cultivation of choice fruit as a means of supplementing their returns from other produce. But, for many kinds of fruit, such as oranges, lemons, pine-apples, dates, figs, grapes, consumed during the winter months, we must depend largely upon warmer and sunnier lands; and here it is that our tropical and sub-tropical Colonies have the opportunity to come forward, each with its special production, and seek a share in what foreigners look upon as the best fruit market in the world.

I mentioned just now that the United Kingdom draws supplies of fruit from abroad to the value of nearly eight millions sterling per annum. The actual figures as given in the trade returns for 1885 are as follows:—

Kind	Value
Apples, oranges, &c.	£3,619,788
Nuts, almonds, &c.	701,910
Currants, raisins, figs, &c.	3,265,825
Total	£7,587,523

I have taken the trouble to analyse carefully these returns of imported fruits, and I find that not quite 4 per cent of such fruits are received from British Possessions. The bulk is produced and supplied to us by foreign States. The exact proportions in respect of each class of fruit will appear from the following table:—

RETURN OF FRUIT IMPORTED INTO THE UNITED KINGDOM IN 1885.

(Published by the Custom House, May, 1886.)

	From foreign countries.	From British Possessions.	Total.
Apples, raw	£623,319	£93,712	£717,031
Oranges and lemons ...	1,474,191	6,819	1,481,010
Fruit, raw (unenumerated)	1,370,743	51,004	1,421,747
Fruit, dried and preserved	488,020	70,757	558,777
Nuts, used as fruit	368,275	79,020	447,295
Almonds	254,524	91	254,615
*Currants	1,458,182	1	1,458,183
*Figs	187,895	8	187,903
*Plums, prunes, &c. ...	94,738	4	94,742
*Raisins	965,237	983	966,220
Total ...	£7,285,124	£302,399	£7,587,523

Fruits from British Possessions equal about one-twenty-fifth of the whole, or 4 per cent nearly. The second of the above tables shows very clearly what a large proportion of our imported fruit is drawn from foreign countries. The figures are:—Annual value from foreign countries, 7,285,124*l.*; from British possessions, 302,399*l.* This is a very striking and suggestive comparison, which it would be well for the Colonies to carefully weigh and consider. If they can grow and ship, at a fair price, any of the fruit which is now supplied to us by foreign States—and of this there can be little doubt—they have here a fair field for commercial enterprise, and one in which they will receive every encouragement, on the sole ground, if no other, of the bond of mutual sympathy and support which binds together every portion of the Empire. Apart from the mere increase of population, the English are, I believe, becoming more and more a fruit-eating community, and this tendency is to be encouraged, not merely as a sign of advance in civilisation and in the use of luxuries, but also as a direct incentive to more rational and healthful modes of living, and to a departure from the strongly heated foods and strong drinks which characterise our habits as northerners, and which are responsible, in some degree at least, for the prevalence amongst us of intemperance and vice. This is a phase of the subject which can only be touched upon here. All I wish to point out, in passing, is that an increase in our supply of wholesome and refreshing fruit, both at home and abroad, is one which is entirely free from objection, either on the ground of health, morals, or political expediency. A fruit such as the banana is in itself a valuable food, but others, such as the orange, grape, and pineapple, are especially valuable on account of the potash salt, the citrate, malate, and tartrate which they contain. When fish, or meat preserved with salt, forms an important article of diet, we are told the blood loses much of its potash compounds and becomes unhealthy, unless the loss is made up. Now fruits, notably those of the orange family, supply these essential salts in a most effective manner. Fruits also by their flavour and juiciness serve to stimulate a weak appetite, to give variety and lightness, no less than elegance and beauty to an otherwise solid diet, and they contribute in a palatable and refreshing form much of the water required for the daily needs of digesting and assimilation.

ENGLISH TRADE IN FOREIGN FRUIT.

It may be interesting, not only for fruit-growers in the Colonies, but for home people as well, to review the character of the different fruits that are now imported into the United Kingdom, to trace their origin, as well as the special circumstances of the countries which now hold the monopoly of supplying them. This will afford the best means for ultimately deciding which of these fruits can be grown in our colonial possessions, and what are the special points to be kept in view before a successful trade in fruit can be maintained between the Colonies and the Mother Country.

In the first table of statistics placed before you to-night, I summarised the total value of fruits imported into the United Kingdom during the year 1885. As showing the gradual but substantial development of the trade in foreign fruit which has taken place in this country, I am enabled, by the courtesy of Mr. Seldon, Chief of

* Subject to a duty of 7s. per cwt. imposed March 7, 1860, yielding a revenue (in 1885) of 513,740.

the Statistical Department of Her Majesty's Customs, to place before you a comparative statement showing the value of fruit of all kinds imported into the United Kingdom in the years 1845, 1865 and 1885 respectively:—

Kind	1845	1865	1885
Apples, oranges, lemons, &c, ...	£158,098	£1,131,183	£3,619,788
Nuts, almonds, &c.	80,682	424,866	701,910
Currants, raisins, figs, &c.	648,108	1,629,935	3,265,825
Total	£886,888	£3,185,984	£7,587,523

This table explains itself. The trade in foreign fruits in 1865 was nearly four times what it was in 1845, while that of 1885 was nearly double that of 1865. With the increased and improved steam communication which we now have with all parts of the world, the probability is that the United Kingdom will take still larger supplies of fruit from abroad, and the indications are strongly in favour of much of that fruit coming from our Australian, Canadian, and West Indian Colonies, which can supply us with fruit equal to any now seen here. I do not wish, however, to confine my remarks solely to what the Colonies can do as regards supplying the English market. Although great interest is taken, as a result of the Colonial Market at the Colonial and Indian Exhibition, in the possibility of the Colonies supplying fruit to the English market it must be remembered that this does not cover the whole of the ground. Many Colonies, such as the West Indies and British Honduras, have developed a large trade in supplying the United States with bananas, oranges, and pineapples; others, like Fiji, in supplying tropical fruits to the sister Colonies of Australia and New Zealand. Tasmania exports its surplus fruits to Victoria, while Queensland sends its bananas and pineapples to New South Wales. In the East Indies the Straits Settlements export choice fruits to India, and so on throughout our Colonial Empire interest has been awakened in the commercial value of fruits which a few years ago were little thought of. While, therefore, in my remarks this evening, attention is specially devoted to the possibilities of the Colonies supplying the English market with fresh and preserved fruits, I shall at the same time endeavour to place before you any local or intercolonial trade which may have been developed in fruit, and then give a general idea of the importance which fruit as a factor in colonial commerce is fast assuming, and the promise it holds out of still greater importance in the future.

If we turn to the second table of returns given above, we find that apples at present are imported to this country to the value of over 700,000*l.* annually. The chief supply, to the value of nearly 500,000*l.*, comes to us from the United States of America. Growers in the States have practically monopolised our market by shipments of this fruit, which, whatever its special merit of cheapness may be, is certainly, as sold here, inferior in flavour and juiciness to the best English-grown apples. Unfortunately, however, the quantity of really good English-grown apples is quite inadequate to meet the demand, and hence we are compelled to fall back on foreign supplies. The next largest supply of apples from abroad comes to us from continental countries through Belgium to the value of 100,000*l.* annually, while the Dominion of Canada occupies third rank, and supplies apples to the value of 91,000*l.* annually. As regards oranges and lemons, the quantity consumed in these islands is very large. We import annually about 500 million oranges and lemons, which is at the rate of 16 per head of population. More than one-half of this quantity, equal to a value of nearly a million sterling, comes to us from Spain. The remainder comes from Italy (Sicily), to the value of nearly half a million sterling; from Portugal and the Azores, to the value of 130,000*l.*, and from Turkey, to the value of 1,9000*l.* The value of oranges imported from Malta and all other British possessions taken together is only 7,000*l.* annually.

The large class of fruit included in the Customs Returns under "unenumerated raw fruit," is composed of grapes, French pears, apricots, plums, pineapples, melons, bananas, prickly pears, forbidden fruit, cherimoyer, pomegranate, and other sub-tropical and tropical fresh fruit from the Mediterranean region, from Madeira, the Azores, and latterly from the West Indies. France is the largest contributor under this head, to the value of nearly half a million sterling. Spain ranks second, and supplies us with such large quantities of Almeria grapes that 20,000 to 30,000 barrels of this fruit alone are sometimes disposed of in the London market in a single day. The other unenumerated raw fruits are supplied by Holland, to the value of 212,669*l.*; Belgium, to the value of 150,882*l.* Germany, to the value of 96,174*l.*; and Portugal to the value of 80,096*l.* The value contributed by all the British possessions is less than either of these—the exact amount being 51,004*l.*

Fruit, dried and preserved, 558,777*l.*, consists of dates, canned Californian fruits, preserved ginger, tamarinds, and a miscellaneous supply pretty equally distributed amongst most countries of the world. Of nuts used as fruits we import the walnut, sweet or Spanish chestnut, filbert—Smyrna, black Spanish, and Barcelona—Brazil-nut, coconut, monkey-nut, butter-nut, cashew-nut, pistachio-nut, pecan-nut, and occasionally other nuts more or less rare. It may be mentioned, in passing, that these are not true nuts in the strict acceptance of the term; some are seeds, others are fruits. France and Spain, again, supply the largest quantity of these nuts, while the West Indies and Brazil and some portions of the East Indies supply such as are specially confined to the tropics. The almond of commerce consists of the kernel of a peach like fruit, probably native of the warm and dry portions of the Levantine Mediterranean. The tree appears to flourish where the olive grows, and, although often seen in England, and found hardy in the neighbourhood of towns, it only bears in exceptional seasons, and after a mild and uninterrupted spring. Our chief supply of almonds, which reaches an aggregate quantity of 400 tons, and a value of nearly a quarter of a million sterling, comes from Italy, Spain, and Morocco. "Jordan almonds" come from Malaga in Spain, while bitter almonds come chiefly from Mogador in Morocco, which, by the way, possesses one of the most charming and equable climates in the world. The well-known fruit called grocers' currants are the produce of the Corinth vine, which is a seedless variety of common grape. This particular vine is almost exclusively cultivated in the Morea portion of the small kingdom of Greece and in the Ionian Islands. We imported in the year 1885 nearly 60,000 tons of currants, of the value of about a million and a half sterling. The vineyards of Corinth grapes are near the sea and cultivated with great care. It is somewhat remarkable that when tried elsewhere, for instance at Sicily and Malta, this usually seedless grape has developed berries so charged with seed as to be useless for commercial purposes. The imports of raisins, or dried grapes, are nearly 30,000 tons annually, of the value of nearly a million sterling. Muscatels, or the better class of stalk raisins, come from Malaga, in Spain, and are in demand all the year round, except during the short English fruit season. Valentia, or loose raisins, on the other hand, are chiefly used during the three winter months when the British housewife is concerned with plum-pudding. Figs, in a preserved state, are consumed to the extent of 6,000 tons annually, of the value of 200,000*l.* They are imported chiefly from Turkey, while the remainder comes from Greece, Portugal and Spain.

Such, in brief, is an outline of the English trade in foreign fruit. Summarising the results, we find that we procure supplies of fruit from Spain to the value of nearly two millions sterling; from Greece to the value of one and a half million sterling; from Italy and Turkey to the value of three-quarters of a million sterling each; from France, United States, and Germany (including Holland and Belgium), to the value of half a million sterling each. The total value of fruit obtained from all British possessions, as noted above, is less than from either of these, and is only a little over a quarter of a million sterling.

REVIEW OF FRUIT INDUSTRIES IN THE COLONIES.

With the exception of one or two, most of our Colonies are separated from the Mother Country by such "countless miles of ocean" that it was thought impossible to draw from them any appreciable quantity of fresh fruit. But the rapid progress made in the construction of large and swift ocean steamers has brought even our Australian Colonies within the compass of a four weeks' voyage; and, if we can draw supplies of oranges, apples, and pears from the far-off orchards of Australia and New Zealand, what cannot be done with the production of Colonies at less than one-half the distance? The voyage to New Zealand is possibly longer than to any other British Colony, and if, as has been proved to be the case, supplies of excellent fruit can be brought from thence, there is suggested to us a possible opening for a trade in fruit with our Colonial Empire at present hardly realised. The establishment of a colonial market in connection with the Colonial and Indian Exhibition was the means of bringing very forcibly before us the characteristic fruit of each Colony, and the lesson taught by it, if rightly followed up, will tend to bring an acceptable supply of food within reach of all classes in the Mother Country, while at the same time it will develop such interest in the resources of the Colonies themselves that attention will be devoted to an almost unworked field of productive industry.

As regards the exhibits of each Colony, which consisted of both fresh and preserved fruits, I may mention that a report, undertaken at the request of H. R.H. the President of the Commission, has been prepared by me, and is now in the press. This report enters as fully into details as was practicable in the limited space at my command. I have briefly summarised under each Colony its capabilities in the way of fruit, and mentioned what appeared to be the most successful of its exhibits. I will not now, therefore, travel over the ground of this report; but, with your permission, shall endeavour to supplement it by such further information as I have gathered during this inquiry, which to me has been throughout of an interesting character.

CANADA.

Following the order in which the Colonies were placed in the Official Catalogue of the Colonial and Indian Exhibition, we begin with the Dominion of Canada, which, as was naturally expected, made a magnificent show of fruit, and there is little doubt the Dominion is destined to become, in the near future, a very formidable rival to the United States in the supply of apples to the English market. The Canadian fruit possesses high colour and delicate flavour equal to the best American apples, and it is merely a question of time whether Canadian apples are not as largely consumed in Europe as American apples.

At present American apples are imported to the value of 500,000*l*, while the value of Canadian apples amounts only to 91,000*l*. It would be unfair to suppose that Canada can produce apples only. In its clear, bright, and stimulating climate it can grow almost any fruit of temperate climates, but at present, through its horticultural societies and other organisations, it wisely devotes chief attention to the improved cultivation of the apple, and to the introduction of new varieties or the acclimatisation of old ones. The Province of Ontario is the most important centre for apple growing, and in good years it is estimated that this one Province alone will produce over a million barrels.

AUSTRALASIA.

The Australian Colonies, although much further off than Canada, possess one great advantage arising from their position in the Southern Hemisphere. Their winter is our summer, and our winter is their summer. The Australian fruits will, therefore, come into the English market at a time when few other fruits are available. As a writer recently remarked: "In May and early June housekeepers are sorely tried to furnish the last course. English apples are few and shrivelled. Those of American growth are spent. Pears are not on hire. The time of strawberries has not come, except for the 'swaggering' classes. Grapes are in their worst season. The nuts of autumn are dry and musty, and oranges are over. It is at this season that we are to be blessed with the noble and beautiful growth of Australia, of which as yet only the timid firstlings have appeared in the fruit market of the Colonial Exhibition."

Taking a rapid review of the Australian Colonies, it might be mentioned that New South Wales and South Australia are destined to produce oranges equal to any in the English market, and in this one fruit alone they possess an opening of great value. Australian oranges are expected to arrive in Europe in June, July, and August, a time when no oranges are found in the Northern Hemisphere. Shipments of this fruit at such a time must naturally cause a change in the characteristics of the English fruit trade, but for fine fruit carefully packed and well placed, there is little doubt it would soon establish itself as a recognised article of trade, and prove adequately remunerative.

Victoria produces excellent apples, apricots, cherries, figs, melons, plums, and raspberries. Fig drying is being taken up as a local industry, and it is to be hoped that some portion at least of the 200,000*l*. we pay at present for our supply of foreign figs will be attracted by our brethren in this Colony. The canned fruit of Victoria has been pronounced in the City to be equal to the best Californian fruit now so largely used in Europe; and, after carefully testing them, one firm has expressed the opinion that "there will doubtless be a large trade done between the Mother Country and the dependency of Victoria."

Each Australian Colony by virtue of its geographical position, its climate, and soil, and the tastes and habits of its people, is enabled to take up its own special branch of fruit industry. South Australia produces grapes and apples, which can be sent here in large quantities; but if all its pears are equal to those which appeared in the Colonial Market, and they can be supplied in large quantities, this Colony will have a distinctive fruit of great value in northern markets.

The weak points in the shipments of last year are, I believe, well recognised at Adelaide, and will no doubt be carefully avoided in the future. I am glad to notice that the Royal Agricultural and Horticultural Society of South Australia is taking action with the view of securing a cool chamber capable of taking 10 tons of fruit by each fortnightly steamer from February 1 to April 30 of the current year. The first consignment of South Australian fruit of this season is probably, therefore, now on its way home; and I feel sure that the members of this Institute, no less than English people generally, wish every success to an enterprise which, although primarily in the interest of trade, tends at the same time to bind us closer together as an Empire in the paths of progress and in mutual well-being.

Queensland is capable of producing rich stores of both temperate and tropical fruits, and there is a local trade with Sydney in bananas and other fruit which no doubt will lead to much greater development. Pineapples of good quality and large size are grown in the Colony, and Mr. Theodore Wright speaks of fruit weighing from twelve to thirty pounds in weight grown at Mackay, on the Pioneer River. While sub-tropical Queensland, with a fine dry stimulating climate, granted only a sufficiency of water, possesses excellent capabilities for producing fruit with good keeping qualities, equal to the best Californian fruit, it is evident that tropical Queensland must eventually become the seat of a large fruit industry, provided a good outlet is found for it.

Western Australia, with an equally dry and stimulating climate, has produced raisins and currants of excellent quality. As regards the latter, it has been believed that the Corinth vine has not proved a success anywhere except in the Morea and Ionian Islands. What may have happened elsewhere I cannot say, but the currants shown at the Colonial and Indian Exhibition from West Australia, South Australia, and the Cape of Good Hope were seedless, and, moreover, were of such good quality that

they could hold their own with any at present imported into this country.

Practically an undeveloped country, Western Australia cannot be expected to show such an advance in matters horticultural as her sister Colonies; but what she has done already is good earnest of what she is capable of doing, and it is evident that choice and delicious fruits are to be numbered amongst the stores of her prosperous future.

Tasmania, unfortunately, was not represented at the Colonial and Indian Exhibition, and, in view of her capabilities as a fruit country, this was a distinct loss both to herself and to those who feel an interest in colonial industries. As regards the importance and value of fruit culture in Tasmania, I cannot do better than quote a few words from the admirable Paper read before the Royal Colonial Institute by Chief Justice Sir William Dobson on May 11 last. He said:—"As might be expected from our climate, the cultivation of fruit forms a staple industry. I cannot demonstrate this more clearly than by telling you that, besides what we consume at home—and we are large fruit consumers—we send away 85,000*l.* worth to the neighbouring Colonies in an unmanufactured state, and we manufacture four and a half million pounds of jam, or more than 2,000 tons, of the value of 86,000*l.*, of which we export 72,000*l.* worth. We also export what is called pulp to the value of 13,000*l.* This is fruit of soft kinds that would not stand a voyage, which is boiled down and put into casks and shipped, for the most part, to our neighbour, Victoria, who imposes a heavy duty on our jam, but imposes a comparatively trivial duty on the pulp, which her jam manufacturers convert into Victoria jam. Our manufactories employ about 300 hands, of whom one-third are women. In the valleys on the slopes of Mount Wellington, and in other moist and sheltered spots, the little settler has his raspberry plot and his black currant plot, for these are the most favoured fruits for jam making. Once planted, they need little attention, and the only labour required is in picking and carrying to market."

Fresh fruit from New Zealand arrived last summer in 30 consignments, and English people were able to realise what the apples of the Antipodes were like, by the beautiful fruit which Sir Julius Von Haast displayed for some weeks amongst the other numerous attractions of the New Zealand Court. The changes of temperature and the daily variations must be considerable in a country like New Zealand, and these are factors which must be well weighed by horticulturists. But it is evident that apples, quinces, and fruits of this character can be very successfully grown there. Moreover, they possess such keeping qualities that fruit stood the long voyage without special storage, and remained good for several weeks afterwards. A writer on fruit culture in New Zealand remarks that since New Zealand fruit reaches Europe when there is little or none in the market it must realise good prices. He adds: "So long as the grower could get 2½*d.* per lb. for his fruit it would pay well."

FIJI.

Although one of the latest additions to our Colonial Empire, the Fiji Islands are striving their utmost to take a worthy place. They possess in their late Administrator, and now Lieut-Governor, the Hon. J. B. Thurston, C. M. G., an officer of great zeal and energy, and one who is not only thoroughly conversant with local circumstances, but who sympathises with any well-directed efforts to develop the resources of these fertile islands. Sydney, in New South Wales, is only seven and a half days distant from Viti Levu, while Auckland, in New Zealand, is only four and a half days distant. Hence it is not surprising that a trade in tropical fruit, begun in 1877, has now assumed considerable importance. In 1885 the value of bananas and pineapples exported from the Fiji Islands reached 24,000*l.* A fruit-preserving company has been established, and the canned Fiji fruits exhibited at the Colonial and Indian Exhibition were attractive and good.

SOUTH AFRICA.

We come now to the South African Colonies, and, if time permitted, I would be glad to enter fully into the merits of the excellent collections which were sent last year from the Cape of Good Hope and Natal. The Cape of Good Hope is so engrossed with diamonds that it has little time for rural industries; but if it seriously devoted attention to the subject of fruit, it could supply European markets with raisins and currants, and with fresh grapes in almost unlimited quantities.

The collections of Natal fruits were most varied and interesting. Many were essentially tropical, others were purely temperate fruits. The varieties indicated a wide range of climatic conditions, while the quality of all the fruits was exceptionally good. The yellow peach is so abundant in the Colony that it is often used for feeding pigs. If dried and exported in large quantities, Natal peaches should prove a valuable addition to the food supply of this country. Fresh fruit from Natal could be placed in the English market during the months of March, April, and May. These are probably the months we most require them. As indicating the interest taken just now in colonial fruits, a correspondent at Pietermaritzburg suggests that, "if Australia can send her oranges over a far greater distance of tropical sea to arrive in good condition in the London market, there is no reason why the Cape should not also engage in the trade, and find it even more profitable."

EASTERN TROPICS.

In the Eastern Tropics we have the Empire of India, Ceylon, Mauritius, and the Straits Settlements. As regards India and Ceylon, it is doubtful whether we can, at present at least, obtain any fresh fruits of a suitable character. In fact, they have very few fruits which they can spare in large quantities capable of bearing a long sea voyage. They might, however, supply some preserved fruits. At the Colonial and Indian Exhibition there was shown, from India, a small dried apricot (*Prunus armenica*, L.), an important article of food in the Punjaub Himalayas, and in the North-West Provinces, which deserve attention as a probable source of an import trade for the English market. This fruit is known in India as the mish-mush, or "Moon of the Faithful." Dr. Watt remarks that it is largely eaten by all classes, fresh or dried, but chiefly fresh, and sometimes in preserve by Europeans. Sometimes the apricots are pressed together and rolled out into thin sheets or "moons" two or three feet in diameter, like a blacksmith's apron. From Afghanistan large quantities of the dried fruit are imported into India, and distributed by trade far into the plains of Bengal.

Mauritius produces most tropical fruits, such as pineapples, bananas, litchis, guavas. The natural outlet for Mauritian fresh fruit would be during the winter months to the Cape and South Australia. Preserved and canned fruit might be prepared cheaply and abundantly, and for these there are markets all over the world. Although no serious attempts have hitherto been made to develop the fruit resources of Mauritius, there is no doubt an external trade in fruit might be established, which would do something to alleviate the present depressed condition in which it is placed by the fall in sugar.

The Straits Settlements yield perhaps the richest stores of tropical fruits of any of our dependencies. The mangosteen, durian mango, pineapple, papaw, duku, attap, loquat, plessan, rambustin, pumelo, bananas, blimbing, guava cherimelia, were all shown at the Indian and Colonial Exhibition in a preserved state, and, with other better-known tropical fruit, they formed one of the most interesting collections of East Indian fruits seen in this country. Singapore pineapples are largely exported preserved whole in syrup, and the enterprise shown by several firms in popularising this article will no doubt lead to a considerable trade being established in this country.

WEST INDIES.

From the Eastern Tropics, I would ask to go with me to the Western Tropics, and especially to those beautiful islands dotted over the Caribbean sea. While

the West has given to the East the pineapple, the banana, and the guava, it has received in return the orange, lime, shaddock, and mango, and its fertile soils and sunny climates have greatly improved them. The Bahamas were the first of the West India islands to give attention to the cultivation and export of fruit. The first cargo of pineapples was shipped to England in 1842. In 1855 the shipments consisted of 16,469 dozens, of the value of 3,415*l.*; in 1864, of 61,500 dozens, of the value of 8,516*l.* To keep the fruit for a voyage of almost twenty-eight days by sailing vessels, the whole plant was taken up and shipped. This was rather an expensive system, as the planters lost the suckers, or shoots, for replenishing their fields, and the quantity taken at one shipment was necessarily small.

Of late years, the bulk of the Bahamas fruit is shipped to the United States, and in 1885 the statistics as regards pineapples stood as follows:—

	Dozen	Value
To Great Britain	31,900	£4,785
To United States	424,065	46,062

The total value of the fruit exports of the Bahamas averages about 54,000*l.* annually.

These consist of oranges, shaddocks, avocado pears, bananas, coconuts, and sapodillas. Canned or preserved pineapples are also exported, but it would appear that much more might be done in this direction. From a letter received recently from a correspondent at the Bahamas, I learn that "Eluthera and Long Island have done fairly well this year, selling their pines at 2*s.* per dozen. But Cat Island, with a population of 5,000, nearly all engaged in pine growing, has done very badly. The people had plenty of pines, but could not sell them. When I was there in the beginning of August there were several thousand dozens still in the fields, and the people would gladly have sold them at 4½*d.* or 6*d.* per dozen—a price which would barely cover their carriage to the beach. But no sale could be made even at that price. The prospects of the orange crop are good, but so long as the fruit is sent to market *in bulk* in the holds of schooners, good prices cannot be obtained, and many cargoes are damaged and lost." From another source I learn "that fully one-third of the fruit crop of the Bahamas is lost through want of care in properly packing and shipping the fruit."

The other West India islands, with the exception of Jamaica, of which I shall speak presently, have not been able to establish an appreciable fruit industry. The difficulty is not in growing fruit, but in securing regular and suitable means of transit. The inter-colonial steamers of the Royal Mail Company cannot be utilised, as they have a purely local itinerary. What are wanted are rapid steamers connecting directly with the United States or Europe, and provided with suitable accommodation for carrying fruit. The fruit trade of the several islands at present is as follows:—Trinidad, chiefly coconuts, 43,000*l.*; Tobago, chiefly coconuts, 2,600*l.*; Grenada, 390*l.*; St. Lucia, 404*l.*; Barbados, chiefly tamarinds, 1,305*l.*; Dominica; 3,444*l.*; Montserrat, limes and lime-juice, 11,000*l.*, St. Kitt's and Nevis, 1,078*l.*; Antigua, chiefly pineapples, 156*l.*

Although Jamaica embarked in a fruit industry much later than most of the others, it now occupies the first place as a fruit exporting country. The value of its shipments is not far short of 250,000*l.*; annually, which go principally to the United States. The chief fruit exported is the banana, which in 1885 reached a value of 130,000*l.* Next comes the orange, to the value of 34,000*l.* Other fruits exported are pineapples, limes, mangoes, coconuts, shaddocks, and tamarinds. The Jamaica bananas are cultivated by both Europeans and negroes, and, according to the season, sell locally for 7*l.* 10*s.* to 10*l* per 100 bunches. Small bunches, less than "seven hands," are not saleable. The bulk of the orange crop is yielded by self-sown trees, growing in pastures or native gardens. When the fruit is carefully picked by hand, graded according to size and degree of ripeness and well packed, it finds a ready market. The demand for Jamaica fruit is necessarily affected by the Florida crop, but latterly the trade is somewhat brisk, and good prices are realised. Even with the trees at present existing, if attention were seriously given to the subject, the export of oranges from Jamaica might be increased fourfold. It reflects somewhat unfavourably on the West India islands, which can grow this fruit so successfully and readily, that oranges from Sicily are still being imported into New York and New Orleans, and that, after crossing the Atlantic, they are placed in the market in a better and more acceptable condition for buyers than West Indian fruit. This is a matter which, with a little more experience and knowledge on the part of growers, might be greatly changed. With suitable storage in cool chambers, Jamaica could supply the English market with pineapples, oranges, cherimoyer, water-lemon, sweet-cup tree-tomato, rose-apple, limes, mangoes, and many others. As regards mangoes, thousands of tons are produced annually, and I have elesewere suggested that, after exporting the best in a green state, using others for chutneys, pickles, and preserves, the rest might be utilised in the production of a useful spirit, or in the manufacture of glucose.

The rapid rise of the fruit trade in Jamaica is due to the enterprising counsels of the late Governor, Sir Anthony Musgrave, who secured regular and rapid communication with the States and subsidised steamers, and connected the fruit ports by telegraph and extended the railways. Much is still needed in the way of roads for opening up fruit districts, and for bringing them into closer communication with the coast. By such means, the fruit would be cheaply and expeditiously brought to the port of shipment, and the small settlers encouraged to embark in fruit culture.

What Sir Anthony Musgrave did for Jamaica, Sir Frederick Barlee appears to have done for British Honduras. The establishment of a regular mail service between Belize and New Orleans was the first step in making British Honduras a fruit exporting Colony. In 1880, it exported no fruit except coconuts. Last year it exported fruits, consisting of bananas, limes, mangoes, oranges, avocado pears, pineapples, and tamarinds, to the value of 14,464*l.*

A very interesting attempt was made last year to import fresh tropical fruit from British Guiana by Messrs. Scrutton & Sons, who had one of their steamers fitted with a cool chamber specially for the purpose. Bananas and many delicate fruits were received from the West Indies during the course of the Exhibition in excellent condition. It is to be hoped that all connected with this interesting experiment will resolve to make it a permanent feature in West Indian trade, and induce the English to become as large consumers of bananas and other tropical fruit as the people in the States.

Before closing my remarks upon the West Indian fruit trade, I would mention that the growing of fruit for export has initiated quite a new departure in the methods of local trade. It is true that fruit-growing in itself is somewhat uncertain, and apt to suffer sudden reverses, but the fact remains that it enables some thousands of small growers to place land under cultivation and to utilise what otherwise would be simply wasted.

Again, a trade in fruit has introduced a system of cash payments on the spot, with the result that the cultivator is placed at once in possession of means for continuing planting operations and extending them to the fullest extent. As a case in point I might mention that the fruit trade in Jamaica is the means of circulating nearly 250,000*l.* annually, amongst all classes of the community, and this large sum is immediately available, without the vexatious delays formerly experienced in establishing other and more permanent industries. Bananas, for instance, come into bearing in about fifteen or eighteen months from the time of planting, and as the return is usually from 10*l.* to 20*l.* per acre, the planter is able, with a comparatively small capital, to establish his land in cocoa, coffee, nutmegs, limes, oranges, and coconuts, which when

the bananas are exhausted, will remain a permanent source of revenue. It is on this account that I look upon the fruit trade of the West India islands, as indeed many other small industries, as calculated in the aggregate to build up, little by little, and improve condition for the people of these islands—a condition which ultimately will enable them to meet much more successfully than they otherwise would the depression under which they are now suffering.

PRESERVED FRUIT.

In my previous remarks I have not touched particularly on preserved fruits, and on such special preparations as jams, jellies, and candied fruits. Where fresh fruit is abundant, local circumstances will determine, whether that fruit can best be utilised in a fresh or preserved state. For Colonies beyond reach of a convenient market for fresh fruit, and where sugar of good quality is obtainable at a moderate price, it would, no doubt, as at Singapore, be advisable to preserve such fruits in syrup, and export them in that state. Taking the preserved fruits at the Colonial and Indian Exhibition as fair samples of productions in this class, the general impression produced was not satisfactory. Pineapples from Singapore and Bahamas were an exception, and appeared to be fairly appreciated. But many other preserved fruits were not presented in an attractive and satisfactory manner, and, compared with the general character of preserved fruits received in this country from California, they were decidedly inferior. This arose from various causes, but it is only necessary to mention here that the syrup was generally too thick, the quality of sugar used too low, and the fruit generally was put up when too ripe, and consequently the flavour was lost. Those who undertake to preserve fruits should obtain a tin of Californian Bartlett pears, and carefully study the nature of the syrup and the excellent manner in which both the flavour and consistency of the fruit are preserved intact. I mention this as the highest standard I know of what a canned fruit should be. If tropical fruit could be preserved with such success as the Californian fruit I have just mentioned, it would command relatively high prices. Such preparations as guava jelly and lovi-lovi jelly (the latter from the fruit of *Flacourtia inermis*) would become recognised articles of commerce, if prepared by experienced and skilled persons.

As regards jams, there is practically no market for those from the Colonies. The abundance of English and continental fruit suitable for jam-making, and the low price of sugar, enable English-made jams to be the cheapest, and possibly the best, of any.

There is, on the other hand, a good opening for attractive and tastefully-prepared candied and crystallised fruits, which come to us now chiefly from France. Of candied limes, oranges, kumquat, rose-apple, loquat, shaddock, coconut, guava, mango, skilfully prepared, and with the characteristic flavour of each duly preserved, there would arise a moderate demand; but, as they would enter into competition with candied fruits now so successfully prepared by the French, this is a fine art department in fruit industry in which the Colonies can only attain success when they have devoted considerable attention to the subject.

There is no reason, however, why they should not at once enter upon preserving their best fruits in syrup, and as I have pointed out above, their chief competitor in this branch is California, which has established a reputation not easily to be surpassed.

Bananas would appear not to be palatable preserved in syrup, on account of a slight astringency which is developed in them, and, in competition with figs, they are practically unsaleable in a dried state. Hence this fruit at present is only marketable in a fresh state. A proposal has been made to import bananas in pulp for the purpose of making champagne. But if fruit pulp, that is, fruit reduced by partial boiling and preserved with salicylic or boracic acid were to become a commercial article, I believe this plan would utilise an enormous quantity of fruit which is now wasted for want of a proper outlet. Fruit pulp, if imported in large casks, might be very successfully treated in this country, where sugar is so cheap; and the conserve made from it could easily be put up in neat and attractive bottles and sold at a moderate price. In the Colonies, strange to say, sugar is much dearer than in England, even in those that grow sugar. Refined sugar has to be imported, and generally costs, for instance in Jamaica, as much as 5*d.* to 7*d.* per lb. Again, attractive tins or well stoppered bottels would be fully one-third more than in England: hence, it is almost impossible for the Colonies to compete with the Mother Country in any preparations of fruit preserved with sugar. With fruit pulp simply packed in casks the case is different: and I commend the subject both to fruit-growers in the Colonies and to merchants at home in search of a new industry. Some hundreds of tons of bananas, where the bunches are too small for export, and several thousand tons of mango pulp could be exported from Jamaica, to say nothing of guavas, pineapples, red plums (Spoodias), star-apples and naseberries.

PACKING AND SHIPPING FRESH FRUIT.

Before closing my Paper it might be useful to growers of fruit in the Colonies to say a few words as regards the various methods adopted for selecting and preparing fresh fruit for export purposes. When fruit is produced in large quantities, and it possesses a distinct value in foreign markets, it is a matter which concerns the Government, no less than the people generally, to take every step that is practicable and suitable to place that fruit in such a market in the best possible condition. Great care is taken generally in the preparation of crops of sugar, coffee, cacao, pimento, tobacco, ginger, and other produce; but the careful and scientific treatment of fruit, although capable of yielding returns proportionately quite as large as many of these, is practically overlooked, and consequently the loss entailed upon both growers and shippers is enormous. The fruit growers of America, France, Spain, and Italy, who at present command the English market, have given for many years past the most careful attention to the subject, and the result is seen in the large sums which they realise for their shipments and the general prosperity of their industries. It is clearly not enough to grow good fruits, but it is necessary also to study carefully how and when they should be packed, under what conditions they should be shipped, and the special requirements of buyers in the markets to which they are consigned. Those who study these matters most thoroughly and effectually must reap their reward in good prices, and their marks would become in time so well known and trusted as to be firmly established. It would be impossible here to enter into practical details respecting the treatment of each class of fruit. As regards apples: given fruit of attractive appearance and good quality, they might, as in America and Canada, be racked in barrels without paper, but so arranged as to lie in tiers and keep firmly together to prevent rubbing or bruising. Apples from Australia and New Zealand of the more delicate sorts would be better wrapped in paper, and with the layers divided by thin strips of cardboard or wood. The best New Zealand apples arrived last year packed in chaff, but it is a question whether this is really necessary. Pears might be wrapped in paper and packed in two or three layers in light boxes.

Oranges for the American market are preferred hand-picked and with a portion of the stem attached, which, it is believed, ensures better keeping qualities, and they are carefully wrapped in soft tissue paper and packed in boxes or barrels. For the English market "stem-cut" oranges are not specially sought; but the plan might very well be tried by Australian growers, to test whether such oranges arrive in better condition than those without stem.

Pineapples will keep very well for ten or twelve days without special stowage. The best fruit received in England from the Azores and Madeira is packed one or two in a compartment in a light box, or in flat cases with about ten or a dozen fruits. Early in the season they fetch as high as 5*s* to 8*s*. each, but sometimes

only 2*s.* 6*d.* each. Pineapples for the American market from the West Indies are packed in barrels, and sometimes in bulk, but the loss, which in both cases is great, might be saved by packing in light boxes or cold storage. Grapes are largely received in England during the winter months, and they come chiefly from Spain, packed in corkdust, in barrels or half-barrels. They fetch from 10*s.* to 20*s.* per barrel. Growers in Australia and the Cape would do well to ship only the best fruit, known to keep well, and possibly they would find paper the best substitute for cork-dust. Chaff packing or ordinary sawdust would appear not to answer.

So far, I have said nothing respecting special storage for fruit during transit. This is a subject which has already received some attention, but it is evident that special chambers in fast-going steamers will become a necessity, if trade in fresh fruit between the Colonies and the Mother Country is to be thoroughly successful. The question of storing fruit to keep during long voyages has often been discussed, and numerous experiments have been tried, with results more or less satisfactory. In the first place, it is absolutely necessary that all perishable fruits intended to be shipped should be gathered before they are ripe. The exact condition when export fruit should be gathered requires some experience; but it is understood in the West Indian expression of "full fruit." It is necessary the fruit should have attained its maturity as regards size, but not in the elaboration of the juices, which gives it its ultimate sweet flavour. What is sought by a special chamber on board ship is to retard the ripening process of the fruit as much as possible without affecting its flavour —in fact, to keep the active principles of life in the fruit in such a state of suspense that it will travel long distances before the ripening process is accomplished. The question is: How can this be done most cheaply and efficaciously? In some experiments tried on board the S.S. "Ivanhoe," trading between Jamaica and New York, a chamber was fitted to contain nothing but nitrogen gas. It was believed that if, deprived altogether of oxygen, the fruit could not ripen, or, in other words, it could not undergo the slow combustion which is a necessary concomitant to the process of ripening. This experiment, although interesting in itself, failed, because its promoters overlooked a well-known fact in vegetable physiology. They found that while the outer-portion of the fruit by means of nitrogen gas was kept from ripening, the inner cellular portions set up a state of incipient fermentation, which rendered the fruit at the end of the voyage absolutely worthless. Of other experiments I need not speak here. So far as we can gather at present, it would appear that a cool and well-ventilated chamber, in which the temperature is kept uniformly low, and in which the air is fairly dry, is the most efficacious of any for the transport of perishable fruits.

Probably the first successful attempt to import fresh tropical fruit in a specially prepared or cool chamber was made by Messrs. Scrutton, Sons & Co., of Gracechurch Street, in the S.S. "Nonpareil," in May 1886. The consignment consisted of 400 bunches of bananas, some sapodilla, the bell-apple or water-lemon, and loquat. In subsequent consignments there were brought bananas, pine-apples, alligator pears, bread-fruit, papaw, limes, oranges, and tomatoes. These fruits were brought from British Guiana, and arrived in excellent condition after a voyage of twenty-one days. The cool chamber on board the "Nonpareil" had a capacity for nearly 1,200 bunches of bananas, and by means of a refrigerating machine fitted by Haslam, of Derby, a dry equable temperature of about 39 to 41 degrees was maintained during the whole voyage. This is probably the lowest temperature necessary for fruits, otherwise it would be frozen and possibly be spoiled. A regular temperature of about 45 degrees might, under ordinary circumstances, be sufficient to keep well-selected and not over-ripe fruit in good condition, and especially if provision is made for keeping the air in the chamber as dry as possible. Excess of moisture or want of proper ventilation very quickly affects fruit in these chambers, and hence it is only by careful and systematic experiments the required conditions can be exactly obtained.

If cool chambers for fruit could be provided at a reasonable cost, there is no doubt that they would greatly enlarge the prospects of a trade in fresh tropical and sub-tropical fruits between the Colonies and the Mother Country. As noticed above, a proposal has been made by growers in South Australia to engage a cool chamber on board the Orient steamers to bring fruits to this country during the present year, and similar arrangements are in course of being made by other Colonies. We shall then, I believe, enter upon a distinctly practical phase of our subject, and the results will, I hope, be as satisfactory to our brethren in the Colonies as they will be beneficial and full of promise to ourselves.—*Colonies and India.*

A Correspondent writes to an Indian paper as follows on Wooden Labels for Trees:—The following method of preserving wooden labels that are to be used on trees or in exposed places is recommended:—Thoroughly soak the pieces of wood in a strong solution of sulphate of iron; then lay them, after they are dry, in lime water. This causes the formation of sulphate of lime, a very insoluble salt, in the wood. The rapid destruction of the labels by the weather is thus prevented. Bass mats, twine, and other substances used in tying or covering up trees or plants, when treated in the same manner, are similarly preserved. At a recent meeting of the Horticultural Society in Berlin wooden labels thus treated were shown which had been constantly exposed to the weather during two years without being affected thereby.—*Journal of Horticulture.*

We have received some packets of Gishurstine from the Belmont Works of Price's Patent Candle Company, reminding us of coming winter and the necessity for providing against wet feet. Ever since this useful preparation has been introduced we have used it, and found it of the greatest comfort in protecting boots from the effects of wet. But there is another use we applied some of it to, which the proprietors of it may not be aware of. We added about one-third of petroleum oil, and in this mixture we rubbed up some red lead, forming a paste of the consistency of cream. This we rubbed on wooden labels before writing on them with Wolff's pencil, and we have found the writing last as long as the label. It soaks into the wood and enables the pencil to make an indelible stain.—*Journal of Horticulture.*

One plant frequently met with on the sugar plantations in the North is the *Caladium esculentum*, an aquatic plant, which furnishes the large Taro root so well known to the Sandwich Islanders and the natives of other groups of islands in the Pacific. It is common on the Johnstone River and many places further north, and appears to be as thrifty as could be desired in those localities. Like rice, marshy ground suits it best, but, like that cereal, it can be grown on well cultivated land without much water. Caladium-like, the large arrow-shaped leaves rise on high foot stalks immediately from the roots; but, although the leaf and stalks are very agreeable to the taste, they are seldom eaten, as they are used for the purposes of propagation, these when severed from the root and inserted in thoroughly moist soil or mud produce in six months a harvest of roots. It is estimated that 1,500 persons can be fed on the produce of a single square mile; but unless this estimate represents the entire food of that number of persons there does not appear to be much that is extraordinary in it. In those islands where it is common the natives make thick paste out of the root; and this, under the name of *poé*, forms their staple article of diet. The South Sea Islanders are remarkably fond of making a patch of cultivation somewhere for themselves on the plantations in the North and growing a few sweet potatoes and their old favourite, the taro.—*Queenslander.*

On the Devonshire coast, a sea-grass *Poryhyra-laciniata*) is boiled, chopped, mixed with a small portion of oatmeal, and made into bread, which keeps from four to eight days, and is much used by the poor Welsh people, most of it being sent to Swansea.—*Am. Grocer.*

The strongest intoxicating liquor in the world is probably "Sham-sho," used by the natives of Burmah, and said to be made of rice and lime. It is so powerful that it will dissolve a Martini-Henry bullet in thirty minutes, and its ravages among the natives are stated to be most deplorable.—*Ibid.*

A new industry has been started in Vermont for collecting the cones of the white or spruce pines and extracting the seeds from them, which are then sent to France, Germany, and other parts of Europe, to renew the forests there that have been cut down. Each bushel of cones yields about two pounds of seed.—*Ibid.*

Close and Open Forest Planting.—In order to test the advantages or disadvantages of planting at various distances, some experiments were instituted in Germany some twenty-five years ago, and the results have recently been made known. An area of about fifty acres of the same average quality of soil and the same exposure was planted, in ten-acre portions, at distances ranging from four feet by four feet to twelve feet by twelve feet. Careful measurement has recently been made of the timber in each plot, and the following table is alleged to show the results in each case.—

Width of Planting.	Average Accretion in the 25th Year.
4×4 feet . . .	181·4
6×6 „ . . .	152·3
8×8 „ . . .	137·3
10×10 „ . . .	136·4
12×12 „ . . .	112·9

It would appear from these figures that the crop decreases in propotion as the width between the plants is increased at planting time. But there is much besides this meagre statement of the results at twenty-five years after planting required to enable us fully to understand the value of this important experiment in arboricultural practice. The management of the several portions of the fifty acres under experiment during the twenty-five years must form an indispensable factor in coming to any conclusion as to the value of these figures, which are put forward as the ultimate result of the comparative experiment. —*Journal of Forestry.*

Wood Ashes and their Uses.—We have had ample means of testing the value of wood ashes or charred earth, both as a means of warding off the attacks of slugs and other garden pests from tender vegetables, and as a material for enriching the soil and consequently accelerating growth. The old remedy, freshly-slaked lime, if used in excess, is positively injurious to some crops, and after it has lain on the damp soil a short period it loses its burning character, and then slugs pass over it with impunity. Ashes of every kind have been used, but more especially those from wood fires, and we strongly recommend that every kind of garden refuse be converted into ashes by burning it. At this season of the year, when the thinning of shrubberies is generally receiving attention, any or every kind of trimmings may be converted into valuable ashes, as when once a good bonfire is kindled, and a glowing red heat is obtained—no matter how green the wood and leaves may be—the fire will burn away as fiercely as the driest straw-stack, if kept constantly fed with fresh material until the whole is consumed; and there is therefore no more certain way of getting rid of noxious weeds, such as couch grass, bind-weeds, docks, etc., than that of passing them through the fire, as it destroys all seeds that generally abound in rubbish heaps that have been rotted away by the slow process of fermentation.—*Journal of Forestry.*

Increase of Strength in Timber by Seasoning, etc.—It is stated as a curious fact, by a writer in the *Building News*, that one of the properties especially conducive to durability in timber is its odoriferousness —woods which are of this character being the most durable. The same authority states that the increase in strength due to seasoning in different woods is as follows.—White pine, 9 per cent; elm, 12·3 per cent; oak, 26·6 per cent; ash, 44·7 per cent; beech, 61·9 per cent. The comparative value of different woods, in respect to crushing strength and stiffness, is thus shown: Teak, 6555; English oak, 4074; ash, 3571; elm, 3468; beech, 3079; mahogany, 2571; spruce, 2532; yellow pine, 2193; sycamere, 1833; cedar, 700. Regarding the relative degree of hardness, shellbark hickory stands highest, and calling that 100, white oak is 84; white ash, 77; dogwood, 75; white hazel, 72; apple, 70; red oak, 69; beech, 65; black walnut, 65; yellow oak, 60; white elm, 58; hard maple, 56; white cedar, 56; yellow pine, 54. Ironwood, hornbeam, almond, hard beech, teak, and thorn are of notable hardness, and, of course, very serviceable where that quality is essential. The finest floors are said to be seen in Russia. For those of the highest grade, tropical woods are exclusively employed. Fir and pine are never used, as in consequence of their sticky character they attract and retain dust and dirt, and thereby soon become blackened. Pitch pine, too, is liable to shrink, even after being well seasoned. The mosaic wood floors in Russia are often of extraordinary beauty. One in the Summer Palace is of small squares of ebony inlaid with mother-of-pearl. A considerable trade is done in Dantzic and Riga by exporting small blocks of oak for parquet floors.—*Journal of Forestry.*

Mechanism of a Tree.—A tree (and I beg my readers to follow this attempt at explanation closely—all depends upon it) receives its nourishment from the roots. These correspond to the mouth in the human frame. Now, as in the human frame the nourishment received is, after being supplied to the blood, exposed to the operation of air in the lungs before it is fit to give material to the body, so in a tree, the nourishment taken in at these tree mouths, the roots, passes to the lungs of the tree, and there, by contact with the air, is rendered fit to supply fresh material to the tree. These tree lungs are the leaves. This operation is effected by the passage upward from the soil around the roots, through the trunk, the branches, and every twig of the tree to the leaves, of a large quantity of water, containing in solution the nutriment for the tree. Arrived at the leaves, a process takes place which separates, by means of contact with the air, most of the water the roots had taken in, from the valuable nutriment, and throws off, in vapour, the surplus water into the air. At this time certain constituent portions of the air are utilized and mingled with the nourishment retained. This is all, now a small portion in comparison with what had arisen from the roots, yet retaining enough water to serve as a vehicle back, returned toward the roots, depositing in its way, in leaf, bark, and root, what is needed there for the growth of the tree. In these they undergo, especially in the bark, further fitting and digesting processes before they assimilate with the substance of the tree. The water which was retained to carry them down, being no longer needed, passes out at the roots. Of the extent of the provison made for evaporation by the leaves, some idea may be formed from a consideration of the number of *stomata* or stomates to be found in the leaves of plants. The number varies in different plants, for which variation a reason may be found in the different conditions of growth to which they are subjected in their several natural habitats. In the back of the leaf of the apple tree there are about twenty-four thousand stomates to the square inch. In the leaf of the lilac there are a hundred and sixty thousand of them to the square inch. In the leaves of the cherry-laurel there are none on the upper surface of the leaf, but ninety thousand have been counted on the lower surface.—*Journal of Forestry.*

THE RED SPIDER--SO CALLED.

BY A. VEITCH.

At a meeting of the Society of Florists in Cincinnati one of the speakers is reported to have said, when the subject of plant enemies was under consideration, "That it is customary to abuse and misuse the weak. This is the case with that small but beautiful insect, the red spider. Like other spiders it is carnivorous and never ate a plant in its life. Microscopic insects come to live upon the plants and the red spider to live upon them. It is a friend not a foe." This statement we regard as made up of fact and fiction in about equal parts. It is true the spider is carnivorous and is in no way dependent upon plant food for subsistence; but the creature referred to here is not a spider, but an Acarus or mite, and lives exclusively upon vegetable products. In zoological classification they both belong to the class Arachnida, but the might is in the order Trachearia, the spider in that of Pulmonaria. The function of breathing in the two orders is different. In the mite it is performed by air tubes distributed through the body, whilst in the spider the air is admitted by spiricles situated on the abdomen, and which are lined by a membrane plaited into numerous folds, which resemble gills. On these characters is founded the subdivision of the class into pulmonary and tracheary Arachnidia.

But apart from all technicalities anyone with a good pocket lens might satisfy himself that the pests of gardeners differ in important particulars from the spider. The head and breast, or thorax, of the spider is connected with the abdomen by a slender cord, as in insects. It has eight eyes, and the same number of legs, besides two short arm-like projections, or palpi, with which to catch and to hold its prey. The body of the mite is not so divided; is somewhat oval in form and tapering to the head, which is terminated by a syphon or sucker, with which to extract the juices of plants. It has six legs, but by undergoing a transformation similar to insects an extra pair is not unfrequently acquired. The body is transparent, with dark vein-like ramifications along the back which we take to be the trachea. The aged females only are red, which may have given rise to the popular name by which they are known. They spin webs, but not so artistically as spiders do, as they seem chiefly designed for nests, or, when the workers are unmolested, convenient residences for large communities; whereas the web of the spider is not only a snug retreat in times of danger, but a base from which to operate against enemies as well as a snare to entrap unwary flies or other creatures upon which it feeds. New Haven, Conn., 1st, 1885. —*Gardeners' Monthly.*

INTER-DEPENDENCE OF RAINFALL AND TEA PRODUCTION IN INDIA AND CEYLON.

The figures placed at our disposal by Mr. Hogarth shewing the rainfall and tea production on typical properties in India, deserve a more extended notice than we gave them. With some exceptions they shew that the winter months, December to February, inclusive, which are generally almost entirely rainless, are blank months as regards tea production; while March, in which flushing recommences after the pruning of November and the rest of the cold weather, and even April, shew but small results. The real tea season is the season of summer heat and monsoon rains which extends from May to October. In some cases, as we mentioned, fully 40 per cent of the whole crop is gathered in the two months of July and August, the very months in which generally, nearly a similar per centage of the total rainfall occurs. For India, therefore, it may be regarded as an established principle, that the tea harvest is not only in proportion to the amount of rainfall, but synchronous with the rainy season. Here, in Ceylon, owing to our insular position, our proximity to the equator, our place in the tracks of the two monsoons, and the consequent moisture held in suspension in the atmosphere for the large portion of the year, our seasons are not so sharply defined and our tea harvest is distributed much more evenly over the year. We should be glad to receive returns from particular properties to compare with those from India, but meantime general results may be deduced from the following table of monthly exports of tea from the island since the new product commenced to assert its position in our commerce:—

EXPORTS OF TEA FROM CEYLON IN EACH MONTH OF EACH YEAR FROM 1880 TO 1886, INCLUSIVE.

(Compiled from the Chamber of Commerce Weekly Export Table.)

	Jan. lb.	Feb. lb.	March. lb.	April. lb.	May. lb.	June. lb.	July. lb.	August. lb.	Sept. lb.	October. lb.	Nov. lb.	Dec. lb.	Total. lb.	Blue Book or Customs Total. lb.	Showing a difference of lb.
1880	1,236	5,804	708	1,928	29,979	3,750	8,432	45,265	184	146	11,578	16,806	125,816	134,523	8,707

1885	294,178	164,637	221,471	330,377	493,186	519,664	564,896	429,631	363,942	208,760	356,717	329,776	4,277,235	4,372,721	95,486
1886	461,539	364,538	530,552	1,063,624	815,854	687,377	1,132,064	777,946	474,304	476,340	626,007	413,048	7,763,213	7,849,888	86,675
Total	989,084	811,947	1,113,983	1,632,398	1,990,894	1,708,474	2,413,473	1,607,841	1,371,505	998,162	1,223,019	1,068,003	16,928,783	17,461,714	532 931
Avr.	141,298	115,992	159,140	233,199	284,413	244,068	344,782	229,695	195,929	142,594	174,717	152,572	2,418,397	2,494,530	76,133

It will be observed that our figures, made up from the Chamber of Commerce returns, shew some discrepancies when compared with the Customs figures in the Blue Book, which are higher in every case, but the differences do not affect the general results. These are that the bulk of our tea goes forward between April and September, the heaviest average figures being opposite May and July. This would seem to prove that our best flushing months are April and June. Taking it for granted that the produce exported in one month was harvested in that preceding, our heavy-yielding season extends, not as in India from May to October, but from March (which is not generally the month of drought it has been this year), to August. In those six months (going on the principle of crediting the export of one month as the growth of the month preceding, we get for our summer seasons the following averages:—

March	...	...	,, 233,200
April	...	...	,, 584,400
May	...	...	,, 244,000
June	...	...	,, 344,800
July	...	...	,, 229,700
August	...	...	,, 196,000
		Total...	lb. 1,532,100

Of course these are the averages of the seven years. And so, going on the same principle of throwing back the export figures one month, we get for our six winter months, figures as follows:—

December	...	...	lb. 141,300
January	...	...	,, 116,000
February	...	...	,, 159,000
September	...	...	,, 142,600
October	...	...	,, 174,700
November	...	...	,, 152,600
		Total...	,, 886,200

It thus appears that if April and June are the best yielding months in Ceylon, December and January give the lowest returns. The figures also seem to prove not far short of two-thirds of the tea produced in Ceylon is gathered in the south-west monsoon period, March to August. This is a result which will probably be considerably modified when the produce of Uva begins appreciably to affect our returns. Meantime, the exact percentages are:—

March to August .. 63 per cent.
Sept. to Feb. .. 37 ,, ,,

If the year is divided into quarters, December-to-February quarter gives by far the lowest yield; September-to-November follows with some improvement; March-to-May comes third, but the total in this quarter is so slightly below that for June-to-August, that they may be regarded as almost equal.

While production in Ceylon is perennial, there is a real lull in the two marked winter months, December and January, while the proportion of the harvest gathered in the six months September to February, is not greatly in excess of one-third the quantity collected between March and August. Our most productive three months are:

April with an average of			lb. 284,400
May	...	...	,, 244,000
June	...	...	,, 344,000
		Total ...	,, 872,400

Or considerably more in these three months, than in the *six* months, September to February. While our best yielding three months are April to June, in most parts of India, the three following months, July to September, are those in which the greatest returns are obtained, one half the whole crop being often gathered in those three months. In our case only a little over one-third is gathered in three months, the rest being so distributed that we have no blank months.

LONDON NOTES ON PRODUCE: TEA AND COFFEE.

There are complaints again as to the quality of Indian teas. The *Grocer*, referring to last week's sales, says:—The quality of the tea now on offer seems to be further deteriorating, as the proportion of common to fine grades almost daily increases; and as continued plentiful supplies are put forward, this week amounting to 23 050 packages, the public sales have gone off with greater heaviness at again rather easier prices. The market altogether is in a much weaker position than before, as not only have the dealers heavy stocks on hand still undisposed of, but the demand from the country is decidedly less active, and orders to buy tea are given with great reluctance. Fine teas sell tolerably well, but all undesirable and poor liquoring sorts have been realised with difficulty at a frequent reduction of ½d to ¼d per lb.

The price current of Messrs. Recker and Lee, of Galveston, Texas, contains the following remarks anent true and false coffee, which are distinctly "pointed":—There is nothing more saddening to the earnest Christian mind than the recipes for making coffee that are given in American cookery books. With hardly an exception, they direct that coffee should be boiled. As well might a Fijian cookery book direct that a missionary should be stewed. Coffee never was, and never can be, made by boiling it. The Americans are a nation of coffee drinkers. The annual consumption in the United States represents over one-third of the entire product of the world; so that the pressing necessity of obtaining good coffee, and knowing how to make it, is of great importance. Thomas J. Murrey, the well-known caterer, author and gourmet, in a recent communication on the subject of coffee in the South, pathetically remarks:—"What oath-breeding formula is followed by these coffee-spoilers I am unable to say, but it must be a very complicated one to be able to convert a wholesome beverage into the vilest compound ever tasted by man or beast." This uncomplimentary, but unhappily too true, reflection is largely due to using rank, low-priced Brazil coffee. However, a gleam of hope appears on the horizon towards an evolution in this respect, and the demand for rich, mild coffee is steadily increasing. It is a remarkable fact that the coffee of a nation is closely associated with its religion. Speaking broadly and generally, it may be said that true or infused coffee is the result of Catholicism, and that false or boiled coffee is the result of Protestantism. France, Italy, and Spain produce true coffee; while England, America, and Germany boil their coffee. Even in the latter countries, when true coffee is found, it is where Protestantism is weak. High Church households in this country and in England frequently drink real coffee; on the other hand, it must be confessed that Catholic Ireland is as ignorant of coffee as is Calvinistic Scotland; and for this exception to the general rule there is as yet no adequate explanation.

JAVA TEA.

Messrs. Gow, Wilson and Stanton have issued a circular, with diagram, showing the quantity imported and delivery of Java tea, during the last six years.

	1881	1882	1883
Imports	1,916,000	2,158,000	3 0 7,000
Deliveries	1,3 5 000	1,78 ,000	2 8 3,000
Stock	411,000	751,000	9 4,000
	1884	1885	1 86
Imports	3,586,0 0	3,344,000	3,946,000
Deliveries	3,709,000	3,537,000	3, 76,000
Stock	875,500	676,000	944,000

Our diagram shows a marked increase in the arrivals of Java tea in London during the second and third quarters of 1886. The above figures are interesting as showing a gradual development of the trade, the deliveries keeping pace pretty evenly with the arrivals.

The direct imports from Java to London during 1886 were the heaviest yet recorded. As large quantities have also been shipped from Java to other countries besides England, it is probable that the yield per acre during the past year shows an increase over recent

seasons; it is to be hoped that growers have by this means been to some extent compensated for the low range of prices current. The contraction in value of Java tea, however, has not been so great as in teas from some other places. Java teas are consumed in so many different markets that the demand from one quarter or another will generally retard a serious and sudden decline in prices, when caused by a drop in similar grades of teas from other countries. This cause has for some time past maintained the value of Java pekoes at a comparatively higher range of prices than Indian growths; it has also frequently retarded —and at a certain period checked—a decline in the value of Congous and Souchongs which might otherwise have been more pronounced. The wide area over which Java tea is distributed thus acts as a great and continuous safeguard. The value of broken pekoes has been greatly interfered with by the unsettled state of affairs in Ireland, where they were at one time largely consumed, and this class of tea being taken in fewer foreign markets than whole leaf descriptions, has probably suffered to as great an extent as Indian growths. Broken pekoes, however, are now becoming more used in some of the Continental markets. Quality.—Looking back over the past twelve months we note with some regret the poor average quality of a large proportion of the offerings; this is specially unfortunate at a time when super-abundance of weak liquoring teas had been arriving from other localties, and had already seriously depressed the market for the lower grades. Future prospects.—The brightest spot in the year is noticed in a few consignments which have stood out pre-eminently over the rest as being unquestionably grown from good Indian seed, and being manufactured with the greatest attention to quality, accompanied by skilled and careful manipulation. The future of the Java tea trade must be largely influenced by the liquoring character of the tea, and now that imports from India have so largely increased, and that there is every reason to anticipate a still greater addition to the tea harvest in Ceylon, this matter of quality may become one of *vital* importance to proprietors of tea estates. We would therefore, again impress upon owners the advisability of planting *good* Indian seed, and neglecting no opportunity of utilising every appliance for efficient manufacture, and for greater economy, which the most recent scientific researches have placed within their reach. Bulking in Java, has perhaps shown some improvement during the past year, but still requires additional attention in many factories. The subject is of greater importance now than ever as an additional charge has been imposed for the performance of this operation in England. Average price: the 56,490 packages of direct import sold in public auction during the year realised an average of 9¼d.; the average for the 31,473 packages sold during the first six months of the year being 9¾d., and of the 25,017 packages sold during the last six months being 8¾d. In 1885, 45,272 packages of Java tea of direct import were printed for public auction; the equivalent in chests being 39,418. In 1886 the quantity had increased to 56,490 packages, the equivalent in chests being 48,038.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

Paris, February 19.

German farmers are discussing a not unimportant question, namely, whether large or small-breed cows are best for milking purposes. Starting from the term of 8 or 10 years, during which the keeping of a milch cow is remunerative, and comparing the relative cost of their feeding and difference in live weight when finally slaughtered for the market, which of the two classes of cows will be on the whole the most profitable to keep, assuming the yield of milk in each case to be equal? Take two cows whose live weight is 8 and 12 cwt. respectively. After utilizing their milking powers during 8 or 10 years, will the superiority in live weight, say 4 cwt. when handed over to the butcher, balance or surpass the greater cost of food consumed by the heavier animal pending ten years?

It is roughly estimated that a cow requires for sustenance 2¼ lb. of dry matters—that science so selects for its standard—per hundredweight; consequently, a cow of 12 cwt. will require in rations nine pounds of dry substances more than the small animal. In the course of a year the excess would amount to 29 cwt., and if valued at fr. 2·50 per cwt., the difference in money value would be per annum 72 fr., or for ten years 720 fr. Now is there any butcher to be found who would pay 720 fr. for a live weight of 4 cwt. of a cow, after serving ten years as a milk-producing machine? Conclusion with German agriculturists: for milk industries small, not large-sized stock, are to be preferred, as they eat less into the bargain.

In France, as a rule, milk is never consumed unboiled; in Germany the contrary is the case. Professor Reichmann has determined the relative digestibility of milk in both these states. Unboiled new milk coagulates in the stomach five minutes after it is swallowed; in the space of four hours it is completely digested. The digestion is produced not by a ferment, but by an augmentation of lactic juice and also of muriatic acid. The action of these acids is at its maximum 75 minutes after the milk descends into the stomach. Boiled milk requires two hours and-a-half to be digested.

Dr. König recommends the more general consumption of butter-milk; it is richer in albuminoid matters which constitute the elements of nutrition than either fresh or skimmed milk being 4 per cent, while the others are but 3; naturally it is less rich in fatty matters, being under one per cent, while fresh milk is 3½. Its taste indicates it contains less milk-sugar, due to the latter being converted into lactic acid. The stomach digests it quite as well as meat, eggs, or whole milk, and in the neighbourhood of towns or factories is in great demand, where it is prepared as an appetizing and nourishing soup.

Since the close of the fifteenth century, when the Moors were definitely defeated, till now, Spanish agriculture remains in the same state. The realm is naturally rich, the climate excellent, yet the population very sparse, does not raise sufficient cereals for its wants. At Florida, near Madrid, an Agricultural College was commenced in 1854; it is still in course of construction, and will not be terminated till the country possesses some solid government. It is what Liebeg would call the "vampire system" of farming which is pursued. One example suffices for all. In the province of Murcia, in the south-east of Spain, it is the old Roman plough which is still in use. The soil is never manured, being by nature rich; the rotation is naked fallow, followed by barley and wheat. There are no black cattle, so there is no manure; there is no pasturage, save what the Merinos eke out in the Sparta fields. Goats replace cows, and straw, hay. Farm laborers are paid 2 fr., and women 1 fr. per day, and are contented, so as Sancho Panza observes, when one is contented there's an end to the matter.

The fallow receives three primitive ploughings: in September the wheat is sown broadcast and lightly ploughed in, so that when the wheat rises, it has the look of having been sown in lines, as the seed falls towards the ridge of the furrow. As the farmsteads are few and far between 8 to 10 miles distant, the owner never visits his fields from the time of sowing the grain till he comes to scythe the crop down in June. When cut the grain lies 10 or 12 days on the soil; then is carted home. There are no roads—the highway is the railroad. There are no spring carts even for travelling.

The sheaves are opened out on a circular "threshing" floor 66 feet in diameter; the layer of straw is twelve inches thick; over this mass is dragged by mules a kind of chaffer, consisting of Silex knives stuck in heavy blocks of wood. The result is not only to shake out the grain, but to cut the straw; a series of riddlings separate the grain from the mass. The straw is the provender for the mules

and sheep; only rye straw is employed as litter. In the absence of irrigation—and plenty of facilities exist to execute it—there is neither grass land nor green crops. The small quantity of manure from the stabling of the mules is applied to the vine.

The culture of the vine is equally primitive; there is one vine per each six square feet; it receives three tillages—between January and May, and one manuring—stable stuff, every fifth year, on each side of the vine alternately; a trench 20 inches long, 8 wide, and 12 deep, receives 25 lb. of manure. The preparation of the wine is simplicity itself. A reservoir in cement, cubing 60 feet, on a level with the soil is filled with grapes and pressed down with the hand. The mass remains thus during four days to ferment, to allow the sugar to be converted into alcohol. The juice is next run off, and the residue carried to the press-vat, which also is the mill for squeezing olives for oil. The vine is then collected into deal vats; German rye whiskey added to make the liquid keep, and at once filled into barrels and exported. The wine has now 16 per cent alcoholic strength, which the blenders water down to 8. The residue of the winepress is either dried for fuel or applied to the vines as manure. Were it distilled as in France, it would yield ample alcohol to save German importations. The backwardness of Spanish agriculture may be judged by this fact; many proprietors are ignorant of the extent of their holdings, as the latter have never been surveyed. It is but just to add the State has promised to do so—since four centuries.

The Agricultural Society of the Loire has taken a step in the right direction; it is arranging to establish a farm, garden, and flower school to train small farmers' daughters and servants, in all branches of domestic economy, as applicable to their expectations in life. There is a great demand for educated helps in the rural districts, and superior young women readily receive higher wages. The school will effect another salutary end; checking the tendency of young women to immigrate to the cities, in the hope to obtain higher paid employment, but which too often terminates in their ruin.

Good oaten straw, that is, free from rust and must, is an important forage in the ration of milch cows. Straw is accused of imparting a disagreeable flavour to milk, and a tallowy character to butter. Such may be produced by some other straws, or even by that of oats if unsound. Experiments made in Silesia confirm these views. In Schleswig-Holstein, where the most scientific attention is given not only to the preparation of butter, but to the feeding of the cows, oaten straw enters into the rations of milch stock in the proportion of 9 lb. per 9 cwt. of live weight. Oaten straw in addition should be chaffed and proportioned to the other rations.

The Russians have been the first to employ compressed rations or cake-feed for horses during campaigning. Since eighteen months trials have been made with the fruit of the *Sterculier acuminé*, or "kola," an alimentary product, native to North Africa. Professor Heckel, of Marseilles, has prepared cake food for horses, in which the Kola fruit enters largely. He attributes to the Sterculia exciting properties akin to oats; in the latter, the stimulating element resides in the delicate pellicle which coats the seed. The food has been tried on cavalry horses at Marseilles and elsewhere, and with satisfactory results. The exciting action on the nerve muscles is only more immediately active in the case of oats. The Sterculia cake is accepted as able to replace one-half the feed of oats; in other words one pound of ordinary oats is equal to two pounds of Sterculia.

In Belgium, Serradelle culture continues to make progress both as a fodder plant and for green manuring. It is sown with winter rye in April, at the rate of 33 lb. per acre. Cows prefer it to any other kind of dry forage, and in nutritive composition it treads closely on red clover. It is neither exacting in point of soil or manure like clover. It produces 32 tons of green stuff per acre, and ploughed in as a green manure can be profitably followed by potatoes.

An enormous quantity of bamboos has recently been shipped to France, and the demand continues.—*Japan Mail.*

In Case of Scalding.—In case a child or other person should accidently drink scalding water, cod liver oil and lime water, mixed in equal parts, should be administered a teaspoonful at a time, to the scalded throat, given slowly so the healing mixture trickles down almost of itself. This not only heals the injured part, but supports the strength of the child as food would until other nourishments can be taken.—*The Farmer's Review, Dec.* 1885

A Mixture of Zinc White with zinc chloride is found to furnish a paint of great value both for wood and metals, as it becomes very hard, and can be washed or brushed without injury, which qualities are, of course, of prime importance. An essential precaution, however, to be observed in regard to this paint is not to apply it in rainy or frosty weather, as it then becomes mealy and scales off.—*American Cultivator, Jan.* 1886.

Several interesting experiments were recently carried on at the Cawnpore Farm, or "The Agricultural Station," in the N. W. P. Notable among the experiments was the use of woollen refuse from the mills as manure. This is probably the first occasion on which this manure has ever been tried in India. The experiment succeeded admirably with crops of all kinds, and the mill-owners will, no doubt, be very glad to get rid of the refuse, as it is of a highly inflammable nature. Refuse from brick kilns, and ashes from reeds, and grass cut green during the rains and buried, were also tried as manures with success. The growth of Nankin cotton proved a failure, but the season was unfavourable.—*Madras Mail.*

The Darjeeling Tea Season.—The tea season at Darjeeling promises to be an early one. Rain has fallen in all parts of the district during the past few days, and in sufficient quantity to satisfy every requirement. The trees on the less elevated parts are quite green with new leaf, and several gardens anticipate manufacturing in a few days. The cold weather throughout has been moist, and with the hard frost experienced in December should, with the present seasonable spring, bring the leaf out strong healthy, with a quick growth. A Darjeeling correspondent writes:—"I should say from the forwardnes, of the leaf that plucking will have begun by the 15th instant on almost every garden in the district. The oldest resident cannot recollect such favourable weather for tea, and undoubtedly the severe frost experienced during this cold season have done much to free the gardens from blight. The gardens are quite clear of the pests which have done so much harm in recent years."—*Times of India*, 11th March.

Java Cinchona.—A well-known Java proprietary planter is on a visit to Ceylon at present in Mr. A. Kessler, who has a very large interest in cinchona in Southern Java. This interest is spread over some half-a-dozen estates and all but one, consist solely of cinchona, of which as many as 2,000 acres are cultivated. The exception is a plantation which is divided between coffee and cinchona. Mr. Kessler's oldest trees are not above five to six years, but he has already harvested a good deal and got profitable returns. He and other Java planters will, however, be shipping on a much larger scale henceforward, and with a quality of bark likely to be far richer than any from Ceylon. Mr. Kessler thinks the returns recently sent officially to Ceylon, of the area planted in Java and the probable quality of the bark, a fair approximation, and as a large holder he is naturally anxious to see and learn about cinchona in Ceylon. We bespeak for Mr. Kessler a courteous reception during his trip through the Central Province commencing today. He will first go to Kandy and then up through the young districts, and, perhaps, on to Uva. We trust he may have a pleasant visit and gain a fair idea of the extent under cinchona here.

INTERDEPENDENCE OF RAINFALL AND TEA PRODUCTION IN INDIA AND CEYLON.

AN INDIAN PLANTER'S NOTES ON TEA IN CEYLON.

In our previous article we noticed the averages of tea production in Ceylon for a series of years and for the months, quarters and half-years of the period since tea became an important factor in our export trade. Most of the tea being, as yet produced in the south-west of the island, it naturally followed, looking at the influence of rainfall on the production of leaf, that more than two-thirds of our crop are harvested in the south-west monsoon months. We indicated that when Uva becomes, as it inevitably will, a large producer of tea, the averages are likely to be disturbed. Meantime it may be interesting to see in what proportions monthly, quarterly and half-yearly the crop of 1886 was produced. Going on the principle of crediting the export of one month as the yield of the previous month, we obtain the following results:—

Months	Pounds Tea Exported	Percentage.
January	364,500	4·52
February	530,500	6·58
March	1,003,600	12·43
April	815,800	10·11
May	687,400	8·52
June	1,132,000	14·02
July	778,000	9·65
August	474,300	5·88
September	476,300	5·78
October	626,000	7·76
November	413,000	5·12
December	777,000	9·63
Total	8,078,400	100·00
Average	673,200	8·33

It will be seen, from the above that March, which is a month of very small yield in India, was the second best month of 1886 in Ceylon while December which is blank in India gave us 9·63 per cent of our crop. Our best month is June, then comes March, followed by April, July, December and May. The period of greatest yield in 1886 was from March to July, thus :—

March	12·43 per cent.
April	10·11
May	8·52
June	14·02
July	9·65
Total in 5 months	54·73

or considerably more than one-half, about the proportion they get in India in June to September or July to October. We differ essentially from India in our appreciable percentages for December, January and February, viz. 9·63, 4·52 and 6·58=20·73 or with 12·43 for March =33·16, or one-third of the whole in the winter months.

On a future occasion we may hope to be able to deal with the figures of tea production as compared with rainfall on particular estates in Ceylon, such as Mr. Hogarth placed at our disposal in regard to typical "gardens" in the leading tea districts in India. These we now proceed to notice. Lukimpur gives the largest production of tea per acre in any district in Assam or all India. Premising that the returns for rainfall are perfect only from 1882, those of 1881 being imperfect and 1880 being nil, the crop being given for the 6 years from 1880 to 1885, while the rainfall is shewn complete only for the four years 1882 to 1885, the monthly percentages of crop gathered and the averages of rainfall on a Lukimpur estate compare thus:—

Months.	Mean percentage of crop.	Average rainfall
January ...	Nil. ...	1·55
February ...	„ ...	3·21
March ...	·35 ...	4·20
April ...	2·243 ...	12·19
May ...	5·59 ...	11·46
June ...	12·915 ...	12·55
July ...	19·2 ...	19·68
August ...	20·4 ...	20·34
September...	17·32 ...	14·79
October ...	14·42 ...	4·19
November...	6·49 ...	0·66
December...	1·07 ...	0·50

The average annual rainfall was 106 inches and as our readers will observe, in this case well distributed. Indeed, if more of the rainfall were concentrated in June and July, instead of falling in August and September, the coincidence with the figures for estates in Upper Dimbula would be very close. The great difference is in the winter cold, which, in India, renders production small from November to April, there being but a slight recovery in May. June, July, August, are the heaviest rainy months, and in those three months more than half the whole crop is harvested. All but a small percentage is gathered between April and September, the other half of the year from October to March yielding a percentage which can scarcely pay for the gathering. But in this case, we may say both rainfall and crops, are more equally distributed over the months than is the case in other places in Assam and Cachar. On another estate in Lukimpur the tea season extended from June to October, 38·9 per cent being gathered in August and September, in which months over 28 inches out of an annual average of 95·5 fell. In this case also crop and rainfall closely coincide. On an estate in Sylhet, where the bulk of the rainfall occurred between May and October, the vast bulk of the crop was gathered between June and November, the heavy months being July to October. For an estate in Cachar with an annual rainfall of 107 inches, there are complete figures for monthly averages of rainfall and percentages of crop for the 6 years from 1880 to 1885, and in this case it will be seen the tea season extends from April to September. The figures are as follows:—

Months.	Percentage crop.	Ave. Rainfall
January ...	nil ...	0·3
February ...	nil ...	1·6
March ...	3·3 ...	8·3
April ...	9·1 ...	12·3
May ...	12·0 ...	17·7
June ...	15·7 ...	17·2
July ...	12·9 ...	15·0
August ...	13·5 ...	16·1
September ...	10·8 ...	12·0
October ...	11·4 ...	5·0
November ...	8·4 ...	1·3
December ...	1·6 ...	0·2

It will be observed that from November to February the rainfall was very slight and that as regards crop December gave very little; so with March, while January and February were blank months. The six months of heavy rainfall extended from April to September, May and June shewing nearly 35 inches. The crop months extended from May to October, the three months of May, June and July yielding over 42 per cent of the whole.

There are figures for estates in Darjiling and the Central Terai which shew that the climate of the Eastern Himalayas is much more rainy than that of the valley of the Brahmapootra. On the well-known Geille estate the annual rainfall ranged from 86·32 inches to 132·21; another estate gave 85·50 to 121·61.

An estate in the Central Terai ranged from 103·33 to 149·48. In another case we get a range of 89·73 to 171·52; sixty-seven inches of the latter quantity having fallen in August 1882. On an estate in the Darjiling Central Terai we find that out of a total crop of 1,581 maunds and 5 seers in 1882, the proportion in the four months—June to September—was :—

June	266·31	maunds
July	289·15	,,
August	290·13	,,
September	257·14	,,

or about two-thirds of the whole. So generally in other cases. One estate yielded 1,533·27 maunds 1885, of which the proportion gathered between June and September was

June, maunds	338·18
July ,, ...	254·
August	272·5
September	200·5

or considerably more than one-third of the whole. On an estate in the Dooars the rainfall in four years, 1881 to 1884, ranged from 112·84 to 184·49, so large a quantity as 70·77 inches falling in August 1882. The vast bulk of the rain falls between May and September, while the bulk of the crop is gathered between May and October, the percentages in July, August and September being :—

July	18·30
August	19·06
September ..	15·88
Total ..	53·24

or considerably more than one-half. In another case the percentages were :—

July	15·44
August	18·66
September ..	17·80
Total ..	51·90

Again more than half in three months.

The general conclusions are as we have stated, that on a large proportion of the Indian tea estates, with a rainfall of from 70 to over 170 inches of south-west monsoon rain, December, January and February are blank months or nearly so as regards crop, while the yield in April is usually small. The real crop season extends from May to November, (in which latter month pruning is usually performed), but the bulk of the harvest is gathered between June and October, as much as two-thirds of the whole crop being frequently gathered in the four months, June to September. Our Indian neighbours are, therefore, much more exposed to a "rush," such as coffee planters were wont to experience, than are the tea planters of Ceylon. The Indian tea planters, on the other hand, can count on the enjoyment of a cold weather holiday, extending from about the middle of November to the middle of March.

Having thus noticed the figures which Mr. Hogarth kindly placed at our disposal, we are enabled, through his further courtesy, to add the following notes of his impressions in regard to our system of planting and manufacture in Ceylon :—

Mr. HOGARTH'S NOTES.

It is only to be supposed that a tea planter from another country would find fault with many things in Ceylon and it is only to be expected that there are faults to be found in a growing enterprise.

The selection of suitable land, the chances tea has of ultimately holding its own against disease, and the time and manner of pruning, are subjects that a travelling planter is cautious in expressing his opinion on. But there are things to which our attention has been drawn and among these are :—

Careless planting.—Many Ceylon planters pull the seedlings up bare of any soil, and dibble them in like cabbages. In Assam the plants are lifted with as much earth round them as can be secured, and the greatest possible care is taken that the tap root is not bent. The tap root can be cut off without injuring the plant, Dr. King of Botanical fame says, but it must not be turned up.

Too early plucking.—Many planters are plucking their plants far too young. Nothing tends to stunt a garden like harsh treatment in its growth. The root system is representative of the branch system and early plucking checks the growth of the former. The excuse given is that "funds are wanted," but things must be desperate when you run in the face of nature.

Economy in everything is advisable, but false economy is ruinous. Already complaints are rife of Ceylon teas not "keeping"—that may or may not be from under-firing; and in a country where fuel is so scarce the tendency will be to fire as little as necessary. Where there are so many operations in the manufacture of an article any-one of which may produce a chemical change, it is most difficult to place one's finger on a blot and the hint of under-firing is simply a hint and nothing more.

A great drawback to Ceylon is the want of power for driving rolling machines. Hard rolling is necessary for strength, but *long* rolling is often mistaken for hard rolling. In Assam Jackson's Excelsior is the machine generally used; it requires about a 6 H. P. engine to do the work rapidly and well. In Ceylon fuel is scarce, and many factories rely on their old coffee wheels of about 3 H. P. to drive the rolling machinery. This in Mr. Hogarth's opinion, means spoiling good leaf. You must have the means, as well as the knowledge, to make good tea. Rapidity of manufacture is of the utmost importance in Assam and Mr. Hogarth doesn't see why it should not be here. He is very cautious about expressing himself on the treatment of the plant, as climatic influences must be considered, but in the treatment of the leaf after it is plucked there can be little doubt, and if Ceylon is to hold its own in the competition that is likely to arise during the next few years, he says, it must be better found in power to drive suitable machinery. He thinks there will be a great struggle for a few years and if you can't afford to meet the enemy well appointed, you had better give up tea planting. Last year has shewn that leading gardens in Assam will do well, but there is not middle class for teas as there used to be, it has come to be fine and common and Ceylon will have to choose one or other place.

On which we would remark, as we did when Mr. Hogarth mentioned the matter to us, that many a planter accused of over-plucking young tea, would reply

"My poverty, but not my will consents."

So with the choice of land: a large number had no choice but to transform their collapsed coffee estates into tea plantations. There can be no question as to the advantages of taking up plants for the field with masses of earth about them, and in the lower and hotter districts transplanters are largely in requisition. In the higher and more moist regions, however, neither transplanters nor shade is necessary, and we certainly do not need to protect our plants against that plague of crickets which is so destructive in some parts of India. Seeing that the cry previously was that we burnt our teas it is curious now to have the alleged liability o our teas to "going off" attributed to under firing from scarcity of fuel. Fuel and suffi

cient power are, no doubt, important considerations and as to quick hard rolling versus long-continued hard rolling, Mr. Hogarth told us that, in his own practice he found it better to put 80lb. at a time into Jackson's Excelsior Roller and get the leaf rolled rapidly, than to put in 300 lb. and take time in proportion. We mentioned to him the very different practice of Mr. Gow, who subjected the leaf put through his hot air withering machine to a full hour's rolling in Jackson's Excelsior, plenty of power being supplied from the resources of Messrs. John Walker & Co.'s Iron Works, where the experiment took place. If we understood Mr. Hogarth aright, hard rolling, long continued will obliterate "tips," while they can resist hard rolling for a short period. As to pruning, we told Mr. Hogarth that the process has been tried in every season of the year in Ceylon and there is scarcely yet a concensus of opinion as to the best period. Planters seem agreed, however, that, thorough pruning once in eighteen months is sufficient, if the removal of crows-feet, blossom, fruit and dead wood is carefully performed when the necessity becomes obvious in the interval.

TEA:—HUGE PROFITS AND QUICK RETURNS.

Having noticed an enquiry in an Indian contemporary as to where the profits go between the price the planter receives for his tea and the retail selling price, the idea occurred to us to send into the East End of London, and to find out by actual purchase, first, what is the smallest amount of tea the shops will sell to customers, and, secondly the prices charged. It is unquestionable that the largest proportion of the tea purchased in London is bought in the very smallest amounts procurable at a time, and consequently the prices charged for these small amounts will best illustrate the profits realised on the bulk of the teas sold over the counter. As the result of our enquiries, we found that the majority of East End shops sold as little as half an ounce, these half ounces being generally kept ready packed in paper. We heard that some shops sold ½d. packets, more particulary to factory hands who purchased from day to day the requirements for each meal separately. We obtained five samples, and sent these to one of the oldest established firms of tea brokers in the Lane where, there being both Indian and China "sides," there was reasonable prospects of obtaining a fair valuation. The following is the reply we have received: "You set us a very difficult task, we are only in the habit of tasting self-teas, we had to bring all the talent we could to bear from both our Indian and China rooms. We have numbered the samples and make the following remarks, viz.:—

No.	Weight purchased.	Price paid.	Rate per lb.	Quality.	Value.
	oz.	d.	.0		
1	.. ½	.. ¾	.. 2	..Mostly Indian mixed, little coarse ..	9d to 9½d
2	.. 1	.. 1½	.. 2	..Nearly all China, little sour	8d to 8½d
3	.. 1	.. 1½	.. 2	..China.. ..	6d to 6½d
4	.. ½	.. 1	.. 2 8d	..Mixed Indian and China and little Oolong, fair ..	..10d to 10½d
5	.. 1	.. 2	.. 2 8d	..Fair Indian and China..	about 11d

To the above values you must add:—

Wholesale dealer	2d
Duty	6d
Retail dealer, some get more ..	6d
Total ..	1s 2d

to 2s 8d. It is far and away, better than any of your samples."

The firm thus reporting were not aware where we had procured the samples, nor what was our motive in sending them for valuation. Hence the above is as unbiassed, and as scientific and honest a report as it was possible to obtain.

Now if we add the wholesale dealer's 2d and duty 6d as mentioned above, to the above valuations, and compared the results with the retail prices actually charged, we have the following significant figures.

Sample No.	Retail price charged. per lb.		Valuation Cost to Retailer. per lb.					Estimated Profit per lb.			
	s	d	s	d		s	d	s	d		s d
1...	... 2	0	1	5	to	1	5½	0	6½	to	0 7
2...	.. 2	0	1	4	to	1	4½	0	7½	to	0 8
3...	... 2	0	1	2	to	1	2½		9½	to	0 10
4...	... 2	8	1	6	to	1	6½	1	1½	to	1 2
5...	... 2	8	1	7		—		1	1		—

Thus on the samples procured by us the retail profit, according to valuation, may be said to have varied between 6½d, per lb. the lowest, and 1s 2d per lb. the highest, which, to use a well known aphorism, accounts for the milk and the cocoanut.

We send you a sample of a mixed tea which costs the dealer here 1s 3d, which he sells, duty paid, at 2s 3d. for the *retail* dealer to sell at 2s 6d.

THE INDIAN TEA SALES SUGGESTED REFORMS.

We insert this week a letter from Messrs. Taylor-Colman, and Sudlow, one of the leading firms of buying brokers in this market, touching upon the size of the sampling breaks of Indian and Ceylon tea. We made some comments on the subject a few weeks ago when it was first mooted, and as our opinions are unchanged we need not refer to them, except to say that there appears to be a singular apathy displayed by the Committee of Wholesale Tea Dealers, the Indian Tea Districts' Association, and the Brokers' Association. Another season will soon open; and as far as we have been able to gather not the slightest action has yet been taken by any of the authorities abovementioned, either with a view to remedy existing defects, or even to discuss them with a view to such results.

The matter concerns these gentlemen much more seriously than would appear by the amount of interest they show in it; and we again urge them to take immediate steps to arrive at a satisfactory reform of the present regulations, as we are convinced they have, worked their last season as they now stand, and must as our correspondents point out, utterly break down under the slightest extra pressure. Indian planters may not see any immediate cause for alarm; but we must remind them that the supply from Ceylon is rapidly increasing—most of it, too, in rather small lots which occupy as much time in the sales as large breaks do, and the two together will, we feel sure, tax the powers of the trade seriously as time goes on.

But we must now leave this subject to refer to the other more absorbing topic which our correspondents touch upon, and which might fitly be headed, *the Ethics of the Pulpit*.

We confess we have quite expected that the present system in the public saleroom would soon end in an explosion of indignation. We believe it was Mr. Gladstone who once expressed his opinion at some ecclesiastical gathering, that, as a rule, "the pulpit did not get justice from the pew,"—the tea buyers evidently seem to think exactly the reverse—in short, that the pew does not get justice from the pulpit. We are quite of their opinion that nothing will last but absolute fair play. An auctioneer has, by common consent and immemorial usage, a sort of prescriptive right to present his wares in the most attractive language that his audience will give him a patient hearing for, but there can be no doubt that what is called "puffing" on the part of the vendor is strictly illegal and immoral. How far the practice

known in Mincing Lane as "jogging" or "trotting" comes within the limits of illegality we are scarcely in a position to say. We would, however, give it as our opinion that in the long run the value of tea is not one fraction enhanced by any such practices. As anyone whothinks calmly for a moment must see that a buyer who is "rushed" into a purchase at a higher price than he can resell at is practically silenced as a competing bidder for some time after. The legal maxim of *caveat emptor* is perhaps sufficient safeguard in such cases. But anyone who is accustomed to attend the sales can read between the lines that the head and front of the grievance consists in this. Certain grades of Pekoe Souchong are valued to a fraction, and when the bottom price is, say 7d a dozen, buyers will want it at 7d. We have occasionally been present and observed with amusement when some desirable lot was put up, a simultaneous shout of 7d, would spring like a volley of musketry from all parts of the room. Of course every bidder considered he was first entitled. But when the smoke had cleared away the auctioneer calmly applied the hammer to the desk as he smilingly decided, "Sevenpence my own bid." Naturally enough, eleven occupants of "the pew" felt aggreived, and manifested their feeling in disrespectful animadversions on "the pulpit." Our correspondents remind us of the committee which was appointed a few years ago, for the redress of grievances, and the abolition of preferential and favoured seats in the vicinity of the pulpit. This committee passed a rule that no buyers should sit in the box with the selling broker. An old custom had been, however, for the selling broker to have a clerk at his side to keep a correct record of the prices, and gradually this official has become a buying broker with a preferential position, far away, the best in the room. There can be no doubt that this is an evasion of the rule and it should be discontinued. The record of prices could be equally well kept in the body of the room, and in fairness to all parties this preferential advantage should at once be abolished. The tone of the Indian tea sale-room has certainly degenerated during the last ten years. It is now much more noisy and disorderly than it used to be, and the general opinion is that this is due in great measure to the impression abroad that even handed justice is not always forthcoming. We trust the selling brokers will gracefully give way without the necessity of another trade meeting and a committee of reformers. We have always maintained that sellers and buyers had reciprocal and mutual interests, and a little kindly forbearance on both sides will, we have no doubt, make matters go smoothly again.—*H. & C. Mail.*

THE SIZE OF THE SAMPLING BREAKS OF INDIAN AND CEYLON TEA, ETC.

To the Editor of the "Home and Colonial Mail."

SIR,—We have been expecting to see some further discussion of this subject in your columns, as it must be evident to anyone regularly attending the Indian tea sales that the present system is unworkable, and in times of the least extra pressure must utterly break down. The buyers cannot accurately taste and value so many breaks as they have had each sale during the last six months. From our knowledge of the views of most of the larger buyers with whom we come in daily contact we believe the tendency is not to look at less than twenty chests; indeed, in times of pressure, it is quite impossible to do so; therefore the question should be at once considered whether breaks of twenty chests and under should not be treated as small breaks, and sold at the end of the sale.

There is another matter which demands immediate redress, and that is the present unsatisfactory practice of selling-brokers putting their own bids in first whilst acting as auctioneers. Anyone can see that the auctioneer doing so has a great advantage over any other buyer, as he alone knows the exact moment when the hammer will fall on the previous lot, and consequently can put in his own bid simultaneously. Friction and unpleasant feeling is caused by the system, and the sellers' interests in the long run must suffer, if anything but pleasant relations exist. A Committee was appointed some years ago ostensibly to rearrange the seats of buyers in the public saleroom, and for the purpose of abolishing any prefential positions which certain buyers had occupied for a considerable time. We expressed to them our apprehension; and also at the same time that the old custom of "last buyer claiming the next lot" was abolished, that some such unpleasantness as this would be sure to arise; and events have but served to justify the opinion we then formed. Nothing will be satisfactory in practice but fair play to everybody; and such there will not be, and cannot be, till the two functions of seller and buyer are dissociated, and no one be allowed to occupy the pulpit but the auctioneer. If the selling brokers' firm receives orders to buy any lots in their own catalogue, the bidding should in fairness be done from the body of the room, and not from the preferential position of the auctioneer's chair.—Yours, &c., TAYLOR, COLMAN AND SUDLOW.

March 2nd 1887.

BRITISH NORTH AMERICA: A PARADISE FOR A FARMER.

Pelee Island, which is situated in the most southerly part of he Dominion, has a mild and most salubrious climate. The land is all that can be desired for raising all kinds of fruit, vegetables, roots, and cereals of all kinds. Timbered land can be had from $10 to $20 an acre, partly cleared from $20 to $30 per acre, and all cleared with good buildings and free of stumps from $40 to $75, according to location. The whole southern shore of the county, extending some 40 miles, is admirably adapted for the raising of grapes, peaches and all kinds of fruit. Early next summer this village will have railroad communication with the railroad system of Ontario by the Leamington and St. Clair railroad, running from Lake Erie to Lake St. Clair, crossing the Canada Southern at Comber station, and thence north to Stoney Point on the Grand Trunk railroad. It is said that Dr. Scudder, of Cincinnati, has bought 5,000 acres of marsh in the island, which has been drained by the Chatham Dredging and Contracting Company, under the supervision of Alexander Baird, P. L. S. The ditches are from 4 to 7 feet deep, with an average width of 30 feet. The water in said drains is elevated into Lake Erie by means of an engine and large wheel, which raises 100,000 gollons of water per minute. This marsh is ditched all round, and will be cultivated next summer. Cattle are at present pasturing upon it. There are large tracts of marsh land in the county, at present unprofitable, which require to be drained in the same way, and will ultimately be the finest land in the Dominion.—*Colonies and India.*

PLANTERS AND HIGH EXCHANGE IN NETHERLANDS INDIA.

(*Straits Times.* March 12.)

Mr. Van den Berg at the close of his pamphlet raises a question hard indeed to solve, namely the effect which an appreciation or a depreciation of currency may have on the wellbeing of a country. In British India, for example, it is generally held among the mercantile community that the fall in exchange has benefited trade by encouraging production. But experts of high authority hold the exact contrary. Equally divided is opinion in Java. Some people there argue that the currency policy of the Dutch Government has advantaged the community materially by protecting the public interest from the calamitous consequences of keeping a fluctuating standard of value in silver. Others are equally positive that the planting interest has been a loser by the Government de ter

mination to set up gold as regulator of the currency in the Netherlands East Indies. Mr. Van den Berg does not try to solve the question brought up in consequence of this conflict of opinion. He simply sets forth his own views. He has all along regarded this topic from the standpoint that a monetary standard should be based on fixity of value to be kept up to the mark by Government using every reasonable means. He comes, hence, to the conclusion that the Netherlands Home Government took action honestly and wisely in doing every thing in its power to safeguard the currency of the colony from depreciation by making gold its monetary standard for the future. This measure called for as it has been under the circumstances has worked detrimentally upon one section of the community. In British India, the fall in silver, however, disastrous to the Government finances, has proved a boon of immense value to the country by stimulating exports. In Ceylon, a new era of prosperity has set in since tea growing has forged ahead. The Straits Settlements have a bright future before them, there being every sign of an enormous expansion of the trade of the colony. China too shows no sign of its commercial, industrial, and productive capabilities having in any way taken a turn for the worse by the depreciation of the silver monetary unit of the country. The contrast between the universal depression prevailing in Java, and the prosperous times falling to the lot of the neighbouring British Colonies and China, has aroused, among the producing classes in that island, strenuous opposition to the currency system enforced there. By keeping exchange quotations high, it places Java at a disadvantage with respect to other producing countries, where the low exchanges ruling have marvellously stimulated the turning out of export articles. In Java, exchange rates have kept at almost stationary figures during the last twelve years, so that producers and exporters there have not benefited one whit by the steady fall of gold prices in the consuming markets. A consignment of Java produce realising in London say £10,000, does not yield the Java planters or shippers a larger quantity of guilders than it used to do before the fall in silver set in, namely 117,500 or 120,000 guilders Netherlands India currency. But at the same time, a similar amount of £10,000 remitted to India at the rate of 1s 5d per rupee brings R141,176 against 100,000 rupees only in bygone years, when that coin stood at 2 shillings. The fall in exchange benefits British India producers by about 40 %. The adoption of gold as standard of value has deprived Netherlands India planters of a similar benefit. They have to put up with every fall in the gold price of their goods, without finding any adequate compensation in a low rate of exchange, by which exporters and producers in India and Ceylon have profited so largely. However harmful the existing currency system may be to the planting and exporting interest in Netherlands India, the author of the pamphlet is dead against a return to an exclusive silver standard of value on the ground of its detrimental effect on the native consumers of imported articles. With an exchange rate of 30 to 35 per cent to the disadvantage of importers, the prices of imports must be raised proportionately, if the trade is to be continued at all, and, the bulk of imports being intended for consumption by natives the latter would, for the greater part, have to bear the burden of the general rise in prices, consequent upon the readoption of silver as a standard of currency. Supposing for instance the native community be taken as paying one hundred millions of guilders a year for imported articles, about thirty five millions more would have to be laid out on the same quantity of commodities, in case the rate of exchange be regulated by the actual price of silver. These figures speak too eloquently to admit of enlarging any further on the baleful effect on the condition of the people of Java sure to follow a change in the direction indicated. This change resulting as it certainly would in capital invested in industrial enterprise becoming depreciated 30 per cent in value would despoil the owners of the same by an equivalent percentage. The same hardship would be felt by all persons living on fixed salaries. As will have been seen Mr. Van den Berg goes upon the sound principle that the good of the bulk of the community, sure to be the losers by low exchanges, should countervail the benefit a few derive from a depreciation of the standard of value.

COFFEE; A STUDY.

Le Cafe—Etude Historique et Commerciale—Tournai 1886.

(*Translated for the "Ceylon Observer" from the "Indische Mercuur," 19th Feb. 1887.*)

This little book written by a wholesale dealer in coffee, and addressed to his customers is, in its way, very interesting, as it treats rather fully of the origin of the use of coffee in the various countries in which it is produced, and of the different peculiarities of each kind.

The writer mentions all the sources whence he has derived his information, and happily eschews statistics, so that the little work affords pleasant reading to the trader as well as to the consumer.

The writer is, however, not always correct, thus for instance in page 18 he refers to Java and Batavia as if they were two separate islands. He considers that 40 years is much too long to adopt as the duration of the coffee tree, and in page 23 he tells us that the coffee of Ceylon and Java is yellow or white, while the Brazil kinds are green. This may be partly true as concerns Java; but Ceylon almost always comes under the head of blue. In his account of the methods of preparing coffee he omits all mention of the West-Indian system, and of its being exported to Europe in parchment, (horn shell) of which he seems to be unaware. In page 52 he speaks of Liberian coffee as having an excellent flavour—d' un gôut excellent—an opinion in which we of the seaports do not join, any more than in the expectation that this kind will be exclusively the coffee of the future.

In page 72 he says :—"The Dutch were so much struck with the perfection of the Brazilian produce, that they sent Mon. van Delden Laërne, a notable specialist, to study the preparation on the spot. ("Les Hollandais onlété tellement pappés de la perfection de la production Brésilienne qu ils out enveyé M. v. Delden Laërne, spécialiste notable pour l' étudier sur place.")

This was not the object of the mission, which was rather to ascertain how far the cultivation in Brazil was capable of extension, and for the general information of our Government.

That Brazil coffee is as good as private Java coffee and far better than Java Government coffee I cannot admit—although I am obliged to acknowledge with much regret the truth of the statement to the effect that Government Java coffee has been losing in quality whilst that of Brazil has by means of a better system of preparation been improving from year to year.

The writer goes on to inform the lover of coffee that he should always have a good supply of the raw material in store, as this article improves with age, and as in the

case of wine, coffee should be used when six, eight or seven more years old.

He greatly extols Maragogipe coffee for its flavour—and predicts large importations of it.

That Java coffee generally goes under the name of Cherebon coffee, I must contradict—such may be the case in Tournai—but certainly not generally.

In page 86 he treats of Padang-coffee and classes it in appearance and flavour far behind Java, in this the Americans will assuredly not agree with him.

Under the heading of Sumatra coffee, he says Bugis (probably meaning Bungi) and Bally coffee are placed, and in this he is very ill-informed—he places both in the same class, and calls them very bad—and names Singapore as the port of discharge. All he says of Macassar coffee is, the coffee of Macassar which likewise is found at Singapore is very superior to the Bugis and Bally coffee, it resembles that of Java, but like that of Padang the flavour is not so fine. ("Le café Macassar que l' on trouve aussi à Singapore est tres superieur aux bugis et bally, it ressemble au Java mais, amme le Padang, il est moin fin de goût.") Altogether the little work impresses me with the idea that the writer is least posted up in the matter of the different kinds of coffee which are produced in Netherlands India. W. H. JR.

HINTS FOR DRAUGHTSMEN.

The surface of a sphere equals the square of the circumference multiplied by 0.3183.

The diameter of a sphere equals the square root of its surface multiplied by 0.56419.

The side of an inscribed cube equals the radius multiplied by 1.1547.

The diameter of a circle equals the square root of the area multiplied by 1.12833.

The diameter of a sphere equals the cube root of its solidity multiplied by 1.2407.

The circumference of a circle equals the diameter multiplied by 3.1416, which is the ratio of the circumference to the diameter.

The area of a triangle equals the base multiplied by one-half of its height.

The diameter of a circle equals the circumference multiplied by 0.31831.

The side of an inscribed equilateral triangle equals the diameter of the circle multiplied by 0.86

The surface equals the product of the diameter and circumference.

The radius of a circle equals the circumference multiplied by 0.159155.

The circumference of a circle multiplied by 0.282 equals one side of a square of the same area.

The area of a circle equals the square of the radius multiplied by 3.1416.

The square root of the surface of a sphere multiplied by 1.772454 equals the circumference.

The area of a circle equals one-quarter of the diameter multiplied by the circumference.

The area of an ellipse equals the product of both diameters and .7854.

The radius of a circle equals the square root of the area multiplied by 0.56419.

The circumference of a sphere equals the cube root of its solidity multiplied by 3.8978.

The side of a square equals the diameter of a circle of the same area multiplied by 0.8862.

The side of an inscribed square equals the diameter multiplied by 0.7071.—*Mullen's Pattern Making.—American Cultivator.*

THE MAHWA TREE.

We copy the following interesting letter from an exchange:—Taking advantage of a wet holiday, and prompted thereto by Mr. Maiden's interesting letter in your issue of December 15, I beg leave to give a few additional items about the Mhowa tree, a very old and well-known friend of mine. Nearly all the wild animals of the jungle are attracted to the vicinity of these trees during the flowering season. By day, parrots, minas, hornbills, pigeons, and other birds, keep up a perpetual motion and clamour as they flit about, darting round hither and thither, and hopping from branch to branch, feeding on the succulent flowers. As night falls, wild hog, deer of various kinds, and even jackals come to feast on the fallen blossoms, and not unfrequently the sloth bear and the big black bear meet beneath the odorous branches, and get almost tipsy on the intoxicating mass of withered blossoms which carpet the sward.

Attracted by such a surfeit of game, the tiger and leopard will often pay a prowling visit, and, therefore, every sportsman is keen to note the neighbourhood of a Mhowa tree, and every native Shikarree, or hunter, can tell with unerring accuracy in what parts of the forest they are to be found. This, of course, refers to the wild parts of the forests where population is sparse.

The tree is not unlike our oak in form, size, and the colouring of the foliage. It flowers in March and April. As the flowers ripen the corollas become fleshy and tinged with the juices they secrete; they then gradually loosen from the calyx, and, falling to the ground, are, in Central India, and in many other parts, carefully gathered by the women and children, the grass round the tree having been previously burnt off, so that none of the precious blossoms may be lost.

In my book on the Nepaul Frontier, p. 106, I make reference to the tree, and speak of the spirit which the natives distil from it, and have said, "The peculiar sickly smell of the mhowa, when in flower, pervades the atmosphere for a great distance round, and reminds one forcibly of the peculiar, sweet, sickly smell of a brewery.

The spirit distilled from the freshly-dried flowers is called, by the natives daru. It is usually diluted with from five to ten times its bulk of water, and is then sold at about a penny per quart. It is largely consumed by the lower caste natives, and, in times of severe droughtiness, when nothing better can be obtained, I have seen "Tommy Atkins" imbibing the vile-smelling potation in the bazaars, holding his nose meanwhile in mute protest against the too aggressive odour. "One hundredweight of flowers is said to yield from four to six gallons of proof spirit. The very carefully-distilled and rectified spirit, if put into oak casks, becomes of a yellowish colour with keeping, and is said to be little inferior to the best Irish whisky.

In France, after a long course of experiment, a means has been found of rectifying the spirit, and the bad smell is entirely got rid of. The result is very good alcohol. In 1884, I gather from the *Indian Agriculturist*, that mhowa flowers were exported to Marseilles for distillation, to the value of 6¾ lakhs of rupees.

"The oil is manufactured from the seeds by bruising, rubbing, and subjecting them to heavy pressure. It is a coarse sort of oil," says the authority I am quoting, "but in the manufacture of soap is largely used in the country, and also for candles. For that purpose it would be worth in England from £25 to £35 per ton. It has been tried by candle manufacturers, and pronounced very suitable and a valuable oil for such purposes."

The tree is a hardy one and even in poor ground flourishes well. It readily propagates itself by seedlings. According to Lieutenant-Colonel Miller, officiating Political Agent at Bhopawar and Commandant of the Malwa Bheel Corps, not more than 40 trees could be planted to the acre, and the yield per tree appeared to vary from about 120 to 240 lb. of flowers. If it be true that the flowers contain about half their weight in sugar, this would mean a yield of one or two tons per acre; but as Mr. Maiden justly says, the idea of mhowa sugar becoming a commercial rival to cane or beetroot is ludicrous. Mr. William Fox, F.C.S., of the laboratory, Great Tower-street, London, submitted the flowers to analysis with the following result:—Honey, 42·03 per cent; cane sugar, 1·04; ash, 2·32

cellulose, &c. 42·20; water, 12·41; total, 100·00. No grape sugar was present. He adds:—"It will be impossible to make ordinary or cane sugar from a substance yielding the above results. The sugar contained in the mhowa can only be utilised for brewing or distilling purposes. The flowers, I may add, are all male flowers."

Yet another authority writes thus:—"When dried, mhowa flowers rather resemble inferior figs. When fresh they have a sweet taste, but by no means agreeable odour. The fruit succeeds the blossom. It is about the size of a very small apple, and the kernels contain oil, which is of an inferior colour, and rancid taste, but is very generally used by the poorer natives for lighting purposes, as well as for cooking; and it is also applied externally as a remedy for wounds, sores, and cutaneous diseases generally."

Lastly, I may mention that I know, from my own experience, that the leaves and flowers, mixed with bamboo leaves chopped straw, dry grass, dry stems of maize or sorghum, no matter how dry, or old, or musty, forms a capital food for bullocks or stock generally, and in seasons of scarcity, the tree will withstand long continued droughts; it should be experimented upon, and attempts should be made to introduce its acclimatistation here. And this leads me to my et cetera.

Your London correspondent went too far when he spoke of "five mhowa trees yielding the same amount of sugar as an acre of sugar-cane." Nevertheless, the mhowa is a very useful tree. The leaves and flowers make an excellent fodder, as has just been stated; the tree itself is strikingly ornamental; it will grow in poor soil, and withstand long droughts and extreme heat. It is but a type of hundreds of other trees fit for "industrial culture in extra tropical countries," as Baron von Mueller terms it.—*Planter and Farmer.*

DESICCATED COCONUT.

It used to excite our juvenile wonder when we were informed as to the many uses to which the palm was applied by Oriental nations. That one single tree should in its various parts have so many virtues, and be capable of so many applications was almost incredible. But years have passed away since then, and such wonders have ceased to astonish. Were it not so the modern uses of the coconut would make us open our eyes. At one time a coconut was a coconut and nothing more. When its milk had been extracted, and its snow-white kernel eaten, there was an end of it, except as, occasionally the shell was transformed into a child's toy or a drinking cup. But now these simple uses are almost too rude and elementary to be mentioned at all. This versatile fruit performs for us so many services, and has, by the ingenuity of modern civilisation, been turned to such varied account, that very few, even amongst intelligent and educated people, would like to be compelled on the instant to pass an examination on the uses of the coconut. One of the forms in which it is most pleasantly utilised is that manufactured by Messrs. Linton, Hubbard and Co., 18 and 19, Red Lion-square, London, W. C., whose "Desiccated Coconut" ("Noix de Coco" Brand) is so largely used in manufacturing and culinary purposes. The Coconut Biscuits, which are so delicious, and have come into such great popularity within recent years, are made of this delicate and palatable preparation; all well-known biscuit firms use large quantities of Linton's Desiccated Coconut. It is also largely employed by chocolate manufacturers, and by confectioners generally in the production of those charming sweetmeats which have displaced to so great an extent the old-fashioned lozenges and sugar-plums that used to be the delight of our children. Beyond these uses, however, it is worth the notice of householders, refreshment contractors, and hotel-keepers, as supplying the material for a great variety of dainty dishes which cannot fail to be acceptable to the most fastidious tastes and stomachs. By its aid, for example, we can have a delicious Coconut Tart, or the most elaborate Coconut Meringue Tart; or it may take the form of a nutritious pudding, or custard, such as would tempt the appetite of the most delicate invalid and do much to supply the nourishment which such a person requires. Indeed the ease with which the "Noix de Coco" is digested, combined with the large amount of nourishment, renders it peculiarly useful in hospitals and for sick cookery everywhere. Again, it may take the form of a tasty and attractive-looking cake, or it may become a speciality of the dessert-table. What, for instance, do our readers think of this little recipe? "Place a layer of sliced oranges in a deep dish, sprinkled over with fine white sugar; then a layer of Noix de Coco; alternate orange, sugar and Noix de Coco, until the dish is full, heaping Noix de Coco on top." We commend the idea to those who may be on the look out for something new and nice wherewith to please their guests. Eaten with cream or milk the Noix de Coco form a delicious dessert without any special preparation, or it can be served in a variety of ways. We have indicated but very few. Any cook who is worth the name will readily find by a little experiment many effective modes of dealing with it, and will be glad to have added to her resources a material which can be so easily manipulated, and which will yield so much satisfaction at the expense of so little trouble.

This Desiccated Coconut or Noix de Coco, is prepared in various forms for manufacturing purposes and sent out in barrels of about 200 lb. each, also in 56lb., 28 lb., and 14 lb. tins. The Noix de Coco for making puddings, tarts, cakes, desserts, ices, &c., is also put up in very attractive, handsome decorated canisters of 1 lb. and ½ lb. each. Again, it is supplied in paper packages with attractive lable in cases of 24 1 lb. packages or 48 ½ lb. packages.

In closing our notice, we may say that Desiccated Coconut is also manufactured by several firms in New York, but the resultant product lacks the properties of Messrs. Linton, Hubbard and Co.'s preparation; as the American is badly adulterated with unwholesome compounds, and is made principally from rotten and stale nuts, which are bought for this purpose at a cheap rate; whereas the firm we are noticing use only the best nuts procurable. Two samples have been examined by us, and the one of English manufacture had a crisp snow-white appearance and pleasant odour of coconut, whilst the American sample was manifestly discoloured, and as manifestly not sweet. Our railway refreshment managers should certainly take note of Linton's Desiccated Coconut. We should state that this firm are the only manufacturers of this article in the United Kingdom.—*Railway Supplies' Journal.*

Successful experiments are said to have been carried on in the Island of Hawaii with tea plants from India and Japan, the latter variety being the better adapted to the soil. A large tea plantation is said to be proposed.—*M. Mail.*

Laudanum-Drinking Extraordinary.—A case of a woman who had for forty years been addicted to laudanum-drinking, and who consumed regularly half a pint of the drug, or ten ounces, daily, was reported to the Solihull Board of Guardians on February 9th as having been admitted to the workhouse. The medical officer was instructed to continue an allowance of the drug or stop it at his discretion.—*Chemist & Druggist.*

Tea.—In a conversation with an Officer who has been some 12 months in Burmah, we were surprised to find that there are several Tea gardens on the hill sides between Prome and Tonugoo in British Burmah. They are said to have been opened up by Indian Planters, and are now doing very well. There is a fair supply of labour at a low cost, and easy means of transport to Rangoon by either river or rail. Notwithstanding things are so unsettled in Burmah, many Englishmen are arriving in the country ready to open up trade or land. Some, we hear, have already hit upon a "good thing."—"Ceylon Advertiser."

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, March 3rd, 1887.)

CEYLON UP'COUNTRY PLANTING REPORT.

LOW PRICES FOR THE CEYLON NEW PRODUCTS IN LONDON—SATISFACTORY RESULTS OF A CINCHONA PLANTATION AND BARK ANALYSES—THE WEATHER : ? ROMISE OF RICH HARVESTS.

28th March 1887.

The late news that tea was down 2d a lb. all round; that cinchona had dropped ¾ of a penny; and that cacao was receding in value was pretty good for one week. The only comfort is that that kind of thing can't go on, but a little of it goes a long way. In these days there is really more excitement in tropical agriculture, than in a gambling table; and although the planter's life is supposed to be a quiet one and his daily occupation void of the fever of commerce, still his waters are troubled now and again, and the fluctuations in the value of his products are so violent, as to upset his calculations and make him feel that ordinary forethought goes for little, and that to be in a state of preparedness for the time he would need to be a prophet or seer of some kind. If the mantles of these long-headed fellows could be imported for the rise of the planting community what a run there would be on them, and what a comfort it would be to get into one.

As an example of the upsetting of a basket of eggs the following figures which are authentic, tell their own tale. Eighteen months ago, there was a parcel of renewed succirubra bark about, 5,000 lb. in weight, sent to Colombo, which showed by analysis the fine outturn of 4·35, and was sold at R1·45 a pound. The Manager of that place was more than delighted with this fine result, and for the last year-and-a-half he has guarded and cherished those trees, as he would an Eldorado. He shaved them again the other day, with hope in his eye, and a vision of funds cheering his heart, and harvested quite as much as before. But from the time he parted with his bark he has had no comfort, for the analysis came up showing 2·20 as against the former 4·35 and whereas the old price had been R1·45 a pound, the broker valued the parcel in Colombo, at 34 cents if sold at once, and he recommended that he should sell! It is when you extend these figures that the superb beauty of the contrast is shown thus:—

5,000 lb. sold 18 months ago..	..R7,250·00
5,000 lb. from same trees worth today..	1,700·00
difference.. ..	..R5,550·00

In this Jubilee year it is perhaps as well that things should be "done handsome" and there is no one will dispute that the figures above are a step in that direction, as a record of the "downs" which the Ceylon planter is subject to—the "ups" he takes more philosophically. I suppose there is nothing specially unique in this, others might tell similar tales. It must, however, be a comfort to the growers of cinchona, that if the experience which I have just chronicled is to be looked for, the export of bark will fall off in time, for it would lead one to believe that one has but to keep one's trees long enough to find them worthless. The behaviour of the manager under his severe disappointment is worthy of all praise. He did not swear at the analysts, as some people do, nor, take up his parable against "those Colombo fellows" which is always a relief to the heart of the stricken planter. No, he sat for a time speechless in the gloom of his depression, and by-and-bye consoled himself with music, for which there are historic precedents. The instrument which is his favourite in his darkest hours is the penny tin-whistle, it is easily learnt, and can be carried about without trouble, and, as he says, "if things go on like this, one never knows what one may have to do to get a living." I suggested that perhaps he might teach his dog to carry "a tinny" in his mouth, for if he succeeded he could then laugh in the face of adverse fortune. When I left him his spirits were steadily rising, and this spite of produce declining all round: but the dog was on his haunches.

This "tropical winter," which was broken a few days ago by welcome rain, seems to have set in again with great intensity. Everywhere there is blossom and flower, and a promise of a rich harvest of fruit. In the matter of coffee, alavanga pruning is evidently going out, and the old methods are being reverted to. But the bug, will that keep away? It is about, and in pretty strong force in some places; but you have to look for it, as the black fungus, which is its baneful shadow, seems to find a difficulty in developing in these dry days, and attention is in consequence less liable to be directed to the presence of the plague. If we are spared an infliction of the pest—and even with that our place would still not be among the highly favoured, as we have plenty of other things to bother us—the coming crop of coffee may be expected to be better than we have had for some years.

PEPPERCORN.

LETTERS FROM JAMAICA:—No XVI.

WEATHER AND CROPS—BANANA CULTIVATION—BUILDINGS.

Blue Mountain District, January 1887.

DEAR SIR,—Since I last addressed you the weather has improved, but it is not yet as settled as could be desired for the "curing for market" of our lower field crops. The weather is very cool, cloudy and pleasant, with occasional light showers, but the sun does not shine continuously all day long: yet when it does come out it seems very fierce for the time of the year. This month usually brings cold winds and hot sun, as it does in Ceylon, and an occasional "Norther," one of which visited us on the 18th-19th and was very strong indeed, and must have done a good deal of damage in exposed places. What causes these occasional wind-storms puzzles me, unless it be the absorption of air into some place where evaporation is constantly occurring.

Crops, judging by my own *lower* fields, have been very good for settlers, especially as they are getting 7s a tub (two Imperial bushels) for their cherry coffee, the price in London being still 64s per cwt. for ordinary Jamaica coffee in bags. What prices will eventually be realized by those who are buying largely, must be causing anxious qualms, for it all depends on the Brazil crop; for if news came of better supplies down would go the market, but we must hope Brazil has seen its best days as regards its slave-grown coffee, and that the West Indies, and other producing countries, will once more have "a good innings."

Three miles farther on brought us to our destination, "Water Valley." We passed some banana walks and sugar-cane fields, all looking very fine, for St. Mary's and Portland are considered the best soil for bananas as well as for sugar, the land being very rich and fertile. During our visit we rode one day into Annotto Bay: it is a mere hamlet as to size and houses, but there is a fine church, a court-house and police-station, barring the Fort and the old Dutch houses. It reminded me somewhat of Matara, as there are no less than three rivers emptying themselves into the

sea, in this scattered township, like our Ceylon back waters. Another excursion was to Port Maria, the "capital" of the Parish: this is as yet the prettiest spot I have seen in Jamaica; picture to yourself a very pretty Bay, with a small islet in the centre, overhanging cliffs, a deep blue Mediterranean Sea, so that were it not for tropical surroundings one might be supposed to be in Cornwall, or Guernsey. Indeed the country for some miles before reaching Port Maria has quite an English look, favouring our Sussex and Surrey hill slopes, and the splendid pastures in which cattle, sheep and stock generally are seen browsing so contentedly. Of course, the sugar, the palms and the bananas break the "home spell;" nevertheless it it is all very pretty. From the Rectory, situate on a hill overlooking the bay and town, the sight is very picturesque: you thence look down upon the pretty Church close by the sea, the fine Court-house, the police station, Wesleyan Chapel, and clean-looking little town, well supplied with water, and boasting two or more fountains. Beyond is a second small Bay or cove; here we lunched and could have fancied ourselves back at Kalutara, or Bentota, as we sat under the shade of the cocoa-nut trees, the waves almost washing our feet. Another visit I paid was to "Claremont," once the residence of the East family (of Tom Cringle's Log fame) in the grand old times; fancy an upstairs house which as you ride up to it, recalls memories of the Pavilion, Kandy, though perhaps not quite as large, but the lower story uninhabited and fast going to decay. These old Jamaican "Nabobs" (to use an Indian term) lived like princes. This property some thousand acres in extent was bought not so very many years ago for £500, house and land full of valuable log wood, trees, and valuable also as a capital grazing pen, and Banana "walk;" but good parochial roads is Jamaica's great want to enable planters to get their produce safely and cheaply to the shipping ports. This log wood, together with the bananas, has been the mainstay of many sugar planters, since prices of sugar fell so very low. It grows, as I have already stated, indigenously and £1 10s. a ton can be cleared off it, delivered at the wharf. As to sugar not paying, I was told it could be produced for about £10 a hogshead, nearly its present value in the market; but when the rum is taken into account it becomes a valuable factor, as it can be produced at a profit of £5, a puncheon, thus leaving the planter something at least to live upon. In good seasons, bananas are also very profitable, yielding all round about £10 the 100 bunches; the price is highest during the summer months up to August. But in all tropical countries one must be prepared for damage by storms floods and hurricanes, and when they are out they sadly damage the planters' prospects. Still we should not grumble for even European countries are subject to like contingences. Witness the late dreadful gales in England which have done so much damage to shipping, and gardens and horticulture generally, branches of fine trees being broken down by the heavy weight of snow.

W. S.

CHINA TEA AND ITS RIVALS.

The cultivation of the tea plant is extending so rapidly, and is being commenced in so many countries, that the Chinese tea growers will have to look seriously to the improvement of their stock, and the Chinese Government will equally have to see that the export duties upon the leaf are not made so heavy as to serve to place it at a disadvantage in its competition with the tea of India, Japan, Java, Ceylon and South Africa. That the product of China is gradually losing ground in the English market, and its place being taken by its younger rivals will be seen by a glance at the imports into the United Kingdom during the past three years, which are as follows:—

	1884.	1885.	1886.
	lb.	lb.	lb.
China tea ..	140,284,000	136,523,020	140,610,749
Japan tea ..	84,000	72,760	51,200
Java tea ..	3,586,000	3,345,020	3,946,110
India & Ceylon tea	67,152,000	66,862,614	83,465,164

Thus, while the total British import has grown from 211,106,000lb. in the year 1884 to 228,073,223lb. in 1886, the increase in China tea is represented in 1886 by only 326,749lb. and in 1885 there was an actual decline in the import of 3,760,980lb. During the same time the import of Indian and Ceylon tea has increased by nearly twenty-six and a-half million pounds. Last year, too, South African tea made its first appearance on the English market, some 5,000'b. having been imported. The land under tea cultivation both in Ceylon and India is meanwhile annually increasing greatly, and it is now seriously proposed to start tea gardens in Burmah. A correspondent of one of our Rangoon contemporaries, discussing the project, says that a market would be found on the spot for all the tea that could be produced, and there would be no necessity for exporting any of it for many a year to come. "The climate and soil," he adds, "are favourable to hybridising, and in this way important improvements in quality would probably be accomplished, and the outturn per acre would soon compare favourably with that obtained in the best tea-growing districts of India." The only serious difficulty in Burmah would be the labour question, but this difficulty would not long stand in the way, seeing the vast supply of surplus labour so easily obtainable from the adjoining provinces of India. The probability is therefore that in a few years more Burmah will take a place among the tea-producing countries, and be one more rival to China. The idea of starting tea plantations in some of the Malay States has also more than once been mooted, and is pretty certain to be carried out at no very distant date. The Chinese tea-planters will therefore in real earnest have to look well to their interests. Sir Robert Hart has already administered one much needed warning that the foreign tea trade will slip from their grasp unless they make serious efforts to retain it, and the Chinese Authorities have recognised the importance of the question by issuing a proclamation to the tea-growers, setting forth the necessity of maintaining the standard of their production, but warnings on such matters are little heeded as a rule in China, the anxiety of the producers being generaly limited to the requirements of the moment. Chinese agriculturists take little thought for the morrow, and they are not only essentially conservative in their methods but greatly prone to kill the goose that lays the golden eggs. In Indian tea plantations science is brought to bear to improve the stock and to facilitate the drying and curing processes; while in China the methods of a century back are still employed, and no effort is made at improvement. The result is a complaint of deterioration of the teas, and their gradual displacement in the British markets by the carefully picked, sorted, and cured teas of India and Ceylon. The latter are also making their way in the Australian colonies. The export of Indian tea from Calcutta to Australia and New Zealand in 1886 was 1,539,530 lb. as compared with 1,867,925 lb. in 1885, and 1,029,463 lb. in 1884. In 1885 the import was rather too suddenly increased, being almost doubled, but that the leaf has grown greatly

in favour there is evidenced by the large increase last year. A few years ago the Australian Colonies drew their entire tea supply from Foochow, and the fact that the Indian leaf has found so good a market there ought to be a significant hint to the tea planters of Fohkien and Chekiang, who have so long enjoyed almost a monopoly of the Australian demand, that this monopoly is at an end and that in order to hold their ground they must carefully maintain the quality of their Congous.—*Hongkong Daily Press.*

INDIAN TEA IN THE FUTURE.

It must be a matter for anxious thought with man. Indian tea planters at the present time,—and particularly with those in hill districts, where the yield is small, and the produce lacking in strength —whether tea will pay in the future, considering how low prices now are, and the improbability of any improvement for some time to come. Supplies have been, as far as possible, kept off the market, but prices have continued to droop, and, on the 4th instant, they stood in London at levels of which there had been no previous experience. "Fannings" of Indian tea were worth 7½d per pound at the beginning of March in 1884, and last year, at the same time, they were quoted at 8½d; but on the 4th instant the price was 5¼d. Indian pekoe was worth 1s in March 1884 and 1886, but on the 4th instant the quotation was only 9¾d. The "recent movements" are said to show "very satisfactory results" as regards the consumption of Indian and Ceylon descriptions. During last month the deliveries of these descriptions in London amounted to nearly 7 2-5ths millions of pounds, or an increase of 1¾ millions as compared with February 1886. So the lower the price the greater the consumption of Indian tea. That tea planting properly conducted under suitable conditions, is a profitable enterprise, even with low prices, is abundantly proved by the dividends paid by the Assam Company, and others, as the result of last season's working. Prices for the lower classes of Indian teas have probably reached their lowermost level, though it would not be surprising if the finer kinds should experience a further decline. What sort of prospect then is held out by a consideration of the figures available? The total shipments of Indian and Ceylon teas for the present season may be put at not over 85 millions of pounds whilst China exports may be reasonably calculated at say 5 millions less than last year, in other words at 135 millions. Taking Java at 8 millions, and sundries at 2 millions a gross total is obtained of 230 millions of pounds. It is admitted that consumption has largely increased, but can it be expected to do so in such a ratio as to dispose of the quantity of tea which estimates for the future show? In the way of extension, thousands of acres have been opened in the last year or two in Assam alone; Ceylon planters talk of tea *et proeterea nihil*; whilst even Java adds some millions to its yield, according to present forecasts. It is not wonderful, therefore, that tea planters speculate anxiously as to their position in 1890. Estimates naturally vary greatly, but some approximate idea may be formed by a careful consideration of probabilities. It should be under rather than over the mark if Indian tea at that date is set down at 90 millions, Ceylon at 35 millions, and Java at 10 millions. Certain sanguine spirits have even predicted that the Ceylon yield will be nearer 60 millions than 30, by that time, but that is an exceedingly hopeful estimate. Taking the above as approximately correct, the rivals of China and Japan will aggregate 135 millions, as against the present 93, an increase of 42 millions in three years.

In spite of all efforts that have been, and may be made in the direction of new markets, consumption cannot possibly keep pace with such an increase in production, and the weakest producer must go to the wall. There seems to be no doubt as to who that weakest producer is, as India's Celestial competitor has already shewn unmistakable signs that the pace is too severe for him, and that the more it is increased, the further he will drop behind in the race China tea seems to be in much the same position with regard to Indian as cuprea bark from South America occupies with reference to Indian bark. In the latter case, when the value of the unit of quinine drops below 6d. it does not pay to send cuprea bark to the English market, though, low as prices are, Indian planters can yet dispose of any stem bark at a profit in proportion to its quality. In the same way, now that Indian tea prices have dropped to what was formerly the China level, the latter country has to retire more and more from competition. The question is, allowing for such an increase in consumption as will take off a fair proportion of the estimated increase in yield, with a sufficient quantity of China tea be forced out of the English market to allow of prices retaining their present position? It seems probable that medium class teas, such as sell at present at 8d. to 1s. 2d a pound in bond will suffer most, as they will be the ones to come most into competition with the average China tea. It cannot pay, as it is, for the Chinese to export to England their lowest classes, considersng the tax which is levied on every pound before it is shipped, thus at once placing it at a disadvantage as compared with the lowest classes of Indian tea. Really fine classes of tea have always held their own well, and such kinds from India and Ceylon, with their superior strength, have little to fear from Chinese competition. Still, the pressure in the market may lead China to make strenuous efforts at retaining her position, either by finer plucking, thereby making finer teas, and a less quantity, or by abolishing her tax on tea. The latter is unlikely; in fact, a heavier tax was proposed not long ago, and the idea was only relinquished because of the urgent representations that any additional increase of taxation would reduce the already minute profit to a vanishing point, and practically put a stop to the trade. The first supposition is more probable, and if it is thoroughly carried out, it would mean a drop in fine teas corresponding to what may now occur in medium classes. But an effort was made by China in this direction at the beginning of the present season, in consequence of influential representations, principally from the London trade, though so far without much success in inducing better prices. Machinery, freedom from local taxation, and careful management are in favour of the Indian planter; he is prepared for the struggle for existence which has already begun; and any proprietor of a good garden under proper care need not fear the result. For those, and they are too many, whose plantations are indifferent, their yield poor, and their means insufficient for proper cultivation, it would be the truest wisdom to give up at once, and look out for some pursuit which is not likely to present such a marked example of the survival of the fittest as, in all probability, tea planting in India will do at the end of a few years.—*Madras Mail.*

THE COW PEA AS A FODDER CROP.—The cow pea is one of the most valuable fodder plants for the South. We have seen a crop of peas which yielded four tons to the acre of most excellent fodder, and it left the ground in the best condition for sowing wheat. Another farmer sowed peas among his corn, at the last ploughing, covering them with the plough, and we should estimate the yield on the ground, of both crops, at a ton and a half of corn fodder, and forty bushels of peas, with the corn equal to thirty-five or forty bushels to the acre, and a large quantity of pea straw, which makes good feed. The common opinion that the South is not a stock country, is entirely unfounded. With the long growing season, the really rich, but badly managed soil, and the great variety of fodder crops and feeding stuffs, it is not at all exaggerating the matter to say, that beef cattle can be reared to one thousand pounds weight in three years, at a cost of one cent per pound live weight, and in addition, there is a large quantity of manure left, which is really invaluable to the Southern farmer.—*American Agriculturist.*

PONDICHERRY STEAM PRESSED GROUND NUT OIL.

The comparatively sudden development of the ground nut traffic in Southern India has opened out markets for the oil which but a few years ago were not dreamt of, and Pondicherry has, from the early beginning of the oil trade, taken the lead in the Indian export markets. Last year's crushing operations were restricted, owing to the unusually high price of the nut, caused by a heavy export demand throughout the whole season, and also by a decreased supply arising from inundation damages to the crops. In 1884, the total crop was estimated at upwards of 80,000 tons. Nearly 70,000 tons were exported in bulk and in oil from Pondicherry alone, and this year's yield is expected to exceed 100,000 tons, about nine-tenths of which will probably find its way to Pondicherry. Just now, however, there is a depression in the trade, in consequence of the exceptionally low quotations at Marseilles; still, there are buyers at growers' prices —mostly, as yet, for crushing and for shipment in shells to Coast ports, Calcutta, Burmah and the Straits. It is calculated that, at R10 per candy at the place of growth, cultivators can realise a fair profit so that, at the present rate of R16-12-0 per candy, either the producer, or "middle men" or both, must be making extravagant profits. Last year the price touched R22, and kept at above R20 for the greater part of the season. The rapid devlopment of the ground nut industry is traceable, in a great measure to the comparatively easy method of cultivation. Beyond the sowing and gathering of the crop there is nothing to be done; it requires no watering, and needs no tending, and, as the coolies who collect the nuts are paid in kind, the capital outlay is limited to the mere cost of labour for scattering the seed. Within the last year or two, and notably from the beginning of the present year, nearly all the Eastern Coast ports and Calcutta, Rangoon, Moulmein, and the Straits. have been regular buyers of the Pondicherry oil; even at the current high rate of the nut, it can be manufactured and sold at about one rupee per imperial gallon. The ground nut oil trade is as yet but in its infancy, and the cheapness and purity of the article, together with its unquestioned general usefulness as a *cuisine* commodity, must cause a steadily increasing demand for it.—*Madras Mail.*

TEA CULTURE IN SOUTHERN STATES OF AMERICA.

BY MRS. D. WALKER.

In one of last year's numbers of the *Gardeners' Monthly*, I gave an account of the success of our tea plants, which this autumn are profusely covered with bloom and buds. The bushes have much increased in diameter, are perfectly healthy, strong and vigorous with dark heavy foliage. They seem impervious to drought and floods, and vie with our native evergreens in beautifying the garden.

Now, about planting the seeds collected last year from our own bushes. The ground where they were to be planted was thoroughly mulched, the soil naturally being very sandy. The seeds were dropped on the ground and left uncovered. No further care was given, the weeds for the whole of the past season not being removed.

And this time, there are a hundred or more fine thrifty plants covering the spot; proving, indisputably, that tea can be grown in this State, and surely such an industry should not be overlooked. What difficulty could there be in importing some Chinese who are accustomed to the manipulation of the leaves; and, in short, understand the proper process of preparing the tea for market?

Assam and other East Indian teas are largely imported into Europe, and commonly drunk. There can be no doubt as to their excellent flavour. While in England this summer, I drank Assam tea every day, and thought it much superior to our ordinary black tea, for which we pay (retail) $1·10 per pound.

Another fact is worth reporting. In England, the duty on tea is twelve cents a pound; here there is no duty, and good tea is far more expensive than abroad.

[This note is very acceptable as keeping before the community a topic it is apt to forget. There is no reason for doubt that the tea plant will grow as well, and produce as good tea in portions of the Southern seaboard States, as in China. The whole question is reduced to one of cost of production. The introduction of Chinese labor would not help the question in the least. All experience has shown that every new locality must be a law unto itself. In the early history of vine-growing in America, it was thought essential to import vine dressers from the vineyards of Europe. Their art was of no value here, and vine-growing was not a success until we cut loose wholly from the experiences of the old world. The most successful vineyardists of to-day never saw the old world. And this must be true of tea culture. When some enterprising young man shall take hold of the tea question, note well just where its weaknesses are, and go resolutely to work to strengthen these points, tea culture will be one of the most profitable industries of theSouth. And that person and that time will surely come.—ED. G. M.]—*Gardeners' Monthly.*

THE SPONGING SEASON AT BAHAMAS.

An old and valued contributor to this paper, now Governor of the Bahamas, sends to this month's *Fortnightly Review* an excellent description of those islands, and we shall be surprised if the varied allurements which Mr. Blake holds out do not cause some of his friends to go over and pay him a visit. Among other things he describes the sponge fishery.

"From October to July the sponging season is in full swing. There are over five thousand men and boys engaged in the fishery, each schooner carrying a crew of five to seven. The sponges are found all over the banks, which vary in depth from two to four fathoms. The fishing is managed on the share system, the crew being thus directly interested in the success of the voyage, which lasts about six weeks. Arrived on the ground, the small boats, of which each schooner carries two or three, put off, manned each by two men, one of whom sculls, while the other, armed with a thirty-foot pole, bearing at the end a double hook, lies extended over the bow, and examines the bottom through a "sponge glass," or bucket with a glass bottom. Laying this upon the surface, everything below is seen as clearly as if no water intervened. Even in fifteen and twenty fathoms the bottom can be clearly seen and examined. The sponges when found are hooked up by the armed pole, and as soon as the schooner's deck is filled she sails away to a "ranche," where she deposits her now evil-smelling load in a "crawl," or enclosure of wattles in shallow water, where it remains for a fortnight, during which the crew are fishing for a fresh cargo. On their return all hands enter the crawl and beat out the now-rotted fleshy part of the sponge, which, when first gathered, presents the appearance of a round mass of dark indiarubber freely perforated. When the fleshy part has been thoroughly removed and the marketable skeleton washed, the heap is laid on h ore in a secluded spot, while the lot that has taken its place remains in the crawl, and the schooner starts again for the sponge banks, At length enough has been gathered and cleaned to load the vessel, when the sponges are sorted by the crew into glove, reef, lambs, wool, grass, &c., and each kind separately strungs in rings of from one to two dozen. In this way they are sold by auction in the sponge exchange, when the first step of the preparation for the consumer is carried out by the sponge merchants. The sponges are exposed to the sun to improve the colour. They are then clipped and all irregularities and pieces of shell or rock removed by the clipper, and once out of his hands they are, so far as the Bahama sponge merchant is concerned, ready to be pressed in bales and exported.

It would be a good thing if all Governors of the Queen's dominions abroad sent to Mr. Escott equally readable accounts of the countries which they rule. It is well known that they are not as a rule overburdened with work.—*Pall Mall Budget.*

CASUARINA EQUISETIFOLIA.

We think the fashoinable fad of Bengal Forest Officers in laying down the general principles of forestry as they hold good in India according to their lights, a great waste of time. Most of the conclusions arrived at are erroneous and must be productive of on little mischief. Forestry is an eminently empirical science, consequently its general principles must be derived from actual experience, and until we have a sufficient store of experience, it is of no use to attempt publishing a general hand-book on forestry as applicable to India. If the object is, on the other hand, to give the general principles of forestry as applied, say to France or Germany, it would be much better to translate one of the leading hand-books of those countries on the subject, or, if necessary, to translate extracts, rather than to attempt the production of a faulty book, which gives itself the appearance of being based on Indian experience, whereas in reality all the difficult points on which Indian experience is wanting are studiously passed over in silence. Our remarks are called forth by some astoundingly incorrect statements which are given as matters of fact in the work of a Bengal Forest Officer who is considered an authority on most planting matters. This gentleman discourses on our well-known Casuarina in the following amazing terms: "the *fabulous* growth of the *Causarina equisetifolia* reported from the Madras Presidency, which, however, is still an *exotic*, &c." Why "fabulous" and why an "exotic?" This leads to the consideration of another assertion on the same subjet which can only be propped up by a maintenance of the most extreme views with regard to acclimatization, or to speak more correctly, lasting introduction, namely, that a permanent and independent position in the new country's flora, like the American Water-weed in English canals or the Australian Wattle (*Acacia Dealbata*) on the Nilgiris. Accepting any definition short of this, *Casuarina equisetifolia* is not an exotic. Though we cannot positively assert that natural reproduction may be reckoned on in a Casuarina plantation, we have good grounds for believing it, at least in the ordinary climate of the Mysore plateau and North Arcot District, beyond which our observations have not extended. In the Bangalore plantations it has been planted pure and made unprecedented growth, which we submit, is a crucial test, the more so as the rainfall seems to be very irregular in most of them. It is certain that in Mysore generally the tree seeds plentifully and produces a crop of seedlings wherever the ground is in a fit state to raise them. Hardihood is a test of successful introduction, and here no arborial species can surpass it over so large an area. Growing magnificently along the sandy shore of the Madras coast, it is quite at home and makes excellent growth on the hard loams and inland climate of Eastern Mysore whence it extends West with its graceful pine-like foliage, in a country where no Conifers are, into a damp climate where few of its late companion species can follow it. At Cotacamund, with a mean yearly temperature a few degrees above that of London, the same wonderful tree turns up again. We may well parody a trite saying by describing it as "all things to all climates."—*South of India Observer.* [If *Casuarina equisetifolia* grows well in Ootacamund, it surely ought to flourish at our highest elevations in Ceylon. What is the highest elevation at which it has been tried. There are species which grow well at high altitudes for a few years and then die out. –ED.]

THE USES OF LIME.

Lime should never be ploughed under, but kept as near the surface as possible. Your directions are precisely right; viz., "spread it evenly in a finely pulverized state and diffuse it well in the soil by harrowing. That is the proper practice, and it is exceedingly rare that when lime is thus used it is not found to be of great service to the crops, especially clover and grass. And as clover and grass are—so to speak—the underpinning of a successful rotation, this is exceedingly important. But farmers are much aided by reasons why things are thus or thus, and minute directions how to secure certain conditions. Now, I would like to give M. P. R. not only my experience during several years, but reasons why lime is useful, and directions how to procure the requisite finely pulverized condition, and its intimate diffusion in the oils.

First, there is a good deal of misapprehension regarding the effect of lime as a fertilizer. It has long been, and now is—by many persons—thought to be a stimulant to the soil, and, therefore, a dangerous substance to use. This is by no means true. It is partly true, and as it contains a little truth, it is, like a little knowledge, a dangerous thing. Lime is a direct and indispensable plant food. This is evidently proved by the following figures, showing the percentage of lime contained in the ash of—

Clover	27 to 40
Potato vines	39 to 46
Turnip leaves	32
Rye straw	7¾
Corn stalks...	10½
Pea straw	38
Hop vines	17
Tobacco	37

Moreover, there is not a plant or any part of a plant that does not contain more or less of lime; this is not surprsing, when it is considered that as animals feed upon plants, and the bones contain about 50 per cent in round numbers of lime; and if the soil is deficient in it, of course the plants do not thrive, and cannot, however much of the other needed elements of plant food the soil may contain. For if one is deficient, the plants cannot make use of the others. The lime also must be soluble, and it is only soluble practically in a caustic or fresh state, and is practically insoluble in its mild or carbonized state. For instance, if a small quantity of fresh lime be put into a barrel of soft rain water, the lime is dissolved, and the water becomes hard; but if a large piece of marble, which is carbonate of lime, be put into the water, the lime is not dissolved, and the water remains soft and pure.

Second, lime is not only a plant food of itself, but it has a strong decomposing action upon fresh organic matter in the soil, and quickly reduces it to a condition in which it is available as food for plants; moreover, it aids greatly in what we call the nitrification of organic matter; that is, the development of nitric acid from nitrogenous organic matter, and the formation of nitrates in the soil, which can be taken up by plants. This is the way in which it is supposed to act as a stimulant; but wrongly so. It is rather an exhaustive agent in the soil, because it rapidly makes soluble and available organic matter, which would otherwise remain longer in the soil, and only become available slowly. Lime is therefore a most valuable addition to a richly manured soil, or to land that is rich in vegetable matter, as newly reclaimed and drained swamps. But caution must be used to feed such a soil well, as—to use a familiar simile—its powers of digestion are very strong indeed and it calls for more food in proportion.

Third, lime also exerts a chemical action upon the mineral particles of the soils, dissolving their silicious surfaces which hold potash and phosphoric acid, and freeing these invaluable substances so that they can be appropriated by the roots of the crops. This is not an exhaustive process, because it is exerted upon an inexhaustible store of material, and as long as any soil remains, this process can go on without danger of exhaustion.

Lime is, therefore, useful in any soil in which it does not already exist in a soluble condition. It is more useful, perhaps, upon stiff clay soils, because it loosens and opens them, and makes them porous and gives admission to the air, than upon sandy soils. It is most useful upon the feldspathic and micaceous clay soils, or sandy loams, because these minerals contain from ten to eighteen per cent of potash, insoluble without the help of lime. It should also, therefore, be used in the finest possible state of division, which is secured by air-slaking, and be most intimately diffused in the soil, that its action may be as effective as possible.—*Southern Planter.*

COCONUT FIBRE.

It was Linnæus who first called the Palms the "princes of the vegetable kingdom," but it has been reserved to writers of the present day to designate the Coconut and the Palmyra respectively the "prince of Palms;" which of these two plants, however, is most entitled to the term it is difficult to say for we read that the Palmyra (Borassus flabelliformis) has been immortalised in a poem in the Tamil language, and though 801 uses of the Palm have been thus recorded the list is by no means exhausted. Whether it be possible to enumerate so many uses for the Coconut Palm (Cocos nucifera), I have not been at the trouble to inquire, but I venture to believe that for sterling value as a commercial plant the Coconut can compete any day with the Palmyra, or any of its allies.

It would seem that with a plant so well-known as this, and about which so much has been written, nothing now remains to be said. It is an old story to be told that the outer husk yields coir; that the inner hard shell can be, and is generally carved into ornamental cups; that the kernel of the nut itself is edible when fresh, and that it yields large quantities of oil when dried. These are facts known to all who know a Coconut when they see it, and what schoolboy is there who is not acquainted in some way with this familiar nut? But each one of its uses might be dilated upon, and to use an oft-repeated term, "volumes might be written" upon each; but our business at present is only with the husk, apparently a minor portion of the Coconut, commercially considered A glance at the engraving, however, will show that a large trade must be centred about these "unconsidered trifles," and that such is the case, I shall endeavour to show by briefly recording what I saw on a visit to the Coconut fibre works of Messrs. Chubb, Round & Co., situated in the West Ferry Road, Millwall. This firm is one of, if not the largest importers and manufacturers of Coconut fibre, and their stock of material, which is well shown in the engraving, is a very striking sight. The enormous heap of husk—which, indeed, is known in the locality as the "mountain"—comes upon view immediately upon entering the premises, and one can scarcely, at first sight, realise the fact that the enormous pile is composed entirely of these apparently useless portions of the fruit. At the time of my visit this reserve stock of husks was estimated at considerably over a million and-a-half, and presented an appearance as shown in the engraving (fig. 186), which is from a photograph taken by Mr. John G. Horsey, only a week or so previously. Before proceeding to describe the various processes through which the husks pass to convert them into marketable material, it will be well to say something about the nuts themselves.

Coconuts, or as they are generally termed in the trade Coker-nuts, to distinguish them from the Theobroma Cacao, which furnishes cocoa and chocolate, are shipped principally from Trinidad, Jamaica, Demerara, Tobago, several of the other Leeward Islands in the British West Indies, Ceylon, Belize (British Honduras), all round the coast of America, and the Fiji Islands; the quantity landed in the United Kingdom being about 12,000,000 yearly. Nearly all the nuts are imported in the husks or outer covering from which, on arrival, they are stripped by men using two fine-pointed steel chisels, and who, by constant practice, become so skilful in the art that many are able to open 1,000 to 1,200 nuts per day. The nuts themselves after being removed from the husks are generally sold to wholesale fruit dealers, who, in turn, supply the retailers. costermongers, and others, but they are likewise often sold under the hammer at public auction.

After removal from the husk they are sorted into seven sorts or varieties, known respectively as large milky middle size, small, starters, milky growers, green, and dry. Those from Trinidad are the sweetest in flavour, and are mostly preferred by the manufacturing confectioners, biscuit-makers and others, though the Ceylon nuts run them very close in quality. Coconuts are largely used in the North and West of England, and they are also in great demand at holiday times, at fairs, on race-courses, and such-like gatherings in all parts of the kingdom. The husks, after the nuts have been cracked, are stacked in the yard in the open air, as shown in the engraving, until they are required for conversion into fibre; for this purpose they are first passed singly through a powerful "crusher," or "back breaker," driven by steam power, with large revolving corrugated wheels which flatten the husks, and to a certain extent make them more pliable; but after this severe pressure, so springy is the nature of the husk that, somewhat like a sponge, they immediately assume their original shape on emerging from the crusher. They are then thrown into huge stone tanks, each holding many thousands, where they undergo several hours' steaming and soaking. Great care and skill are required to know how long to keep them in the tanks, husks from different countries requiring more or less time according to circumstances, such as age, thickness of outer cuticle, substance of fibre, and other peculiarities known to the manufacturer. In the tanks the husks swell considerably, and have to be kept down by heavy pressure. One of the tanks filled with husks is shown in the centre of the engraving.

After the husks are sufficiently soaked they are ready for the mills, which are technically known as "Teasers" or "Devils," and consist of cylinders or drums, each being studded on the outer circumference with about 3,000 fine or thick 3-inch steel teeth, specially tempered. The mills vary slightly according to certain requirements. They are driven by steam, and revolve with great rapidity, requiring the utmost care and constant attention of the workmen. Each husk is divided longitudinally into thin pieces, and each piece is passed into the mill separately by the workman between two steel rollers, the workman retaining a firm grip of it so as not to allow it to pass out of his hands, but the few moments he holds it there, the drum with its numerous steel teeth is revolving and combing out the irregular fibre and refuse. After one half of the slice of husk is thus cleaned the workman reverses it passing in the other half. The continual feeding of these mills gives such strength of wrist and dexterity to the workmen that what appears a very dangerous operation is gone through with wonderful rapidity, and each slice of husk is passed through three of these mills in succession, occupying but a few seconds from the time that the crude husk is passed into the mill until it comes out a perfectly cleared bundle of light brown separated fibres; these bundles are next laid out in drying rooms on heated iron tables to perfectly dry them, when they are ready for making brushes and brooms of various kinds.

But to return to the mills. It will be seen that the principal attention has been given to the long clean fibres used for brush-making, but there are other products to which I have not yet alluded. If a coconut husk is cut through transversely, it will be found that immediately under the outer woody coating the long brush fibres, if we may so call them, are deposited to the thickness of about half-an-inch; nearer the centre, and immediately surrounding the nut, the fibres are more irregular, somewhat matted, and mixed with soft brown refuse. In the process of passing through the mill and separating the brush fibre, this finer fibre and refuse is thrown out at the back, from whence it is collected and placed on elevators, and carried automatically into the mouths of double rotary screens, or "willows," peculiarly made for the purpose, a spindle fitted with arms or roads running the entire length, and after many revolutions and much tossing about the fibre is separated and falls out at the lower ends clean and ready to be dried. This fibre is used for matting, and is not only supplied by the firm in large quantities for mat-makers, but also to the Government for mat-making in prisons; it is further largely used for stuffing mattresses, saddles, &c. The refuse, by a special process of the present proprietor, is separated into two different qualities, the ordinary coarse kind being used for

general horticultural purposes, and the granulated for conservatory use and potting.

Enormous quantities of this Coconut fibre refuse are produced by the firm. A heap is shown behind the tank in the engraving, and I was imformed that it was no uncommon thing for them to despatch 20 tons in one consignment, and that the material is sent to all parts of the world, including America, Africa, Australia, Sweden, Germany, France, Holland, &c.—the latter countries using it extensively for bulb growing. It is not a little remarkable that this refuse Coconut fibre should, in some cases, find its way back in a changed form to the countries from whence the nuts were originally brought.

In conclusion, I have to acknowledge my indebtedness to Mr. Thomas Nevell, the present proprietor, for his kindness in allowing me to inspect the works, for his courtesy in personally showing me over them, and carefully explaining the details of manufacture; as well as for much the information contained in this paper.—JOHN R. JACKSON, Museum, Royal Gardens, Kew.—*Gardeners' Chronicle.*

INDIAN CATTLE AND SHEEP.

In a country such as India, where the agriculturist and the carrier depend almost entirely on bullocks for doing their heavy work, special attention, one would think, should be paid to the breeding of animals fitted for draught purposes. But with few exceptions the natives seem willing to allow natural selection to work unhampered, forgetful that Nature at best works slowly, and that much may be done to aid her by the judicious selection of breeds, and careful crossing. Now that interest is being shown in the improvement of Indian agriculture, and that the introduction of new ploughs, which do something more than scratch the surface, renders it necessary to have powerful bullocks, the ryots are beginning to appreciate the importance of improving the breed of their cattle. Of course it will take many years before much will be really done in this direction, still it is encouraging to see that even a few are willing to take steps to make use of the facilities offered by Government for improving their stock. The plan recently approved of by Government for purchasing sires, and placing them in selected tracts, ought, before long, to lead to a marked improvement in the breed of cattle in the selected districts. The proposal is to open a central depôt in the South Arcot District, where a number of selected stock animals could be kept; these, when of suitable age, would be distributed through the district, or districts, chosen for the experiments, in the same way as is now done with stallions in the Coimbatore district.

If this scheme is to work successfully, it will be necessary for district officials to exhibit some sustained interest in the matter, for we have by no means as yet got beyond the stage in which a little interest shown by one in power acts as a strong incentive to work in the way desired. If this interest is to be an intelligent one, the district officers must themselves know something of the subject, and fortunately the necessary imformation is ready at hand in the second edition of Deputy Surgeon General Shortt's work on Indian Cattle and Sheep, which was recently published.* This little book gives a tolerably full account of the various breeds of cattle and sheep which are either indigenous to India, or have been imported from other countries, along with practical instructions as to their management, both in health and in disease. The Indian ox, we are told, is still met with wild in some parts of the country, but we fancy it must be very rare. The only two instances of its being shot, which Dr. Shortt seems able to mention, are in 1843 and 1848, and these dates are rather a long time ago. The last case we remember to have heard of was one in which a sportsman after having, as he thought, obtained a specimen of this rare animal, learned, to his chagrin, that he had shot not a wild ox, but one which had been turned loose in the jungle some years before as being too old for work. In any case, they are so rare that they can hardly be considered an important branch of Indian cattle. Of the cattle of the Madras Presidency, the most important are probably those of Mysore and Nellore. The Mysore bullock is from twelve to fifteen hands in height and is celebrated for his spirit and powers of endurance. The Amrit Mahal herd is said to date back to the time of the Hindu Government, but its special development for transport service was due to Hyder Ali, who, by introducing a breed of cattle from the Trichinopoly district, and crossing them with the indigenous Mysore stock produced the Hallikar breed, which is generally reckoned the best of the various breeds in the country. The importance to Hyder Ali of this superior type of cattle for transport purposes was very great. They enabled him, for instance, to march 100 miles in two days to relieve Chilambram, and, after a repulse, to draw off his guns in face of the enemy. The Duke of Wellington, when on service in India, experienced the value of this herd, and during the Peninsular war, as his despatches show, he often wished that he could have had Amril Mahal cattle with him in Spain. An interesting account of the management of these herds is given by Dr. Shortt, but it is not brought up to date, the historical account ending with 1871 since which time various changes have taken place. The Nellore breed is famous rather for dairy purposes than as draught cattle. They grow to a very large size, sometimes reaching a height of as much as seventeen hands, and when well bred, they can draw very heavy loads. As milkers they are much sought after in Madras, and some have been known to yield as much as eighteen quarts of rich milk in twenty-four hours. First class animals consequently fetch high prices in the market, cows selling for R200 each, and bullocks for from R150 to R350 per pair. Bulls have been bought for importation into other districts at R300 to R350 each. Various attempts have been made to obtain improved breeds by crossing the better kind of cattle, and considerable success has been met with, especially by the introduction of cattle from Guzerat, Aden, and England. But much yet remains to be done in this direction. The efforts hitherto made have been chiefly spasmodic, and carried out by individuals having no permanent interest in the country. Dr. Shortt complains greatly of the want of interest shown by the ryots—"why, they argue, should they trouble themselves about improving their cattle, which will cost money when they have none to lay out, while, by following the practice of their forefathers, things take their natural course?" This, doubtless, represents pretty accurately the opinion of a majority of the ryots, but it is by no means true of all, for many are showing a distinct and growing interest in improved methods of agriculture as is proved, amongst other things, by the large numbers of European ploughs that have been sold in the Presidency during the last few years.

Turning now to the subject of sheep, we find that Nellore comes well to the front again. The Nellore sheep is the tallest in India and, well fed, will weigh from 80 to 100 pounds when alive. In Coimbatore there is a wool-bearing breed of sheep, and though small, these fatten well and yield a mutton which is probably as good as any that is to be had in India though it is closely approached by some obtained from Mysore, where there is another breed of wool-bearing sheep. The latter breed furnishes the chief fighting rams in India. They are very pugnacious, and not only butt furiously, but also use their forefeet, and at times even bite. During Sir Mark Cubbon's time of office there was an experimental sheep farm at Heraganhalli, under the charge of a European Commissariat subordinate officer. For this farm merino rams were imported annually from Australia, and the distribution of the cross breeds raised from these has improved the sheep throughout the country to a marked extent, as regards both size

* *A Manual of Indian Cattle and Sheep, their Breeds, Management and Diseases*, by John Shortt, M.D., V.S., F.L.S., F.L.S., &c. Second Edition, Higginbotham & Co., Madras, 1885.

and quality of mutton and wool. The farm was given up in 1863 because it did not pay its working expenses, but such expenditure as this is repaid to a country over and over again when the experiments are so evidently successful as they have been in the case of Mysore. We have not touched on the parts of the book connected with the treatment of diseases and accidental injuries: Dr. Shortt's reputation is a sufficient guarantee that this will be found satisfactory. But there is one feature of the book which we cannot speak of with the same satisfaction, and that is the illustrations. How an author could be persuaded to allow his book to be disfigured with such dreadful lithographs we cannot conceive. We do not deny that the characteristic features of the animals are, in many cases, reproduced, but anything less artistic we have seldom seen. Many of them are taken from photographs in which the picture has been blurred by the motion of the animal, and the lithographer has reproduced this blurring. We are quite aware of the difficulty of getting a book well illustrated in Madras, but if it was impossible, on account of the expense involved, to get wood-cuts from home, we think it would have been better to omit them altogether rather than to disfigure with them an otherwise valuable book.—*Madras Mail.*

FROGS do no manner of harm in a garden, and are probably the gardener's best friends. The food of the frog is wholly of an animal character, consisting of slugs, worms, and insects of nearly every kind.—*Indian Gardener.*

DISINFECTANTS.—A great deal of disappointment may be experienced if people do not realize that deodorizing substances, and even antiseptics like green vitriol, are not true disinfectants. They have their advantage in removing evil odour, or checking putrefaction, but they do not necessarily kill the germs on whose life and activity many epidemic diseases depend. Destruction by fire of infected material, and where that is not practicable, chloride of lime is the best germicide for general use.—*Indian Gardener.*

SOIL CULTIVATION AND INSECT PESTS.—"At the time of the discovery and early settlement of this country," (United States,) says Prof. J. A. Lintner, "the number of insects existing in the soil was very small, but, with the cultivation of the ground this number was increased, until now there are thousands of insects, which destroy vegetation. Aside from the increase by cultivation the number has been added to by grubs and worms imported with grain from foreign countries. There are 9,700 different kinds of coleopteræ or beetles and 200 kinds of insects found in apple trees. In the Palæozoic age there were 625 kinds of cockroaches."—*American Grocer.*

VARIOUS substances have been used to make stoppers for bottles that will replace corks, and paper has formed the basis of many of these. We now have a more novel use of paper in the drug business in the form of paper bottles. The difficulty of making them waterproof has been overcome, as well as their tendency to be affected by spirits of any kind. The only difficulty that remains is that they must be made in halves, and be joined together after taken from the moulds where they have been enduring a severe pressure, and where the albumen of some of the ingredients has formed an impenetrable protection, and it only requires that some deserving mechanic eliminate a pulpy alloy that can be used as a solder. —*Planter and Farmer.*

DIFFICULTY OF BREATHING CAUSED BY PELARGONIUMS.—The *British Medical Journal* for November 28th contains a note on difficulty of breathing produced by *Pelargonium grossularioides*, by Dr. G. Bidie, Deputy Surgeon General, Madras. Dr. Bidie says that the odour which the plant gives out after rain &c., is agreeable to most people, but that in the case of a lady who came under his observation it immediatly produced dyspnœa. As the plant was in flower at the time, it was thought that the pollen grains caused the trouble, as in hay fever, but on experiment it was found to be due to the effluvia of the leaves. Whenever plants were brought near the lady she was affected by them, and when out driving or walking she would announce the presence of the enemy when the plant could not be seen by the eye, and whilst other people could not smell it until their attention was directed to it. This is, therefore, a new example of an "idiosyncrasy of olfaction."—*Indian Gardener.*

BEVERAGES OF BARBARY.—Besides wine from the grape, whose preparation calls for no special notice, there is a kind of "palm wine" or *lakmi* furnished by the sap of the date palm (*Phœnix dactylifera*). Trees in full vigour are selected for tapping. If the life of the tree is to be sacrificed, the incision is made so as to destroy the terminal bunch, but more generally the tree is to be preserved, and in that case the cut is kept clear of the terminal bunch, and is carried round the stem. The juice escaping from the wound is conducted by a reed into an earthenware pot (*karreri*), and may amount to nearly two gallons daily at first, gradually sinking to about half that quantity towards the end of the tapping, which is seldom allowed to exceed a month. The collection being terminated, the incision is carefully plastered up with clay, and after about two years, with irrigation, the tree will resume fruit bearing. Much of the "wine" is drunk fresh, when it resembles sparkling cider, but becomes insipid after losing its carbonic acid. Its colour is opalescent and milky. After undergoing alcoholic fermentation, it contains 4·38 per cent of alcohol 0·22 carbonic acid, and 5·60 of mannite.

The Moors make extensive use of a spirit prepared from the water in which comb is boiled in treating beeswax. This water, being impregnated with honey, is allowed to ferment, and is then distilled; the spirit is called *maharya*. It is flavoured with aniseed or with *naffa, i. e.*, fennel acid (*Fœniculum dulce*),—*Journal of the Society of Arts.*

STIMULATING AGENTS IN GERMINATION.—Allusion has already been made to different means of hastening the germination of seed, such as breaking the shells, soaking in very hot water, or even boiling for a short time. There are some substances which appear to exercise a stimulating effect in the germination of seeds and the future growth of the seedlings. Camphor, a vegetable product itself, appears to possess this property in an extraordinary degree. Indeed, it has been averred that camphor has the power of revivifying seed, or at least of causing them to germinate when ordinary treatment failed. Benjamin Smith Barton was the first to point out its action upon plants at the end of the last century; and a few years ago a Mr. Vogel, of Munich, carried out a number of experiments with camphor on old seeds. Controlling experiment, were conducted simultaneously, ordinary water being employed instead of camphor water. Seed of Cress three or four years old, treated with ordinary water, germinated very imperfectly and long after sowing, while that moistened with camphor water germinated quickly; that four years old in twenty-four hours, and that three years old in seven hours. Radish seed, which is usually regarded as useless after it is three or four years old, was tried seven years old, and in germinated in four days, or in a much shorter period than good fresh seed under ordinary favourable conditions. Seed of the Pea eight years old germinated in forty hours, and many other old seeds treated with camphor water exhibited equally rapid germination. Some that would not germinate at all under ordinary treatment, had their germinative force revived by camphor. Other seeds, Clover for instance, appeared to derive no benefit from the solution of camphor; but where it acts its influence is not limited to germination, but is extended to the subsequent growth. Humboldt discovered that chlorine accelerates germination, and acts as a restorer where the vital force is almost exhausted or quite lost, so far as the usual method of treatment is concerned. This must be used in a highly diluted form; about two drops of an aqueous solution of chlorine in 2 oz. of water. Iodine and bromine are said to possess similar qualities. Acid and ammonia salts in very small quantities in the water have been found to hasten germination, but they have not the power of reviving seeds.—*The Garden.*

EXPORTS OF INDIAN TEA AND OTHER PRODUCTS IN TEN MONTHS: 1886-7.

Today concludes the Indian revénue year, and in about six weeks hence we may look for the Annual Report of the Customs Department. Meantime it may be interesting to look at some of the items in the accounts for the ten months ended January, which are before us. And first as to tea. The export of the Indian leaf in pounds for ten months of three years has been

1884-85	...	...	...	58,381,000 lb.
1885-86	...	...	...	63,887,000 ,,
1886-87	...	...	...	73,37,000 ,,

It will be observed that the increase in 1886-87 over 1884-85, is not less than 15 millions of pounds. Of the quantity exported in the latest period of ten months, the proportions were 71,559,000 to the United Kingdom; 1,420,000 to Australia and less than 100,000 to the United States! To other countries went 258,000, so that out of 73¼ millions of pounds of Indian tea exported, only 1¾ million pounds were diverted from Britain. The local consumption of Indian tea is usually taken at 2 millions of pounds, but China tea continues still to be imported, some to be consumed and some to be "re-exported to Afghanistan and other foreign States bordering on India." The figures for the ten months were :—

From China	...	...	2,663,000 lb,
Other countries	...	...	572,000 ,,
		Total...	3,235,000 lb.
But in foreign merchandise exported we find tea given at...			1,557,000 ,,
		Retained ...	1,678,000 lb.

The export of Indian tea direct from India to the United States has averaged only about 100,000 pounds for the ten months of the three past years, the figures really showing a decrease from 150,000 pounds in 1884-85 to 99,000 in the latest period. Exports to Australia have fluctuated, but on the whole increased, beginning with 1,066,000, rising to 1,621,000 and going down to 1,420,000. We observe that the 73¼ millions of pounds exported are valued for Customs purposes at R44,177,000, or somewhat over 8 annas per lb. average.—Turning now to coffee, we find that contrary to the process in Ceylon, there has been a steady though not large increase in the periods of ten months, thus :—

1884-85	..	..	206,000 cwt.
1885-86	..	..	211,000 ,,
1886-87	..	..	245,000 ,,

The total export for the 12 months will probably range about 275,000. Of foreign coffee (from Aden to Bombay, no doubt), India imported in the three periods, 34,787; 14,000; and 19,666 cwt. In the case of India, it cannot be doubted that a much larger proportion of the coffee locally grown is locally consumed than is the case in Ceylon. Of the foreign coffee imported, the following quantities were again exported :—13,600; 5,000; and 4,000 cwt. We think it quite probable that the total coffee crop grown in India is fully 400,000 cwt., of which 125,000 cwt. is locally consumed.—The export of coconut oil from India has gone down rapidly and largely, thus :—

1884-85	..	..	1,054,000 gallons.
1885-86	..	..	916,000 ,,
1886-87	..	..	770,000 ,,

The export of cardamoms has, with fluctuations, increased, thus :—163,000; 234,000; and 210,000 lb.

The same may be said of cinchona bark, the exports being fractional compared with those of Ceylon. The returns are 411,000; 656,000; and 568,000 lb. It is clear that even now and allowing for the bark used up for manufacture and experiments, private properties have but added little to the bark from the Government gardens. The exports of bark from India in the year are not likely to exceed 700,000 lb., the total produce being probably under a million. The exports of unmanufactured coir have sunk to insignificance, thus :—14,000; 7,000; and 9,800 cwt. It would appear that now nearly all the coir is manufactured, for the figures for the article in this shape (excluding cordage which is mixed up with jute and other rope), show up thus :—175,000; 155,000; and 170,000 cwt. But manufactures of coir (again excluding rope) were imported thus :—9,700; 11,000; and 11,666 cwt. The exports of coconuts from India are, as might be expected, very small, ranging from 213,000 to 117,000 and 164,000; but copra was exported thus :—15,000; 21,000 and 8,800 cwt. Coconuts were imported at the rates following :—15,129,000; 11,500,000; and 14,058,000; while the increase in the imports of copra has been very large :—38,100; 92,400; and 106,000 cwt. The import is mainly from Ceylon, we suppose. Besides paddy or rice in the husk, which is not shewn separately for Ceylon, the exports of rice to our island have been :—

	Quantity. Cwt.	Value. R.
1884-85	.. 2,447,000	8,588,000
1885-86	.. 2,565,000	10,024,000
1886-87	.. 2,450,000	9,222,000

The increase in the exports of wheat from India has been marvellous,—from 13,000,000 cwt. to 19,416,000 cwt. and 21,172,000 cwt. The total export for the 12 months will probably be 25 millions of cwt., against somewhat less than 20 millions of rice. Arecanuts, or, as they are termed in these accounts "betel nuts" are classed, curiously enough, as spices, and some of the facts embodied are curious, one being the much higher valuation placed on Ceylon nuts than on those from the Straits. For instance 11,533,000 pounds imported from Ceylon in the 10 months are valued at 1,546,000 rupees; while 14,417,000 of Straits nuts are down for only R1,387,000. As Penang derives its name from the arecanut, we were prepared to find the Straits the great source of supply of this masticatory. Sumatra adds a fair quantity. Out of 26,820,000 pounds imported in the 10 months, less than half was contributed by Ceylon, but our produce gets credited for more than half of the whole value. Notwithstanding local manufacture of febrifuges, India still imports quinine, some of it, we suppose, prepared in London from Government bark. The figures for the three periods are :—10,707 lb., R519,772; 11,004 lb. R416,672; 9,320 lb. R282,165. Cinnamon has no heading in the imports, but cassia lignea (coarse cinnamon from China) figures for 13,255 cwt, 12,290 cwt, and 24,315 cwt. Castor oil is an important item in the export trade of India, the quantity for ten months being 2,339,000 gallons, valued at R963,000. "Mica" (commercially called talc) having recently attracted attention here we may say that in the ten months the exports from India were 780 cwt. valued at R191,700. The exports of linseed have averaged 8 millions of cwt., the value ranging about R47,500,000. The duty levied on rice has ranged about R1,000,000 or, say, R1,500,000 for the 12 months. This is the only export liable to duty, and the only imports so burdened are salt, liquors, opium and a few other articles,

PEARLS IN COCONUTS.

A correspondent writes :—"I am somewhat surprised that the fact has escaped you that this subject was fully discussed in the Ceylon *Observer* some years ago, with extracts given, if I recollect aright, from the Straits or Java papers. If such a fact as the occasional occurrence of pearls in coconuts existed in Rumphius' time it was sure to be recorded by this most excellent and industrious writer, and the statement made by your correspondent that Rumphius alludes to this fact is likely to be correct. You will find Rumphius' *Herbonium Amboinense* in 6 folio volumes in the foreign list of books in a shelf in the north end of the Colombo Library, and a glance at the index at the last volume, and another at the description of the Coconut given in double columns, one in Dutch and the other in Latin, will very soon enable you to see if Rumphius has alluded to pearls in the coconut. If this be a fact the hackneyed expression 'and this accounts for the milk in the coconut' may be changed into 'the pearls in the coconut.' And why not Pearls in the Coco Nut?"

On which we have to remark that we hope to refer to Rumphius in due time and if, as we suppose, from the statement made not by "our correspondent," but in a quotation from a Java newspaper, the accomplished Dutchman did refer to concretions in coconuts, we feel quite certain that instead of asking "Why not pearls in coconuts?" he noticed the phenomenon as exceedingly rare and very curious. And for this reason,—that, unlike the pearl-bearing shells, which are formed of carbonate of lime and have the power of secreting that mineral to any extent, the coconut has the slighest possible amount of lime in its composition. "The milk in the coconut" is first highly saccharine and then as it coagulates highly oleaginous, and true pearls can be formed neither from sugar nor oil. We are quite prepared to learn that the concretions on analysis differ entirely in composition from the nacre of which pearls are built up. We have no recollection of this subject of pearls in coconuts having been discussed in our paper but a very vivid remembrance of our having quoted, only to cover with deserved ridicule, a paper in the transactions of the Straits Asiatic Society by a Mr. Dennys in which people in this nitneteenth century were asked to swallow the outrageously unscientific statement that grains of rice shut up in a box developed into life and then became pearls which increased in size with efflluxion of time! That we believe, was substantially the story, which even the most pronounced evolutionist could not swallow. The question we should now like to ask of men like Mr. W. H. Wright, Mr. W. B. Lamont, Mr. Jardine, Mr. Piachaud and other coconut planters, is, "Have you, in all your Ceylon experience, seen or heard of so-called pearls in coconuts?" *We have not.*

HINTS TO FRUITGROWERS.

Mr. James Inglis, M. L. A., delivered a lecture in the hall of the School of Arts, Paramatta, on the 9th Dec. to the members of the Cumberland Fruitgrower's Union. The hall was well filled by the more active members of the Union and others interested in the great industry of Central Cumberland. Mr. John Nobbs occupied the chair. We extract from the report of the *Cumberland Times* the following portions of the address:—Mr. Inglis said that when he was contesting the election for New England—which he had the honour to represent in the Parliament of New South Wales—the slogan or war-cry of his party was "Auld Scotland for New England." He told them it was his intention to avoid prolixity; but, at the same time, he intended to take his audience with him on an imaginary journey of 25,000 miles; and if in that journey he did not weary them, he would return to the starting point and deal with matters which might be more immediately connected with the Central Cumberland Fruitgrowers' Union. He expected great things from the Union. Those interested in the fruitgrowing industry had hitherto been a heterogeneous mass of incoherent atoms, each pulling in opposite directions; but now they had determined on unity of action. The importance of the fruitgrowing industry it would be difficult to overestimate, and the large possibilities involved in it, and the immense proportions to which it might attain, were already attracting the attention of outside nations. The importance of fruit from an economic, sanitary, and dietetic point of view, was pointed out, and extracts quoted from the *Journal of Health*, showing how valuable an aid to health would be the substitution of fruit as an article of diet for the messes of bacon and grease with which the majority of the people were in the habit of regaling themselves. There was no more wholesome and nutritious article of diet than a peach, nor anything more delicious; nor could anything be more conducive to health than substituting cooling sub-acid fruits in the dietary scale for the different kinds of animal food which constitutes the staple diet of the country. The medicinal value of various fruits was also pointed out, and the watermelon was instanced as an example of a natural febrifuge and diuretic than which few were more valuable. The only caution to be observed was to see that the fruit was fresh and ripe. It was a frequent reproach, levelled against the people of New South Wales, that they were lagging behind in the race for national pre-minence. For this some assigned one reason, some another. One said Jennings-Dibbsism was to blame, another said free trade was the cause of it; but there existed an universal consensus of opinion that there prevailed among the people of New South Wales a certain sluggishness of character and temperament which invited the rivalry and quiescently submitted to the attempts of more energetic if less favoured nations to distance this colony in the race for national pre-eminence. With respect to the rival systems of free trade and protection, he had the courage of his opinions, and, like most Scotchmen, held a tolerably good opinion of himself. He did not intend to approach these subjects in any gingerly fashion, with his fingers encased in plush-tipped silken gloves. The man who considered protection to be a panacea for all political and social evils must be either a bigot or a fool. The cry for protection was neither more nor less than the wail of sluggish eneptness—the puling cry of those whose want of Anglo-Saxon stamina was betrayed in every evidence that surrounded them of their want of capacity to take advantage of the opportunities which bountiful nature had lavished upon them, and who contented themselves with praying to Jupiter, instead of throwing off their coats and setting their own shoulders to the wheel. Having himself boundless faith in the potentialities of the fruit-growing industry in New South Wales, he desired to impart a little of that faith and fervour with which he was filled to the members of the Fruitgrowers' Union; and, in order to do that, he would endeavour to show them what was done in countries where fruitgrowing took the place to which its importance entitled it among the industries of the people of those countries. He had been 12 years in India, had been through

Afghanistan, Persia, Abyssinia, and along the shores of the Mediterranean, and he could assure them that among the wild tribes of Afghanistan the fruitgrowing industry was pursued in a way which not only outvied but outdid modern European culture, whether regard were had to national manner or scientific method. The Afghan was an arrant thief, dirty, loud-smelling, and treacherous, as all Asiatics are: but as brave as a lion, as we had on more than one occasion found to our cost. The lecturer than went on to describe how the mountain men of Afghanistan, filthy and unkempt as the specimen he had told them of, made annual journeys from their mountain valleys in caravans of camels, loaded with dried fruit, which they sold to the inhabitants of the thickly-populated plains of India, leaving here a bale and there a bundle, until when they reached Calcutta they realised enormous prices for their merchandise. The natty way in which the semi-barbarous Afghans brought their fruit to market was compared with the slovenliness with which fruit was treated in New South Wales, from the hour it was gathered to the time it reached the hands of the consumers, in a condition more calculated to inspire disgust than to excite appetite, very much to the disadvantage of the latter. The fruit-markets in the bazaars of Asian cities were described and compared with the abomination which does duty for a fruit-market in Sydney, and the Union was adjured to use every effort, and never to rest satisfied until a building was erected in keeping with the admirable site now occupied by the market shed, a building worthy of their noble industry and their splendid city. Many practical hints were given to growers how they might, by introducing productive trees for break winds, instead of the unproductive hedges in vogue, add to their profits, and the pistachio, chestnut, walnut, almond, hazel, egg-plant, and several species of *terminalia* were instanced as suitable for the purpose, and for the products of which there was an unlimited market. The potentialities of the fruit industry were illustrated by reference to the Vale of Cashmere, to the Khanates of Central Asia, Merv, Herat, Khiva, &c., and all along the banks of the Oxus, where fruit constituted an important staple of the food of the people. There the value of irrigation in fruit-growing was seen to the greatest advantage, and their fruit was put to a use which the people of New South Wales might well take a lesson from. They had there a method of mixing the pulp of fruit with the kernels of nuts, melon seeds, and camels' milk. This was pressed and formed into a cheese, which, when properly made, would keep for years, and which improved with age, and was highly nutritious and wholesome. He had, without exaggeration, walked up to his knees in masses of egg plums fallen from the trees in a New South Wales orchard, and which the owner had not even the wit to convert into pork by turning the pigs in to eat. Now, had a daughter of the household turned to and run the pulp of these through a sieve, and converted it into a fruit cheese after the manner of the Central Asians, it would have prevented waste, which was to him, of all things, most hateful, and turned the plums into a wholesome article of diet. The fruitgrowing interest in California was next glanced at, and the amazing results of irrigation, by which the desert had been made to literally blossom like the rose, was dwelt on at length. The vastness of the possibilities lying before the union was illustrated by the growth of the trade in America, and statistics showing how rapidly that trade had been evolved from small beginnings. India he considered to be the nearest and best market for Australian grown fruit, although he could see no good reason why fruit should not be shown in Covent Garden market within 50 days of its being gathered in a Central Cumberland orchard. Having proved his position by incontrovertible figures, Mr. Inglis said:—Before I conclude, let me say one word about the shameful neglect of manuring which largely prevails throughout the colony. If you desire that your children should develop into specimens of humanity like William Beach, you will not begin by stinting them in their food. If fruit trees are to be kept in a state of prolific health, something must be returned to the soil for what is abstracted from it by every successive crop of fruit; and in addition to all that I have told you, ineffectively I fear, because hurriedly—but you have been such kindly attentive listeners that I have been impelled to go on and to cover a more extensive ground than I had originally intended—if you desire your union to become a powerful means for the populsion of the colony in the pathway of progress, let me recommend you to cultivate some of the old-fashioned, but not on that account less valuable characteristics of sterling manhood, such as self-reliance, thrift, industry, and manly uprightness of thought and action, avoiding pretence, evil speaking, and fraud in all its multifarious phases.

SILK.—Recent experiments have resulted in a use being discovered for the wild silk plentifully found in the valley of Kyushu, and a company is being formed to work up the material, which is found to be well adapted for mixing with cotton and wool. The silkworm lives on maple trees and produces a large cocoon.—*American Grocer.*

A LARGE amount of sago has been exported of late, owing to the immigration of Brunei sago-workers, and to the seasonable rains which enable the producers to float down the numerous tributaries of the Padas and Klias Rivers the sago in its raw state. The price of Sago Flour in Singapore, has risen from $2·07 to $2·18 per picul, and this has given fresh impetus to the industry. When the price is quoted at $2·50 per picul, the enterprising Chinese Sago-factory managers will according to agreement made two years ago, willingly pay a small stipulated increase of Royalty to the Government on both the raw and manufactured material.—*Borneo Herald.*

A NEW FODDER.—The Assistant Director of Agriculture in Burma, about this time last year, in reply to some inquiries from the Military Department with reference to the fodder supplies of Burma, recommended the cultivation of crab grass. He has just published a report on the system of cultivation then recommended, which was adopted this season at the Kyauktau farm, and gave an outturn of nine tons per acre for the first cutting in July, whilst another cutting can be made in October. The first cutting can either be used as green fodder or preserved in a silo, whilst the October cutting can also be cured as dry hay. The hay that was made last October kept in excellent condition until the rains commenced this year. This grass is but little valued in India, whilst in America it is much valued as a hay crop, and is still more valuable in Burma, as it gives twice the amount of grain and also an extra cutting. In Burma it grows to the height of about three feet, and horses and cattle of every kind eat it with great relish, and will remain in good condition if fed on it without any other grain. Its cultivation appears to be very simple, as the land only requires to be ploughed twice at the beginning of the rains with a turn plough, and then harrowed twice with a triangular harrow, when the grass will germinate of its own accord.—*Calcutta Englishman.*

All the fruits that grow with a pit, a core, or with seeds, can be made to grow without them, when it is understood, says the *Live Stock Record*. It is accomplished by reversing the scion—rooting the top end of the plant. To do this you bend the scion to sprout down and cover with dirt. After rooting, cut it loose and let the root end be up. Apples are grown without cores, peaches without seed, and grapes and other vines also, by simply reversing the plant.—*Southern Planter*.

Tea.—In the course of a recent discussion at the Society of Arts, Captain Temple mentioned a fact which should commend itself to the attention of Indian tea-growers. The natives of India, said Captain Temple, were very fond of tea, but they liked a peculiar quality, which was ascertainable by the people who grew it. He had himself seen in the Kangra district a native owner who made a tea estate pay because he supplied the kind of tea which the people of the Punjab like; whereas the European tea planters did not do this, and while they were complaining that they could not find a market, this native grower was making a good thing.—*Pioneer*.

Ceylon Arrack.—At present distillers manufacture for home consumption principally; would they be able to meet a large demand for export? Our inquiries tend to show that they would not, at least for some time, because the supply of the toddy is limited and their apparatus imperfect. Moreover, before the spirit is fit for export it must be much more carefully rectified, and stronger than it is made at present. The expense required to effect these improvements would bring the price up to at least 2s per gallon in the Ceylon market. The additional charges for freight, &c., would bring the price on the English market to about 2s 6d—quite a prohibitive sum in these days of cheap German spirit, which is placed on our market at about 1s 6d per gallon, duty unpaid. We refer more particularly to spirit suitable for manufacturing purposes, but we should be pleased to learn that our calculations are excessive. It is far better if we have to import such products that we should secure our supplies from our own dependencies, and we at present undoubtedly obtain from Continental distillers much of the spirit that we use. If Ceyon is able to compete with them, it is not too late to begin.—*Chemist and Druggist*.

On the subject of fertilizers Messrs. Edward Packard & Co., of Ipswich and London, have issued a circular to West Indian planters, in which they say:—"We have much pleasure in directing your attention to the following facts in connection with our manufacture of specially prepared fertilizers for the West Indies. The differences of climate, soils, period of growth and system of cultivation between those colonies and home, and, as regards many of those conditions, between one colony and another, materially affects the composition of the fertilizer best suited to meet the requirements of the planter, and to give an adequate return for the outlay of capital. Although manure manufacturers are well informed upon the question of fertilizers for home crops, grown in a few months, they are often at considerable disadvantage when preparing them for the very different conditions of tropical agriculture. With a view to placing ourselves in the best position to formulate really suitable fertilizers, we have secured the services of Mr. George Hughes, F.C.S., as our consulting chemist for the West Indies, knowing that he has had long and practical experience upon these important points. We have also consulted Mr. J. McCarthy, F. C. S., Chemist to the Government of Trinidad, especially in reference to our cocoa manure, and the formula those gentlemen have determined upon will be carefully adhered to by us. All manures will be sold under distinct guarantee, and all exports will be accompanied by Mr. Hughes's certificate of analysis of a sample authentically drawn at the time of shipment. Under these conditions we trust we shall be favoured with your esteemed orders for the new year, and take this opportunity of expressing our hope that i may bring better times to those interested in the success of our West Indian Colonies."—*Home and Colonial Mail*.

Indian and Ceylon Teas.—Although the supplies of Indian tea continue to be much smaller than during the earlier weeks of the year, they are apparently amply sufficient to meet the present limited requirements of the trade. Prices have been irregular, and the depreciation in values has in some instances made further progress. As was to be expected with such a preponderance in the supply of very common teas, these have suffered in value to a greater extent than other discriptionss, so long as the supply of very common tea outweighs to such an extent as at present that of other sorts, none but very low prices can possibly be anticipated, especially as many of the so-called "common" parcels are much commoner than the bulk of Indian teas usually coming under that definition, Large quantities are being sold at the exceedingly low prices of 5½d to 6½d per lb.; but many of these draw so thin an infusion that they cannot be described as particularly cheap when compared with teas at some pence per lb. more. The better kinds of tea have fetched prices quite equal to those ruling a few weeks ago, notwithstanding a marked dulness in the general inquiry, but the quantity of good tea at present offered is comparatively small. As there appears every probability of the supplies of the medium and better descriptions continuing on a limited scale for the present, buyers will probably not be wrong in holding reasonable stocks of them, as even a moderate improvement in demand bids fair to strengthen the present very low range of values. A larger quantity of Ceylon teas has been brought forward, and has fetched generally declining rates, as the quality of most of the parcels was very poor. Increased supplies of Java growths have also been offered, and have sold at easier prices. At the public sales 18,407 packages of Indian, 2,655 Ceylon, and 1,894 Java teas were offered. With the exception of tea possessing quality, values were rather easier, and about 3,400 packages were withdrawn.—*Produce Markets Review*, Feb. 26th.

Ceylon Tea.—The event of the week has undoubtedly been the sale of 27 packages Ceylon Tea, "Mariawatte" mark, in the new Andrew's patent steel chests, realizing a half-penny or a farthing above valuation on account of the package. There was a good competition for these, and the prices realized showed that the contents of the new packages had come to hand in excellent condition, and no doubt is entertained in the Lane that as these steel chests become more generally known they will be favorites, and always meet a ready sale. Their cost on the estate is said to be one rupee and ten cents, very nearly, if not quite, the same as wooden chests; and, looking to the difficulties attending the employment of woods for tea chests, the damage to packages from which these are free and the greater uniformity in weight secured, I should say there can be no doubt that Andrew's patent steel chests will come into use pretty generally. Previous to the sale I inspected the whole of the packages lying in the Cutter Street warehouse, where I found only two that had sustained any damage, all the others being in excellent order, and their contents in good condition. As I mentioned in a previous letter, succeeding shipments of these will have an inside coating of lead deposited on the steel; but the necessity for this precaution is not obvious, as the contents of the present chests are in first-rate condition. There is but one change which occurs to me as perhaps desirable—viz., the dispensing with the metal rings in the wooden surface of the lids, placed there to enable the lid to be readily removed. The warehousemen thought these were intended for fixing ropes through for the purpose of hoisting up the chests; and the same idea may occur to ship's crews, and then the fear would be that if the rings be so used the great strain brought on the lid would destroy its air-tight property, notwithstanding the screws inserted for holding it in its place. Instead of the ring I would advise the use of a simple "thumb catch," which would serve all the purpose of the ring without the possibility of any misapplication of its use.—London *Cor*, Local "Times."

FLORIDA ORANGE CROP.

From memoranda appended to the various reports it appears that comparatively few bearing trees have been killed. Nursery trees in many localities were killed. The damage to older trees cannot be estimated at present, but the general opinion inclines to the belief that but few bearing trees were materially injured. An unfavorable report (from Sumter county) on this subject reads as follows:—"About one bearing tree in one hundred was killed to the ground, and perhaps one-tenth of the bearing trees are slightly killed back, some to the main trunk and some slightly only. A great many will shed their leaves, but this will do no harm. Some groves seem to be entirely uninjured from the freeze and look nice and green." *To the Editor of "Bradstreet's."*

SIR—My estimate of this season's crop was about 1,000,000 boxes; 50 per cent of this I think had been marketed, leaving 50 per cent on trees and in packing-houses. That in packing-houses, however, amounts to very little, only a few thousand boxes. That on the trees was more or less frosted, and but very small proportion of it can be marketed, and I think I am safe in saying fully 90 per cent of the frosted fruit will be a total loss. I hardly think the bearing trees are hurt to any extent, and it is the belief of many of the experienced growers that we can look for fair crop next season. At present, however, it is hard to tell just what the damage to trees is; in a month or six weeks we can answer that question better. The nursery, or young trees, in many localities were killed. —Yours respectfully, A. M. IVES, General Manager, Florida Fruit Exchange.

The price of frozen oranges has been about $1·66 per box in New York, but no more are coming here at present. The result appears to be that about one-half of the Florida orange crop has been lost. Several cargoes of foreign oranges are already well on their way to this port to supply the deficiency.—*Bradstreet's.*

TEA IN GUATEMALA.

The *Guatemala Star* is urging the Government of the Republic of Guatemala to foster the cultivation of tea. It says:—

A wide field is offered to prospective tea-growers in the large uncultivated tracts of land on the sides of the hills and mountainous regions of the country which are admirably adapted for the purpose of cultivating the fragrant leaf. The soil is just the thing, and the climate is all that can be desired. Here in Guatemala, as is done in China, tea can be raised by the poorer classes in small quantities, who can cultivate a few hundreds of shrubs on their own lands, and either cure the leaves themselves or sell them to their richer neighbors after assorting them according to their quality. If the large *finqueros* were to assume the responsibility of extensive tea plantations, it would give employment to the very many destitute and labor seeking Indians who are now very poor and desirous of having a wider field for their labors than is afforded them in the present less than semi-cultivated state of the country. Men, women and children could all alike be employed in cultivating the plant and in picking and curing the leaf. This employment would not last, like in the cultivation of the coffee tree, for two, three, four or five months, but would extend throughout the entire year, and the benefits arising from the constant employment of the working classes would be incalculable towards the political, moral and intellectual status of the country.

An idea has been formed by many people who have given this subject their attention, that it will be necessary to import into the country a great number of Chinese laborers in order to make the cultivation of tea a profitable enterprise; but such is far from being the case. It will only be necessary to make a contract for five years with a dozen or twenty thoroughly experienced Chinese in order to instruct the natives here in the various processes of tea cultivation, and, at the expiration of that period, a sufficient knowledge will be gained to enable the project to be carried on by the Guatemaltecans themselves without further aid.

The *Star* claims that one great advantage which Guatemala will have over the rest of the tea-producing world is that the teas produced in this country will be upon the Markets of London and New York some five or six weeks prior to any other kinds, and thus its value will be greatly enhanced.

If the climate and soil of Guatemala is as favorable to the production of tea as it is to coffee we can see no reason why tea cultivation should not become a profitable industry, and we receive from the new field tea of as rare and exquisite flavor and quite as marked in its characteristics as the coffee there grown, and which has for years been a favorite with epicures. We certainly hope the Government will lend its aid to give the industry a start and a foothold.—*American Grocer.* [Here, as elsewhere in America, the enterprise cannot succeed for want of abundant and cheap labor.—ED.]

THE BHUTAN AND THIBETAN MARKETS.

About the middle of last month I visited the Bhutia encampment of Dewangiri, and amongst other matters I enquired into the subject of Tea. I found that the Bhutias had as usual brought with them a few bricks of the commodity they designate Tea. I obtained a small quantity and noted a few particulars, which may possibly prove of interest.

2. The Bhutias stated that the Tea was brought by traders from a place called Janarjippoo, situated a year's journey to the north east. To indicate the direction, they pointed at first due North and then due East, intimating that a traveller to Janarjippoo from Bhutan would have first to go North and then East. They stated that they had given in exchange for a brick two cloths of Eri Silk, each cloth containing as much thread as they had bought for the equivalent of R1-4 in the Assam Valley. Estimating roughly the labour of weaving at 12 annas per cloth the cost of the Tea would appear to have been R4 per block. That this could not be its real price in Bhutan was proved by the fact that I bought it at R3-8 in Dewangiri. The price last year was, as far as I can ascertain, R2-4 in the same place. The Bhutias stated that it had become dearer in the interior. I enquired why they drank Tea which had come such a distance when a much cheaper kind was to be obtained in Assam. They stated that Assam Tea was bitter, but that the Tea they had with them was sweet.

3. I watched in one instance the process of making the infusion: Two pots, one of brass and filled with water, the other an earthen one and empty, were put over a fire; a piece was broken off a brick of tea and crumpled up in the hand to separate the adhering leaves and twigs. The handful so obtained was put into the dry earthen pot and stirred up for a few seconds till hot. Then, about a couple of wine-glasses full of potash water (made by straining water through ashes) was poured on the dry tea, and when the heat had almost evaporated the moisture, another spoonful of water (now hot) was added from the brass pot. The tea meanwhile was kept stirred to prevent its burning, and when nearly dry, a second, and then after an interval a third spoonful of water was added; when this, too, was almost dry, all the water from the brass pot was poured in, and a teaspoonful of salt having been put in, the mixture was boiled. As soon as the bubbles showed that the liquid was boiling, it was ladled out with a spoon formed from a gourd into a sort of churn, made from a thick piece of bamboo about two feet long. The churn was provided with a wooden cover, through a hole in which a piston rod worked, the piston being simply a round piece of wood roughly fitting the interior of the churn. The boiling liquid having been poured in, the churn was worked for a few seconds, and then about a tablespoonful of ghee was added to the mixture. The churn upon this worked vigorously for a few minutes, considerable pressure being evidently required to force the piston up and down. The Bhutia next poured back the liquid into the earthen pot (which meanwhile had remained on the fire) and tested the tea. He stated that more salt

was wanted, and added accordingly about an eggspoonful. The whole was boiled again for about a minute and then tested and pronounced excellent. The amount was about equal to the contents of two ordinary quart bottles.

4. Attempts have, I believe, been made to produce from the refuse of Tea gardens a substance resembling Bhutia Brick Tea, but so far, I believe, they have been unsuccessful. It would seem, however, that the endeavour should not be given up, as there can be little doubt that if Planters could manufacture a commodity which would suit the taste of the Bhutias, Assam Tea might penetrate eventually into Central Asia. Bhutia Tea can hardly be the produce of any country but China, and although recent enquiries tend to show that China Tea can be carried wonderfully cheaply into Thibet, yet it is hardly possible that Assam Tea could not undersell it. Even supposing that the Bhutia's more than doubled the real price in their statement to me, and that in Bhutan Chinese Tea can be bought at R1-8 per brick (about 5½ annas per lb.). I imagine an Assam planter, if he could produce a similar article at all, could do so for 3 annas a pound, or even less. This would certainly enable him to sell with a profit, and yet at a price which would probably induce the Bhutias to buy.

5. The obvious objection to any attempts to manufacture Brick Tea is that, even if made, trade with the savage tribes on the Assam borders is too inconsiderable to produce an effect on the Tea Industry of Assam. The objection is perfectly sound as far as these tribes are themselves concerned, but it will not apply if we can once break the Chinese monopoly. If the Bhutias perceive that they can buy the materials for the extraordinary mixture they call Tea at a cheaper rate in Assam than in Bhutan itself, they are certain to make their purchases here instead of in the interior. Once introduced at a cheap rate into Bhutan, it is more than probable that our Tea would pass into Thibet, and its spread in the interior of Central Asia would be then regulated mainly by the cost of its carriage from Assam as compared with the cost of carriage of Chinese Tea from China.

6. The above considerations have led me to obtain samples of the stuff the Bhutias use, and I am sending you a small box containing three bricks of tea and two sealed bottles of the infusion I saw manufactured. You will be the best judge of the method in which to utilize the samples, should you consider the subject sufficiently important to justify your taking action.—H. Z. DARRAH, Offg. Director of Agriculture, Assam.—*Indian Tea Gazette.*

SILK CULTURE IN SIAM.

In a report issued by the Foreign Office on the condition of Siam, it is stated that the culture of silk is strictly confined to the numerous Laos settlements throughout the country, and to the Cambodians in the south-eastern provinces bordering on Cambodia; nowhere are any Siamese known to rear the silkworm. The reason generally given is that whilst the art of silk culture, which is deemed a difficult one, has been transmitted to the Laos through successive generations, the Siamese are in complete ignorance of it. The great centres of the production of silk in Siam are Korat 130 miles to the north-east of Bankok; and Battambong, 200 miles to the south-east. Beautiful cloths, sometimes of great value, are woven in Chiengmai, and a certain quantity of raw silk is said to be exported from Hluang Prabang, on the Mekong river, to Chiengtung, one of the principal Shan States. The production, however, is small in comparison with that of Cambodia and Annam, and the export is, consequently, unimportant, consisting entirely of so-called Korat silk. It is taken to the latter place in small quantities from the neighbouring Laos and Cambodian provinces, such as Buachum, Pimai, Suwanaphum, Sisakat, Khukan, Sangkha, and Surin, and there sold, or more generally bartered for cotton and other goods, to Chinese traders, who re-sell it a Bangkok to the exporters. At present, half the number of families in a village composed entirely of Laos rear the silkworm, but they almost all, without any exception, weave their own cloths. The silk culture is confined solely to the women, who take a share even in the cultivation of the tree. A large proportion rear the silkworm only in the wet season, when the plant is in leaf, and, therefore, obtain the seed from the few who rear a small quantity throughout the year, barely sufficient to keep up the breed, or only a small quantity of leaves is furnished by the plants during the hot season. The tree is called by the Laos, *ton mon*; and the worm, *tua mon*. There are two kinds of trees, and it appears doubtful whether they were originally distinct. The large kind is similar to the mulberry tree, and in its full growth attains a height of from twenty to thirty feet. This tree is by no means common, as it is found very difficult to rear, requiring great care when young, though when it has firmly taken root it requires no attention, and is said to attain a great age. Like the European tree, it has a small white flower in cluster, but it bears no fruit. In Hluang Prabang, about four-hundred and fifty miles to the north, it is said to bear a red berry, and is probably the same as the European black mulberry tree. It is reproduced from cutting, and is found to grow best on dry sandy soil. The common description of tree is much smaller, and consists of a stem about half an inch in diameter, with small branches at regular intervals. Its height is generally about five feet, but it sometimes reaches seven feet. The bark is similar to that of the large kind, and the leaf appears to differ only in size. It is planted on dry ground, and requires constant watering and some care until it has grown to a height of one or two feet, and is measured once a year, in the sixth month before it is cut. The shape of the leaf is cordate or deeply indented. Its size does not exceed two or three inches in the small kind, while that of the larger is often more than double. Both kinds bear leaf all the year round, but very little in the hot season. It is from the eighth to the eleventh month, that is to say, from June to September, that the new trees bear a sufficient quantity of such tender leaves as are most suitable for the young worms. The silkworm rearing season is, therefore, from the end of June to the end of September, and two broods are generally reared. The eggs are hatched in the period of ten days, the worms are then kept on the same piece of cloth on which the eggs have been laid by the moth for four or five days, when they are large enough to be taken off and placed on a round flat tray of bamboo wickerwork about three feet in diameter, with a rim one inch high, in which they are kept until ready to spin the cocoon. The wicker-work is not close, but sufficient space is kept for the litter to pass through without the worm falling off, and the basket is then called *takrĕng*; this precaution, however, is often neglected, and the ordinary baskets used for winnowing rice are commonly used. These are called *kadong* both by Siamese and Laos, but in the north the rim is generally higher, and they are then called *hô*. The worms are not fed for the first few days, they are then fed three times a day. They cast off the skin four times, and the size of the worm at the third casting of the skin is about an inch, and it is then of the ordinary greenish tint. The worms that are ripe are removed to a tray similar to the one described above, but having on its flat surface a number of concentric circles of bamboo trellis work about an inch and-a-half high; there is thus between the circles a series of compartments one inch and a half broad, in which worms spread their web and spin the cocoon in the course of a day or night. This tray, called *tcho* by the Laos, as well as the other ones containing the worms or seeds, are all placed on a series of frames called *khĕng*, made in such manner as to prevent ants or other insects from molesting the worms or cocoons. The contrivance is very simple, and is constructed as follows. A series of four or five oblong frames are formed by four vertical pieces of bamboo, or sometimes rope, about four feet long, which are kept apart

at intervals of about ten inches by horizontal pieces two feet long placed broadwise, and rather less than four feet long placed lengthwise. The whole is firmly attached, and the two vertical pieces on either side are tied together after the topmost tray, and the rope is made to pass through a cup, generally half a coconut, filled with water. The whole is then suspended to a horizontal pole which hangs from the ceiling in the corner of the common sitting-room or bedroom. In size, the Siamese cocoons compare unfavourably with the European kinds, being only about two-thirds as large. But in the Northern Laos provinces, where there are two rearing seasons, one in the late summer and the other in late autumn, the cocoons of the first produce are said to be of a large size. The following is a description of the spinning machine in vogue in Siam. It is very simple, and consists of a thin piece of soft wood about two inches broad; bent in the shape of a horse-shoe; about ten inches from its extremities a piece of wood of like thickness and breadth, and having a small hole in the middle, is fixed horizontally, and about six inches above it is a small winder placed horizontally in the same manner. The two extremities of the machine are fixed on two small flat pieces of wood, having a groove on the inner side, which enables it to be fixed on to the rim of an earthen pot. it thus stands over the mouth of the pot filled with boiling water, in which a number of cocoons have been thrown. The spinner sits before a small fireplace, on which is placed the pot with the spinning-machine fixed firmly on to it, and with a stick having a small slit at the top, shakes the cocoons in such manner as to collect the threads of about half the number in the pot. Having twisted them with the hand into a single thread, it is passed through the small hole and fastened loosely over the winder. It is then pulled out with the right hand, the winder being thus caused to revolve, and is gradually heaped up in a basket close at hand. In the left hand the spinner holds the stick described above, with which to keep down the filament when it becomes entangled. Th is macihne is called by the Laos *mak khueng talok*, and its height is generally about three feet. The method of reeling is as follows:—The thread is reeled on a winder twenty inches long, fixed horizontally on a stand, on which the thread is improved by scraping off with a knife where it appears irregular, and by removing any blemishes. It is then re-reeled on another winder made of two sticks, fixed horizontally on the extremities of a piece of wood about two feet high. This is held in the middle with the left hand, and the thread wound in zigzag fashion with the right over the extremities of the cross sticks. The skein thus takes the shape in which it is generally sold. Sometimes this winder is replaced by another, formed of four cross pieces instead of two, the extremities of which are joined with string; it is then laid horizontally on a stand, is furnished with a handle, and the thread is reeled over the strings. This winder, called *ra wing*, is used both by the Laos and the Siamese. When it is required to twist a double thread or tram another instrument comes into use. A narrow stand, about four feet long, contains at one end a large wheel turned by a handle; a string is passed over the latter and round a piece of iron a foot in length, projecting from the stand on one side and rounded at the end. Some rough cotton is wound over the middle part in which the string catches so that in turning the wheel the iron point revolves quickly. The two or more threads are tied together to the extremity of the iron instrument, and this in revolving twists them firmly together.—*Journal of the Society of Arts.*

RAINFALL PER ACRE.—People scarcely understand by rainfall in inches what this really means, but an inch of rain means a gallon for every two square feet, or 100 tons per acre.—*Gardeners' Monthly.*

TEA CULTURE.—Unless we are wise, Italy will get the start of us in tea culture. A plantation at Novaro has been so successful that the Italian government is arranging to plant largely the coming year. —*Gardeners' Monthly.*

SPIDERS.—Dr. C. Keller, of Zurich, claims that spiders perform an important part in the preservation of forests, by defending the trees againts the depredations of aphides and insects. He has examined a great many spiders, both in their viscera and by feeding them in captivity, and has found them to be voracious destroyers of these pests and he believes that the spiders in a particular forest do more effective work of this kind than all the insect-eating birds that inhabit it. He has verified his views by observations on coniferous trees, a few broad-leaved trees and apple trees.—*American Grocer.* [The many thousands of spiders whose webs can be seen on dewy mornings on tea bushes, are probably doing a good work.—ED.]

SUGAR.—*The Journal des Fabricant de Sucre* gives an account of a new process for filtering beet sugar through sand instead of animal charcoal. By the new system considerable expnse is saved, and a brilliant yellow sugar superior to Demerara crystals is produced. It is impossible to make white sugar by this process only, and if charcoal is done without carbonataion—that is, the separation of carbonic acid from carbonate of lime, and the use both of the lime and of the resultant gas in the saccharine liquid—is substituted for it.—*Home and Colonial Mail.*

MILDEW.—We are often asked what can be done to master the frequent attacks of mildew on plants. One of the most recent recommendations for this purpose is sulphide of potassium, which is a compound of sulphur and potassium—not potash. This used in solution at the rate of ½oz. to the gallon of water is fatal to mildew and fungoid parasites; and is besides destructive to many pernicious insect pests. Lime and sulphur mixed in the proportion of four parts lime and one sulphur may also be used successfully either by dusting it on the affected parts dry, or by pouring boiling water over them and making them into a solution. The solution must be used while fresh, and should be applied with a brush. Some soft soap mixed with it will make the mixture more effectual where scale and the like is concerned.—*Planter and Farmer.*

PLUNGING PLANTS IN POTS—The meaning of the term plunging—well known to gardeners—is that the pot is sunk in some substance that will retain moisture—soil, sand, coal ashes, sawdust, and cocoa fibre refuse being the substances commonly used, and of these the lastnamed is considered the best. The effect of plunging pots is that the soil they contain remains longer in an equable condition, and plants suffer less from the frequent excesses of moisture and drought, to which they are subject when the pots are exposed to the air. It may be easily understood that the daily watering of plants is an unnatural process, and therefore must be more or less injurious, retarding the progress of plants subjected to excess of moisture at one period, and perhaps in a few hours to immoderate drought in the soil, the process of assimilation being checked both when the soil is saturated, as it must be for some time after watering, and also when too dry; both of these evils being reducable by plunging the pots, whether in the house or out of doors. Plants on window sills are especially liable to these fluctuations, and frequently also in plant houses, especially when the sun is allowed to shine on the pots; while plants in pots set on the surface out of doors can hardly be got to thrive unless closely shaded, although watered twice or thrice a day, suffering not only from alternations of drought and moisture, but also of heat and cold, the rapid evaporation through the sides of the pot chilling the roots, which are again subjected to intense heat when the moisture has evaporated. Independent of the benefits resulting from the plunging of pots, the saving of labour is also worthy of consideration, being in nearly all circumstances very great; and nurserymen as well as other plant growers should take advantage of it to lessen their very heavy labour accounts, to which watering in summer time causes a large increase.—*Planter and Farmer.*

WASTE COAL AS MANURE.—Mr. J. A. Price, Scranon, Pa., believes that coal dust will make an excellent fertilizer. Mountains of it, brought from the mines as screenings, are piled up in the coal regions. Its dark colour is in its favour. Dark soils are always more favorable than light ones for many purposes, by reason of their absorption of heat; and its carbonaceous properties ought to give it additional value.—*Gardeners' Monthly.*

NORTH BORNEO.—It is stated that the British Borneo Trading and Planting Company, to which we have previously called attention has proceeded to allotment, so that the Company may now be considered as definitely started. Mr. Walker, who will be the Manager in Borneo, was to leave London about the end of February for Singapore and Borneo, to commence active operations on behalf of the Company. We understand the British North Borneo Company, who have granted the concession, accept payment for the 20,000 acres allotted to the Company in shares. The directors are Messrs. C. Bennett (Brolin Bennett & Co.), E. Locke (Taylor & Locke), J. A. Travers, and J. J. Dunn, the concessionaire.—*Straits Times.*

"COCOES"—(WHERE IS THIS CONFUSION TO STOP?).—At a meeting of the Linnean Society on March 3rd, there was read a paper on "Disease of Cocoes at Jamaica," by Messrs. G. Massee and D. Morris, F.L.S. It appears that a somewhat virulent disease has made its appearance amongst cocoes (or, as they are sometimes called, tanias eddoes or taros) in the parish of Portland, Jamaica, and the matter has been taken up by Government, by whom specimens were sent to Kew for examination. Cocoes form an important item in the food supply of the negroes, and the loss of such a food would be a serious matter to them. It appears that the plants are attacked by a disease very similar to the potato mildew, and which, being a new species, has been named *Peronospora trichotoma*. The authors of the paper have drawn attention to the nature of the disease, and indicated the practical steps to be taken in order to contend successfully with it. It is hoped that stringent measures will be adopted to confine the affected plants within the district in which they were first found and that they will be thoroughly destroyed by burning. Fresh cultivation should be started with plants from a district free from disease.—*Colonies and India.*

AVENUES OF DISTRICT ROADS.—The following letter appears in the *Indian Agriculturist*:—

To the editor.—Sir,—Referring to the letter on "Avenues on District Roads" appearing in the issue of your paper dated 1st April 1879, page 139, I shall feel greatly obliged if you will be good enough to inform me whether any great extent of the roadsides in India have been so cultivated; and if so, the number of miles so cultivated, the aggregate number of trees and plants now growing, the system of cultivation, whether by day labour or otherwise, the average expenditure on each tree till maturity, and the average estimated profit to Government on each tree at felling.

CHAS. STOUTER,

Jany. 30th, 1887. Audit Office, Colombo, Ceylon.

NOTE.—This is rather an extensive enquiry, requiring much time and trouble. We shall do what we can in a future issue to supply the information to some extent; meanwhile some of our readers might help our correspondent.—ED. *I. A.*

To which we have to add that Mr. Stouter of the Audit Office, Colombo, is very comprehensive in his enquiries and the editor of the *Indian Agriculturist* very good-natured in not having referred him to the Agriculture Department of the Indian Government. Since the days of the Mogul Emperors tree avenues, on the great trunk as well as district roads, have been encouraged. Recently a fresh impetus has been given to the enterprise. Be it remembered that it is only in climates which for large portions of the year are rainless that trees can be planted along side of roads without serious injury to the roads. In the hot season in India the shade of the pipul, nim and cassia trees is most grateful.

GOOD; IF TRUE.—According to the London correspondent of the *S. M. Herald*, a sugar-tree more productive than the sugar-cane, is attracting attention in India. It is called the mahwa or moola tree, and grows in Southern Hindustan, and in the northerly regions abutting on the Himalaya Mountains. The mahwa bears about a ton of blossoms, and each flower is little else but a vegetable envelope filled with pure saccharine matter. One ton of blossoms will yield about half-a-ton of sugar. The best managed cane-plantations of the West Indies do not, at the outside, yield more than two and a half or three tons of sugar to the acre. The French and German beet-fields do not produce more than fifteen to twenty tons of beet to the acre, which yield about 7 per cent of sugar, or rather less than an acre of sugar-cane. Five mahwa trees will yield the same amount of raw sugar as an acre of sugar-cane; and an acre which would contain from 200 to 250 trees, would produce enough blossom to give from 100 to 120 tons of sugar, beside which no expense would be incurred either in growing or harvesting. A consignment of the mahwa blossoms is on its way to the Continent, for the opinion of the sugar refiners to be given thereon.—*Planter and Farmer.* [There is sugar enough in the mahwa blossoms to render them acceptable and nutritious food to the natives, and spirits can be distilled from the blossoms. But the statements about sugar obtained from them is from gross exaggeration.—ED.]

BADULLA DISTRICT, 26th March.—Heavy showers, accompanied with much thunder and severe lightning, have fallen over the greater portion of Upper Uva. The electric disturbance has been very great; the thunder clouds seemed to gyrate round and round from Idulgashena or Haputale to Hakgalla, across to Udapussellawa and Maturata, and from Narangalla to Hewa Eliya rock, along the whole Madulsima range to Namunakuly and Ella rock to Leangahawella and Haputale. The showers have been heavy, but partial; still I do not think any part of the district can have escaped getting a portion of the very welcome rain. The long-continued, dry weather, amounting in some places to absolute drought, is almost unprecedented here at this season, and tea and cinchona refused to flush or to grow; the cold, dry wind, sometimes almost a hurricane during the night, followed by scorching dry sun without a cloud in the sky, was trying to all vegetation; only coffee, where sheltered from the wind, seemed to revel in the dry sunshine, and even green bug has departed, for the time being at least. Canker in cinchona has almost disappeared, but only the hardy acclimated varieties are now grown. Uva cinchona has barely "touched" the market yet, and wise planters continue to plant their own seedlings on the principle of the Scotchman's advice to his son: "Keep sticking in a tree, Sandy, they will grow when you are sleeping." No fancy varieties of cinchona are planted here now, costing fabulous prices for seed—say "R150 per gram."!—but there is no estate where thousands of hardy, acclimated, self-sown hybrids and "sports" cannot be planted at a nominal cost, without risk of failure, and without hurt to other products. These trees grow whilst the proprietor "sleeps," but some day he wakes up to find a very valuable property in large, healthy cinchona trees, scattered over his property in places where nothing else would grow, and, even at 3d. a unit of quinine, a very valuable accessory to the other produce of his estate. Let no one think Uva cinchona will shortly be "snuffed out," "cropped out," or "cut out." Cinchona will continue to be a *large* export from Uva as long as the Province lasts.

CINCHONA IN JAVA, INDIA AND CEYLON.

We have already referred to the opinions of Mr. Kessler, on the prospects of cinchona in Java where he holds extensive proprietary interests. Mr. Kessler has now returned from his visit to our hill country and as the result of his observations and enquiries, his opinion is very much strengthened that the future of cinchona lies with Java. The large exports from Ceylon, he considers, will be played out in the course of two or at most three years and by that time, Java planters will be fully coming on the market with their fine barks giving results in sulphate of quinine which will make one million lb. Java equal to several millions from Ceylon, so far as concerns results to the manufacturing chemist. Mr. Kessler is therefore of opinion that the Ceylon cinchona owners stand between two fires :—for them to harvest before 1889-90 will be a necessity, and yet by so doing freely the market is likely to be kept in its present depressed condition—that is, if the 15-16 millions lb. of export can be kept up so long. Mr. Kessler is strongly of opinion that even now, the average of the Java bark exported is much more than 3 per cent of sulphate of quinine, while three years hence, he thinks 6 per cent would be a low estimate of the average result from the large bulk of the exports. The extent covered with cinchona in Java, he thinks has been underestimated. He has scarcely seen anywhere in Ceylon—unless it be on Lover's Leap and in that neighbourhood—cinchona fields equal to those which for their vigour and fine growth distinguish Western and Southern Java ; but then Mr. Kessler although he has learned a good deal from Uva planters, has not visited the estates beyond Badulla. The 100 acre field on Cannaverella, for instance, we should say is as good of its kind for big healthy growth as any in Java. The great difference is however, that Java planters have discarded all inferior kinds and give their attention solely to the better kinds of *Calisaya*, more especially *Ledgeriana*. *C. Officinalis* is almost unknown with them : whereas of course in the climate and soil of Ceylon this hardy species, and its hybrid *Robusta*, is the most successful. Altogether Mr. Kessler's advice to those thinking about planting Cinchona in Ceylon is "Don't", because (as he supposes) the inferior Ceylon barks are bound to be thrown out of competition by the superior Java. Many, however, will doubt this—or at any rate the ability of the Java planters to send away so much bark as will meet an increased demand besides the deficiency created by a great falling-off in Ceylon exports. We shall see.

In respect of tea, Mr. Kessler feels and acknowledges our great superiority : he thinks there is something in our climate, but also that superiority of jât must have a good deal to do with it, and for this reason Java planters are freely rooting out their poorer jât trees and planting anew with Assam-hybrid plants. Mr. Kessler who is now in his way to Europe, has been so much interested in Ceylon and its plantations by this visit that he is likely to send us contributions from time to time on planting topics, more particularly for our *Tropical Agriculturist*.

In contrast to the picture offered of the future of cinchona in Java, is that supplied by Mr. Hamlin, with his very wide experience of the same cultivation in the various districts of India. Mr. Hamlin does not believe that there is at present any chance of Indian planters getting above a total of a million lb. in exports, apart from the out-turn of the Government Gardens, most of the latter at least in the North, being utilised for local manufacture of alkaloids. Mr. Hamlin has left at our office some fine specimens of bark (grown under his own direction) six years old renewed, cultivated at 6,000 feet in the Upper Ouchterlony Valley, of which, trees at 4 years old he gave a very satisfactory report in our *Tropical Agriculturist*. But the show piece before us has been stripped off a Succirubra tree, and is 3 feet long by 10 inches in circumference, while in appearance it is simply magnificent, although in analysis the value is probably *nil*. As show barks for druggists' windows, such pieces ought to sell well however ; and for 20,000 lb. of the same—to be placed on the market gradually,—Mr. Hamlin will be disappointed if the average result is not equal to about 5s per lb. Some years ago, 10s a lb. would be readily paid by wholesale and retail dealers for such show barks. Mr. Hamlin promises a memorandum with the history of the barks in his case of samples and when this is received, we shall send the collection round the mercantile offices in the Fort for inspection.

PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

A sugar estate in the province of Kedirie which under European management, had only been a source of loss has this year, after it had passed into Chinese hands, yielded a splendid crop, and given a handsome profit. Instances of the kind pretty common in that island, show conclusively that Chinese can make money where European enterprise breaks down.

Recent researches in the island of Java and Sumatra have proved the presence of petroleum springs there. It seems they are of some value. In order to ascertain the best method of turning these productive resources of the country to account, the Netherlands Minister for the Colonies has despatched Mr. A. Stoop, a mining engineer, to the petroleum districts of the United States, to get himself fully posted as to the most practicable methods of working them. Private enterprise has already set to working the petroleum springs on the East coast of Sumatra with every prospect of success.

The Planters' Association at Sukabumie in Java have petitioned the Netherlands Indian Government praying the latter to grant a subsidy for the setting up of an experimental plantation for hill cultivation. A movement has also been started for the additional purpose of securing State aid for trial plantations in general.

LIQUID FUEL.

Details of Trials on San Francisco Bay.

For two or three years past some very interesting trials of the use of oil for fuel, instead of coal, have been conducted by the Central Pacific Railroad Company on the freight and passenger ferry steamers on San Francisco Bay. When, therefore, a short time since the use of this liquid fuel was abandoned by the company, and the furnaces of the boilers again altered to burn coal, it was concluded that oil burning was a failure. It was thought strange, too, because it was understood that the oil was the more economical fuel, doing away, as it did, with the numerous firemen on the steamers, since the oil was fed to the furnaces by an automatic arrangement. A number of reasons

were given by the general public for this abandonment of oil as fuel, among them that the supply was insufficient; that it cost too much, and finally, that it burned the furnaces and boilers out so badly that it cost more than it came to finally.

As the matter is of considerable general, as well as local, importance, we have obtained some information on the subject, which, being mainly official, will be read with interest.

In the first place, as to the character of the liquid fuel itself. It is not a crude petroleum, as many suppose. It is a residue or refuse. The Pacific Coast Oil Co., before selling this material, remove the lighter oils, which enables them to sell the refuse at low cost. The first product removed is gasoline of 84° specific gravity; the second is naptha of 74° specific gravity; the third is benzine of 63° specific gravity; the fourth is what is known as water-white illuminating oil of 48° specific gravity. Then they remove the standard white illuminating oil of 44° specific gravity. This leaves a refuse of about 26° specific gravity, which is the fuel oil used on the steamers.

The Steamer's Records.

The liquid fuel was used on three of the largest steamers of the company, the "Thoroughfare," "Piedmont," and "Solano"—the latter the largest ferry steamer in the world. The records of the runs and results of work on these steamers we obtain from the office of the Auditor of the Motive Power and Machinery Department of the railroad company.

The first steamer to consider is the "Thoroughfare," which runs from Oakland Creek to the depots at the southern end of this city, carrying freight trains across the bay.

Steamer "Thoroughfare," Dec. 1883, to Dec. 1884, with coal:

6,169 tons Ione coal at $3.96	..	$25,617 24
62 tons Carbon Hill at $5.50	..	506 00
		26,123 24
Pay of firemen	..	3,049 61
Total cost of fuel and firemen	..	29,172 85
Miles run .. 22,662½		
Cost per mile in cents—fuel .. 115.27		
Do do —firemen 13.46		
Total cost .. 128.73		

Steamer "Thoroughfare," Jan. 1885, to Aug. 1886, with oil:

2,135¼ barrels of oil at $1.65	..	$ 3,523 16
11,519¼ do do 1.70	..	19,582 72
		23,105 88
Pay of firemen	..	2,227 35
Total cost of fuel and firemen	..	25,333 23
Miles run .. 40,800¾		
Cost per mile in cents—fuel .. 56.63		
Do do —firemen 5.46		
Total cost .. 62.09		

The above shows 66 64.100 cents per mile in favour of oil, or 51 77.100 per cent. In this statement it is shown that 58.14 gallons of oil equalled one ton of coal.

The "Piedmont," a large steamer, is in the ferry traffic between Oakland Mole and San Francisco. She was originally devised for coal, but was afterwards fitted for oil (as were the other steamers).

"Piedmont," Nov., 1884, to Aug., 1885, with coal:

4,029¼ tons Carbon Hill coal at $5.00	...	$24,646 25
1,285 tons Carbon Hill coal at 5.50	...	7,067 50
		31,713 75
Pay of firemen	..	7,658 04
Total cost of fuel and firemen	...	39,371 79
Miles run ... 43,525		
Cost per mile in cents—fuel 72.86		
Cost per mile in cents—firemen 17.59		
Total cost ... 90.45		

Steamer "Piedmont," Sept., 1885, to Aug. 1886, with oil:

4,136 barrels of oil at $1.65	...	$ 6,829 35
15,983 barrels of oil at 1.75	...	27,174 50
		34,003 85
Pay of firemen	...	4,541 76
Total cost of fuel and firemen	...	38,545 61
Miles run ... 44,307		
Cost per mile in cents—fuel 76.74		
Cost per mile in cents—firemen 10.25		
Total cost 86.99		

The above shows 3 46.100 cents per mile in favour of oil, or 3 8.10 per cent. In this case it took 133.63 gallons of oil to equal one ton of coal.

The "Solano" is the immense steamer which takes the overland trains, freight and passenger, across Carquinez straits, between Benicia and Post Costa. The run is very short.

Steamer "Solano," Dec., 1883, to Feb., 1885, with coal:—

1,027½ tons Carbon Hill coal at $5.00	...	$ 5,137 50
2,090½ tons Carbon Mill coal at 5.50	...	12,047 75
5,724¼ tons Empire coal at 3.79	...	21,694 91
	...	38,880 16
Pay of firemen	...	8,476 70
Total cost of fuel and firemen	...	47,356 86
Miles run ... 7,504		
Cost per mile in cents—fuel ... 518.12		
Cost per mile in cents—firemen. 112.96		
Total cost ... 631.08		

Steamer "Solano," March 1885, to Aug., 1886, with oil:

2,395¼ barrels of oil at $1.65	...	$ 3,952 16
16,909 barrels of oil at 1.70	...	28,745 30
		32,697 46
Pay of firemen		8,496 84
Total cost of fuel and firemen	...	41,194 30
Miles run ... 7,308		
Cost per mile in cents—fuel ... 447.42		
Cost per mile in cents—firemen. 116.26		
Total cost ... 563.68		

The above shows 68 40-100 cents per mile in favour, of oil, or 10 68.100 per cent. This gives the result of 94.16 gallons of oil equal to one ton of coal.

Last month the Pacific Coast Steamship Company, desiring to get some idea of details of cost of use of oil, with a view to adopting it on their steamers if possible, had Mr. John Bermingham examine the matter for them. He wrote the following letter to Edwin Goodall, Secretary of the Company:

"Edwin Goodall, Esq.—Dear Sir,—I have examined the condensed results of the relative values of coal and oil on the "Solano," "Thoroughfare" and "Piedmont." There is great apparent saving in favour of oil fuel on the two first-named steamers, and a slight apparent saving of 3 3.10 per cent. in favour of oil fuel on the "Piedmont." I have no means of knowing whether the price charged for Carbon Hill coal is excessive as compared with other well-known fuels consumed here, or to the reverse. But there is one very important element that has not been taken into account by the railroad company's statistician, and that is, the relative speed developed by the "Piedmont" while using the different fuels above mentioned. In journeying

across the bay on that vessel I have been informed by her officers that the trips were made with coal in from 17½ to 18 minutes, while with oil 19½ to 20 minutes were consumed. If *that* be *true*, the difference in speed in favour of the coal would be almost one mile per hour, which means 25 per cent., as it requires that percentage to increase the speed of a vessel one mile per hour ('eight times the power to double the speed'), so if the speed obtained by the use of oil *could* have been brought up to that obtained by the coal, 25 per cent, more oil would have been consumed; or, *vice versa*, if the coal speed had been brought down to the oil speed, 25 per cent. less coal would have been consumed.

"It required from eight to twelve per cent. of the water evaporated by oil fuel to perfect its combustion. The rail-road statistician does not appear to have taken the cost of that water into account.

"The "Piedmont" had to keep her oil fuel burning all the time between trips in order to 'bottle up' steam to give her a spurt across the bay. I know nothing of the relative speeds with oil and coal in use on board the "Solano" and "Thoroughfare," where the oil *appears* to be the most economical.

"Your oil steamers might possibly use that fuel with diminished speed, but you would have to make provision for three tons of fresh water per day for its consumption.

"J. BERMINGHAM."

A copy of the above letter was forwarded to Master Mechanic Stevens, of the Southern Pacific Co., who brings out further facts in connection with the subject in his answer, which is as follows:

"SACRAMENTO, Dec. 3rd, 1886.

GEO. LOOMIS, ESQ., PRESIDENT PACIFIC COAST OIL CO.—Dear Sir,—I am in receipt of your favour of the 22nd ult., inclosing copy of a letter written by Mr. J. Bermingham to Edwin Goodall, Esq., in regard to oil fuel burned on the steamer "Piedmont."

"Mr. Bermingham figures in this instance altogether from theory. At the outset he says: 'There is a great apparent saving in favour of the oil fuel on the two first-named steamers, and a slight apparent saving of the three and three-tenths per cent. in favour of the oil fuel on the "Piedmont."'

"So far he is correct; but he does not take into consideration the saving effected on board the steamer "Piedmont" by the use of oil fuel in the reduction of firemen—an item amounting to about $14 per day. Neither does he consider the $6 per day which it costs to place the coal on board the boat—the oil was handled by the deck hands at no extra expense whatever.

"Further on Mr. Bermingham states: 'There is one very important element that has not been taken into account, and that is, the relative speed developed by the "Piedmont" while using the different fuels above mentioned.'

"The element of speed *was* duly considered; and permit me to say, there was no such difference as the gentleman mentions— coal 17½ to 18 minutes and oil 19 to 20 minutes. True, the time of crossing of the "Piedmont" was somewhat less with coal than with oil, but not to exceed half a minute less per trip run on an average. In the case of the "Solano" the speed was always equal to and usually greater with oil than with coal, and the steam could be increased while under way to any pressure desired.

"In making this comparison there is another important factor which Mr. Bermingham and others who have manifested so much interest in the matter seem to have entirely overlooked: that is, the construction of the "Piedmont" boilers. These boilers were constructed specially for burning coal; they are flue boilers and not adapted for oil fuel; while with the steamers "Solano" and "Thoroughfare" the case is materially different; the boilers of the latter boats are of good design or pattern for burning oil fuel.

"Mr. Bermingham further says: 'It requires from 8 to 12 per cent of the water evaporated by oil to perfect the combustion. The railroad statistician does not appear to have taken the cost of that water into account.'

"Our records show nothing of the kind. They show, however, that the consumption of water with coal and oil was the same per trip run. True enough, it took some steam to perfect combustion, but it was hardly appreciable, though, of course, it amounted to something.

"Referring again to steamers "Solano" and "Thoroughfare," I will say that the saving effected by those steamers by the use of oil was considerable (I believe you have the reports showing just what it was), and if the saving by the use of oil was so great on those boats why should it not be just as great on the "Piedmont"? The reason, the true reason, and the only reason, lies in the difference in the design of the boilers. I will state further that during the time the different boats were burning oil, we were not called upon to make repairs to the boilers; while with burning coal there is not a week when more or less repairs are not necessary.

"I will add, taking Mr. Bermingham's statement, that '12 per cent. of the water evaporated was required to perfect combustion.' Assuming this to be the case, 12 per cent. of the water actually evaporated during the test of oil for six days is 19,968 gallons. Our records of the test show the same number of gallons evaporated in both cases.—Yours truly,

A. J. STEVENS,
General Master Mechanic."

From these statements it will be seen that the oil fuel was the most economical, notwithstanding it has been given up by the company. The only explanation of this is in the surmise that as the company owns an extensive coal mine, coal steamers, &c., they can afford to use coal when others cannot.—*Mining and Scientific Press*, San Francisco.

TOBACCO CULTIVATION IN MEININGEN.—The last harvest of the tobacco cultivated in the Leimbach district according to the American method has recently been sold. Though the average yield is less as to quantity than in 1884 the quality is decidedly better. The price given is 36 Mks. per centner and tax in addition. Such a yield of the soil is not obtainable with any other field produce, not even with sugar beets, and it is to be desired that small agriculturists would, in view of the low price of corn, turn their attention to the cultivation of American tobacco which now is only carried on in a few places in the Salzungen district. The Meiningen lowlands with their sandy soil are very suitable for the cultivation of tobacco. If the new method of cultivation were more widely known it is quite possible that the growing of tobacco, which for ten years has only been carried on at Wasungen, Schwallungen, Breitungen, Wernhausen, and Helmers, would become a prosperous industry. It is beyond doubt that with more careful handling the yield of American tobacco could be materially increased. Though this method of cultivation has been followed for three years, it is still new, for it cannot be mastered at once. The method was first adopted in Germany by Leimbach. German legislation did not permit the American way of cultivating tobacco previous to 1883, and when Herr Hartmann Schmeer returned in that year to Leimbach from America for the purpose of beginning the cultivation of tobacco, he had to obtain the sanction of the Bundesrath.—*Kuhlow's German Trade Review.*

RHEA IN EGYPT.

A correspondent of the *Manchester Guardian*, writing of the progress of this industry says that "there are over 40 millions of established yearling Rhea plants ready for sending to Zagaloun, near to Zagazig Station on the Cairo Suez Railway, and supplies of selected plants from the same source—the Franco Egyptian Rhea Company (Limited)—are not only being forwarded to other intending growers in Egypt itself, but are now ready for exportation to India and Central America." Rhea admittedly thrives best in Egypt, sun, soil, irrigation, and cheap labor being in its favour. It does well so in India; but the plant being at its best in the rainy season, in India there will always be some difficulty in collecting and preparing it for market. It is said that amazing profits can be made from the cultivation of the new plant and it is expected that we shall see, before many months are over, Ramie becoming a formidable rival to cotton and even to wheat cultivation in the purely agricultural land of Egypt. The whole of the produce raised, however, is likely to flow to France for the exclusive use of continental looms, unless English capital and English enterprise bestir themselves.

There is room for twenty Companies of the kind, and the native proprietors would be more willing to invest their money in organisations conducted by competent Englishmen, than embark in any enterprize controlled by French administration. In time small landed proprietors will begin to cultivate this hardy plant to the almost total neglect of cotton, wheat, and rice, which have not proved lucrative recently. It is estimated that the yield of an acre of Rhea fibre will produce from £15 to £20 per acre at one cutting, but in good years from four to five cuttings can be counted upon, or better still, the stems may be cut from day to day as they attain a fixed standard height, and are stripped by hand, when even the highest estimate of profit will be exceeded. The plant is perennial, and the two best seasons for planting out Ramie roots are March and September, although it is possible to transplant the stools at almost any time if water is abundant.—*Fiji Times.*

THE FRUIT TRADE OF THE WEST.

As the orange trade of this island with the States is increasing every year, the following extract from the Boston *Evening Transcript* may prove interesting to the general reader and instructive to growers and speculators who may be erroneously anticipating high prices this year:—"I said in my last letter that estimates of the amount of damage done to the orange trees were merely guesses and that the facts could not be known until the sap started. Since that time I have been pretty well over the State and can give the results of my observations. In the northern portion of the State quite a number of trees were killed or severely injured by the January frost, and Jacksonville shows the effects of the freeze more than any place I have visited. In the central portion of the State about Ocala and Citra, but little damage was done beyond the destruction of the fruit on the trees. The trees are all putting out their new growth and seem as healthy as last February. Lemon trees, however, have been generally killed throughout the State. Early vegetables were scarcely hurt at all, and cabbages, lettuce, turnips, etc., are simply a little backward. Strawberries are uninjured, though they will not come in as early as usual, owing to the long-continued cold weather. Above Palatka to the south, one sees little to remind him of the low temperature of last month, and in another week the new growth of green will assume such luxuriance in all directions that the past will be forgotten and forgiven.

About Enterprise and Sanford effort was made to save the oranges, but all in vain. Immense fires were built and kept burning during the three days of cold, but strange to say, scarcely a man thought of picking his oranges after the first cold night and thus surely saving them. If the "lady from Philadelphia" of the "Peterkin Papers" had been ubiquitous, your readers might be eating some Florida oranges now instead of the once-frozen-never-to-be-forgotton-delusive fruit which is on the market. Indian River I have not visited yet. General Chamberlain of Maine told me on my arrival in Jacksonville that he saw one-half inch of ice on the India River, Feb. 5, when the South was visited by that entirely unnecessary second edition of frigidity."—*Dominica Dial.*

DRIED FRUITS.

We quote from the New York *Merchants' Review*, the following account, by U.S. Consul Mason, of the French process of crystallizing Fruits:—"The fruit is first carefully assorted in respect to size and uniform degrees of ripeness. Pears, pineapples, and quinces are pared, citrons are cut into quarters and soaked a month in sea-water, and the 'pits' of apricots, cherries, and peaches are carefully removed. Even this preparatory process requires a certain degree of skill, since the stone must be removed with as little injury as possible to the form and solidity of the fruit. This work is done mainly by women, who earn thereby 50 cents per day. Thus prepared, the fruit is immersed in boiling water, which quickly penetrates the pulp, dissolving and diluting the juice, which is thereby nearly eliminated, when the fruit is subsequently taken from the water and drained, leaving only the solid portion of the pulp intact. This process of 'blanching' must also be done with exact nicety, the period of immersion in the hot water being determined by the size and ripeness of the fruit. If immersed too long, the pulp is either overcooked or is left too dry and woody. If taken out too soon, the juices left in the pulp prevent perfect absorption of the sugar afterwards, and, by eventually causing fermentation, destroy the value of the product. In this, as in other stages of the process, the only guide is experience. A skilful workman can tell by the colour and appearance of the pulp when it is properly 'blanched,' and this knowledge invariably commands employment and liberal compensation. After being thus scalded, some fruits, apricots for example, are again assorted into two or three classes, according to the degree of softness that has been produced, for the reason that if kept together they would take up the sugar differently, some losing their form entirely, while others would remain sufficiently impregnated. For these different grades sugar-syrups of different degrees of density are required, the softer the fruit the stronger the syrup required for its preservation. For the same reason each of the different varieties of fruit requires a syrup of corresponding strength. Pears, citrons, and pineapples, which remains hard and firm, take best a syrup having a density of from 18 deg. to 25 deg., while apricots, plums and figs are treated with syrups which gauge from 30 deg. to 42 deg. by the aerometer. The requisite syrup having been prepared by dissolving the sugar in pure water, the fruit is immersed in it and left at rest for a certain period in large earthenware pans, glazed inside, and having a capacity of about 8 gallons. The syrup penetrates the pulp, and gradually withdraws and replaces the remaining fruit juice, which, as it exudes and mingles with the transparent liquid, produces a certain filmy or clouded appearance, which marks the commencement of fermentation. When this has reached a certain stage, the vessel containing the syrup and fruit is placed over the fire and heated to 212 deg. F. This corrects the fermentation and raises all impurities to the surface, whence, if necessary, they can be removed by skimming. If the syrup is of proper density, this process of impregnating the fruit with sugar will be complete in about six weeks, during which time it is usually necessary to perform this heating process, as above described, three times. The impregnation of the fruit with sugar being thus complete, it is taken out, washed in pure water to remove the flaky particles that adhere, and is then submitted to one of two finishing processes, as follows: If the fruit is to be 'glacéd,' that is, covered with an ice or transparent coating, it is dipped in a thick, viscid syrup of sugar, and left to dry and harden rapidly in the open air; if it is to be 'crystal-

lized,' it is dipped into the same syrup, but is then cooled and dried slowly in a kiln or chamber warmed to a temperature of 90 deg. Fahrenheit. This slow cooling causes the thick syrup with which the fruit is covered to crystallize and assume the usual granulated appearance. The work is now finished. If properly done, the fruit thus preserved will bear transportation to any climate, and will keep, firm and unchanged, for years. It is packed in light wooden or cardboard boxes, and may be shipped in cases containing several hundred pounds each."—*Produce Markets' Review.*

DR. GEORGE WATT, C.I.E., ON "GANJA."

At the evening meeting of the Pharmaceutical Society held in November, Dr. Watt, in speaking of the propagation of ganja, stated that native experts were employed to go through the fields in order to cut down the male plants while they were in the young state; and that if one single male flower were left in a whole field cultivated for ganja, not a single particle of ganja would be produced, but that bhang would be the result.

A Demarara correspondent (Mr. T. W. Hutton, of George-town), writing on this subject, says:—

"If such is the case, can you afford any explanation regarding the presence of fertile seeds in the accompanying sample of ganja, which is considered by the East Indian dealers here to be a very good one? It is received here in original packages from Calcutta, and is labelled 'Ganja.'"

We have submitted the sample to Dr. Watt, and he has sent us the following reply, dated "India Office, February 16":—

"Sir,—I had much pleasure in receiving your letter forwarding a specimen of 'ganja' for my inspection, and asking me for further information to what I gave at a meeting of the Pharmaceutical Society regarding that narcotic. I was not permitted to see the proof of my remarks made at that meeting, and, having a pressing engagement that night, I had to leave before the close of the proceedings. From both these considerations I was unable to correct a defect in what appeared in the Journal. In the first place, I seem to have forgotten to conclude my remarks with what, after all, was the important point, namely, that the 'ganja' made in all other provinces is inferior to that produced in Bengal. The Act regulating the trade in 'ganja' is only enforced to its full extent in Bengal, and hence the 'ganja' of other provinces costs only about one-twentieth of the Bengal. In Bengal a licence has to be taken out to grow, to trade, and to retail the article; and, over and above these charges, the 'ganja' produced has to be stored in the Government 'golahs,' and when removed has to pay a duty of 10*s.* for every two pounds. Naturally only the very purest article goes into the 'golahs;' adulteration, if it takes place at all, occurs in the retail merchant's shop, for while in the hands of the wholesale dealer it passes under a sealed permit. Every stage of the cultivation is carefully supervised, and in no instance are the male plants allowed to grow up with the female, since it has been ascertained that when fecundation occurs the 'ganja' is injured and greatly diminished. The sample you sent with mature seeds cannot possibly be Bengal 'ganja.' In the second place, I should have liked to correct a mistake made by a Bombay gentleman who spoke at the Society's meeting after my departure. He referred to purchasing Bengal 'ganja' in Bombay. I venture to think not one ounce of 'ganja' ever goes to Bombay. We have no record of 'permits' to Bombay and no 'ganja' can leave the Bengal stores without a permit. Again, the 'ganja' from the Central provinces and that grown in the Bombay presidencies is sold in Bombay for about 1*s.* a pound, whereas Bengal 'ganja' costs not less than 20*s.* a pound. It is thus conclusive that the Bombay 'ganja' cannot be Bengal produce.

"In a paper I read the other day at the Society of Arts, I recommended chemists desirous of making the very best extract of Indian hemp to pay the full price for Bengal 'ganja,' and to import the article from Calcutta instead of from Bombay, when there would be every chance that the defects complained of in the extract as now prepared would disappear completely.

"I observe in your letter that you say the sample of 'ganja' sent for my inspection was obtained from a shipment from Calcutta. There is no record of any 'ganja' having been exported from Calcutta to England. Naturally the difference in price would be prohibitive, or be sufficient to tempt an unjust trader in declaring a consignment as having come from Calcutta when in reality it came from Bombay. Be assured of one point,—while we cannot absolutely prevent smuggling from one province to another, since all the Bengal 'ganja' is kept in a secure store, none of it can leave that store or 'golah' for England or for any other country or province except under a permit, and only then after paying the duty. It is therefore possible to speak with absolute certainty as to whether or not any shipments of 'ganja' left Calcutta for England or Bombay.—I am, yours truly, "GEO. WATT."—*Chemist and Druggist.*

ON QUININE SULPHATE MANUFACTURED BY THE AUTHORS OF THE DISCOVERY OF QUININE, PELLETIER AND CAVENTON.

BY DR. J. E. DE VRY, C.I.E.

At the evening meeting of the Pharmaceutical Society held on Febuary 9, 1887, Dr. Paul read a paper, "The Tests of Quinine Sulphate," published on page 645 of the *Pharm. Journ.* of February 12 last, in which the following sentence struck my attention:—"When we call to mind the fact that cinchonidine is almost always associated with quinine in the bark from which quinine sulphate is manufactured, and also the fact that up to the year 1844, cinchonidine was not known as an independent substance distinct from quinine, it will be evident that there is, on these grounds alone, very good reason for believing that prior to the date mentioned the article known as quinine sulphate was really a mixture of the sulphates of quinine and cinchonidine. It would be possible to mention in support of this view many circumstances recorded by trustworthy observers, but I will merely refer to the fact lately made known *by Dr. de Vry, that the quinine sulphate originally manufactured by Pelletier contained a considerable amount of cinchonidine.*"

As I had the honour to be personally acquainted in 1835 with Pelletier, I am indebted to his memory to protest strongly against the underlined assertion. I really cannot conceive how the editor of the *Pharm. Journ.*, Dr. Paul, could make such a statement, for in his capacity of editor and reader of German periodicals, he should have been better informed by the paper of Dr. G. Vulpius, in No. 29 of the *Pharmaceutische Centralhalle* of July 22, 1886, p. 345. But whatever this be, the editor of the *Chemist and Druggist* can convince himself that I have said quite the contrary in the lecture which I delivered on November 2, 1886 to the Academie de Médecine in Paris, of which I sent him a copy, as also to Dr. Attfield, and some others of my English friends. In that paper I stated the following:—

"Since the discovery of quinine in 1820, chemistry and its application to chemical industry have made immense progress, and we should consequently have the right to expect that the quality of the actual quinine sulphate was at least as good as in the time of the discovery of quinine. Thanks to the kindness of M. Génévois, Director of the Pharmacie Centrale de France, I was put last May in possession of a specimen of calisaya bark from the collection of Pelletier himself, from which I obtained 64 per cent of quinine tartrate. The optical observation proved that it contained 95·4 per cent of quinine tartrate and 4·5 per cent of cinchonidine tartrate, which alkaloid was unknown in Pelletier's time. Therefore the quinine sulphate manufactured from such barks *could not have contained more than 3·26 per cent of cinchonidine sulphate.*"

Consequently, instead of making progress, we have retrograded, for the actual commercial quinine sulphate contains generally more cinchonidine than that manufactured by Pelletier. The cause of this fact is that calisaya bark (*Quinquina jaune*) was orginally exclusively used for the manufacture of quinine sulphate till about 1849, as the first barks from New Grenada were introduced into Europe in 1848 by Auguste Delondre, one of the partners of the firm, Pelletier, Delondre et Levaillant. Many of these barks contained, besides quinine, appreciable quantities of cinchonidine, the consequence of which was that the quinine sulphate manufactured from these barks contained more cinchonidine than that formerly prepared from caliysaya bark. This amount of cinchonidine in French quinine sulphate was the cause that my lamented friend, Dr. C. Zimmer, the well-known quinine manufacturer, issued in 1851 a circular to his customers to warn them against this quinine sulphate, which he supposed to have been *mixed* with cinchonidine sulphate. This, however, was not so, for the presence of such a large quantity of cinchonidine was only the consequence of the use of barks containing much cinchonidine besides quinine, Zimmer's circular contains the following sentence:—

"We know still little about the therapeutic action of this alkaloid (viz. cinchonidine), but whatever results the impending experiments may afford, such voluntary substitution is under all circumstances unaccountable, and makes honest competition almost impossible."

I conclude by expressing the hope that these lines may have convinced the readers of this journal that I never made myself guilty of the assertion attributed to me by Dr. Paul. It is, however, true that in the spring of 1883, I communicated orally to the Société de Pharmacie in Paris that Pelletier never knew "chemically pure" quinine, because the small specimen of "quinine pure" with which he presented me in 1836 contained a "trace" of cinchonidine which I found out in 1856 by the use of the polariscope. But every one will agree with me that a "trace" is quite different from "a large amount."—The Hague, February 16.—*Chemist and Druggist.*

THE LAWS OF NATURE IN RELATION TO HEALTH.

The above was the title of a very interesting address delivered at the annual meeting of the Hertfordshire Natural History Society, at Watford, on Tuesday last, the 15th instant, by the President, Professor Attfield, Ph.D., F.R.S., &c. Subjoined are extracts from the address.—

THE FLUIDS WE DRINK.—After showing the necessity of water taken in one form or another, Professor Attfield said:—

From the standpoint of nature, some little interest—and from the standpoint of man, a great deal of interest—attaches to the use of stimulants in the fluids we drink; for it would seem to be not more instinctive to man to cook his food than to discover in nature, or by more or less of art to manufacture, substances which are almost purely stimulating principles. The instinct of man, in his uncultured and uncivilised state, and in widely separated countries, has led him to discover just those four or five plants, which even now, so far as we know, are the only plants that, like the tea-plant, contain one and the same stimulant. Nearly everywhere, also, man's needs seem to have led him to the process—a perfect natural process, by the way; an accompaniment of the growth of the yeast-plant—by which sugar is converted into the stimulant termed *alcohol*. What is the use of such stimulants? Taken *in excess* they are poisons more or less insidious and harmful. The *theine* of tea, coffee, mate, and guarana is least liable to be taken in excess, and is least harmful. Alcohol is most likely to be taken in excess, and is, therefore, most harmful; on in the epigrammatic words attributed to the Scythian prince Anarcharsis, "The first draught serveth for health; the second for pleasure; the third for shame; and the fourth for madness." If mankind, especially in civilised countries, would consent to live at a slower rate, the second draught would be unnecessary, and probably even the first. But mankind cannot now thus live, apparently.

Man's life was spacious in the early world:
It paused, like some slow ship with sail unfurled
Waiting in seas by scarce a wavelet curled.

Now, with civilisation has come the stimulation of alcohol or theine. The first draught and the second are taken by most of the youth and nearly all of the adult of both sexes, either as theine or alcohol; while, as alcohol, the third and the fourth are taken by sadly too many. Children do not need, and, indeed, rarely take, either alcohol or theine, nor, for that matter either pepper or mustard with their food. These things are mere stimulants. They are not used in the early life of the individual, they were not used in the early life of the race. But swallowed in proper and moderate quantities, at proper times, in these days of civilisation, what office do stimulants fulfil in the system? It would seem, as stated elsewhere by the writer, that they do the important work of aiding the system, whenever necessary, to digest and to store up food, and to utilise its existing stores of fat and of flesh. In other words, the purpose of stimulants is, apparently, to stimulate the system the better to live upon itself, and the better to replenish its store of life-sustaining, work-performing flesh and blood. The imprisoned miner, having no food ordinarily so called, but having stores on his own frame, is able to exist for many days, if only, by a periodical sip of brandy, he can stimulate his organs to utilise those stores. The Indian performs a journey of two or three days on foot without any so-called food; but he really lives and works on the flesh stored in his frame, and lives satisfactorily if only he can chew his coca leaves, and so obtain the stimulus that shall induce his flesh to yield so much extra force. The invalid, unable to take solid food, can generally take stimulating beef-tea, and thus stimulate his own flesh to maintain his life until he again is able to take true nourishment. These are extreme cases of what appears to be the ordinary action of stimulants when taken in proper quantities.—*Chemist and Druggist.*

THE MOOR CULTURE EXHIBITION.

The exhibition, instituted by the Society for the Promotion of Moorland Culture, was opened and closed in Berlin last week. The object of the exhibition—the first of its kind—was to bring before the public the methods of processes by which it is intended to attempt to bring our moorland into a state of cultivation, together with the various implements, machinery &c. by which these methods and processes are to find application. When it is considered that there are 25,000 square kilometers of such land in Germany, the greater part of which is utterly worthless, it will readily be seen that any means whereby such unproductive land may be brought under cultivation (and made to yield such field and garden products as the best of our land which has been under cultivation from time immemorial) would prove of immense advantage both to individuals and the country and State generally. To say nothing of the extra work which would be afforded to thousands of willing hands, the fact of the acquisition to the State of an immense tract of land equal in size to the province of Saxony is one alone of immense importance, for it certainly might be looked at in the light of an entirely new acquisition. To attempt to give a detailed report of this most unique exhibition in the space allotted us would be an impossible task, and we must content ourselves in the present article by bringing under the notice of our readers a few of the most important points that came under our notice while paying a too brief visit to the Exhibition. The first group, and perhaps the most interesting, which attracts the visitor's attention is that containing both deep-ground and surface specimens of the moorland in every part of the country, together with the plants or peculiar products which are found thereon. Here, too, we find the valuabl

collections of the Agricultural High School, as well as collections from the peculiar provinces of several well-known professors. Particularly noticeable was the magnificent herbarium collection of Professor Willmack. In the next group were exhibited the various ways and means by which the moorland is to be reclaimed. By the well-known Rimpau process, "dam culture," the sand obtained by the digging operations in connection with the cutting of the drains is spread over the ground, a proceeding which is said to have attained very favourable results. Various other plans and projects for the cultivation of moors by dams are on view, perhaps the most noteworthy being that of the Schweder Techno-Cultural Bureau at Great Lichterfelde, whose system has already met with a fair amount of success. After the preliminary preparation of the land comes the manuring. The substance of moorland being of a highly organic nature, necessitates the application of mineral matter, and moorland districts are likely to prove good sale spheres in the future for kali salts, tinsel phosporite, and Thomas slack. There are here rich selections of every sort of manure, as well as representations of the working effects of the same. The kainite producing salt works as the Stassfurt State works, the Leopoldshall works, the New Stassfurt works in Loederburg, and the Hereynia kali works in Vienenburg have all contributed to a single group of magnificent raw salts; the ground article being also represented. The New Stassfurt works sent besides manufactured manure, while the Thomas slack came from Nienburg, Schalke, &c. Among the Berlin firms represented we noticed the Berlin Steam Bone-Dust Manufactory, (Dr. Wilhelm Cohn); Professor Orth also exhibited some manure. The manurical effects, however, are principally represented by the show of the Bremen Moorland Experiment Station. But agricultural conversion is not the only method of utilizing moorland; many moors produce that valuable fuel turf, which in spite of coal and lignite is yet thought a good deal of. This department of moorland cultivation is not overlooked by the promotors of the Exibition, and find representation through the collection of Professor Greiner. Turf is put to other uses besides burning; its high absorptive qualities make it peculiarly adaptable as a litter material, and the show of the Gifhorner Turf Bed Manufactory is not the least important one of the Exhibition. Turf also find its way into the surgery, as certain sorts of wounds and cuts are much benfited by the application of this material. This was one of the exhibits which particularly interested the Crown Prince. Particularly noticeable was the application of the turf fibre to weaving. Mixed with 30 per cent of cotton, wool, or hemp, the fibre of the turf-moss turns out a good yarn, which, as we noticed in Professor Gruner's collection is exhibited in different colors and patterns. In addition to what we have already mentioned we find on view various plants and fruits which have been obtained by the applications of the different methods to moorland. Among them we noticed giant specimens of the potato, beetroot, &c. The machinery department of the Exhibition is not the least interesting. Among other firms represented we noticed the H. F. Eckert Co., Berlin, Glogowsky & Son, Berlin, Th. Floether, Gassen, Glaser & Baare, Berlin, Friedrich Hoffmann, Berlin, R. Dollberg, Rostock, and Orenstein and Koppel, Brodnitz and Seydel, and C. W. Hall, of Berlin, &c. &c. As regards the awards, the first prize is a miniature picture of the Emperor in gold enamel, executed by Bastanier. The court jeweler, Paul Telge, presented for competition a silver cup of the renaissance period, bearing an inscriptive couplet to the effect that he who raises Germany out of slough and moor is worthy of the title of a true hero. There are several other valuable prizes which, however, call for no special comment.—*Kuhlow's German Trade Review.*

THE SCARCITY OF CUBEBS.

With a few slight interruptions the price of cubebs has been steadily rising for many months. Genuine berries, almost free from stalks and dust, are now quoted at about 22*l.* on this market, a price which in recent times has seldom been exceeded. The cultivation of the drug must have been a very profitable one during the last few years, although the total value of the crop, compared to that of the staple articles of Javanese produce, is so infinitesimal that it can scarcely be considered an adequate set-off against the evil times with which the Java planters have had to wrestle during the last decade or so.

Considering the enormous prices at which the drug has been sold during the last few years, it is remarkable that its cultivation should not have been extended. Many drugs shipped from India, Ceylon, and South America have suffered such depreciation in value lately, that they cannot leave any large margin to growers; but we believe that if a few planters, say in Ceylon, had commenced cubeb-growing, when the price of the drug first began to advance about six or seven years ago, they would now have reason to congratulate themselves upon the result of their venture.

Hints on the cultivation of cubebs have repeatedly been published in trade journals, and planters in India and Ceylon have been urged to make experiments in the cultivation of the shrub; but in no instance does this advice appear to have been followed, and the cultivation of cubebs for commercial purposes is, we believe, still confined to the Dutch possessions.

The eastern residencies of the island of Java produce the bold grey berries, the genuineness of which has been a matter of considerable doubt, and is generally disputed in this country and in America. The small, dark-coloured, genuine berries are all, we believe, grown in Central and Western Java, notably in Banjoemaas and in Bantam. The shrub is occasionally met with in the wild state, but it is more generally cultivated, sometimes in special plantations, but usually in the coffee-gardens. Some years ago the Dutch Indian Government, with a view to encourage the cultivation, distributed a large number of young plants to coffee-growers throughout Java. The *Piper Cubeba* requires very little attention; it climbs round the large trees which are grown for shading in coffee-plantations, and attains, when full-grown, a height of 18 to 20 feet. The statement formerly often made that cubeb plantations in Java were being uprooted in order to make way for coffee-gardens may, therefore, be regarded as fabulous. Cubebs are also grown largely in the Lampong districts, the extreme southern portion of Sumatra, and in certain parts of Southern Borneo. The yield is collected by Chinese dealers, and exported *via* Batavia or Singapore. Shipments from the former place usually find their way to Holland, while the cubebs exported *via* Singapore are generally forwarded to London or New York. An important part of the crop is consumed in Eastern countries.

The price of cubebs has always been subject to sudden and violent fluctuations, and extreme rates are by no means of exceptional occurrence. Thus we find that in 1859 and 1860 genuine berries occasionally realized 11*l.* to 12*l.* per cwt.; but it may be assumed that in those days the value was more or less artificially kept up by the peculiar commercial policy of the Dutch-Indian Government, which compelled planters to sell to them their produce at a fixed rate, at the same time limiting the area and amount of the production. From that time the value has apparently been declining, for in 1865 the price of cubebs averaged about 77*s.* 6*d.*; in 1869, 40*s.*; and in 1875, 25*s.* per cwt. Between the latter year and 1880 cubebs were a much neglected article, and could be bought at figures ranging from 25*s.* to 55*s.* per cwt. The stock was never a large one—usually averaging 125 to 180 bags in London—and the imports were extremely uncertain. More than once it appeared likely that supplies would cease altogether, owing to unremunerative prices.

In 1879 a craze originated in America for asthma cigarettes, of which cubebs formed an important ingredient, and which were recommended as a remedy

for catarrhal affections. Prior to that period the use of the drug had been chiefly confined to the treatment of gonorrhœa, though cubebs formed a principal ingredient in some proprietary lozenges. Asthma cigarettes soon became extremely fashionable in America, and a few speculators bought up every parcel of cubebs upon which they could lay hands on the European market, with the result of quickly forcing up the price of the drug to 10*l.* or thereabouts. The enormous demand then prevailing for cubebs may be illustrated by the fact that in February, 1880, no less than 737 bags of cubebs arrived at New York in a single shipment.

Stimulated by the high prices prevailing the production in Java had extended considerably, but by this time the American speculators had obtained a tight grip of the article, and manipulated it at will, sometimes flooding the European market with large shipments in order to momentarily depress the value of the drug and secure at a low rate any parcels which second-hand holders might offer. At the same time all sorts of tricks were resorted to in order to keep alive the demand for the article in America; but the asthma-cigarette craze has by this time subsided.

Notwithstanding this the American speculators have continued their game, and as the article is a comparatively small one, they succeed without much difficulty in controlling the bulk of the supply; hence the continued dearness of the drug.

The consumption of the article cannot now be said to be on the increase, in fact, during the last few years, the imports in America have been falling off. At present our stock has been very much reduced, and at the commencement of the month amounted to only 41 bags in the first hand, while from 21*l.* to 23*l.* is quoted for stalky to good genuine berries. In Holland the imports during 1886 amounted to about 200 bags, less than half of which belonged to the acknowledged genuine variety. The Dutch market is now said to be very bare, the stock at Amsterdam not exceeding 1,050 lb., 600 lb. of which are grey berries. The quotations at Amsterdam for genuine berries appear to be slightly in excess of those prevailing here. If recent mail advices from America can be trusted, the stock at New York is also very low, being estimated at less than 7,000 lb., or barely sufficient for one month's requirements.

All indications, therefore, point to the maintenance, for some time at any rate, of the excessive prices now prevailing. It is true that several shipments are reported on the way from the East Indies, but unless these should be of exceptional magnitude, they will in all probability be quickly brought up for consumption.

Arrivals of cubebs take place at regular intervals all through the year, but the bulk of the Java crop leaves that island between the months of May and September, the first arrivals generally reaching Europe in June or July. It is extremely difficult to obtain reliable information concerning the prospects of the crop in Java, but there is an impression that the yield this season will not exceed that of 1886, when only about 200 bags found their way to Holland.

A highly objectionable result of the enhanced value of the drug has been the appearance on the European market of various species of spurious cubebs. Formerly deliberate sophistication was seldom practised, and although occasionally a few fruits of the *Piper crassipes* occurred among genuine cubebs, the only charge which could be fairly brought against shippers was the frequency with which fruit stalks occurred among the berries, owing to imperfect garbling of the drug before shipment. At present, however, we have no hesitation in saying that more than 50 per cent of the berries imported as cubebs are not the genuine article at all.

Adulteration with common black pepper can be readily detected, but it requires considerable care to distinguish the many varieties of false berries now so frequent. Perfectly genuine cubebs have often been classed as spurious, simply because of their altered appearance when over-ripe; but *Daphnidium Cubeba*, *Piper crassipes*, and *P. caninum* are now frequently met with, both in conjunction with real cubebs and without any admixture of the true fruit. A few years ago a consignment of nineteen bags of spurious cubebs was stopped by the New York Customs authorities and destroyed. It was then announced that all cubebs imported into the United States would be subjected to a close examination; but if the parcels which are frequently purchased in London for the alleged purpose of exporation to America are in reality shipped to that country, the vigilance of the American Customs officers must have greatly relaxed of late. On the Amsterdam market spurious cubebs are now very frequently sold at 18*l.* to 19*l.* per cwt., chiefly, it would seem, for export to France. It is only fair to state that the French druggists are said to entertain great objections to the spurious berrics, though why they purchase them at all, knowing them to be false, is not explained.

It is a fact that the administration of spurious cubebs has often caused considerable inconvenience to patients, and, if only for the sake of rendering unprofitable the wholesale adulteration now practised at the shipping ports, it is devoutly to be wished that extended cultivation and increased competition will ere long again bring the price of cubebs within reasonable limits—*Chemist and Druggist*

["Cubebs is a sore subject with me," says a Ceylon planter. "Years ago I resolved to go in for them and got a plant form the Royal Botanical Gardens, Peradeniya, and they declare it to be cubebs, but I can scarcely believe it, and my time has, I am sure, been wasted. It grows well and fruits, but does not bear the kind of fruit that books say it should."]

TEA MACHINERY.—The London correspondent of the *Indian Planters' Gazette*, writes:—There has been a new tea rolling machine on view recently at the offices of the Planters' Stores and Agency Co. Limited in the City where it was seen by a good many planters. This specimen was for hand-power. If there is any justice in patent law, I don't give this machine a long life, so it is almost waste of time describing it, further than by saying that it is a Jackson's roller with obsolete motions in place of his driving gear, and with sundry other retrograde alterations, made in an attempt to do as Jackson does in another way. Apart from these advances in wrong directions, it has several weak points structurally, but without a diagram these would be difficult to describe. Mr. Jackson will probably take no notice of so feeble a competitor unless people having the ordering of tea machinery should have less sense than they are credited with, in which case, 'ware! Mr. Davidson's last improvement in his T Siroccos is a great one, and will increase their popularity vastly. I have seen the one he has over here on show, and its advantages are patent at a glance. He estimates that this type will turn out double the outturn of the first T Sirocco. The original T Siroccos may be converted partially to the new type but not completely; certain great improvements in the new not being applicable to the original type. The heat being saved, less heat is required, and the stoves will consequently last for years. Mr. Gibbs' new withering appliance is so cheap and its possibilities are so great that it is much to be hoped that a few enterprising managers will give it a trial next season. Even should the *drying* of the air by means of the chloride of lime prove to be the failure anticipated by many, still the *heating* of the air by this little appliance and the distribution of the heated air from it to the *machans* and *challonies* is so practical and efficient that it should be put to the test on some gardens as soon as possible. It can be wheeled or carried along over the *machans* as the leaf on each *machan* or portion of a *machan* is withered. This will, if the appliance is successful, at all events save having to carry the leaf from the worst to the best withering machans as the leaf is removed from the latter to be rolled, and will thus save considerable labour and handling of the leaf, apart from any success in the direction of rapid withering of wet leaf, such as is anticipated by inventor.

CULTIVATION OF IXTLE IN MEXICO.

The ixtle, or Tampico fibre, is stout, cylindriform, and of the strongest descriptions of fibre known. It has a yellowish-white colour, and varies in length from one to three feet, according to localities where the plant grows. The fibre designated as *tula* measures an average length of 24 inches, and the *yanmave* averages 30 inches. Consul Cassard, of Tampico, states that the ixtle is extracted from the leaf of the *Agaves Mexicana*, to which species belongs the *maguey*, or aloe, and much resembles the latter in the form and conditions of growth, although smaller in size. It has an elongated, sharp, thorn-edged leaf, containing about three parts of aqueous matter, and one part of solid, which is all fibre. On maturing, the ixtle shoots up from its very centre a long round flower-stem, which, on attaining its full growth, falls to the ground, carried by its own weight. The special botanical name, Consul Cassard says, is not known in Mexico. Ixtle is its Indian name, and the Spaniards have given it the local appellation of *Lechuguilla*. It grows wild in the stony sections of the table lands of the States of Tamaulipas and San Luis Potosi, and its most extensive fields lie in the vicinity of the towns of Tula and Yanmave. Growing with extraordinary luxuriance, in inexhaustible fields, it is never replanted, and the cropped fields lie in barrenness with but a few isolated leaves growing sparsely from the old roots. To become an article of commerce, the ixtle is submitted to a very simple process of curing, which consists in completely purging from its leaf the watery matter, and then in exposing to the sun the cleansed fibres, which are thus dried and bleached. The contrivance used in curing the leaf is very primitive, consisting simply of a triangular smooth edged piece of iron, measuring about sixteen inches long and two inches broad, with a handle at one end and a hook at the other. A board is laid at the foot of a tree, and over it crosswise is placed the iron or presser, one end hooked on to the roots of the tree, and the handle end resting in the operator's hand, with which he strongly presses the leaf against the board, while with the left hand he draws it its full length, repeating the operation until the leaf is completely purged of its aqueous matter. By the above process an Indian is enabled to clean on an average twenty pounds of ixtle per day. The cutting and curing of the leaves have no special season; both these operations are performed while the plants ripen, and this occurs throughout the whole year. A large trade is carried on in the export of ixtle from Mexico. From the port of Tampico alone about 7,000,000 pounds are annually shipped to Europe and the United States.—*Journal of the Society of Arts.*

TAPEWORM REMEDIES.

Chloroform has been found very efficient against tapeworms. Doses of 30 grains have been given, repeated after twenty or thirty minutes, but troublesome cardiac symptoms may be avoided by giving smaller doses (a few drops) every few minutes for a few times. Thompson successfully prescribed chloroform, ʒj. (by weight), simple syrup to ʒj., to be given in three doses, at intervals of two hours, in the morning fasting, with castor-oil to follow.

An Italian physician recommends thymol as a remedy for tapeworm. A dose of about half an ounce of castor-oil is given in the evening, when the patient should abstain from food, and take, next morning, two drachms of thymol, divided into twelve doses, one every quarter of an hour. About half an hour after the last dose has been given a dose of castor-oil should be administered. This is usually followed by the expulsion of the dead worm. Thymol quickly depresses the pulse, respiration, and temperature, and to obviate any ill-effects from this cause frequent doses of brandy or spirits should be given at the same time. The advantages of thymol are said to be that it produces no disturbance of the stomach, is rapid in effect, is both a tæniacide and a tæniafuges and, while certain in action, will do no great harm if an error in diagnosis has been made.

A correspondent of the *Med. and Surg. Rep.* states that he has met with a case in which the administration of the following mixture to a boy of nine years caused the expulsion of a tapeworm ten feet long. No directions as to the preparation of the mixture are given:—

Ol. terebinthinæ	ʒj.
Ol. cinnamomi	ʒj.
Mist. curcurb. peponis	℥xj.

The pumpkin seeds, say 1 oz., should be beaten up in a mortar, and an emulsion of them formed with water, similarly to mist. amygdalæ. The dose of the mixture is an ounce every hour.

Recent trials appear to show that pelleteirine may be used successfully against tapeworm, especially in children. The dose for children from three to five may be from ½ to 1 grain in solution, followed in about half an hour by a brisk purge. The alkaloid does not appear to have the same physiological action on children that it has on adults.—*Chemist and Druggist.*

AUSTRALIAN ARGOL.

In last week's drug sales in London there were sold some parcels of red and white argols, amounting to half a ton, which had been imported from New South Wales, and which formed, we believe, the first consignment which has come to this country. The red argols sold readily at from 90*s.* to 97*s.*, and the white at 100*s.* We have so long been dependent upon France and Spain for this important commodity that supplies from British colonies cannot fail to command the interest and attention of merchants. For many years argol has been regularly received from the Cape, and, so far, the quality of the argol imported from South Africa has been moderately good. But with the development of wine-growing, which seems to be assured in Australia, the supply from that source is likely to be an important factor in the market. The cultivation of the vine was commenced in the Australasian colonies nearly half a century ago, and has since been fostered in a very enterprising manner as well as in a scientific spirit. The methods of cultivation and the processes for manufacturing wine which are followed in the wine-producing countries of Europe have been carefully studied, and both soil and climate seem to be well adapted to place Australian wines, and consequently other grape products, in a commanding position in the near future. Some idea of the importance of the industry may be gathered from the fact that in the Rutherglen district of Victoria there are 3,000 acres devoted to viti-culture, the estimated production of which is 750,000 gallons of wine annually; and this does not represent one half of the present production over the whole of that one colony. In South Australia, where vine-planting was commenced in 1840, there are now about 5,000 acres under cultivation, with an annual production of 500,000 gallons. New South Wales has the credit of having started the industry in Australasia, and the total production of that colony is equal to that of Victoria, there being several vineyards which produce 40,000 gallons and upwards annually. It will be seen, therefore, that with stocks representing at least three years' harvests the yield of argol must be enormous and increasing. The juice of the grape in the unfermented state contains the acid tartrate of potash in solution; but with the change of the sugar into alcohol the solvent power of the liquid is diminished, and the tartrate is deposited as argol within the casks while the wine is fermenting and maturing. The normal composition of argol shows it to consist of acid tartrate of potash, tartrate of lime, and colouring matter, but the custom in some wine-producing countries of plastering the wines introduces a large percentage of earthy constitutents, including barium, so that argols containing half their weight of calcium tartrate have been met with. The argol which was sold last week was of superior quality, and the price obtained for it should induce a constant supply. One sample of the red variety which we received was in

semi-translucent crystalline pieces over a quarter of an inch thick, and of a pale claret colour. Its solution in water possessed a faint vinous odour. The sample yielded 93·5 per cent of acid tartrate of potash, 3·5 per cent of tartrate of lime, the rest being colouring matter, glucose, and vegetable refuse. The sample, therefore, compares well with other commercial argols, which rarely contain more than 90 per cent of acid tartrate of potash.—*Chemist and Druggist.*

CHINA GRASS OR RHEA FIBRE.

At a meeting of the Society of Chemical Industry, held in Manchester, Eng., on the 2nd inst., Mr. A. Sansone, Director of the School of Dyeing in the Manchester Technical School, read a paper on China grass or rhea fibre. He said that after giving the matter considerable attention, and after experimenting for several months both on green and dry stems, he thought that if the fibre were used at all it must be produced at a price as low, if not lower, than that of cotton; therefore the methods of treatment must not be expensive. Division of labor would have to be resorted to in order to accomplish that end successfully. In large plantations it would be difficult to obtain the number of persons necessary for peeling off the bark by hand when they were needed, while if machines were employed a large number would be riquired which would mean a large outlay. He had, therefore, devised methods for doing the work all the year round. One method he proposes is a very simple one. The stems, either green or half dry, or even dry, are simply boiled with a solution of carbonate or caustic soda; the bark can then be peeled off with the greatest ease. With green stems five to ten minutes' boiling would, he said, be found necessary, while the drier they were the longer they required to be boiled. He stated that he had on many occasions peeled many of the stems in his laboratory without the least difficulty. Even dry stems of several months' standing had been peeled off in the laboratory at the School of Dyeing after being boiled in the model boiling kier possessed by the school. Specimens were shown in the different stages, finishing with the bleached fibre which Mr. Sansone had extracted, with the help of some of his pupils, by a chemical process. With regard to countries like India, where the drying of the stems is impossible in the rainy seasons, he proposed that the stems when freshly cut should be placed in pits or cisterns with a solution of sulphurous acid or bisulphite of soda or lime, which could be readily and cheaply produced on the spot. This would prevent fermentation, and would keep the stems fresh until they could be treated by any suitable process of decortication. Green stems obtained by him from Kew Gardens last summer were kept for several weeks in his laboratory, and were at the end found perfectly sweet. They were afterwards treated without difficulty for the extraction of the fibre. He had noticed also that the fibre was even bleached to a certain extent by that treatment. He suggested a method of ungumming and partial bleaching of the fibre at the same time by successive boiling with alkalies, and afterward immersing the material in a cold sulphurous acid or bisulphite solution, this treatment to be repeated once or twice according to the state of fibre required. The bleach of China grass was, he said very similar to that of linen and cotton, and the same precautions should be taken in employing hypochlorites; bleaching, however, of China grass was very easily effected, in fact more easily than in the case of flax. In all cases the hypochlorite of lime should be avoided, and soda or magnesia salts used instead. For scouring the fibre or ungumming the bark such agents as lime, resin, soap and mineral acids could be used just as well as for other vegetable fibers. The dyeing and printing processes offered no great difficulties, but by dyeing the fibre before spinning brighter colors were produced and the fibre was more lustrous. Some colors, however, deprived the fibre of its luster. In conclusion, he recommended the utilization of the wood residues of the stems for industrial purposes. He had made a great many experiments, and considered the material very suitable for manufacture into a kind of wood-pulp suitable for paper-making and for other purposes. By that means two products would be obtained at the same time from the same plant.—*Bradstreet's.*

SOMETHING ABOUT JAVA AND THE JAVANESE LABOURERS.

A solution of the plantation labour question seems to have been found in the introduction of a number of Javanese labourers for the northern plantations. Java —or more probably Java and Madura—including the small islands administratively connected, had a total population in December, 1878, of 19,067,829, and of these 18,824,574 were natives, the rest being Europeans, Chinese, and Arabs. The population is fast increasing. In 1868, it was 15,265,931 and the annual growth had been up to that time large and regular. We have no figures since 1878, but we believe that the increase has continued and is continuing. The area of Java is limited. Many years ago the density of population in the purely Javanese districts was greater even than in Belgium, and although a tropical country in a high state of cultivation can produce more food and thus support more people than one situated in a temperate climate, it is probable that the Dutch are becoming a little alarmed at the increase of their native subjects. No doubt Java could spare, without perceptibly affecting the local labour market, from 50,000 to 70,000 men annually.

Javanese have the reputation of being strong, good laborers. They are Malays, but of quite different type from the same race in other islands of the Indian Ocean and the native states in the vicinity of Singapore. The Javanese is above all things, docile and obedient. The Dutch rule is a "paternal" despotism of the most elaborate kind. A writer on Java says :—

The Javanese knows no freedom. His whole existence is "regulationed." If he is bound to render "culture" service, the administration shows him to what department to apply himself, when and how he must plant. If he is not bound to render culture service, but has the position of a so-called free agriculturist, the administration prescribes the time and method of sowing and planting his land. If he wishes to fix his habitation outside his village, the village chief, may prevent him. If he has a dwelling of his own, the administration decides for him what sort of materials he must use for the roof. If he has a hanging night lamp in his bamboo hut, he must not hang it against the wall.

This elaborate system of regulation designs to make Java profitable to its European owners, is carried out through the native chiefs, who are highly paid but carefully watched servants of the Dutch. But the docile and gentle Javanese do not seem to resent their subjection. They certainly thrive under it. When the islands first fell into the hands of the Dutch they were thinly peopled. Even in 1815 the whole native population only numbered about 4,500,000, so it has more than quadrupled during the present century. The fact is that the Dutch system, which while keeping everyone at work, secures food and the necessities of life to the whole population, is conducive to the material welfare of such a people, though it would gall and embitter a more independent race.

It may be said that the whole population of Java is agricultural. The populations of the three principal towns—Sourabaya, 118,884; Batavia, 97,585; and Samarang, 76,443—are exceedingly small for a state of nearly twenty million inhabitants. Coffee, sugar, and spices, are the chief agricultural exports, and it is not improbable that the increasing demands for food crops, due to the growth of population on the area under tillage, may have something to do with the willingness of the Dutch authorities to allow the emigration of laborers. However that may be, a sufficient supply of Javanese labor would entirely remove the labor difficulties of our Northern planters. They are, we believe, as good workmen as the best Indian coolies, and are even more docile and amenable to control. But it would be a singular outcome of our anti-coolie

movement if it should result in the introduction of a flood of dark-skinned laborers, not hindered by caste prejudices, and probably capable of being trained to perform manual labour of every description.—*Planter and Farmer.*

JOHNSON-GRASS.

The following letter, received by the Secretary of the Planters' Association from Mr. D. Wilkinson, accompanying a small packet of the above grass seed, was read at the meeting of the committee held on Thursday evening last and is now published for general information. It will be noticed that packets of the seed can be obtained from the Secretary upon application to this office.

"To the Secretary,
"Planters' Association.

"SIR,—Having just received from the Department of Agriculture, U. S. America, a small quantity of 'Johnson Grass' *Sorghum Halapense* seed, I beg herewith to forward a packet for distribution through your Association to stock breeders and those interested in the improvement of pasturages in the colony by the introduction of suitable grasses. Perhaps I ought to state something of the history and how I obtained the seed of this very highly recommended species, and for general information, what is known of it.

"In reading the *Australian* in America (by Mr. Dow, special correspondent of the *Melbourne Leader*, a book full of useful and interesting information) in the chapter on 'Grasses,' Mr. Dow says:—'The Johnson-grass has strong, vigorous roots, like sugar-cane, and has an abundance of long broad leaves. It grows to a considerable height when cultivated for hay on bottom lands, while it thrives well as a pasture grass on the up-lands, being hardy and resists drought.' Acting on his recommendation that 'any person desirous of trying any of these special grasses described should apply to the Botanist of the Agricultural Department of State, Washington.' I received a most prompt and courteous reply with some of the seed from F. C. Nesbitt Esq., the Acting Commissioner of the Department, who says:—'I shall be pleased to send you a large quantity, but am forced to restrict myself to a small quantity by mail only, which I hope will reach you safely and prove to be the nucleus of supplying a valuable forage plant to your colony.' From the same authority the grass is thus described:—'It is a perennial rapid grower, having long cane-like roots, or more properly, underground stems, every joint of which is capable of developing a bud. These literally fill the ground. Short pieces of roots planted in rows two feet apart and from one to two feet in the row quickly form a sod over the entire surface. It is exceedingly difficult to eradicate. Do not sow or plant where you expect to cultivate the land. Some plantations of Johnson-grass are more valuable, acre for acre, than the best cotton land. One bushel of seed (28 lb.) is sufficient for an acre. Brush in the seed or use the roller, as it must be covered lightly. For hay, cut it as often as it obtains the height of 24 to 30 inches. On good soil it yields from two to three tons per acre and can be cut three times during the summer in the Gulf States. It is not regarded as being hardy north of where cotton is successfully grown.' In a note just received from Mr. Holmes, whose practical knowledge as well as the time and careful attention he has devoted to the successful introduction and cultivation of useful grasses at once constitute him an authority, he says:—'I have sown a little of your 'Johnson-grass' to test its soundness, but I have little doubt about it as the seed is hard and glossy. It is a great acquisition to our grasses if half what they say of it be true. The only doubt in my mind is whether a grass that stands such frosts in Kansas, &c, will equally thrive under our tropical sun. Still the genus *Sorghum* is, as a rule, quite at home in hot countries.'

"Perhaps I ought to apologise for this intrusion not being a member of your Association, but hope some of your members and perhaps others may be disposed to try and prove whether this grass is adapted to our climate and soils and that it may assist in some degree in the permanent improvement of our stock pastures.—I have &c.,

"D. WILKINSON."

—*Fiji Times.*

OLIVE CULTURE IN CALIFORNIA.

The following extracts are taken from the recent work on the olive by Mr. Cooper, San Francisco:—The common and preferred method of propagating the olive is to plant the cuttings, taken from the growing trees of sound wood, from three-quarters of an inch in diameter to one and a half inch, and from 14 to 16 inches long. These cuttings should be taken from the trees during the months of December and January, neatly trimmed, without bruising, and carefully trenched in loose, sandy soil, a shady place preferred. They should be planted in permanent sites from February 20th to March 20th, depending upon the season. The ground should be well prepared and sufficiently dry, so that there is no mud, and the weather warm. In Santa Baraba, near the coast, no irrigation is necessary, but very frequent stirring of the top soil with a hoe or iron rake for a considerable distance around the cuttings is necessary during the spring and summer. About three-fourths of all that are well planted will grow. My plan is to set them 20 feet apart each way, and place them in the ground butt end down, and at an angle of about 45 degrees, the top to the north, barely covered. Mark the place with a stake. By planting them obliquely, the bottom end will be from 10 inches to 1 foot below the surface. In Europe the trees are planted from 27 to 33 feet apart. My reasons for closer planting will be given in a subsequent article. All trees, as a rule, should be propagated from seeds. The roots are more symmetrical, the tree not so liable to be blown over, and the growth more healthful; but I have not been successful in germinating them, hence I recommend the cutting. If the trees are propagated from seeds, budding or grafting is necessary. I have seen the statement that it was necessary that the seeds should pass through the stomachs of birds before they could be sprouted, also that by soaking in strong lye the sprouting would be secured. I have not seen the result of either experiment, and accept the statement with more or less distrust. I presume cuttings can be obtained from any of the Mission orchards in the southern counties.

PRUNING.—The cutting will throw up numerous shoots or sprouts, all of which should be left to grow the first year. Any disturbance of the top affects the growth of the roots, it would be advisable, however, where there are two or more vigorous shoots of about the same size and height from the same cutting, to pinch the tops of all excepting the one to be left for the future tree, so as to throw more force and vigour into that one. In the following spring, when the ground is warm and sufficiently dry, all sprouts excepting the one to be preserved should be carefully removed by the aid of a sharp saw. A post should be firmly planted, so that the tree can be well secured to keep the trunk straight and avoid any disturbance of the roots, and should be kept until the tree is four or five years old. By adopting this method, a great deal of time will be saved and better trees secured. The lateral branches should be allowed to grow until the tree is two or three years old, but in every case, when any of the said branches are rapidly making wood, they should be removed, and not allowed to rob the trunk.

In the pruning during the first years, have only the one object in view, that is, to force all the woody growth into one main trunk. This being done, the tree will naturally form a beautiful shape. The cultivator must not look at the tree of to-day or to-morrow, but the tree of 10 years hence. All branches to the height of five to five and a-half feet should be removed, so as to admit of close cultivation by horses.

Trees planted at the distance of 20 feet and well kept will in 10 years touch each other. When this condition is reached they will be in full bearing, and therefore will require constant pruning or cutting back. It is much easier and less expensive to gather the fruit from small trees; besides it the pruning is intelligently done, it will improve the fruit and secure a greater quantity to the acre than can be produced under any other conditions.

Some orchards in Europe are planted in "threes," that is three trees in each place planted in the form of a triangle, and three or four feet apart. This method would require the rows to be 33 to 35 feet distant, and would give him about the same number of trees to the acre as by planting at 20 feet, one tree in each place. It is claimed that by planting in this way no staking is required, the trees protect one another from the most violent wind-storms, the trimming is simplified, and less care and labour required in the cultivation.

Fruit-bearing.—Trees growing from cuttings will produce fruit the fourth year, and sometimes, under the most favourable circumstances, will give a few berries the third year. It is the habit of the tree to overbear, and as a consequence will give but very little fruit the year following a heavy crop. This statement is verified by the most reliable books published on the subject in the French, Italian and Spanish languages. There are, however, exceptions to this rule in California. Mr. Davis, who had charge of the San Diego Mission orchard in 1875, assured me that he had gathered from the same tree, two years in succession, over 150 gallons of berries. I have also observed that some trees in my orchards have borne well successive years. The fruit-bearing can be controlled by the pruning. The cultivator will not forget that the shoots or branches must be two years old before they will give fruit; hence partial pruning every year will give partial crops. My oldest orchard was planted February 21, 1872. At four years I gathered from some of the trees over two gallons of berries; in 1878 over 30 gallons each off a few of the best trees, the orchard being then only six years old; in 1879, the seventh year, the crop was not nearly so large. I had planted several thousand cuttings in the spring of 1873, but these trees did not give at six years a result equal to the first planting. The present crop (1880) is quite good, the oldest orchard now being eight years; and I think I do not over-estimate when I state that the yield of some of the best and fullest will be over 40 gallons. Trees large enough to give this quality of fruit planted at a distance of 20 feet, will occupy nearly all the ground, and therefore will give all the fruit that can be produced on one acre. An orchard bearing uniformly the quantity as above, would give the following result:—One hundred trees to the acre at 40 gallons each, 4,000 gallons. This would be an enormous crop, unprecedented, and far beyond any statistics given in European publications. The one-fourth of the quantity yearly would be a very profitable crop. In estimating an orchard, the yield of isolated trees or trees of great age, occupying considerable areas of ground, must not enter into a basis of calculation of the probable production. The tree mentioned in the San Diego Mission orchard as yielding 150 gallons of berries was more than 50 feet distant from those surrounding it. My agent, while travelling in Europe through the olive district, measured a tree growing in the "Alpes Maritimes" that was 8 feet in diameter, 6 feet above the ground, and at the ground 15 feet in diameter. Only a few trees of such trees could be grown on one acre. A. Coutance, Professor des Sciences Naturelles aux Ecoles de Medicine de la Marine of France, compiled a very exhaustive work on the olive, published in Paris in 1877, from which I copy and translate as follows:—"Large olive trees occupy 1,000 square feet of ground—that is, require to be distant from each other about 33 feet; will produce every second year 37 gallons of berries, and occasionally as much as 125 to 150 gallons. One tree, 9 years old and 9 inches in diameter, will produce 16 1-5 gallons; one 12 inches in diameter 24 gallons. The measurement and number of trees occupying one hectare (two-and-a-half acres) is given as follows:—15 trees 12 inches in diameter, 75 trees 9 inches in diameter, 60 trees 5 inches in diameter: total, 150 trees. Product of same, 3,000 gallons of berries. This would be equal to 1,200 gallons to the acre. Another authority gives 2,250 gallons per hectare. Still another gives 2,150. All of the above results once in two years. Several authorities quoted by the same author reckon 200 trees to each hectare. This would be 80 trees to the acre, and distant apart 23½ feet. French cultivators give the quantity of oil contained in a given quantity of fruit as one-eighth, and in weight one-tenth; that is, eight gallons of berries to one gallon of oil, and about 50 lb. of berries to one gallon of oil. Taking the average quantity of the production as given above from a mature orchard, we have in oil per tree two to two and a-half gallons every second year. This result is obtained by thorough fertilising, without which the berries would yield but little oil. Olive trees grown from seeds are not removed from the nursery until about seven years old; grown from cuttings they bear in Europe as early as they do in California. The newness and richness of our soil will probably give, the first 50 years, double the results given in those countries where oil-making has been the business of so many generations. Our climate is congenial to the habit of the tree; it bloome from the 1st to the 10th of May, and the fruit forms from the 1st to the 10th of June. At this season ws have our best weather, free from extremes of either cold or heat. Nowhere in the world are all the conditions so favourable to the perfect fruit-bearing.

Fruit-picking.—The olive usually ripens in November. In some localities in Eastern countries, during favourable years, the fruit-picking for oil begins as early as October, and for pickling in September. In Santa Barbara the crop of last year 1880, as also that of 1878, was unusually late in ripening, not being ready to pick before the middle of January—a delay of fully two months—the cause, no doubt, owing to the extraordinary rainfall of these two years. In 1878 we had after the middle of February and up to the middle of April, a rainfall of over 14 inches, and in 1880 over 16 inches, being more than our yearly average. The fruit should be gathered as soon as it turns purple and before fully ripe, as the oil will be lighter in colour and more fragrant, but somewhat less in quantity. In Europe the common method of gathering the berries is to knock them from the trees with poles. They are then picked from the ground by old men, women, children, and cripples. This plan has many objections, the fruit being more or less bruised, causing decomposition, and the contact with the earth is liable to give the oil an unpleasant taste and odour. The most economical plan of gathering is to pick from the trees by hand, and by the aid of intelligent contrivances, an active man can pick 400 lb. each day. I have arranged on a ranch waggon platforms with ladders securely fastened, so that the fruit from the different heights of even large trees can be gathered from the waggon, which is driven along the rows, and one-half of the trees picked from each side. This plan obviates the necessity of moving ladders, climbing, &c., and relieves the pickers from the labour of carrying the fruit, as the sacks containing the same are always at hand on the platform. The leaves and imperfect berries are separated by passing the whole through a winnowing mill. This process leaves the fruit in the best possible condition preparatory to manufacturing the oil.—*Sydney Mail.*

TEA: INDIA, CEYLON, JAVA, JOHORE, NATAL.

(Geo. White & Co.'s Annual Indian, Ceylon and Java Tea Report.)

London, 2, Great Tower Street, E.C.,
18th March, 1887.

Close of Last Season.—Our last Annual Report was issued on the 20th March, 1886, when, with decreasing quantities offered at auction, the market was gradually assuming a firmer tone for fine kinds,

especially Pekoes. With some fluctuations, these maintained a strong position as the season advanced and they became scarcer, but prices for other grades declined, as the export from Calcutta proving rather above the estimate, our market was over-supplied.

In consequence of the heavy clearances in anticipation of the Budget in the Spring of 1885, a considerable quantity of duty paid stock remained in the hands of Dealers up to the close of last season, so that the monthly returns were no guide as to consumption. A year of steady trade has now, however, disposed of the old stock, and figures have become more indicative of actual movements.

The London bonded stock of Indian and Ceylon Tea on the 30th June, 1886, was 18,345,000 lb. a considerable increase on the amount in the previous year, when it was reduced to 12,359,000 lb. on account of the Duty scare. The stock at the end of last month was more than seven millions over what it stood at the close of February, 1886, though with an increased consumption this surplus may disappear before the close of the season.

The average prices obtained during the season have been about as follows, viz., Ceylon, 1s. 1¾d. per lb.; India, 11d. per lb.; China Congou, 8¼d. per lb.; against 1s. 3½d. 1s. 1½d. and 10½d. per lb. last year, which shows that tea generally has fallen about 2¼d. per lb.

INDIAN AND CEYLON TEA.—The gradual increase in the deliveries of Indian and Ceylon Tea must be most satisfactory to growers, as shewing the hold they are getting on the taste of the British public, while the demand from abroad is also on the increase. Not only have the fine teas from China (partly owing to the crop being thin in cup) had to give way before them, but Indian and Ceylon planters have undersold the medium and lower grades of China Congou, and by sheer weight of quantity forced their produce to the front. The deliveries of Indian from the London warehouses during February nearly equalled those of China Congou, while Indian and Ceylon together exceeded them by over 400,000 lb.

This result has not been achieved without some drawback however, as the low averages obtained by many gardens shew, and the question as to whether "it pays" will become a serious one, especially to some of the smaller properties in India. No doubt the cost of manufacture has been considerably reduced of late in the case of some of the larger gardens, whose produce it is reported can be laid down in London at 7½d. per lb., and so tempted them to go in for quantity. Small gardens, probably, will find it difficult to compete in this way, and perhaps their best chance of success lies in striving after quality rather than quantity.

The Indian crop this season, with few exceptions, has been disappointing in quality, owing principally to unfavourable weather for growth and manufacture, and with the abundant supply of thin and undesirable Tea from all quarters, lower quotations than previously known have been recorded, common Souchong selling down to 6d. and Pekoe at 7½d. per lb.

The shipments of Ceylon Tea arriving before August were not up to the average in quality, and prices were, consequently disappointing. Later on, however, they shewed a considerable improvement, and as they appeared to advantage in comparison with the general run of Indians then coming forward, they secured the attention of the trade and realised good averages until the past few weeks. Recent arrivals have generally shewn a falling-off in the cup, as they consist mostly of first pickings after pruning or Teas manufactured during unfavourable weather.

Deliveries have hitherto kept pace with the increasing Imports in a most satisfactory way, but as larger supplies reach our market, it is to be hoped that growers will continue alive to the great need of keeping up the standard of excellence already attained, as full flavoured parcels are usually sought after and always command good prices. During the current season Ceylon Teas have, in many quarters, taken the place of fine China Congou, both for Home Trade and Export, principally to the Continent. With the prospect of annually increasing crops, it is most important that foreign buyers should be encouraged, as fresh outlet both for Indians and Ceylons are almost a necessity, unless such a low average is established as to stop supplies from China.

JAVA TEA.—The advantage of having more than one market has been particularly exemplified in the case of Java Tea, for on several occasions when Indians have been depressed, owing to the dulness of Home Trade, Continental orders have kept the former steady. Consequently the fluctuations in the price of Javas are comparatively smaller throughout a season than for other kinds, and the averages obtained have been in several cases above those of some Indian invoices. This no doubt is partly attributable to an improved general demand following on the Teas showing better quality, many of them resembling flavoury Indians and Ceylons, to be accounted for from the fact of the plants having in some cases been grown from seed from these countries.

JOHORE AND NATAL TEA.—During the past season several parcels have been shipped from Johore and also from Natal. The former require more care to be exercised in the manufacture before they can take a good position on the London market. The latter, judging from some of the small lots received, give good promise, being well made and possessed of useful quality.

BULKING AND NET WEIGHING.—In previous annual circulars we have referred at length to these important matters, and in the case of the first are pleased to note that it is receiving more attention, both in India and Ceylon year by year. The shipment of large breaks carefully bulked will not only save the time of buyers here, but will also do away with the charges incurred for bulking at the London warehouses, no inconsiderable item in the expense of working a garden now that the average price is so much reduced. Unless it is well and thoroughly done, however, the labour spent in bulking at the factory is thrown away, as the work has to be gone over again in London.

Attention should not only be given to proper blending, but the packing of Tea should also receive more care than is at present often bestowed on it. The appearance of the leaf is, in some cases, spoilt by its being crushed into the chest, or the end of the pile, which is usually dusty, being placed on the top. A good "packer" would be a valuable addition to the machinery on an estate.

Much dissatisfaction is expressed by Dealers, both wholesale and retail, with net weighing, and at a meeting of the Wholesale Tea Dealers' Association a short time since a resolution was passed unanimously that notice should be given that after this season the Trade would only buy Indian Teas upon the ordinary gross and tare system, though nothing definite has yet been arranged.

PROSPECTS OF THE COMING SEASON.—Looking at the coming season from the point of view of the planter and garden owner, the low range established is anything but satisfactory, the more so as there is no probability of much permanent rise. The public has become accustomed to cheap (*i.e.* low priced) Tea, and the 1*s.* 8*d.* and 2*s.* canisters have in many cases been reduced to 1*s.* 4*d.* and 1*s.* 6*d.* The best hope of raising prices from the dead level they threaten to fall to seems to be an improvement in quality. For the past few years the crops, roughly speaking, have been alternately bad and good, and it is to be hoped that this next season will bear out the rule, for as the export increases, quality becomes of the utmost importance, as unless the forthcoming crop should be better than this year's, prices may fall even lower than they are now, and with accumulating supplies from all quarters there is nothing to prevent undesirable Teas falling 2d. per lb. beyond their present value.

MANUFACTURE—Successful manufacture is the important factor in determining the financial results of a Season's workings, for well made tea should cost very little more to lay down in London than rubbish. It is well known that occasionally an excessive flush or bad weather make it difficult to manipulate the green

leaf properly, but (as the art of tea making is now so much better known than formerly) good quality can be made under ordinary circumstances if only care is bestowed on each different process that has to be gone through. This is proved by the produce of certain gardens being so well known owing to desirable quality, and those marks which can thus make a name invariably command pence per lb. more on this account.

Some Planters advocate long withering, some hard rolling if care is taken to avoid the expressed juice being lost, others believe in firing at a high temperature after very full or light fermentation, but so much depends on the state of the leaf when it is plucked that no hard and fast rule can be laid down.

Heavily fermented Teas with bright copper coloured infused leaves and a full rich flavoured liquor which creams over when cool have for a long time been in favour, and always command full prices. On the other hand there has been a growing demand for lightly fermented parcels with greenish infused leaves and sharp pungent liquors, as they are found useful for mixing purposes. Sterling quality in the cup is the thing to be aimed at, as the appearance of leaf is a secondary consideration.

SORTING, &c.—In sorting and classifying it is desirable to make as few kinds as possible, especially on small gardens, so that breaks may be of a saleable size, say from 30 to 100 chests or half-chests. This is especially important as owing to the large number of breaks in the catalogues it is proposed that parcels of under twenty chests or half-chests (instead of eight as hitherto) should be sold as small breaks at the close of the auctions when most of the buyers have left the sale room. Boxes of flavoury Pekoe or Pekoe Souchong, suitable for self drinking, also sell well at times, if not less than thirty in number. The gross should be under 28 lb. to avoid the 1 lb. draft allowed in packages over that weight. Broken Pekoe should not be sent in boxes as they do not sell readily, and thus the extra expense incurred is lost.

PACKAGES.—Complaints as to the wood used for chests have not been numerous this season, but we would again draw attention to the desirability of not marking either weight or tare on the packages, as it causes dissatisfaction to buyers even if they differ ever so little from the Customs weights. A few parcels of Ceylon Tea packed in A. Andrews' patent metal chests, sold lately, appeared to meet the approval of the Trade, as they realized slightly better prices than the balance of the break in ordinary wooden packages. If these should come into general use the difficulty as to even weights and tares would be solved, much to the advantage of all concerned.

SHORT WEIGHT.—Instances of short weight have not been so numerous with Indian Teas as formerly, though there have been many in the case of Ceylons, especially purchases made in Colombo. It is to be hoped that this may be avoided in future, by more careful weighing at the gardens.

FIGURES.—There is still a great discrepancy between the Calcutta exports and London imports, both being apparently inaccurate and misleading. If actual weights were given, especially in the London warehouse returns, instead of estimates, the arrivals and also bonded stock, at the end of each month, could be correctly ascertained.

SALES IN CEYLON.—A considerable business has been done in the sale of Green Leaf in some parts of Ceylon, as managers of young gardens, in accordance with the practice of the Chinese, find it more convenient to realise in this way than to incur the expenses of manufacture on a small scale. The market in Colombo is gradually rising in importance, but up to date transactions there have only been comparatively limited. We are still of opinion that the small lots sold there might, to advantage, be bulked, refired, and shipped in merchantable-sized breaks.

Comparative Quality of the Outturn of the Different Districts for the Past Three Seasons:—

ASSAM.

1886 CROP.—On the average under an ordinary crop a few gardens having sent desirable Tea throughout some others good and bad alternately, whilst the produce of many has all been poor.

1885 CROP.—Quality on the whole good, though crop in some districts very short. Teas received during August and September very fine, and even better than those of the previous season.

1884 CROP.—Similar to previous season, many well made, but light in cup. During August and September, some very desirable Teas were received, quite up, if not superior to those of the past few years.

CACHAR AND SYLHET.

1886 CROP.—Large supplies of undesirable quality have come to hand, as if quantity had been aimed at. Only a few really choice liquoring invoices realized comparatively high rates.

1885 CROP.—Outturn large, but the crop as a rule poor. A few exceptions, however, which prove that fine Teas can be made if proper attention be paid to manufacture.

1884 CROP.—Early part of season undesirable as a rule, with the exception of several favorite marks which have kept up quality throughout. Later arrivals were much better.

DARJEELING, KURSIONG AND TERAI.

1886 CROP.—On the whole disappointing, and in some cases the worst seen for many years. A few really fine flavoured parcels received during September and October, also January and February, realized extreme rates, proving that this District's Teas when fine are much appreciated.

1885 CROP.—On the whole disappointing, many of the invoices being dry and sapless. The few fine Teas consequently commanded very full prices.

1884 CROP.—Quality very irregular, but on the whole disappointing. Early arrivals good, especially some sold in August, but September imports shewed a great falling-off in the cup. Towards the close some choice parcels were received.

DOOARS.

1886 CROP.—The season opened well, but the Teas fell off shortly after. Sufficient useful quality was sent to prove what might have been done under more favourable circumstance. Late arrivals showed every sign of excessive flushes, and lack of care in manufacture.

1885 CROP.—As usual there has been much irregularity shown in the outturn. With a few exceptions the Teas lacked quality, though for a time they were good, being full in the cup and drawing thick liquors.

1884 CROP.—On the whole good, and a great improvement on previous year. Some very desirable full flavoured parcels, especially the autumn pickings.

KANGRA VALLEY, KUMAON, AND DEHRA DOON.

1886 CROP.—With a few exceptions, the former has sent thin pointless Teas, unsuitable for this market. Rich flavoured lots always sell well, and the few received were eagerly bought up at 6d. to 1s. per lb. advance on similar grades, with poor quality. From Kumaon and Dehra Doon only limited supplies have been received, and chiefly of low class.

1885 CROP.—A few choice parcels were received from the former which commanded high rates, but the produce of the other districts has been poor and in comparatively short supply in this market, a considerable quantity being sold locally.

1884 CROP.—From the former some very choice invoices received at early part of season. The quality fell off later, owing to the unfavourable weather. Recent shipments have again been good. From the last two districts quantity received was very limited.

CHITTAGONG.

1886 CROP.—Like other districts, the proportion of useful to fine has been small. For a time some good prices were paid, but the general average must be a bad one.

1885 CROP.—Some useful Teas received, but a large proportion has been below the average and therefore realized low prices.

1884 CROP.—On the whole fair, but quality irregular, similarly to that from other districts.

NILGHERRIES AND TRAVANCORE.

1886 CROP.—Only a limited quantity has been received, and this generally of the worst description. It is said that most of the best Tea made in the former district is used for local requirements. From the latter some very desirable parcels have come to hand, similar in flavour to Ceylons.

1885 CROP.—Supplies only moderate, and as a rule of undesirable quality, far behind that sent some five or six years ago. A good portion of the crop sold locally.

1884 CROP.—In short supply and quality with a few exceptions below the average. These Teas, like Kangras, command very full prices when really fine.

CEYLON.

1886 CROP.—On the whole the quality has been good, and full prices have been realized. The average being about 2¼d. per lb. above that of Indian growth, proves the estimation in which these are held. Thin and undesirable shipments have sold badly, and should discourage garden owners from going in for *quantity*.

1885 CROP.—Still in favour with consumers, and whenever supplies have fallen off, there has been a strong demand and full rates obtained. These Teas have made a great name for themselves which will probably be maintained if the quality is kept up.

1884 CROP.—Still in favour owing to their useful qualities. Some undesirable shipments however have realized low averages. Demand likely to continue for all parcels with full flavour.

JAVA.

1886 CROP.—Some really useful Teas have come to hand, and they are gradually gaining favour with home and export buyers, especially where attention has been paid to manufacture. The quality, however, must be kept up and in some cases improved if they are to take further hold on consumers.

1885 CROP.—Since the introduction of seed from India, and English machinery for manufacture, there has been a marked improvement in quality, many of the teas having full rich flavour.

1884 CROP.—These teas have gradually increased in favour, both with home trade and shippers, as more care has been bestowed in the preparation. Only a portion of the crop, however, is shipped direct to Great Britain.

GEO. WHITE & Co., Tea Brokers.

TEA PROFITS.

Communicated.)

In an ably written *communique* in your issue of the 1st February, under the heading "Tea Profits," the writer makes the perplexed planter ask, "Why is it that while the retail price of tea to the individual consumer remains the same, my price realised is becoming small by degrees and beautifully less, &c.," and then, after showing who do not make money out of the sale of tea, he asks, "Who makes out ot tea in this present jubilee year of grace? Who absorbs the difference between the admittedly poor average prices realized by the producer, and the steady rates paid by the consumer?" He adds in conclusion, "The reason of the failure of the many attempts on the part of the planter to place his tea directly in the hands of the consumer and so realize the intermediate profits for himself seems very obscure, and affords a fruitful field for discussion."

1.—It is assuming too much to say that "the retail price of tea to the individual consumer remains the same." A short time back when the retail tea trade was entirely confined to what would, in an age now rapidly passing away, have been called "legitimate channels," to wit grocery stores, &c., the price to the consumer certainly did remain the same and for a considerable period even after market prices had come down heavily. In those days the reason why the price to the consumer did not come down *pro tanto* was this: The grocer trusted to his tea sales as to the sheet-anchor of his business, his profit on his tea sales was enormous, and to encourage customers to buy their tea from him he used to sell his sugar to them at a positive loss. That, of course, means that tea had to make two profits to the retailer the profit on sugar as well as its own profit. Naturally so long as the grocer had the tea trade in his hands as a monopoly, the retail price to the individual consumer remained the same under those circumstances. But these huge profits leaked out, as huge profits always will, and then commenced the outside competition to be expected in all similar cases in these latter days, when "legitimate trading" as formerly understood by the adage, "let the shoemaker stick to his last," is ancient history. Drapery shops, haberdashers, small newspapers and stationery vendors *et hoc genus* began to dabble in packet tea. Then came reduced ladies, with a wide circle of acquaintance, who were not above personally canvassing for customers for their "really delicious tea supplied direct, so much cheaper and fresher you know than nasty, musty shop tea with a mixed flavour of cheese, tallow candles and bacon." For a time prices still kept fairly well supported, as it was owing to the temptation of the huge profit that so many entered the field—all equally interested in keeping up the profit as long as possible. Then began a new era, that of the big advertizers. These men had to trust to being able to win customers from the classes above enumerated who were already in the field. They had to offer inducements superior to those offered by those in possession of the field. Quality everybody boasted about, so that was used up cry. Economy was left them, on this they "banked" and two shilling teas suddenly burst upon us in all directions. Ubiquitous advertising is a most serious expense, and it is of course impossible to say how much a pound it adds to the cost of the tea to the retailer as that depends upon the number of pounds sold as compared with the expenditure on advertising. It might easily amount to pence per lb. even in a large business. For a time the reduction to 2s per lb. held its own, till the profits even at this lower rate, permitted by the further decline in market prices, tempted other new advertisers into the field, and we have now a Tea Company largely advertising teas at 1s 3d, 1s 6d, and 1s 9d per lb. "worth a shilling more at any shop." Now, as your correspondent points out that at 1s 5¾d exchange, a 6-anna per lb. pekoe souchong would cost delivered in London 1s 2½d per lb if we add the cost of advertising, rent, insurance, office and staff expenses, loss in turn of the scales, making up into packets &c. &c. the above rates as last quoted, do not suggest either steady rates being paid by the consumer, or that any very serious difference will soon remain to be absorbed by the retailer. I do not mean to say that grocers in many cases and the older advertising houses too, do not still make from 3d to 8d per lb. on the actual book cost of their teas according to quality,—and in the case of some grocers, be it added, according to the customer's ability to pay—but when advertising and other expenses are deducted this profit is considerably reduced; and it will not be long before the new advertisers of these, now still cheaper teas cut down the popular rates once again.

2.—The reason of the failure of the many attempts on the part of the planter to place his tea directly in the hands of the consumer is explainable upon several grounds to meet different cases. In the first place the qualities that go to make an excellent planter do not necessarily qualify him to make an excellent retail salesman, up in all the tactics necessary here now-a-days. In the second place to open up a connection now-a-days means indefatigable personal canvassing for customers, a sphere in which a planter would feel very much more abroad than he did in India and which would prove much more distasteful to him, than all the worries of planting; or else, it means tens of thousands spent on advertising, and as planters who have started so far have been without the capital to indulge in the latter alternative they have entered the business only to retire from it in disgust when the nature of and the necessity for canvassing became apparent to them, or else to drag on in a one-horse sort of way without hope or prospects. I do not forget two or three noteworthy exceptions, one in Belfast, one in Dublin and perhaps another there may be, but the rule has been as above stated, and the exceptions had exceptional advantages in their favour—at all events one of the exceptions had—which conduced to success, but which advantages were purely local and out of the normal.—*Indian Planters' Gazette.*

SUBTROPICAL CULTIVATORS AND CLIMATES.*

The *Gardeners' Chronicle* has had the following appreciative notice of Mr. Haldane's book which, we are glad to learn, has been selling very well:—

The object of this book, as stated by the author, is to call attention to some of the lesser-known agricultural industries of subtropical regions, which are sources of wealth to the inhabitants, but which are almost unknown to the ordinary class of settlers in our Australian and other colonies. With the exception of Sir Ferdinand Mueller's *Select Extra Tropical Plants*, we had no book which dealt authoritatively with this subject, and Mr. Haldane's carefully compiled and eminently practical work is destined to have a useful career. In it are given plain hints as regards the cultivation of fruits, alimentary plants, condiments, vegetable wax and tallow, oil-plants, fibres, drugs, tanning materials, dye-plants, as well as tables of the mean temperatures of subtropical countries in both the Northern and Southern Hemispheres. Mr. Haldane, himself an experienced and successful planter, brings to his aid a large and varied experience gathered in many lands, and hence his book is not merely a compilation, but the result of practical knowledge and observation, which fits it in a special manner to meet the requirements of "colonial settlers and emigrants." The chapters on Tea, Coffee, Olive, Fig, Orange, gave within a short compass all that is necessary to enable an intelligent planter to draw his own conclusions as to the suitability of these industries to the temperature, soil, and climate of the country in which he dwells. Cinchona, although it bears a cooler climate than Coffee, is for some unexplained reason left out. The chapter on fibres is possibly the weakest in the book, for while it gives Sorghum dura as the first on the list of textile materials, it omits the celebrated China-grass, Bœhmeria nivea, and passes over the Agave hemps, which latter supply, next to hemp, the chief rope materials of the world. These and similar omissions will, no doubt, receive due attention in a subsequent edition, and by means of judicious pruning in such chapters as those on Tobacco, Cotton, &c., the size of the book need not be greatly enlarged. As a first attempt to deal in a practical manner with subtropical cultivations Mr. Haldane's book is decidedly a success, and the publishers have done everything they could to issue a neat and attractive volume.

FEBRIFUGE.—Several years ago, Dr. Peraire, of Bordeaux, France, recommended a substance known as ursa-quinine as a febrifuge, in doses of a quarter to one grain per diem. The preparation was composed of ordinary quinine and pure crystallized uric acid. Urea itself has also been recommended as a febrifuge.

OYSTER CULTURE IN CHINA.—My attention was specially called to the stalls of the fishmongers, who not only have river and sea fish, salt and fresh, in great abundance, but an excellent store of bamboo oysters; and if you wonder what they are, I may as well explain that artificial oyster culture is largely practised on this coast, and a bamboo oyster field is prepared far more carefully than a Kentish hop garden. Holes are bored in old oyster shells, and these are stuck into and on pieces of split bamboo, about two feet in length, which are then planted quite close together on mud flats between high and low water mark, but subject to strong tidal currents. This is supposed to bring the oyster spat, which adheres to the old shells, and shortly develops into tiny oysters. Then the bamboos are transplanted and set some inches apart until within six months of the first planting they are found to be covered with well-grown oysters, which are then collected for the market. The oyster shells are turned to very good account, being scraped down until they are as thin as average glass, when they are neatly fitted together so as to form ornamental windows, such as we see in the inner courts of wealthy houses.—*Wanderings in China*—C. F. GORDEN.—*American Grocer.*

**Subtropical Cultivators and Climates.* A Handy-book for Planters, Colonists, and Settlers. By R. C. Haldane. Blackwood & Sons, 1886, pp. 308.

DR. DE VRY, C.I.E., the eminent Dutch quinologist sends us an interesting communication in reply to a statement recently made by Dr. Paul. The latter had quoted Dr. de Vry as authority for an assertion that Pelletier's original quinine sulphate contained a considerable quantity of cinchonidine. Dr. de Vry, however, declares that he never said so, and Judges, moreover, from his analysis of some of the same lot of bark as that on which Pelletier worked, that his sulphate of quinine could not have contained more than 3¼ per cent of sulphate of cinchonidine.—*Chemist and Druggist.*

COFFEE.—"OF GREEN BUG we have all a horror. I mean all who have any coffee left to be frightened about. One man tries a *new* cure and finds it to be better than anything he has tried before, yet he never publishes it! I have heard of several so-called *cures* lately, but surely they ought to see the light in the daily papers; and, if *there is any real good cure*, all might then receive benefit and assist in destroying the common enemy."—So writes a coffee proprietor, but he must have overlooked the full particulars we gave the other day of Capt. Bayley's successful experiments on Nonpareil estate, and the cures he recommends?

CACAO PLANTING IN DOMINICA.—On Thursday evening Mr. D. Morris, late Director of the Public Gardens, Jamaica, and recently appointed Assistant Director of the Royal Gardens, Kew, gave under the auspices of the Agricultural Society an able and highly interisting lecture at the Court House, on the important subject of the cultivation of cacao as an industry in Dominica. The Lecturer, who is on his way to England to take up his appointment, has visited most of the islands of the West Indies, and arrived here by the Royal Mail steamer on Friday last week, it being his intention to proceed by the same Company's boat due here to-day. It is to be hoped that the useful and practical hints given by Mr. Morris on this subject will not be thrown away on those planters and gentlemen who listened to him with wrapt attention throughout his lecture; and notwithstanding the promise given by him to reproduce in the form of a treatise the most salient features of the subject, we shall endeavour to place before our readers in some future issue of this paper the principal points of his discourse. To Dr. Nicholls and the Secretary the thanks of all those to whom the welfare of Dominica is dear are due for having in a great measure brought about the lecture. The former gentleman took the chair and the latter genleman organized and carried to a successful termination all the arrangements incidental to the undertaking.—*Dominica Dial.*

DRUGS IN 1756.—Our colonial empire was still in its infancy, although our West Indian colonies were certainly more prosperous than they have been of late years, and the East India Company had taken firm root in India. Canada was still a French possession, while Ceylon, Guiana, and the Cape were Dutch Colonies, and Australasia was practically a blank on the map of the world. Among the products of the New World, gum guaiac, Jesuit's bark, ipecacuanha, sarsaparilla, snake root, Peruvian balsam, and tolu balsam are quoted, each drug at rates far in excess of those now current. Guaiacum resin was at that time considered one of the most active and valuable drugs known, and was used as a remedy in a variety of diseases for which it is now never administered. Cinchona bark, of which so many varieties now appear in commerce that none but a few specialists can be said to possess a really thorough knowledge of the article, is quoted with refreshing simplicity in two varieties only; "Jesuit's bark opt.," at 3*s.* 6*d.* to 4*s.*; and "Jesuit's bark secund.," at 1*s.* 6*d.* to 2*s* 6*d.* per lb. These two varieties are probably the bark known as "Loxa," and now chiefly consumed in France, for until 1752, that is, eighty-five years after the drug first appeared in the London Pharmacopœia, the habitat of the cinchona tree was believed to be confined to the neighbourhood of Loxa, in Peru, where the Jesuit missionaries first administered it as a febrifuge.—*Chemist and Druggist.*

Correspondence.

To the Editor of the "Ceylon Observer."

DEW: NEW THEORIES AND OLD PRACTICE.

DEAR SIR,—Some time ago the scientific world was delighted with a new theory on dew. The old theory that dew came out of the atmosphere, that it was moisture deposited from the air on cold substances in contact with it, was said to be all wrong; for, according to the new hypothesis, dew came not from the air, but from the very substances themselves on which it was found deposited. The new notion was, of course, proved true by many arguments and alleged experiments.

The *Observer* is not usually dry reading, but I so exposed a copy for twelve hours to the heat of a blazing sun, that for once it became very dry indeed. At evening I spread it out on the top of some stakes a little way from the ground, and left it for the night. Next morning I found the under half-sheet, that next the ground, quite dry, but the upper half was as wet as could be and covered thick with large drops of dew. This dewy moisture did not certainly come out of the *Observer*, and, as I keep a rain-gauge, it was not rain. The following night I repeated the experiment with the same result. I may add that the surrounding vegetation &c., was also dewy, but the *Observer* seemed specially addicted to the mountain dew.

1,700 FEET ELEVATION.

P.S.—Your esteemed correspondent "W. F." hardly does justice to the new theory; according to it, dew is not merely the condensed result of moisture from the ground, but from all substances on which it may be found.

CINNAMON AS IT WAS AND AS IT IS—A VISIT TO THE NEGOMBO DISTRICT.

Negombo, 3rd March.

DEAR SIR,—After a period of many years I have come over here on a pleasure trip, and to visit the old places where I was interested in coconut and cinnamon. It is a sad sight to see the once flourishing cinnamon estates, which used to give very handsome income, neglected and abandoned. Two of the crack estates in the Kadirana district are getting on with peeling. I wonder how they manage to peel in this hot and dry weather. I shall feel obliged if the Superintendents of the two estates will let me know through your journal how they manage to peel their cinnamon. Some of the estates in Katunayaka belonging to the natives are kept in fair order. It is surprising how the coconut palm stands the drought in the Negombo district; the trees are looking fresh and green, while at Mirigama and Veyangoda the trees are suffering dreadfully: the leaves all hanging down and you can hardly see the trunks of trees, and the nuts drop and the branches break down. Propping up the bunches in the season does more harm than good. The tender nuts that drop are sold at 25 cts. per 100 to the villagers, who turn it to copra and sell it to traders, and the traders mix it with good copra and sell it to the merchants. Buyers ought to be very careful as to how they buy this season copra, as these nuts that drop down this drought are immature; they are only fit for cooking purposes. I have no faith in the Mirigama, Ambepussa and Veyangoda districts for coconuts; the trees will not last long. The way the trees shed their branches and get them at the top, and at the age of 30 years the trees will hardly give any crop. The great mistake done in this district is planting on the surface; the soil in these districts is of a hard gravelly soil, so for the convenience of the cultivators they take a handful of soil and place the plants. When I was in Negombo I went along with the late Mr. Jeaumax to his property at Veyangoda and warned him as to the way the goyas were planting. Mr. W. H. Wright is doing the correct thing in planting deep. If he plants his coconuts 5 feet deep, he could be certain of his trees bearing in 3 or 4 years, and say in the 8th year he could calculate on a good return. By planting your plants say 4 to 5 feet deep you could put your plants all through the year; as the plants are under ground the sun does not affect them. I shall feel very much obliged to Mr. Wright if he could let me know through your journal the depth he puts down his plants. I took a run up to Ekala. What a change there is in the place—it is quite a little town. I visited some of the cinnamon estates and made enquiries for an old friend of mine; he was away from his estate. I am sorry I missed seeing him. I took the liberty as he was an old friend of mine, and went over his estate. It is kept in perfect order, the cinnamon and coconuts are looking their best. My old friend Mr. Piachaud, deserves credit for keeping his estate in such good cultivation in these hard times with low prices. I went over the the large Ekala estate, one time owned by Messrs. Darley Butler & Co., but now in the hands of natives; it is kept in a most disertable state and the bungalow standing on the hill is no more, where I spent pleasant days with poor Jim Minto. On my way from Mr. Piachaud's I was obliged to pass Mr. Drieberg's estate to get to the high road. I am sorry I missed seeing him and making his acquaintance. Of the little I saw of his property it looks well cared for, the cinnamon bushes stand 8 to 9 feet high. I saw some nice species of cacao on this estate, the trees stand 7 to 8 feet. I went to the Resthouse and was surprised to see the new building. It is a great pity the old building was pulled down; it used to face the canal. I can't say much of the new one. I took boat at the Resthouse and returned to Colombo and enjoyed my trip exceedingly.—Yours truly, S.

[For answer to this, see page 746.—ED.]

ROYAL JUBILEE EXHIBITION, MANCHESTER, 1887.

(SILK INDUSTRY SUB-SECTION.)

To the Editor of the "Tropical Agriculturist."

Leek, Staffordshire, 18th March 1887.

SIR,—I send you by this mail a series of circulars which will explain the honorary work which I am doing for the beuefit of silk culture and also my position as Chairman of the Silk Sub-Section of the forthcoming Jubilee Exhibition at Manchester.

My friend Mr. J. F. Duthie of the Government Botanical Gardens at Saharanpur suggests to me that I should ask you if you would be kind enough to help these Sericultural investigations by advertising in your paper as much of these Circulars as you think would interest your readers and would assist in serving the very important objects aimed at.—Yours truly, THOMAS WARDLE.

Directions for Collecting Silk producing Lepidoptera.

The *Caterpillars* or *Worms* should be collected when full-grown, and whilst alive put into a bottle of spirits (gin, or common white spirit of the country). When dead when they should be taken out, those of each kind kept separate, and then be labelled with a number (as 1, 2, 3, etc.), written in *pencil* on white paper, or scratched on a piece of tin. Several specimens of each kind, with its numbered label, to be wrapped together in a cotton rag and loosely tied up with cotton thread or thin string, and again placed in the bottle (a good, stout pickle bottle, with wide mouth, is best, and easily obtainable), filling up the bottle with spirit and corking it tightly.

The *Cocoons*, in good condition, to be placed together in small batches, labelled with the same number as that on the worms which produce them. The batches should then be wrapped in coarse, cotton rag and marked with the number on label, and tied outside.

The *Moths* to be collected in perfect condition' killed with care, so as not to rub or break the wings. Before they get dry and brittle the wings to be placed over the back, with the underside lying flat and uppermost. Each specimen, when dry, to be placed in a folded paper envelope, and labelled on the outside with the same number as on the worm and cocoon of the kind to which it refers. These moths in the envelopes to be placed in a small square box (a cigar box if obtainable), and gummed paper fixed round the edges.

The Bottles should be wrapped in some soft wool, cotton, or other fibre to keep them from being broken. The bottles, batches of cocoons, and boxes containing the moths, to be packed in a larger box for despatch to England.

Descriptive notes on the food plants, times of appearence, number of broods in the year, and any other useful information should be sent home with each box.

QUERIES RESPECTING PLUMBAGO, CITRONELLA OIL AND KITUL FIBRE.

Galle, 21st March 1887.

Dear Sirs,—Can you or any of your numerous readers inform me, who first discovered the value of Ceylon plumbago as a mercantile export. I have always believed that it was the late Mr. George Winter of Baddegama; but I was told last night, on the authority of a statement made some years ago in your paper, that the late Mr. John Armitage was the first to discover the value of this mineral? I suppose I am right in attributing the discovery of citronella oil, to Mr. George Winter?—Yours truly, X.

P. S.—Talking of discoveries, who first discovered the mercantile properties of kitul fibre which is now so largely exported from Ceylon?

[For full information as to every known fact of importance regarding Ceylon Plumbago, our correspondent may consult a paper written for the Ceylon Branch of the Asiatic Society by Mr. A. M. Ferguson and printed in their Transactions. A very full abstract was printed in the *Observer* and is included in the latest edition of the Ceylon "Hand Book," From this paper our correspondent will see that neither Mr. Armitage nor Mr. Winter can be credited with the discovery of the commercial value of plumbago. Our predecessors, the Dutch, knew something about the mineral and would our correspondent be surprised to hear that the last King of Kandy combined dealing in plumbago with his regal functions! As to kitul fibre, we believe, it first became commercially important in the time of Sir George Anderson, but we are not aware that any particular name is associated with the discovery of this substitute for horse hair and bristles.—Ed.]

TEA AND CRITICISM.

March 28th, 1887.

Sir,—In reading the Annual Report of the Ulapusselawa District P. A. in your issue of 21st instant, it is mentioned in 2nd paragraph under Tea heading :—"So far experience goes to prove that we may look for remunerative returns when the trees reach maturity."

As one interested in our future tea prospects, I fail to understand these remarks and have been asked by a few the mature age of a tea tree. As a cultivator records his fruit trees or bushes when they reach the age of full bearing with the fruit matured in due season, in like manner the tea planter would say, "My tea bushes are fully grown and I can give a correct estimate from the returns of manufactured leaf." A cabbage or lettuce may be full grown when fit for use. When a timber tree reaches maturity it is fit for commercial use and beyond that age a form of decay commences.—Yours,

SIGNET.

CINNAMON AND COCONUT CULTIVATION—PRACTICAL INFORMATION.

Negombo District.

Dear Sir,—Your correspondent "S." is pretty correct in saying that many of the cinnamon estates in the hands of natives are in a disgraceful state: a large number have not been weeded for many years. All that is done is to cut and peel such sticks as nature gives them, pruning once a year, and at the same time chopping down jungle growth. The cinnamon bush being a very hardy plant stands much neglect; would it were otherwise for the sake of those who do give it justice! What is another puzzle is that though many old estates from neglect give barely 50 lb. an acre, the export of the spice, instead of diminishing, increases. Can this be that those estates in Awisawella, Kalutara and Galle, planted in the palmy time of prices are now coming into full bearing? I fancy this is the explanation. We cannot, therefore, look for a rise in prices from diminished production. Prices are so low that the greatest economy in working has to be practised to give the proprietor a very miserable profit. "More power to your elbow" is the means by which the two crack estates he alludes to manage to peel just now. Friction has to be used to almost every stick, yet the colour of firsts and seconds is good, while that of thirds and fourths is rather dull. What would you have—if the wood now being cut and peeled were left in the bushes it would get very coarse, and either all go to fourths or chips; besides, if not cut now, new wood for the year after would not shoot up, thus a double loss would be incurred. Better to risk a little loss in colour than the disagreeable certainty pointed out above. I fancy, too, that Kadirana has had more rain in February than some other parts where cinnamon is grown, and this has given us an advantage; on the 9th a little over an inch fell, and on the 25th almost an inch-and-a-half.

Your correspondent is surprised at the healthy appearance of our coconut trees contrasted with those in Mirigama, Ambepussa and Veyangoda. I think that those places have had quite as much rain as we; and really there has been no drought this year. Certainly, December was dry, but there was about 14 inches in October and 7 inches in November, which though not quite so much as is usual in the north-east, is very good. January had 3·25 and Feb. 2·63. When there has been no rain for three months I then begin to talk of drought. No doubt the water is much nearer the surface in the Negombo district than in the other places enumerated and that is greatly to our advantage and the soil being free the roots have easy access to it. I cannot agree with your correspondent in his recommendation to plant coconuts four to five feet deep. It is against nature and experience; all fruit trees are surface feeders, where they find the nourishment necessary for their growth and fruiting. A young plant will not throw out its roots into subsoil, as it is not fitted to sustain it. But if from any extraordinary combination of circumstances a plant so placed did escape drowning or getting smothered, and did eventually mature a *stem* to the height of the surface of the ground, what it would do would be to throw out roots into the surface soil, and all that portion below would gradually dwindle away; so that the time it took to reach the surface would be thrown away. I have seen many trees that have had earth or even leaves heaped round the stem, throw out roots over the whole of the portion covered, while the roots below have died off and the trees have broken off close to the ground. In my opinion coconuts should not be planted deeper than one foot below the surface. Make the hole as wide and as deep as you like; but fill it up with good earth and manure well tramped, so that during heavy rains water does not percolate into the hole and form a quagmire. If the soil is very stiff, in the second year dig the ground for about three feet all round the hole about

18 inches deep with pickaxes, and lime liberally: this will render the soil friable and the effects of the lime will be felt another foot at least below the dug depth. After other two years, increase the width of the circle dug and lime till the whole surface has been done. Ploughing once a year after this will be necessary. My advice, however, to those who think of planting on say cabooky soil is DON'T. Moderately stiff clay, if well worked, might make a valuable and lasting property.—Yours, TENNAM PELLAI.

COCONUT PLANTING IN THE WESTERN PROVINCE.

Veyangoda, 7th April 1887.

DEAR SIR,—I was very much interested in lately reading in the *Observer* a communication signed "S."; interested, because it contained glimpses of the past. His letter makes it very apparent that "S." is no coconut planter. Comparing the appearance of coconut trees in this and the adjoining districts, with those of Negombo at the present season, he infers that those in the latter district look better because they are planted deeper. To anyone who has given the subject a little thought the reason will be sought for elsewhere—the low-lying ground which constitutes the bulk of these estates and the free sandy soil. "S.", too, seems afflicted with the new-born craze for deep holes for coconut plants and suggests five feet as a good depth. If he were a coconut planter he would have observed that even with holes of the usual depth plants get drowned during the monsoons. What the object of deep holes is I cannot divine. The richest soil is always at the surface and plants always seek for it there. Coconut holes can be made too deep, but never too wide. I would never cut holes deeper than two feet and five or six feet wide, and I will fill them a foot with surface soil and ashes. If holes of less width were cut, the excellent advice of "Tennan Pillai" can, with advantage, be followed and an annually increasing circle be dug round the trees, though as regards the application of lime I would first satisfy myself whether the nature of the soil is such as will render the application advantageous. As to ploughing, I think annual ploughing disadvantageous, as tending to break and disturb the roots formed since the previous ploughing. "S." seems to have an idea that deep holes favour early bearing. The popular belief is just the other way, I believe. A sandy soil favours early bearing, early maturity and early decay, while a soil with more body will be very much more lasting, though trees planted on it will not be so heavy-bearing at an early age. A sandy soil will benefit the father, while the second description of soil will benefit his descendants. —Truly yours, B.

TEA HOUSES AND WITHERERS: COFFEE *V.* TEA FOR THE FUTURE.

9th April 1887.

SIR,—Is it not time now we have got an approved withering machine which may be capable of improvement to do something towards putting a stop to the mania which at present exists for erecting palatial tea-houses? These are made to cost a lot of money, which is simply thrown away. The conversion of coffee stores into tea-houses is also a fruitful source of wasted capital. It was only the other day I was told of a building of this sort, which had, in the transformation process, occupied a period of nearly two years, and was even now not quite completed. I should not like to be the unfortunate person who supplies funds for this costly experiment. The V. A. evidently wants waking up, but possibly there is no V. A in this case. How is it that Ceylon does not produce more men of Mr. Barber's stamp? He is certainly a credit to his class, and it were well for his countrymen, if they made stronger efforts than they do, to follow his example.

With the coffee market in such a satisfactory condition, and the prospect of still better prices, it behoves all who have any fairly good coffee left to preserve and cultivate it, and so come in for a certain run of luck.

The sudden fall in tea prices is rather discouraging, and the rate at which production is increasing, and will increase, is not likely to induce an improvement. G. W.

RUBBER CULTURE.—A Haputale planter writes:—As to rubber cultivation, my advice to those intending to plant Ceara rubber is "don't." To those who have a large area under Ceara rubber trees only, my advice is let it grow, but spend nothing on its cultivation, suchas on weeding. I have not yet found that it pays, even the cost of tapping and curing of the rubber, and some of the trees in my charge are 5½ years old. We have the assurance that the trees give a plentiful supply of rubber when they are older and I have no reason to doubt it. Meantime, I am not aware of its having proved a paying investment to anyone in Ceylon by harvesting the rubber, therefore, I do not recommend its cultivation. It is my honest opinion, there are far too many acres under the product already and as regards rubber anyone with land suitable for rubber would do better to select some other product.—Yours sincerely, J. W.

UDAGAMA.—The papers have not been troubled with many planting reports of late from hence, and your notice in yesterday's *Observer* regarding the intended auction sale by the proprietors, of Ginniedominie land, reminds me that a line on our doings and prospects may be in place. We rank, if I mistake not, as the youngest of the lower districts that rushed into Liberian coffee or certain fortune, and the last, unfortunately, to replace it with tea; and it makes one heave a sigh to think of the amount that, humanly speaking, must already have been realized here had the latter by good luck been made our sheet anchor from the first. But let prices keep up fairly, and to judge by the working of the small quantity of old tea lately cut down, and the promise of several young clearings, we have quite as good a time before us as any district in the island. As to its appearance neither the Kelani or Kalutara valleys can boast much, or probably better things in regard to soil; which here is usually light and stony at the surface, with as good depth of friable subsoil. Where we have our great full is in the even distribution of the rainfall—equal to about 160 inches! For practical evidence of this, the bushes have continued to improve their yield steadily at each flush since January, during a season which, in most other districts—for drought has probably never before been paralleled—"tea looking as if it would die out" or "flushing at a complete standstill" being the general burden, as far as I have read, of your planting reports of late. The flush taken from the old bushes on this estate just before the first general rains come, and the outery was at its height, was at the rate of 600 lb. of made tea to the acre; and this at the next, after heavy rain had fallen, ran up to nearly double. The recent verdict of, I may say as high, and safe, an authority on tea, as there is out here, is that we may calculate on a steady 400 lb.; and with exceptional facilities for cheap transports and work generally, when a property is in bearing, can contemplate the future with a cheerful countenance! Time will, I am convinced on properly opened land, prove his words.

SAMPLE BARKS FROM THE NILGIRIS.

(Communicated by Mr. Hamlin.)

The sample of quill bark 3 feet in length taken from the whole circumference of the stem and which weighs 3½ lb. is a specimen of a large quantity I am sending home this year from the Baimadies estate situated on the Nilgiris at an elevation of 5,500 feet. About 15 acres of 23 year old trees were partly coppiced and the total crop of quill bark now going home will reach about 75,000 lb. If you examine the sample closely you will observe a renewed strip, but as the stem was operated on some 12 years since, the bark has become covered with lichen and moss, closely resembling the original.

The smaller pieces of quill bark were taken from C. Ledgeriana trees. In the *Tropical Agriculturist* of April 1885, I gave the history of these trees which, at five years and eight months old, gave from twenty-one trees, an average of 11·31 sulphate of quinine. I have only now to add that the trees are of vigorous growth and are bearing a very small crop of seed—a few of the trees, now nearly eight years old, have never produced any seed.

[The box of samples may well be shewn now at the Kandy Agri-Horticultural Exhibition.—Ed.C.O.]

SAMPLES OF GREEN TEAS FROM AMERICA.

Mr. James Irvine sends us a packet of samples of green teas from Chicago with the following remark:—

"Here are the samples of tea I promised you with Messrs. J. W. Doane & Co.'s sample memorandum. The prices are splendid."

The Memorandum is as follows:—

J. W. Doane & Co., 61 and 63 Wabash Avenue, Chicago, October 14th, 1886.

(Dollars and cents of a dollar.)

COCONUT TISSUE AND FIBRE.

(Straits Times, March 21st.)

A product of French origin is now beginning to attract attention in Europe. Several years ago, a French naval officer, Paula de la Barriere by name, took note of the very remarkable compressible properties of the cellular tissue underlying the bark of the coconut tree. From this substance, he has prepared a material passing by the name of cofferdam. The cellular tissue in question has the peculiar property of closely compressing itself, and then again expanding to the fullest extent after a projectile had gone through it, by closing up the hole and thereby preventing the water from forcing its way within through the opening. It acts as an automatic stopper. The discovery is of importance. The subjoined particulars show that it has been quite unexpectedly found to be serviceable in another direction than that of war. We may here state that Miss Wood has discovered a stopping material still more approaching perfection than coconut tissue, as regards its compressible quality. Woodite as this material is called, strongly resembles vulcanised caoutchouc. Experiments have been made in Britain with discs lined with woodite and exposed to fire from Nordenfeldt machine guns at right angles and under an angle of 45 degrees. The woodite facing and the iron discs were literally strewn with projectiles. After the experiments, when the discs were examined not a hole was to be seen. A few discoloured spots only showed the places where the projectiles had impacted. No dents were noticeable. The closing up was perfect. Miss Wood had sought for this material with the object of protecting torpedo boats, the hulls of which are so light and so easily damaged by the smallest projectile. M. Germain, a young French chemist has hit upon the idea of turning the fibres of the coconut to account in solving quite another question. It is well known that very generally electric batteries are at present coming into use, for house bells and telephones for military requirements, and for naval purposes. These batteries contain fluid substances which might spill or leak. Now an empty battery is utterly worthless for the end in view. Moreover, these fluids, however carefully compounded are liable to give rise to stains and burns &c. It is true that, formerly, there was some thought of filling the batteries with acidulated moist sand, sawdust, sponge &c, but these substances increased too much the electric resistance. M. Germain has fixed his attention on the fibre of the coconut, and has thereby achieved important results. He utilises not the inner tissue of the nut, but the outer fibres. The raw material is separated, stamped to powder, and cleaned. The product turned out looks then like powdered cocoa. Its density amounts to no more than 0.08. Its compressibleness is such that, by pressure with the hand only, its volume can be diminished one third. When thus compressed the material possesses a density of 0.22, which is 3 or 4 times that of sponge. Its absorbent properties greatly exceed those of all other known substances. It takes up its own volume of water, and strangely enough, its whole volume amounts then to hardly a little more than that of the fluid alone. It is a bad conductor of heat, but prevents from evaporating or freezing, the substances with which it has been mingled. It is perfectly insoluble in most acids, salts and lyes. Under these circumstances, batteries without fluid adjuncts have been invented. Some have even been put together of great power and remarkable lightness. The electric resistance on application of the coconut fibres, is almost the same as when fluids, without fibres, are used. M. Germain's method of applying electrically the so called cofferdam and woodite, makes it possible to put batteries together, which cannot become exhausted with the additional advantages of handiness and lightness. In course of time, this will lead to light batteries and accumulators, intended as electric motors for cars, torpedo boats, and balloons. The above described discoveries show that waste products often only need research conducted in the right spirit, to become useful and serviceable in the arts and sciences.

THE PREVENTION AND DESTRUCTION OF BLACK WEEVIL IN GRAIN BINS AND GODOWNS.

The black weevil is an insect well-known to grain-dealers the world over, especially in "tropical climates." In India it eats the grains of wheat and maize, and also paddy. It is found in every rice, paddy, wheat and maize bin in Burma.

Like any other insects, the black weevil seems to flourish particularly well in Burma. This is owing to the even temperature of the climate, as it dislikes the sudden changes to heat or cold. It is impossible to estimate the amount of damage caused by this insect in Burma, but it is enormous.

A large percentage of the shrinkage in stored grain may properly be attributed to this awful destruction by this insect. It is not detected unless in very large numbers, but when the grain is cleaned by being passed through a fan or winnowing machine, grain which has been thoroughly cleaned will show a large percentage of dust and a material falling-off in the weight and bulk of grain.

The natives try to combat the ravages of these insects by spreading the grain in the sun and then placing gunny cloths on the grain, when the insect disturbed by the heat of the sun, crawls out of the grain to the top of the cloth, and is then shaken off, and the grain again returned to the bin. This method of temporarily getting rid of the insect cannot be followed when there is a large amount of grain in store on account of the expense of handling the grain. The cheap and simple method of preventing the ravages of the disturbing of the weevil is "Naphthaline powder." The method of application is this: it is but to place the Naphthaline powder at the bottom of the bin or bulk of grain. To accomplish this, take a bamboo about 1½ inches in diameter and long enough to reach from the top to the bottom of the bulk of grain, *punch* the *joints* out of the bamboo so as to enable to pas; a stick from one end of the bamboo to the others have the stick made to fit the cavity in the bamboo; pass the bamboo with the stick in it down through the bulk of grain from the top to the bottom; withdraw the stick and drop into the top of the bamboo, about half a tea spoonful of the powder; the bamboo then can be drawn out as the powder will be safe at the bottom of the bulk of grain. If the bulks are large this should be done to every 10 feet square of the bulk. Repeat the application every 15 or 20 days as the powder evaporates. The weevils that can leave the grain, will do so, and these that cannot leave are killed by the odour of the powder. Naphthaline thus used does no harm to the grain. For such purposes the grain is not affected in the least—rather improved as it is not damaged by this cursed grain pest.

For marketable grain the colour is not affected, and the odour will leave in a short time if fresh Naphthaline is not applied to it.

The quantity of powder used is infinitely small in proportion to the quantity of grain and the powder is entirely destroyed by evaporation, so that for food purposes the effect is *nil*. Naphthaline powder can be had at any respectable Medical Hall for R2·50 per *ounce*; a few ounces will be sufficient for a larger quantity of grain.

I send you this for the good of my old enlightened friends, the Sinhalese and Moormen of your Bonne Island, Ceylon. J. D. W.

TROUT FOR MADRAS HILL WATERS.

Mr. H. S. Thomas, F. L. S., author of the "Rod in India," writes to us:—"As the accompanying papers are likely to interest not a few of your readers, may I beg the favour of your inserting them in an early issue. I have a subsequent telegram from Mr. Le Mesurier, that the trout fry, which are being so handsomely presented, were to leave Nuwara Eliya on the 15th ultimo, but in what numbers, and with what arrangements for ice and carriage, I have no information as yet. If there are enough to justify dividing them into two batches, I think it would be well to send one batch to Ootacamund, and the other to Kodaikanal, on the Pulney Hills. If there is only enough for one batch, I am inclined to think it will be best for the trout, and therefore most to the public advantage, that they should go to Kodaikanal, because the Kodaikanal lake is so very much richer in *ephemera*. They are bred in countless myriads on the rush with which the whole lake is surrounded. The trout are more likely to thrive and reproduce where they are best fed, and if they multiply at Kodaikanal, their progeny can easily be removed to Ootacamund hereafter. Also the trout-like Barilins thrive excellently at Kodaikanal, so that I have taken seven dozens of a morning with a fly. Still, I am afraid that there will be a good many who will think that they ought to go to Ootacamund, simply because Ootacamund is the larger place, just as one gentlemen wants one to put them in the Madras People's Park! I only hope we may get the little strangers safely to their journey's end somewhere, and as it is for the public, not for myself, that the effort is being made, I don't wish to decide the destination without the public having their say and then if we fail once, or twice, I shall hope they will be the more patient of failure till at last we succeed."

Dear Sir,—Your letter to Mr. Kirwan, of the 27th February last has been sent to me for reply. Mr. Kirwan was mistaken in saying that trout fry had been brought out to Ceylon. What we got were trout eyed ova (S. Fario) and so far the experiment shows every sign of being successful. We got them out in two batches of 15,000 each from Mr. Andrews, of Guildford, by two P. & O. Steamers. The first batch was almost a failure, only 562 hatching out, and of these about 500 have survived, and are now healthy young fry. I turned out 200 of these into the stream that supplies our lake here, last week and they seem to be doing well. The rest I am feeding so as to give them a better chance of surviving, when turned out. The second batch was a very successful one, nearly 50 per cent. of the ova hatching out. These are still in the alevin stage, but, so far as appearances go, they will do as well as or better than the others. I shall be very happy to send on full details of our hatching apparatus &c., if you wish it. Judging, however from the condition in which the ova arrived and the rapid manner in which they hatched out, I should be inclined to doubt the possibility of your being able to introduce trout into your hills, by means of ova, unless a different system of packing than that of Mr. Andrew's is adopted. Nearly all our first batch had hatched out before they arrived though very carefully looked after on the voyage, and the second batch only came just in time, (nearly 3,000 hatched out the first night). The longer sea voyage from Madras, and the far longer railway journey to the hills, to say nothing of the trip up country, would, I fear, be fatal to the ova. Nor was this our first attempt. In 1882, and twice since, we tried the same experiment, but each attempt failed and it is only at our fourth that we seem about to succeed. On the other hand, I believe you could transport fry from this to Madras without difficulty, and if you could arrange for their transport, I shall be happy to give you some. The best way, of course, would be for you to get some Indian visitors to this station to take charge of the tank, and to see that the water was constantly changed, and the fry fed now and then. At any rate, if I can assist you in any way in this matter, you may command my services. And now, per contra, may I ask a favour from you, and that is, can you help me towards the introduction of mahseer into Ceylon? Could you send me some fry: and give me full details of how to treat them &c.? Perhaps we could arrange an exchange, and by the same hand that you send me mahseer I could return you trout.

C. J. LEMESURIER.

DEAR SIR,—With reference to my letter of the 20th, I am going to make an attempt to send you a few trout by Mr. J. Howard, the Manager of the Murree Brewery Co. here, on the 5th or 6th proximo. Mr. Howard is away from Nuwara Eliya just now, so that I cannot give you the exact date and name of ship, but will write you again *in re* when he returns to the station.—C. J. LEMESURIER,—*Madras Mail*,

PLANTERS IN DELL.

(Translated for the Straits Times.)

Barring estate incendiarism by Battaks, planters in Deli are getting on very well. They will, however, have soon to look out sharp, now that North Borneo is coming into prominence as field for tobacco cultivation. A new company formed for growing that article there has just raised at Batavia the full amount of the capital required for the purpose. From Siak, too, a keen competion in the same direction may be expected erelong. It is a pity that the economic conditions prevaling in Deli, favour tobacco planting exclusively. The Government neglects doing anything to bring about a healthier state of things in this respect. So long as the east cost of Sumatra supplies the European market with tobacco only, that country will always run the risk of some day finding its most fertile land becoming almost worthless. It is evident that planters there should continue to direct their energies to one main point, namely the possibility of introducing a sound system of rotation of crops. In Java, the exclusive growth of tobacco in certain districts has resulted in whole estates becoming quite worthless. Deli planters would do well to profit by example.

LIME JUICE.—Looking to the value of lime juice in this country the *Grenada Chronicle* wisely advocates a larger cultivation of the lime. This journal has often impressed upon its agricultural friends the advantages to be derived from the production of limes, but hitherto with very little success. There are acres upon acres of land in Grenada unadapted to the production of the present staples that would readily yield the lime tree.

COCONUT PLANTS.—Transplanted plants of one and two years' old will certainly bear in three years and I take it that Mr. Wright's plants were such. I appeal to such veterans as Messrs. Schrader, Lamont, Jardine, Poulier, Joronis Peris, Justice Dias, Piachaud, Shand, Stork &c., to endorse what I have said. Mr. Wright's treatment of cocoanuts with expenditure *ad libitum* must certainly push the plants forward, but I should be glad to learn from the gentlemen I have named or any of them, whether they know of any estate in the country that has 75 per cent of the trees on the land in bearing in 10 years. I trow not; twenty more likely excepting perhaps those in the far famed district of Madampe and Chilaw. Mr. Wright's venture in the vicinity of Mirigama is being cultivated, I understand, in his usual liberal style. When it is giving a return we shall be glad to hear from him how much it has cost him per acre and what percentage he reaps on the expenditure. I have nearly 30 years' experience of this district and I have no hesitation in saying that with all Mr. Wright's "energy" he will not bring 75 per cent of his trees to bear in 10 years. If we live we shall see.

ALLEGED SOLUTION OF THE RHEA FIBRE DIFFICULTY.—If the following statement in the *Indian Agriculturist* should turn out to be correct, the importance of the discovery can scarcely be exaggerated. Rhea is one of the finest of all plant fibres, but it has hitherto been one of the most intractable:—"Many of our readers will be glad to learn that Mr. Charles Maries, of the Durbhunga *Raj*, has solved the Rhea fibre problem. Mr. Maries has discovered a process by which he can decorticate the fibre in the green state with extraordinary facility, after which he works it up to the required standard under his new process. We have seen some of this fibre, and can state with certainty that we have seldom seen Rhea fibre to equal Mr. Maries specimens. It retains all its strength of tension, while the floss is as soft as silk. Mr. Maries, we understand, has shown his fibre to some of our large Calcutta merchants who deal in fibres, and their opinion is a very favourable one indeed. We congratulate Mr. Maries on his discovery, which ought to prove a perfect "mine of wealth" to him. Any one wishing for further particulars should address himself to Mr. Charles Maries, Durbhunga."

"REVUE AGRICOLE."—We have received the first No. of this publication edited by Mr. A. Daruty de Grandpré, President of the Acclimatation Society of Mauritius, and we cordially recommend it to all our readers. The name of the Editor is in itself a guarantee of the quality of the contents, for he is an accomplished botanist and throughly at home in the Agricultural History of the colony in all its details, and in the various subsidiary cultures which might be carried out in Mauritius if only once started. Among the contents there in an excellent summary of the Sugar Industry of Mauritius, and a very well written article upon the manufacture of perfumes which, in the case of Jamaica appear to be a very paying speculation, also one upon the profit that might be derived from the pine-apple which grows almost wild here and might with a very small amount of ordinary care turn out excellent wine and spirits of exquisite quality. The Revue is very well printed and we wish it every success, for it will supply a long felt want.—*Mauritius "Merchants' and Planters' Gazette."*—[The "Revue Agricole" has reached us and we shall have some of the papers translated and printed in the *Tropical Agriculturist*, which we are specially asked to exchange.—ED.]

GUARANTEED MORTGAGES.—In a recent number of *West Indian Quarterly* Sir John Gorrie formulates a scheme by which money might be safely advanced on guaranteed mortgages and help to make estates reproductive. As what Sir John Gorrie says is closely allied to the questions which the sub-committees on State-aided Emigration have to define, the following extract may prove useful:—"As recently there was some talk of buying up Ireland, "why no give the West Indian communities the right to borrow upon the best terms, and to offer security such as has never been offered to lenders on mortgage since the world began? . . . For the want of this privilege the poor islands, which might have been getting their heads above water, have been unassisted in their hard struggle against ruin. Although such a scheme would not be workable at home, or in large representative Anglo-Saxon Colonies, yet it might probably be considered with great advantage in Trinidad, Barbados Demerara, and Jamaica, as well as the smaller islands. Recent events in the former have shown how precarious an industry is which draws its working capital from mercantile sources. These are so subject to the fluctuations of the money market that no dependence can be placed upon their permanence. A failure here or there sufficient to alarm a Bank manager in London may dry up in a night the fountain which irrigated a great estate with the necessary supplies. How much better to depend upon capital advanced upon specific terms which cannot be called up without giving the borrower time to turn round to avail himself of other resources. In an ordinary case he might find the ear of the oracle deaf to the charmer, but if he as a borrower can come to say that he not only gives land as security more valuable than the sum asked for, but that a Colonial Board will guarantee the principal and interest by means of a fund levied, collected, and invested by law and that the interest will be paid in London as regularly as the dividends on Government stock, depend on it, the oracle will be deaf no longer, but open, generous, confiding, and liberal."

THE PRESERVATION OF TIMBER.

In buildings of timber in whole or in part, it is commonly found that from exposure to weather, insects and other causes the timber frequently decays in the course of a few years and has to be replaced. To avoid this extra expense the process of injecting some chemical substance into the timber is worthy the attention of selectors and others, who, in erecting the necessary buidlings are sometimes obliged to use timber of inferior quality owing to deficient seasoning or some other cause, which tends to lessen its durability, and which, if it could be cheaply prevented, would certainly be worthy of being put in practice.

The decomposition and decay of timber is a natural process, which, sooner or later, renders it useless for economic purposes, but for nature's purposes the more rapidly it is decomposed into its component elements and mingles with the soil the better it is for living vegetation. This being the case it is evidently the business of men to retard, if they cannot altogether stop, decay from proceeding. One of the first and most common of the various methods that have been employed is to shelter it from the weather, a method which in the case of all, but more especially some particular kinds, enables it to remain sound for many years, even for centuries, in the case of some species. Pillars of mosques in Kashmir of the wood of the Deodar are found sound after being 400 years in use, and, says Baron von Mueller, bridges of still greater antiquity are in existence. Most sorts of timber, however, decay much more rapidly, some not lasting even a lifetime, and to abate that failing and render the timber more lasting, various substances have been used and processes proposed, some chemicals acting in one way and some in another. By one process the destruction of the sap is aimed at and the consequent drying and hardening of the woody fibre; in another the attempt is made to destroy or alter the albuminous matter in the sap; while other experimentors have endeavored to effect the object by forming insoluble precipitates with metallic salts. To effect the destruction or elimination of the sap heat has been employed from the earliest ages, and the practice of charring the ends of posts to be sunk in the ground has been universal, and is still practised to a large extent, though it does not prove very satisfactory. A much better method of effecting the object is to dry the timber in the warm atmosphere of a heated chamber; by this means the sap may be nearly or altogether expelled, and the timber so consolidated as to become extremely durable if kept dry; but the process, like most others, is expensive. The total expulsion of the sap through the production of a vacuum has been recommended. Various methods for the neutralisation of the properties of the sap have been recommended, among others floating the timber in water for a time has been practised. Half a century ago kyanising timber was all the rage in Britain. Mr. Kyans process was the injection of chloride of mercury into the timber, but the practice fell into disuetude after a short time. Then Burnett proposed the injection of chloride of zinc; Lege and Pironette that of sulphate of copper; Payne's preparation of sulphate of iron and muriate of lime were all experimented with and had their day. Bethell's creosoting process, on the same principle, has led to an adoption of that substance in the northern hemisphere, and also in Australia, though it is generally applied by merely painting the surface of the sawn timber. The *ratiouale* of Bethell's process is described thus:—"When injected into a piece of wood the creosote coagulates the albumen, and thus prevents putrefactive decomposition, and the bituminous oils, being insoluble in water and unaffected by air, render the process universally applicable." This method is one which can be easily practised anywhere. Unrefined creosote can be obtained at a low rate, and merely requires to be laid on with a painter's brush. It can be used for quartering, battens, laths and other timbers required for roofing and other parts of house building. It is especially applicable to stables and other outbuildings; increasing the endurance of the timber, and saving it from the attacks of ants, other noxious insects and fungoid parasites.

Lime is another useful preservative. It has been observed that old lime boards hardly ever decay, and when posts in the ground are surrounded with lime they remain sound for a great length of time. The scientific method of using lime is to form a solution of it in water in which to immerse the timber, which causes similar chemical changes as when subjected to the action of the metallic agents or to the process of creosoting, precipitating albuminous matters, and thus rendering them inactive. The timber also takes up lime as caustic lime, and on the subsequent exposure of the wood to the air the excess of lime which remains in the wood gradually absorbs carbonic acid, and the woody fibre throughout the whole mass becomes coated with insoluble carbonate of lime, and the wood may be said to be mineralised to some extent. As described in the *Garden*, "pits or ponds may be constructed, varying in size and position with the locality in which they are made and the quantity of timber to be soaked, a common pond being quite sufficient for the purpose; all that is essential is to have sufficient size and depth to hold the timber requiring to be soaked." Thus in the building of a farm house, if a pond is not available, a reservoir capable of containing the timber required may be easily formed, its sides and bottom planked or merely clayed, so as to retain the water, of which a comparatively small quantity will suffice to cover the timber when immersed. The water is first to be run into the tank, and then sufficient lime to completely saturate the water and some to spare, for as the water will only take up a definite portion, an excess of lime will do no harm. It requires only 88 grains of chalk or stone lime to impregnate a gallon of water, so that a bushel of lime will suffice for several barrels of water; but as it is best to err on the safe side an excess of lime should be used.

It need hardly be expected that many persons will take the trouble to prepare their timber so that it may last during two or three generations instead of only one, still there are many things, such as tools, implements and machines, that are much exposed to the weather which would repay any outlay that might be incurred in such a simple process. The timber ought to remain in the lime water for ten days or a fortnight.—*Leader*.

FISH WASTE.

TO THE EDITOR OF THE "INDIAN AGRICULTURIST"

SIR,—As British Vice-Consul in the Loffoden Islands, I have pursued with much interest Dr. Aitken's excellent article on the important subject of fish waste, and I heartily agree with all he says in favour of fish as a manure, and also with his remark that a "more perfect utilisation of the refuse would enhance the value of our fisheries and prove a national gain."

Dr. Aitken's description of the wonderful richness of the Norwegian fisheries is not exaggerated, but there are one or two slight inaccuracies in regard to the manufactures which I may correct in passing. The oil in cod-fish is contained exclusively in the livers—in the flesh the quantity does not amount to 1 per cent, consequently the only oil obtainable from cod is the *liver* oil, which is used for medicinal purposes and for *leather dressing*, not for lubricating. As a lubricator it is useless, for exposure to the air deoxydizes it, and it becomes quite viscous. In the herring the livers are exceedingly small; the oil, therefore, is contained chiefly in the flesh, and the percentages vary from 3 per cent to 10 per cent, according to the season and the fatness of the fish.

During my visit to England last winter there was some discussion in *The Times* on the subject of fish *manure*, as Dr. Aitken so properly terms it. Fish *guano* is the excreta of birds whose diet consists solely of fish. Fish manure is refuse dried by machinery and ground to powder, it is less soluble than the guano, or huano, which is the Spanish term. Sir J. B. Lawes drew attention to the wonderfully similar chemical composition of cattle and of fish, both of

them, he asserted, containing 33 parts in 1000 of the essential ingredients—nitrogen, phosphoric acid, and potash.

One of the common sayings of my farmer relatives is that, "You must give back to the land what you take from it, otherwise crops are unprofitabe," and this, in spite of protestation to the contrary is just what agriculturists fail to do. The cattle eat the produce of our fields, and the best of the food goes to build up their frames, the bone, the flesh, the blood, the hoof, and the horn. What farmers return to the land with such unwavering belief in its virtue is simply the waste consequent on this process, the slag of the iron, so to speak, with the minimum of the valuable ingredients and the largest bulk, but cattle cannot be killed for the purposes of manure, and the circle is broken because the flesh and valuable parts, which in our turn we eat, are not returned to the soil as they ought to be, consequently we can only fall back upon the equivalent of oxen, &c., in flesh and bone, viz., fish, which nature has provided for us in abundance, if we will only trouble to avail ourselves of it.

Sir J. B. Lawes, in writing to *The Times*, 29th December 1884, said:—"The chemical composition of fish does not differ much in some of their most important ingredients from that of stock fed on our farms." In 1000 lb. of sprats, Professor Way found 20 parts of nitrogen, 8½ of phosphoric acid, and 4½ of potash. In the animals of the farm at Rothamsted, we found 20 parts of nitrogen, 10 to 12 parts of phosphoric acid and 4½ parts of potash. Although varying in their relative proportions, it will be observed that these important ingredients are almost the same in fish as in cattle or sheep, amounting in each case to about 33 parts per 1000. In the case of agriculture long experience has shown that exhausted soil can be restored to fertility by the application of manures.

The experience of each succeeding year teaches me that there is more than sufficient surplusage of fish in the sea to provide this country with all the fertilising material it needs. Indeed, in the same letter of Sir J. B. Lawes, he speaks to this effect, viz:—"So long as fish live upon each other, the sea resembles a soil covered by forest untouched by man. A growth of firs will follow a growth of oaks, the land is at the same time continuing to increase in fertility, Cod-fish eat herrings, and they in their turn eat smaller fish, but there is no exhaustion of ingredients." In one square mile of the Loffoden fishing ground, it is calculated that the cod-fish devour more herrings in one week than are exported from Norway in one year, viz, 800,000 barrels.

In my small district alone, the firm of J. Jensen & Co., whose advertisement I notice in your columns, have collected, received, and converted into a portable manure in 1885 no less than 19,000 tons of refuse, and it is safe to say that double or treble that quantity would have been at their disposal had they possessed means of dealing with it. In September and October they could have commanded 1000 tons per week of herrings alone—the surplus from curing stations—had their plant sufficed to deal with it. J. Jensen & Co. have grappled with and conquered the innumerable difficulties attending the manufacture of such intractable articles as fish heads, backs, and entrails into a dry, portable manure, and working day and night for greater part of the year, they cannot at present deal with more than 500 tons of refuse per week, from which 400 tons of water are extracted, leaving 100 tons of dry and portable manure. As far as I can learn, there is not such another establishment in the world, but there are places where the trade might easily be conducted, and on a much more important scale, were the same appliances used.

In the waters of the West Indies, on the coasts of South America and Africa, around the Mauritius, Newfoundland, Labrador, Vancouver's Island, and Japan, fish abound in such exhaustible numbers that it would pay to establish factories and employ the natives to catch fish simply for manure. The agriculture of this country is suffering untold things from inadequate fertilising of the soils and unless our farmers bestir themselves to obtain manures which will restore to the land what has been taken from it the present unsatisfactory condition of things will remain unchanged.

Unless land is made to produce the larger possible crops, there is waste in every degree. Labour, interest, rent and farming here will never hold its own against foreign competition.—I am, &c. THO. S. WILSON, British Vice-Consul.—*Indian Agriculturist.*

DRUGS.—The most notable features in the drug and chemical markets are the extreme scarcity of carbolic acid, an advance in bleaching powder, and increased firmness in opium. Reports from Norway confirm those we have already published of the failure, so far, of this year's cod fishing.* The cinchona sales this week have hardly realised anticipations, and quinine tends flatter. Our special report from Buda Pesth indicates a probable scarcity of belladonna.—*Chemist dan Druggist.*

To many mechanical minds a square hole auger would appear an impossible achievement, but a correspondent at Wooster, Ohio, saw the machine manufactured by a company there in operation. It makes a square hole, 2×2 inches, with smooth walls, clean, sharp corners and no splinters, and works easier than a 2-inch round auger. The cutting is done by a rocking motion of a cutter head with knife attached, which cuts upward. The work is smooth and rapid, all waste being got rid of so that choking cannot take place.—*American Grocer.*

DR. BEYERINCK, one of the most distinguished naturalists in Holland, has been investigating the origin of the masses of gum collecting on the limbs of certain kinds of trees, especially plum, apricot and others bearing stone fruits. He finds that the exudation is due to a disease produced by the presence of parasitic fungi; and when healthy trees are inoculated with the gum thus produced, they speedily contract the disorder, which is highly contagious. The disease is disseminated by the drying of the gum by oxidation, and its circulation in the wind, which thus wafts the germs for many rods, so that one diseased tree may infect a whole plantation.—*American Cultivator.*

ONE elementary principle which the many cultivators fail to appreciate is, the grand and important one of DRAINING. Misconceptions with reference thereto are common because easy. What is absolutely false often strikes the mind more readily than the truth. What conclusion is more natural than to think if you thoroughly drain a piece of land that it cannot hold water for the same length of time as undrained land? But it is an immense fallacy nevertheless. Countenance is lent to it by the well known fact that if you draw off a body of water from a swamp by an open drain, that swamp cannot have water in it so long as if it were undrained. This obvious fact notwithstanding, it is the well-drained land that will furnish moisture the longest time during a spell of dry weather to vegetation of any description growing upon it. There are many who know this; there are plenty of Queensland facts that demonstrate it; and there is clear logic and sound reason in the premises which support it. Take a square foot of soil that is firm and close and see what amount of moisture it contains; then try a similar quantity of open and porous soil and it will be found to contain much more moisture. Nor will the porous soil give out its moisture half as freely as the close soil. But what—says one—has this to do with drainage? Everything. Well drained land will be porous, and sodden land closed. The material of a sponge could not hold much water were it pressed into close quarters. Close material of any kind is a conductor of heat and gives out its moisture quickly in consequence by evaporation; and hence sodden lands rapidly, lose their moisture through evaporation, when well drained lands will not and cannot.—*Planter and Farmer.*

---

*Noted with reference to Codliver Oil, of course.—ED.

PEACHES AND NECTARINES.

Many years ago the peaches and nectarines grown in South Australia were very fine both for size and for flavour, whilst the beauty of their exteriors could not be excelled. These fruits were grown chiefly in the gardens upon the plains because the rich land amongst the hills had not then been taken up so extensively as at present. After a time the fruits began to deteriorate and to decrease in size, the trees became sick, and at last the fruit was worthless and the trees were chopped out of the ground. Why did the trees become diseased, and why did they fail to yield crops of good fruit even when young trees were reared in their places? Perhaps it was through neglect of the ordinary rules of the gardeners' art. The trees were allowed to bear at three to four years of age; to produce excessive crops; the land was never enriched, but the spade was freely used and the fine fibrous roots were chopped off in the digging; the trees were never pruned, or, if pruned, the work was done any way and without method. The curl-leaf fungus became introduced along with new varieties of peaches; also the shothole fungus and other destroying agents, and no trouble was taken to cure the diseases, so that at last they became so common that no peaches, apricots, or nectarines could be grown with satisfaction anywhere. Some people say that these trees are not long lived, and that this is the reason; but there are trees that are over 30 years old at Kangaroo Island and in the old-settled south district, where the fruit is as good, as large, as handsome, and as abundant as ever. The growers in these places seem to know the value of mulching, the danger of overdigging, the beneficial effects of judicious pruning, and the folly of allowing the tree to produce overabundantly. Perhaps the opossum performs a beneficial work here, for they knock off large quantities of green fruit. As the cultivators had already in their orchards more fruit-trees than they could fairly manage, they were not anxious to introduce new sorts; and the result has been that in these old and still productive orchards they have no serious diseases amongst the trees. Neither the peach nor the nectarine require exceedingly rich soil to grow in, but they must not be starved, and in summer they must have a sufficient supply of water. Both kinds of flower upon wood produced the season before, so that in pruning it is necessary to bear this fact in mind. They can be grafted or budded upon almonds, plums, or apricots; but the union is never satisfactory, and the only proper plan is work the tree upon stocks of their own order. There are a great many varieties of peaches, but it is not advisable to plant more than three or four sorts, including those that are earliest and those that are latest in ripening. Nectarines are not so numerous in varieties, nor are they so popular as a fruit, from the fact that they are surpassed by the peaches in every respect and are in season at the same time. Still, they are very superior to many other fruits, and are worth a place in a fruit garden.—*Adelaide Observer.*

PRODUCTIVENESS OF THE ORANGE TREE.

There are but few trees or plants in nature to be compared to the orange for fruitfulness; very few so prolific and commercially valuable. Besides its delicious fruit, enjoyed both by the rich and the poor in nearly all countries, it produces several other most valuable products. There are five distinct and highly esteemed perfumes obtained from it. *First.*—The true orange flower odour, obtained by digesting with fat by the process called *enfleurage*. *Second.*—Oil neroli petale or oil neroli begarade, by distilling the flowers of the sweet and bitter orange respectively. *Third.*—Oil neroli petit grain, by distilling the leaves and unripe fruit. *Fourth.*—Oil of orange Portugal, obtained by rolling the fruit in a metal cup covered with small spikes, for puncturing the oil glands. It is called an *ecuelle*, which wounds the fruit and causes the oil to flow. *Fifth.*—Commercial oil of orange, obtained by expressing or distilling the orange peel. Besides these valuable products the dried peel is largely used in medicine. The essential oils enter into the following perfumes:—

Essence of Orange Flowers.—Orange flower pomado 16 ounces; pure spirit of wine, q.s. or 16 ounces. Place the pomade and alcohol into a jar of half-gallon capacity. Digest by means of a water-bath until the pomade is barely melted; shake well together, and repeat the shaking frequently until cold. Allow this to stand a fortnight, then drain off the essence. If this falls short of one pint, repeat with a sufficient quantity of spirit to make up that measure. A second washing can be done and another pint of essence obtained, which though much weaker will be found useful in a cheaper perfume.

Spirit of Neroli.—This is made by mixing oil neroli petale, 4 drachms; pure spirit of wine, 16 ounces. Mix and dissolve.

Eau de Portugal.—This was at one time a very popular perfume. Essential oil of orange peel, 8 ounces; essential oil of lemon, 2 ounces; essential oil of bergamot, 1 ounce; otto of rose, ½ ounce; rectified spirit at 75°, 1 gallon. It is most charming and refreshing during the heat of summer or in the heated ball-room. In the ever-popular perfume "Eau de Cologne," as is well known, the predominating odour is lemony-orange. The following formula for which is given in the new French Codex:—Ol. Portugal (orange flowers), 10 parts; ol. bergamot, 10 parts; ol. lemon, 2 parts; ol. neroli petali, 2 parts; rosemary, 2 parts; alcohol, 1,000 parts. Dissolve and filter. This is much simplified, and may with age give a better result than the old complicated formulæ. Throughout the whole range of perfumes known to us we think there is no perfume so fully answers the word "refreshing" as the lemon and the orange. The violet and the jasmine may be lovely, the rose and sweet-brier delicious, the musk and others, when artistically blended, charming, but none have the invigorating effect upon the olfactory nerves as that possessed by the orange, lemon, and citron family. There are very few compound perfumes (bouquet) of any merit that do not contain one or more of these odours as part of their composition.—*Burgoyne, & Co.'s Monthly Export Prices Current.*

THE TREE TOMATO.

So much interest has been expressed with reference to this fruit, which is occasionally seen in our own markets, that we have thought it desirable to copy a coloured illustration which appeared in the *Revue Horticole* in 1880, p. 150 (see p. 383), and to request Mr. Morris, the Assistant-Director at Kew, to give us the benefit of his experience. This he has kindly done in the subjoined letter:—

"A full account of this plant was given by myself in the *Gardeners' Chronicle*, vol. xxi., n.s., April 10, 1884, p. 510. It is of shrubby habit, with broadly cordate and pubescent leaves, sometimes a foot long. The flowers are borne in sub-axillary cymes, of a pale fleshy colour with bright yellow stamens. They have the odour of Violets. The fruit is about 2 to 2½ inches long, and about 2 inches in diameter. When ripe it is of rich orange colour. In the West Indies it is called Tree Tomato; in Peru (its native country) it is known as Tomato de la Paz. It sometimes appears in Covent Garden Market, as I am informed by the Editor, under the erroneous name of Granadilla, as an importation from the Azores.

"When in Jamaica I was very favourably impressed with the value of this comparatively little known fruit, as it answers in every respect the purposes of the ordinary Tomato, while the plant itself is perennial and easily grown. The fruit is also produced abundantly during the winter months, from November to March, when ordinary Tomatoes are not easily obtained. Unfortunately the plant is not hardy in England or in corresponding latitudes, nor will it stand extreme tropical heat. It is, therefore, sub-tropical, and flourishes best in hilly districts in the tropics, with a mean annual temperature of about 68° Fahr,

"During the last three years several hundred packets of Tree Tomato seed have been distributed to various correspondents in the Colonies, and very favourable accounts have been received of the introduction of this fruit to Ceylon, Southern India, and Eastern countries. Lately Dr. Shortt, of Yercund, sent to Kew a pot of preserve made from the Tree Tomato fruit grown in Southern India.—D Morris, Assistant Director, Royal Gardens, Kew."

To this we may add that the fruit is occasionally grown in this country, as we remember to have had specimens sent us for identification, and they have also been exhibited before the Scientific Committee. As is the case with most cultivated plants, there is a considerable amount of variation in the size, colour, and form of the fruit. Those now figured are more pointed than we have usually seen them.

In the *Revue Horticole* for 1881, p, 470, is a second coloured plate, representing two varieties obtained from seed of that originally figured. One of these is yellow, and we mention the circumstance as we have just received from Messrs. Viccars Collyer & Co., of Leicester, a fruit under the name of Melon-Pear, which is clearly the fruit of a Solanum, very nearly allied to, if not identical with, the Tree Tomato and with the "egg plant." The specimen sent is seedless, and does not admit of absolute verification, but we have no doubt that the fruit in question is the produce of a Solanum. Assuredly it is not a Melon and not a Pear—sufficiently good reasons to the framers of popular names to call it a Melon-Pear. It has, it is true, much of the fragrance of a Melon. We are promised further specimens with flowers and leaves at another time, when the identification of this so-called Melon-Pear can be rendered certain. According to an article in the March number of the American *Gardeners' Monthly*, this plant is called, in Central America, Pepino, or Cucumber.—*Gardeners Chronicle.*

SERICULTURE IN INDIA.

The following extracts from a letter to the Journal of the Society of Arts from Mr Cunliffe Lister will be of more than passing interest:—

"Chinese *tassar* waste is worth to-day at least 25 per cent more than Indian. I use considerable quantities of both. It is quite a folly to suppose that that tassar or any wild silk can be reared to pay, because in all cases it will cost as much, and in many (more particularly *tassar*) vastly more than mulberry, and when done, the cocoons are only worth about half as much. Wild silk has a future, but it must be limited beyond all question to what the jungle can produce at little cost, and that I consider is not a very large quantity.

Tassar might be the fashion, and might, for some special purposes, be as valuable as the *bombyx mori*, but it would be of a fictitious value, as its fibre lustre and dying properties are not comparable.

Some twenty years ago I read in Dr. Ure's *Dictionary of Arts and Manufactures* that there was a species of silk (the *eria* worm) grown in Assam that was so abundant and cheap that the natives over a large extent of country were clothed in it, and that it was so durable that mothers hand down garments to their daughters. This description of Dr. Ure's so exactly suited and described what was wanted, that in March, 1865, I wrote to my agents in Calcutta "with a monthly crop it should be produced almost as cheaply as cotton—that it can be produced for little or nothing is beyond dispute, or why are all the poor natives clothed in it?" From that day (now more than twenty years ago) I have never been able to obtain any supply worth notice; each year I have imported a small quantity, but nothing of any importance. At the present time Manchester prints have to a great extent superseded it amongst the natives. Before going to India, in 1884, I had two acres planted with castor-oil, in order that when I arrived there I might have some eria worms reared under my own supervision, but I soon found that it was a mistake, as they required the same labour and attention as the *bombyx mori*, and the cocoons were only worth half the money, as they could not be reeled, and must be used as waste; so I had my castor-oil plants dug up and planted with mulberry.

Wild silk can be used, when produced at a low price, but can never be a large article of commerce, like the *bombyx mori*. In 1874 I bought 1000 acres of land, at a cost of £3,000 or £4,000 in Upper Assam, for sericulture, but it was afterwards found that labour was too scarce and dear, and I then turned it into a tea garden. Some years after that, in 1878, I made another attempt at sericulture at Mádhopur, in the Panjáb, the Government being exceedingly anxious to promote cottage cultivation. At that time I had but little practical knowledge of the proper method of treating and rearing silkworms, and very foolishly, as it turned out, imported during two or three years a large amount—above five thousand pounds worth—of the best Italian and French seed, which was given out to the cottage native rearers, and for which I got absolutely nothing in return. It might have just as well been thrown into the sea. A very large sum was spent in various ways (most of it very foolishly), but all in vain. It was a complete failure; and well it might be, when we consider the miserable huts in which the worms were reared, and the imperfect knowledge and want of cleanliness of the rearers. There must be ventilation, absolute cleanliness, and abundant space, if silkworms are to be reared with any chance of success. All these conditions are wanting in a native cottage. Although I joined the Government in offering prizes for the best cocoons, and everything possible was done, no expense being spared, it was all in vain, and I had to begin again this time, I hoped, with a better chance of success.

In August, 1882, the Government of the North-Western Provinces gave me a grant of about 3,500 acres of jungle in the Eastern Dún, on certain conditions; one being that I was to have 3,500 acres more when I had planted a thousand with mulberry, and as I have planted about two thousand acres I am entitled to a further grant. The Eastern Dún was pronounced by the doctor of the district as so malarious during the rains as to render its cultivation exceedingly difficult and dangerous, and at first I had no end of trouble from that cause. It is, however, much better now, and as the jungle is cleard away and it is brought into cultivation, it will in time, I have no doubt, be as healthy as any other part of the Dún. I have built a large number of rearing houses for silkworms, a shed for reeling the cocoons, also a large number of workmen's houses, or coolie lines as they are called, also bungalows for the managers; in fact everything has been done to insure success, and to show, if possible, how far the first time in the history of sericulture (at least so far as I know) it can be carried out and made to pay on a commercial scale. Hitherto it may be said to have been altogether cottage cultivation. It is no doubt a large and costly experiment, but I have great hopes of succeeding. The mulberry plants grow most luxuriantly, but we have not yet had sufficient experience to say whether the climate will suit all descriptions of silkworms. Until this year, on a small scale, European seed has done very well, but this year the crop was destroyed by a thunderstorm, and I am disposed to think that there must always be considerable risk attending sericulture, even under the most favourable circumstances.

The Bengal multivoltine worm which I have tried to rear during the rainy season has not so far done well. It may be the climate, or it may arise from bad and diseased seed. If the multivoltine of Bengal should fail, some other species from China or Japan will have to be tried, as it is very important to have two crops in the rainy season, as without that the remuneration would be comparatively small. As time goes on and my plantations grow, and are capable of giving a sufficient supply of leaf for rearing on a large scale, it will be possible then to have a thoroughly practical result that can be relied upon.

There are many problems yet to solve,

(1.) What part of India is best adapted for the purpose? as you must in all cases have abundant labour, cheap land, and above all, suitable climate.

(2.) What is the best system? cottage cultivation or large rearing establishments under European supervision, similar to what is now being tried in the Eastern Dún.

(3.) Will the climate and soil that suit one species of worm suit another? For instance, will the damp climate of Bengal agree with the Italian or Chinese worm?

(4.) What is the best kind and what is the best system of planting mulberry? In the Dún the trees are planted about fourteen feet apart, and the intermediate space is filled with plants, which are plucked and then removed when the standard trees are grown.

These and many other questions, time, experience, and careful observation can alone solve.—*Indian Notes and Queries*

COFFEE: ASSESSMENT OF COORG LANDS.

On the 26th ultimo, the Honorary Secretary, Coorg Planters' Association, wrote to the Secretary of the Chief Commissioner of Coorg, Bangalore, on behalf of the Association, to acknowledge the receipt of the minute (vide *Madras Mail* of April 26) dated 18th March, by the officiating Chief Comissioner, on its memorial praying for a reduction of Assessment on all coffee lands in Coorg. He said:—"As this minute has been published in extenso in the *Madras Mail*, we feel called upon, to reply to an official document so misleading in its statements and inaccurate in its data, as we trust that, although the Government may not see their way to relieving us of a portion of our present assessment, still we shall be able to point out to them that our claims to the same rest upon a far better foundation than the Acting Chief Commissioner would infer. The minute points out the many mistakes that have been made by planters in the selection of land—capital borrowed at too high an interest, planting without shade, want of manure, &c,—but it forgets to add that coffee planting in Coorg was entirely a new industry 25 years ago, and we were only following in the footsteps of the planters of other districts, not knowing what systems were best adapted to the different parts of the country, and having all our experience to gain, which we have certainly done at last after many years, but with heavy loss to the majority of the pioneers of coffee in Coorg. It makes but small account of our losses from leaf disease, borer, or drought, and other climatic causes, without which we should have no reason to complain, and coffee would not only be a thriving industry in Coorg, but we should now be a prosperous body of men receiving a fair return for our capital and labor, which is very far from being the case at present. The reduction in the assessment may seem too small to have any perceptible influence on the future of coffee, but it would have enabled the planter to devote the money thus saved to the purchase of manure, and the improvement year by year of portions of his lands already much impoverished for the want of it. We grant that concessions have been made in individual cases, but too late in the majority of instances to have any effect, and thousands of acres have been abandoned, and thrown back on the land of Government from which they now derive no benefit, and it is to prevent in some measure this further throwing up of lands, and consequent loss to Government, that we proposed a reduction of the present assessment to an amount which the land would be better able to bear. Little new land has been taken up in Coorg during the last five years, but on the contrary, many applications have been allowed to lapse, there being no capital in the country to open up fresh land, and hardly a single estate has changed hands except to go into that of the Agents, who have been compelled to take them over much against their will, and would gladly part with them at a heavy sacrifice if purchasers could only be found.

"The statistics given in this minute of the average amount of production and cost of cultivation are most misleading and inaccurate. So far from the average yield per acre being 5 cwt., it is not one and a half, talking it all over, as is shewn from the official figures given, which are 37,544 acres as under cultivation by Europeans in 1884-85, and which yielded 2,006 tons, or an average of 1 1-12th cwt. per acre, so that it took 18 acres to produce a ton. Again the average nett amount per ton for coffee in London for the past four years has been nearer £50 than £60; but to take the figures given by the Acting Chief Commissioner, we have at the latter price £36 per ton, or at present rate of exchange R520 for cost of cultivation, which for 18 acres to the ton is R29 per acre, whereas the lowest sum on which coffee can be cultivated at a profit is from R60 to R120 per acre, and the better the cultivation the larger the crops, and consequently improved chance of obtaining a profit. The margin therefore left of 25 ber cent, out of the London receipts as shewn in this minute, for interest on purchase money of the estate, and capital borrowed for carrying on the cultivation, as well as to provide a profit to the proprietor, has all vanished, and there is nothing left but a heavy deficit. A more accurate statement would, however, be an average on the better class of estates only, over a series of years of 4 cwt per acre at £55 nett per ton, which at present rate of exchange would give R140 per acre for cultivation, manure, cost of carriage to the coast, and curing, and when this is all deducted it will be found there is very little left for interest on capital and profit to the proprietor. If the crop should, however, fall below this average, which is too often the case, there remains nothing but heavy deficit, as the estate must be cultivated, whatever the crop may be, or allowed to go to ruin. We must decline to touch upon the point of the expensive mode of living referred to in the minute, but it would appear to be a most uncalled for reflection upon a large body of gentlemen, who have barely enough to support themselves as such, and whose incomes have been reduced year by year as the prices of coffee have fallen in value. The Acting Chief Commissioner assured us that, although Government were unable to reduce our present land taxes, still it would be their duty to see that the wants of the planters were attended to, more particulary as regards our communications, which he allowed were in a very unsatisfactory state. We maintain that this by no means sufficiently states the case, but that they are in a far worse condition now than they were fifteen years ago, and that, with the exception of the bridge over the Cauvery at Siddapur, which unites North and South Coorg, and its connecting line, little or nothing has been done to open up the country. The road through North Coorg, a most important feeder, although commenced in 1862, is still unmetalled and unbridged, and the causeway quite unfit for wheeled traffic. We respectfully trust, therefore, that something will really be done to improve the state of the communications in Coorg, which are year by year becomiug worse instead of better under the present regime.—*Madras Mail.*

INSECT POWDER.*

The Dalmatian insect powder, Chrysanthemum cinerariæfolium, B. et H., known also by its Dalmatian name *buhach*, has been cultivated for several years past on a large scale in certain portions of California, the cultivators being Dalmatians who have settled there.

The best soil for this plant is loam, with a large proportion of sand. This kind of soil is particularly suitable for sowing, but it should be well mixed with old dung. The seed itself is mixed with sand and distributed over the soil as uniformly as possible, after which the soil is raked to the depth of about half an inch, and then gently pressed by passing a roller over it. Until the plants spring up, the beds must be irrigated every evening, unless it rains. But great

* Abstract of a chapter on the subject in *Die Tropische Agrikultur*. Von Heinrich Semler, in San Francisco. 8vo. 1886, vol. i., p. 207. Reprinted in the *Journal of the Pharmaceutical Society* from the *American Druggist*, January.

care must be taken not to overdo it, as the plant is very sensitive, throughout its whole life, towards undue moisture of the soil. After the plants have sprung up, they need not be watered more than twice a week. Weeds must be kept away until transplantation takes place, which occurs when the plant is about 6 inches high. It is then set out precisely like Cabbage, about 20 inches distant from every neighbour, and afterwards needs no further attendance.

Buhach is a biennial (?) plant, therefore it flowers in the year subsequent to that of sowing. The flowers must be cut off just when they are about to open, as they contain the largest amount of essential oil in this condition. The cut flowers must be carefully guarded against dampness, and must be dried in the shade, never by exposure to the sun or to artificial heat. After the period of flowering is over the plants are cut off 4 inches over the ground, reduced to powder, and this powder mixed with that of the flowers, in a proportion not exceeding one part of the former to two parts of the latter. [This is the statement made by the author of the work from which we quote. It is made in such a manner that it appears to be the regular process followed, there being no intention at all to utilise the flowers alone.] The finer the mixed powder of herb and flowers is, the more effective will it prove to be. If any one wishes to prepare the powder himself, and does not possess a suitable mill, he may use a mortar covered with leather. The quantity thus worked in a mortar should however, not exceed about 1 lb., to avoid heating the powder. When the substance appears to be communicated, it is transferred to a fine hair-sieve, and the refuse remaining on it put back in the mortar. It is very difficult to reduce the stems to powder in this manner, which—as the author naïvely but truly states—is not a serious disadvantage, as the flowers are the most valuable portion of the plant. Insect powder should be preserved in glass or metallic vessels, which should be closed air-tight.

Insect powder may be used either in form of dry powder, or by fumigation, or in form of alcoholic extract, or mixed with water, or in form of infusion.

The work from which we quote advises to make the first-mentioned method of using insect powder cheaper by mixing it with flour, saw-dust or wood-ashes, which do not interfere with the insecticidal powers. [Of course, this may be done by the user of the powder, provided the dilution is carried too far.] The mixture ought to be made at least twenty-four hours before it is to be used, and should meanwhile be kept in air-tight vessels. Experiments have been made which show that such mixtures acquire greater efficiency by keeping. It was found, for instance, that a mixture of one part of insect powder and eleven parts of flour, applied, immediately after being mixed, to certain caterpillars, was just sufficiently strong to kill them. But the same effect was produced by applying to them a mixture of one part of insect powder and twenty-two parts of flour which had been mixed twenty-four hours before. [The explanation of this may be that the volatile oil of the flowers probably becomes more thoroughly diffused through the mixture in the course of time.—ED. *Am. Dr.*]

The employment of insect powder by way of fumigation is exceedingly effective, particularly in closed rooms, where the dense smoke produced by it, which is not at all disagreeable to human beings, soon kills all insects, particularly those having tender or soft bodies. This method is especially valuable for the purpose of killing mosquitos in rooms. All that is necessary is to place a burning coal in a spoon or other receptacle, and to sprinkle insect powder upon it. In larger rooms, the spoon may be carried about, or several may be thus used in order to distribute the fumes properly. After a few minutes every mosquito will be found dead; and, if the fumigation be kept up for about half an hour, the same fate will have overtaken also—according to the author—any fleas that might have been present. [He says nothing of bed-bugs, but it is certainly worth while to try the above method for getting rid of this troublesome pest, which is spreading gradually into houses of opulence and comfort, where such disgusting visitors had been previously unheard of!—ED. *Am. Dr.*]

The third method of employment, in form of alcoholic extract, is the most advantageous for use in the fields and garden.

The principal drawback connected with the use of insect-powder is this, that its effect, when applied in substance, is only certain when it comes in actual contact with soft-bodied insects. In the case of hard-bodied or haired insects it often produces only stupefaction for a time this drawback is to a great extent removed by employing the alcoholic liquid extract, which may be prepared by percolation, or, according to the author, by macerating 1 lb. of insect-powder for four or five days with 2 pints of alcohol in a warm place, then separating the alcohol and adding 1 pint of glycerin. This liquid extract is to be diluted with water before use. For hard-bodied insects it may be diluted with twenty parts, for more sensitive insects with thirty to forty parts of water. If it is to be used out-of-doors it is self-evident that it should not be applied while rain is threatening, nor during the hot part of the day. The best time is early in the morning while the dew is on the ground, or during cloudy days.

If a decoction of insect-powder is desired, this may be readily made by pouring boiling water upon it, and macerating in a covered vessel until cold.

In many cases a simple mixture of insect-powder and water will be found quite effective. A good proportion is, according to the author, ½ oz. to 2 gallons. [This seems to be altogether too weak.]

The decoction, however, is much more effective. It must be used as soon after preparation as possible, and at a time when its effect will not be interfered with by the condition of the atmosphere.

It should be stated that the majority of insects do not die immediately after having come in contact with insect-powder or one of its preparations. They are at first only stupefied, but death usually ensues after a few hours, and in some cases not until after several days.—*Gardeners' Chronicle.*

THE UPAS TREE.

BY REV. L. J. TEMPLIN.

Among all the deadly poisons of nature, that of the Upas stands pre-eminent for its terrible virulence. Much of fiction has gathered around this subject, and wonderful stories have been told concerning this tree. About 1775, a Dutch surgeon, Foersch, who had travelled extensively in Java, published an account of the Upas poison valley. According to this author, such were the deadly exhalations from the Upas tree, that no living thing could exist nearer than fifteen miles of the tree. That the whole country within a radius of this distance of the locality where the trees grew, was a lifeless, barren waste, strewn with the bones of animals, birds and human beings that had inadvertently ventured within the deadly influence. The poison was obtained, we are told, in the following manner:—Criminals, condemned to death, were given a chance for life and freedom, on condition of their procuring some of the Upas posion. An old priest lived on the confines of the "valley of death," whose duty it was to prepare the Upas hunters for their duties, and administer the consolations of religion to them before they started on their perilous journey. Here they rested till a favorable wind blew towards the tree, when, furnised with a leathern mask or cowl, and a box to contain the poison, they set out on their dangerous mission. If a man possessed a robust constitution and vigorous health, he might return in safety; otherwise not. The priest stated, that in the thirty years he had officiated, only about one in ten who had gone forth on this errand, had returned alive. Nearly all of this has been proven to be pure fiction. No such poisonous exhalations taint the air for miles around, though the deadly character of the juice of the tree has not been, and cannot be, exaggerated.

According to Thunberg, the famous Swedish botanist, "the Upas tree, an evergreen, is easily recognized at a great distance. The ground around it is sterile, and looks as if it had been burned. The sap is of a dark brown colour, and becomes liquid by heat, like other resins. Those who gather it, have to employ the greatest care; covering the head, the hands, the whole body, to protect themselves from the poisonous emanations of the tree, and especially from the drops which fall from it. They avoid even approaching too near, and they provide themselves with bamboos tipped with steel heads, having a groove in the middle. A score of these long spears are stuck into the tree, the sap runs down the grooves into the hollow bamboo, until it is stopped by the first joint of the wood. The spears are left sticking in the trunk for three or four hours, so that the sap may fill up the space prepared for it, and have time to harden, after which they are drawn out. The part of the bamboo which contains the poison is then broken off, and covered up with great care." Again, this author says: "Persons passing beneath the branches bare-headed lose their hair. A single drop falling on the skin produces inflammation. Birds can with difficulty fly over the tree, and if they by any chance alight on its branches, they fall dead. The soil around is perfectly sterile to the distance of a stone's throw." This poison is used to put on the arrow points, and also in the execution of criminals. When the point of a lance that has been dipped in this poison pierces the skin the individual is "instantly seized with violent trembling, then with convulsions," followed by death in a few minutes. The Upas is found in different parts of the East Indies, in Java, Borneo, Sumatra and in the Celebes. The leaves are figured in many books as those of Antiaris toxicaria. Rumph describes it under the name Arbor toxicaria. The tree grows with a rather thick trunk 60 to 80 feet high with extended spreading branches. The bark is rough and knotty and of a brown color. The wood, which is hard, has a pale yellow color, and is marked with black spots. This tree belongs to the same family with Strycnos Tienté, S. nux vomica, S. Ignatii, S. Colubrina, from which the alkaloid strychnine is obtained. These two poisons—strychnine and the Upas poison—are the most virulent of all poisons known. From the S. tienté is obtained the Rajah Upas, or poison of princes. This is a climbing plant that rises spirally around the colossal trunks of trees, and over-tops them at a hundred feet from the ground where they spread their large, green, glossy leaves and hang their fragrant clusters of white flowers in the air and sun light. It is only in the root of this plant that the deadly strychnine, the only active principle it contains, is found, while that above ground is harmless; even the sap containing no dangerous properties.—*Cannon City, Col.*

[Our correspondent is mistaken in classing the Antiaris with the same family as Strychnos. The last is an apocynaceous plant—the same family as the common Periwinkle, and Oleander. Some of these are very poisonous. The Antiaris or Upas belongs to the same family to which belongs the Mulberry and Osage orange—Urticaceæ—and few of these are noxious. The Editor of this once had a plant of the Upas tree under his charge for a year. It was between 3 and 4 feet high, and growing in a 12-inch pot. He had to handle and care for it the same as other plants. His "skull and cross bones" are still in their proper places, nor does he know that he was ever in the slightest danger of having them misplaced by reason of any deadly emanations proceeding from the plant.—Ed. *G. M.*]—*Gardeners' Monthly.*

[We can only wonder at the patience of the Editor of the *Gardeners' Monthly*, with such exploded rubbish as this Rev. Mr. Temple reproduces. Every intelligent schoolboy now knows that the valley in Java owed its pestiferousness not to the libelled upas trees, but to malarious gases from the soil.—Ed.]

PLANTING THE RED CEDAR.—It is proposed to plant extensively the Red Cedar in Bavaria. The superiority of the wood of this tree (Juniperus Virginiana) over all other kinds of cedar is well known.—*Garden.* [This Virginian juniper ought to succeed in the hill country of Ceylon, where varieties of junipers flourish. —Ed.]

THOSE HARDY COCONUTS.—By a casual expression we judge that the recent learned editorial in a Philadelphia newspaper on planting coconuts along the Jersey coast, was made up by an "intelligent correspondent"—that is to say, a wise reporter in a fifth story of a printing office—from a paragraph in a London paper referring to the fruiting of the Chili Pine, or Araucaria imbricata. These fruits were said to be "twice the size of the ordinary coconuts," and the "intelligent correspondent" aforesaid, who (in imagination) saw the trees along the cost, got "coconut" in his mind, and thus became a mixed being.—*Gardeners' Monthly.*

SOLOMON'S MINES.—"Foma Dabu" writes from Oloncurry, Queensland, to the *Mining Journal*:—"In looking over the correspondence in your valuable journal of the 19th December, 1885, the following enquiry interested me immensely:—'Solomon's Gold Mines—Where are they?' Whilst proceeding to Australia in the month of October, one of my fellow passengers on board, who had for years been a railway contractor in India, said to me, in course of conversation. 'As you are a mining man, I know you are interested in anything connected with ancient mining; what is your opinion about Solomon's gold mines, and where are they situated?' My reply to the last question was 'Either in India or Africa; which, I can't say'. He said 'I know it's India, for I believe I have found the Ophir of Israel, and shall some day work it. It's situated in the side of a hill, and was worked as an open cast of quarry, but is now overgrown with tropical trees and plants, but its base still shows a reef of quartz 20 ft. wide, grand looking quartz for the production of gold.' The place mentioned by this gentleman is not the Mysore district, but in Ceylon. This may not be interesting to many of your readers, but it shows the Ophir of Israel is looked for in various parts of India and large reefs found in different parts.—*Madras Mail.*

THE GREAT FORESTRY QUESTION.—Often the Editor of a magazine like ours must be tempted to cry "what is the use" and put down his pen in despair; yet time tells often that his labors have not been without result. Years since we started to show that the so-called forest science, initiated by Marsh in his "Man and Nature," was a complete farrago of nonsense. It is pretty well understood now that trees are a result and not a cause of climate.* The hobgoblin being out of the way, there was nothing left for city foresters to worry about but the short supply of timber in the near future. Thus it became a practical question only, and trees will be planted wherever it will pay to grow them. Necessarily, as we then had to say, there was nothing left but sentiment to care for the old forests. We cannot by all the legislation on the law-year's shelves prevent forest fires in old forests, and the sooner these forests are gone and new ones planted the better for all of us. These views also are prevailing, and though we personally get little credit, it is some satisfaction to feel that the work has by no means been lost. The very fact that the strange idea has become so much a part of the general thought of the world, till its parentage has been lost, is the more encouraging. *Forestry* says:—"The writer who says that our hope of a timber supply does not lie in the direction of preserving the old forests, but in producing the new, comes pretty near hitting the nail on the head. Little good can come from allowing timber to stand until it has seen its best days and begins to decay and lose strength. It is not the 'primeval' but the young forest that needs protection." This is not only our idea, but the exact language.—*Gardeners' Monthly.*—[We heartily concur.—Ed.]

* The opinion which we formed forty-five years ago in Uva, when requested to spare the forest so that a river near Kataragama might not dry up, and from which we have never swerved.—Ed.]

FOR IMPERMEABLE PAPER, dissolve one and one-half pounds of white soap in a quart of water; then dissolve two ounces of gum Arabic and six ounces of glue in another quart of water. Mix the two solutions; warm the mixture; dip the paper in the liquid; pass it between two rolls (a clothes-wringer, for example), and put it to dry. In default of rolls, hang the paper up that it may drip well, or, better, pass it between two sheets of dry paper. Then let at dry in a mild temperature.—*La Nature.*

A CURE FOR PHYLLOXERA.—It was stated at a recent meeting of the Académie des Sciences that after numerous experiments, MM. Couasnon and Salomon had ascertained that this insect will not resist a temperature of 45° C. (113° F.), and that even the eggs of the creature are destroyed by immersion in water of that temperature. Supposing the statement to be correct, it is evident that the plan would be very serviceable in the case of pot-Vines. In the meantime, it is a long while since we have seen any Vine-louse either on the roots or the leaves.—*Gardeners' Chronicle.*

DR. GEORGE WATT, C.I.E., who acted for the Indian Government as Superintendent of the Economic Court of the Colonial and Indian Exhibition (Indian section), communicates an interesting note on Indian hemp, supplementary to the statement made by him last November. Dr. Watt's suggestion that only the Bengal "ganga" should be used in medicine is a valuable one. There are few official drugs which are so uncertain in therapeutics as Indian hemp; but this uncertainty may, it appears, be entirely removed by using a drug which has been carefully cultivated. The price of Bengal ganga may be prohibitive, but the whole subject should be considered by authorities.—*Chemist and Druggist.*

AUSTRALIAN vinegrowers will be sorry to hear that another vine pest has appeared. This is known as the black rot, and is believed to have been brought into France from America, where it has wrought terrible havoc about the Missouri. It has now broken out in the department of the Hérault, France. This disease appears first in a small red spot on the grape, and rapidly infects the entire cluster. The fruit then dries up completely. When the disease first attacks the foliage, the spot is black. Vines growing in rather damp soil, or in regions liable to flooding by overflowing rivers, are most liable to this disorder. The American vines are the cause of this pest coming into France. It is not known exactly how to meet this new plague, but sulphur has been advised.—*Leader.*

PORTLAND CEMENT.—This material may be used for repairing the woodwork of hothouses and all kinds of structures where heat and moisture cause decay in wood. The lower part of the door-jambs and the sills soon become decayed and dilapidated, and I find by experience that these can best be repaired and rendered durable with the above cement. Take 1½ yards of Portland Cement, mix well together, and make soft like mortar, then remove all the decayed parts of the sills or uprights of any parts in the woodwork, put a few nails into the old wood to hold on the cement, then place a straightedge in front of the dilapidated parts, and fill all the holes up with cement; bevel the surface of a sill so that water can run off. I have used cement for repairing wood for fourteen years, and have found from experience that the treatment will preserve wood for many years although partly decayed.—WM. SMYTHE.—*Gardeners' Chronicle.*

THE "PITURI" TREE.—A Southern India contemporary is glad to learn that the valuable Australian tree known as *Pituri*, is about to be introduced on the Nilgiris. It is greatly valued by the natives of South Australia, pieces of the wood being carried by them for hundreds of miles for barter. It is chiefly used as a medicine, and as a masticatory, somewhat in the same way as tobacco, by mixing a little of it with the ashes of acacia leaves. It is very pungent in flavour with a pleasant aromatic odour. The scientific name is *Duboisia Hoopwoodii*, and Mr. G. Goyder, who made an analysis of it, writes as follows regarding it:—"*Duboisia Hoopwoodii*, F. Von Muller, the *Pituri*, Inland desert regions from New South Wales and Queensland to near the West Coast of Australia. This plant deserves cultivation on account of its highly stimulating properties. *Duboisia myoporoides*, of East Australia and New Caledonia, has come into use for ophthalmic surgery. The alkaloid of the latter (*Duboisia*) is allied to *Pituria*, the alkali of the *D. Hoopwoodii*. Important for midriatic purposes in medicine. The tree attains in deep forest glens a height of sixty feet, but flowering already as a shrub. Mr. Cornish, its discoverer, expresses the hope that, taking into consideration the great value of this plant, it may be protected by the pastoral lessees and the travelling public. Mr. Cornish found the plant only between lat. 24 and 25 degrees S. and long. 138 and 139 degrees E." It ought to prove a great acquisition if the plant succeeds in the Nilgiris. —*Indian Agriculturist.*

INCIDENTAL ADVANTAGES.—What one may do has often advantages never foreseen. A miner, for instance, goes into a dry and arid country, wholly unfit for horticulture, and what he needs to support him has to be brought hundreds of miles; yet when he has done all he can and deserts the place because it produces nothing, that which he has done enables thousands to live on it after he has been obliged to leave it. Thus the early miners in California had to leave after the precious metals were exhausted, but the ditches they dug were what the farmer wanted. Many of these ditches which were constructed at enormous cost in the heyday of placer mining, now that the placers are all worked out, constitute a perennial source of increase and wealth to the husbandman, who has succeeded to the miner and come to stay. One of these ditches, called the Bear River Ditch is 70 miles in length and cost 2,500,000 dollars to build, in the year 1851; it carries about 3,000 miners' inches of water, or about 45 cubic feet per second. It was constructed to bring the water of the Bear river down to the rich placer mines of Placer county, and was used for mining exclusively, but not now at all. Running, as it does, through the fertile foothills of that county, it is a permanent guarantee of fruitfulness to the vineyards ard farms which are being planted at either hand, on lands which lie below the level of the ditch.—*Gardeners' Monthly.*

AN exceedingly fine specimen of the Japanese persimmon (*Diospyros*) has been forwarded to us from the orchard of Messrs. Johnston Bros., Wellington Point. It measured 15 in. in circumference, and weighed 17oz. This specimen was from one of the seedless varieties, and consequently can only be propagated by grafting upon seedlings of the other varieties. In flavour and appearance the fruit is not unlike a luscious apricot. It is a tree that should be in every garden, as it is handsome in appearance and comes quickly into fruit; if we remember rightly, the tree from which this fine specimen is sent to us is only three years old. The tree attains a height of about 12 ft. and when in full fruit is a most beautiful object. It requires no particular attention besides being provided with a good garden soil. There are several species of *Diospyros* which are useful to man. The name signifies the character of the fruit, for it is from *dios* (divine) and *pyrus* a pear. The Chinese date plum is the *D. kaki*, and is well known now in our gardens; the *D. lotus* is the European lote, or date plum, to which was attributed the power of causing oblivion when eaten; the *D. ebenus* is the ebony wood of commerce, and and *D. virgiana* is a lofty tree 60 ft. high, the persimmon of the settlers in the Southern States of America. Those settlers who are planting orchards in this colony should on no account omit either the Chinese date or the seedless persimmon from their list when ordering from the nurseryman. May is quite early enough to transplant, unless they can be obtained in pots. One advantage these fruits have is that they are so fearfully astringent that neither insect, flying-fox, nor boy will touch them until quite ripe, and they can be gathered when still astringent, and will ripen in the house or during the journey to market.—*Queenslander.*

THE NEW ENEMY OF COFFEE:—GREEN BUG.

["OBSERVATIONS ON THE GREEN SCALE BUG IN CONNECTION WITH THE CULTIVATION OF COFFEE," BY E. ERNEST GREEN, PUNDALUOYA—PUBLISHED BY THE CEYLON GOVERNMENT.]

This little pamphlet has hitherto—somewhat unaccountably—escaped our notice. It has been compiled at the request of Government by Mr E. E. Green, whose efforts have resulted in a very interesting life history of the most recent pest which has affected coffee cultivation in Ceylon, and —like the locusts that ate up all that the hail had left—has devoured all that was left by the leaf-disease in the northern districts, and to a considerable extent in other coffee-growing portions of the country.

This scale bug is named *Lecanium viride*, to distinguish it from the *Lecanium coffeæ* and the *Lecanium nigrum*, which constituted the old black bug known in Ceylon from the very early days of coffee planting. The presence of all these scale bugs is alike followed by the black fungoid growth which induced the commonly-used term black bug. Mr. Green gives us a description of the *L. viride*, and compares it with the other species, in size and appearance, and adds a plate of beautifully executed coloured figures both natural size and highly magnified. The greater destructiveness of the green bug compared with the others is explained by the difference in its reproduction. Impregnation of the female of the brown and black *Lecanium* is direct—the male insect being a small winged insect, and "the eggs are not hatched until after the death of the parent insect whose body shrivels internally whilst the external scale becomes firmly attached to its support and forms a protection to the eggs and young larvæ." This was well-known to all our planters but the *modus generandi* of the green bug is very different and will, no doubt, be new to many of those who have been accustomed to consider the old and new bug as one and the same insect.

"The eggs of *Lecanium viride* are hatched under the body—and during the life of the parent insect, which possibly produces several successive broods. (Since writing the above I have found immature eggs inside the body of the parent insect after the first brood has been hatched). This may account for the greater numbers and destructiveness of the species under notice. The eggs which vary in number, but are seldom more than twenty, are hidden by the body of the living insect, and are hatched in that position. The young larvæ is only visible to the naked eye as a minute speck. It is very active and moves freely from leaf to leaf deserting the old, and spreading over the young shoots where it finally settles itself, and soon developes the scale characteristic of the mature insect. It is in this early larval stage, probably that the pest is chiefly propogated, as besides its own powers of locomotion, it is liable to be transported by wind, in the feathers of birds, and upon coolies' clothing. The young insect (as I have proved by experiment) will live for many days without food, and might easily be unconsciously transported from one district to another over considerable distances."

Here then we have an explanation of the extreme apidity with which the green bug has spread over the country and the extraordinary destructiveness with which its career has been characterized, rendering it by far the most formidable enemy with which the planter has had to contend. Mr. Green puts forward a supposition as to the impregnation of the female insect which we recommend to the attention of entomologically inclined readers. We merely quote the paragraph with the remark, that as far as can be learned from the text—the only reason he has to give for adopting it as probable, is the fact of the male insect being at present unknown :—

"It is probable that the insects now existing though externally resembling the female form, are asexual, and that their broods are produced by the phenomenon known as 'Partheno Genesis,' by which several successive generations are fertile without the aid of the male element (as is known to occur in the development of aphis and a few allied insects). Professor Huxley states that the number of successive broods has no certain limit, but is, as far as we know at present, controlled only by temperature and the supply of food."

"Effect of the green scale bug upon coffee" is unfortunately too well-known in Ceylon to need reproduction in our columns. "The results of manuring and liberal cultivation" may be condensed into a single sentence "manure has been of use only where the trees have not quickly succumbed to the effect of the bug; on poor soil the tree seems to be permanently injured upon the first appearance of the pest—and manure entirely fails to revive them."

"Will trees badly attacked by the bug, eventually throw it off and survive? It is difficult to obtain reliable information upon this question; but there seems to be no doubt that in some few cases the pest has disappeared from once badly infested coffee." Here a few facts are mentioned as proof which need no comment and it is when we come to "proposed remedies" that our readers will be interested. Writing of the remedies for the old bug, Mr. Green says that maana grass has no effect; caustic lime is equally useless, the same in regard to wood-ashes. If the caustic lime could possibly be applied to every insect it would prove fatal, but that is an impossibility. Acting on a suggestion of the late Mr. Neitner in his "Enemies of the Coffee Tree," that tar applied to the roots and "taken up into the system of the tree throws off the bug." "I have tried the solution of Phenyle brought into notice as an insecticide" a few years ago. It is one of the extracts of coal tar, and probably contains most of its active properties in a form that can be more easily taken into the system of the tree. The mixture used consisted of one desert spoonful of phenyle to two quarts of water. The soil around the root of the tree was thoroughly broken up with a digging fork, and the liquid applied from an ordinary watering can. My experiment was limited to a single tree, and scarcely a sufficient time has elapsed to judge of its success. But it has seemed to me that the pest upon that tree has been gradually disappearing although the surrounding trees have not altered their condition. Dec. 31st.—after an interval of a month I now find that this tree has entirely thrown off the bug, although on neighbouring trees the pest has rather increased than otherwise."

This is so far satisfactory as phenyle could be obtained in large quantity at a very small cost and we should like to hear more of this experiment and of similar ones on a larger scale. Mr. Green has also heard of the success of an application of Schrotky's cure for leaf disease 15 per cent carbolic lime, 3 bushels to an acre, in ten days the bug turned white and died, and after 3 months the coffee is looking remarkably healthy.

"Origin of the Pest:"—First attracting attention in Matale in 1882, it had reached Pusselawa in 1884, Ramboda in 1885, and Badulla 1886. The only suggestion as to its introduction is one Mr. Green has heard from another person, namely, that it came with Liberian coffee from the West Coast of Africa. We append a communication on this point from a planter, who, we believe, first pointed out that the green bug must be a different species from the old one—even though he had not then seen it—arguing from what he had heard of its habits and effects at low elevation and in dry weather. Finally we learn that, "this species of scale bug is by not any means confined to the coffee tree. I have found it flourishing upon cinchona though it does not seem to injure any except the very young trees. I have frequently observed it upon orange and lime trees, upon guava, and a large number of wild plants. I have occasionally seen it on tea bushes, but not in sufficient quantities to effect the healthy growth of the plant."

Mr. Green deserves the thanks of his fellow-planters for giving them the benefit of his labours in this investigation, and we may hope that he will from time to time let us hear of any new discoveries he may make elucidating questions effecting the planting industries of the island. The communication from a planter to which we have referred, is as follows:—

"I see Mr. Green in his monograph on the green scale bug has just touched on my pet theory of its introduction with Liberian coffee from the West Coast of Africa. There is no doubt in my mind that as regards time they made their appearance together. In this respect my assertion is supported by Messrs. Alex. Ross and J. Holloway and also by W. A. Lyford whose experience of it lies chiefly at Amblangodde. The bug came with Liberian plants into Pundaloya and was visible on them long before it spread to the other coffee. Still this does not prove anything, and I think the Government having induced Mr. Green to tell us all he can about it should now send the "life history" to our Consuls on the West Coast of Africa and request their investigation, and report. The Consul for Imperial Germany told me he would willingly do all he could in that direction if copies were put into his hand. It would indeed be a curious instance of the 'irony of fate' if Liberian coffee which was to revive the fallen fortunes of coffee planters should prove to have been the indirect means of destroying them altogether. Possibly Mr. Shelton Agar might be able to tell us whether he noticed any black or green bug on the coffee he saw in Liberia. Scale bug of kinds and black fungus may be met with in almost all tropical countries, and probably everywhere in the world."

Our latest news is of a bad attack of the green bug on 150 acres of fine coffee in Dikoya which had always been well cultivated and generally treated with cattle manure; the prospect of a fine crop this year was very good, but just as the spike of blossom appeared it got all nipped off by the green bug. We have already referred to the way in which this enemy has disappeared from many Uva estates after being supposed to have fairly established itself. We have also noticed successful experiments by Capt. Bayley's manager with kerosine and caustic lime, in getting rid of the pest, which was also killed out by the frosts of the present season in Udapussellawa. There is no doubt that the owners of good coffee should be on the alert to fight this enemy in one or other of the ways as may be found most suitable, mentioned by us or by Mr. Green—giving their neighbours the benefit of their experience.

We have just learned from Mr. Shelton Agar that he never saw or heard of green bug, or bug of any kind, on coffee on the Liberian Coast. He found some coffee leaves there affected after a fashion that reminded him of our leaf disease and sent them to Kew for report. The answer was that there was nothing approaching to the *Hemileia vastatrix*, and that the cause of discoloration was one of no moment.

CREOLE CORN MEAL.—An experiment was being made by a well-known Georgetown (Demerara) establishment, to introduce creole corn meal into the local market. The meal is made of corn grown in Demerara and ground by a mill imported especially for the purpose, and it is recommended by the *Argosy* as being "of decidedly superior quality to the ordinary run of corn meal imported from the States." It is offered for sale at less than the price of the American article.

FIXATION of atmospheric nitrogen of soils, says the *Agricultural Students' Gazette*, is a vexed question, and still undecided. A large number of experiments, extending over two years, the results of which have recently been published by Mons. M. Berthelot, tend to show that argillaceous soils have a very distinct power of absorbing and fixing atmospheric nitrogen. The soils experimented with were placed under different conditions, in closed flasks, in a well-lighted room, in a meadow under shelter, and on a tower 28 metres high, without shelter. In all cases there was a gradual increase of combined nitrogen, and this not in the form of ammonia nor of nitrates, but apparently of amido compounds. Berthelot believes the action to be due to micro-organisms, for when the soil was sterilised by heating to 100° C. it no longer took place; cold also stopped the absorption. He calculates that at least 20 to 32 kilograms per hectare are thus absorbed by clay soils per annum. Mons. Joulie also has published the results of some experiments which appear to prove that when crops are growing on soils there is a very considerable fixation of atmospheric nitrogen.—*Indian Agriculturist.*

NORTHERN PLANTATION EXPERIMENTS.—The *Cooktown Independent* speaks as follows of Mr. Dick's planting enterprise on one of the branches of the Endeavour River:—"There are four acres under coffee, chiefly Liberian, the plants varying from 2½ to 5 feet in height, according to age, (from 1 to 3 years transplanted). There are nearly 100 in bloom, with here and there the gorgeous little berries peeping out from among the leaves. Every plant looks healthy, and the whole forms a pretty little scrap of landscape, quite new in the Far-North of Queensland. There are 4½ acres filled with a great variety of tropical fruit trees, including several species of oranges, citrons, tamarinds, mangoes, lemons, figs, apples, cinnamon, nutmeg, (in flower) annatto, (in seed) grenadillas, mulberries, jack fruit, pomegranates, mangosteens, pa-paws, a magnificent tree laden with Brazilian apples, and a couple of very healthy looking tea plants in bloom. There are a few peach trees, each about 5 feet high, but neither they nor the vines seem to thrive very well. Mr. Dick had previously grown fine sugar cane on the levels and as an experiment tried it on the high lands and ridges, resulting in equal success, and proving beyond a doubt that there is scarcely an acre of his 640, which will not grow almost any known tropical production. The soil is execellent and well watered throughout, but only about 30 acres are yet cleared for cultivation, the rest being used for grazing. Considering the cost of labour and the expense of bringing plants and seeds from Ceylon, India, Batavia, and China, Mr. Dick has done wonders with his limited means, and has paved the way for capitalists to prosecute tropical agriculture on a large scale." We cheerfully endorse all this, for we had the pleasure of inspecting the favoured locality in May, 1883; and formed our own opinions on the suitability of the soil, climate, and locality, just as expressed above. —*Planter and Farmer.*

FRUIT GROWING IN FLORIDA.

Fiji is far behind Florida as a fruit-growing country, as evidence the following statements in the *Scientific American* supplement of 26th Nov., headed, "Profit of Fruits and Vegetables grown in Florida." The writer commences:—"I now speak from my own knowledge of what can be done at Crescent City, Putnam Co., Florida. Of the orange, banana, and pineapple, I can speak with more certainty than of any other product. Upon each acre of ground seventy-five orange trees may be successfully grown. Some persons plant more than this number per acre, but I will assume 75 as a basis of my statement; when in full bearing it is far within the truth to estimate 1,500 oranges as the annual yield of each tree, and it is not at all difficult to realise $ 10 per 1,000 for them, which gives the aggregate of $ 1,225 per acre. The orange tree may be brought to bear in six years; the first crop will be light.

Pineapples are propagated by setting out the shoots of mature fruit; some thousands or more plants may be successfully planted upon one acre, and, at $15 per 100, would yield an annual income of $1,050 per acre.

The banana is propagated by planting out suckers, and will bear from the second year, and annually, thereafter, for an indefinite period. It requires no cultivation, and only needs to be let alone to grow, and constantly enrich its owner. About 500 plants may be successfully grown on one acre. As each plant produces from five to seven bunches of fruit, it follows that the return to the grower at, say, fifty cents per bunch would be $1,500 to $1,700 per acre. To convince my readers how far within the truth I endeavour to keep, I will say that a party, in Bradentown, Florida, has just sold his banana crop, from off one acre, for $3000.

The coconut is a good paying tree; the yield annually is about 150 nuts per tree; they come into bearing seven years after planting the nut, and there can be put about 300 trees upon one acre. They require no cultivation. Under these circumstances an acre would yield, at a net return of $3 to a tree, $900 per acre.—*Fiji Times.*

FRUIT TREES IN CALIFORNIA.—The number of fruit trees in California is: Apple, 2,700,000; peach, 1,200,000; pear, 500,000; plum and pruen, 600,000; cherry, 400,000; apricot, 500,000,; orange, 1,600,000; lime and lemon, 500,000. It is estimated that there are 70,000 acres of grape-vines.—*Planter and Farmer.*

MANILLA HEMP IN INDIA.—There is reason to believe that this fibre has been placed in a position of importance to which it is not entitled. Traditon has no doubt handed down the fact that it is of great strength and durability, and capable of sustaining a great strain. It is possible that in Manilla, where probably fibre-yielding plants are not plentiful, and in its native soil, the *Musa textilis* takes a high place among fibres, but the results of its cultivation in India have certainly not realized the expectations entertained of it. We have in these columns from time to time noticed the results of experiments with this plant in different parts of India, and in no one case do we recollect these results to have been satisfactory in any sense of the term. The Government of India has doubtless spent a great deal of money in the conduct of these experiments, and it is our opinion that they should now cease. Sufficient time has been given to the Manilla hemp, and after many trials, it has been found wanting in two of the essential qualities necessary for the successful cultivation of any economic plant in this country, viz., low cost of production, and cultivation without artificial irrigation. There are numerous plants, indigenous to the country, which yield a fibre in every respect equal, if not superior, to that of Manilla hemp, and which can be grown with the minimum of trouble, and at a very low cost, in addition to which they have the further advantage of being known to the people. When one of our commonest fibre-plants, *Sun* hemp, (*Crotolaria Juncea*), yields a large crop per acre, at less than one-third the cost of a better quality of fibre, it is time the *Musa textilis* was given up.—*Indian Agriculturist.*

96

CUBEB VINE.

Another new product suitable for Ceylon cultivation has quite recently been brought to my notice by a Mincing Lane broker, who inquired why no attention has ever been given by any planters in your island to the growth of the cubeb vine. The *cubebs* of the druggist are the product of a vine having all the appearance of, and grown in a similar manner, to the pepper vine; and as we all know that pepper was largely grown in Ceylon by the Dutch for the purpose of packing amongst their cinnamon, there can be no good reason why cubebs may not also be produced. From some cause not understood in Europe the production of *cubebs* in Java has seriously declined during the last six or seven years; whilst on the other hand the demand for them, at any rate in the United States, has considerably increased owing to their recent use in the cure of asthmatic affections, and in many cases of catarrh. From the very low price of 30s. per cwt. the article has advanced steadily until it stands now at £21 to £23 per cwt! A trade report on this article says:—"The consumption of the article cannot now be said to be on the increase; in fact, during the last few years the imports in America have been falling off. At present our stock has been very much reduced, and at the commencement of the month amounted to only 41 bags in the first hand, while from £21 to £23 is quoted for stalky to good genuine berries. In Holland the imports during 1886 amounted to about 200 bags, less than half of which belong to the acknowledged genuine variety. The Dutch market is now said to be very bare, the stock at Amsterdam not exceeding 1,050 lb., 600 lb. of which are grey berries. The quotations at Amsterdam for genuine berries appear to be slightly in excess of those prevailing here. If recent mail advices from America can be trusted, the stock at New York is also very low, being estimated at less than 7,000 lb., or barely sufficient for one month's requirements. All indications, therefore, point to the maintenance, for some time at any rate, of the excessive prices now prevailing. It is true that several shipments are reported on the way from the East Indies, but unless these should be of exceptional magnitude they will in all probability be quickly bought up for consumption." No doubt the present high price will not continue, but the production for some reason does not seem to be on the increase in spite of these figures. The eastern residencies of the island of Java produce the bold grey berries, the genuineness of which has been a matter of considerable doubt, and is generally disputed in this country and in America. The small, dark-coloured, genuine berries are all grown in central and western Java, notably in Banjoemaas and in Bantam. The shrub is occasionally met with in the wild state, but it is more generally cultivated, sometimes in special plantations, but usually in the coffee gardens. Some years ago the Dutch Indian Government, with a view to encourage the cultivation, distributed a large number of your plants to coffee-growers throughout Java. The *Piper Cubeba* requires very little attention: it climbs round the large trees which are grown for shading in coffee plantations, and attains, when full grown, a height of 18 to 20 feet. The statement formerly often made that cubeb plantations in Java were being uprooted in order to make way for coffee gardens may therefore be regarded as fabulous. Cubebs are also grown largely in the Lampong districts, the extreme southern portion of Sumatra, and in certain parts of southern Borneo. The yield is collected by Chinese dealers, and exported *via* Batavia or Singapore. Shipments from the former place usually find their way to Holland, while the cubebs exported *via* Singapore are generally forwarded to London or New York. An important part of the crop is consumed in Eastern countries. In the belief that the cultivation of this climber might be profitably carried on in the low districts of your island, such as Kurunegala, Kalutara, Yatiyantota, and other such localities, I paid a visit to Kew Gardens, where I

interviewed Mr. D. Morris on the subject. This gentleman showed me colored engravings of the plant and also a living plant, not very vigorous, in one of the glass-houses. He grew the plant in Jamaica, and knows of no reason why it should not thrive in the low, hot, moist districts of your island. It is propagated by cuttings, which take root very rapidly. He thinks it probable Dr. Trimen may have some in the Peradeniya Gardens, but supplies might be obtained from Batavia through some commercial agency, or better still through the Director of your Botanic Gardens, as the Dutch Government are jealous of any rivalry in this direction, and might throw obstacles in the way of private efforts. It would really seem as though this industry is worth attention. The outlay on an experiment need be only very trifling. I was not able to ascertain data as to yield or age for bearing.—*London Cor.* Local "Times."

THE CULTIVATION OF COCOA IN VENEZUELA.

Report by Consul Bird, of La Guayra, Venezuela.—*Theobroma*, a Greek word signifying *food of the gods*, is the botanical name of the cocoa plant. As Striffler has said—"The *feculæ* and oleaginous matter that are *par excellence* the alimentary substance dispensed by the vegetable kingdom are often found combined in the same vegetable, and nature, responsive to the necessities of our ephemeral existence almost always adds to this combination some aroma, thus blending the agreeable with the useful. This triple combination is especially noted in the cocoa, and for this, Linnæus, in his enthusiasm, gave it the name of *Theobroma*. Indeed, it only wants the property of sweetness to give us an idea of the fabled ambrosia that, with the delicious nectar, furnished aliment for the mythological deities." This genus comprises some sixteen species that pertain to the warmest zone of America, and that it would be unnecessary to enumerate. We will only consider the two most important that are cultivated here, a knowledge of which will suffice for the cultivation of all.

The red cocoa, commonly known as violet cocoa. is a plant thirteen to sixteen feet high, with upright and slender branches. The leaves are slightly pediculate, eight to ten inches long, oblong or ovate-oblong, alternate, perfect, smooth, and of the same colour on both sides. The flowers are small reddish or yellow, and numerous stigmas caulinareus, pendulous, or axillary; the fruit reddish, high-coloured or yellowish, smooth, ribbed like the musk-melon, forward somewhat like the cucumber, but pointed at the extremity: beans larger than the almond.

The green variety, commonly called white cocoa; is a plant six to ten feet high when cultivated; but in its wild state attains to a height of twenty-five to thirty feet, with outspreading branches. The leaves are very similar to those of the variety just described. The flowers are also similar, though somewhat violet-coloured; fruit of clear green colour very wrinkled and resembling the fruit of the balsam-tree, though, of course, much larger. The beans are smaller and less nutritious than those of the former variety, though equally esteemed.

All authors agree that—(1) the cocoa is indigenous to the soil of America; (2) it flourishes in the shade of the forests, and is developed with luxuriance at the bases of mountains, where it is watered by running streams or near rivers, where the soil is alluvial or mixed with sand and clay; (3) it requires a temperature that does not fall below 75 deg. Fahr. It may therefore be deduced that for its perfect development cocoa requires shade, warmth, and moisture. In low land, on the banks of streams—that is to say, in alluvial soil—it can always be safely, if carefully, cultivated. Although in such cases it is liable to inundation, yet all danger will be avoided if the land is well drained and kept free from the drifts and deposits of the waters. An excess of moisture will rot the roots and destroy the plants; and so, if the land does not drain well, it is necessary to open trenches in the direction of the greatest declivity.

Cocoa needs the shade of trees to maintain a humid atmosphere and to preserve the moisture of the soil. In a hard or clay soil, not naturally moist, it will be impossible to grow it unless so located that, by means of small trenches, water may be turned upon it every fifteen days during the summer months. A virgin soil is considered best, but fertile fallow land, suitable for corn or bananas, is adapted to its cultivation. In the territory of Loba, province of Mompos, Colombia, are to be seen some hundreds of cocoa trees upon a hill, growing vigorously without irrigation. This, however, is rare. It may be laid down as a safe rule that where the palm and banana grow naturally the soil is well adapted to cocoa and coffee.

The general rule is that all fruit possesses the full germinative quality when well ripe; but the cocoa is an exception to this rule, since beans matured, though not fully ripe, are considered best, and as in this stage it is much easier to hull them, they are preferred. Seed pods chosen for the purpose should be a brighter colour than the green pods, and on thumping them with the finger will emit a sound like that of a ripe water melon. The beans will be found loose in the shell. The pods should be carefully opened with a knife and the beans emptied into a tub of clear water, to remain for twenty-four hours, in order that the cuticle around them may be softened and easily pulled of. As they are divested of this cuticle they should be thrown into another tub of pure water, from which they should be planted within six hours; if allowed to remain longer they turn red and are lost. The beans that, after being peeled, swim on the surface of the water are worthless.

The beans are planted in a nursery or the orchard itself. A good nursery is, however, considered most proper and reliable. It should be five feet wide and as long as necessary. It should be well ploughed or spaded, covered with a brush arbour to shade from the sun, and laid off in cross-ridges eight inches apart. The seed should be planted four inches apart on the top of the ridge, and a little more than half underground, and all covered with banana leaves. They should be watered every morning and evening. Before planting they have a whitish or violet colour. After ten hours the leaves may be removed, when it will be observed that the seeds are rising out of the soil, urged thereto by the germinating roots. If they assume a greenish colour it is an indication of perfect germination. The irrigation must be continued, in the absence of rain, for six months, when the plants are ready to be set in the orchard. It is found best to plant the nursery in this climate in November, to transplant in April or May. At the period of transplanting a rainy reason should be selected, each plant taken up with the earth attached and carefully set in its place. If properly done at a propitious time, there is no danger of losing a single plant.

If the seed are to be planted in the orchard, three should be placed in each spot in the manner before described, and covered for eight days to protect them from the sun. When the plants are twenty inches high, two plants may be drawn out and the most flourishing one left.—*Planter and Farmer.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

Phosphorous or phosphoric acid, is the most important of food element of plants, and consequently an invaluable fertiliser of the soil. Now the greater part of phosphoric acid, taken from the land by the crops, is not returned thereto, and so is a dead loss for agriculture. A little intelligent attention could readily save a large portion of this great waste, estimated at several thousand tons annually.

A man weighing eleven stones, represents in his organization 38 ounces of phosphoric acid. During a twelvemonth, he requires for his life-wants about 2 lb. of it to replace a similar amount equally eliminated.

A population of 38 millions, such as that of France, borrows then from its alimentation some 80,000 tons of phosphoric acid per annum. If the death-rate of this population be reckoned at 23 per 1,000 inhabitants, the amount of phosphoric acid in their remains represents a proportionate total of the acid, definitely abstracted from arable land.

Per contra, the annual dejections of a city's inhabitants constitutes a partial restoration of the acid to the soil some forty per cent of it is however totally lost for agricultural wants. The extraction of the fertilising elements from the soil—chiefly phosphoric acid—without any being restored thereto, was one of the main causes of the decay of the empires of Greece and Rome; of the power of the Arabs and of the prosperity of Spain. When the sources of their food-supply were exhausted by a vampire system of cultivation their power and prosperity followed suit.

Moderns are more fortunate than their ancestors in being able to secure to-day inexhaustible supplies of phosphoric acid. French agriculturists are indebted to the late M. de Molon, for his discovery of natural beds of phosphate of lime. Messrs. Thomas and Gilchrist have utilized the slag, cinders or scoriæ, this once useless out-put of metallurgic industry, but now invaluable for its richness in phosphoric acid resulting from the dephosphorization of iron. The employment of phosphorus has become to-day the *pabulum vita* of crops. Continental farmers rush after the fertilizer almost like diggers to a gold mine.

There are three natural groups or sources of phosphates; nodules, incorrectly called coprolites peculiar to stratified rocks, and containing 34 to 60 per cent of phosphate. When ground down to a fine powder it is easily absorbed by plants. Its action is almost equal to that of phosphoric acid when rendered soluble in water. The second group is called *apatite*. It is one of the constituent elements of an eruptive rock, in the middle of which it is disseminated more or less frequently, but ever variable. It is almost pure phosphate—as high as 95 per cent crystallized, very hard, and imbedded in a vein enclosing potash. The third source is included under the generic name of *phosphorite*. In structure, it partakes of the shapeless coprolite and the crystllized apatite. The latter and phosphorite even when reduced to an impalpable powder are less assimilable than the pulverized nodules. Their principal employment is for the production of superphosphates due to their richness in phosphoric acid and carbonate of lime. However, they are the nodules from the South of France, Nassau, and Spain, which furnish agriculture with four-fifths of its commercial phosphates.

As already stated, the nodules when in a state of powder, are rapidly taken up by plants. The apatite and phosphorite present a greater resistance to the action of the internal juices of the plant, which take up—by the process of diffusion—through the external envelope of the root, the phosphoric acid of the soil. Obviously, the practical consequences flowing from these remarks is, to reduce the fertilizers to a state of extreme division, before applying them to the soil. And let the dose be liberal, say 2½ cwt. per acre, which will tell on four or five consecutive crops.

The apatite and phosphorite can be quickened in their action if when reduced to powder they are made into a compost and watered with urine. But as the nodules and slag powders answer so well, and are so cheap, there is no necessity for recurring to the others. In the case of organic superphosphates, the only superiority they can claim over the powders is that of being more immediately soluble. But against this advantage must be placed the greater expense. M. Wagner of Darmstadt has clearly proved by his experiments the necessity of employing the powdered cinders in a state of great fineness. At Quareux in Belgium, the employment of nitrate of soda with the pulverized slag has given important results in the culture of oats. The cinders reduced to powder cost fr. 45 per ton, and represented about 28 per cent of phosphoric acid.

The agricultural problem consists to produce much at a little outlay; but remunerative crops cannot be produced without abundant manurings, no more than could a good dinner be prepared from nothing. Heretofore, soluble phosphates cost half a franc per lb; now the insoluble acid in the form of powder costs fifty per cent less. The slag gave wonderful results when applied to grass land. Near Freising in Bavaria, a dose of 8 cwt. of the cinders per acre and costing only 9 fr. doubled the yield of hay. Associated with nitrate of soda equally gratifying results were produced.

The movement of opinion for the extension of experimental farms is rapidly extending. The Government accords sometimes material aid for the execution of the experiments, but more usually lends its agricultural representatives to superintend their carrying out and to report the results. Ordinarily, a spirited proprietor places some acres, and all corresponding facilities at the disposal of the officials. These experimental acres are ostensibly devoted to the solution of local or rather regional questions, such as the most suitable seeds, time and manner of sowings, manures, and the influence of climate &c. thereon. Each experiment is tested pending four years and controlled by an impartial official. It is on these lines that M. Hardon has placed five acres of his farm near Melun to test wheat-experiments; at first, the farmers kept aloof, but now they watch the proceedings with something like the interest of a horse race. Nothing is concealed; all accounts and progress are open for any person to consult, and a register is kept for visitors to make suggestions or record their impressions. In a few years when the reports on these disinterested experimental lands are co-ordinated, they must give rise to a consensus of practical conclusions, equivalent to a positive code for agriculture in general and for the localities in particular.

Science has long ago established the indispensableness of nitrogen in the production of plants, and that agriculture appreciates practically by the importance of that element in the manures furnished to the soil. But what is still uncertain is to know, if the atmosphere, which is an inexhaustible store house of azote, and offers it gratuitously to plants, is the source of nitrogen for the vegetable world. The whole subject has just been discussed at the Congress of Scientists held at Berlin, so we have all that is known up to date on the question of the absorption of free nitrogen from the air.

We know that an electric spark converts the azote of the atmosphere into nitrate of ammonia, and which the rain brings down with it to the soil; but it is calculated that during a year an acre of ground does not receive more than 9 lb. in this form. Practice, however, has not the less affirmed, that certain plants, clovers especially, had the exceptional power to utilize free nitrogen for the formation of their tissues, while at the same time enriching the soil. The results of Schultz's experiments at Lupitz seem to roughly confirm this opinion. On the other hand the researches of Boussingault are decisive respecting the non-absorption of free nitrogen from the air.

Boussingault raised leguminous plants on a soil deprived of nitrogen, and so they had no other source of deriving it save from the air. On analysing the plants, he only found in their tissue a quantity of azote equal to that existing in the seed, and so only obtainable during the process of germination. This was precise negative evidence.

Now the importance of these issues is plain; if a farmer pursues a system of culture counting on the air to supply the nitrogen, he may come to grief. Dietzell unlike Boussingault, operated on the arable soil itself, and arrived at the same results as that distinguished chemist. Joulie and Berthelot in France, and Frank in Berlin, obtained results opposed to Dietzell. Doctors differ. Joulie asserted that rye, clover and rye grass absorbed free nitrogen from the air. Berthelot only occupied with the soil itself, stated, that after a lengthened lapse of time a sterile soil, if possessed of a certain warmth, became rich in nitrogenous compounds. Frank, with a remarkable exactness on the same soil, cropped and uncropped found that nitrogen had been absorbed, but how or

from where, he could not state. He considered the soil to be merely the seat of the phenomena, and modified by the covering of vegetation; that is to say, the more the soil was aërated the less was the absorption of azote. Thus, two apposite phenomena are recognized; the elimination and the fixation in the soil of nitrogen which vegetation favors.

About a year ago M. Frank discovered certain bulbs or nodules at the extremity of the rootlets of plants. Some believed these bulbs were mushrooms; some that they were animalcules. Frank considered they were humus in a stage preparatory to being taken into the tissue of the plant; others, a kind of magazine of albuminous or plasmic matter prepared in advance by the plant for the wants of fruit time. M. Hellriegel sustains these fungi-like bulbs absorb free nitrogen, which at best is but a gratuitous assumption. He confounds cause with effect, since the bulbs only are formed, or at least appear when the plant has reached an advanced stage of its growth, when the leaves are in full development and active function, and the organs of assimilation at work.

Conclusion: The question of the free absorption of atmospheric nitrogen by the soil or by the plant, has not advanced a single step towards a definite solution. More rigorous experiments are necessary, and in the meantime let farmers rely on fertilizers and not the air for azote.

Extreme attention continues to be given by vine-yard proprietors to the phylloxera. No further preservative or remedies have been found to supersede autumnal irrigations, followed by rich spring manurings, or sulphuret of carbon or the graftings of American vine cuttings. Mildew and its varieties has not been very serious; it was tormenting rather than a subject for anxiety. Besides it is a meteorological calamity, not like the phylloxera—"always with us"—like other miseries.

In Belgium, the sugar-beet crop has suffered from the malady of "black heart." It is a disease produced by a fungus, which settles in the heart of the leaves, down even to the neck of the bulb, and produces black rot. Only cultivating beet on the same land, once in three years, and removing the necks of the roots, and making a compost of them with live lime and earth will get rid of the nuisance.

The agronomic school at Nancy has conducted a series of experiments on the temperature of soils. Turf has proved to be the warmest, and sandy the coldest soils: the latter is the most sensitive of all to fluctuations of temperature becoming the warmest in day-time and coldest at night, hence the most subject to suffer from spring frosts. As a general remark it is the water in the soil regulates the temperature: vegetable tissues are bad conductors of heat.

GEOLOGICAL DISCOVERY IN THE SALT RANGE.—We see from the February No., Vol. XIX., Part I., of the records of the Geological Survey of India, that Dr. Warth has made a very important discovery of fossils in the Salt Range, which proves that the bed in which they lie belongs to the carboniferous age. The Salt Range according to Dr. Waagen, from whose paper on the Palæozoic glacial beds of the Salt Range we quote, "formed the northern shore of a continent extending from Afghanistan throughout India, and at the Salt Range there was probably the mouth of a great river, down which large masses of ice floated, whilst in other parts of the world the coal measures were being formed, and the ice masses drifted along the shore depositing large boulders, gravel and fine silt." All this points to a galical period at first restricted to the Southern Hemisphere, and spreading later on to the Northern one. But we must refer our readers to the Records for the rest of Dr. Waagen's interesting note, and only quote his concluding sentence—"It has been made possible to ascertain all this by the assiduous investigations of my old friend Dr. Warth, who has thus made one of the most important discoveries that ever could be made in the Salt Range."—*Indian Forester.*

BRAZIL: DEPARTMENT OF AGRICULTURE; SUGAR; LABOUR; SLAVERY.

Central Sugar Factories.

Notwithstanding the guarantee of interest on the capital necessary for the establishment of factories destined to the preparation of cane sugar by means of perfected machinery and processes, a large number of concessionees were unable to carry out their privileges by domestic or foreign capital, through which 35 concessions were declared lapsed. One privilege for a central factory at S. Fidelis, Rio de Janeiro, was granted with such favors as were allowed under Art. 6 of Regulamento No. 8,357 of December 24th, 1881, except an interest guarantee, or free entry. With this concession the number now in force is:—

With an interest guarantee:

33 factories with a total capital of ... 21,800,000$

Without guarantee:

19 factories ..... —

—

52 do

The 33 factories are thus distributed:—

Province	*No.*	*capital*
Alagôas	1	500,000$
Bahia	6	5,600,000
Espirito Santo	1	500,000
Minas Geraes	1	300,000
Municipio Neutro	1	400,000
Parahyba	1	500,000
Pernambuco	11	6,950,000
Rio de Janeiro	5	3,450,000
Rio Grande do Norte	3	2,100,000
S. Paulo	1	500,000
Sergipe	2	1,000,000
	33	21,800,000$

of which 2,400,000$ has a guarantee of 7 per cent and 19,400,000$ a guarantee of 6 per cent.

The production of sugar and rum of the factories for the crop 1884-85 is given as follows:—

	Sugar kilos.	*Rum litres.*	*Value.*
Pernambuco	2,349,175	301,395	336,127$
Rio de Janeiro.	2,905,800	1,723,200	60,795
S. Paulo	429,600	480,000	112,221
Minas Geraes	183,300	302,400	—

Immigration.

During the past year 22,727 immigrants arrived at this port, considering as such all third-class passengers, of which 10,567 accepted accommodation at the Ilha das Flôres Government station.

There were 14,271 departures for the following destinations:—

S. Paulo	5,163
Rio Grande do Sul	4,643
Minas Geraes	1,434
Sta. Catharina	1,368
Rio de Janeiro	1,006
Paraná	429
Espirito Santo	167
Pernambuco	53
Pará	26
Bahia	23
Amazonas	19
	14,271

At Santos, S. Paulo, there arrived 6,681, thus increasing the total arrivals in the Empire to 29,408. Of the arrivals at Santos 3,705 remained in the province of S. Paulo, the others leaving for Paraná, Sta. Catharina and Rio Grande do Sul.

New works during the year at the Government station cost 10,410$ and the board of the 10,579 immigrants arriving three cost 35,747$, or 834 rs. per day per individual; say 2$502 per capita for the three days allowed the immigrant. Only 3 deaths were reported,

The *Colonization Society of* 1849 *in Hamburg* has not faithfully executed its contract which was to introduce annually 1,000 immigrants. Under a clause in the contract which allowed the completion in the following year of the total for any one year, the company need only bring into the country a sufficient number last year to complete the contract for the preceding. Not even so was the total made up, for only 954 immigrants arrived for 1884 and none for 1885. A fine was imposed for non-execution of the contract in 1884, but as no penalty is marked for complete evasion of the contract in 1885, against which the subvention for six months had been paid, the minister suspended further payments to such a time as the company shall fulfil its engagements.

The Government proposes to spare neither efforts, nor sacrifices to attract colonists and immigrants, and if furnished with means proposes to organize a regular propaganda in favor of European emigration to Brazil; to aid in the transportation of the emigrant from his residence in Europe to his destination in the Empire; to reorganize the service of surveys and sales of public lands, so that the immigrant may meet ready and convenient establishment.

The propaganda will promote emigration by rendering Brazil favorably known and will do away with so-called official immigration agents. Exercised under the responsibility of the Government, openly, without tricks or prevarications, the propaganda will certainly produce excellent results, as happans with other countries which have used it as a powerful instrument to attract immigration.

Circumstances render necessary the advance or payment of passage money. This may be effected in various manners, viz., payment in full of passage to the immigrant; by a reduction on the fixed price; or by the advancing of the cost, in full or in part, with an obligation of re-payment. However onerous the assistance may be to the State it cannot be avoided, as the sincere desire of the Government is to develop immigration. It is not meant to pay, nor to indiscriminately advance passage moneys; the payment of full cost might be exclusively restricted under the law of September 28th, 1885, to immigrants who establish themselves on agricultural settlements, the reduced price could be extended to a limited number of immigrants who may establish themselves in the country as proprietors, and the advance with the obligation of re-payment would be extended to such as fix themselves in nuclei created by Government, and subject to colonial regimen for a certain time.

The prompt and convenient settlement of the immigrant being the principal pre-occupation of the Government, the pre-eminent necessity arises for its preparation as to sales of well situated and appropriate lands, surveyed and divided, to the immigrant. This is the base stone of the administrative plan of the Government. To promote the arrival of the immigrant, to pay or advance his passage money and then give him an unfit establishment, is to advance a step and immediately retreat, to the sacrifice of the legitimate interests of immigration.

With these seemingly practical measures, the minister believes the service of immigration may be fairly organized, to which a necessary addition will be the reform of the location of services law, to the end of abolishing imprisonment for non-compliance with contract by the colonist, and the nullification of contracts made abroad to have force in the Empire.

The Government will present a law for reforming the land law of 1850. The principal acts of the administration touching the subject of immigration were the continued suspension of the payment of passages, because the minister on assuming office found there were at the department applications to introduce 40,000 immigrants, while the Government only had disposable 1,926 lots of land, surveyed and divided, or only about room for 10,000. Various commissions were organized to expedite the surveying of lands.

Slavery

The minister is happy to announce that law No. 3,270, dated September 28th, 1885, for the gradual extinction of slavery, has been met throughout the Empire, as to its execution, with the same zeal and respect as was extended to law No. 2,040, dated September 28th, 1871. All classes of society are persuaded as to the inevitable necessity of a solution of this great problem, with such precautions as are necessary in a subject so intimately connected with interests of the greatest importance, in a manner definitive and safe, although slow.

Although the number of 60 year old slaves was not known with certainty, the following table will furnish an idea of the average of emancipations under law No 3,270 of September 28th, 1885:—

Provinces.	*Emancipations.*
Rio de Janeiro	11,035
Espirito Santo	1,224
Parahyba	602
Pernambuco	3,204
Alagòas	1,072
Maranhao	665
Paraná	278
S. Paulo	363
Goyaz	213
Sta. Catharina	108
Minas Geraes	18,595
Matto Grosso	231
Rio Grande do Sul	213
Rio de Janeiro, Municipality	3,055
	40,668

(This table adds up 40,858.)

[It is only just to call special attention to the fact that the efforts of Sr. Prado to collect full statistics for the above table have been met with something like obstruction. His native province, S. Paulo, shows unfavorably in this matter; for with a very large slave population, only three districts of that province reported in season for the preparation of the minister's *relatorio*.—EDS. *News*.]

The law of 28th September, 1871, has been scrupulously observed and the following table shows the emancipations under its clauses, up to the latest information:—

Provinces.	*Emancipations.*
Amazonas	52
Para	566
Maranha	1,408
Piauhy	710
Ceara	1,805
Rio Grande do Norte	320
Parahyba	783
Pernambuco	2,249
Alagoas	734
Sergipe	659
Bahia	3,202
Espirito Santo	422
Municipio Neutro. (capital)	754
Rio de Janeiro	4,115
S. Paulo	2,791
Parana	200
Sta. Catharina	355
Rio Grande do Sul	1,406
Minas Geraes	4,230
Goyaz	97
Matto Grosso	138
Total	24,165

(This table adds up 27,166.)

There have been six distributions of the emancipation fund employed, and the seventh, amounting to 2,000,000$ was authorized on April 7th last.

The total cost of freeing the slaves is stated to have been as follows:—

Emancipation fund	16,443,682$372
Contributions from freedmen and others	972,902,663
	17,416,585$035

On 30th June last, the slave population was estimated to be 1,133,228, or 107,578 less than in the preceding year; from the total, however, the sexagenarian slaves do not seem to be deducted.

The statistics are as follows:—

Provinces	No. 30th Sept. 1873	Arrivals.	Departures.	Deaths.	Emancipations.	No. 30th June 1885
Alagoas	35,002	7,248	10,422	3,761	3,957	25,046
Bahia	169,766	14,766	21,171	14,879	15,660	132,822
Espirito Santo	22,284	5,900	2,503	3,769	2,150	19,762
Goyaz	10,771	1,665	1,916	1,418	1,314	7,788
Maranhao	52,733	6,638	9,654	13,929	3,887	31,901
Minas Geraes	340,444	107,615	105,349	49,316	17,119	276,275
Matto Grosso	6,547	499	585	756	889	4,816
Municipio Neutro	47,084	17,149	9,695	9,447	15,182	29,909
Parahyba	27,651	509	3,951	3,677	1,708	18,824
Para	31,216	5,502	4,593	3,962	7,945	20,218
Parana	11,867	1,312	2,511	1,368	2,404	6,836
Pernambuco	92,745	21,132	17,690	13,271	10,546	72,370
Piauhy	24,016	2,477	5,414	2,392	3,189	15,498
Rio Grande do Norte	13,165	2,520	5,997	846	1,633	7,209
Rio Grande do Sul	99,401	10,806	26,486	9,692	46,787	27,242
Rio de Janeiro	303,807	92,568	60,485	63,938	21,052	250,896
Santa Catharina	15,220	1,773	3,103	1,939	3,730	8,221
S. Paulo	166,427	77,585	42,744	31,699	16,299	153,270
Sergipe	35,187	8,654	11,698	4,753	3,105	24,325
Totals	1,505,273	386,354	345,931	234,812	177,656	1,133,228

The above table is stated to be defective. Nine provinces forwarding defective returns, or none at all, while Ceara and Amazonas are omitted.

The emancipations are thus classified:—

With conditions	69,430
Without conditions	108,226
	177,656

and the slaves in the Empire on the 30th June, 1885, were:—

Men	598,635
Women	534,593
	1,133,228

The free-born children of slave mothers numbered on the 30th June last 439,831, of which 219,071 are of the masculine and 220,760 of the faminine gender.—*Rio News.*

BRITISH NORTH BORNEO AND ITS RESOURCES.

The following interesting paper was read at a meeting at the Conference Hall at the Colonial and Indian Exhibition on the 25th October, 1886, by W. B. Pryer, C.M.Z.S, F.G.S., Australia, Her Britannic Majesty's Consular Agent for Sandakan, Resident in the service of the British North Borneo Company, &c., &c. Sir Rutherford Alcock, K.C.B., was in the chair:—

Mother-of-pearl shells and Pearls occur more amongst the seas of the Sooloo Archipelago than on our own coast, though off Port Elphinstone there are large banks of them; the Ada Bank, in particular, hardly at all worked at present.

The Oyster, scientifically known as *Meleagrina margaritifera*, which yields the finest shell, is also the one in which pearls are found. The collecting is done by divers, who, without any aid go down to extraordinary depths in the sea, twelve fathoms and over. When the depth is greater, or where sharks abound a sort of drag or trawl is used. Pearls of all sorts and sizes are always being found, and are brought chiefly by Chinese for sale in China, where they fetch a higher price than in England.

Keema is the fish of a large clam shell or bivalve *Tridacene gigas* which often attains dimensions of four feet or more; wherever there is shallow coral-bottomed sea, they abound in quantities, and are but slightly collected. Many of these Keema shells are to be seen in the fountains and grottoes in the Exhibition gardens here; off the coast of Tawi Tawi there is one which the natives say is as big as a house. Bajau huts are not very large however.

Borneo camphor is obtained from a large forest tree, which has to be felled and split up for the purpose. It is worth from 35s. to 70s. a pound, and, like many other expensive things, has a higher price in China than elsewhere. It is obtained from one of our commonest forest trees, but which has to be of great age before it attains the proper stage of ripeness. In many places the natives do not understand its collection, which is somewhat of a mystery. The Quarmote River is said to be such a district, and it is reported that one party who went there got several thousand dollars' worth. A very large value of this camphor is, no doubt, not entered at the Customs, but is simply taken out of the country in luggage boxes and so forth.

The quantity obtained from one tree is usually within 50 dols. worth, but a good deal more is occasionally obtained. The natives say that if a man obtains over 600 dols. worth from one tree he will die within the year. This is based on the law of compensation I suppose.

The one forest of many millions of acres, with which the greater part of British North Borneo is covered, is mainly composed of valuable timber trees of which the best known are billian or ironwood, serayah or red cedar, kapor or Borneo camphor, kruing or wainscoting, Penargah or Borneo walnut, bintangor, peune or mastwood. Chindana, marrabow and many others. Billian is the one of these for which, perhaps, the best demand exists, it is well known both in Singapore and Hongkong, which have been supplied hitherto mostly from Sarawak, in which country now, however, supplies are falling off. Billian planks are greatly esteemed on account of their extreme durability, large orders for them for planking wharf frontages at Singapore have had mostly to be cancelled owing to the want of appliances and capital in Sandakan, to carry them out, notwithstanding the profit that would have accrued. The supply of this wood in British North Borneo is very large, of the forest trees in the district from the Segaliud to the Segama, a considerable percentage are billian, in some places thirty trees in a hundred are of it. The last valuable discovery in Province Dent, is of this timber there in large quantities. Owing to its weight, great difficulty is experienced in handling the logs, but the number of rivers which everywhere permeate the forest greatly facilitate its transport as well, of course, as that of all our timbers. With regard to our timbers generally, my hearers may judge for themselves by looking at the benches in this hall and elsewhere in the building as well as at the planks and mouldings here shown, and the exhibits in the British Borneo Court. In view of the rapidly increasing demand for planks and other woods in Australia, India, China, the Mauritius and elsewhere, the increasing difficulty experienced in Singapore, hitherto the chief source of supply, in obtaining wood for their mills, and the enormous resources possessed by North Borneo, there seems little doubt but that we shell in time come to the front as one of the chief timber exporting countries in the East, when the matter is once fairly started. I have made an estimate of the timber growing by rivers either running into Sandakan Bay, fairly accessible from Sandakan, or at all events from which timber could be obtained in Sandakan with less difficulty than Singapore now experiences in getting her supplies, and the

result is so enormous that I am really afraid to quote it. The river service of the district may be imagined when I say that I have included 73 rivers and tributaties in my estimate, all reachable within a very few hours steam from the town of Elopura. In most part, of the East, even where the country is least inhabiteds there are comparatively few places where the natives, fields and clearings do not line the rivers, thus driving the forest far away back, whereas with us, owing to the lack of inhabitants, the land is clothed with fine forest trees down to the rivers edge, magnificent timber in fact overhanging many of the rivers for miles of their courses; only 10 of the 73 rivers are inhabited at all and even on most of these the clearings are but very few and far between. The opening of even many tens of thousands of acres of land for agricultural purposes would not have much effect in clearning away this vast forest, and it may safely be said that, presuming the larger trees in the nearer districts to have been felled and shipped off, so many years would elapse before the wood in the more remote districts was used up, that the places which had first been exhausted would again be covered with large timber trees. Not that there is any chance of these nearer districts being exhausted: in our generation at least.

Agriculture.—Notwithstanding, however, great the benefits may be that British North Borneo may derive from a properly organized concentration chiefly upon one place of her trade; from the development of the timber resources, and from the proper opening up of the gold fields, agriculture will in the future prove to be its mainstay and chief source of prosperity and revenue, and I have always felt that the future success of the country is bound up with the development of the agricultural resources of the Sandakan Bay district. The whole of the vast acreage referred to as at present covered with timber, is exceedingly well adapted for the growth of tropical products, but the soil to the south side of the bay is that which can be best spoken of from actual results, and in addition to this there is also the proximity to the town of Elopura where supplies of all kinds, from fresh food to labour are always procurable, as well as the facilities of transport afforded by water-carriage there and the fact of its already being a fairly large shipping port, which counts for a great deal when undertaking the planting of cheap prodcuts such as sago, Manila hemp, &c. With the exception of tobacco, no systematic attempts have yet been made to prove the capabilities of the soil. With regard to tobacco, however, a crop raised on the Suan Lambar river in Sandakan Bay, which was sold last week, brought very high prices.

The following figures will give some idea of what tobacco planting means. The dividend paid by the Deli Maatschappÿ Company for 1882 was 65 per cent; for 1883, 101 per cent; 1884, 77 per cent; 1885, 107 per cent. The Tabak Maatschappy Arendsburg, Rotterdam, paid 22 per cent in 1881; 25 per cent in 1882; 50 per cent in 1833; 60 per cent in 1884; and 100 per cent for 1885. The Amsterdam Deli Co. paid 10 per cent in 1882; 30 per cent in 1884; and 60 per cent in 1885. Besides paying these enormous dividends, I understand that the immense estates of the Deli Maatschappy Company, have been entirely paid for out of profit, and only appear in their accounts as valued at one florin. The emoluments of many of the gentlemen connected with these Companies, also, are said to be something enormous, being principally calculated on the part profit system. I did hear that one gentleman made over £40,000 last year. Profits by individual planters also, are extremely large. When in Singapore last spring, a private planter was buying up most expensive things, horses and carriages and what not right and left.

There is no question as to the similarity of British Borneo tobacco to that from Sumatra.

Besides tobacco, pepper, Manila hemp, sago, Indian rubber, kapok, gambier, coconuts, and cocoa are among the things that hold out most hopes of profitable cultivation. Tobacco and sugar cane are probably the best plants as regards the richness of the soil; tobacco, I have already spoken of, sugar cane also flourishes in Sandakan Bay in a way said to be unprecedented in the experience of several sugar cane growers who have visited us, and the juice yielded by it has been demonstrated to contain an unusual percentage of saccharine matter. At present prices for sugar, it is of no use thinking of profitable cane growing, I suppose, but if sugar cane can be grown anywhere to a profit, Sandakan Bay is that place, with its good soil, favourable climate, cheap labour, and facilities of transport and export.

I have spoken of the profitable results of tobacco growing; pepper is hardly less profitable in places where it thrives; Sumatra used to be the chief producing country, but the long-continued Acheen war, has destroyed this industry beyond hope of recovery. Pepper is thus spoken of by Mr. Crocker, in a memorandum written by him on its proposed cultivation in North Borneo. "In June, 1880, Singapore and Penang black pepper was selling at 3¾d. to 4d. per lb. in London; in June, 1881, prices had advanced to 5d and 5½d.; in June, 1882, it was 5½d.; in 1883, it was the same, but in June, 1884, it had advanced to 6½d. per lb., while last year the price had reached 7¾d. to 7⅞d." As there are no signs of a cessation of trouble in Acheen, the pepper trade in that country is more likely to decrease than increase. It is as difficult to find countries with soil and climate as suitable for pepper growing, as for tobacco like that from Deli, but there seems to be a great similarity between North Borneo and Sumatra in these respects. Mr. Crocker was chiefly the means of introducing pepper and gambier planting into Sarawak, and as a result the revenue of that country has increased largely chiefly owing to this reason, from 158,000 dols. in 1875 to 276,000 dols. in 1884. This is another of those hard facts which have a particular signification for the shareholders of the British North Borneo Company.

For the benefit of those who have never visited the East, I may mention that pepper grows much in the same way as the hop vine, and like it, is trained on poles, the only difference being that whereas the hop vine is cut down yearly, pepper when once it begins to bear goes on continuously, and the poles up which it grows must be calculated to last for many years. The initial expense of working a pepper plantation is, therefore, somewhat large, as the woods selected must be of a very durable description. The vine begins to bear at between two and three years of age; the pepper corns are in bunches something resembling currants. The gardens must be well raised, and well drained; as the pepper roots cannot stand damp ground. Tobacco land for instance, would not suit pepper. At 8 dols. the picul, Singapore price, pepper paid remarkably well. Last June the price, however, was but a trifle below 20 dols., and since then the growing scarcity of the article has had a strong effect on the market, and prices rapidly advanced over 4 dols. a picul more.

I have myself devoted no small attention and expense to trying some of the more noteworthy plants, pepper included, and most of them (coffee excepted) were looking remarkably well when I left Sandakan. There was always a good deal of difficulty in getting pepper slips, the Chinese, the principal growers in Singapore, being by no means inclined to let their virtual monopoly be infringed upon. Finally, however, by the courtesy of a Sarawak gentleman, I received some from there.

The cultivation of gambier is usually associated with that of pepper, and is also found to be very profitable.

Manila Hemp, or Abaca, a well-known and highly-priced fibre, extracted from the stem of *Musa textilis*, a plant of the Banana tribe, is the means of causing a large annual inflow of wealth to the Philippine Islands. *Musa textilis* has not been found to grow satisfactorily in any part of the world, except in the neighbourhood of the Philippines, which have therefore, up to the present, had virtually a monopoly of its production. As yet but very little has been tried in North Borneo; but if once it is largely grown there, there is little doubt but that we should soon supplant the Philippines, where shipping and commerce are both exposed to so many restrictions and duties, not to speak of extortions, that those connected with

them would far rather go elsewhere if they had the chance. A correspondent of the *Hong Kong Daily Press* writes as follows, with regard to the profit to be made on Manila Hemp:—"I have before me a prospectus for the production of hemp in the Philippines, showing a profit of something like 80 per cent per annum. It is well known that the profit on hemp cultivation in the Philippine Islands is over 100 per cent per annum; but English capital once invested in any business in these delightful islands is seldom or never seen again; this I know from sad experience.

The quantity of fibre obtained from each stem is very small, and up to the present time the process of extraction has been a very lengthy hand-labour one; but a machine, lately invented by Mr. Death, considerably simplifies it. The stem being so bulky, the main consideration in the manufacture of Manila hemp is that of porterage, and the sites of plantations should, therefore, be selected chiefly with a view to this end, in places affording a maximum of water carriage. The stems are not properly ripe for cutting under fifteen months of age, but when once ready, the stool continues to yield a ripe stem every two months or so continuously,

Indian Rubber is growing scarcer yearly, and as wherever it has been found the practice has been to cut it down and destroy it, its production seems likely to decrease, and its price to increase considerably. Our Indian rubber is obtained from a creeper, a species of *Willoughbeia* which grows wild under forest shade, so that if young plants are put out at the foot of each forest tree, no further expense need be incurred in connection with its cultivation beyond a slight watch being kept to see that bands of native collectors do not visit the locality, and in four years a large quantity would be ready for collection. There need be scarcely any limit to the size of the space planted up with it, and the work of taking care of a large acreage planted with Indian rubber would seem to be particularly fitted for anyone with natural history or sporting proclivities. There would be some difficulty at first in getting seeds or slips to plant in nurseries, but once they were obtained, all the rest would be easy.

Sago is the product of a palm tree which flourishes to perfection in Borneo. The following remarks by Mr. W. M. Crocker on its cultivation will be of interest; he says that its production in Sarawak "affords a steady industry to some thousands of inhabitants, all living in comparative wealth. It may give some idea of the enormous rate of this product if it be considered that three trees yield more nutritive matter than an acre of wheat, and six trees more than an acre of potatoes."

The main drawback to the investment of capital in sago planting is the length of time that elapses before the trees are ready to cut; but it must be understood that when once they commence yielding, they go on continually without cessation, so that the only expense attending their cultivation, when once they are in bearing, is the upkeep of fencing to keep out pigs. It is also to be added that the expense of planting is very small compared to the returns when once they begin to come in. Mr. Crocker calculated that a plantation of 2,000 acres would give a profit of £15,560 a year. Since this calculation was made the price of sago has declined, but there is no chance of its not yielding a good profit to the grower. It is also to be remembered that the sale value of a newly-planted sago plantation would rise heavily yearly.

Amongst other things, cocoa will, I think, be found to thrive particularly well in British Borneo, judging from the few trees grown in the native gardens on the Segaliud and elsewhere; while coconuts flourish extremely well, are a safe investment, and yield some two years quicker in British Borneo than elsewhere.

I will conclude my remarks upon agriculture by again expressing my extreme desire to see general plantations started on land in the Sandakan district, and my confidence that if rightly managed they would prove a profitable investment to their owners, and lead up to their being the main prop of the country generally in the future.—*Straits Times.*

Tobacco for Ceylon.—The attempts now being made to grow the tobacco plant on a good scale in this country have induced the trade section of the London Chamber of Commerce to offer two prizes of fifty guineas each for the best specimen of tobacco grown in the United Kingdom, and for that produced in India, or in any of the British colonies and possessions. It is stated that these prizes will be awarded as a means of definitely ascertaining how far the above sources of production can add to the supply of tobacco suitable for the English market, and to what extent, if any, these growths can compete in quality and price with those of foreign countries, from which the consumption of the world has hitherto been chiefly drawn. Each specimen is to weigh not less than 400 lb., and must not consist of picked leaves from a large quantity. The specimens not grown in the United Kingdom shall be submitted for competition in London, and in the bonded warehouse of either the Victoria, the London and St. Katherine's, the East and West India Docks, or other bonded warehouse. Specimens of British-grown tobacco will only be admitted under bond at the Haydon Square bonded warehouse. The tobacco grown in the United Kingdom must be sent for inspection on or before the 1st March, 1888, and that of other places on or before the 1st of December of the same year. I shall hope to hear that both European and native tobacco growers in Ceylon will compete for the colonial prize, as there is very little doubt they would stand a good chance of success. In 1851 Jaffna tobacco, sent to the Great Exhibition by some American missionaries in the north took a prize medal; and competent judges pronounced some of the Trincomalee-grown leaf first class, but spoilt by over-pressure in the bales. This and the presence of not more than 15 per cent of moisture in the leaf are essential points.—*London Cor.* Local "Times."

Indian Figs.—A paper by Dr. George King of Calcutta, on "The Genus Ficus, with special reference to the Indo-Chinese species," was read at the Linnean Society on March 17, in which it was shown that insects play a considerable part in the fertilisation of certain forms. Dealing with the structural peculiarities of the flowers in the genus Ficus, he specifies:—1, male; 2, pseudo-hermaphrodite; 3, neuter; and, 4, female fertile flowers. Besides these there occurs a set of flowers originally named by himself "Insect-attacked females," but for which he has adopted Count Solms Laubach's term, "Gall Flowers" (see *Gardeners' Chronicle*, vol. xix., p. 530; vol. xx. p, 22, 1885)—the latter botanist having anticipated him in publication, though King's researches had commenced earlier. As to the question of these gall flowers, Dr. King states that the pupa of an insect can usually be seen through the coats of the ovary. The pupa when perfected, escapes into the cavity of the receptacle by cutting its way through, and fully developed winged insects are often to be found in considerable numbers in the cavity of the Fig. The pupa of the insect must become encysted in the ovary of the gall flower at a very early period, for about the time at which the imago is escaping from the ovary the pollen of the anthers of the male flower is only beginning to shed. Thus Dr. King holds that through the interposition of insects the malformed flowers doubtless become functionally important in the life history of the Fig trees. From the peculiarities in the structure and arrangement of the flowers Dr. King is of opinion that the evolutionary history of the genus Ficus may be traced. On data derived therefrom he arranges the Indo-Malayan species into two great groups, the second of these being again divided into three subsidiary sub-groups as follows:—

FICUS, *Linn.*

Group I. Pseudo-hermahphrodite ...			... Galœomorphe.
Group II. Unisexual.	Sect. I. ...		... Urostigma.
	Sect. II. ...		... Syncœcia.
	Sect III	A.	Sycidium.
			Corwellia.
		B.	Eusyce.
			Neomorphe

—*Gardeners' Chronicle.*

PROSPECTS OF TEA IN BURMAH.

(Communicated.)

Before we give an estimate of the expenditure necessary in opening out and maintaining a tea garden in Burma until it becomes a profitable speculation, we think it necessary to give our readers a clearer insight into the enterprise, by explaining the kind of land best suited to the cultivation of tea.

For this purpose, the land most suitable is high land gently undulating and with a rich dark, sandy loam or a moderately heavy soil. The land chosen should be near a road, navigable river or railway, for despatch of the product of the garden to market, but it is still more important that it should be near a virgin forest for the purpose of keeping up a continuous supply of timber for the manufacture of charcoal and tea chests, and for building requirements. About 600 acres of such forest would be necessary for the proper working of a garden of 150 acres. It is our belief that such land as we have just described can be had in any quantity in Burma.

The question of labour can be easily settled by application to the numerous cooly agencies in India, who could supply the right kind of labour at a very moderate charge per head.

The seed can be procured from Assam and Cachar through the Agents of tea concerns in Calcutta, and we would recommend a high class China with a fair admixture of Hybrid, say 30 per cent. This mixture should be obtainable in Calcutta at R25 per maund, or even less. The implements necessary are axes, dhas and hoes, all these are obtainable in our local bazaar at moderate prices.

It is in the power of Government to assist intending planters in many ways, by furnishing information as to likely sites, opening up nurseries at central places for the supply of seedlings at moderate prices, and more particularly by protective measures with reference to the labour question, as was done in the early days of tea planting in India.

We will now give an estimate of the probable cost of starting a garden of 150 acres, and maintaining it until it becomes a profitable concern, keeping well within our supposed capital of one lakh of rupees.

	Rs.	A.	P
Land 600 acres (on a thirty years lease from Government at R10 per acre ...	6,000	0	0
Seed 100 maunds at R30 or 35 landed on the garden	3,500	0	0
Labor, cost of importing 100 coolies at R30 each	3,000	0	0
Implements	500	0	0
1st year expenditure from October (say 87-88) to October inclusive of Manager's salary and buildings	12,000	0	0
Total...	25,000	0	0

With this expendiure a pushing Manager should be able to open out from 80 to 90 acres; the remaining 60 or 70 acres can be undertaken during the second year, when the cost of maintaining the area under plant (if 90 acres) will be R7,560.

2ND YEAR'S EXPENDITURE.

Maintaining old garden for 12 months ...	7,560	0	0
Seed 50 maunds at R35	1,750	0	0
Cost of planting out and maintaining new garden 50 acres for 12 months ...	6,000	0	0
Cost of importing 50 new Coolies at 30 each	1,500	0	0
Cost of Building Bungalow for Manager and Tea Factory	3,000	0	0
Total..	19,810	0	0
Grand Total...	44,810	0	0

3RD YEAR'S EXPENDITURE.

Maintaining 150 acres at R84 per acre ...	12,600	0	0
Seed 10 maunds R35 ...	350	0	0
	12,950	0	0
Grand Total...	57,760	0	0

4TH YEAR'S EXPENDITURE.

Cost of working 150 acres with manufacturing charges at R120 per acre	18,000	0	0
Deduct price realised by sale of 150 maunds of Tea at R50 per maund ...	7,500	0	0
Total...	10,500	0	0
Grand Total...	68,260	0	0

5TH YEAR'S PROFIT.

Sales of 450 maunds of tea at R60 per maund	27,000	0	0
Cost of working garden Commission, Freight, Brokerage, &c.	20,000	0	0
Net Profit...	R7,000	0	0

—*Rangoon Gazette.*

CINCHONA PROSPECTS.—Messrs. James Cook & Co., in their latest report, do not make much of the probable Java exports of bark in the future—at any rate for a long time yet. The export of 1886 is in fact not likely to be much exceeded in 1887. For last year they give:—

Private exports	1,626,000 lb.
Government account ..	546,000 lb.
	2,172,000 lb.

CEYLON TEA: SPECIAL ANNUAL REPORT.

13, Rood Lane, London, E. C., March 24th 1887.

Dear Sirs,—We beg to submit for your consideration a few facts bearing upon Ceylon tea, together with some suggestions concerning the opening up of ne markets for British Grown tea.

At the first sight, the average price is no doubt disappointing, but it must not be forgotten that the value of Indian tea has fallen to a far greater extent. Indeed, it is almost surprising that the value of Ceylon tea has not been even further depreciated, considering the great influx of tea from India and the additional supply from Ceylon. These imports amounted together in 1886 to 83,460,000 lb., against only 66,863,000 lb. in 1885. No doubt a portion of the fall in price during a few months of the year can be accounted for by the poor quality of the majority of arrivals during that period.

The main reason for the high value at which Ceylon tea has been maintained is due to the manner in which it has been advertised throughout the country, chiefly through the enterprise and perseverance of Ceylon Planters. Through their instrumentality it has been introduced into localities where it had previously been quite unknown. Once introduced, its quality commanded attention, and met with such general appreciation that a steady demand ensued.

THE COLONIAL and INDIAN EXHIBITION which was opened in May last, was destined to become a powerful advertising medium for Ceylon tea, not only from the attractive display of handsome specimens and the instructive lectures which were delivered, but especially from the quantity disposed of as a beverage, as well as sold in the dry condition. An influential Committee was appointed to guarantee the genuineness of the tea, and great care was taken to purchase the mellowest liquoring and most delicate flavoured descriptions. Such success followed this carefully devised scheme that no less than 6,055 lb. of tea were used in the infusion sold as a beverage at the Exhibition, to about 360,000 people. 23,086 lb. in the dry state were also sold in the building; this quantity, comprising a vast number of small packets, exercised an important distributive influence. At the same time the article came prominently and favourably under the notice of the press. Thus the practical outcome of this Exhibition was a more general knowledge of Ceylon tea, combined with a growing appreciation of its qualities by a continually increasing number of the British public. A powerful impetus was thus given to the trade. This was speedily followed up by the establishment of various agencies for the exclusive supply of Ceylon produce,

The growing demand was more than sustained, and so greatly increased that Ceylon tea has since maintained a comparatively high value, with the result that no difficulty has been experienced in dealing with a supply amounting to nearly double that of 1885.

LIVERPOOL EXHIBITION, 1887.—It will be encouraging to planters to learn that at the Jubilee Exhibition to be opened in Liverpool next May, arrangements have all ready been concluded, whereby Ceylon tea will again be specially brought before the public. It may be well to add that there is great probability of this Exhibition being visited by an entirely different section of the public to that frequenting the Colonial and Indian Exhibition of 1886. Hence there is reason to anticipate a continuance of the beneficial results already attained through that Exhibition.

QUALITY.—After the above remarks, it should be hardly necessary to impress upon planters the absolute necessity of maintaining the quality of their produce. No effort should be relaxed, and no opportunity missed, whereby an improvement can be effected in the general quality of the liquor. The greatest care should be exercised to avoid the recurrence of so unfortunate a deterioration in quality, as took place during the earlier months of last year. There is no doubt whatever, that Ceylon is capable of producing tea, the quality of which can only be pronounced as unexceptionable. If the enterprise is to prove a lasting success, it must be the aim of each individual planter that his tea shall attain to the highest standard of excellence.

QUANTITY.—There is good reason to suppose that the exports from Ceylon this year will be about double those of 1886. So large an increase is not unlikely still further to depress values. This probability should induce Planters to neglect no opportunity of economising, where such can be effected without in any way depreciating the quality of the Tea. On the other hand no expense should be grudged, whereby actual improvement can be effected in its liquoring qualities, an object which it is impossible to attain without a more adequate supply of water or steam power than at present exists upon many estates. The one great axiom to be observed should be *quality*, not *quantity*.

NEW MARKETS.—The severe drop in the price of Tea generally, during the past year, forcibly illustrates the importance of opening up New Markets, both by extending the area over which Tea is consumed, and by the further development of the trade in those countries where as yet it has scarcely obtained a sure footing. The education of any popular taste must of necessity be gradual. Its attempt is fraught with danger lest the slow process by which changes in national tastes can be brought about, should be partially or it may be entirely overlooked and forgotten. Thus it sometimes happens that a new article which, judiciously introduced, would have probably met with entire success, has *through lack of adaptability to the habits and tastes of the people*, ended in disappointment and failure. As an instance, it may be mentioned that where strong, pungent descriptions of Indian Tea have been suddenly introduced in those countries accustomed to drink poor China Teas, the experiment has proved unsuccessful and that those Indian Teas which ultimately succeeded have been such kinds as approached the nearest in general characteristics, although superior in quality, to the Teas previously in use amongst the population.

ADAPTABILITY.—In the United States of America a large portion of the Tea consumed is a kind of Oolong. There is no reason why Ceylon should not supply this demand, with an article not only similar in character, but undoubtedly superior in quality—at a rate which should compete favourably with similar descriptions from other countries. This Tea is easy and inexpensive to manufacture, and an effort might be made to adapt a portion of the produce of Ceylon to a market of such magnitude as that of the United States, where over seventy million pounds of Tea are annually consumed. Here, there is also an extensive sale for Green Tea—a fact of which Planters are doubtless well aware.

DISTRIBUTION OF CEYLON TEA.—That Ceylon Planters are alive to the necessity of pushing their produce in New Markets is evident from the following statistics, showing the different places to which Tea has been exported from Ceylon during the past year, viz.:—

United Kingdom.	Australia.	India & Eastwards.	Mauritius.	America.
lb.	lb.	lb.	lb.	lb.
7,580,000	148,154	24,775	8,147	6,621
Hamburg.	Marseilles.	Trieste.	Genoa.	Other Continental Ports.
lb.	lb.	lb.	lb.	lb.
7,137	4,630	620	96	10,256

Their next step should be to study carefully the different tastes of those countries whose markets they wish to supply;—their object being first to *meet* their tastes and then to *improve* them. There is no doubt that much time will be required for the accomplishment of this end,—a circumstance which still further accentuates the importance of immediately discovering new outlets, in order that Ceylon Tea may become thoroughly established in different markets before the output is developed to its full extent.

The quantities taken by the majority of the largest Tea drinking countries show a decided increase; a number of the minor consumers have also imported more Tea. Our principal Colonies show very satisfactory increases, especially Australia and Canada. The figures for the United States are also encouraging. There is reason to believe that Tea consumption in France is likely to increase.

DUTIES.—The rates of duty in some European countries certainly appear prohibitive. In most of our Colonies, only light duties are imposed. In the United States—and practically in Canada,—the article is admitted free, and thus our attention is again drawn to the Markets of North America as extensive fields for future enterprise.

GOW, WILSON & STANTON, Tea Brokers.

SUGGESTIONS REGARDING MANUFACTURE.

We trust it will not be considered out of place in a "Statistical Circular" if we call the attention of our planting friends, in a general way, to a few points of interest in regard to manufacture.

PLUCKING.—The excellence of the tea appears to us almost as dependent on the careful treatment of the plant in the field, as on the subsequent process of manufacture in the tea house. A proper balance must be preserved between the leaves and roots of a plant, as the health of the one depends entirely on the vigour of the other. If the bushes are *overplucked* the leaf action speedily becomes impaired; as a consequence the leaves will be produced in smaller quantities, and the plant will soon assume a stunted and unhealthy appearance (planters will understand what is meant by "crow's-feet") while the quality of the tea, must of necessity be deteriorated. Let the plucking be regular and often, say once a week, and the taking of "immature" and "coarse" leaf guarded against. Leaves should not be stripped off promiscuously, otherwise such shoots will be left without the power of reproduction. It is customary on some estates to pluck half leaves; but we feel sure a natural and more luxuriant growth is obtained by leaving the *full leaf*. We believe that in the process of withering, the "stalk" which is tender and succulent, improves the flavour of the tea.

"Coarse" and "hard" leaf should be left on the bushes, where it is of more value in assisting the functions of the plant. If plucked it does add much to "quantity," but it can and does damage the "*quality*." Indeed, it is self-evident that leaf which toughens instead of turning soft and flaccid in the withering and fermentation, and will not even turn black in manufacture, is not worth the plucking. Again, when there is much "red leaf," the bulk has to be picked over, and during this operation, the tea is of necessity exposed for hours to a damp atmosphere, which cannot but injure it.

WITHERING would appear to be for the purpose of evaporating as much of the fluids as possible without injury to the odorous principle or aroma; or rather to

induce a slight degree of incipient fermentation or *eremeausis* which is a process of slow combustion. In certain conditions of weather it is next to impossible to obtain the required "wither," without which teas of first quality cannot be produced. From our own observation it occurs to us that the "jute hessian tats" have much to answer for. They imbibe and retain moisture, and leaf which in fine weather becomes partially withered by the evening, may be found, if the humidity of the atmosphere has increased, to be quite fresh the next morning, and totally unfit for manufacture. This is a serious difficulty to combat, and we would suggest a trial of something which is less liable to absorb moisture. A free current of air is absolutely necessary, and all leaf lofts should be perfectly ventilated and have an opening along the ridge to allow the partially saturated air to escape.

ROLLING.—This operation requires attention as much as any of the other stages of manufacture, but without efficient steam or water-power it is hopeless to expect justice to be done. Many pence or pounds are lost in consequence of this part of the manipulation not being *thorough*.

SORTING.—A uniform standard should be maintained, and every Tea should be good of its class. *Dust* should be carefully avoided, as it seriously depreciates the value of Broken Pekoes; even small Pekoe Faunings should have the dust removed with a muslin sieve. *Small Broken Pekoes* say under a No. 14 wire sieve *if possessing liquor and quality* are much sought after by the Irish trade, but leaf Bro. Pekoes under a No. 12 are more suitable to the English market.

On estates producing only a small quantity of Tea, we would suggest that, in order to meet the requirements of the trade in respect to size of breaks, the bulk should be sorted into two classes only, viz.: Broken Pekoe (or Broken Orange Pekoe, if very tippy) and a Pekoe Souchong; the former, sorted through a No. 12 wire sieve, and packed in boxes, *under* 28 lb. *gross*, or in half chests; the latter graded through a No. 8 and packed in half chests.

BULKING.—We incline to the belief that some of the deterioration of the tea may be traced to the system of "binning," for it stands to reason that unless the bins are *absolutely air tight* the tea must imbibe a large amount of moisture, to be driven off in the final firing when owing to the "steaming" which naturally takes place, it must lose "point," and to some extent flavour. In many instances we think it would be better to sort and to pack the tea as made, *leaving the bulking to be performed in London.*

GOW, WILSON AND STANTON,
24th March, 1887. Tea Brokers.

COFFEE AND GREEN BUG AND ITS REMEDY.

A planter in charge of good coffee who is naturally very anxious to do it justice and to preserve so valuable a culture for the proprietor, favours us with the following notes. They were written before he had read the recent remarks on the subject in the *Observer*:—

"April 17th.—I am sorry to say that green bug which has been the ruin of so many estates on the Kandy side, is now spreading over Dimbula, Dikoya and Maskeliya. Now that coffee is up to 90/ and rising, now that blossoms have been more like those of old times and that leaf-disease is not so prevalent as it was, this spread of a new pest is serious indeed. It affects the growers of coffee directly and the growers of tea indirectly, as the more coffee land is converted into tea, so much the more is the chance of overproduction increased. The question, therefore, of battling with this new enemy is one of interest, more or less to all, and as from the reports of successful experiments carried on by Mr. Green, it appears *that there is a remedy.* I think no time should be lost in ventilating the question. To my thinking this can be best done by the *Observer* calling on some of the oldest planters to give you their opinions. I am sure much good would come of it. Many planters (and there are experienced V. A.'s among them) look upon the attack as fatal and consider any expense incurred in combatting it, as so much time and money wasted. They tell you of the disastrous effects in Matale and elsewhere and will not admit any arguments suggestive of exhausted soil, overcropping, or climatic influences—'No, it was green bug pure and simple did it.' These opinions have influenced some planters to such an extent that, fearing their credit might suffer, they have kept the fact that their estates were attacked, to themselves. Others again say that tea is doing so well, that they don't care if coffee does disappear—to them the lesson of not having all their eggs in one basket will never be taught.

"I refer to these two classes of fatalists, to show how difficult it will be to carry out any common line of action—and yet, if the remedy is not jointly carried out and heartily supported in each affected district, the cure will be difficult and expensive, if not impossible. I have not yet ascertained the particulars of Mr. Green's treatment, but I believe it was by applying a solution of Phenel by the roots. If the cost were reasonable, I am sure many would try the experiment. Would Government allow the materials to be imported duty free and charge a low rate of railway freight?* These are questions which ought to be raised and without any loss of time too. The pest spreads very rapidly. I know an estate where not three months ago, green bug could hardly be found. It was then only on the backs of a few leaves scattered here and there. It is now not only all over these leaves, but all up the green stalk as well, and the trees are beginning to turn black.

"Some hope that at the higher elevations, where the coffee is still young and vigorous, where the soil is good and where we are free from excess of drought, or rain, the blight may pass away, just as in olden days black bug did. But the suddenness of the attack and the rapidity with which it spreads, makes me begin to feel doubtful and unless some common action is very speedily resolved upon, and it is not too late yet, it very soon will be."

We can only urge all our coffee planters to tell us what they can of this fell enemy—what they are doing to fight it and with what result. Let no false delicacy stand in the way of publicity.

REVIEW OF THE CHINA TEA TRADE FOR 1886.

LONDON, E.C., 23rd March 1887.

The past season has been full of incidents and more or less eventful. Yet the lessons to be learned are difficult to demonstrate and in many cases unpalatable to the scholar. The Hankow crop was reported of unquestionable excellence and he was considered fortunate who secured many parcels of it. It has not, however, borne out this character. The Tea arrived home to a poor market the result of general depression and political complications—pronounced fine by connoisseurs in Mincing Lane it was condemned by the Old Lady in the country and shelved and discarded for Indian and Ceylon Teas, the lower Chinas being considered good enough for mixing purposes. Throughout the last five months of 1886, holders continued to "Bull" the market for first crop teas without even provoking enquiry of any importance, month on month passed away until February when it was thought best to be "getting on" and the Auctions were pretty freely resorted to and prices realized for teas costing in China from 1s 5d to 1s 9d little over the price obtained in July for Shuntams.

To speak of the Teas themselves, no doubt they were fine, but they were thin and weedy showing no mettle, indeed scarcely a tea fit to drink by itself. There was a great want of point no enquiries came for counterparts ex this ship or that, a sign we take it that but little satisfaction was obtained from a purchase at the supposed low prices ruling in July.

To say that the English taste for China Tea is destroyed is not accurate. A Rich Kaisow, Souchong, or Moning of ancient days would still hold its own with either Indian or Ceylon Teas, but this dead level of weak quality (insipid hot water with some flavour) has

* No doubt if the P. A. applied in due form.—ED.

had the effect of sending large quantities of Indian Tea into consumption for mixing purposes.

General depression has forced the retailer to reduce his prices. 1s 6d and 2s are now the every day duty paid prices for tea; a curtailed profit has made the grocer a keen buyer and as some tea had to suffer the weak China became the butt. What does it profit a retail dealer to select teas with no point or character so long as it is ¼d cheaper? it is mixed off and its little character lost in a malty Indian blend, without undervaluing the responsibility of buyers in China the future seems simple enough.

For thin and weak teas such as this season £45 to £80 per ton *i.e.* 4¾d to 8½d per lb. would we think be a full range. But we cannot believe that Cathay is played out as a tea producing country we look with some hope to receiving fine teas again from Hankow and Foochow.

If the China tea is to compete with the Indian and Ceylon, the teas must be strong, and full ripe Pekoe Souchong flavour with a cup that will give a rich cinnamon brown when milk has been added, the tea, taster using a little more of his mother wit, and a little less of his scientific knowledge. Still it must be borne in mind that the quantity of *finest* tea sold in this country is now comparatively small, Kaisows we would suggest should be tested on the basis of Ceylon teas, those ranging from say 9d to 1s 2d; curio leaf teas we except as being a fancy article.

Finest Ningchows. Russians may pay rates far beyond safety for England for these. Ordinary finest chops if well made, free from dust, strong and full flavoured, would we think be a fair risk from 1s 1d at 1s 3d.

Finest Oonfaas. If quality is good and the leaf unmixed and well made 1s 2d at 1s 3d, if only fine teas and no finest come down of this class 10d to 1s

Finest Yung-Low-Tong-Chun sou-kai, Sun-Yongs and Oopacks generally if choice 1s to 1s 1d. Second chops 8d to 10d Nip-ka-Szee, and Ho-How 9d at 11d second chops 7d to 8d, Thuntams 6d to 7d if well made and good quality. Prices for second crops will be ruled by the total supply of the first crop.

These ideas are based on a probable supply from all sources, China, India, Ceylon and Java, of say 230 millions and with a strong useful crop of tea to handle.

(Signed) N. McNAIR & CO.

COCONUT NOTES: SEED NUTS.

(*Communicated.*)

In view of the great variety of habit and bearing power in different coconut trees, it is the business of the planter to use great precaution in the selection of seed-nuts. The usual practice hitherto has been to take nuts for nurseries indiscriminately from the heap, or if any choice was made, it was in favour of the largest nuts. By selecting seed-nuts from early and heavy bearing trees, there is no certainty that the same variety will be reproduced, but there is a better chance of getting good varieties from selected trees that show desirable qualities than by the other system. The tree selected for seed-nuts should be strong, full-leaved, and heavy bearing; nuts of medium size with thin husks and green colour. Very large nuts are not desirable, because the enclosed nut is generally small in proportion to the bulk of the husk, and any advantage gained in size is more than compensated by deficiency in numbers.

It has been recommended in laying down a coconut nursery to place the nuts on their side, so that the contained water may cover the germ. As to the welfare of the future plant, it is of small consequence in what position it is laid, because the first event in germination is the conversion of the water into a light spongy substance that fills the whole cavity, and the upright position has advantages in the subsequent management of the plant, chief of which are, that in planting out, the nut can be put deeper in the soil, and the tender bud may be easier preserved from white ants.

In some parts of the country the natives do not make nurseries, but heap the nuts in a dark corner till they germinate, the advantage said to be gained is that no roots appear outside the husk till they are planted out. The roots of nursery plants have to be shaved off, and the plant has to supply fresh ones before it can get a hold of the soil. In one place I saw the seed-nuts hung on the branches of a thickly-leaved tree: I have not heard what success has attended the experiment.

REMINISCENCES OF A VISIT TO THE PEARL FISHERIES AND THE "BURIED CITIES" AND TANK REGION OF CEYLON.

THE LONGEST DIVE ON RECORD AT THE PEARL BANKS —THE "ARAB" DIVERS—NATIVE AND REGULAR DIVERS CONTRASTED—OYSTER-BEDS AND OYSTERS.

Before resuming my notice of the truly grand Kalawewa (*wewa* in Sinhalese as *kulam* in Tamil always = tank), I must acknowledge a most interesting communication which has reached me from Capt. Donnan. It is to the following effect, the date being the 13th :—

"We are now working on the Cheval, having left the Matarakam* on Saturday last, and if the weather keeps fine, of which there is every appearance at present, we shall do much better in the way of revenue than I expected when I recommended the fishery. I have been ashore only once since you left. You will remember that 'Arab' diver with the nose nipper. Well, I had him alongside this morning and told him to let me see how long he could remain under water and I carefully timed him, one minute and 49 seconds, which is the longest dive on record on these banks or beds. The other 'Arab,' with air-pump and dress, only worked one day with it, when he only sent up 1,500 oysters, and now, without the dress, he is sending up from 2,500 to 3,000 oysters per day; so that the helmet, dress, and air pump are not calculated to succeed at pearl-diving. I found also in 1884, off Chilaw, with four of Mr. Kyle's divers, that the natives sent up more oysters per day, man for man, than they did; a result which very much surprised me at the time, and now it has been confirmed again."

It will be observed that the so-called "Arab" diver, really a Hindu, from the Bombay Presidency, remained under water for a period extending to 109 seconds, or, within 11 seconds of two minutes. What that means, only those know who have watched for the re-appearance of a human being who has remained half the time under water. It really seems "an age" to those who "watch and wait." Not only is 1½ minute the longest dive on record in the annals of the Ceylon banks, but I suspect that if sceptical criticism were brought to bear on the stories which allege subaqueous existence by divers for periods up to six minutes, this latest feat would be found to take rank amongst the most remarkable in the annals of diving where the diver has not been artificially supplied with air. No doubt the organs of the human body are capable of being educated, by continued practice to endurance of abnormal conditions and of adaptation to such conditions: to those of extreme heat for instance, if gradually applied. I could, therefore, understand a man who commenced a diver's life "sound in wind and limb," obtaining gradually the power

* Popularly Modregam

of remaining under water and repressing inspiration and respiration for two minutes, or at the very utmost two and a half. But those who know that the blood is the life, and that it must, as it circulates be ærated, or lungs and heart will cease to act, will be slow to believe in a staying power under water of three minutes, far less of six. If such dives have ever been really made, *the record being accurately kept*, the conclusion must be that in such cases the respiratory organs were in an abnormal condition, or that some means of obtaining fresh air were adopted. It is not obvious how the use of a nose-compressor (made of horn, I believe,) could have aided the man who made the long dive. The other "Arab" alluded to by Capt. Donnan had an imperfec diving dress which, it will be observed, was rather an encumbrance than a help to him as a regular diver, in which capacity he was only thoroughly successful when he abandoned the adventitious aid. Much service to the pearl fisheries of Ceylon was naturally expected from the class of European divers who, by means of external air supplied to them, can remain not minutes but hours under water. But the hopes entertained have not been realized. For the ordinary operations of rapidly collecting and bringing shells to the surface, a regular diving dress is as much of an impediment as was Saul's armour to the shepherd lad who slew the giant with the simple weapons of a pebble from the brook projected by a sling. For exploring the banks and reporting on their condition, more might have reasonably been expected. But a thickly mailed and heavy booted European diver, with 7 to 9 fathoms of water pressing on him, is no light entity to walk over and inevitably crush the colonies of molluscs. Sir Henry Ward, in his graphic account of his visit to one of the series of pearl fisheries in his time, did not fail to notice the heavy and awkward movements of the regular diver under water, as contrasted with the lithe and rapid action of the next to nude native professional. As a matter of fact, Capt. Donnan, by the aid of a few well-trained and experienced native divers, who not only bring up specimens of the shells, but report on the conditions they have observed below, (for the divers keep their eyes open,—very wide open,) is better able to judge of the state and prospects of a bank, than he could be by any aid rendered by men in cumbersome diving dresses. Most useful are such men in exploring wrecks and in carefully and patiently building up submarine structures, such as our grand Colombo breakwater. But there are limits to their functions, and those limits are reached when it is attempted to employ them in connection with pearl banks or pearl fisheries. In calm clear weather, I believe the bottom is distincly visible through seven fathoms of water, (the *average* on the pearl banks,) and with a good glass to aid the eye, so, also, I should think, are most details of coral and algæ, living and dead shells, and even the movements occasionally of such fishes as skates and "old women," destructive enough, in all conscience, but not to be compared I suspect to the deadly operations of the voracious whelks, who only want a small chip on the edge of a shell, or the incautiously prolonged opening of the lips of its prey to make short work of the animal, whose nacre-secreting powers has made it so famous and so valuable. For scientific observation, however (observation which may lead to important economic results), I should think the electric light might be employed with advantage. There is very much in "the life history" of the pearl mussel (*Avicula [Meleagrina] margaritifera* of LINNÆUS), which is obscure or utterly unknown. We know that on banks with the proper conditions of depth of water and other circumstances, but the bottom of which is merely sand, the bivalves will not settle, because the ground presents no solid object to which the creature can anchor itself by its byssus, or beard, an organ which it has the power, often resorted to, of throwing off and renewing. A sandy bottom strewed profusely with coral or other rocky fragments, capable of offering a steady resting-place to the aggregated mollusks, presents the necessary conditions, with, always, about seven fathoms of water over the bank. So essential is this latter condition that if ever the hitherto abortive experiment of breeding pearl oysters artificially is to succeed, it must be secured. Shallow estuaries, the water of which has a warm temperature, such as the edible oyster rejoices in, would, we now know be fatal to "the pearl oyster." But all the conditions of a coral-strewed bottom in seven fathoms of water may be present, as they are in many places between Aripu and Chilaw, and yet the pearl shells will either never settle on them, or never settle long enough or in sufficient numbers to render a fishery of such banks profitable. Even on the two banks on which the oysters do settle and sometimes remain until they more or less attain maturity (the full term of life being seven years, but their fishing age ranging from 2½ to 4 years), the effects of currents by which the masses of spat are driven hither and thither, and the other conditions which lead the spat to settle, and fix themselves and grow for a longer or shorter period,—sometimes the whole millions vanishing as suddenly and mysteriously as they came,—are all wrapped in much obscurity and require patient investigation.

Of one thing my recent visit and observations have convinced me, that amongst the main reasons why, in the midst of all their capriciousness and precarions, the Modregam bank just fished and the Chevalpar now having so successfully dealt with are such favourite resorts of the pearl oysters, is *the large quantity of fresh water*, with all that it contains of vegetable and animal matter suitable as food for the animals, which several large rivers pour into the bay of Silavaturai. The fresh water, of course, floats for a long period over the salt, and Mr. Twynam told me he has dipped perfectly fresh water from the surface many miles from the shore. No doubt, in periods of extreme flood, the rivers may do harm instead of good to the oysters on the banks, by bringing down such enormous quantities of alluvial matter, that the bivalves are smothered in the resulting mud. This effect, when it has occurred has been easily seen and duly recorded, but I cannot at this moment recollect if due prominence has been given to the theory I venture to advance, or support, if it has been advanced, that under ordinary circumstances the rivers which embouch into the bay opposite the Modregam and Cheval Pars, which are only about twelve miles from the shore, must have an important influence for good: probably in modifying the temperature and quality of the sea water with which the fresh gradually amalgamates, but especially in the quantity of vegetable and animal matter, (land plants, leaves, and flowers, fresh water algæ, earth worms, insects of various kinds &c.,) they bring down and which, first their own momentum and then the currents carry over the bank and deposit amongst the oysters. Such is the strong belief forced on me, and I also feel that the Pearl Banks of Silavaturai, the "buried city" of Anuradhapura, and the Great Kalawewa lake, are connected together by a chain of most interesting physical circumstances, to which further reference may

be made. Meantime, let us congratulate Mr. Twynam and Capt. Donnan as well as the Governor and all the inhabitants of the Colony on the gratifying success of the JUBILEE YEAR PEARL FISHERY.

SLAVERY IN BRAZIL.—The Centro Abolicionista of Porto Alegre, Rio Grande do Sul, is proposing to inaugurate a popular subscription for the liberation of all the slaves in that province, which it is thought do not exceed 10,000. —*Rio News.*

MYSORE GOLD MINES.—Last month 674 tons 7 cwt. of ore were crushed by the Mysore Gold Mining Company and gave 906 3-5th oz. of gold. The Nundydroog Company crushed 65 tons of ore in February and March, and obtained 54½ oz. of gold. —*M. Mail*, April 9th.

A NEW INDUSTRY.—Mr. Evenor de Chazal, who is always foremost in advancing Colonial Industry, has just obtained the authority of the General Board to work a factory in St. Georges Street for the preparation of wine (*boisson vineuse*). We have at present no particulars as to the process, but we are told that it is calculated to be the means of producing a step in advance to colonial industry. We sincerely wish Mr. de Chazal every success in his enterprize.

"STROPHANTUS" is apparently the latest important addition to the "Pharmacopœia" and Mr. Neil S. Campbell has been sending the first specimen pods to the island, one of which has been sent to our office. Strophantus is described by competent authority as a great improvement on digitalis, for its influence over the heart—increasing blood tension, producing diuresis, and reducing temperature. The plant, the seeds of which are used is "Strophantus hispidus" which is widely distributed in Equatorial Africa.

THAT COFFEE TRADING COMPANY has at last been organized in Campinas, S. Paulo. The name is to be "Sociedade Anonyma Cooperativa dos Interesses da Lavoura" and the capital is 1,600,000$. It is needless to predict the result. We regret to notice the suicide, on the morning of the 19th, of Mr. S. A. Herforth. Mr. Herforth was a partner in the late firm of Kern, Hayn & Co., which become seriously embarrassed through unfortunate coffee operations some two years ago. Mr. Hayn committed suicide about a year ago, and Mr. Kern was, and possibly still is, confined in an insane asylum. Coffee has a good deal to answer for.—*Rio News.*

CURING COCOA.—The following advice on cocoa fermenting occurs in a report on Jamaica economic plants, probably by Mr. Morris: has it been tried in Ceylon? :—

A very simple means by which the process of fermentation may be set up in small quantities of the 'nibs,' is to put them into an empty kerosine tin or 'pan,' and then place them in the full sun, taking care to cover the opening close with a thick cloth, so that the sun, striking on the outside of the tin, raises the temperature. Two, or at most three, days is sufficient for this purpose; they should then be carefully washed with clean water until all the adhering mucilage has disappeared, then thoroughly dried in the sun. Cocoa dried by this method brings a much larger price than that sent to market without fermentation, and the practice is one by which small cultivators could not fail to be largely benefited were it made known among them by clergymen and others who come into frequent contact with the people."

THE TALLOW TREE OF CHINA.—Vegetable fats and wax have long been known, but it is only recently that the above has attracted the attention of the soap manufacturing fraternity. It is cheaper than animal tallow, and is said to be capable of producing very good soap. The tree which yields it is a native of China, and it is from the kernel of the fruit, says the *Technische Seifensieder*, that the tallow and oil are obtained. A thick layer of tallow envelopes the nut, which also contains a yellowish aromatic oil, used for heating and other purposes. When the fruit is gathered, hot water is poured over it, which is allowed to cool, and the tallow which has congealed on the surface is easily removed, after which it is again carefully melted, and run into moulds, ready for the market. It possesses a peculiar odour, which is not unpleasant, is crystalline, of a greenish colour, and melts at 40°.—*Burgoyne Burbidges.*

A WATER PLANT CATCHING FISH.—The bladders of the curious water weed—Utricularia—still occupy the attention of the curious in the Old World. The fact that these bladders caught living things was first observed in this country by Mrs. Mary Treat, of Vineland, N. J.; but the fact does not seem to have attracted the same wonderment in America as in the Old World, where it is a continuous topic with newspaper writers. The bladders are very small, not much larger than small bird shot, and when the magazines which love to put the sensational into scientific topics talk about the plant being a dangerous enemy to the fish culturist, we have to make all due allowances. Very small fish are caught, and larger ones, as Professor Mosely says, held by the tail till they die; but these unfortunates will be but a small portion of those that would be caught and eaten by the larger fish. Very few of the immense number spawned reach maturity, plentiful though the stock may seem to the fisherman. For what purpose the bladders catch the animalculæ and minute creatures is not known, if, indeed, there is any special purpose of this kind. Professor Mosely says that it has not been found that there is any digestive operation going on, as it is believed there is in some of the carnivorous plants, more properly so called.—*Independent.*

OUR PEARL OYSTER BEDS.—We read:—The forty years' experience of Messrs. Barnett & Foster, Forston Street, London, as manufacturers of submarine appliances of all kinds was exemplified in a display of divers' dresses and equipments, atmospheric engines, compressing-pumps, and safety-lamps. The last-named exhibit was certainly *the* novelty of the display, and carried the palm in point of interest. Foster & Fleuss's new lamp, broadly described, is a modification of Foster's submarine lamp, being, so far as the production of the lights is concerned, an adaptation of the well-known lime-light. The lamp may be said to consist of two parts, the lower portion or bottom comprising the gas reservoir; while the upper portion forms a sort of double hood, nearly one inch apart, which is filled with water to keep the lamp cool for mining purposes, and which screws on to the lower part, so as to form an air-tight joint. Shortly prior to the invention of this lamp Messrs. Barnett & Foster patented a new diving-apparatus, which entirely dispenses with pumps, tubes, and all extraneous arrangements. Together these inventions represent the most noteworthy advance in this direction of modern times; while at the same time they mark an important revolution in the theory and practice of submarine exploration. Provided with these truly invaluable appliances, it is possible for a man to continue to work for several hours at a time without any communication with the external atmosphere, thereby justifying the hope and belief that, with further practice and experience, the new principle may be largely applied in exposing and recovering life after colliery explosions.—*Home Paper.*

[By means of such apparatus we ought to obtain better knowledge than we possess of the laws which rule the life and progress of the pearl shells, so that the regular cultivation may yet be rendered possible.—ED.]

THE INTRODUCTION OF COFFEE CULTURE INTO THE ISLAND OF CEYLON.

To Mr. Advocate de Vos of Galle, we are indebted for the following translation of some notes of P. A. Leupe on the history of coffee culture in Ceylon found among a collection of Dutch MSS. Mr. de Vos found the writing very indistinct, but he has done his best with it. Can the original of this be in the Government Record Office? The letter dated 27th July 1719 was written by the Directors to the Principal Government, that is at Batavia. As it referred to Ceylon, a copy of it must have been forwarded in the usual course to the Ceylon Government:—

In the "Nieuwe Amsterdamsche Courant" Algemene Handelsblad (General trade list) of the 29th January No. 19,704, we read under the East Indian intelligence from Batavia of the 16th December last year in a report of the officer the Heer C. W. P. A. van Spall on coffee culture in Ceylon, amongst others the following:—"That the cultivation of coffee in Ceylon by the native population was commenced in 1690 when that island was under our rule: that that culture was continually encouraged by the servants of the East India Company with more or less earnestness with "the result that the exportation of coffee in 1739 from that island amounted to 100,000 pounds etc." This is in a certain sense—so far as the introduction of coffee culture is concerned—opposed to fact. We are forced to infer that Heer van Spall is unacquainted with a little work entitled "Invoering van Koffy Kultuur op Java" (Introduction of coffee culture into Java) contributed by us to the "Koninklyk Instituut voor de Taal—Land—en Volkenkunde van N. I." (The Royal Institute of the knowledge of language—countries and peoples) and incorporated by the Government into their memoirs where it is said, "that in the year 1719 in Ceylon, the experiment should be tried to make the leaseholders of legally and illegally acquired lands being suited to the cultivation of coffee to reserve (unite) them for that culture."

Thus it was not before 1719 that people thought of trying the experiment of planting coffee in Ceylon. We are in a position to state what brought this about. In the letter sent by the Directors to the Principal Government in that year, 27th July 1719, we read the following:—"The low and marshy lands mentioned by Governor Rumph and Council in their letter have made us think of coffee culture (being a tree) which requires almost no trouble or labour, and the Company will in the present state of affairs, profit much if people will zealously engage in it and if it could be obtained from its own soil and marshes. Therefore, we cannot refrain from taking this opportunity of submitting to your consideration what has occurred to us in respect of this matter, viz., that this tree prefers a shady spot or marshy soil and once planted grows without need for any further trouble, nay ought or can one prune it being in need of no other care than only when the tree becomes big and sometimes through over-bearing some of its branches, which are always thin and long, fall off they must be broken to make room for the new ones which soon shoot out from the stem. The gathering of the berries is also not much trouble; for, to get good, ripe and full coffee-berries, they ought not to be plucked from the tree but one should wait till they fall off and then collect them in a dry place with a small wooden rake with teeth so close to each other as not to allow the berries to pass between them till they are again stored in a dry place under cover without anything further being required. The stones sufficiently grow of themselves if only they are not too dry and hard of kind as we found out from the coffee seeds formerely brought from Mocha, and it is reckoned that each tree produces in the third year at least one and in the tenth year at least 5 lb. of cured coffee. Remembering, therefore, the benefits which will result not only to the owners and renters of lands but also to the Company, we think that it is well worth trying the experiment."

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, March 19.

M. Andourd, chemist, draws attention to the loss of nitrogen resulting from the mixture of nitrates and phosphates. In one of the departments of France, a mixture of nitrate of soda and mineral phosphate was carefully prepared and sold to various farmers. The mixture represented six per cent of nitric acid. In a short time the fertilizer rapidly lost its fertility which went on steadily declining. Between the 6th June and 14th July, the percentage of nitrogen declined from 6½ to 3½. Another mixture at the moment of fabrication, registered 2 per cent of nitrogen, lost in fifteen days, something over the moiety. In some of the samples, the alteration of the nitrogen was so rapid that the mass was full of bubble-holes, caused by the elimination of nitrogenized gases. Indeed some of these were gathered in a receiver. Artificial experiment confirmed the escape of nitrogenous gases from the two mixed fertilizers, varying in the space of one month, between 17 and 33 per cent.

In the case of sulphate of ammonia, the loss was from 5 to 15 per cent. What then must be the loss at the factory, where the mixture is prepared in large quantities, and exposed to the sun's rays? because, between a temperature of 77 to 100 degrees F. the disengagement of nitrogen is very active, and once commenced will be kept up even when the temperature falls as low as 54 degrees. Slow or quick, the elimination of the gas is certain when the nitrate and phosphate are intimately mixed. And yet the escape of nitrogenous gases can be only checked by employing the nitrate in a lumpy form, that which is injurious to vegetation. Clearly the mixing of the fertilizers should take place close to the time of using them.

Since nearly quarter of a century, Saxony suffers from a scourge of insects—*nematodes*—which prey on the roots of sugar beet, as the phylloxera does on those of the vine; the damage is relatively as serious Professor Kuehen has tried sulphuret of carbon, but not with much result. He relies on "trap plants," to catch the myriad-enemy. The nematodes are also partial to all cruciferæ plants; on a soil infected with the insect, sow white mustard, rape &c. When the latter have attained a pulling height, pull them; cast them away, as the roots will be a mass of the insects. Repeat this plant-trap two or three times, and the enemy will be extirpated, while the beet which had fallen to seven tons per acre, will increase to seventeen. M. Girard relies on sulphuret or carbon; dose, 10 ounces per square yard, deposited in the soil, the fumes of the chemical killed the insects right off, and the land, purged from the enemy, the yield of beet rose from two to nineteen tons per acre, and the saccharine riches of the roots, from 4 to 12 per cent.

French farmers appear inclined to pay serious attention to tobacco culture. It would seem that seed from Southern Russia suits best their soil and regions. Many authorities maintain, that the Russian equals the best second class Turkish tobacco, while the plant is more hardy.

THE JAPAN CEDAR.

(Cryptomeria Japonica).

The following are extracts from a notice in *Forestry* of the Japan tree from with most of the tea boxes which Ceylon is now receiving from Japan are made:—

Forty-one years ago, or during 1844, the Horticultural Society of London, through their collector, Mr. Robert Fortune, sent seeds of the above interesting tree from Shanghai, the produce of which has now in this country attained, in several instances at least, heights varying from 60 feet to 75 feet—rapid growth, it must be admitted, for a Japanese conifer in Britain. Delighting and thriving most luxuriantly in cool, damp soils, the humid atmosphere of Great Britain is peculiarly well suited for the successful cultivation of this handsome conifer. When seen at its best, the

Japan Cedar is a tall, portly tree, of somewhat conical habit of growth, with a clean, straight stem of fully 1000 feet high, and 4 feet or so in diameter.

The branches spread horizontally, are slightly drooping with up-curved tips, the lateral ones dividing into numerous frondose branchlets, thickly covered with bright, glossy green foliage.

Leaves fully half-an-inch in length, rigid, incurved or awl-shaped, and oppressed to the stem, obscurely quadrangular, and marked rather indistinctly with two glaucous silvery lines beneath. The flowers are monœcious, or both male and female on the same plant. Male catkins of an oval or oblong shape, and produced in great abundance in the axils of the leaves at the extremities of the branchlets. Cones globular, about three-quarters of an inch in diameter, terminal, singly, and usually erect. This distinct and beautiful conifer, although at first branded with a semi-tender character, is found to be perfectly hardy, sound in constitution, of very rapid growth after it has become thoroughly established, and by no means fastidious as to soil or situation, provided the former be naturally sweet and healthy, or artificially made so. Although usually asserted that this tree only thrives, or at least thrives best, on damp soil and in low sheltered situations, a comparison of the trees growing in Penrhyn Park and in other situations over the estate, hardly upholds this theory, for some of our most luxuriant specimens are growing in deep, sandy loam, with the happy medium of neither excess nor want of moisture. Judging from the specimens here, I should say plant the *Cryptomeria* in good dampish, but not stiff loam, where partial shelter is afforded, and all the better if in a shadyish situation—by this I mean a northern or eastern aspect, where direct sunshine is prevented. Better, indeed, than the generality of coniferous trees, the Japan Cedar seems to thrive in the dense, still air of mid-woodland, and is even not fastidious about the juxtaposition of surrounding trees, so as their extending branches do not actually commingle with its own.

Both in Japan and China, into which latter country it is generally supposed to have been introduced, this tree is largely employed for ornamental planting, such as in the formation of avenues for clumps and groves, and as single specimens in the gardens and grounds.

In Japan there is an avenue of fully thirty miles in length closely planted with this tree, while others of shorter lengths are not uncommon.

The timber of *Cryptomeria Japonica* is light but lasting, and largely employed for room-panelling, for furniture generally, and in the making of light packing-cases. It is white, soft, and easily worked, with a pleasant perfume, which makes its adoption for panelling or room furniture particularly desirable. As might be expected, the wood of this tree produced in Britain differs but little from foreign specimens, at least such was our verdict after an impartial examination.

A. D. WEBSTER.

Penrhyn Castle, North Wales.

COAL.—At a recent lecture delivered in Philadelphia by a promisent scientist, the gentleman said it takes a prodigious amount of vegetable matter to form a layer of coal; that the present growth of the world would make, a layer only one-eighth of an inch thick, and that it would take a million years to form a coal-bed 100 feet thick.—*Journal of Forestry.*

AMONG articles exported from India spices figure to the extent of 43,061,335 rupees, an augmentation of nearly 100 per cent during the last five years, notwithstanding the decline in the exports of pepper. The shipments of ginger are growing very rapidly. About 7 millions out of 10¾ millions lb. exported were sent to Europe, where a fine appetite for Indian ginger seems developing. Exports of cardamoms are falling heavily, and no wonder, since Ceylon—which is not, of course, included in the report—has nearly supplanted India as a purveyor of that spice.—*Chemist and Druggist.*

WE see it asserted in a French medical journal that a correspondent has "killed" the phylloxera by planting Datura Stramonium among his vines. We venture to doubt the correctness of the assertion, or at least to suggest that more evidence be forthcoming.—*Indian Agriculturist.*

MOSQUITOES.—It is said that nitre paper burned in a room will drive out mosquitoes. We have not tried this, but a mixture of equal parts of essential oils of eucalyptus and lavender applied freely to the skin will repel their attacks. And we can assert from experience that essential oil of lavender applied to a bite without delay will at once relieve all irritation and prevent swelling.—*Chemist and Druggist.*

TIMBER merchants are anxiously watching the progress of an American invention for drying wood by a quick process in which cold air plays an important part. Instead of wasting time and causing loss of interest on capital in the shape of timber on hand, which needs three to seven years to mature naturally, it is claimed for the new process that it matures wood in three days. A tree felled to-day can be delivered, sawn into shape, and ready for use in the building and furniture trades next week.—*Journal of Forestry.*

TEA PLANTS AND THEIR LEAVES.—The Editor of the *Forestry* replying to a correspondent, who stated "the Tea plants live though denuded of their leaves," wrote:—That "tea plants will live without leaves" for a time is true (so also will plants generally), but that they will do so for long or indefinitely is an error borne out by everyday experience. Responsive action between the leaves and the roots must be sustained, else there can be no living and thriving for any length of time in any plant. The herbaceous condition of the shoots that spring from the roots of recently felled trees enable them to fulfil the functions of leaves for a time, till leaves are put forth, and prove that nature is not without resource when by accident or design disturbance of the balance of functional action takes place.

A SHORT time ago it was given out that paper rails had been made and successfully tested. Now, the same material has been utilised for making pipes, and a certain quantity of such pipes have been exhibited in Vienna. The process is as follows:—Strips of paper, the width of which corresponds with the length of one pipe section, are drawn through melted asphalt and wound upon a mandril. When the pipe thus made has cooled the mandril is withdrawn, and the inside is covered with a kind of enamel the nature of which comprises the main secret of the invention, and is, therefore, not made known. The outside is painted with asphalt varnish, and dusted over with sand. It is stated that such a pipe will resist some 2000 lb. internal pressure, though the thickness of the stuff is only about ½ inch. *Indian Agriculturist.*

EUCALYPTS IN ITALY.—We learn from a German authority that the plantations of eucalypts made in malarious districts in Italy have so far proved a failure. The trees do not grow; either the soil or the climate, or both, are unfavourable. This is somewhat wonderful in a tree that in this less favoured climate makes astonishing progress in summer; only, however, in the milder districts, and not always in even them, to be spared by our severe winters. It is not only wonderful, but disappointing that a tree which a few years ago was trumpeted so loudly as a specific against malarial fever, should fail in the largest experiment ever tried with it. We are afraid it is no fit subject to plant in marshes, for even if it succeeded in growing well, the growth would be of such a spongy nature that winter's frost even in many parts of sunny Italy would be fatal to it. We find the same authority recommending *Laurus glandulosus*, various American and Indian *Acers*, *Salix Babylonica*, and several poplars as substitutes for the eucalypts, and claiming for them several febrifugal properties to those claimed for the eucalypts. We are not aware that this claim for the latter has ever been advanced on reliable grounds, and this grand Italian experiment having failed, we are not likely soon to have the point satisfactorily settled.—*Journal of Forestry.*

CHINA TEAS.

We have been favoured with a copy of a London Circular prepared by a Broking Firm for its constituents concerned in China teas and, as everything connected with the subject is of interest to the Ceylon planting and mercantile public just now, we append the greater part as follows :—

As usual at this time of year we have the pleasure of giving you our ideas as to the position and prospects for the coming Tea season, and our views as to probable safe limits, which we commend to your attention. The political outlook is not reassuring, and affairs at home certainly do not show much advance from the late continued depression in trade. The state of Ireland, too, is most critical, and there is no certainty as to the continuance in office of the present Unionist Government. The position you have to face is this—the taste of the public is fast leaving China Tea. In the coming season 100 millions from other countries, costing the grower no more than an all-round price of 7½d to 9½d, according to the locality, will be knocked down as it arrives at the best price it will fetch. To compete, therefore, you must send us a better article (strength the great desideratum), at a low cost, and even to support present currencies much less of it. For the coming season we estimate this supply at—

India	... ...	82,000,000 lb.
Ceylon	... ...	18,000,000 „
Java	... ...	5,000,000 „

Leaving 115,000,000 lb. to be provided by China to make up our probable delivery, including Exports, of 220,000,000 lb. Our delivery is not increasing by "leaps and bounds," but since 1884 has remained stationary, we, therefore, do not require 128,000,000 lb. from China, as estimated by some brokers. We give you the usual table of deliveries which speaks for itself.

Deliveries excluding shipments to the Continent and elsewhere.

	Indian.	Ceylon. lb.	Java. lb.	Chinas. lb.
1886	68,420,000	6,245,000	3,677,000	98,249,000
1885	65,677,000	3,218,000	3 536,000	105,710,000
1884	63,038,000	1,179,000	3,709,000	107,395,000
1883	59,096,000	incl. in Indian	2,893,000	111,291,000
1882	50,497,000	„ „	1,787,000	115,990,000

The Home consumption of Chinas falls off 7½ millions, and that of Indian, Ceylon and Java increases nearly 6 millions. The Chinas showing a reduction of 17¾ millions in five years.

For the first two months of the year the comparison is even more marked:

	Indian, Ceylon and Java...			
	10,741,600	12,643,144	12,236,052	15,778,098
Chinas	...18,609,600	18,283,299	17,301,221	15,176,993

Our stock of Congou on the 1st July will be rather larger than last year, and with the experience then gathered, we see no great chance of improvement from our present scale of values for common Teas. In regard to fine Teas, both black and red, Indians and Ceylons have taken their place for Home trade, and there is now hardly a quotation over 1s 3d. For months hardly a sale of fine Tea took place, except at auction, and results to holders are simply disastrous.

NORTHERN TEAS.—The crop of last season was undoubtedly a fine one, but was generally so thin as to be very unsuitable for the Home trade. Even with the scarcity of fine Indians, prices for choice Chinas could not be kept up to anything like old levels, and fell away from 4d to 8d per lb. This drop in fine and finest acted on the grades below, and brought them down too. Keemuns have suffered most in the general depression, and finest first chops have been sold under 1s per lb.

We give below a range of prices, which with a crop of average quality, we consider it safe to buy at, including the usual buying and selling commissions :—Finest 1st Pack. Ningchows and Keemuns (a few exceptionally choice parcels up to 1s 6d.) 1s 3d to 1s 4d per lb.

1st Pack Ningchows and Keemuns, if not quite up to finest 1s 1d to 1s 2d per lb.

Finest 1st Pack Taow Yuens, Oonfaas, Cheong-Sow-Kais, and Suun Yangs, also finest 2nd Pack Ningchows and Keemuns 1s 0d to 1s 1d per lb.

(Should the Kiukiang crop be very inferior, a few of the choicest Taow Yuens might be bought up to 1s 2d per lb.)

1st Pack Taow Yuens, if not up to finest, the best of the 1st Pack Tong Shans, and fine 2nd Pack Ningchows and Keemuns 0s 11d to 1s 0d per lb.

Good first Pack Oonfaas, Cheong-Sow-Kais, Suun Yangs, a few of the choicest Yung-Low-Toongs and Kut Oans, and the inferior 2nd Pack, Keemuns and Ningchows 0s 9d to 0s 11d. per lb.

For last crops of grades below the above 10 per cent. under last year's selling prices on arrival are the safest limit.

Second Crops.—The best Ningchows might be bought up to 10d and Keemuns up to 9½d., while 7d. is the highest that should be paid for Hankow district Teas. These limits, however, are only safe if the first crop prove a small one.

Red Leafs.—We have had a steady market all through the season for these, but with anything like the same quantity next season a smart fall in values must be expected. Paklum, the finest Tea of the year was sold ex first steamer at 1s 3½d., and there is no reason to think that this will not again be the top price. Soomooas, Qui Fars and Cheong Loks, "Une Heong" was the solitary sale over 1s 6d but we should be sorry to place the value of this exceptional parcel over 1s 4d., and the rest of the crop in proportion. Pan Yongs, one of the finest Teas of the season was sold on arrival at 1s 6d., but at this price the Trade would take no more, and the next sale for a crack chop quite as good was 1s 4d. 1s 3d has been the top price for the last five months for retail quantities of the choicest chops shipped. If the Colonies can afford to pay 1s 8d for a similar quality, naturally they must take the pick of the crop but 1s 3d. s quite enough to pay for anything to this market

Saryunes: One or two chops that always stand out may fetch 1s. Ordinary finest first chops are not worth over 9d, in fact at the lowest point of the market this season they sold down to 7¾d. Paklings. The market was regularly opened at 1s 0½d for crack chops and this price may be again obtained if the supply of boxes is not overdone. Souchongs: To make Teas with any quality at all the Sinchune district can evidently not produce 57,000 chests. Probably with a 20,000 chests less crop, and a return to their old standard of excellence, they would again come into favour. As a guide we give the following limits :—

Soomoos.	Crack Chops of the Cheang-Mow class	1s 3d to 1s 4d.
	Crack Chops of the Cheang Kee class	1s 1d to 1s 2d.
	The inferior class of first Chops	0s 10d to 1s.
Paklums.	Choicest with true Flowery pekoe water	1s 3d.

Pan Yongs. Finest 1s 1d to 1s 3d 2nd class 9d to 10d 3rd class 7d to 8d.

Paklings. Finest 1s to 1s 1d 2nd class 8½d to 9½d 3r d8d.

Saryunes. Finest 8d to 9½d 2nd class 7d to 7½d 3rd 6d to 6½d.

Yunghows. Finest 8d to 8½d 2nd 7d 3rd class 6d to 6½d.

Suey Kuts. Finest 8d to 9½d 2nd class 7d to 7½d 3rd class 6d to 6½d.

The value of second and third crops will depend, to some extent, on their quality; but more on the size of the first crop.

Souchongs. Choicest 1s 8d. Finest 1s 4d. Fine 1s 1d.

We have been told that at these prices "we should not have 5 lacs of Congou," with which statement we do not in any way agree; but, at any rate, our proportion of 5 lacs would be much more in unison with our requirements than 7¼! In the old days the crack Soomoos were bought at Tls. 17 and 18. Why not again? Filth such as we have received at the

end of this season, with a black infusion may be knocked off the Export altogether. Our present quotations of 4½d to 5d should settle the question, as it must be under the cost of production.

NETHERLANDS INDIA: JAVA.

We are always pleased to see, and to listen attentively to, anything that Mr. J. P. Van den Berg writes on Java. He has lately compiled two exhaustive letters on the financial and commercial condition of Netherlands India. If any one desires to make himself acquainted with the present condition of Holland's colonies in the East, he cannot do better than turn, when he has an opportunity of so doing, to any work by the President of the Java Bank. The tolerably heavy pamphlet which Mr. Van den Berg has written for H. B. M.'s Consul at Batavia, in reply to queries from the British Indian Government, is marked only for private circulation. We trust that it may be formally published, as the facts are martialled in proper array, and one can tell at a glance the economic position of the countries. Broadly speaking, it deals first with the financial situation; secondly, with the commercial condition; and, thirdly, in a second letter we have some remarks on the question of currency. We will take them in the order Mr. Van den Berg places them before us, only regretting that space will not permit us to do so at a length that the importance of the subject demands.

One very import point to be noted in connection with the finances is the extreme instability of the revenue of Netherlands India, the fluctuations being really of a violent nature. This is of course in large part due to the fact that the colony is dependent on the prices it realises for produce sent to Europe for sale. It has always occurred to us, and the system has been more than once animadverted upon in these columns, that the custom of including the Budget of the colonies in that of the mother country is exceedingly inconvenient, and approximately accurate figures cannot be determined on. It must be apparent that the figures which, at the time we write, have, say, just been despatched for next year (1888), can only be roughly put down. By all means let the Colonial Minister retain the power of vetoing the colonial proposals, should he have sufficient cause to do so; much in the same way as is adopted in the case of British Crown Colonies. This is a detail; but the suggestion is, we think, worthy of serious consideration. We wish that the question of the deficits were as easily reckoned with. From 1876 to 1884 the Netherlands India have been spending on an average eight millions of guilders more than their revenue. The Acheen war is the primary cause of the disturbance in the desired equilibrium. Before it commenced "the normal military and naval expenditure may be taken in round numbers as having averaged f. 30,000,000 per annum. During the period of 1873-1884 the yearly average increased to about f.50,000, thus showing a difference of f. 20,000,000 a year, or f. 240,000,000 in the course of the last twelve years, which amount may be taken as the usual actual cost of the Acheen war, apart from the expenses for civil purposes in the newly-annexed territory, which appear under other heads of the Budget." Railways the Batavia Harbour Works, and the measures for the suppression of the cattle disease also made heavy inroads in the revenue, amounting in all to some 335,000,000 guilders. In the connection of Public Works Mr. Van den Berg contends that the money should have been procured on loan, as circumstances required, and not have been charged against current revenue. To meet all these heavy calls the Government had to resort to new taxes, and readjust others, so that they yielded their maximum. So much were the imposts increased that once or twice trouble has been on the verge of being the result. And yet the deficits were not overtaken; despite the fact that the system of taxation included many items which are generally of a purely municipal character. This may, perhaps, be owing, however, to the fact that the country is destitute of any special provincial or municipal funds.

Of the commercial condition Mr. Van den Berg, though he points out the disasters which have to be met, conveys a more hopeful impression than most writings on Netherlands India have assumed since 1884. That matters are bad in sugar, however, he thus points out:—"On the whole the actual position of the Java sugar industry which, as stated in my former letter, is a matter of vital importance to the welfare of the island, may be called rather critical. Many estates have run largely into debt, and unless a material improvement of prices sets in, it may be taken for granted that the year 1887 will bring ruin on more than one estate which till now has been able to keep up the struggle, on the issue of which the future of the colony so largely depends." Sugar is, of course, the most vital interest of Java, and thus of the whole colony. It is a matter discussed by every one who has any interest directly or indirectly in the colony, and the system of bounties and the production of beetroot are more keenly studied than in this country, deputations and Chambers of Commerce memorials notwithstanding. Van den Besch's system created in 1831, and which has in the past very largely conduced to the prosperity of the colony, is now shown to be of no further practical utility. This system, as far as sugar is concerned, will be terminated in 1889, and only coffee will then remain, which in turn will, we presume, be likewise turned over to free labour and private enterprise, what is to be done for the future then? The Acheen war seems farther off a conclusion than it was at the commencement of the present decade. We wish that Mr. Van den Berg had proceeded and answered this question, as from his long experience he would be well qualified to do.

We can only mention the long dissertation on the question of currency which Mr. Van den Berg so ably argues out. As a banker and a person who has devoted considerable attention to the questions of bimetalism, the appreciation of gold, &c., his opinions carry considerable weight. He concludes that the disadvantages, by raising so largely the prices of imports, would more than counterbalance the increased rates obtained for produce, whilst it would be unfair to Government officers dependent for their incomes on silver, and to capitalists in Holland who have invested in estates in Java, to upset the present equilibrium. He therefore argues against any change in the present currency regulations.—*L. & C. Express.*

THE BREAK IN QUININE.

(New York Drug Reporter, March 16.*)*

The cause of the depression in the quinine market is one of the mysteries that defy investigation. No one appears to have any decided opinion as to the reason why prices should have taken such a remarkable tumble during the past week or two, but the impression prevails that it is due to one of two causes; namely, that either the small holders became frightened when the market fell off a cent or two at the beginning of the downward movement and have been unloading ever since; or that the market is being depressed by some large operator or operators with a purpose. In support of the first mentioned reason it is stated that when prices were so low a few weeks ago and everybody was talking of much higher prices as the inevitable outcome of the position of bark at that, time, many small speculators including clerks and even truckmen connected with the large houses, and not a few similarly situated in other branches of trade took a flyer in quinine. Without capital to hold out for any length of time they were forced to sell as soon as the market developed any signs of weakness, and their anxiety to get out precipated the decline. Those who hold to this version believe that nearly all of the weak holders have unloaded, and that in a few days a decided change for the better will occur. There seems to be less tangible grounds for the impression that large operators are bearing the market, the only cause for such a belief being apparently the favorable opinion of the future that such operators are believed to entertain, because of such remarks as they may have let drop in confidential moments.

Probably both of these have been factors in bringing about the depression, but possibly the present situation

of the bark market is at the bottom of all the trouble. At nearly all the public sales of bark in London for several months past the representatives of American manufacturers have been conspicuous buyers, bidding up prices until the foreign manufacturers had to stand aside and let them make the bulk of the purchases. During all this time reports have been freely circulated on this side to the effect that a very large decline in the production of bark would greatly reduce the supply for consumption this year and must inevitably result in much higher prices for the alkaloid. As these reports were fully substantiated, apparently, by the very convincing array of facts and figures accompanying them, they had a very decided effect upon the market for a time and when prices for quinine did begin to advance early in the year it was believed by many to be the direct result of the causes indicated by these reports. Now, however, it would appear that the bark situation is not so encouraging as the people on this side had been led to believe, if the result of the last fortnightly sale is a criterion. From late mail advices we learn that at this sale the German manufacturers, who heretofore had been virtually kept out of the market by the spirited bidding of the Americans, were the principal buyers, and that they got all they wanted at their own prices. This would indicate either that the makers on this side were satisfied to let the price of bark drop for a time, or that they had discovered new facts which induced them to change their views regarding the supply. In referring to the last bark sale a London contemporary says: —"That the affair has been badly managed on the other side there is no doubt, for it was little short of madness to attempt to bull the market without first of all ascertaining the prospects of East India barks. As it stands the shipments are fully up to last year, and the market upset; besides which all the advances in prices have been not only lost, but the unit lowered without doing the slightest good, beyond putting a few thousands into the Ceylon planters' pockets."

CEYLON UPCOUNTRY PLANTING REPORT.

WEATHER CHANGES AND PLANTERS' FEELINGS—THE LITTLE MONSOON AND TEA FLUSH—THE 'SHADOW' OF BUG—CACAO.

24th April, 1887.

A change in the weather has a marked effect on a planter's feelings; as well as in his ideas of the value of estate property. After some weeks of roasting weather, when all growth has been checked; the ground baked into the hardness of the kiln-dried brick: the mind wearied out with an unprofitable wrestle to know the future, and the solution of the questions what will the place do? and what is its worth? then comes the rain, and with it what a change.

The soil which had looked as unfruitful as the public highway, becomes a rich loam dropping with fatness; the bursting buds of promise whose growth may almost be seen, fail to expand themselves with anything like the rapidity which marks the opening of the vision of the cultivator; and where before there was but the potential grave of a buried treasure or at best the scene of long and unrewarded labour, there is now the site of a successful venture—an apocalypse of a glorious resurrection of buried coin.

It is well we have these bright days. "Look here," said a man to me the other day, "I would not sell my place now for four times what it cost me." I suppose he will stick to that—till he changes his mind.

Certainly this little monsoon has altered the face of things. Tea has almost run away with itself; cacao looks fit for anything; and the green of the foliage of the cinchona trees deepens its shade daily. As to coffee, it has allured us with blossoms so abundant that as "Tip Thompson" used to say "you could not put another spike on, even with a pair of pincers"; and there is such a promise of harvest that we all are ready to declare that even in its best days, better was not to be seen. Bright-eyed hope is wide-awake, we all look forward to fortunes, and the value of estate properties has risen all round. Pretty good results these to point to from a change in weather.

Of course there are shadows, and the worst is the bug. What an infliction that means, can sometimes be calculated by a man's diminished rotundity—a loss of flesh, as well as rupees. In whatever form the insect makes itself felt, none is agreeable. It is the "Kismet" of the planter which "sits and waits;" and is as seemingly hopeless to struggle against as any other form of fate before which the mind of the Eastern collapses. It is not until a man has had a real tussle with the green bug that he knows its power and the despair it inspires. I have seen it attack fields of coffee which were fit almost for a place in Paradise, and in a few months there was little to be seen but a howling, blackened waste, and to cure it I have never known anything do any good. When I read, therefore, of the efforts which are being put forth, by those unfortunates who are but making their first acquaintance with this pest of pests, of kerosine, mana grass, lime, sulphur, manure *et hoc genus omne*, it is like the re-acting of your past, a revival of blasted hopes—a wasting of good coin. We have reached that startling crisis which never comes very kindly home to our people—that of having *wholly* to "lippen to Providence," as to whether this insignificant visitor will swallow up what little good coffee is left, or disappear as mysteriously as it has come. Of course, there is the disposition with the price of coffee rapidly approaching 100s a cwt. and our trees bearing an extra fine crop to be more than usually staggered at this new influx of bug and perhaps to express a puzzled surprise as to what Providence is thinking about!

It is a comfort to know that the increase of cocoa stocks in London, which has had the effect of lowering its price so much, is not likely to go on, and that the prospects are favourable for a turn in the tide in regard to selling rates. This result is ours through the misfortune of the Demerera men having a bad cacao crop. Cacao is looking as if it would do its best to supply what is wanting.

PEPPERCORN.

COCONUT NOTES: COPRA DRYING.

(*Communicated.*)

COCHIN *v.* CEYLON OIL—WESTERN PROVINCE COPRA *v.* NORTH-WESTERN—WHAT THE VILLAGERS DO?—DIFFERENT KINDS OF COPRA—A PRACTICABLE COPRA DRYING-HOUSE FOR THE SOUTH-WEST OF CEYLON.

By last report Cochin coconut oil was selling at £37, while Ceylon could only obtain £26. At no former time has the one been so high and the other so low-priced, the difference being equal to 45·44 per cent. It has been suggested locally, that there may be a difference in the chemical constitution of the two commodities, but Mr. Field ascribes the inferiority of our product entirely, to colour and smell in his report to our Commissioner. If the inferiority should turn out to be due to a chemical defect there would be little hope of finding a remedy, but if the colour and smell are the faults—the only ones—the remedy is on the surface. Ceylon coconut

oil may be made as bright and colourless, and when newly drawn almost as scentless as filtered water. The colour and most probably the disagreeable smell are entirely due to bad treatment. Many of the villagers gather unripe nuts and pay very little attention to the drying of the copra; they thus produce a dirty half-rotten copra that sells very low. The Western Province estate proprietors almost to a man sell their nuts to traders, who smoke the copra when half-dry. The planters of the North-Western Province enjoy dry weather during the greater part of the year which enables them to dry their copra with very little trouble and being a long way from the market, it goes on drying in the boats even if only partially dry when dispatched. This is the cleanest, the driest, and consequently the highest-priced copra, and if manufactured separately, would probably yield an oil equal to Cochin, but it suits the oil-maker's book to mix all the various qualities of copra and make one uniform quality of oil and the inferiority of our produce in the European markets is the result.

When the villagers are not induced to take greater care in the preparation of their copra by the relatively low price they obtain, there is little hope of reaching them in any other way, but the class that own estates of 10 acres and upwards are, as a rule, more intelligent and energetic, and generally sufficiently awake to their own interests. Estate proprietors say, however, that they make more of their crops by selling them to traders than by preparing the copra, and disposing of it on their own account. This to a simple mind seems an incredible statement, for the trader will certainly not continue to carry on a business that yields him no profit, while exposing him to the risk of loss in the fluctuations of the market; nor can the trader prepare the copra and send it to market at a cheaper rate than the estate proprietor. The statement is true, nevertheless, and two causes operate to make it so. The experienced trader knows to a nicety the amount of drying that will pass muster, while the planter anxious to produce a good quality, continnues the drying far beyond the trader's point and in consequence takes from 5 to 100 more nuts to the candy than the trader. This would be all right were a close and skilful discrimination exercised by the buyers, but what nicety can be expected from those who do not take clean and dry as their standard, but fix the price by the mode of bringing the article to market. Thus we find the prices stated in the market reports as boat copra R38·50, cart copra R32·50. The way to test the value of copra would be to weigh a sample carefully, and then subject it to 250 degrees of heat for two hours, then weigh it again and note how much it has lost. Thus if the price of the day be R40 for perfectly dry and clean copra, say the sample has lost 8 per cent in the process of desiccation reducing the value by R3·20 and it is discoloured by smoke for which deduct R1·50 more, making R4·70; the value will, therefore, be R35·30 and so on for still worse lots. The drier copra is, it yields the more oil in proportion to its weight; the cleaner it is, it yields the better quality; an inferior quality may suit the trader and the oil manufacturer, but it is on the producer of the raw material that the loss of the difference in price of Cochin and Ceylon oil ultimately falls and with him lies the remedy, if a remedy is ever to be applied. All that the planter can do in the first place is to dry his own copra with due care, and thus do away with the trader. If he then finds that he cannot obtain the true value from the oil-makers, the second thing is to make his own oil, and third if he cannot get the true value in the local market, export it on his own account.

It is possible that soil and climate may affect to some extent the quality of coconut oil. The best sample at the Colindies was from British Guiana, and is described as not only pure white, but unusually solid. But Mr. Field has not mentioned solidity as a test of quality, and we have the remedy for colour in our own hands as it consists of care in preparing the copra; whereas qualities depending on soil or climate are beyond our reach, as we cannot materially modify one or the other.

As the climate of south-west Ceylon is not to be depended on for nine months of the year, and the other three are not altogether safe, as rain falling on copra exposed to dry in the sun is seriously injurious, as the heaviest gatherings of nuts come in the wettest season, and as they cannot be kept in husk for much over three months without serious deterioration, I would recommend every proprietor to provide his estate with the means of drying his copra independently of the weather. I have seen a perfectly successful experiment in this direction with the material of an old rusted iron tank cut up and substituted for the "warratchy" shelf in the common smoking shed, the seams being plastered over with tempered clay: newly broken coconuts were then put on and piled up to the roof, the usual fire of dry husks was kept up night and day for forty-eight hours, when the copra was taken out perfectly clean and dry. All that is essentially required is between the fire and the copra, a substance that freely conducts heat, while turning aside every particle of smoke. As a drying house should be a permanent institution on every estate of ten acres or upwards, the temporary makeshift above described would be as little appropriate as a patent desiccator. 1,000 broken coconuts in the shell, 250 cubic feet, thrown loosely together, $3 \times 10 \times 8$ feet, will give very nearly that space; therefore, a house 10 feet in length 8 feet in width, will hold 1,000 three feet deep; and working 300 days it will dry 150,000 nuts, say 120 candies of copra in the year. Cabook walls 9 feet high and a tiled roof at 4 feet high, a sheet-iron floor resting on iron bars one inch square, and at 5 feet another floor of wooden spars one inch apart gridiron fashion for the charge to rest on: such a structure would not cost R100 and besides saving some labour, would render the planter independent of weather.

TEA-PLANTING IN CEYLON.

The Tea-Planter's Manual. By T. C. Owen. pp 162, with Coloured Lithographed Plates of an Iron and a Wood and Stone Tea Factory drawn to scale. (Colombo, Ceylon: A. M. and J. Ferguson, 1886.)

Eight years ago, on account of the depression in the coffee industry of Ceylon, the prospects of the colony were of a sufficiently gloomy character. A great improvement has, however, been effected by the partial substitution of tea and cinchona for coffee, and by the general attention given to cacao, cardamoms, and other subsidiary subjects. Ceylon has also been fortunate in possessing a practical scientific institution in the Botanical Gardens of the colony; and its local press is enterprising and well-informed.

It is well to mention here that the excellent growth made by tea plants at the Peradeniya and Hakgala Gardens fully justified the advocacy of tea-planting in Ceylon by the late Dr. Thwaites in his Annual Reports, while it is also due to the Colonial Office to state that through Lord Blachford it warmly supported the introduction of Assam tea plants into Ceylon in 1867. In 1877 Ceylon tea in commercial samples was submitted, through the Royal Gardens, Kew, to the Indian Committee of the Society of Arts, and the Report of this Committee clearly foreshadowed

the high place which Ceylon tea has since taken in the London market.

The present manual is one of a series issued by the *Ceylon Observer* press, and is intended to be a complete hand-book to all the multifarious duties of a successful tea-planter. Colonel Money's "Essay," and the "Tea-Planter's Vade Mecum," both publications having special reference to the circumstances of Indian gardens, have hitherto been the only books on the subject.

As stated in the preface, Mr. Owen's manual "is more a compilation of the opinions of others and the results they have arrived at than an original work." The very valuable notes of one of the earliest and most successful of Ceylon tea planters, Mr. Armstrong, of Rookwood, form an important portion of the book. The compiler wisely avoids an extended disquisition on the original home of the tea plant and on the question whether the "Assam tea tree" and the "China bush" are specifically distinct. In the latest works on the subject they are both included under *Camellia theifera*, Griff. There is no doubt that the Assam tea tree—for in a wild state it often reaches 40 to 50 feet in height—is indigenous to the mountainous district lying between South-Western China and the River Brahmaputra. It is probable also, although not clearly proved, that the China tea plant—of a somewhat shrubby habit—is derived from the same stock; although, as we now know, it was greatly altered by persistent cultivation for several centuries in a soil and climate different from those of its original home. The China tea plant has been found wild in no part of China. Under cultivation in Ceylon the Assam variety is suited to the plains, a hybrid form is sought for mid-elevations, while the China variety is useful only for the highest elevations up to 6000 and 7000 feet. Mr. Owen recommends that for all new plantations the best "jat" of Assam or hybrid plants should be obtained, as "no amount of care or skill will make up for a bad class of plant put into the garden at the outset." To a beginner in Ceylon, or to a planter, in any other country, unacquainted with the particular methods pursued on Ceylon estates, the book would prove at first somewhat perplexing. Too much knowledge is assumed on the part of the reader as regards the important questions involved in the selection of land, while as regards "the details of cultivation the particular "fads" and "fancies" of individual planters are too largely dwelt upon. It would have been more to the purpose to present a clear and simple statement of the first principles upon which the growth and culture of the tea plant, as a plant, should be based, in order to produce the best results. As regards the details of the manufacture of tea, quoting authorities is no doubt the best course, for the process of manufacture consists of a series of purely empirical operations, and a statement of principles alone would not meet the case. After discussing selection of land (Chap. I.), varieties of the tea plant (Chap. II.), seed and nurseries (Chap. III.), lining, holing, and planting (Chap. IV.), field cultivation (Chap. V.), topping and pruning (Chap. VI.), plucking (Chap. VII.), and manufacture (Chp. VIII). ,the writer devotes the remainder of the book to buildings end machinery (with plans), and to statistical returns connected with yield and cost of production.

The rapid progress made by the tea industry in Ceylon is exemplified by the fact that, while in 1878 only 282 pounds of tea were exported, during the past year 1886 the exports reached over 7,000,000 pounds. The probable exports in 1887 are placed at 12,000,000 pounds, while in 1888 they are expected to reach 30,000,000 pounds. So far, the price of Ceylon tea has maintained a slight advantage over Indian teas—the average price during 1885 being 1s. 3½d per pound for Ceylon tea, as against 1s 1½d for Indian teas. The combined effect of large shipments of Indian and Ceylon teas will no doubt lead in time to a displacement of much that now comes from China. And while the general character of tea obtainable in European markets will improve, there obviously must come a fall in prices for which both Indian and Ceylon tea planters must be fully prepared. At the Colonial and Indian Exhibition, thanks to the energy of Mr. J. L. Shand, Ceylon tea was admirably brought before the English public. Tea from Natal, Fiji, and a small sample from Jamaica were also shown; but the tea from fiji possessed such special qualities that we shall probably hear more of this promising article.

To return to the subject of this notice, the "Tea-Planter's Mannal" is a useful summary of the knowledge gained respecting tea-planting in Ceylon, and it embodies much valuable information for the use of practical planters. What fault there is to be found is not with the book itself, but with the system of cultivation it inculcates—a system which unfortunately appears to be adopted in the treatment of most tropical economic plants by European planters. These plants are treated too purely as so many "rupee making" machines. Too little attention is given to the characteristics and habits of the plants as living subjects, and too much to the details of an unsympathetic and essentially artificial system, already proved in Ceylon to be unsuited to the coffee plant, but into which there is now a strange tendency to force the tea plant. As there are diversities of soils and climates, so there are also diversities of industrial plants exactly suited to them. Where all such considerations are ignored, there is danger both to the plants and the planter; and this danger ought in the present case to be avoided. D. M. —*Nature.*

N.B. FOR CEYLON TEA PLANTERS.—Says the *Produce Markets' Review*:—

The rapid increase in the production of Ceylon tea, and the augmented quantities brought forward at the public sales, will necessitate the importance of avoiding small breaks as much as possible, and Importers will study their interests by giving this subject their attention. If the Ceylon season's out-turn reaches the estimate of from 14,000,000 lb. to 15,000,000 lb., it is evident that, with the anticipated larger imports of Indian tea, the trade will have little time to devote to exceedingly small lots. Of the 1,621 packages of Ceylon offered this week, no fewer than 76 breaks consisted of ten chests and under; and, when it is considered that the same expense and time are necessary to sample and value these trifling lots as is required for parcels of four or five times the size, it will be obvious to Importers that they will consult their interests best by combining lots as much as may be practicable. Very small lots in times of pressure stand little chance of being properly tasted, whereas if five or six were clubbed together the trade would give them a due share of attention.

THE KALUTARA TEA DISTRICT is described as the scene of great activity at present—not only among the planters in overtaking flush, and manufacturing tea, but in the erection of new factories and other indispensable buildings—the number employed (artisans and other Sinhalese, apart from coolies) is very considerable, and the money spent must benefit thousands all along the Galle road. The best carpenters are from Ambalangoda. A very narrow escape from lightning was experienced by the much-liked Chairman of the District P. A., Mr. Morison, whose bungalow on Culloden—on the top of a high rock,—was struck in his absence and some damage done in a place where he usually sits when at home. The electric discharge ran from the factory chimney, down the three wires supporting it, and killed the three trees to which they were tied. No wonder though lightning conductors have since been fitted up for bungalow and factory. Some coolies in the factory were paralysed so completely that life seemed to have departed from them: but by the use of mustard plasters over their bodies and whiskey given internally, after a time pulsation was restored, and in a few days they were about their work as usual.

PERAK SUGAR CULTIVATION COMPANY, LIMITED.

THE annual general meeting of the shareholders of this company was held at their offices No. 3, Nanking Road, Shanghai, on the 24th March.

REPORT.—The directors have now to submit to the shareholders their report of the working of the company during 1886; the first year of practical results from the Gula Estate.

The principal evnts which have happened since the last annual general meeting, held on 10th May, 1886 were made known to the shareholders at a special meeting held on 8th October, and also by circulars issued by the directors about that date. As the shareholders are aware, the chief work of the directors in Shanghai has been to give effect to the sanction to a debenture issue, as authorised by the shoreholders, while at Gula the manager has been using his utmost endeavours to carry on his work efficiently despite the absence of many necessaries required for the proper equipment of the estate.

The directors are happy to be able to report that the endeavours in both quarters have met with fair success. They have succeeded in issuing debentures to an extent of about Tls. 30,000 and hope to be able to procure the remainder of the Tls. 60,000 authorised as it becomes necessary for the extension of cultivation. The success which the manager has been able to achieve is now given in the following report:—

Canes have been cut from an area of 450 orlongs, say 600 acres, producing piculs 12,040 of sugar and realising (gross) $61,340 (including estimated value of "Sugar in stock" on 31st December). The averages given by these figures are:—

Production per orlong.....piculs 26·75
Average price per picul.....$5·09

In comparing these figures with the estimates given in the circular of 21st September, it will be noticed that the area of production is 12½ orlongs less: these 12½ orlongs though technically "in cultivation," *i. e.*, cleared, drained, &c., have not so far been planted with canes. The actual weight of sugar produced per orlong is, on the other hand, slightly better than the estimate. As to price, the average of the first six months was not maintained in the latter portion of the year; this was primarily the result of a fall in the Penang market, but was also in considerable measure due to the straitened circumstances of the estate, which prevented a full supply of labour being maintained and proper cultivation of the canes during their earlier stages—the result being sugar of a lower quality. This trouble, however, has ceased and the sugar now being made is fully equal to the earlier standards. It should be mentioned that owing to the absence of any appliances for dealing with the molasses upwards of $7,000 has been lost to the estate during 1886.

The average of piculs 26·75 of sugar per orlong from the estate in its first year is highly satisfactory and confirms all the opinions given as to the excellence of Gula soil for sugar cultivation.

The failure to get money when first asked for in May last year, and the consequent inability to procure the labour required to cope with the cultivation, has not only adversely affected the results of 1886, but has interfered to some extent with the prospects of 1887, it having been impossible to carry on the work of replanting the fields as they were cut; consequently though the area of cultivation has been increased to 510 orlongs (=680 acres) the area planted for the coming crop is not greater than in 1886. It is satisfactory to be able to report that the condition of the young canes is excellent, the "earwig" trouble has, as the manager predicted, disappeared, and it may resonably be expected that the estimate of piculs 28 per orlong, given in the circular of 21st September for the second year's crop, may be considerably exceeded.

With reference to the necessities for the equipment of the estate as set out in paragraph IV., of the 21st September circular, it seems possible that the expense of a "Still," which as the shareholders know is desired to work off the molasses, may be saved; negotiations are in progress which it is hoped may result in a market being found for the molasses, and if these succeed there will be so much more money to devote to the all important object of extending the cultivation up to the capacity of the mill. The other necessities are being provided for.

ACCOUNTS.—The year's working shows a profit of Tls., 1,961·41, which amount is carried forward; and amount of Tls. 2,500 is transferred from working account to "Estate Cost" for 47½ orlongs added to cultivation and for sundry expenses which have been met out of income, but which ought to have been provided out of "Capital." Amongst the liabilities, that "Due to agencies" is nearly covered by "Sugar in stock;" the other outstandings have since been cleared off. The "Debenture loan" which appears as Tls. 24,560 has since been raised to Tls., 30,300.

The Chairman said: Gentlemen, with your permission we will take the report and accounts as having been read. Since the date of the last report the news from the estate is extremely satisfactory. The returns of last year, both as to quantity and quality of sugar, were exceptionally good for the first year of a cane estate. The damage done by insects to the estate which is a common incident in first years on cane estates has disappeared, as was predicted by the manager at the close of the first year. There was unfortunately a delay of about 5 months last year in raising the necessary amount of additional capital required to complete the estate and to carry out extensions. This has thrown us back and the returns on our crop last year will come in during the latter half of this year. The danger which at one time existed that we might lose possession of the estate for want of sufficient capital has been averted, and there is now no danger of the company losing possession and control of the property. All the work on the estate is now going on very satisfactorily and there is no cause for anxiety on any ground. Of the Tls. 60,000 debentures which the shareholders authorized should be added to the capital, the Directors have already issued Tls. 30,000 and as further applications are now coming in the Directors will no doubt issue debentures to the full amount, so that everything that is necessary will be done for the estate. It is a common Shanghai saying that "it is an ill wind that blows nowhere" and it is therefore perhaps necessary that I should mention to the shareholders, in fact they are entitled to have the information, that in the event of war breaking out on the continent, it must, of necessity, greatly reduce the supply of bounty-fed beetroot sugar, and any stoppage of that would be an immediate and immense advantage to us, alike improving our position and prospects. I do not think there is anything more to which I need allude, but I shall be happy to answer any questions you may wish to ask before putting any formal resolutions.—*Straits Times.*

FOOD FOR THE GODS.

The grateful mortal who first named the plant from which we obtain a certain very delicious and very wholesome berry *theobroma* must have had a keen insight into the possibilities which lay undeveloped within the rough exterior of the pods of the *cacao* plant. Crude as must then have been the means of preparing the rich, nutritious berry, there must have been unmistakable evidence of its value, even in that condition or so ambitious a name would surely never have occurred to the mind of its discoverer. "Food for the gods," was his verdict upon the fruit of the cocoa plant—fit rival to the claims of the famed ambrosia, a boon indeed to men.

Nor, of a truth, now that civilisation has brought its skill to bear upon the preparation of this cocoa, does its pretentious name seem unwarranted by facts. Under the separate styles of "cocoa" and "chocolate" various preparations of the nuts of the cacao plant are now made with such delicacy and skill that, whether regarded as necessity or a luxury, *theobroma* plays a most important part in modern domestic economy. Whether it is in the form of the cheering, comforting

cup of cocoa, the fragrant, steaming chocolate, the sustaining, wholesome bars and "drops" of the same toothsome dainty, or in the delicate and delicious confections into which chocolate, cream, cocoa-nut, vanille, and other pleasant things enter, *Theobroma*, "food of the gods," is constantly before us. The weary workman fortifies himself for his long trudge homeward through the snow, when the short winter day has closed in, with a cup of cheering cocoa; the butterfly of fashion sips its cocoa from tiny Sèvres cups in my lady's boudoir; the hard-worked governess, toiling from house to house for a poor pittance, supports exhausted nature by furtively munching chocolate as she goes, knowing well its exceptional powers; and her pupils are not, we may be sure, innocent of the delights of the more luxurious forms of the sweetmeat. It is not always that the luxury of the rich is equally the wholesome and attainable indulgence of other and less fortunate classes; but in cocoa and chocolate we have not only a delicacy fit to be dubbed *theobroma*, but at the same time a nutritious food and beverage for all sorts and condition of men.

That this is so is of course due in no small degree to the skill and enterprise brought to bear in the manufacture and manipulation of the material. The mechanical requisites in the making of cocoa and chocolate are now brought to a rare degree of perfection, and in addition to this the "putting up" of chocolate by a first-rate firm evidences so much taste and refinement that the very appearance of the boxes stimulates the appetite and acts as a fitting herald of the dainties to be found within.

It would be difficult to find a more complete example of the nicety, scrupulous cleanliness of manipulation and surroundings, and for that matter of the extreme delicacy and toothsomeness of the manufactured article, than may be found in the extensive manufactory which stands hard by the Avon, in the good old city of Bristol, from which emanate the productions known all over the world, and bearing the time-honoured name of Fry. It is not too much to say that Fry's cocoa is a household word all the world over. And it is no matter for surprise that such should be the case. Those who have been priviledged, like ourselves, to go over the well-ordered works, and inspect the various processes of manipulation, and admire the all-pervading air of extreme method with which the processes in question are carried out, can readily understand the firm hold which Messrs. Fry's productions have obtained upon the public. Here we see for ourselves that the materials used are of the best, the apparatus of the most perfect, the *employés* of a class which speaks volumes for themselves, and the great firm whose interests they serve, order, cleanliness, method, reign supreme, and the outcome is not merely excellence but economy. Messrs. Fry can compete with the world both as regards the quality and cost of their productions—hence the secret of their success. The public are too critical and too well informed nowadays to be satisfied with crude, imperfect, or extravagantly dear conditions in the commodities which enter into their everyday life, and they know by experience that they may safely accept the name of Fry as a guarantee of excellence. The Manufactory is an extensive range of buildings. It has grown with the growth of a firm which has been in existence more than a hundred and fifty years. The original premises gradually absorbed the houses right and left for a considerable distance. At the back of these some years later was built a factory of four floors, what then doubtless was looked upon as a great extension.

Later on another building of seven floors was added, double the size of the former works, and later on the extension of the trade again compelled the erection of yet another building of seven floors. Upon entering the buildings one is at once struck with the sight of corridors lined with oblong blocks of cocoa and chocolate, as one ascends to the eighth floor, where the roasting-room is reached. Here the raw material is first utilised. In revolving cylinders the beans, from which all palpably imperfect specimens have been picked, are carefully roasted, a process upon which very much depends. The nuts are shot into hoppers, and crushed and winnowed in order to remove the thin adhesive shell, the crushing reducing the nut itself to the form of the familiar cocoa-nibs. Both shell and nibs are articles of commerce, the former being used in Ireland and in some parts of the Continent for the manufacture of a cheap drink. The clean nuts are then ground. The mills being warm, the fatty part of the cocoa-nut, or cocoa butter, is partially freed, and the hard dry nut is thus reduced by grinding to an oleaginous paste, which is further ground to a finer paste of a creamlike consistency. For storing purposes this paste is poured into cold moulds, from which it emerges in solid blocks of pure cocoa. To make the famous "Cocoa Extract" this liquid passes through some further important stages. Well-filled canvas bags are placed in metal cylinders with punctured holes, hydraulic pressure is applied to the extent of 1,200 lb. to the square inch, and out comes the cocoa butter, when warm as liquid as salad oil. Collected in oblong tins, it cools to the consistency and appearance of clarified beeswax. Solid blocks of it adorn the multitudinous floors and passages; some of it is used on the premises, some sold for surgical purposes. It possesses the rare quality of never becoming rancid. When taken out, the dry mass is broken, ground many times, and sifted with fine sieves, constituting "Cocoa Extract."

Not content with bringing the "Extract" before the market, Messrs. Fry, determined to solve once and for all the problem how to secure extreme solubility and absolute adaptability to all digestions, have, after some research, produced what they term "Pure Concentrated Soluble Cocoa." The already finely ground powder is ground again and again, and passed through sieves with 2000 holes to the inch, securing perfect fineness. By a new scientific process the finest flavour of carefully blended cocoas is developed, and the result is the excellent preparation we all know.

The fancy confectionery department is more complicated. The "creams" may be taken as typical of more classes than one. The chocolate used for covering these "morsels of delight" is reduced to a thin and workable paste. To prepare the "cream," pure boiled sugar is poured into an open pan and allowed to cool. It is then efficiently stirred, till it assumes the opaque creamy consistency so much desired. By means of an adaptation from the printing-press, hundreds of tiny moulds are "dabbed" out on trays of powdered starch, and into these moulds the sugar, with any flavouring or colouring required, is rapidly poured by dexterous assistants. Thence the tiny globes are taken to the covering rooms, where scores of girls with trays of thin prepared chocolate perform their part. Here again, it is only necessary to change the mould and the particular flavouring to produce vastly different forms of sweetmeat. There are sugar boiling rooms, moulding rooms, and covering-rooms apparently without number, to detail which would encroach too much upon our space. In short, it only remains to add that the skill and enterprise of the firm has not gone without its due reward. Two members of the family enjoy the honourable distinction of being Members of Parliaments, and the firm of J. S. Fry and Sons is honourably known in every quarter of the globe.—*British Mercantile Gazette.*

FOREST TREES are now felled in America with dynamite. A cartridge of the explosive substance is placed in a channel board directly under the tree to be operated upon, and when exploded the tree is simply forced up bodily and falls intact on its side. In most instances it is found that the tree is not fractured by the force of the explosion; a large proportion of valuable wood at the base of the trunk can be utilized which is now lost. For clearing forest properties this method is admirably adapted, as it brings up the root of the tree at the one operation, and dispenses with the tedious and costly process of grubbing the roots of the felled timber.—*Journal of Forestry.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, March 31st, 1887.)

LETTERS FROM JAMAICA.—No XV.

WEATHER, CROPS AND LABOUR—JAMAICA BOTANICAL DEPARTMENT: A CORRECTION—JAMAICA "GLEANER" ON LOCAL TAXATION—MORE JAMAICA PROVERBS.

[This is the missing letter to which we referred a short time ago, but its contents are still of interest. —ED.]

Blue Mountain District, Jamaica,
17th December, 1886.

DEAR SIR,—I am pleased to be able to chronicle an improvement in the weather. The rains continued very steadily until about the 10th November. We have since had some very fine days, but even now it is still unsettled and occasionally showery. The coffee in the upper fields is beginning to recover from the effects of the two terrible storms of 27th June and 19th August, and needs "handling"; but the crop will be very short indeed except on coffee at a low elevation, which was sheltered and escaped the violence of the storms. It is, therefore, a good season for the settlers, as not only have they got a much better crop than has been the case for some years, but the quality also is good, for the ample supply of rain with which we have been favoured has been beneficial, and as, moreover, prices are 10s. to 12s. per cwt. better than they were last year, our Creole friends have every reason to rejoice, for "every dog has his day," and "Buchia" must sometimes come off second best. I have yet to learn what beyond a decrease in European stocks has caused the rise in the medium qualities of coffee. It will be a good thing for all coffee planters if it be true that the Brazils will henceforth commence to yield annually lessening crops, because of some disease in the trees and the now gradual emancipation of slaves, which will eventually enhance the price of labour. It is time that John Bull, who paid millions to emancipate the slaves in his own dominions, should put some check on slave-grown products, and cease to allow sugar and coffee &c., from slave-owning countries to come to England on a par with his own colonies, where all are free, and already overweighted with competing with bounty-fed sugar and adulterated coffees, by the imposition of a protective duty, thus guarding the interests of his own colonies and dependencies, without which he would find it very hard to find employment for his superabundant offspring; for, (as an old lady in Ceylon, a Mrs. Malaprop in her small way, once observed to a near relative of mine, alluding to a gentleman much esteemed and respected,) "John" is a very "populous" man.

Mr. Hart, of the Jamaica Botanical Department, has asked me to make a correction. He writes that in my letter No. 13, I stated that he had been appointed "*Pro-tem*" Superintendent of the Cinchona Plantation, which I think most people will have understood to mean that he had been appointed acting head of the department. But he writes as follows, believing my statement would bear unfavourably upon him unless corrected:—"I have held the appointment of Superintendent of the Cinchona Establishment ever since 1881, and was appointed acting head of the whole department in July last, which was probably what you meant to convey. To friends in a similar position in other parts of the world the statement will be misleading, and they will think I have been assuming a false position for the last five years, unless your mis-statement is contradicted." Trusting the above will satisfy our friend's *amour propre*, who has been very deservedly promoted to the charge of the Botanical Gardens, Trinidad, on which piece of good fortune he is sincerely congratulated by all his Jamaica friends, who wish him every success in his new position.

The local *Gleaner* newspaper,—under the influence of its new American editor, who, with evident Irish proclivities, like the famous St. Kevin, of Vale-of-Glendaloch renown, was very anxious to have "a taste of land" the property of King O'Toole, whose gander he had revivified—has started a theory that Government should levy a sufficiently heavy tax on all large land-holders to compel them to cultivate all they do not actually use, and if they will not pay the said tax to compel them to give back all land except they are willing to pay tax on, so that Government may hand it over to the native settlers to be cultivated. In this district such lands are either "ruinate" and exhausted, or too steep and rocky, or too high and exposed for cultivation, so that even were the planters to be forced to give up these lands, it is not likely they (the settlers) would avail themselves of them, though they might in the pen and sugar-cane parishes. The plan proposed is that Government should sell and make over these and other lands to all applying settlers in lots of 50 acres, and make them a loan of £50 on each tenure to enable them to cultivate it, the money, I conclude, being lent on interest, and to be repayable in yearly instalments. In answer to the *Gleaner's* plea, that most of the people are poor, and cannot get work, or grounds of their own, I would reply that Government have thousands of acres which they cannot sell for even 2s or 3s an acre, that there are numbers of old and abandoned properties, whence land can either be purchased or rented at reasonable prices, if the natives would but work, and avail of them. If the *Gleaner* scheme were successfully carried out, it would drive all sugar and coffee planters, pen-keepers and large fruit growers out of the island, simply because they would be unable to obtain labour, unless it were imported at a cost that would not pay them to keep up their properties, and make from them a reasonable income. But would such a scheme be likely to succeed? Now I do not wish to be understood to class all Creoles, that is African descendants alike, there are exceptions to every rule, and there are doubtless good and true men and women amongst them, honest, even hard-working, who lead virtuous lives, but it would be expecting the leopard to change his spots, that Quashie would rouse himself from his natural inertness and love of ease to work 50 acres of land, and to repay Government the interest and principal, (they deem their present taxes sufficiently onerous.) I believe the majority would soon run through the money, building houses and in other congenial ways; at most cultivating a few acres as they do at present, just enough to give them food and clothing, only working on the estates sufficiently to enable them to indulge in a few luxuries. In the end Government would probably have to take back most of the land, and what would they do with it? Would it be worth the borrowed capital they had lent upon it? If, as in some few cases, there is not labour to be had for all from the estates all over the island, the people can and do rent land, they could cultivate more coffee, more fruit, more coconuts, more cocoa and many minor products, for all which they would find a ready sale at the various shipping ports. If labour were ample but could find no employment, how is it that the sugar and coffee planters were obliged to submit to a heavy export tax in order to enable Government to procure cooly labour, at a very large cost to the colony and themselves? No; Jamaicans are not so eager for work though they know the planter

would prefer them to coolies, for they *can* work hard and well when they like, and when they get job and piece-work, though for "Master" and day wages their energies are far less active. Jamaicans have been attracted to Colon, in the hope of making money, their large numbers have died, and of those who have returned many are lastingly shattered in health—many of those who died have left wives and families to fight the battle of life unaided by the natural bread-winner. If the Jamaica revenue is deficient and the land must "pay the piper," then as suggested in my reply to the *Gleaner's* article "Tax the Land," let a sufficient but moderate additional impost be put upon all cultivated land, and let all landholders, large and small, white, brown or black pay the same rate per acre. "Ruinate," reserve, and uncultivable lands already pay a sufficient tax, but to force holders of large areas, obtained in "old times" when Government was only too glad to encourage the settlement of capitalists: to have their properties studded over with Negro settlers, because they cannot afford to, or will not pay an unjust tax, would be odious. Fancy having native grounds all over one's estate, with free right of way? Petty larceny is rife enough already without opening such another encouragement. Another argument I read in the *Gleaner* was a complaint that no sooner did a man make money than he was taxed; that there was consequently no encouragement to the people to better themselves and that the right thing was to tax the land, was the only proper way to raise revenue. How absurd? as if it were not right that those who can afford it should pay the taxes, not the poor. Says the *Gleaner* writer, if a man makes money and buys a horse and carriage he is immediately made to pay tax thereon, and rightly so, for he should contribute to the upkeep of the roads which he uses and without which his carrage and horses would be of no use; this is but one example made use of for taxing land, and making it pay for anything else.

In my next letter I hope to be able to tell your readers something about the "North-side" as I am going on a short visit to St. Mary's; it is a parish of sugar and banana estates and "Pens," large numbers of coconuts are also grown. I may also see "Castleton," the Botanical Garden of Jamaica. I will close with a few more Jamaica proverbs:—

Behind dog, it is dog, before dog it is "mister" dog.
Big blanket make man sleep late.
Cotton tree nebber so big, but little axe cut him.
Finger nebber say "look here," him say "lookdere."

—Yours faithfully, W. S.

MR. VON DONOP'S LATEST REPORT ON PLANTING, &c., IN BORNEO.

Sapagaya River.—I visited this river to ascertain in what condition the property owned by Mr. Major was in. I regret to report it is fast returning to jungle though I noticed coffee, and fruit trees, &c., all battling against the grass and small jungle growing up against them. The buildings which are all temporary are rapidly decaying.

The property of the China Sabah Company on the Suanlamba river is, I regret to say, in a similar state to that of Mr. Major's the plants I saw of Liberian coffee, cocoa, &c., were looking fairly healthy but unless immediate steps are taken they will soon be choked and die. The policemen are in charge of the property and live in the bungalow. The Condenser is in good order—I gave instructions, however, to have it carefully oofed over. The tobacco press is also in good order. There is a small Bajow village on this river the inhabitants of which are cutting timber for Mr. Koh Heen's firm. I consider both the China Sabah Company's property and Mr. Major's would be very suitable for Chinese to cultivate. A large acreage is already cleared of the forest but immediate steps should be taken to clear away the grass and small jungle. The land having been cleared for some time back should render the locality healthy.

I visited Messrs. E. E. Abrahamson & Co.'s Timber works on the Domondong river which I found a scene of busy activity. There are at present 120 men cutting and hauling out timber. Of these 90 are Chinese and the rest Malays. The Bajows work independently and seem to take to the business.

I had no time to visit the Blacking river but I learn a Chinese firm employ about 200 men, Malays, Bajows and Sulus in cutting and removing timber.

Mr. Henry Walker made a complete survey of the Labuk river as far as Limantic. I called at the Governmeut station Balmoral which is at the mouth of the Labuk. It is in charge of a native with two policemen. I regret I am unable to report favourably of it. No progress has been made since my last visit when I was accompained by Your Excellency. There are only 3 houses (including one belonging to Government) on an average only 3 boats call at the station each way per month. No fees, dutice, &c., are collected. There is no appearance of Bajows who I at one time hoped might be induced to settle there, for the reason they are what they have been very properly termed Sea-gipsies and lead a roving life. In the meantime the station costs the Government annually about $400. The Government building is in fair order. I do not consider the native in charge a suitable man for the post. He can neither read nor write and appears to have no influence or tact with the natives and gives me little or no information of the affairs of his district. Should the Government decide to continue this station (which I cannot recommend them to do) I would suggest a suitable substitute be put in his place. Around the houses I noticed sugar cane growing and a few other products. Pigs, however, appear to do considerable damage. Proceeding from Balmoral (the native name of which is Piluran) we arrived at Galagan two hours journey. I visited Galagan a few months ago and I am glad to say this settlement formed by people of Bulungan has progressed most favourably and will I am sure progress still more. There are about 65 houses most of large dimensions, the occupants of which, putting them down at 10 per house, would make a population of 650 people. There are several new arrivals from Bulungan who reside in houses of their own.

The inhabitants give one the idea of being a very industrious lot. On their first arrival they busied themselves with clearing the jungle building their houses around which fruit trees are thickly planted. At the present time besides what might be termed an orchard, large tracks of land are being planted with paddy which before long will I think be an article of export. I noticed sugar cane being crushed in the usual native fashion. To the Chief, Dato Mumucno Nagara I handed 2,000 sago plants which were eagerly seized upon and with your approval I wish to indent for a further supply from Province Dent. I had a long evening "bichara" with the Dato and settled many matters upon which he wished to obtain information and *vice versa*. The people of Bulungan are not the same rovers as the other inhabitants of the river; They set-

tle down in a certain locality and remain there though they may have their paddy fields at a distance. I would recommend in the event of the station of Balmoral being given up the two policemen be transferred to Galagan. From Galagan we proceeded up the river as far as Limantic, Mr. Henry Walker being anxious to survey the river as far as he could in the launch. Limantic is only a small village consisting of two houses. Returning from here we proceeded down the river to Kolapis a small Bajow village on a river of that name. There are only two houses. I was in hopes at one time that this race might have settled at Balmoral but the term sea-gipsies is a very applicable term for them as they are always roving about the sea and have not as a rule any settled abode. From Galagan to Balmoral two hours. From Galagan we proceeded to the village of Tetabuan situated in the Labuk Bay. I made this visit especially for the purpose of gaining information concerning the pearl beds that exist here—and which with your approval it is intended to farm out to Panglima Butu the Bajow chief in that district and who with his men have been in the habit of collecting them no collecting has yet been begun but I am informed the collection will shortly commence. I enquired from the chief the reason he did not migrate to a better position where he could have a plantation, he informed me in reply that he was afraid to leave as if he did somebody might come and claim the pearl beds. The Panglima arranged to be at Sandakan in a week's time to sign an Agreement concerning the custody of the Pearl beds. These people have nothing to do with the pearl beds at the Maroap river which will be farmed out to others. While at Tetabuan I received information of the wreck of a "Prahu" with a cargo of rattans from Sisip. Out of the 8 people on board two were drowned. In reply the Panglima informed me the reason he had not sent me information to Sandakan on the subject was that there was a heavy sea on at the time. From Tetabuan I paid a visit to Lincabo a small Sulu village and from there proceeded back to Sandakan.—*North Borneo Herald.*

COCONUT REFUSE is thus alluded to in an article in *Forestry* on the Resuscitation of Choice Trees by top-dressing:—Failing loam, the next best top-dresser is, on the whole, coco-fibre refuse. It is less feeding, and perhaps almost more conservative alike of heat and moisture, also free from offensive odour, decomposes very slowly, and finally forms a fine mould of which the roots of all trees seem specially fond. [This is rather a different verdict to that delivered by Mr. Symons.—Ed.]

FLOODS IN DEMERARA.—Disastrous floods of an unprecedented kind have been experienced on the east coast of this Colony, by which the poor inhabitants of the district are suffering severe losses and indescribable privations. The following description of the scenes is taken from the *Argosy* :—Many villages with their provision and pasture ground annexes are (or were, for we are glad to be able to say the rains are abating) from two to four feet under water, the villagers' huts looking like bathing machines in a placid sea, water up to the doorstep, frequently above it, no road to be seen, not a blade of grass for cow or mule, or a dry foot of ground for the smaller stock. The people were helpless and no help could be extended to them in the way of relieving their lands of the deluge; they had simply to sit and suffer, to awake in the morning with nothing to do, their farms all lost to sight, crops ruined, and all attempts at cultivation impossible.—*Colonies and India.*

THE NORTH BORNEO Land and Saw Mills Company (Limited), referred to in our last issue, has been registered. The first subscribers are:—Major-General Sir A. Anson, St. Leonards; Mr. E. Lucas, Kensington-square; Mr. F. K. Barclay, Crucifixlane, Bermondsey; Mr. T. L. Jeyes, C. E., 9, Victoria-chambers: Mr. J. R. Boulter, engineer, Blackfriars-road, and Mr. J. S. H. Drake, solicitor, 50, Old Broad-street. The first three named are to be directors of the company, in conjunction with Messrs. Walmisley Stanley and W. J. Tanner. The board of directors is to number not less than five nor more than nine, the qualification being £300 in shares or stock of the company. The director's remuneration is to be £600 per annum each.—*L. & C. Express.*

CEYLON TEA IN AMERICA.—Of the venture of Messrs. Pineo & MacCombie Murray we have received some particulars:—"Office of the Ceylon Pure Tea and Coffee Company, Philadelphia, 10th March 1887. I send you by this mail our Circular through which we endeavour to make known our brand of Ceylon tea. The label is also enclosed, and I hope it will meet your approval. We have done what we can to advertise our pamphlets, of which 20,000 will be distributed shortly, and more when these are given away. We have been at great expense in this line and can only hope that our endeavours will meet with success. The tea is not liked generally *at first*, but by talking over the matter with people we may accustom them to the new flavour, and get the thin end of the wedge in. Our business is conducted methodically, and we hope to reach every respectable family in Philadelphia through canvassers. I am afraid the Ceylon Syndicate may be likened to a wheel without a nave. If they had a little capital they could boom some of the large cities in this country with every chance of success, but I fear there is a want of a spirit of unanimity among planters which will always stand in the way of any great enterprise in this line. You will perceive by our prices that we sell teas from 50 cents to $1·10 the ruling prices of teas sold. The profits are not so large as they would appear, as 30 per cent commission must be given to canvassers or retailers in any way. The $1·10 is a fancy tea sent us from London of which the sales are limited. Then we have 10 cents per lb. to pay for delivery and packing expenses in tin foil inside boxes,—reduce our profits to a minimum. I may mention that even by allowing a retailer 30 per cent. commission on sales, we are unable as yet to do much through the trade, as *retailers* make more profit out of Japans than we can make at these prices as importers. Teas bought by retailers at 20 cents to 30 cents sell at 50 or 60 cents, and sometimes they will consider it proper to sell the same tea to one who can pay for it at 75 cents. There is no rule in the retailer's business. Although they have only one tea, they sell it for all kinds of tea and charge according to the general appearance of the customer. Sad, but true! These practices are very much against the introduction of our teas, especially as we have to *make* demand, before any one will handle them. We are prepared for uphill work, and it is well that we are so. We are both very thankful to you for remarks you have from time to time made in your columns with reference to us. We are much encouraged thereby, and we can *assure* you that every encouragement given us by you and others in Ceylon is greatly appreciated by us." The pamphlet and circulars prepared by Messrs. Pineo and Murray are very neat and attractive and show a good deal of enterprise on their part. We wish them all success.

PHARMACY IN CEYLON.

The style of business out here is much the same as a country business at home; we are "Chemists, Druggists, and General Dealers," though in some Stores the Chemist's Department forms only a small part of the business. We do not get very remunerative prices—Eno's Salts, 2 rupees; Clarke's Blood Mixture, 2 rupees; Cockle's pills, 2*s.* 9*d.* size, 2 rupees, 6-oz ordinary mixtures, 1 rupee; 8-oz, 1½ rupee. The rupee being so low in value—under 1*s.* 6*d.* sterling—the prices are much the same as one has been accustomed to in England. Our expenses in importing home goods are very heavy; we have a 6-per-cent *ad valorem* duty on goods coming into the colony, which, in addition to agents' buying commission, shipping, landing, and railway charges, and other incidentals, together with 33⅓ per cent premium, which we have to pay in exchanging rupees into sterling, causes an advance on many goods of 50 to 60 per cent. over London invoice prices. We are in the land of "spicy breezes"; we do not wish to detract from the island, but cannot help thinking there has been a mistake somewhere; certainly we get breezes—incidental to a hot climate, we suppose—the spice in them being rather conspicuous by its absence.

Our beautiful scenery and foliage is always admired by passengers taking a trip into the interior. Indian visitors, who have been accustomed to the hot and parched plains, say the visit to Ceylon is a glorious change for them, and admire very much the luxriant growth of vegetation for which our island is so famed. Our climate is like a perpetual summer; the year is marked, not by four seasons as at home, but by the two monsoons, the one from the North-east, which comes in about October, lasting till the following April, when the South-west comes and stays till the next October. The burst of the monsoons is accompanied by plenty of stormy weather, when we get thunder and lightning, and rain in torrents. We have several botanical gardens in Ceylon; those at Peradeniya are especially good. I will send you a little paper on what I see there at a future date. I met Dr. Bonavia, Brigade-Surgeon of the Indian Medical Department, a little while ago. He has been carrying on a research into the properties of the orange family, and told me of the excellent results he has observed from the use of "Decoction of Lemon." As it may interest some of your readers, I give the recipe for the preparation of the medicine in full, copied from a letter by Dr. Bonavia to the *Ceylon Observer*.—"To make decoction of lemon, take one Malta lemon, or three sour limes, cut into thin slices, rind, pulp, and all, add three breakfast-cupfuls of water, and boil in an enamelled saucepan until the liquid is reduced to one cupful, then leave it exposed all night to the air; next morning strain through muslin, and drink the liquid early on an empty stomach." Dr. Bonavia adds: "In quotidian fever simply, decoction of lemon given only once a day acts like cinchona febrifuge. In enlarged spleen of recent occurrence (within few months) the decoction has a wonderful effect. In loss of appetite and weakness after illness, decoction of lemon may be prescribed with marked benefit." The wholesale houses at home seem very anxious to do business with their colonial customers direct. We get hosts of price-lists by every mail, and occasionally a traveller from the old country drops in. "Siegel's Syrup" people have been sending their almanacs through the post to almost every person in Ceylon, and within a few days after the arrival of these almanacs all the Stores had run out of stock. By the time new stocks arrive it may possibly happen that the interest of the patent-medicine-taking public will be taken up with something else.

I notice you are altering the publication of THE CHEMIST AND DRUGGIST to once a fortnight, and no extra charge to subscribers—another instance of the liberal spirit you have always shown to us; a years' numbers and the Diary, all post-free for ten shillings—marvellously cheap. May you continue to go on and prosper!—CINNAMON.—*Chemist and Druggist.*

DOMESTIC REMEDIES OF THE ARABIAN DESERT.

Dr. E. Gordon Hull, in the *British Medical Journal*, gives some particulars of observations on the diseases and remedies current among the Bedawin of Arabia Petræa and the Arabah Valley, made during the autumn and winter of 1883-84, while he was acting as Honorary Medical Officer to an expedition sent out by the Palestine Exploration Fund. He remarks that chronic bronchitis and chronic articular rheumatism are almost universal. He measured twenty-six men and nearly all their shoulder-joints creaked and groaned as they raised them. This will account for the curious inability of the Arabs to move about, or do any work in the morning before they are "thawed" and rendered supple either by fire or by sun. Nevertheless, the Arabs appear to be a very healthy people.

The remedies they are in the habit of using are not many in number, and are usually derived from those plants which are most widely distributed. As a diuretic, that is, for pains in the back and gravel, they use the retem, or broom (*Spartium monospermum*), making a decoction of the top shoots in hot water, and drinking it; they say it is also purgative. This shrub, which provides them with fuel, and their camels with a scanty nourishment, is almost universal; we saw it in flower on the way to Petra, and the inflorescence, which is purple and white, gives out an exceedingly sweet perfume. It has a very bitter taste.

Several species of wild melon, of the family *Bryoniæ*, allied to the elaterium (which also grows in these parts), are in common use as purgatives; the native method of using them is ingenious. A fruit is split into halves, the seeds scooped out, and the two cavities filled with milk; after allowing it to stand for some time, the liquid, which has absorbed some of the active principle of the plant, is drunk off. A milder remedy is camel's milk, which appears under some circumstances to be purgative to the Arabs.

The order *Compositæ* furnishes several medicinal herbs of which the Arabs make use. The *Santolina fragrantissima*, a graceful plant of a sage-green colour, bitter taste, and strong fragrant odour, furnishes them in the form of an infusion, with a carminative, good for colic and all painful affections of the abdomen. In the bazaars of Cairo the fragrant dried heads are sold for the same purposes as camomile. I was told that there are no snakes in the districts where the plant grows, and the natives believe that the odour of the plant is sufficient to drive reptiles from a house, and it is used for this purpose in Cairo and other towns.

Another plant of the same order is an artemisa, or worm-wood, with a very strong aromatic odour and bittter taste. The fellaheen use it to put in their bedding to drive away vermin. This use of the plant appears to be very universally known, witness the old English rhyme:—

> When wormwood bath seed, get a handful or twain,
> To save against March, to make flea to refrain:
> Where chamber is swept, and wormwood is strewn,
> No flea, for his life, dare bide, or be known!

From the seeds of some of the kinds of artemisia be which grow in these parts, santonine appears to obtained. In the wilderness of Judæa, near to Beersheba, we found a pretty little calendula, or marigold, very common. It became extremely abundant along the Mediterranean seaboard, and is used by the natives as a sort of tea for flatulence and pain in the abdomen. Knowing how largely a liniment derived from this plant was advertised by homœopaths, I tried to find out if they used it as an external application, but they did not know of its virtues as such. One of the commonest desert plants is the zygophyllum, so called from the leaves being composed of short succulent jointed segments; these, bruised in water, form a mucilaginous liquid of which the Arabs are very fond as an application for sore eyes. It has an exceedingly nauseous taste, but this fact only appears to commend it to the notice of the camel, who devours i greedily. A curious tropical plant, which we foun

in the Ghor, at the south end of the Dead Sea, is the osher (*Callotropis gigantea*), a large tree-like asclepiad, containing simply enormous quantities of milky acrid juice. Its properties are stated by Endlicher to be powerfully purgative and emetic; but the natives use it to give to women whose milk is scanty, probably in accordance with the doctrine of signatories. Here, also, grows the castor-oil plant, but its virtues are unknown to the natives. A very striking plant, which, perhaps, I should have mentioned before, and which often hangs in graceful dark-green festoons from the granite walls of the gorges of Arabia Petræa, is the caper plant (*Capparis spinosa*). The natives are very fond of the fruit, which has a warm aromatic taste, and they stroke the region of the epigastrium appreciatively after eating one or two. The cortex of the root is said to be aperient and diuretic. Another fairly-common plant is a hyoscyamus, called by the natives "sekharan," with fleshy leaves and purple flowers. The dried leaves are used by the natives to smoke, and produce a kind of intoxication or delirium; and an infusion of the fresh leaves possesses strong narcotic properties. It is nearly allied to the mandragora, which becomes common on the limestone downs in the South of Judæa. The Arabs are extraordinarily susceptible to narcotics. Our tobacco they could not smoke at all; a few whiffs make them giddy, and give them a headache; even a "Richmond Gem" cigarette is too much fo them. Only two mineral substances appear to be regarded by the Bedawin as medicinal. One of them, sulphur, I have already mentioned; the other is a kind of common red coral, found on the shores of the Red Sea and Mediterranean, and sold in the bazaar at Gaza. As far as I could gather, they only use this as a charm.—*Chemist and Druggist.*

EUCALYPTI: BOTANICAL DISTINCTIONS OF THE OIL-PRODUCING SPECIES.

The popular nomenclature of the eucalypts is as confused and thoroughly bad as it could be. In the first place the generic name of gum-tree is rather poor, as true gum is by no means an abundant or characteristic product of the eucalypt; but the faults of the generic name could easily be forgiven it, if a a happy and discriminating series of specific names had been attached to it. Probably no great *genus* has ever had its species so irritatingly mixed up by careless popular naming. It must be allowed that the specific separation of the eucalypts has proved a task of extreme difficulty to botanists with the largest share of classificatory talent, and the amateur will find it a matter of some little trouble to acquire moderate facility in distinguishing many of even the commoner eucalypts without good specimens of flowers and fruit. Broad general characters, by which to distinguish the more nearly related species, are hard to lay hold of, as will be recognised when it is considered under what diverse forms the individuals of a single species can present themselves according to the locality of their growth. Thus trees which on the ranges appear as forest giants shooting up straight, with colossal smooth white trunks are found in barren reaches near the sea as scrubby stunted specimens, with wrinkled dark bark. An idea of the utter confusion of the popular nomenclature, may be gathered from the facts that there are no less than six distinct species in Australia called the blue-gum, the most important being the *E. globulus*, sometimes distinguished as the Tasmanian blue-gum. There are three peppermint trees, namely, *E. amygdalina*, *L. odorata*, and *E. piperita*; there are three red-gums, three mountain ashes, one of which is the *amygdalina*, which has already figured as a peppermint tree; there are nine white-gums, *amygdalina* again figuring in the list; there are eight ironbarks, and finally there are fourteen boxes, very inadequately attempted to be distinguished. The stringy-bark of South Australia and Tasmania is the *E. obliqua*, which in Victoria is mostly known as messmate, while the tree called stringy-bark in Victoria is the *E. macrorrhyza*. Under these circumstances the student of the eucalypts will find it discreet not to take his lessons from the bushman or elector, but to go and consult the *Eucalyptographia*, and learn to ignore the popular trivial names as completely as he can.

The distinguishing characteristic from which the *genus* got its name of eucalyptus, meaning "well-covered" is the deciduous operculum or calyx-lid, which is supposed to represent the united petals. It varies in shape from hemispherical to elongated conical; it is always simple, sometimes thin, but oftener thick: sometimes fleshy, but mostly woody; the veins run through it lengthwise, and are approximately parallel; the line of separation of operculum from calyx tube is nearly always distinct in the bud. Often in the young bud a thin membrane is found covering the operculum. The stamens are numerous and arranged in series; the shape of the antlers was first employed by Bentham as a diagnostic character for the systematic classification of the eucalypts, and with this Mueller has joined the mode of opening the anthers. The woody fruit consists of the bell-shaped calyx tube enclosing the capsule; the seeds are mostly infertile. The flowers as a rule are arranged in umbels, although in a few exceptional cases they occur singly and sessile.

E. Amygdalina has an unfortunate specific name as there is nothing the least almond-like about it. This species is remarkable as containing perhaps the tallest trees in the world and also trees with a larger secretion of oil than any other known tree produces. The tree varies considerably in external appearance, from the giant "white-gum" form to the stunted rough-barked form known in Victoria and Tasmania as a "peppermint" and in New South Wales as a "messmate." Its leaves are thin and equally green on both sides, the veins do not spread out much, and the oil dots are abundant and clearly visible. The flowers are small and grouped in solitary umbels, the operculum is almost hemisperical and almost half as large as the calyx tube, the anthers are kidney-shaped and open by confluent slits; the fruits are small and truncate globular, with depressed border and valves enclosed. This tree ranges along the south-east coast of Australia and Tasmania; it is always interspersed with other trees, and its timber is not much valued.

E. oleosa.—This species will be taken as representative of the four species that are mixed together in the mallee scrub; it is a dwarf, ranging from 12 to 18 feet in height, its leaves are of an equally bright green on both sides, the flowers occur in solitary umbels with slender stalks and short stalklets. The operculum is semiovate, passing into a pointed cone, and is a little longer than the calyx tube. The anthers are roundish, opening by longitudinal slits, the fruits are truncate ovate with compressed border, while the valves are half inserted and prolonged into decided points. The oil globules are plainly visible in the young leaves, but tend to get concealed in the older ones. This is a desert species found in the large tracts of mallee country in the regions round the mouth of the Murray and inland along it and its tributaries.

E. Globulus has its leaves long, thick, and equally green on both sides with the circumferential vein well in from the edge, and the oil dots concealed. The flowers are large, for the most part solitary, and almost sessile. The operculum is crown-shaped, and like the calyx-tube is covered with the same blueish white waxy bloom as gives the large ovate leaves of the seedlings and young trees of this species so characteristic an apperance; the anthers are distinctly longer than broad, and open by parallel slits. The fruit is large and hemispherical, whence the specific name. The trees occur mostly dispersed, but sometimes gregarious in the humid regions of the south and east of Victoria, and in Tasmania. This is the eucalypt that has become famous by reason of its unequalled rapidity of growth, its fine timber and its malaria destroying reputation.

E. leucoxylon has its leaves equally dull green on the two sides, the flowers are mostly arranged in solitary umbels of three flowers each, the operculum is semi-ovate and pointed, the outer rows of stamens are sterile, the anthers are roundish and open by pores at the summit, the stigma is broadly dilated, and the fruit semi-ovate in shape, has a compressed border, and

enclosed valves. This species has a wide range from the south of Queensland to Spencer's Gulf. Like the *amygdalina* it presents two very different external appearances, one of which is known as a white gum on account of the smooth pale stem left by the deciduous bark, the other as Victorian ironbark on account of the fissured hardness of the retained bark. This bark is pretty rich in kino.

E. macrorrhyza:—The leaves are long and equally green on both sides, with the oil dots hidden, the operculum is as long as the tube, and is concavely attenuated to a sharp point, the anthers are kidney shaped, opening by slits, the stigma is not broader than the apex of the style, the fruit is hemispherical below with a convex border, and the valves much inserted. The species is very widely spread in Victoria and New South Wales, being the commonest of the stringy barks in Victoria. The trees are gregarious, and there is a great demand for their timber on account of the readiness with which it splits for the manufacture of rails and shingles. They often occur mixed with E. Obliqua.

E. obliqua has its leaves equally green on the two sides, and shining with the oil dots concealed. The specific name was given to indicate the marked inequality of the leaves at the base, but this is a feature in the leaves of many eucalypts. The calyx is rough, and its tube is longer than the hemispherical operculum, the fruits are truncate ovate with the border compressed and the valves enclosed. The trees occur gregariously in large forests to be met with between St. Vincent's Gulf and Gippsland, but not spreading far into New South Wales, they furnish most of the ordinary sawn hardwood. The two last species although their yield of oil is not high, offer considerable advantages to the distiller by reason of their gregarious habit and their vogue as hardwood timber trees, which makes the gathering of their leaves cheap.

E. rostrata:—The leaves are of the same colour on both sides and of a lanceolate shape, the veins are crowded, and the oil, dots though visible are scanty; the flowers occur in solitary umbels of from 4 to 14 flowers, the operculum is longer than the semiglobular tube, from its hemispherical base it rises into a beak-like prolongation, from which the specific name was taken; the anthers are ovate with longitudinal slits, the fruit is roundish with a protruding convex rim, and three, four or five highly exerted triangular valves. This species is found chiefly along the river margins of south-east Australia.

E. odorata has equally dull leaves with the veins spread out at an acute angle. The operculum varies in shape from broad conical to bossed hemispherical, and is shorter than the calyx tube; the antlers are small and roundish, with pore-like slits, the fruit is bell shaped, with valves enclosed. The species is almost entirely confined to South Australia in the neighbourhood of Spencer's and St. Vincent's Gulfs. It is probable that in Victoria the E. Melliodora has sometimes been confounded with E. odorata, to which it is closely allied, and to which it is very similar, the most salient point of distinction between the two is that the fruit of E. melliodora is decidedly contracted at the summit, while that of E. odorata preserves the pure bell-shape.—*Chemist and Druggist of Australasia.*

THE SUGAR CANE AND THE SUGAR INDUSTRY AT MAURITIUS.

(Translated for the "Tropical Agriculturist" from the 1st number of the "Revue Agricole.")

MAURITIUS, Jan. 1887.

The sugar cane (*Saccharum officinarum*) is a gramineous plant, which appears indigenous to India and Indo-China, whence it has extended from time immemorial to the Oceanic Islands.

Towards the middle of the 13th century the traders who carried on commerce with India brought home with them this plant, and introduced it into Arabia, whence it was extended to many points in the basin of the Mediterranean, notably to Egypt, Spain, Sicily and up to the South of France,

The sugar yielding reed was soon transported into Madeira, thence in 1420 to the Canaries, and in 1506 the Spaniard P. d'Arrança introduced it into St. Domingo, where it multiplied rapidly. Gonzalis de Meloza established the first sugar factories there. In 1643 the English began to cultivate cane at Barbadoes, and the French at St. Christopher's in 1644, and at Guadeloupe in 1648.

For a long time the process of extracting the juice of the cane remained in a rudimentary state. The mills moved by bullocks or mules, were composed of three vertical cylinders. Two men, placed one on each side passed the canes, first between the cylinders the widest apart, and then through those which were closer together. As it was necessary to hold the canes in the hand to keep them horizontal in going through the vertical cylinders, it frequently happened that the men thus employed were from carelessness, or when overpowered by sleep, subject to having their fingers caught between the cylinders, the rotary movement of which was very rapid, and the whole arm and sometimes a portion of the body were crushed before there was time to stop the mill.

Stedman, in his voyage to Guyane, relates that in the sugar factories of that colony there was a well sharpened axe kept near the cylinders, for the purpose of cutting off an arm, in case of such an accident.

The use of horizontal cylinders and of water wheels and wind-mills, were so many steps in advance, which were successively realized, to be superseded at the present time by steam power.

The process for extracting sugar from the juice of the cane followed the same steps. At first the manufacturers were content to carry on the evaporation by means of single boilers. Afterwards these were arranged in rows (batteries). Towards 1840, Howard constructed for refining purposes the first apparatus for boiling in vacao, and in 1840 Mons. Rillieux conceived the idea of employing the steam developed by the boiling juice to evaporate another portion of the juice, and constructed the first apparatus for producing the two effects (appareil à double effet), which Mons. Tischbein introduced into Europe in 1880, and which Mons. Robert, a Seelowitz, modified so as to produce a triple effect.

During three centuries, the system of "purging" (égouttage) for the purpose of separating the molasses from the crystals of sugar contained in the concentrated juice, set in a mass by cooling, remained the same. The boiling mass was placed in forms, barrels or cases, the bottoms of which were pierced with holes, through which the molasses escaped. To expel, more or less completely, the molasses adhering to the granulations, cane juice concentrated to 32 degrees Baumé (this was what used to be called clearing le clairçage) or a thick layer of wet clay was poured over the surface of the sugar, the water from which percolated through the sugar, clearing the crystals of molasses. The latter was called claying (le tenage).

In 1849 Mons. Sèrigue invented the plan of applying centrifugal force to drive out the molasses held in suspension by the boiled mass of sugar, and constructed the first turbine.

The processes adopted for purifying the cane juice remained equally stationary for three centuries, and until towards 1848 the sugar maker confined himself to adding a little lime to the juice, though the proportion of this agent, was in no degree based on scientific principles. In 1849 Mons. Melsens suggested the use of bisulphate of lime which was soon abandoned—as the proper way of using sulphurous acid for depriving cane juice of colour was then insufficiently known. Then came carbonatation discovered by Mons. Rousseau, the application of which to the manipulation of cane juice gave but questionable results.

In 1867 the lamented Dr. E. Icery made the first important and practical use of sulphurous acid, which he employed in the form of monosulfite of lime, at the same time he taught the rational employment of sunflower paper (papier au tournesol) to test the cane juice in regulating the quantity of lime to be used for the purpose of separating the mucilage from the cane juice. At last in 1880, Messrs. C

Bernard and L. Ehrmann first used phosphoric acid with the aid of which they obtained sugar that rivalled in whiteness, the best refined sugar.

II.—If from this general exposition of the origin and developement of the colonial sugar enterprize we pass on to what was its past history in our colony, we shall see that it was not till towards 1735 during the time of Labeurdonnais that sugar cane commenced to be of commercial importance and that it was only in 1836 with the introduction of Indian labourers in Mauritius that the sugar industry began to develope itself to such an extent as to become in a few years the one great enterprize which attained its apogœum in 1863, the year in which the crop reached the figure of 316 millions of pounds.

The principal varieties of cane cultivated at Mauritius have been

1st. The white cane of Otaïti;
2nd. the bambu cane or Batavia cane;
3rd. the Gingham—or ribboned cane;
4th. Belouguet cane, or the violet cane of Java;
5th. creole cane, small with very close joints;
6th. Mozambique cane, dark in colour, and leaves tinged with deep brown.

Of these different kinds, the white cane was most generally cultivated, and until 1848 it formed at least nine-tenths of the plantations. At this time a peculiar disease, called the white disease, broke out on the white cane, so that very soon after the planters were obliged to abandon the cultivation of this variety, which previously had been considered the most advantageous. As there was then a prejudice unfavourale to coloured cane, efforts were made to obtain new species of white cane from Java, and two kinds were received from that country, the Penang and the Diard, which for many years were in great esteem, but before long they were given up in favour of the Bélouguet previously despised, but which soon became recognized as the most productive of all the kinds introduced up to that time.

Previous to this period, that is to say until towards 1855 the cultivation of cane was confined to the sea coast of the island. In these low grounds, sufficiently watered, the cane generally flourished with exceptional vigour, in a rich deep soil, and, without manure, gave numerous successive crops. In virgin soil from 15 to 20 crops, and on second planting from 8 to 10 crops. Two or three years of change of cultivation for peas or "embrevattes" (called in Ceylon the Angola pea) were afterwards sufficient to renovate the soil. So soon as the cultivaters went further from the coast, the conditions became very much changed. The soil which was neither so deep nor so rich, yielded, without manure, but very inferior returns to those from the coast lands. The planted canes gave but two or three crops and the manufacture presented great difficulties, consequent on the frequent rains, which hindered the drying of the sugar.

Two new introductions, that of the turbine and that of guano of Peru came to change this state of things. Whilst on one hand, the employment of the turbine obviated the necessity of drying in the sun, and facilitated the manipulation in rainy districts; the Peruvian manure tripled the returns obtained in moist and elevated regions. The consequence was that the forests which in 1855 still clothed a large portion of the centre of the island were gradually felled to make room for cane plantations.

The result of this agricultural revolution was the displacement of the sugar industry. The island in general was desiccated by the destruction of the forests, the coast lands ceased to be sufficiently watered to afford remunerative crops, and a great number of estates in this portion of the island were successively abandoned. The aggregate produce of the country, however, increased, as we have already said up to 1863, the period of its apogœum. After that commenced the era of trials. The Bélougnet cane after having produced so well, became effected in its turn, as well as the kinds called Penang and Diard, it became necessary to fall back on the Bambu and Gingham kinds which were notoriously inferior, and which, after a few years, were in their turn attacked by the same mysterious disease, which under forms varying with the kinds attacked, caused such disastrous loss to our agriculture. To provide against this eventuality, which had been foreseen, means for introducing fresh canes had been organized on a methodical system, and over two hundred new species or varieties were successively introduced, which rendered it possible to form fresh plantations.

It is worthy of remark that among all the new kinds of cane, a very few species were found fit to be compared as regarded production to the old kinds previously introduced and none were superior. At the same time that our different kinds of cane were successively attacked by disease, the planters of Mauritius found themselves called upon to struggle against new difficulties of another order.

The deposits of guano on the Chincha Islands became exhausted, and Peru only exported guano of inferior quality—which gave rise to the formation of establishments for making chemical manure, much more costly and greatly inferior to the old guano of Peru.

It has been said that misfortunes never come single. The truth of this aphorism has verified itself, as far as our sugar industry is concerned. To the diseases of the cane, and the increase in the cost of manure has succeeded a crisis in the market which has for several years struck at the sugar industry in all producing countries; a crisis to which it is impossible to assign a limit, and of which it is equally impossible to foresee the ultimate consequences.

After having viewed the origin, the developement and the present state of our sugar industry, it remains for us to inquire as to what are its present necessities, and the way towards which it is desirable to direct it, so that it may be placed in a position to sustain the struggle for existence, which is at the present moment imposed on all sugar producing countries.

C. B.

(To be Continued.)

TROPICAL FRUITS IN THE KEW MUSEUM.

In connection with the subject of tropical fruits recently brought before the Royal Colonial Institute by Mr. Morris, and referred to in the *Gardeners' Chronicle* for February 26 last, it may be useful to those interested in the matter to know that most of the fruits under review, as well as others not mentioned, but which might prove of equal value, are to be found in the Kew Museum. The collection of tropical fruits preserved in fluid has always been a distinct feature of the Economic Museum at Kew. Those sent home by Henshall and Rattan from the Malay Archipelago some thirty years since were not only remarkably good specimens, but, up to a certain point, were very complete. The addition of fresh specimens, acquired from various collectors and botanic gardens, as well as from the several Exhibitions—notably the Health Exhibition and the recent Colonial and Indian Exhibition—has made the Kew collection unique in this respect. It may, perhaps, be remembered that at the Health Exhibition, Siam made a great display of native fruits, extremely well preserved in a solution of salt and water, the whole of which collection was made over by the Siamese Commission at the close of the Exhibition to the Kew Museum. This collection placed many of the fruits of the East in an entirely new light; some notes on them and others in the Kew Museum may therefore not be without interest at the present time.

The Siam collection included some very fine specimens of the commoner or better-known tropical fruits, such as the Mango, Mangosteen, the Anonas, &c.; but it is to those that are less known that we wish to draw especial attention, and for this purpose it will no doubt be more generally useful to the readers of the *Gardeners' Chronicle* if we refer to the individual fruits under their several natural orders,

BIXINEÆ.—*Flacourtia inermis*, Roxb.—The name of Mad Apple is applied to this fruit in the Siamese collection, while in India it is known as Country Plum. The tree is a native of the Moluccas, but seems to be much cultivated. The fruit is about the size of a Cherry, of a red colour, and has a smooth skin, and is described by Roxburgh as being "too sour to be eaten raw, but makes very good tarts." Under the name of Luvi-luvi, or Lobi-lobi, the fruits of F. cataphracta, Wild., are used in Java for making into preserve: they are globular, with a smooth purple skin, and are about the size of a common Plum. *Aberia caffra*. Harv. and Lond.—The Kei Apple is perhaps better known than the last. It is the fruit of a shrub, native of the Cape of Good Hope and Natal. When ripe the fruits are of a golden-yellow colour, about the size of a small Apple. They make an excellent preserve, but are said to be so exceedingly acid when fresh that "the Dutch settlers prepare them for their tables as a pickle without vinegar."

MALVACEÆ. *Durio zibethinus*, L. (the Durian).—This wellknown fruit is included here only on account of the possibility of the edible pulpy portion being brought to this country preserved in syrup, like Pines. A specimen in the Museum from the Siam collection suggests this possibility, though it is probable that the flavour of the Durian, as described by travellers, would not recommend it to European palates.

GERANIACEÆ.—*Averrhoa bilimbi*, L. (the Blimbing).—This, and the Carambola—A. carambola, L.—are useful Indian fruits, valued on account of their acid taste for making pickles as well as for preserves.

RUTACEÆ.—*Triphasia trifoliata*, DC.—A spiny shrub, native of Southern China, but now naturalised in India and the West Indies. The fruits are about the size of a large black Currant, with a reddish skin: In an unripe state they are said to have a stickly tenacious pulp, and a turpentine flavour, but when fully ripe they have an agreeable sweet taste, and are preserved in syrup. They occasionally come to this country in this form under the name of Lime berries. A closely allied plant is the Wampee (Clausena Wampi, Blanco, better known perhaps as Cookia punctata), a small globular body, esteemed in China and the Indian Archipelago.

MELIACEÆ.—*Lansium domesticum*, Jack. (Lansa, Langsat, or Dooku.)—A tree of India and the Malay islands, the fruit of which is about the size of a pigeon's egg. The skin is of a yellow colour, and the pulp of flesh white. When fully ripe it is of a pleasant, sweetish, acid taste, and is highly esteemed by the people in the Malay islands, either in the fresh state, or cooked in various ways, or made into a preserve. Duku jam was shown in the collection from the Straits Settlements at the Colonial Exhibition, and its flavour was certainly very agreeable.

OLACINEÆ.—*Ximenia americana*, L. (the Amatunduluku of Natal).—It is a shrub or small tree, and is found widely spread over tropical regions. The fruits are fleshy, somewhat ovoid, about an inch long, and when fresh, of a sweetish colour; they have a sweetish, acid taste, and are generally eaten in the countries where the plant is grown. A form of this species has been described under the name of X. elliptica found in the Pacific islands, where it is eaten in large quantities by the natives, and is said to be extremely acid, and to possess an Almond-like smell. It is of a globular form, and not elliptical.

SAPINDACEÆ.—This order contains the well-known Litchi and Longan, and the less known Rambutan and Pootassan. I mention the first only to draw attention to the forms in which these fruits might be introduced. In this country we know the Litchi (Nephelium Litchi, Camb.) only in its dried state, that is, when the outer warted shells have become woody and the inner pulp, or aril, which envelopes the seed, has somewhat shrivelled and become black. In this state the pulp has simply a sweet taste, but in the fresh state the pulp is whitish, or slightly tinged with pink, and has a refreshing acid taste. A sample of these fruits, with the woody coat removed, showing the inner pulp preserved in fluid, from Siam, is shown in the Kew Museum, and they suggest the possibility that this pulpy portion might be preserved, in tins in a similar manner to Pine-apples, and sent to this country. The fruits of the Rambutan, or Rambustin (Nephelium lappaceum, L.), might also be treated in a similar way. The pulp makes an excellent jam, samples of which were exhibited in the Straits Settlements collection. The pulp of the Pootassan (Nephelium mutabile) is similar to the last.

Otophora fruticosa, Bl. (the Phamarieng of the Siamese), produces a two or three-lobed fruit about the size of a Cherry, of a bright shining black when ripe, and containing a large proportion of pulp of a pleasant sweetish, slightly astringent taste.

ANACARDIACEÆ.—Besides the Mango and Cashew nuts, and the several species of Spondias which furnish fruits of varied quality, two species of Bouea yield large, pulpy edible fruits; these are B. macrophylla Griff., and B. burmanica, Griff., both of which are known in Siam by the name of Maprang.

ROSACEÆ.—*Chrysobalanus Icaco*, L.—This is the Icaco, or Coco Plum of the West Indies and South America, The fruits are about the size and appearance of an ordinary Plum, but vary in colour from white to yellow, red or purple. The pulp is described as having a sweet but somewhat austere taste, and is used either raw or for making a conserve.

MYRTACEÆ.—In this large order many fruits suggest themselves as being likely to prove valuable either in the state under which they are at present known, or under an improved condition from the effects of cultivation. The Guava (Psidium guayava, Radd.), and the Rose Apple (Eugenia Jambos, L.), are amongst the best known fruits of the order; these latter however, are but little esteemed in their fresh state by Europeans, in consequence of their generally insipid taste, but candied with sugar they are very agreeable, and have a distinct Rose flavour. Rose Apples preserved in this manner were sent from Jamaica to the Philadelphia Exhibition, and were awarded a Silver Medal. The tree is commonly cultivated in gardens in India, and the fruit is eaten either raw or made into a preserve. Another species of Eugenia, namely, E. Jambolana, Lam., is much valued in India for the sake of the fruits, which are mostly about the size of a pigeon's egg, but vary under cultivation, and are eaten by all classes of the people. The tree is an evergreen, common throughout India, both wild and cultivated, and it is also found in Ceylon, the Malay Archipelago, and Australia.

Ugni (Myrtus ugni), a Chilian shrub, has long been valued in its native country for the sake of its fruits, which are of brownish-red colour when ripe, and about the size of a large black Currant; it has a soft juicy pulp, with a sweetish, somewhat aromatic flavour. It is described as being cultivated in gardens and used as dessert in Valparaiso, and the expressed Juice of the fruit mixed with water is said to form a very refreshing drink, having an odour of Rosemary. The plant has been recommended for cultivation as a fruit-bearing shrub in the warmer parts of England. A fruit very similar to the Ugni is produced by Myrtus salutaris, H. B. Samples are shown in the Kew Museum from Venezuela. On the banks of the Orinoco they are said to grow as large as Sloes.

PASSIFLOREÆ.—Several of the fleshy fruits of this order are utilised in tropical countries for making preserves, as, for instance, Passiflora quadrangularis, L., and P. maliformis, L., and Carica Papaya. Jams made from the first named species were shown in the Colonial Exhibition from Dominica, and from the second from Natal; both, however, lacked any distinct flavour to recommend them, and this was generally the case with the Papaw, which was shown from several of the colonies preserved in various ways. The most curious, however, if not the best in point of quality, were those shown in the Straits Settlements collection where the fruits were cut into various ornamental forms and preserved in syrup. Under the name of "scented Lemon" (a label probably misplaced) was shown some attractive looking substance of a bright green colour, also in syrup, which upon examination I found to be the flowers

of the Papaw. They were crisp to the taste, but had no flavour besides that of the syrup. Papaw jam and candied Papaw were amongst the other preparations of this well known and apparently useful fruit.

CORNACEÆ—*Nyssa capitata*, Walt. The fruits, which are about an inch long and ovoid, of a green colour and very agreeable flavour, are known in North America as Ogeechee Limes, and are often preserved in syrup and used as Limes.

SAPOTACEÆ.—This order contains several genera which furnish valuable edible fruits, such as the Chrysophyllum, Cainito or Star Apple, Lucuma mammosa, Griseb., or Mammei Sapote, and the Achras Sapota, L., or Sapodilla or Naseberry. Of this frut, Dr. Watt says that it is not much appreciated in India, but it is surreptitiously sold in the streets as Mangosteen. The fruits of Mimusops Kauki, L., are perhaps less known. They are about the size of a small Plum, and are known in Siam as Lamut. Those of M. Elengi are also edible.

EBENACEÆ.—Besides the Persimmon (Diospyros virginiana, L.), which is edible when fully ripe or bletted, the fruit of the Chinese Date Plum (D. Kaki) is important in China. The fruits are about the size of a large Apple, of an orange-red colour, and contain a quantity of edible pulp. The Chinese and Japanese use them both in the fresh and dried states and also preserved in syrup.

APOCYNACEÆ.—In this order, containing as it does many plants with elastic milky juices, yielding rubber, and many of them poisonous, one would scarcely expect to find many edible fruits; several of them, however, are valuable on this account, the following of which may be mentioned:—

Hancornia speciosa, Gomez (the Mangaba or Mangabeira, of Pernambuco).—A small tree, the milky juice of which furnishes the Pernambuco rubber. The fruits are yellow when ripe, marked with red streaks or spots, about the size of an Orlean's Plum; when perfectly ripe or somewhat bletted they are said to be very delicious and are a favourite fruit in Brazil. They have occasionally found their way to this country, and I have seen them sold on costermonger's barrows in the streets of London but very rarely.

The *Amatungulu* of Natal (Carissa [Arduina] grandiflora) is the fruit of a large spiny shrub which makes an excellent preserve, and is much used in Natal for that purpose; the fruits are pulpy and very similar to a Plum in appearance, about 2 inches long and 1½ inch broad. Another species of Carissa, namely, C. Carandas, L., known as the Karenja or Karaunda fruit in India, is cultivated in many parts of India for the sake of its fruits, which are used in an unripe state for picking, and when fully ripe for tarts and jelly.

MYRISTICEÆ.—This order is included only for the purpose of drawing attention to the use to which the outer fleshy part of the Nutmeg fruit is put in the East. Cut into various fantastic shapes, as representations of birds, flowers, &c, sometimes with the Nutmeg still enclosed, they are preserved in syrup, and form a very attractive preserve. It has a distinct Nutmeg flavour, and, like preserved Ginger, would be a useful adjunct at dessert.

EUPHORBIACEÆ.—*Phyllanthus emblica*, L.—Known as the Emblic Myrobalum. A tree of the dry forests of India and Burma. The fruit is about the size of a small Damson. The natives eat it raw, preserved, or made into a sweetmeat, while it is used by Europeans for tarts and jellies. It is stated that a "half-ripe fruit, if chewed, has the effect of making water taste sweet." The Otaheite Gooseberry (Phyllanthus distichus, Muell., Arg., better known perhaps as Cicca disticha, L.) is another valuable fruit, used in Java for pickling. Antidesma Bunius, Spr., a native of Java and the neighbouring islands, furnishes small fleshy, berry-like fruits, of a bright red colour, ripening into black; they have a subacid taste, and are used chiefly for preserving. Two or three species of Baccaurea (Pierardia) yield edible fruits; those most valued are B. edulis, Muell., Arg., a Malayan species, known as the Rambeh, the fruits of which are about the size of a large Cherry, yellowish in colour when ripe, and containing a sweet delicate flavoured pulp. In Sumatra it is called Choopah, and in Siam, Mafai; B. racemosa, Muell., Arg., is also a Cherry-like acid fruit of Java, as is also B. sapida, known in India as the Luteo.

The foregoing enumeration of fruits is not by any means an exhaustive one. I have brought those forward which are the least generally known, but of which the Museum contains good specimens.—JOHN R. JACKSON, Curator, Museum, Royal Gardens, Kew. —*Gardeners' Chronicle.*

THE OLIVE IN SOUTH AUSTRALIA.

BY SIR SAMUEL DAVENPORT.

"So similar is the climate of the settled portion of South Australia to that of countries in Europe and Asia where the olive thrives, that some Colonists were early induced to procure stocks from France, Portugal, and Spain, and these were planted in and about Adelaide. Their healthy growth and abundant fruitfulness after a few years proved the soundness of these opinions.

"It was under the stimulus to inquire into new productions given by the announcement of the London International Exhibition, 1851, that the first attempt was made to extract the oil from the olive. Then the late Mr. William Giles, manager of the South Australian Company, who, in 1844, received from Marseilles 51 plants, comprising five choice varieties of olives, and planted them, and could now gather their berries, employed Mr. George Francis to express the oil, and, at the London Exhibition of 1851, this produce gained 'Honorable mention,' on the ground of 'its clearness, color, and flavor.'

"Since that event a gradual advance in the cultivation of the olive has been made by some individual believers in its special adaptation for South Australia, and now the Conservator of Forests favors its distribution in public reserves.

"Meanwhile the high prizes uniformly acquired at International and Inter-Colonial Exhibitions in different quarters of the globe, even in an old and eminent olive country like France, have confirmed the highest views held of the olive and its oil as a local production. In a little brochure on "Olive Culture," published in 1877, at the printing office of the *South Australian Advertiser* newspaper, is the assertion that 'No oil that has ever been sent into the market surpasses in quality, lucidity and creamy delicateness of moist, delicious flavor the oil that is now produced on the Adelaide plains.'

"There being many varieties of cultivated olives whose merits for quantity or quality of oil differ, or whose rank is held in degrees of estimation relatively to national tastes. South Australia has now become rich in the possession of olive stocks of reputation secured to or from Malaga, Gibraltar and Lisbon: from Cannes 'Nice and South of France, via Marseilles; and from Florence and Bari via Brindisi. Some skilled French pruners of the olive have also been introduced, whose labors, and the instruction they must impart to others, cannot but prove of great advantage to the future cultivation and production of the olive.

"Had South Australia been colonized by Greeks, Italians, or French olive growers, it most probably would, long ere this, have produced large quantities of oil and preserved olives for the various markets of the Old World. Nevertheless, in many gardens, and in some special plantations of the tree in and about Adelaide, the silvery hue of the under surface of the foliage, as inverted by the winds calls strikingly to mind the scenery of wellknown localities of its cultivation, as of Cannes or Mentone on the Mediterranean, or of the Upper Tagus.

"The calcareous nature of the soil around Adelaide, and the warm and dry climate, assist in bringing the fruit of the olive, as to the vine to remarkable perfection: whilst, for the benefit of the laborers as well as of the farmers, the olive harvest conveniently follows on the vintage, as the vintage follows on the harvest times of wheat and other grains."—*Colonial Druggist.*

TEA COMPANIES LIMITED FOR CEYLON.

There is a feeling prevalent we find among a number of practical men in Ceylon, who may be said to be disinterested in the matter, that the tea enterprise in the island cannot be put on a satisfactory footing as regards manufacture at least, until large central factories fully equipped with all the best machinery and latest improvements, become the rule in place of being the exception. It is of no use as a permanent arrangement we are told, for every owner of 100, 150 or even 200 acres of tea to busy himself in altering his old coffee store into a tea factory or to spend money in running up some ramshackle concern where even if machinery adequately driven, were available, it is almost impossible to do justice to the tea leaf. There is again the very real difficulty of individual proprietors not being able to command a sufficiency of power to drive the required machinery. And it is now well-known that this is the greatest obstacle of all to the proper utilisation of rollers, dryers, &c., even when these are obtained of the best description. Tea far more than coffee requires plenty of motive power in the store or factory. Now, as the public servant who has drawn our attention to the matter, pointed out: in every planting district where tea has become the supreme object of attention, there are certain estates which naturally fall into groups and for which it should not be at all difficult to find a central suitable spot for the erection of such a Factory as would take in all their tea and where full justice could be done to it in manufacture. It is impossible to find waterpower enough on each estate; but with few exceptions where three, four or even six properties are grouped under one management, it ought not to be difficult to arrange for adequate waterpower, or if not available for an adequate supply of fuel to keep the inevitable steam engine as well as the driers fully supplied. There is undoubtedly a very great deal worthy of attention in this argument, whether regard be had to practical or economic conditions. No one can visit such factories as those of Carolina and Mariawatte without feeling that they must afford great advantages in the regular, equable and economical reparation of large quantities of tea. It may be said that while Carolina or K. A. W. factory commands over a thousand acres of tea, the case of Mariawatte with comparatively limited acreage, rather tells against our argument. But such is not really the case, for apart from the extension of the property in new and large clearings, the exceptionally heavy bearing of the tea there, puts the Factory on a par with the average that would be required in most districts for perhaps double the acreage.

In the item of machinery and store accommodation, the grouping of three to six tea gardens or plantations into one for factory purposes, ought to effect a very large economy. In that of store superintendence and labour, too, we should think, the comparison would be greatly in favour of grouping. But how is this desirable arrangement to be effected? It is not possible for individual ownership and separate management to be maintained with a Central Factory on joint account for manufacture. There must be one equal ownership and one management for the whole group, or else inevitably there would be collapse and failure. The only feasible scheme would seem to be the formation of Limited Companies to deal with such groups of estates as clearly afford the elements requisite to success in the utilization of a Central Factory. In the leading districts in India, the Tea Enterprise seems chiefly carried on through the agency of Limited Companies, and we fancy capital would be available for shares in "tea" in Ceylon with its high name, quite as readily as for Assam. In such cases too as where tea is coming into bearing, giving business at once, there ought to be no difficulty in interesting London capitalists. The proprietors of the estates to be grouped (their mortgagees or both) would no doubt be expected to take the major portion of the shares; and, perhaps, the mention of "mortgagees" suggests the chief difficulty in the way of making any arrangement for amalgamation of estates in the manner described. But there must be cases where such difficulty can be overcome, and if our remarks only serve to turn the attention of tea estate owners, who are puzzling their brains how to get up suitable factories and provide machinery, to the advantage of grouping and co-operation, benefit may result not only to individuals but to the general community.

ESTIMATED INDIAN TEA CROP FOR 1887.

The Indian Tea Association has favored us (W. Moran & Co.) with a copy of their circular giving the estimate for 1887-8, as follows:—

"The Committee has now the pleasure to hand you the following estimate of the crop of 1887, taken from figures which they have been able to collect and from other sources:—

	Estimated outturn of Crop of 1887 lb.
Assam	35,903,520
Cachar and Sylhet ...	27,631,100
Darjeeling, Terai, and Dooars ...	14,703,300
Chittagong and Chota Nagpore ...	1,544,000
Dehra Dun, Kumaon and Kangra ...	3,750,000
Private and Native Gardens (estimated)	1,500,000
Total ..	85,031,920

"The exports to Australia, America, and other places (principally Bombay and Madras) during the past season, have amounted to 2,725,000 lb., and if this quantity, together with the requirements of the Government and the local consumption of Northern India calculated at 1,500,000 lb. be deducted from the estimate, there will remain 80¾ million lb. for shipment to Great Britain during the season of 1887."

PACKET TEA FOR NATIVES.

The Indian *Planters' Gazette* has an interesting letter on "Packet Tea for Natives," and directs attention to the Kaiser-i-Hind Hydraulic Tea Press, the property of a London Company, having their head quarters at 188, Strand. These presses turn out tea in cakes weighing ¼lb each cake being divided into eight sections of equal weight, the cake being somewhat similar in form to a double cake of chcolate as made up by confectioners. The proprietors of the patent are disposed to sell the sole agency for using these presses in India. Compressed tea is no novelty, but the promoters claim that their plan offers special facilities for getting Indian tea into consumption in India. Tea thus treated is said to lose none of its qualities, there is no damping and tampering with the leaf, and each packet bears the impress of the Company. At 8 annas per lb. retail, the purchaser would be entitled of two sections of the packet for one pice, which would give 10 to 12 cups of good tea as natives drink it. The reduced bulk would, other conditions being favourable, probably induce the Commissariat to give the process a fair trial, but the field to work would undoubtedly be the native market in India, and if a brand such as the one under notice could once be popularized through the native fairs and melas, every bunniah's and modee's shop throughout the country would be selling tea, and tea, moreover, that even the bunniah would find it difficult, to adulterate. That the natives of all classes have a taste and liking for tea is well known; but, as a rule, it is not obtainable in such quantities and at such prices as to induce

them to purchase. We know of one garden where the proprietor has had his broken tea made up in ounce packets, each packet labelled in two or three vernaculars with the price, "two pice," distinctly marked on them. These packets have been sold largely along the line of railway, and in the larger towns, and the sale is steadily increasing. This is doubtless one of several instances of similar enterprise, but as yet the consumption does not affect the gross outturn. That it will eventually do so, if the trade is properly fostered and encouraged we fully believe.

TOBACCO IN NETHERLANDS INDIA.

(Translated for the *Straits Times*.)

Count de Gelvos d'Elsloo has started a venture under the style of the Borneo Tobacco Company, of which he will be manager. The company which is domiciled at Batavia, intends to carry on the cultivation of land in British North Borneo for tobacco growing, besides taking in hand the purchasing and curing of tobacco and its sale in Netherlands India and elsewhere. The articles of Association provide for the existence of the company during thirty consecutive years. The company has acquired rights in four thousand acres of waste land near the Ranau River in British North Borneo. The company's capital, has been fixed at two hundred and forty thousand guilders in two hundred and forty shares. The management of the company will be conducted by one director and two commissaries. In Borneo, the affairs of the company will be looked after by a manager under instructions from the director.

TOBACCO PLANTING IN DELI.

(Translated for the *Straits Times*.)

The *Deli Courant* takes up the subject of the vast power for mischief exercised by tindals on estates in Deli, which the Chinese official commissioners recently on a tour of inspection reported upon as one drawback to cooly life there. The evil is inseparable from the difficulties of getting on there with labourers, whose language hardly any planters are masters of. But it has been intensified by the employers leaving the hands of the tindals free to deal with the coolies without exerting themselves to keep them in check. At present, the assistants, from ignorance of the Chinese language, have to rely on the tindals for interpretation. The only remedy for this spreading evil seems to be to raise the salary of assistants who set to work studying the Chinese language, and who endeavour as soon as possible, however defectively, to make themselves understood by the coolies. It is expected that, on estates where many newly arrived immigrants are engaged, the presence of European employees so qualified will bring on satisfactory results. It is well known that the Chinese tindals are most successful in impressing upon these new comers a high idea of their power, and of the need for their interference.

Even European assistants abuse their power over the coolies of whom they have charge. Early, last month, the authorities in Deli had no other alternative than to deal sternly with the manager of the Ludwigsburg estate, charged with ill-treating coolies. An arrest like this will be sure to deepen the unfavourable impression of cooly life in Deli entertained in some quarters, though bringing him to book shows that the authorities not only have the power, but also the will to protect the coolies. Many planters do not seem to realise this. The arrests of several managers on similar charges within the last few months have failed as deterrent examples. They cannot understand that the Government will not allow coolies to be ill-treated. Under such circumstances, those who will not hear must be made to feel the consequences of flagrant wrong-doing.

The tobacco grown in North Borneo turns out to be nowise inferior to the Deli article, as is evidenced by the high prices it commands. From all accounts, the climate and soil of North Borneo are admirably adapted to that branch of cultivation. Reports of the granting of land concessions and the floating of companies to operate there, are in the air. Tobacco growing has indeed come into prominence in that quarter. Under the Netherlands Indian Government, as soon as a planter begins to make money out of his venture, the fiscal screw is at once put on. Taxes, rates, and cesses are piled on him. Their crushing weight stands in the way of sound development, and stunts the growth of planting enterprise. Not only in North Borneo but also in Siak, competition is springing up. But, owing to the latter country being under the Netherlands' flag, the danger is not so great. The Government will not fail quickly to lay taxes on the planters, when they have just started on the hard task of bringing primeval waste land under cultivation. For all that it is competition, however shackled. Its inevitable effect will be to bring on increase of production. These two factors when they once come into play, bid fair to put an end to the monopoly hitherto enjoyed by Deli planters, which in addition to the excellent quality of the tobacco turned out, has had a material effect in keeping up the extraordinarily high prices realised by that article. In Deli, eyes are beginning to be opened to the necessity for turning the land there to account for other kinds of cultivation than that of tobacco. It is only by resolutely working on these lines, that Deli will continue to be a money-making settlement, an exception, by-the-bye, in Netherlands India.

PLANTING &c., IN MANILA.

TOBACCO, DYEWOOD, COFFEE, INDIGO, PEARL-SHELLS.

(Translated for the *Straits Times*.)

All through last year, the depression of trade had prevailed far and wide in the Philippines. The value of hemp exported has fallen off by nearly half a million of dollars. The decrease in this respect, partly arises from inferior quality of the fibre brought to market owing to bad curing. The supplies available either fetch low prices or are rejected, the producers suffering in either case. Sugar shows a still more marked falling off, it being one-tenth compared with the export figures in 1885.

Dyewood exports have not escaped from being affected by the prevailing depression. Neither have those in cigars undergone any change for the better. Several houses see the importance of turning out a serviceable product, so as to keep up the whilom high reputation of the Philippine article. But others setting present gain above future loss, counteract their efforts by bringing out low priced cigars, no matter how indifferent the quality may prove to be. The inferior articles are exported on their account, thereby doing wide spread harm to the reputation of a product which had distanced all competitors up to the time of the abolition of the tobacco monopoly in the Philippines.

The abolition of the Government tobacco monopoly in the Philippines, has taken effect unfavourably not only on cigars, but also on leaf tobacco exported. Four years have passed away since that measure came into force. However beneficial the reform may prove to be in after years, tobacco as raw material or as cigars, still falls short of the mark reached in monopoly times, both in yield and quality. Growers have never realised the fact that free trade in tobacco did not mean liberty for them to cultivate that article badly and cure it worse, but afforded them an opportunity for turning out a product superior enough to bring higher prices than the Treasury paid them in the days of the monopoly. In those times, the Government had an interest in the outturn proving of marketable quality. Nowadays, with no influence for good to keep them on the right path, the cultivators, naturally heedless and neglectful, grow a crop anyhow without a thought of the care and finish required to render the article acceptable. Their only object is to bring it to market as soon as possible, no matter how inferior the quality. Sometimes the crop is sold before it is cut, neglect in the case being grosser. The crop, under such circumstances, fails to bring the prices expected when it reaches Manila. Cultivators become discouraged. In place of trying to mend matters, they grow reckless. A few growers and dealers are

more conscientious, but their efforts are of no avail to keep up the reputation of Philippine tobacco. The soil and climate of the islands are as suitable as ever for the cultivation of the leaf. The only way to improve matters is to bring home to growers, the need of improving the quality of their produce, by cutting the crop in due season and curing it in a businesslike manner. In no other way can the abolition of the tobacco monopoly be expected to result satisfactorily. In 1886 the leaf tobacco exported reached 120,793 quintals against 136,144 in 1885. Under present circumstances, with greed and indifference in the ascendant among the planting community, the experiment of free labour in tobacco growing in the Phillppines set about with such a great flourish of trumpets amid highly strained expectations, bids fair to become a failure. A deplorable result truly.—*Comercio.*

Coffee on the other hand is recovering, the returns showing an export of 117,392 piculs against 83,337 in 1885. Yet its cultivation does not seem to spread, though the local environment admits of a higher outturn. The efforts made to mend matters have failed from lack of push and go. A few years back, the Government directed the provincial authorities to order the natives to plant coffee far and wide. The authorities turned to with a will. Coffee plants were set out in thousands. Glowing anticipations were built on the prospects of their yielding plentifully. Other matters engrossed the attention of Government. Interest in the work so well begun flagged. The newly laid out coffee plantations soon went to wreck and ruin. Nothing has been done to repair the neglect. Further comment is superfluous.

Indigo is another export article which shows a heavy falling off. In the olden time, Philippine indigo enjoyed high repute, until a consignment of inferior quality brought on mistrust in markets abroad. Since then, no amount of good faith and careful preparation can restore the reputation once lost. In bygone times, the trade in this article was of much importance to the Philippines. Last year the exports totalled 1,284 quintals against 5662 in 1,870.

Pearl Shell figures low indeed in the export list, owing to the article being now forwarded from Sooloo to Singapore and other ports direct. The exportation of hides shows almost stationary figures with a downward tendency. Why it should be so is inexplicable, considering that cattle raising ought to succeed better in the Philippines with their fertile soil, liberal laws, and a population open to improving ideas. Districts of note formerly prosperous in the plamy days of the hide trade, have now become impoverished.

CEYLON: NATIVE AGRICULTURAL REPORT ON THE WESTERN PROVINCE.

THE WEATHER—COCONUTS AND THEIR CULTIVATION—FEVER AND QUININE—FARMING.

Hapitigam Korale, 30th April.

The drought broke up early in the month and we have had frequent but not very heavy rain almost daily for the last fortnight and everything is again looking fresh and flourishing. The drought has done some harm to weak coconut trees that were bearing beyond their strength on heavy loams and thin gravels, but less than might have been expected from the long spell of dry weather.

Since my last, several questions have been raised about the proper soil and treatment of COCONUTS. One of your correspondents gives his vote for great depth and width of holes, while others object to the system in toto. So far as I am concerned, I only limit my holes in size by the cost of digging them; I make them as deep and as wide as I can get them made for four cents, and I fill them up with loose earth to within one foot of the surface by breaking down the sides. In no case should the crown of the root be more than one foot below the general surface. In sandy land depth is of no importance but in loams and gravels the deeper the better, always provided the holes are filled up to the regulation one foot. A deep sandy loam is the most amenable to cultivation, and gives the best return for manure; though the strong loams have more of natural fertility, they do not so readily respond to cultivation and till the trees attain to a wood age, say fifteen to twenty years, they suffer from drought. Cabook lands are not guilty of the general condemnation given them by one of your correspondents. They range in quality from utter barrenness to a considerable degree of fertility, and the better kinds are more responsive to cultivation than the heavy loams.

With exception of the dwarf Maldive, I have never, under the most favourable condition, seen a coconut tree flower before the fifth year. Some one challenges old planters to state whether they have ever seen a coconut field with 75 per cent of the trees bearing in the tenth year. I must answer that I never have simply from the fact that I have never seen a coconut field treated fairly during the first ten years of its existence. I do firmly believe that under liberal and skilful cultivation every coconut tree will be in full bearing *before* its tenth year.

I approve of annual ploughing or digging, merely because it cannot in general be done oftener. To keep the soil pulverized to the depth of eight or nine inches is the first of the two things that the coconut requires to give a satisfactory result. As to disturbing the roots it is a matter of no consequence; no coconut tree ever suffered from a deficiency of roots to take up any plant food in the soil; I want no main roots within nine inches of the surface, as the deeper laying mains send up abundance of feeders into the upper soil.

I know no economic plant that will grow and bear fruit on soil so poor and under such utter neglect as the coconut, nor do I know any that so immediately and so amply responds to even minute quantities of manure. Say a ton of bone dust, costs laid down on an estate R75, that properly applied to 370 trees already bearing more or less, they will within three years yield at least 12,000 nuts additional to their former crops, worth at the lowest price R300. Allowing R45 for additional labour the cost will be R120, leaving a profit on the investment of R180. Lime is a very good application to heavy soils if put on in sufficient quantity, unfortunately it will not pay at the local price of the article.

I have never seen or till recently heard of pearls in coconuts. The testimony is too weak so far to convince a person of a sceptical turn of mind. I would hardly believe it if I saw it.

This is awful season for fever in this neighbourhood; there is hardly a house for miles round free from it and in some cases whole families are suffering. My own household is laid up as I write, except myself, and I have no patent protection. We are consuming quinine at a rate that would be ruinous if we had to pay the price of English dispensing druggists.

I am trying to combine some farming with coconut cultivation. I am still in doubt if it will pay directly, but if not, the coconuts will get the benefit of the work and manure. Local prices are not encouraging. Our climate cannot be depended on for any of the more valuable minor products and however successful we may be in growing such things as cassawa, sweet potatoes, pumkins, pineapples and so forth, they are not worth taking any trouble with, unless so far as they can be consumed on the place. Cattle and poultry thrive on cassawa, especially milkcows, who give a double supply under this feeding. I know no plant that yields so large a bulk of substantial food for man or beast with so little labour as cassawa, but its very productiveness renders it an unprofitable crop in larger quantity than required for home consumption.

THE ANTIGUA average rainfall for 1886 at 41 stations is 47 89 inches. This, we believe, has been considered an exceptionally wet year for Antigua. Compare Roseau Valley 208·19; Roseau 94·31!—*Dominica Dial.*

Correspondence.

To the Editor of the "Ceylon Observer."

CINCHONA IN MADULSIMA: INTERESTING ANALYSES.

DEAR MR. EDITOR,—Below, you will find result of analyses of cinchona bark: Renewed and thatched and unthatched. The bark was taken from off trees growing together in lines, shaved at same time. I had heard so many conflicting opinions passed on the matter of thatching the trees after shaving, that I sent Home samples and had them analyzed, the result of which may be of interest to some of your readers. Calisaya marked No. 1 was analyzed by Messrs. Symons & Cochran, and certified at ·32.—Yours faithfully,

C. ESDAILE.

No. 1 Calisaya	0·63	A.
	0·20	Cinchonidine
	0·69	Cinchonine
No. 2 Succirubra Renewed, *thatched*	3·06	A.
	4·02	Cinchonidine
	1·77	Cinchonine
No. 3 Succirubra Renewed, *unthatched*	3·36	A.
	4·20	Cinchonidine
	2·98	Cinchonine

[The results here given are extraordinary. Even the English analysis of calisaya, leaves the yellow bark very poor, in comparison with the red barks which are both good, the uncovered, contrary to previous experience being the better of the two. —ED.]

CINCHONA BARK HARVESTING AND ANALYSES.

Maskeliya, 23rd April 1887.

DEAR SIR,—The public are much beholden to Mr. Esdaile for his interesting communication in your journal regarding cinchona shaving; but the information would be more complete if he will kindly say if the trees experimented upon were all of the same age and all stood under the same conditions in respect to light and shade; that is, if the stems of the trees operated upon were all under the same conditions of exposure to rain and sunshine. Mr. Esdaile would confer an additional favour if he will say if the unthatched trees suffered more from the barking process than those which were thatched! And again, did the thatched trees renew any more quickly than the unthatched? E. F. T.

PEPPER AND CUBEBS.

Upcountry, 23rd April 1887.

DEAR SIR,—I noticed a short time ago that you had collected in the columns of the *Observer* a considerable amount of information on the subject of Rubber Cultivation. You would, I think, confer a boon on owners of land at a low and medium elevation if you would do the same for *Pepper*. This product has one great advantage over rubber, that we know it *has* been successfully cultivated in Ceylon. All the same, comparatively little seems to be known about it now. I put out a good many plants two years ago under various conditions as regards shade and soil, but their growth is not very encouraging and this in land which I should have imagined was admirably suited to them and is doing well in other products. I think it likely enough that I may have got hold of an unsuitable variety as I have heard that some kinds do best in damp and others in dry soil, while some succeed best in shade and others in the open. Then of course one would wish to grow the most valuable sorts only. Any information about "Cubebs" would also be of value. When so many products are suffering from low prices, I cannot help thinking that something might be made of pepper were more information available. PLANTER.

[We thank our correspondent for his suggestion. Everything that we can find about "Pepper," "Cubebs" or any other likely new product for the Ceylon or tropical planter, we put into the *Tropical Agriculturist*, and there is a mine of valuable practical information in successive volumes if "Planter" and others will only kindly consult the index to each. We shall be much obliged if anyone can send us extracts from contemporary literature in the East or West bearing of any likely product which has been left out of *T. A.* —We may collate "All about Pepper and Cubebs" a little later on; but certainly for the present, the *T. A.*—and every first-class estate should have a set of the volumes—should meet the requirements of "Planter" and others similarly situated.—ED.

COFFEE AND "GREEN BUG."

Mausagalla, Badulla, April 29th, 1887.

DEAR SIR,—Can you give me imformation on the following questions?:—

1—When was green bug first noticed in Ceylon?

2—Are there any cases, where the coffee having undergone a severe attack of green bug, it has eventually come round, and is now cropping?

3—Has any large acreage of coffee being *killed* by it?

I do not seek for a remedy, as it is, in my judgment, practically impossible over a large area to apply one, but for information. I would solicit answers upon the above points. Many coffee estates in the island were converted into tea gardens, *before* the arrival of this blight owing to failure of crops from leaf-disease; capitalists declining further advances against coffee cultivation, and the price down to 60 shillings; but, given a good coffee estate this 29th April 1887, free from leaf-disease, coffee rising to 100s, but green bug taking the place of *H. V.*, what course is recommended?—Yours faithfully, GEO. KENT DEAKER.

[Mr. Deaker will find on referring to *Observer* of the 14th ultimo, answers to most of his questions:—(1), "Origin of the Pest:—First attracting attention in Matale in 1882, it had reached Pussellawa in 1884, Ramboda in 1885, and Badulla 1886"; (2), we say "yes, we believe, estates in Haputale that were badly attacked are now free"; (3) yes, in the Kandy district decidedly. There is, no doubt, much reason for experiments in fighting green bug.—ED.]

PHENYLE AND GREENBUG.—There is quite a run by coffee proprietors on "phenyle" to be used as a remedy for greenbug—so much so that, it is said, local stocks are exhausted! Kerosine, Carbolic, and Lime are however well worth trying.

MOUSAKELLIE ESTATE, KELLEBOKKE VALLEY.—This once famous coffee plantation and now favorite and very promising tea estate has lately changed hands we hear. The purchase has been effected by Mr. Gow on behalf of a London syndicate, his offer of close on R80 000 telegraphed out, being accepted by the representatives of the late A. H. Fryer. We do not know that we have seen more promising tea in Ceylon than on a part of Mousakellie, during a visit to the district a short time ago. The property covers 600 acres altogether.

ARTIFICIAL RUBIES.—At the Academy of Science's meeting held on March 14th M. Fremy read a memoir on the researches which he has made with M. Verneuil to artificially produce ruby. An Alumina crucible was used, so as to avoid the presence of silica, which has the effect of imparting a lamellar structure to the product. Under such conditions, with alumina separated from calcium fluoride by a perforated platinum septum, they have obtained perfect crystals of alumina, which, being coloured with traces of chromic acid, were an exact counterpart of the natural stone.—*Chemist & Druggists.*

CANNAVERELLA CINCHONA BARK.—We learn that the parcel of bark sold the other day was taken from a portion of the 100 acres on this estate, but most of the fields have not yet had an ounce of bark taken from them. The bark sold was from the older trees, from the seed of which the clearings were planted. A sample of the bark just sold, taken from the bulk of the parcel, was sent to London for analysis and showed 5·56 sulphate of quinine as compared with the Colombo analysis of 5·04 sulphate of quinine. The trees were *not* thatched. These particulars are interesting. We certainly would recommend Mr. Macfarlane not to leave the trees in his several fields much longer without shaving, so as to get the full benefit of renewed bark.

TEA MACHINERY.—We have had a visit from Mr. John Greig of the well-known Edinburgh firm of Tea Machinists. Mr. Greig was a long time a planter in Western India, and afterwards in tea in Assam. He visited Ceylon in 1868 and made the journey from Gampola to Haputale to visit poor Pitratmalie Wylie; but within the tea era he has not seen Ceylon and consequently perhaps, his various machines have not attracted the notice here to which they are entitled. Mr. Greig is especially confident about the success of his combined Withering, Drying and Sifting machine (his "X L All") with the latest improvements. He is now on his way to Assam to erect a large machine of this kind; and there is one also to be put up in Travancore in supercession of a Sirocco. Mr. Greig has superseded the iron flue pipes by a special kind of fireclay pipe which is expected to prove practically everlasting. Mr. Greig intends to spend some time in Ceylon on his return, and we suppose will then see that a proper series of trials is given to one of the latest improved of his machines, the working of which can be contrasted with that of "Gow's Witherer" in Carolina Factory.

THE CEYLON TEA PLANTATIONS COMPANY, LIMITED.—The possessors of Mariawatte, Dunedin, Sembawatte and Dewalakande estates, have held their first annual general meeting in London. The result of the first year's working shows a profit of 20 per cent on the paid up capital of £75,000, but the Directors have decided to declare only a dividend on twelve months' expenditure and ten months'crops, or on the crops *actually* sold to 31st December of last year. This is equal to 12½ per cent, and they carry forward to this year the value of 117,000 lb. of tea unsold or about R76,000. The crop from the estates was 501,700 lb. and 69,660 lb. bought leaf tea, making a total outturn of 571,360 lb. The average yield was 500 lb. per acre over young and old fields. The tea was produced at 30 cents per lb. which rate includes cost of cultivation of clearings not in bearing. The average price obtained was 65 cents per lb.—*Cor.* [Could the local manager or Mr. Rutherford kindly tell us *pro bono publico* what was the London report and prices for the tea manufactured in Gow's "Witherer" at the trial duly reported by Mr. Jameson some months ago? —ED.]

DISTRICTS AND ESTATES IN CEYLON which for coffee proved failures through the prevalence of wind, have in several cases been found to suit tea admirably. Of such is the Lagalla district in Matale east. We hear the most favourable reports on tea in this quarter. Mr. Armstrong has lately been giving a report on a well-known property there as almost "perfection for tea," and we learn that equally good are the prospects—based on some experience of growth along with professional reports —on the Kalupahane Valley, Western Haputale.

THE CULTUREE OF TOBACCO IN NORTH BORNEO seems to be advancing and we suppose all attempts at restriction in a settlement where the great difficulty is to attract settlers, must be regarded as out of the question. But experience in Virginia and to come nearer home, in Java have proved that a more ruinous cultivation cannot curse a country or exhaust a soil. We have only read of Virginia, but we have seen the extensive wastes in Java and our feeling is that tobacco culture is the least advantageous to a country which can be engaged in.

"THE TEA INDUSTRY IN CEYLON—illustrated in a series of etchings by Ernest F. Vandort."—We have seen a series of etchings prepared under the above title by the son of the well known Colombo Artist, which show that the skill and genius of Mr. J. L. K. Vandort have descended to Mr. Ernest Vandort. The series include well-finished sketches of coolies engaged in the various estate operations :—Pruning, Picking flush, Weighing, Withering, Rolling with machinery, Drying, Bulking, Carrying boxes away, all etched round a central coloured piece showing the bungalow and tea field. The whole is to be framed and sent to the Kandy Agri-Horticultural Exhibition, where we have no doubt, it will attract attention both for its own sake and on account of the youthful artist whose work it is. We do not see why this young Ceylonese gentleman should not aim at getting on the staff of an Illustrated journal either in England or the Australian Colonies.

THE DEVELOPMENT OF ASSAM.—Under the auspices of the East India Association, a meeting of officers and gentlemen interested in the commercial development of the British Empire in the East was held at the Westminster Town Hall on Monday, April 4th, under the presidency of Col. G. B. Malleson, C.S.I., for the purpose of considering various suggestions for the commercial development of Assam, offered in an elaborate address by Mr. Oswin Weynton. Attention was specially directed to those unutilised products bountifully furnished in the uncultivated portions of the tea estates, and Mr. Weynton urged that were Assam brought into communication with the over-populated districts of Bengal, the North-West Provinces, and Madras, a stream of emigration would set in therefrom that would supply the required labour for the full development of the province's resources, to the benefit equally of natives, Europeans, and Government revenue. Meantime, the Assam settler must remember that he is in precisely the position of the Australian colonists forty years ago. The latter did not wait for that influx of labour they knew would be inevitable, but prepared for it in anticipation by utilising their runs to the utmost, and though fruits, corn, and sheep increased on their hands to an unprofitable extent for years, when immigration did set in everything was prepared for it. Assam, either hill or plain, has an equally prosperous future before it if its capabilities are developed with the same energy, though now it is to most people an utter *terra incognita*, whose past and varied indigenous wealth is as yet appreciated by few.

PLANTING IN JOHORE.

[This prospectus and Company proved abortive after publication.—ED.]

THE JOHORE COMPANY, LIMITED.

CAPITAL.—Ordinary Shares (of £10 each),

£600,000. Total Capital £850,096.

PROSPECTUS.

This Company has been formed for the purpose of acquiring the valuable Concessions obtained in November, 1884, and May 1886, from the Sultan of Johore, by W. McGregor Smith and Dalton Sayle, in the name of Mr. William Keswick, of Hong Kong, and of No. 3, Lombard Street, in the City of London, Merchant, as their Trustee.

These Concessions comprise (with the special privileges hereinafter more particularly described) the right to select 100,000 acres of land (an area of upwards of 156 square miles) in the territory of Johore and Moar, in the Malay Peninsula, which is distant only about 90 miles from Singapore. The concessions are held direct from the Government of Johore, which has recently entered into an offensive and defensive treaty with the British Government.

Of these 100,000 acres, upwards of 80,000, believed to be the choicest and most valuable land in the territory, have already been selected, the survey being now in progress as regards the remainder. A skilled planter accompanies the surveyor, with instructions to reject any land not of the richest character.

The tenure is for a term of 999 years, and the property is not burdened with any fixed payment the rent being 2½ per cent. of the gross products on the spot.

Opium is a Government monopoly, but its cultivation by the Company is not contemplated. With the exception of Opium, Pepper, Gambier, and one or two other items of an unimportant character, Export or other Duties cannot, under the terms of the concessions, be imposed upon any of the products cultivated upon the property. As such duties, which will probably vary with the requirements and expenses of the Government, are chargeable to other Planters in the territory, it is at once apparent that the value of the concessions is enormously enhanced.

The climate of the southern portion of the Malay Peninsula, situated within three degrees of the Equator, and practically surrounded by the sea, is both humid and equable the mean variation of the temperature of Singapore and Johore being from 70° to 90° (Fahrenheit). The rainfall averages 100 inches, which renders land in this territory peculiarly adapted for the growth of tropical products, one special advantage being that they are capable of cultivation *all the year round* without intermission. There are no regular wet or dry seasons, as in most other tropical countries, but the rainfall continues at short intervals throughout the year. For example, it may be mentioned that *two distinct crops of Tobacco*, the same as the well known Sumatra Tobacco grown by the various Deli Companies can be produced in one year, Johore is only divided from Sumatra by the Straits of Malacca.

The lands acquired by the Company are of virgin soil, and contain forests of primeval timber, including Teak, Ironwood, India Rubber, and various other tropical and valuable woods. Many and various specimens of this timber were shown at the Forestry Exhibition in Edinburgh, in 1884, and a large number were awarded prizes.

The lands are remarkable for the numerous Fibrous Plants, such as "Rhea." "Mhoorva," &c., which are indigenous to the soil; "Rhea" and "Mhoorva' are used as substitutes for Cotton, Flax and Wool, the former being also employed for mixing with Silk. These fibres will, on account of their low cost, gradually but surely revolutionise the manufacture of many descriptions of staple goods, and a reference to the annexed report of Mr. W. E. Death shows the profits which the growth and preparation of these fibres are calculated to produce.

The long standing difficulty in connection with the separation of the fibre from Rhea stems which has for so many years occupied the attention of the Government of India has recently been overcome, and Machines have been invented which are able to reduce these fibres to a marketable condition.

The lands are also specially suitable for the growth of Tobacco, Pepper, and other products, and it is proposed to expend the Capital of the Company now asked for in the cultivation of about 17,000 acres in the following proportions:—

	Tobacco. 10,000 Acres.	Pepper. 2,000 Acres.	Fibres. 5,000 Acres
* Estimated Working Capital.	£275,000	£54,000	£145,000
Estimated Annual Profit.	£260,000	3rd Year £90,000; 4th „ £90,000; 5th & subsequent years £140,000	£205,000

Estimated Ultimate Annual profit on Expenditure of £500,000 ... ... £605,000.

* It must be borne in mind that a considerable portion of Capital expenditure is returned with each crop, and is available with the reserve fund for the planting of further land.

Such an Estimate of profit as the foregoing may at first glance, be sceptically regarded, but in evidence of the immense profits which are being derived through the employment of capital in undertakings precisely similar in character to that of this Company, the following particulars of dividends paid by the Deli Companies of Sumatra, may be quoted:—

DIVIDENDS PAID BY.

In	The Deli Maatschappy.	The Tabak Maatschappy.	The Amsterdam Deli Company.
1882	65 per cent.	25 per cent.	10 per cent.,
1883	101 „	50 „	30 „
1884	77 „	60 „	30 „
1885	107 „	100 „	60 „

The Returns for 1886 are not yet available.

The Singapore and Straits Directory, which contains a record of Estates and Lands held in the Straits Settlements, Sumatra, &c., shows that the lands leased by the three above-named Deli Companies, collectively embrace under 77,000 acres (of which it is understood that only a small portion is at present under actual cultivation). The total paid-up Capital of these three Companies amounts to upwards of £400,000. Not only have the Deli Companies paid these dividends, but they have in addition set aside 15 per cent of their profits towards a sinking fund for redemption of capital. The Deli Companies' Leases have moreover only been granted for a period of 75 years as against 999 years, the term for which the Johore Company's Estates are held. The present price of the Deli Maatschappy 100 guilders shares is 680.

A considerable portion of the Estate will, when cleared for cultivation, be let to tenants, who are readily obtainable from the Malay and Chinese population. The rental for which it is estimated will average £4 10s. per acre per annum.

The work of clearing and cultivating the land must necessarily occupy some time, but with special regard to tobacco, a crop can be raised and realised during the current year, and assuming that at least 5,000 acres—a moderate estimate—can be brought under cultivation within the first 15 months, and that in each following year a further 5,000 acres can be made productive at least £100,000 net profit should be realised during the year 1888, and in subsequent years this profit should be proportionately increased. The following condensed summary shows the profits which, under such circumstances, would accrue to the holders of the Ordinary Shares, a sum of £16,000 being allowed in the calculation for each year for Establishment expenses.

Minimum Estimated Net Profit during 1888, say £100,000.

6 per cent. Interest on Debenture Bonds, £250,000, will absorb £15,000

10 per cent. Dividend on Ordinary Shares, £600,000, will absorb	60,000
	£75,000
10 per cent. for Reserve Fund to be set aside	10,000
Total ...	£85,000
Minimum Estimated Net Profit during 1889, say, £200,000.	
6 per cent. Interest on Debenture Stock, and 10 per cent. Dividend on Ordinary Shares will absorb	£75,000
10 per cent. for Reserve Fund	20,000
Total	£95,000
Leaving a Balance of	105,000

Three-fifths of £105,000=£63,000, will provide a further Div. on Ordinary Shares of 10½ per cent. In all

20½ per cent.

It is considered needless to pursue these calculations further in detail, but an annual rate of increase in profits, if only half such amount, would enable the Company in the fifth year, namely, 1892 (when it is presumed that the 17,000 acres will have been brought under profitable cultivation), to divide among the Shareholdrs nearely 55 per cent., besides having appropriated to the Reserve Fund nearly £150,000.

The importance of securing skilful and competent management on the Estates is an element of the first consideration, and in order to make due provision for the same, the service of three Resident Managers (one of whom, Mr. Tom Gibson, is now on the Estates) have been secured. The other two Managers, who have been especially selected on account of their practical experience in planting, &c., will immediately proceed to Johore, both being prepared to at once enter upon their respective duties.

A plentiful supply of cheap labour is available; Chinese coolies (the best labourers in the world for tropical climates) are readily obtainable in Johore and Singapore at seven dollars, equal to 23s. 4d. per month, while in neighbouring countries their wages are not less than ten dollars, equal to 33s. 4d. per month, a difference of £6 per coolie per annum, in favour of the Company.

One of the great advantages in connection with these concessions is the water frontage which the land possesses. A reference to Map No. 1 will show that the River Moar forms a water highway for many miles through the property; the Moar is at all periods of the year navigable by vessels drawing 10 feet of water, while those of the heaviest draft can anchor off the mouth of the river, which is in the direct route of the China Mail Steamers. The water facilities thus afforded reduce the cost of transport to a minimum.

THE WEIGHT, says an American writer, affords the easiest test for the purity of guano. A bushel of pure Peruvian guano, according to most authorities, should weigh almost exactly seventy pounds. If heavier than seventy-three pounds, it is adulterated with clay, sand, marl, or some other impurity.—*Indian Gardener.*

SUBSTITUTE FOR BOXWOOD are noticed by Mr. Jackson of Kew in *Forestry*:—Amongst the woods being that of *Hunteria zeylanica*, Gard.—A small tree, common in the warmer parts of Ceylon. This is a very hard and compact wood, and is used for engraving purposes in Ceylon, where it is said by residents to come nearer to box than any other wood known. On this wood Mr. Worthington Smith gave a very favourable opinion, but it is doubtful whether it would every be brought from Ceylon in sufficient quantities to meet a demand.

MANUACTURE OF PAPER FROM WOOD.—The idea of utilizing wood for the manufacture of paper was first suggested to Reaumur in 1710, from his noticing that the fabric ot wasps' nests was formed out of wood reduced to a pulp. This industry has of late years acquired great importance, and is rapidly increasing, as the supply of rags, on which paper-makers formerly depended for their stock, is inadequate to the demand for the manufactured material. Were it not for this factor in paper-making, paper would now be one-half as much more, if not double, the price it is to-day.—*Journal of Forestry.*

THE *Pharmaceutical Journal* states that the administration of one drop of croton oil and a drachm of chloroform in an ounce of glycerine having been recommended as useful in obstinate cases of tape-worm, Mr. McCullum, of Ontario, writes to say (*Brit. Med. Journ.*, June 13, p, 1231) that the vehicle only is necessary for the purpose, since the glycerine will kill the tape-worm quite as effectually without anæsthetising it with chloroform, or purging it with croton oil. This property of glycerine, he states, he first observed one day when removing a worm from the stomach of a fish, and putting it into a drop of glycerine upon a microscope slide, where it died almost immediately. He was therefore led to try the experiment of substituting glycerine for the nauseous male-fern dose with good results. Sometimes he has found it necessary to follow the glycerine with a gentle purgative, but not always.—*Indian Agriculturist.*

ACCORDING to the *Paper-Maker*, a paper-making firm in New Jersey has for several weeks been turning out counterpanes and pillows of paper. No. 1 Manila paper is used, two large sheets being held together by a slender twine at intervals of three or four inches. The twine is gummed, so as to hold the sheets firmly together where it lies. A hem is placed on the counterpane to keep it from tearing; the safety edge is composed of twine. Ornamental designs are stamped on the outer surfaces of the covers and cases, giving them a neat, attractive appearance. When these counterpanes and pillow-cases become wrinkled from use they can easily be smoothed out with a hot-flat iron. The counterpanes can be left on the bed when it is occupied, and in cold weather will be found a warm covering, paper preventing the escape of heat. The new paper bedclothing is 75 cents per set, and will probably become popular.—*Indian Agriculturist.*

We have received Part IV of the *Journal of the Agricultural and Horticultural Society of India* which, we are glad to see, contains some very interesting papers. Mr. Wood-Mason's paper on the *Paraponyx oryzalis*, or the insect-pest of the rice plant in Burmah, heads the *Journal*. We were favoured with a copy of this publication in pamphlet form last year. Mr. R. A. Manuel contributes some interesting notes on some of the silks of British Burmah. Mr. S. Jennings, well-known to agri-horticulturists in India, has supplied a valuable paper on Rhea, which should be widely read. Mr. Minchin's note on raising Rhea from seed is also valuable. Mons. Dumaine, who is well known as an enquirer in the sience and practice of sericulture, furnishes some interesting particulars on the wild silk-yielders found in Hazaribagh. Dr. Bonavia, whose prolific pen has been busy for many years in efforts to benefit the country, has elaborated his ideas regarding the value of the citron order of plants in a paper on Citrus decoction as a fever remedy. Mr. C. Maries, who is an authority on the mango, contributes a few practical remarks on the propagation of this fruit tree. But by far the most interesting paper in the current number of the *Journal*, is the sketch of the rise and progress of the Agri-Horticultural Society of India, by Mr. A. H. Blechynden, the able and courteous Secretary of the Society, who for so many years has held this onerous post with so much benefit to the Society, and such credit to himself. He begins at the beginning, describes the early struggles of the Society after its establishment by its founder, the Rev. Dr. William Carey, one of the greatest men, in one sense, India has ever seen; traces its progress, and reviews the wide scope of the Society's labours in the fields of agriculture and horticulture, and in the development of the various industries that come within its purview. On the whole, the present number of the *Journal* contains about the most interesting papers we have seen in its pages for some time past.—*Indian Agriculturist.*

ARTS AND INDUSTRIES IN EASTERN AFRICA.

Domestic arts and industries have not yet reached a high state of development. Most of the agricultural implements are made from a hard wood, called "blackwood" or "coast ebony." The Makuas make a fine string from the roots of a tree termed *mlamba*. The Watussi draw out fine copper threads, with which they fabricate *nierees*, a kind of ring composed of giraffe-hair bound spirally with the metallic thread, and worn as leglets.

In Usambara, native talent has devised more than one form of musical instrument. A small clarionet, called *zomali*, about 18 inches long, and with a reed mouthpiece, gives out sounds much resembling those of the Welsh bagpipe without the drone; it ranks second to the drum in public favour. The *pangu*, or *zeze*, is a doble-stringed lute, in which half a calabash serves as a sounding-board. The *kwacha* is a shield-like board, about 2 feet long and 8 inches wide, rounded at the ends, into which two round notched sticks of hard wood are inserted, so as to form a curve over it; these notched sticks are then rubbed up and down with smaller sticks, so as to produce a rasping and most unmusical noise. A more capable instrument is the *riringa*, a large, rude, paino-like contrivance, formed of two thick banana-stems laid parallel, and of pieces of hard wood fastened crosswise between these, made so that those giving the highest notes are in the middle, the lower at each side. It is played upon by striking the notes with two sticks.

In the Massasi district ironstone abounds, and is utilised by the natives. They smelt this mineral in furnaces dug out of old ant-hills, and then forge hoes and axe-heads from the iron thus obtained. One of the chief employments of the people of Makua is the smelting and working of iron, the ore of which is procured from the hills of Chiga. The manner of working is very similar to that practised by the Ajawa or Yao tribe. The charcoal furnace is blown to a white heat by four separate blowers worked by hand, consisting of skins of a small deer, into each of which is bound a retort made of clay, the mouth leading into the fire. The anvil is a slab of granite; the hammer a heavy cube of stone, slung with fibre cord let into grooves at its sides. Hoes, knives, and axes are thus made at very cheap rates.

Every woman in Chole, south of Zanzibar, appears to be engaged in plaiting grass mats, which are largely exported. In this district, near each village, bark hives are fixed on cross branches about 6 ft. from the ground, bees being very numerous, and the wax of good quality, is brought to Samanga for barter. The Rufizi delta furnishes an almost inexhaustible supply of mangrove wood, which is shipped to the Red Sea and Arabia as "Zanzibar rafters." In the forests and jungles of this region the rubber vine (*Landolphia*) is plentiful, and the product is collected. The produce of the Mozambique coast consists chiefly of oil-seeds (*amendoim* and *gergelim*), rubber, ivory, copper, and wax. Rubber vines compose much of the forest in Massasi; the trees are gashed, as the escaping fluid soon assumes a pasty consistence, and is then rolled into orange-like balls for sale. Somaliland exports myrrh and incense; the forests of Usambara afford "ebony," copal, "teak," acacia, rubber, orchella, betel-pepper, prickly smilax, and other useful plants. The bagamoyo coast exports copal, grain, semsem, ivory, wax and rubber. On Lake Ugombo the hard reed-grass called *miombo*, when beaten, rubbed and twisted, makes splendid rope, while another reed termed *mdete* affords excellent material for sun-blinds. The finest timber tree met with in Gaza is a species of *gardenia*, known as *umshanatse* or *mapani*, furnishing planks 2 ft. wide and 40 ft. long. In Usambara gates to towns are made from the wood of a species of *Acacia*, called *mkongolo*, black within and white without, which is so hard as to almost withstand the attacks of white ants. The *mbunga* vine (*Landolphia*) is known from Pangani to Handei, and the copal tree (*shakasi*) is abudant in the woods adjoining the inner side of the wilderness of Usambara.—*Journal of the Society of Arts.*

101

TOBACCO GROWING IN DELI.

The *United States Tobacco Journal* published lately a report by the German Consul at Singapore on the cultivataion of tobacco in the Island of Sumatra. This report gave first a detailed account of all the localities in Sumatra suitable for tobacco raising; it then described minutely and graphically the process of planting, &c., and lastly, it gave a pretty close calculation of the cost of production. To buy a plantation of a hundred fields, says the report, and to put it in a perfect state ready for cultivation, inclusive of the erection of sheds and houses for the men and tobacco, cost about from $25,000 to $30,000. The raising of the tobacco is done by coolies, who receive from $2 to $8 for every thousand plants, the price depending on the quality and yield of the crop; while every plant is permitted to bear only twelve to twenty leaves. We will take an average of fifteen leaves to the plant, that will give 15,000 leaves to a thousand plants. Let us average a hundred leaves to the pound, of fine grade of Sumatra, and we shall get 5½ cents (of dollars) as the price of labour represented in one pound of Sumatra-grown tobacco. A plantation of a hundred fields, representing an investment of a capital of, say $30,000, will yield on an average 225,000 pounds per crop; the interest of the capital at six per cent. amounting to $1,800, will add another ¾ of a cent. The freight-charge from the eastern coast of Sumatra to Amsterdam has just been put down to $1·31, per bale by the Nord-deutscher Lloyd, consequently the entire gross outlay to raise a pound and ship it to Amsterdam amounts to about c.7½. Considering the depressed state of the tobacco leaf market of the United States, the *Tobacco Journal* refers its countrymen to this mine of wealth, open to American enterprise, and is surprised that the Americans generally having the reputation for smartness, should have allowed the Germans and other nations to get the start of them. Likely they (the Americans) are deluded by the belief that none but Netherlanders are permitted to acquire land in Sumatra. On this point we dare say that a considerable part of the tobacco growing in Deli, by which name a large part of the eastern coast of Sumatra is called, is in the hands of foreigners, notably Germans and Swiss. Among the planters of Deli proper every European nation is represented. We should have omitted this remark had it not been that in the report by the German Consul at Singapore the contrary is intimated. A report compiled by this official is certainly very inaccurate in several particulars, and no wonder that the United States Journal thinks its countrymen somewhat behind the times if such were the case.

A tobacco plantation is not a pear garden, purchased in spring to sell the fruits in autumn, however, and we need not explain how much labour and capital are required before the grounds are ready for cultivation, and ready to yield the first leaf of tobacco. But besides this, we do not understand where the Consul got his statements. He first calculates that a plantation of a hundred fields will yield on an average of 225,000 pounds of tobacco, 2,250 pounds, or 18 piculs per field; it is generally known that an average of 7 piculs per field is very satisfactory, and one of 8 piculs may be considered as very successful indeed. There are really fields yielding exceptionally 10 or 12 piculs, but, on the other hand, there are a great number of fields yielding only 3 to 5 piculs. The freight-charge calculations to raise a pound of Sumatra and ship it to Amsterdam is so ridiculous that we shall say no more on the subject. It may be sufficient to state that the following expenses are omitted, viz.:—Salary of managers, clerks, mandors, &c., in India, and in the Netherlands for directors, administration, outlay of capital on buildings and materials, carriage, freights on board, charges for unloading and storage, &c. It comes to the amount of c. 18¾ (Netherlands currency) per pound. In order to warn our American friends we add hereunto that with a single exception a pound of Sumatra

tobacco, generally bought at the Amsterdam market, costs the producer f.0.80. to f.0.90, which amount on a produce of only 4 to 5 piculs per field certainly far exceeds f.1.

In conclusion, we refer to the *United States Tobacco Journal's* assertion that Americans are not acquainted with the fact that foreigners also are permitted to acquire land in Sumatra. If we have to consider this as the opinion of tobacco-men, we think it rather naïve for smart men like the Americans, which proves at the same time that the information of American Consular officers is not always reliable. However, American people ought to know as well as we do that not every part of the east coast of Sumatra yields results like these on which the first-comers could pride themselves, and that, as Mr. G. Harkema observes in *de Indische Mercuur* of Jan. 1, the results have often proved to be very deplorable.

On this subject Mr. J. F. Cremer, member of the Second Chamber of the States-General, late Chief Manager of the Deli Company, states:—We can indeed reckon, on an average, on fifteen leaves per plant, but not that of *such leaves* as that every hundred make a pound; such is, indeed, the case with the best leaves of Sumatra tobacco, but not with an average number of leaves of the crop. For the lower leaves of a plant, especially when gathered in a rainy season, contain a good deal of broken and spotted or decayed leaf that weighs much less. On an average we may reckon that 1,800 plants furnish 1 picul, or 125 Amsterdam pounds. For this from $2 to $8 per 1,000 plants is paid; but as $2 to $4 is the exception the real average is $6 per 1,000 plants, or $10·80, so fully 8 and not 5¾ cents per pound. The freight per German Lloyd is f.55 per last of 800 K.G., or 10 bales; so not $1·31, per bale, but, reckoning the dollar at f.2·50, $2·20. Therefore if these data of the Consul are incorrect, the great fault of his computation is this, that he calculates the percentage of the capital required for the outlay of a concern at 6 per cent. per year, to pay the costs of European and Chinese supervision, of drying-sheds which require complete renewing every two years, of houses for medical attendance, of losses (absconding or deaths of labourers), of jungle clearing and making of roads and drains, of horses and carts, and the necessary drivers, of Java and Kling auxiliary workmen for the sorting and packing of the tobacco, with other needed arrangements. The Deli Company yields crops from 3¾ to 4 million pounds. The produce was lately fully f.1.60 per Amsterdam pound. If this cost 7½ dollar cents, or f.0.1875 at Amsterdam (plus 10 per cent. for tandil wages), then the gain per pound would be f.1.4,125 or 5¼ to 5½ million guilders. The dividends would then be fully 250 per cent. If the Germans and Americans are to set about colonising on such data as supplied by the Consul at Singapore, they will meet with sad disappointments.

"I can further inform you," continues Mr. Cremer "that from a statement of eleven nominally working concerns in Deli and Langkat in 1886 I perceive that they required on an average 2,000 plants per picul, which cost on an average $6.10 per 1,000, without the wages of the tandil or Chinese superintendent; with these wages the picul yielded about $13.45, or per half kilogram 10¾ dollar cents. In 1886, on account of copious rain, the crop was rather light; in more favourable years the above calculation will hold." We may add that we were officially informed by the manager of the Deli Company that in the preceding year the product of one of their estates realised f.1.60 per pound on the Amsterdam market, while the costs of production had amounted to f.2.25 per pound; a loss, therefore, of f.0.65 per pound. And yet the sale of that product had been effected under very favourable circumstances. An additional proof that not all concerns in Sumatra are remunerative. To conclude, we wonder at the startling fact that the Americans, whose Government is constantly supplied with the best and most reliable reports on everything concerning tobacco culture in Deli from their own Consul in Holland, Mr. Eckstein, should have allowed themselves to be led astray by the report of the German Consul at Singapore. In one of the reports of Mr Eckstein we read, among other things, that the costs of production on a kilo. of Deli tobacco on the Dutch market can be regarded as 70c. or 80c. per kilogram.—*London and China Express.*

ROYAL GARDENS, KEW.

Bulletin of Miscellaneous Information—Fibre Plants.—It is proposed in the following notes to deal briefly with fibres derived from tropical endogenous or monocotyledonous plants which yield what are known in commerce as Sisal Hemp, Manila Hemp, Bowstring Hemp, and Mauritius Hemp. These are used chiefly for rope making and cordage, and are to be distinguished from flax, cotton, and other fibres used purely for textile purposes.

The large and increasing interests taken in fibre plants and the numerous references made to this establishment on the subject render it very desirable to place within reach of cultivators in India and the Colonies a summary of information on the subject.

The Hemps above enumerated are derived as follows:—

i. Sisal Hemp,
Agave rigida, MILL.
(A. Ixtli, *Karw.*
A. elongata, *Jacobi.*
A. Sisalana, *Perrine.*)
ii. Mauritius Hemp,
Furcræa gigantea, VENT.
iii. Manila Hemp,
Musa textilis, NEES.*
iv. Bowstring Hemp,
Sansevieria zeylanica WILLD.*

The fibres of endogenous plants, the chief of which are enumerated above, are generally white if cleaned without fermentation, but are easily discoloured and also weakened by the decomposition of the mucilaginous and saccharine matter associated with them. Hence it is important that they should be cleaned either by mechanical or chemical processes as soon as possible after they are harvested. The resulting fibre if of good quality, is white, bright, and glossy, and the individual filaments are straight and free.

Although grouped together here for convenience of treatment, the plants yielding these hemps require severally very different treatment under cultivation, and it is important to bear in mind that they will prove objects for remunerative culture only under certain special circumstances.

For instance, the Agave plants yielding Sisal Hemp flourish in the dry districts of Yucatan, they require little cultural attention, and the fibre is cleaned by means of cheap native labour, which is probably attainable in few British Colonies.

Manila Hemp is produced entirely in the Phillippine Islands from a species of wild banana or plantain (*Musa textilis*). It requires rich moist forest land, and while in its native country it is found to be easily cultivated; it has been only moderately successful under cultivation elsewhere. Here again the industry is supported by an abundant and cheap labour supply, which enables the fibre to be cleaned by hand at a cheap rate.

Bowstring Hemp is scarcely an article of commerce at present, although locally it is used for many purposes, as in Ceylon, India, and the East and West Coasts of Africa, where species of Sansevieria are found.

Mauritius Hemp is obtained from *Furcræa gigantea*, known in the island as *Aloës vert*, but elsewhere as the green or fœtid aloe. It is a large unarmed species, native of tropical America, but found in both the East and West Indies and also at St. Helena. At Mauritius it has established itself spontaneously on abandoned sugar estates. It is easy of cultivation, and partakes much of the character and habit of the plants yielding Sisal Hemp. Machinery has been used for preparing Mauritius Hemp, and while good prices ruled the industry was fairly remunerative.

* These will be discussed in Bulletin No. 4 for April.

V.—SISAL HEMP.

Under this term are included fibres derived from probably more than one species of Agave, and it is probable also that one species of Furcræa is used. According to the locality where the industry is carried on or the port of shipment the fibre produced in Yucatan is called Sisal Hemp, which is the recognised name in the English market; or Jenequen or Henequen Hemp, which would appear to be the term more commonly used in the United States. Pita is another Central American fibre but whether the produce of an Agave (*A. americana*) or of a Bromeliad (*karatas Plumieri*) is not quite clear. Probably it is loosely applied to both.*

As regards the species of Agave yielding Sisal Hemp Miller first described *A. rigida* (Dict. Ed. 8, 1768) in the following words:—Long, narrow, stiff leaves, "entire, and terminated by a stiff black spine. These "leaves are seldom more than two feet long, little "more than an inch broad, being of a glaucous colour. "The side leaves stand almost horizontally but the "centre leaves are folded over each other and "enclose the flower-bud."

This may be accepted in a large sense as the representative species of which there are several subspecies and varieties cultivated by the natives of Yucatan from time immemorial.

According to Dr. Engelmann (Trans. Acad. Science. St. Louis, Vol. III., Dec. 1875) a common native species in Yucatan called Chelem by the aboriginal inhabitants is identical with *Agave rigida* of Miller; but a number of varieties, characterised by longer leaves or the absence of spines, have been recognised, to which names more or less distinct are now applied.

Mr. Baker has given a Synopsis of the Genus, Agave in the *Gardeners' Chronicle* (Vols. VII and VIII, New Series, 1877). The plants mentioned below are included under the Group *Rigidae*, having the edge of the thin horny leaf without any distinct border, and the teeth (when present) small but distinct and deltoid. He remarks that this is a considerable group of which *A. lurida* and *A. rigida* may be regarded as the types intermediate between the groups *Americanae* and *Aloideae*.

From a study of plants at Kew, Mr. Baker was inclined to look upon *A. Ixtli*, Karw., as the type and *A. rigida*, Mill., *A. elongata*, Jacobi, and *A. Sisalana*, Perrine, as synonyms or varieties. But as in the first place *A. rigida*, Mill., has the priority in point of time, and (if we follow Dr. Engelmann) also represents the old aboriginal fibre plant of Yucatan (the Chelem), it would be better to retain this as the aggregate species and place the others among the varieties which have arisen in course of long cultivation in different parts of the peninsula of Yucatan.

We have then.

A. RIGIDA, *Mill.*

var. 1. *A. Ixtli*, Karw.; *A. ixtlioides*, H. K. leaves 1½—2 ft. long, teeth distant.
2. *A. elongata*, Jacobi: leaves 4—5 ft, glaucescent and toothed.
3. *A. Sisalana*, Perrine; leaves 4—6 ft. long, pale green not glaucous, generally without teeth.

Dr Engelmann in his notes cited above mentions that the original plants of *A. rigida*, was, according to Miller, brought from Vera Cruz, but his own specimens were collected in Yucatan by Dr. Schott. He states that Dr. Perrine, and Dr. Schott independently studied and described in Yucatan this interesting plant, with its different forms and economic uses (Senate Doc. 300, Washington, March 12th, 1838; the latter in the Report of the Agricultural Department at Washington for 1869. According to Dr. Engelmann, "both agree that there is a common native species in "Yucatan, called *Chelem* by the aboriginal inhabitants; "but from time immemorial a number of varieties, "all characterised by much longer leaves, and one also "by the absence of marginal spines, and differing "among themselves in the quantity and quality of "their fibre, have been cultivated by the natives of "Yucatan, and are a staple product of that country "to this day, furnishing the well known Sisal Hemp. "the people know them as *Jenequen* (Schott) or *Hene-*"*quen* (Perrine), and distinguish, as Dr. Schott reports, "the *Yaxci* (Yashki) as furnishing the best quality, "and the *Sacci* (Sacqui) with the largest quantity of "fibre. *Chucumci*, larger than the last, produces coar-"ser fibre; *Babci* has fine fibre, but in smaller quan-"tity; *Citamci*, with small narrow leaves and poor "fibre, stands probably nearest to the wild plant. "Dr. Perrine mentions another variety *Istle*, evidently "the *Ixtli* of Karwinski, as furnishing a fine fibre, "called *Pita*. These plants yield a return of leaves "when four or five years old, and may last 50 or "60 years under proper management; the flowering "scape is cut off as soon as 4 feet high, when, evidently, "axillary branches continue the growth of the plant, "which is thus kept so long alive by being prevented "from flowering.

"The trunk of the wild plant of Yucatan, which "I refer with little doubt to Miller's old *A. rigida*, "is 1—2 feet high; leaves 1½—2 feet long, and as "many inches wide, contracted above the broader base "and widest about the middle; lateral teeth ¾ or "even 1 inch apart, mostly straight, from a broad "base 1—2 lines long, rather unequal, with smaller "ones interspersed, dark brown; terminal spine 1 inch "long, 1¾ lines in diameter, straight, or often some-"what twisted, terete, scooped out at base but not "channelled, dark red-brown, a dark corneous margin "extending down the leaf-edge for several inches and "bearing the uppermost teeth. Scape 12—15 feet "high; flowers pale yellowish green, 2¼—2½ inches "long, perigone 16, tubes 6—7, lobes 9—10 lines long; "stamens inserted about the middle of the tube, 'blood-"red upwards,' 1-inch longer than the perigone; an-"thers 10—10½ lines long; styles at last as long as "stamens.

"*A. Ixtli*, which in 1872 flowered in the gardens "of the late M. Thuret at Antibes, is entirely similar, "flowers of the same dimensions, anthers a little "larger (11½ lines long); capsules, which grow with "the bulbs on the same panicle, oval, over 2 inches "long, 1¼ wide, very short stipitate; seeds uncommonly "large, 4½ lines high, with a ventral hilum (in many "other Agaves I find the hilum of more basal, "a character which may be of some value). I believe "this is the first time that the flowers of the Ixtli "have been described;* they identify the plant with "the old *A. rigida*, or at least the above described "Chelem. *A. Karwinskii*, Zucc., is probably the same "thing.

"With the name of *longifolia* I designate the "variety known as *Sacci* (Sacqui) and extensively "cultivated in Yucatan; it is principally distinguished "by its much longer spiny leaves, 4—5½ feet long, "3—4½ inches wide; flowers very similar to those of "the wild plant, but filaments greenish. *A. four-*"*croyoides*. Jacobi, Agav. p. 107, probably belongs here, "and *A. elongata*, Jacobi, p. 108, I would also refer "to this form if the description did not expressly "mention a channelled terminal spine.

"*Agave Sisalana* is the name that Dr. Perrine gave "to the plant known to the natives of Yucatan as "*Yaxci*, the most valuable of the fibre-producing Agaves, "which was introduced by him into South Florida "some thirty-five or forty years ago, during his efforts "to acclimatize commercially valuable tropical plants "in that almost tropical portion of our territory, "efforts which were aided by Congress by a large "grant of land, but which were destroyed together

* According to Miller Pita fibre is derived from *Furcræa gigantea* which would make it identical with Mauritius Hemp. Dr. Perrine on the other hand mentions *Agave Ixtli* "as furnishing a fine fibre called Pita."

* This remark made by Dr. Engelmann in 1872 is, however, not quite correct. The *ixtlioides* form (*Agave Ixtli*) were fully described and figured by Sir J. D. Hooker from a plant which flowered at Kew in 1871, (Bot. Mag. t. 5993.)

"with his own life, during the subsequent Indian wars. "With this Agave, however, he has been successful, "as it is now fully natuaralized, and is quite abundant "at Key West and the adjacent coast. Dr. Parry "found it there in full bloom in February 1871, and "gives the following description of it:—Trunk short; "leaves pale green but not glaucous, 4—6 feet long "and 4—6 inches wide, generally smooth-edged, but "here and there bearing a few unequal, sometimes "very stout and sharp teeth; terminal spine stout, "often twisted, purplish-black; scape 20 or 25 feet "high, panicle 8 feet long and half as wide. One of "the largest plants examined had 35 branches in the "paniele, the largest (near the middle) 2 feet long, "upper and lower ones shorter. The flowers are "slightly larger than those described, with a shorter, "thicker ovary, stamens inserted a little higher up in "the tube. The plants bore no fruit, but produced "an abundance of buds, by which they propagate "themselves and from which this interesting form has "been multiplied in this country and in Europe.

"If this plant is, as is most probable, only a cultivated variety of *A. rigida*, it is of the greatest "importance for the study and the understanding of "the Agaves, indicating, as it does, the extent of "variation which they may undergo. It shows that "the size of leaf and scape, or colour of leaf, are of "no great specific value, and also that the presence "or absence of spiny teeth on the margin is not an "unalterable character, not any more than the cartilaginous margin decurrent from the terminal spine. "The presence of a trunk, the proportions of the "leaf (in *A. rigida* and all its varieties the length "equals 12—14 times the width), probably the form "of the terminal spine, the character of the inflorescence, and, above all, the form and proportions "of the flower and its parts, remain constant, and "perhaps also the proliferous character of the inflorescence of some species."

In a Report on fibre plants prepared by the late Director of the Botanical Department, Jamaica, in 1884, it is mentioned that with regard to the value of *Agave rigida* and its allied forms as the sources of the Sisal hemp of commerce, there are two important points deserving attention. The first is the universal increasing demand which exists in all countries for this fibre, and the, second is the drought enduring character of the plant and the simple and economical treatment which it requires at the hands of the cultivator.

The fibre of these Agaves under their own name or as Sisal hemp and Henequen is quoted at the present time at 38*l.* per ton, which is a little over 4*d.* per pound.

In Yucatan the Agaves are planted about 9 feet between the plants each way, with intervals of 15 or 18 feet at certain distances for carting out the leaves and young shoots. In regularly planted areas there should be 400 plants to the acre. Plants put out as suckers about 1½ to 2 feet high commence to yield in the fourth or fifth year and they "continue to do so for fifty or sixty years and even longer."

As an example of what the probable returns may be from a Sisal hemp plantation, it is stated by Dr. Perrine that each plant at four or five years old yields on an average 25 leaves per annum, the aggregate weight of which is one "arroba" or 25 pounds. Out of this weight of green leaves there is obtained by hand scraping one pound of clean marketable fibre, which at 38*l.* per ton is worth a little over fourpence per pound.

The annual gross return per acre may therefore be set down at 400 pounds of fibre, which at 4*d.* a pound, gives a gross yield of 6*l.* 13*s.* 4*d.* The actual cost of producing and preparing the fibre would vary according to the circumstances of the locality; but where ordinary facilities exist for the transit and preparation of the leaves, and especially with the aid of simple and effective machinery, the cost should not exceed one penny per pound. Hence the net returns may be set down at about 5*l.* per acre per annum.

The export of Sisal hemp exceeds that of any other article of Mexican growth. The export value of fibres from Yucatan in 1883 reached the large sum of 658,000*l.*

Dr. Schott. in the report of the Department of Agriculture, United States of America for 1869, remarks that "while other products of Yucatan agriculture may occasionally have become unprofitable "either in consequence of adverse climatic features "to which the peninsula is subject, or through commercial fluctuations, the Sisal hemp has never been "subject to such drawbacks, a fact attributable to the "universal usefulness of its fibre and the unconquerable vitality of the plant, which easily survives the "effects inherent to the nature of a riverless rocky "desert, and the severe trials of a six months' "tropical sun. For a knowledge of the Sisal hemp "plant," continues Dr. Schott, "its culture and uses, "Yucatan is indebted to the Maya Indians, the "direct descendants of those remnants of the Toltecs "who, after the fall of their empire in the valley "of Mexico, emigrated to Central America and "Yucatan.

An account of the Sisal hemp industry in Yucatan has lately been published by the Government of Jamaica. This was furnished by Mr. Stoddard, who for a time was practically engaged in the industry. It contains information on some points not hitherto available. According to this writer the plant known locally as Sacqui (probably according to Engelmann, the variety *longifolia*) is most generally cultivated. This is said to yield the largest quantity of fibre, which is characterised by flexibility, whiteness, strength, and weight. It has been already mentioned that Dr. Schott selected the *Yucci* as furnishing the best quality, and the Sacci (Saequi the largest quantity of fibre. It is, however, generally agreed that the bulk of the fibre exported from Yucatan, and called from the former port of shipment Sisal hemp, is the produce of the Saequi. The chief port of shipment now is Pregresso.

The land which supports the fibre industry in Yucatan is of a gravelly, stony, and in some places of a rocky character. The plants thrive best and yield the largest amount of fibre in comparatively arid districts, only a few feet above the level of the sea. Moist land or rich land is considered unsuitable, for although the plants would grow in the latter, the quantity of fibre yielded would be comparatively small. For convenience of carriage and general management level land is preferred.

Plantations are established by simly clearing the land of trees and scrub. Stumps are uprooted to give an even surface. Shade is a disadvantage. Plants are generally put out during the rainy season, at 12 feet by 6 feet (equal to 605 to the acre) in holes proportional to their sixe. All fibrous roots and lower leaves are removed before planting, to facilitate new growth. It is estimated to cost "four shillings and six pence per acre to line, dig holes, drop suckers, and plant." A well established plantation has an extensive system of roads all converging on the works, which latter are placed in as central position as possible.

After planting, the chief cultural operations are confined to keeping the fields clear of weeds, and removing suckers which grow around the parent plants. These latter are utilised to extend cultivation by being planted in nurseries, or are thrown away. Their removal is considered necessary to the success of the plantation.

A fibre plantation started with plants about 1½ feet high, begins to yield in about three years after planting. Any appearance of the "pole," or flowering spike, is watched, and when 3 or 4 feet high it is cut out. Otherwise the usefulness of the plants for fibre purposes would cease.

The length of leaves cut for fibre should not be less than 3 feet; their ripeness is judged by the colour and by their position in the rosette. Consequently the outer leaves are always cut first, being the oldest. The harvesting of the leaves, which goes on all the year after once started, is effected in the following manner:—Men armed with suitable knives select ripe leaves, cut them close to the trunk, remove prickles from the edge, and point and make them up into

bundles of 50 each. Thirty such bundles is a day's task. These bundles are put out on the edge of the cart road, and are taken up by drays, carrying 1,500 leaves to a load, to the works. Cutters, carters, and machinists are paid so much per 1,000 leaves.

The works are placed near a regular supply of water. The power of the engine and the number of machines required all depend on the size of the plantation. One fibre machine is stated to be required for every hundred acres of plants.

After the fibre has passed through the machine it is placed on a drying stand fully exposed to the sun and thoroughly dried. If it is desired to bleach the fibre to a high degree of whiteness it is left out all night and during the next day and carefully turned. The fibre is made up into bales by means of a screw or hydraulic press; care being taken to keep the fibre straight and prevent "fringes."

Each plant when matured yields 30 to 35 leaves per annum, and the return of hemp is at the rate of 1,000 to 1,200 pounds per acre, or about half a ton per acre per annum. The net return on a fibre plantation in Yucatan is estimated at between 4*l.* or 5*l.* per acre.

Plants received at Kew from Yucatan marked "Sisal Hemp" are now growing in the Succulent House No. 5, and lately an experiment was made to test the quality of the fibre yielded by them.

The fibre was extracted by Mr. W. E. Death's fibre machine, and the following report was received upon it from Messrs. Ide and Christie, fibre brokers, of Mark Lane:—

"We are in receipt of the parcel containing a leaf "of *Agave Ixtli* and sample of hemp made from "leaves grown in the gardens. These are most interesting to us, and we have much pleasure in reporting "favourably on the hemp. The quality and strength "are very satisfactory, while in respect of colour, "lustre, and fineness of fibre, your sample is superior "to the average Sisal hemp that comes to this country. "The value of this article is exceptionally high at "present, 27*l.* per ton in London. You will see from "the statistics given in enclosed circular that this "material is an important one and is extensively used "both in England and America. It enters into com-"petition with Manila hemp and was regarded as an "adulterant of the latter in rope; but as its price "is now nearly as high as that of Manila the rope-"makers have not the same inducements to mix the "hemps."

VI.—MAURITIUS HEMP.

A hemp industry was started at Mauritius to utilise the large number of plants of *Furcræa gigantea* Vent., which had spontaneously established themselves on low lying lands near the sea coast. This is one of the oldest and best known species of *Furcræa*, and is now universally spread throughout tropical America and also in India, Ceylon, Mauritius, and St. Helena. The trunk below the rosette of leaves reaches a height of 2 to 4 feet. The leaves are 4 to 7 feet long, 4 to 6 inches broad at the middle, unarmed, bright green and channelled down the face. The scape or terminal flowering stem reaches a height of 20 to 30 feet. Like all the other Furcræas this species produces copious oblong bulbillæ in place of or in addition to flowers, which falling take root and reproduce the plant. It has often flowered under cultivation in England; the last time at Kew being the autumn of 1874.

A full account, with description, of the various species of Furcræa is given by Mr. J. G. Baker in *Gardeners' Chronicle* (1879, pp. 623, 624). *Furcræa gigantea* is figured in the Botanical Magazine, t. 2250: Wight Ic., tab. 2025: Decandolle, Plantes Grasses t. 126.

Although *Furcræa gigantea*, known locally as *Aloës vert*, is the chief fibre plant in Mauritius, there is evidence that *Furcræa cubensis* is also found there as well, as species of Agaves such as *A. americana* and others.

Bojer (Hortus Mauritianus, p. 353) mentions the *Aloës vert* (*Fourcraea gigantea*) as common in 1837, and states Croit sur la Montagne Langue dans les endroits vides et les basilages des habitations dans tous les quartiers d'île." He does not mention *Furcræa cubensis* at all, so the latter must be a later production. Plants of both species have been received at Kew from the Mauritius Botanic Gardens.

Furcræa gigantea is supposed to have been introduced from South America to Mauritius about 1790. It has evidently found a congenial home there for without any effort on the part of man it has covered waste lands and abandoned sugar estates to such an extent as to lay the foundation of a considerable fibre industry. The leaves are often 8 feet in length and from 6 to 7 inches in breadth. The pulp of the leaves when crushed gives off a strong pungent odour, and hence this species is sometimes called the *foetid aloe*. The juice is strongly corrosive and soon acts upon wrought iron; it is said to produce less effect on cast iron, while it is practically inoperative on brass and copper.

The plant grows in all soils and up to an elevation of 1,800 feet about the level of the sea. It has, however, more generally disseminated itself on the lowlands near the coast, and on a few of the abandoned sugar estates that have become too dry for cane cultivation.

A fibre industry was started at Mauritius about 12 years ago when the wet or retting system was tried. The cut leaves were first passed through the rollers of a sugar mill and steeped in water for some days. The fibre was then washed and beaten out by hand in running water. This process was soon found unsuitable as the fibre was discoloured and rendered weak; consequently it obtained comparatively low prices. Attention was then directed to extraction by means of *grattense* or scotching machines. Many machines have since been tried, and it is believed that the purely mechanical difficulties connected with cleaning the fibre have been for the most part overcome. The amount of fibre obtained from leaves of the *Aloës vert* was at the rate of 3 per cent. by weight of green leaves. The yield of fibre was at the rate of about 1½ tons per acre. A set of six machines driven by a steam engine of 8-horse power (nominal) cleaned 1,155 pounds of fibre per day, which is at the rate of 197 pounds for each machine per day.

At one time there were eight fibre or hemp companies formed with a total capital of Rl,182,500. The total quantity of fibre exported in 1872 was 214 tons, of the value of 4,934*l.*, which would be at the rate of 21*l.* 13*s.* per ton. In 1880 it had increased to 662 tons, which sold in England at 28*l.* to 32*l.* per ton. Some samples in 1882 sold as high as 38*l.* per ton. Since that time low prices have ruled, and this added to the fact that the cost of production was considerably increased tended to discourage the industry. It is evident the industry was first started to work off the leaves of self-grown plants which were ready at hand in great abundance. When these leaves were exhausted it remained either to wait until the plants were regrown or to procure supplies of leaves at increased cost from the surrounding country. This latter course being adopted at a time when the market value of fibre was low rendered the enterprise unremunerative. In the returns of 1885 we find that Mauritius hemp imported to this country amounted to 255 tons of the value of 39*l.* per ton. In Messrs. Ide and Christie's monthly circular, Dec. 1886, Mauritius hemp is quoted "in good demand" at 28*l.* per ton.

The following extracts taken from Mr. Horne's Report on the Agricultural Resources of Mauritius will sufficiently explain the circumstances under which the fibre industry was started and the causes which have operated to produce the present depression, which in the interest of the island it is hoped will be only of a temporary character:—

"The industry of extracting fibres from the leaves "of the *aloës vert* is by no means exhausted. There "is ground for believing that it has yet a future in "Mauritius. The fall in the price of this fibre in "the European markets broke several local companies "that were formed for the working of the aloe

"estate. There was far too much money invested "in them for them to pay."

* * * * *

"On many of the estates self-sown plants abounded "in great numbers. It was from the leaves of these "that the companies made money and paid large "dividends when the price of the fibre was good. "The plants had grown naturally on the land, and "their presence on it had not cost a cent. In such "cases results materially differ from those of reaping "the crops of regularly laid out plantations with low "prices for the produce. The soil and climate of the "localities referred to favour the growth of the "plants in such a degree that little expense need be "incurred in introducing it to new grounds. The "plant produces plantlets in great abundance in this "colony. These plantlets grow viviparously on the "parent plant, and adhere to it till they have developed "into almost perfectly formed plants. When the "young plantlets drop from their parent they are "perfectly fitted to stand by themselves, Excepting "the want of roots they are perfect. The roots are "emitted as soon as the plantlets come in contact "with the moist soil, even when they are lying on the "surface of the ground. It seems, therefore, that to "increase this plant rapidly and cheaply over a given "area, due advantage should be taken of its peculiarities "and the facilities which it naturally affords for "propagation and increase."

At St. Helena *Furcræa gigantea* has been for some time under cultivation as an introduced plant. Experiments on a small scale have been carried on, and samples of fibre have appeared in the English market. (Report on Resourses of the Island of St. Helena, Colonial Office, African No. 275, 1884).

Messrs. Collyer & Co. reported in 1883 on fibre from St. Helena as follows:—

"Aloe fibre (*Furcræa gigantea*) St. Helena. Good "length, full strength, rather dull colour, generally "well cleaned but with some runners untouched and "barky. Value 28*l.* to 30*l.* per ton. This sample is "very different in appearance from the *Furcræa gigantea* "of Mauritius, owing probably to differences of both "growth and treatment."

While on the subject of fibre from *Furcræa gigantea* it may not be inappropriate to say a few words as regards the merits of another species, *Furcræa cubensis*. This, as already pointed out, is possibly one of the plants under the name of *Cajun* from which some of the Yucatan fibre is obtained.

It differs from *F. gigantea* in that it has no distinct trunk, or a very short one, below the rosette of leaves. The latter are 3 to 5 ft. long, about 5 inches broad at the middle, bright green, rigid in texture, and armed with regular, hooked, brown prickles.

It is a native of tropical America and cultivated in most tropical countries. A variety of this plant—*F. cubensis*, var. *inermis*—is figured and described in Bot. Mag., t. 6543

In addition to flowers it produces bulbils on the flowering scape, from which the plant is readily increased. The plant is common in Jamaica, and it is said that there "would be no difficulty in establishing there a large area under cultivation." The fibre is white, strong, and bright looking. It yields at the rate of 2·05 to 3·15 per cent. by weight of green leaf. From experiments carried on at Jamaica under a committee appointed by Government it was found that leaves of *Furcræa cubensis* weighing 366½ pounds yielded 28 pounds of green fibre, which when perfectly dry weighed 7½ pounds. This was at the rate of 2·05 per cent. by weight of green leaf. In the report of the Committee this plant and its fibre are described as follows:—

"Silk grass (*Furcræa cubensis*). Leaves 5 to 6 feet "long, generally armed with strong prickles, but some-"times unarmed or with few prickles. Common in "Jamaica and might be largely propagated at once. "Value of fibre—(*a.*) 28*l.*, good quality, but might "be whiter; (*b.*) fairly clean, fair colour, value about "28*l.* per ton; (*c.*) superior to Sisal and worth 27*l.* "per ton. A good fibre, not quite sufficiently white "in the centre."

The above plants constitute the chief species of Agave and Furcræa yielding commerical fibres.

It may be mentioned here that many Agaves yield fibre, but the fibre may, as in the case of the Jamaica Keratto, prove unsuitable for industrial purposes. The Brokers' Report on Keratto fibre was:—"Little "strength: not an even (but a curly) fibre: towy: "value 12*l.* to 14*l.* per ton."

Plants yielding true Sisal Hemp might be obtained from Yucatan in large quantities.—D. M.

THE TEA TRADE OF CHINA FOR THE YEAR 1886.—Mr. E. B. Drew, Statistical Secretary of the Chinese Foreign Customs, makes general remarks on the foreign trade of China for 1886, in the just published "Returns of Trade," for 1886. We quote the paragraph on "Tea":—"The export of Black Tea is the greatest in quantity for at least six years, and a like remark is true as to the estimated value of it. But if we turn to the Reports from Hankow, Kiukiang, Shanghai, and Foochow, we are speedily convinced that while the quantity of the export has indeed been great, the result of the year's transactions has been extremely disastrous to the Chinese teabrokers and to the Foreigners whose capital has been engaged in them. From this statement the business done for Russia, which has much increased, should probably be excepted. It is enough to say here that probably the growers of Tea and the ocean carriers are the only ones who have been benefited by the exceptionally large operations of the year,—unless we include also the Government, which gets a revenue proportional to the amount of the export."

THE CUBEB OR WILD PEPPER.—Our Galle correspondent writes:—"I read with considerable interest the contribution in your impression of the 16th instant, from your London correspondent dealing with the subject of the cubeb vine as a product suitable for cultivation in the low districts of the island. It may perhaps be within your recollection that I wrote on this subject about eight or ten months ago, mentioning that the vine, acknowledged to be that of the cubeb, and identical in its growth and produce with the cubeb of the druggist as described by your correspondent, grew in profusion in its wild state in the jungles here, especially about Baddegama, and that the berry, which has an aromatic smell, and is exceedingly acrid to the taste, attracted the attention of more than one European visitor, from whom the Mudaliyar of the district gathered the fact that it possessed some marketable value. But beyond small parcels being collected and taken away no inducement appears to have offered for growing it systematically. Now, however, that your London correspondent has fully demonstrated the worth of a product which may be very profitably cultivated with the possession of the necessary conditions of both soil and climate favorable to its healthy growth, strong encouragement is afforded for the development of the industry, as a gentleman to whom I showed the article in question has fully made up his mind to embark in the enterprize in a tentative way. But the important question which requires to be settled is whether the kind of cubeb found in its wild state in the jungles of the low country really belongs to the acknowledged genuine variety said to be grown in Central and Western Java, although the product in several particulars corresponds exactly with the description given by your London correspondent—viz., the vine attains a height of from 18 to 20 feet, climbing round large trees, it is readily propagated by cuttings, and is so grown by natives, who utilize it for medicinal purposes: and the berry is likewise small and dark-colored when dried. Whether this is really the genuine article for which a demand exists is worth knowing. I trust the subject will recieve attention at the hands of some of your readers interested in low-country products and lead to satisfactory practical results."—Local "Times."

WESTWARD HO! [OPENINGS FOR YOUNG MEN IN AMERICA.]

[TO THE EDITOR OF THE "SPECTATOR."]

Sir,—It must be nearly thirty years since I first wrote to you over this signature, but never before except in long vacations, and from outlandish parts. Why not keep to a good rule? you may ask, at this crowded time of year. Well, the fact is I really want to say something as to this "Westward Ho!" gadfly, which seems to have bitten young England with a vengeance in these last months. I am startled, not to say alarmed, at the number of letters I get from the parents and guardians—generally professional men—of youngsters eagerly bent on cattle-ranches, horse-ranches, orange-groves in Florida, vineyards, peach and strawberry-raising, and I know not what other golden dreams of wealth quickly acquired in the open air, generally with plenty of wild sport thrown in. I suppose they write from some fancy that I know a good deal about such matters. That is not so; but I do know a very little about them, and may possibly do some good by publishing that little just now in your columns.

First, then, as to cattle and horse-raising on ranches. This is practically a closed business on any but a small scale, and as part of farm work. All the best ranche-grounds are in the hands of large and rich Companies, or millionaires, with whom no new-comer can compete. It will, no doubt, be a valuable experience for any young man to work for a year or two on a big ranche as a cow-boy; but he must be thoroughly able to trust his temper, and to rough it in many ways, or he should not try it. At the end, if prudent, he will only have been able to save a few hundred dollars. But this is not the kind of thing, so far as I see, that our youngsters at all expect or want. Orange-groves are excellent and profitable things, no doubt, and there are parts in Florida and elsewhere where there is still plenty of land fit for this purpose, though the choice spots are probably occupied. But an orange grove will not give any return till the sixth year, cautious people say the seventh.

Vineyards may, with good luck, be giving some return in the third or fourth year; but the amount of hard work which must be put into the soil in breaking up, clearing out stumps, and ploughing, even if there is no timber to fell, is very serious; and the same may be said of peach-orchards and early fruit and vegetable-rearing. Moreover, the choice places for such industry, such as Look-out Mountain, are for the most part occupied. In a word, though it is quite possible to do well in other industries, and in ordinary farming, nothing beyond a decent living can be earned, without at any rate as free an expenditure of brain and muscle as high farming requires at home. On the other hand, sport, except for rich ranche-men who can command waggons, horses, and men, and travel long distances for it, is not to be had generally and apt to disappoint where it can be had.

So much for the working side of the problem. The playing side—outside whisky-shops, which I will assume the young Englishmen means to keep clear of—ought also to be looked fairly in the face before the experiment is tried. Perhaps the most direct way to bring it home to inquirers will be to quote from the letter of a young English public-school boy who has lately finished his first year as a cowboy on the cattle-ranche of one of the big Companies:—

"Friday night we had quite a time. We went to an exhibition of the home talent of ——, and really of all shows this was the worst I ever saw. One man, the town barber, and our greatest 'society man,' played a nigger, and played it so well that one could not help fancying he has at one time been a 'profesh.' The rest were so dull and such sticks that it made him shine more than ever. After the home talent, there was a 'social hop,' at which Jerry and I shone as being the 'bored young men.' You can, of course, see why I was bored; and Jerry, he is from Ohio, and of course —— cannot compete with Ohio. However, as Jerry was somewhat of a great man, the quadrilles being all called by him—*i. e.*, he stood on the stage and shouted, 'balance all,' 'swing your partners,' 'lady's chain,' at the right time—we had to stay, and more or less to dance. Jerry took great pains to find me partners worthy of a man who had danced in a dress-coat. He did not succeed but once, when he introduced me to a very lively little school-lady, 'marm,' I should say; the rest were very wooden in movement and conversation. The school-marm amused me very much. She had not long returned from the —— University, where all the young ladies, though they met the other sex at school, were not allowed to speak to them at other times. The girls were allowed to give dances, but she and three or four others thought that a 'hen-pie' dance was too much of a fraud, so they contrived a plan by which they could get three or four dancing men in without going to the door. They fastened a pulley on to the beam where the bell hung, and with the aid of a clothes-basket and a rope they spoiled the 'hen-pie' with two or three young men. This plan worked well several times, till one night three or four of them were exerting themselves to get a very heavy boy up, when instead of a boy they perceived the bearded face of the head master. In horror they turned loose the rope and fled, leaving him twelve feet from the ground, hanging on by his fingers to the window sill, from which, as no one would respond to his call for help; he finally dropped. The young lady told it much better than I have. Jerry was very popular as a 'caller.' I noticed he understood his audience well, and whenever they got a figure they didn't know, he came in with 'grand chain,' which they all knew and performed very nicely; so you would see a whole set lost in the intricate feat of 'visiting' (say) and all muddled up, when you would hear the grand voice of Jerry, 'grand chain,' and all the dancers would smile and go to it, and Jerry was quite the boss. We, however, lost our reputation as good young men, as towards midnight we were overcome with a great thirst; so wicked I, a hardened sinner, persuaded the social barber to let me have half-a-pint of whisky; and J and I were caught in the barber's shop, eating tinned oysters with our pocket-knives, and biscuits, and indulge ing in whisky-and-water. We were caught by three young men who had 'got religion' last fall, and who were, of course, highly shocked; but I think they would have overcome all their scruples but for the stern mothers in the background, and they not only envied us our whisky-and-water, but also our mothers. Half the fight in drinking, I think, is to have been 'raised' to look upon it as an every-day luxury, and not as a thing to be had as a great treat on the sly. Well, good-bye! I have written a lot of rubbish, but beyond that am fatter than I have ever been in America."

This will probably give readers a pretty clear notion of the social life available in the West. It is, as they will see at a glance, utterly unlike anything they have been used to. If this kind of social life (and there is something to be said for it) is what they want, in the interludes of really hard manual labour and rough board and lodging, let them start by all means, and they may do very well out West. Otherwise they had better look the thing round twice or thrice before starting. In any case, no young man ought to take more ready-money with him than will just keep him from starving for about a month. If he cannot make his hands keep him by that time, he has no business, and will do no good, in the West.—I am, Sir, &c.

VACUUS VIATOR.

OYSTERS.—According to recently published statistics, the export of oysters from France during the year 1885 was no less than 600 millions, 236 millions of which were supplied from the famous Arcachon oyster parks only.—*M. Mail.*

DRUGS AND QUININE.

Mr. C. W. White, who was in Ceylon on his way round the world about six years ago, is again on a short business visit here. Mr. White is well-known as the representative of the great drug houses of Burgoyne, Burbidges, Cyriax and Farries—from whose monthly publication we often extract into our *Tropical Agriculturist* with advantage to planters of new products, the T. A. being as often honoured by references in this Firm's London "Monthly"—also of Burroughs, Wellcome & Co., whose name as manufacturing chemists and wholesale drug distributors is worldknown. Mr. White also represents the house of Messrs. Wm. Harland & Son, Varnish and Japan Manufacturers. We have been urging on Mr. White to make known to his principals in the great Drug Firms, the importance of their taking special steps to bring the cheapness of quinine before masses of people in districts and countries where a febrifuge is as great a necessity almost as daily food. We had a notable case reported in the English papers the other day, in which a country druggist was tried for putting much less quinine in a preparation than was prescribed; but the important fact came out in his evidence that the rule of his establishment (and of most other English druggists' stores) was to charge 1d per grain of quinine prescribed, irrespective of ups and downs in the wholesale London market. This was, of course, at the rate of 40s per ounce! Now, we have the fact that in the malarious Fen, Essex and Kentish-Gravesend districts, numbers of poor people have got into the habit of buying laudanum (opium-drinking) by the wine-glass to soothe and check depression and other symptoms actually due to low fever. For the same reason, thousands, if not millions, of Chinese in the malarial flats of the Middle-Kingdom, have taken to opium. The cure in both cases is plenty of cheap quinine. Archibald Colquhoun, as we have often mentioned, found a pinch of quinine the most valued gift he could make to the Mandarins away up the Canton river and "across Chryse." In the same way we found Missionaries carrying packets of quinine pills back from America for the benefit of poor Chinese about the coast settlements. Again when travelling in the Southern States of America, we had repeated evidence of the immense value attached to cheap quinine: the ex-Surgeon General of the Confederate Army assured us in Richmond that Lee's Army could have withstood Grant's invading force for another campaign at least, had he (the doctor) only had quinine or "bark" to enable him to put back from the hospitals and villages in the field thousands of ague-stricken veterans. "The utter want of bark"—the blockade being strictly enforced—"more than any thing else" said the old Doctor, "broke the power and spirit of the South." Now we suspect that neither in China nor in the Southern States of America, nor yet in the Fen districts of England have the present abundance and cheapness of quinine been realised as they ought. In respect of China, we have suggested to Mr. White that the big London firms should employ Chinese as "medicine men" to travel through the country with supplies of quinine preparations, making known where such could be obtained in their coast agencies. We were interested in learning that Messrs. Burgoyne Burbidges & Co., went to the expense some years ago of printing in Chinese a list of suitable English medicines with explanations—probably the first foreign list ever printed in Chinese—and distributed the same by thousands if not millions of copies, and it must be remembered that all printed matter is venerated by the Chinese. But this ught to be followed up we think, especially in respect of quinine, by the employment of a staff of "medicine-men" to peregrinate the provinces of the great Empire, selling at least enough to pay the expense of the experiment and above all making known where the medicine to take away the taste for "the black-smoke poison" (opium) could always be procured. We trust Mr. White will forward our suggestion and that it will be acted on by the great London drug houses. To whom else are the Cinchona planters of Ceylon, Java and India to look to, for to make known the present cheapness as well as the virtues of the invaluable febrifuge which their enterprise has lowered from 11s to 13s the wholesale price between 1877 and 1881, to 2s or 3s per ounce in 1887.

JAMBUL SEEDS.—A correspondent of one of the medical journals calls attention to the value of these seeds (the produce of Eugenia Jambolana) in chronic diabetes. In what way the seeds influence this mysterious disease is not stated.—*Gardeners' Chronicle.* [This is surely the Jambo or Rose-apple tree.—ED.]

AMERICAN-GROWN RHUBARB.—The *Nationale Druggist* states that it has received a piece of the root of *Rheum palmatum*, grown in the garden of Mr. J. W. Colcord, a pharmacist of Lynn, Mass. The seed was planted in 1884. The specimen compared favourably with the foreign drug as far as taste, smell, and general appearance were concerned. A microscopic examination showed a preponderance of starch, and less oxalate of calcium. —*Chemist & Druggist.*

CEYLON GEMS, &C.—A chatty writer on "The Fashions" in the *Overland Mail* writes thus in a late No.—I lately had the pleasure of inspecting a large and very interesting collection of precious stones, brought over from Ceylon by the well-known expert, Mr. Hayward. Here they were to be seen from their rough state just fresh from the pits to the perfect gems in their artistic settings, ready to wear. He most kindly took me into his inner room where sapphires and rubies were to be seen galore. It reminded one of some enchanted place where one might pick up literally handfuls of jewels, so plentiful were they. But first I was deeply interested in an enormous hexagon crystal, one of the finest ever seen, inside which one could distinctly detect the watery fluid. Also a wonderful mineral known as rutile, full of needle-like spines, that were quite visible on looking through it. Then a curious green smoky looking stone called jargoon. I was informed that sapphires and rubies belong to the same family of stones, and are composed of the same materials. Certainly I never could have believed that what looked like a diamond could possibly be a sapphire, nor another clearly yellow, as well as a green stone; yet such strange metamorphoses do they show, and take hundreds of various shades between these hues. One of the most beautiful novelties was the star sapphires. These curious greyish stones are in cabochon form, and polished conically. On the top, if one shades them from the light, one can instantly perceive a delicate star that moves like the light in a catseye. Of catseyes, also, Mr. Hayward had a wonderful collection, as also pearls, jaciuths, moonstones, topazes, exquisite tourmalines, with their soft-green tint, and chrysoberyls. Also an Oriental amethyst, which is truly a magic stone, for by daylight it is of the richest purple, and by candlelight a superb red. As I was leaving this very interesting collection my eye caught what I took for a very fine line engraving surrounding, as a border, a map of Ceylon. In the centre was the map, beautifully executed, and, in ornamental *encavedments*, a drawing of every animal and reptile indigenous to the island. I was told to my very great surprise that the whole thing was the handiwork of a native boy. I never saw more perfect etching nor neat drawing. [This map, we believe, is a Zoological Map of the Island—the work of one of the pupils of St. Benedict's Institute.—ED. Local "Examiner."]

PLANTING IN NETHERLANDS INDIA.

(*Translated for the "Straits Times."*)

The Chinese Commissioners recently travelling through Java, have returned to China direct. The Batavia *Nieuwsblad* reports that, among the Chinese there, rumours are afloat to the effect that the Chinese Government intends, shortly, to station consuls at all the chief towns in Java. These consuls will be charged to look after the interests of the Chinese there in every way.

It is said that plently of land highly suitable for tobacco cultivation is available in the islands round Lingga and Rhio. Where the soil does not answer, there is coal enough underground to reward the judicious investment of capital. The Sultan of Rhio is reported to be well disposed towards Europeans. Assistance on his part may be confidently counted upon.

A Java Newspaper calls attention to the fact, that, though the so called betel nuts or rather arecanuts have long been articles of trade, and have been used for a considerable time as medicine in Europe, yet betel leaves did not reach Europe until recently. The latter are derivable from the betel or sirih vine. Etherised oil from them has been found useful in catarrhal affections and as an antiseptic. Experiments made in Germany, have proved that etherised betel leaf oil is a sovereign remedy in throat diseases, diptheria &c. The importation of the leaves is attended by difficulties owing to the oily substance therein deteriorating by the action of the air.

PLANTING: COFFEE, CINCHONA AND TEA IN CEYLON.

We are now in the interval of broken, but on the whole, moderate weather, between the "little" and "big" monsoons. Already this very moist hot weather has made tea come on with such a rush in the lower districts that the flushing can scarcely be over taken. But higher up there has been dry and less forcing weather. Everything however points to a very busy tea season with full croppings from all acreage in bearing. In the Kelani Valley we hear of some wonderful returns of tea: as much as 85 lb per acre being made in one month off tea bushes 2¾ years old, while 130 acres are said to have given 10,000 lb. made tea in the same time. This is from properties owned by Messrs. W. Mackenzie and Forsythe.

Coffee also is looking up with good crop prospects and high prices; while Cinchona, reviving in price with less supplies, is likely to be of great help, and Cocoa is quite as promising in price and crop as coffee. Labour supply is the present bugbear before many of our planters, but in a number of districts, Sinhalese can be freely availed of to pluck the tea leaf and do other estate work.

QUININE.

The necessity for urging the great wholesale Drug Houses or Manufacturers of Quinine, to devise and carry out some means of bringing the fact home to the masses—especially in feverish countries and districts—of the present abundance and cheapness of quinine, is being afresh realized out here. There must be immense scope for extending the use and consumption of the most valuable of febrifuges in the Fen and low riparian or marshy districts even of England; also in the South of Europe especially in the Eastern portion, and in the Southern States of America, apart altogether from the great fields presented in Asia, Africa and Central America. It would be well if English philanthropists—more especially Anti-Opium and Temperance Societies—realized that one of the best means of fighting opium, of putting down the taste for it as well as often for intoxicating liquors is by supplying cheap quinine. In this way India (and adjacent countries) may give the cure to China for the evil (opium) which it has so freely bestowed on the Chinese.

TEA.

We omitted in our last issue to give a place to some useful figures respecting the sale of our teas in Colombo compiled by Messrs. Wilson & Co., Brokers of this city. A glance at the table we append shows that "during the past six months 14,752 packages have been offered at Public Auction locally (against 11,637 packages during the corresponding months last year) at rates which must be very satisfactory to Planters. Judging from the prices realized in London of some of the Colombo bought teas which we have been able to trace, we cannot but think that those planters who have sold their teas locally have benefited considerably in a pecuniary point of view":—

TABLE showing the Colombo monthly sales of seasons 1885-1886 and 1886-1887 with averages, also London sales and averages for the corresponding months.

	Season 1886-1887				Average price about per lb. in cents and equivalent value in London calculating exchange at 1/6 per rupee.	Season 1885-1886.				Public sales in London Season 1886-1887	Average price per lb. in London

* The average of seasons 1885-1886 was 60 cts.= in London 1/1¼ per lb. calculating Exchange at 1/6 per rupee.

WILSON & Co., Tea Brokers.

In this connection we may mention as an instance of the progress making in tea that at last Colombo sales, tea prepared by Mr. De Soyza's Sinhalese Superintendent on Charley Valley estate, Maturatta, realized over R1 a lb. Mr. De Soyza's extensive properties will no doubt turn out an immense quantity of tea by-and-bye; but still

more, we may be sure that a large body of Sinhalese ex-coffee-cultivators in the high, as well as low country, will very soon be cultivating and preparing large quantities of tea through small gardens opened on their own account.

We have advocated the grouping of three, four or even six adjacent tea properties in Ceylon into one proprietorship and management so as to arrange for one thoroughly well-equipped Central Factory sufficing for all. We call attention to our remarks on the subject elsewhere, and trust home capitalists will take an interest in the matter, as only through Limited Companies could this great economic reform be effected.

COMPETITION IN THE SALE OF CEYLON TEA.

It would be impossible to deny that competition is the very soul of trade, and that healthy competition does perhaps more than anything else to produce success. But all experience teaches us that, when that competition passes a certain boundary line, it almost invariably produces precisely opposite effects to those we have referred to as being beneficial. A friend writing to us from England expresses the fear, lest the very numerous agencies started for the sale of Ceylon teas may tend towards exciting a competition, which, passing the limits of prudent trading, may constitute an element of some danger to the high reputation at present maintained by the produce of our island tea-gardens. He tells us that those agencies now amount to nearly twenty in number. The greater part of them are supported by influential and moneyed men, nearly all of whom have an interest in the tea estates of the island, and that so strong is the rivalry between these agencies, that, although for the present the field is undoubtedly wide enough for them all, he thinks there is reason to dread a coming time when their endeavours to out-do one another may bring about results much to be deprecated.

Certainly, if in the future, Companies formed for pushing the sale of Ceylon tea increase in number in anything like the ratio that the past twelve or eighteen months have witnessed, it will be difficult to deny our correspondent's proposition that sooner or later they will be likely to perform that cutting of one another's throats which has been proved to be the bane of so much of the speculative trading which has been so rife in England during the last half century. As yet, as we have said, the field of operation is wide enough for all; but we may be sure that for some time yet to come the adventurers with Ceylon teas must to a great extent restrict their operations within a comparatively narrow circle. It requires a very large expenditure of capital, and must probably entail a very considerable initial loss, to extend that circle so as to compensate for the overworking of the area first occupied. That area may be described as at present almost confined to London and the home counties. When the force of circumstances renders necessary the extension of trading to the more distant parts of the United Kingdom, our friend fears lest the harm that he anticipates may already have been accomplished by the high reputation of our teas being lowered by the course forced on by the keenness of the rivalry existing within what may be termed the Metropolitan sphere of occupancy.

London and the home counties, it is known to a very large extent direct and guide the tastes of the more distant provinces. Appreciation in London means appreciation throughout the Kingdom. If, from any cause whatsoever,—be it that to which our correspondent makes allusion or any other,—the reputation of Ceylon tea is made to suffer at the heart of British trade, it will be found, when that outer extension which we have named occurs, that the loss of the present standard will have inclined the extremities to view with distaste that which has lost the *imprimatur* of the "head centre."

All the gentlemen who have associated themselves together to form the many Ceylon Tea Agencies now established in London have started with the declaration, honestly enough made no doubt, to sell none but the highest classes of our island produce. So long as they adhere fully to that stated intention, the results that are deemed probable of realization, are not likely to make themselves apparent. But we know too well what competition, when carried to an excessive degree, has done in the past not to think it wise to raise a word of warning as to what it may effect in the future. Companies as well as individuals must live. Their directors must be on the *qui vive* to seize every opportunity of so extending trade that they may meet their shareholders with a satisfactory balance-sheet. To do so under the circumstances of strong competition they must put a certain amount of driving pressure on their *employees*. It is in that necessity that there exists the risk of those evil effects arising to which our correspondent draws attention. Those employees will almost be forced to buy in the cheapest market, and it may well be dreaded if, under such compulsion, the guarantee can always be assured that inferior grades of tea may not be distributed bearing the trade mark of Companies which at the beginning sold nothing but the finest and made a public reputation thereby.

Directly such a result is attained, then that boundary line that we have mentioned as existing between healthy and unhealthy competition will have been passed and the worst prognostications of our correspondent will approach realization. We always much regretted the failure to establish what might have been termed an *official* Syndicate of Ceylon Tea-growers. That failure has necessarily led to an extension of private enterprize which is, no doubt, at present doing great things for our Tea Industry; but there is the danger we have pointed out that that enterprize may extend itself beyond the bounds of prudence. It is to be hoped, therefore, that for some time to come we may hear of no further Companies being formed for the sale of Ceylon teas as a speciality. To those already established we wish every success, and we are certain that they are sufficient in number for effectual and profitable work.

CHEAP QUININE—HOW TO SELL IT!

The purest, cheapest, simplest and most invaluable medicine in the world and its growers starving owing to defective (?) machinery at present employed in its distribution.—*Merchant.*

With reference to our remarks on page 809, a merchant writes:—

"Taking quinine, say Howard's, at 2s 8d per oz., surely it would pay to make up small phials—sealed with Howard's seal—and stitch them in cards to be sold at all Railway Book stalls and elsewhere under the veteran Bookseller's (W. H. Smith's) world-known name to prove the genuineness of the article. A good lot could now be given for 6d and leave W. H. Smith a vast profit in a year, and that net profit he might be disposed to give to hospitals

throughout the United Kingdom in honour of the Queen's Jubilee year. This would more than anything else that I can think of help to break the necks of the members of that cruel gang (as far as quinine in feverish districts is concerned) at any rate (and *especially cruel to the poor!*)—the dispensing chemists in the regions referred to. They could not complain and if they did, who would pity them?—Or, if W. H. Smith would not care to do this, would he allow an Association of philanthropists the use of his vast machinery (his bookstalls) for distribution of *quinine*. To carry out the idea a few thousand pounds to float it would be all that would be required."

ROYAL BOTANIC GARDENS: CEYLON.

REPORT OF DR. HENRY TRIMEN, DIRECTOR, FOR THE YEAR 1886.

INTRODUCTORY.

As I have been absent from the Colony on leave since the middle of March, I am necessarily dependent for much of the contents of the following pages on the reports of the subordinate officers of my department. During my absence the general oversight of all the Gardens was entrusted to Mr. Nock, the Superintendent of Hakgala, who, I am glad to be able to report, carried out his additional duties with energy and discretion. The other members of the Establishment have all worked well and diligently, and on my return I have found the condition and progress of the Gardens all that I could wish.

As regards the *personnel* of the Department, it is with much regret that I have had to record the death, on Oct. 10, of an old and devoted native member of the staff, Don Seman De Silva Gunaratne, Muhandiram, the principal plant collector at Peradeniya for many years. His death is a serious loss, not only to the Gardens, but to me personally, for he has been my constant companion (as before of my predecessors Thwaites and Gardner) in all my botanical tours, when his intimate knowledge of the country and extensive acquaintance with its flora have been of the greatest assistance. He was a first-rate and untiring collector, and the discoverer of many novelties. I have commemorated the name of this unassuming votary of practical botany in a new species of *Sonerila* which he collected in the Pasdun Korale. The native rank of Muhandiram was conferred on him by Sir H. Robinson, in 1866.

PERADENIYA GARDENS.

RODS AND PATHS.—The principal heavy work, which has taken up the greater part of the year, has been the re-making of some of the carriage roads in the Garden. The greater part of the Main Central Drive and its branch to the Museum building, the Monument-road, and that round the large circle (in all over 1,500 yards) have been thoroughly re-made, re-metalled, and gravelled, and will now last for many years. We are fortunate in possessing in the grounds an abundant deposit of rolled flint pebbles, which form excellent road ballast when broken; I regret, however, to notice that the beds of gravel which have supplied the wants of the Garden for over sixty years are now beginning to give out.

With the object of improving the appearance of the entrance I planted, a few years ago, a row of Saman trees on the opposite side of the high road where the race-course runs alongside it. At the request of the Race Committee I have now planted a mixed ornamental hedge along the whole length of the road where it bounds the course. This will much improve the appearance of the surroundings of the Garden entrance.

BUILDINGS.—These are, generally, in satisfactory repair, it being always my practice to attend to small dilapidations at once. The building, however, now used as the Director's Office and Museum requires some general attention, re-painting, and whitewashing, by the Public Works Department.

The new cooly lines were completed during the year, and now consist of three substantial buildings, well built and tiled, and containing twenty-six rooms. Their cost has been entirely met out of the Departmental vote, and I am very pleased to have been thus able to do away with the old lines, which were a disgrace to a Government establishment. As the lines are very close to the high road, a dwarf bamboo hedge has been planted, which will form a screen; and behind the buildings the river bank, which is here very steep, and constantly wearing away from the set of the current against it, has been strengthened and planted with riverside bamboos.

THWAITES MEMORIAL.—This little Kandyan building has been finally completed by the addition of four strong seats of "Wa" wood and the erection of a brass tablet with a memorial inscription.

CULTIVATION, NURSERIES, &C.—New and extensive nurseries have been formed, as planned out in my last year's report, in that part of the Garden abandoned in 1881 and lying fallow ever since. The ground has been deeply trenched and well manured, there is a constant supply of water, and the locality is convenient for the Garden Office and Stores. This nursery is 350ft. long by 70ft. wide, and contains 132 beds 28ft. long.

A raised bed has been made round the interior of one half of Plant Shed No. 3, for plunging pans with germinating seeds.

The Herbaceous Ground in the South Garden has been taken in hand and well manured. This is very exposed, and it is found that only a limited class of plants will grow in it; a large additional number of species have, however, been planted during the year, and the condition of the beds is improving.

In the Orchid House a great number of species have flowered during the year. Mr. Clark has effected an improvement in the cultivation of these plants, by obtaining from Horton Plains—the only locality in Ceylon—some sacks-full of *Sphagnum zeylanicum* This useful moss is, however, so rare, that it will not I fear, be possible to use it generally. I contemplate if funds will allow of it, the erection of a new and more suitable house for the cultivation of Orchids, as it is found that the present glass-roofed structure is too hot and dry for most species.

Much attention has been paid to the flower-beds and borders during the year, and a very large number of new plants have been put out. The circular bed near the Garden Office was planted at the end of the year with a collection of varieties of *Hibiscus*.

The paths of the Ferneries near the Plant Sheds have been laid with a gravel of broken white quartz, which has a clean and cheerful effect.

LABELLING.—The new teak labels are gradually taking the place of all other kinds, and prove the most durable yet tried. About 250 have been put in position during the year. I have now a man constantly employed in painting the names, and the work will be more rapidly pushed forward.

VISITORS.—The Gardens are becoming increasingly popular, but are perhaps better known to travellers from abroad than to the residents in this country. No numeration of visitors is attempted, but a book is kept at the lodge, in which those Europeans who are not known by sight to the gate-keepers are invited to enter their names. In 1886 as many as 1,090 such visitors signed in this book.

I feel sure that these beautiful grounds would be much more frequented if access from Kandy were easier. The distance (four miles) is beyond a walk for the majority of persons, and the road hot, glaring, and dusty. The railway station called Peradeniya is a mile from the Garden gate on the opposite side of the river, and awkward of access. To get thence to the Garden involves the payment of a heavy toll for horses or carriages at the Satinwood bridge, and neither the one nor the other are to be obtained at the station unless previously sent out from Kandy. Since the formation of the loop line this station has ceased to be a junction, and is no longer on the main line from Colombo to Nanu-oya, but merely a station on the Kandy branch; and I would wish to represent that the public would be better served if it were moved from its present position on the Gampola-road, where it now serves no useful purpose, to a point within a

quarter of a mile from the Garden, viz., where the line crosses the Deltota-road. Trains have already several times found it convenient to stop here on the occasions of the annual Peradeniya races and school treats in the Gardens, and I believe that if a permanent station were placed here a large local passenger traffic would result between Kandy and the Gardens. [N. B.—ED.]

WEATHER.—The rainfall was much as usual, but August appears to have been remarkably wet. Mr. Clark's record is given below:—

1886.	Rainfall.	Rainy Days.
January ...	5·10 ...	8
February ...	0·75 ...	2
March ...	3·84 ...	5
April ...	8·61 ...	13
May ...	11·24 ...	10
June ...	8·02 ..	11
July ...	11·66 ...	14
August ...	12·88 ...	17
September ...	11·63 ...	12
October ...	8·00 ...	16
November ...	7·74 ...	10
December ...	1·99 ...	9
Total ...	91·26 ...	127

The heaviest fall in any 24 hours was 5·82 in. on August 6-7.

2.—HAKGALA GARDEN.

The alterations and improvements commenced in 1882 have now been almost wholly carried out under the zealous superintendence of the Superintendent, Mr. Nock. By the gradual way in which they have been effected, scarcely any extra cost on the whole departmental vote has been involved; yet we have at length what in my Report for 1881 I set before me as the object to be attained,—an interesting and beautiful botanic garden, well stocked with the useful and ornamental plants of the sub-tropical and warm-temperate regions of the world, and possessing some facilities for their culture, propagation, and distribution. Much of course remains to be done, but it is with great satisfaction that I see the increasing utility of the Garden and the public interest taken in its welfare. The carriage drive through the Garden has been finished during the year: the whole metalled and gravelled, the embankments and verges turfed throughout, and several culverts and drains put in. This has been a heavy piece of work, and as usual labour has been lent from Peradeniya to carry it out. The additions and improvements to the Superintendent's bungalow have been finally completed, and the building is now in very good order. The long verandah has been fitted with flower-stands, and now gives considerable additional accommodation for pots, which was much needed. All the smaller buildings were re-thatched with mana-grass during the year. The new cooly lines commenced in 1885 were completed. They are much better placed than the old ones, and contain ten rooms. The old lines will now be pulled down to allow of an extension of the nurseries and kitchen garden, which are too small, and have much deteriorated in soil. The glass propagating house has been re-painted, and a coating of cement laid over the brick floor. This small house requires to be supplemented by a few brick frames or pits, so as to enable sufficient plants to be raised to keep up a succession of flowers in the house, which at present has to be itself mainly employed for propagating purposes. I purchased in London a small "Easy" lawn-mower for Hakgala; this has proved of great use, and saves much labour. Several other garden implements would be supplied if my resources were larger. The small vote for labour renders it especially desirable to employ means of rendering rapid and easy the work of the labourers. I extract for publication the following portions of a very comprehensive report of the Superintendent for the year:—[We give only a few paragraphs here.—ED.]

"No less than 45,948 cuttings of various plants have been put in the nursery beds and propagating-house 24,600 seedling plants picked out in pots and pans 5,472 plants potted or re-potted, and 426 pans of seeds sown.

"Seven hundred and twenty plants of various species of eucalyptus were planted in the patana round about the new lines. Of the plants planted on the patana above the road by the entrance gate, the junipers, *Capressus torulosa* and *Frenela rhomboidea* are doing very well indeed, but the species of pinus have nearly all died. *Cryptomeria japonica* is doing fairly well here.

"The little dwarf variegated bamboo (*Bambusa Fortunei*), which was brought by the Director from the Darjiling gardens three years ago, has now become quite established. It grows only about 4 in. high here, and forms a very pretty edging plant.

"VISITORS.—The number of visitors during the year was 1,011, April again showing the largest number (193) and July the smallest (35).

"The total rainfall for the year was 86·43 in., which fell on 211 days. The greatest fall in any 24 hours was 3·92 in., which fell from the 7th to the 8th of August."

HENARATGODA GARDEN.

This garden suffered severely from drought in the earlier part of the year, and several palms, cacao trees, and one of the cow trees (*Galactodendron*) died as well as the majority of the foliage plants and flowers in the borders; a fresh supply of all these was, however, planted up in the S. W. monsoon, and the opportunity taken for raising and manuring the beds. A new fernery was also made in a more sheltered position.

An improvement of that part of the garden near the river has been made by the formation of a new path to the mangosteen plantation through the strip of wild jungle.

The old plant-shed being in a decayed condition a new one of a more permanent character, with brick pillars, has been put up, but is not yet finished.

The various tropical plants of interest in this Garden are for the most part in a flourishing condition, and notes on several of them will, as usual, be found in the section referring to economic plants. I regret that no more of the *Lodoicea* seeds have germinated, and I fear that, as it is nearly three years since they were planted, there is now little chance of their doing so. The one which sprouted, looks vigorous, and has sent up a second leaf, standing about 6 ft. high. A considerable distribution of seeds of economic plants, such as Castilloa and Hevea rubbers, cacao and shade trees, pepper, &c., has been made during the year, but the demand for such does not increase. The Muhandiram in charge continues to give complete satisfaction. He complains of a great falling-off in the number of visitors to the Garden, and indeed there were scarcely any in 1886. This diminution is obviously due to the new train arrangements, by which only the slow trains stop at the Henaratgoda station. I would venture to suggest whether it would not be a matter of easy arrangement, that (as is the case at many small stations in England) the quick trains might stop by signal to take up or set down passengers here. The stoppage, which would not very frequently be required, could not delay the train more than two or three minutes.

ANURADHAPURA GARDEN.

The rapid growth of most plants in this Garden is remarkable, and strikingly exhibits the great capabilities of the soil for varied cultivations, given only a water-supply and ordinary attention. Though only in the fourth year of its existence, the Garden already begins to look stocked. As was expected, however, many of the economic products so freely grown in the south of Ceylon will not thrive here, and no further attempts to grow to any advantage tea, cocoa, rubbers, nutmegs, cloves, &c., need be made. On the other hand, several plants belonging to the same class appear to be fairly well suited here, such as cinnamon, breadfruit, pepper, cashew-nut, and Liberian coffee. Of the latter, there are numerous bushes cropping well, and if this cultivation prove to be permanently successful, no more useful introduction to the villages of the North-Central Province could be found. Of plants native to the drier tropical countries, many succeed here much better than at Peradeniya or Henaratgoda, such as cotton, tobacco, and numer-

ous ornamental and fruit trees and shrubs from India, N. Australia, and the West Indies.

A large collection of additional plants and seeds have been sent from Peradeniya during the year, and I am glad to be able to report that the Conductor, by the careful attention he gives to their culture, continues to merit my approbation.

Notwithstanding this success, it is disappointing to find that, at present at all events, one object of the formation of the Garden remains almost in abeyance. The natives and settlers show no inclination, and indeed are averse, to cultivating anything beside paddy. Areca and mango plants are offered at a nominal price, and jak plants free, but almost in vain. So far from seeing any advantage in possessing these additional future sources of food or income, it is but too evident that the ordinary cultivator regards them with indifference, and would consider any official recommendation to plant them as merely an additional trouble and hardship forced upon him by Government. But it may be hoped that when the tanks are more steadily full and paddy cultivation more regularly established and easier, a different temper will prevail.

The vote for this Garden is very small but, as previously, I have had this year the use of a small provincial vote also, and this has enabled the Conductor's little house to be properly finished, and lines for the coolies to be made. We have missed this year the assistance of prison labour, nearly the whole having been required for the clearing and repairing of the ancient ruins*; and in dry weather our staff of five coolies find it difficult to keep up with the necessary watering.

BADULLA GARDEN.

The piece of land acquired for an experimental garden in Badulla has been taken in hand, and a commencement toward fitting it for its intended purpose has been made. I find that some dissatisfaction with the site and surprise that it should have been selected, have been locally expressed. Certainly, had it been possible to secure a piece of jungle near the town I should have preferred it to old paddy land, but none such was available, and of the three plots of ground I had to choose from, that selected was unquestionably the best. It is at present of course quite bare; and several years must elapse before any efficient shade and shelter can be provided: but it will, I hope, prove of some utility before it presents much beauty.

Work was commenced, on February 10th, by putting up a temporary bamboo fence round the ground, and planting outside it a line of green aloes (*Furcræa gigantea*). It is intended to form a bank along the whole boundary, and plant a strong live fence of Madras thorn; and this would have been done during the year but seeds were not to be obtained.

A small bungalow has been erected for the Sinhalese conductor at the east end of the ground, where are also placed the cooly lines and a bamboo shelter for raising seedlings, &c. In front of the bungalow a flower garden of 47 beds has been made, and separated from it by a hedge of Hibiscus, a nursery of 32 beds.

By far the principal work of this first year has consisted in the formation of a carriage drive. In the making of this, which is nearly completed, we have had the advantage of prison labour, and for this and much other help my thanks are due to the Government Agent, Mr. Æ. A. King, and his Assistant, Mr. S. M. Burrows. The drive is 365 yards long, and forms a direct continuation of a new road leading by the mosque; it passes out of the Garden into the "Green-lane," This is not the course which I had planned for it, but the change was necessitated by the abandonment of a projected public road to the cemetery, which was to have formed the northern boundary of the Garden, and from an entrance gate on which I had intended the drive to make the circuit of the Garden. It is hoped that this road, or some equivalent public one, may still be made; as when the Garden gates are put up it will not be possible for the present garden drive to be constantly used as a public thoroughfare. A large collection of ornamental shrubs, palms, &c., sent from Peradeniya, have been planted out along the sides of the drive, and efforts are being made to get up a stock of economic plants and fruit-trees suitable for Uva. A commencement of sales has begun, and a small quantity of young trees, &c., supplied for planting about the town. Ordinary garden plants appear to have done very well in the new beds, and Mr. Nock tells me that the show of dahlias and chrysanthemums was really very fine. I observe that the chocho, the loquat, and *Erythroxylon Coca* are all growing vigorously. The climate of Badulla differs from that of the other Gardens under my charge, The rainfall is mainly under the influence of the north-east monsoon, and is heaviest in November and December, but rain falls more or less in all months of the year, June and July being the driest months. The mean of the years 1876-1885 was 78·62 in., falling on 91 days. The elevation of the meteorological station—a few feet higher than the Garden—is 2,225 feet above mean sea level, and the annual mean temperature 72·2.

NOTES ON ECONOMIC PLANTS AND PRODUCTS.

COFFEE.—The export of coffee from Ceylon has sunk, in the commercial year ended September 30th 1886, to the very low figure of 223,693 cwt., being over 65,000 cwt. less than in the previous one, and lower than any year since 1846. In rightly estimating this fact, however, one must not fail to take into full consideration the greatly reduced area under this crop. I do not think that there is now going on a further progressive diminution in the yield *per acre* on estates in good cultivation; in the Province of Uva especially, as I gather from the reports of planters and others, there are no signs now of increasing deterioration, and coffee-growing remains a remunerative industry. The general destruction of badly diseased coffee over many square miles has doubtless greatly diminished the supplies of *Hemileia* spores, and there is good evidence that, as was to be expected, since the chances of infection are lessened, the "attacks" of leaf-disease occur less frequently and at longer intervals, and the trees suffer less proportionally. It is satisfactory to learn that in Uva, though a considerable acreage of tea has been planted, this has not been done to any large extent by the sacrifice of coffee,—as in other parts of Ceylon,—but mainly by opening new land; for I cannot but think that a *general* substitution of the new product for the old one is not justified, either by existing circumstances or in view of the future.

Apart from coffee, the increase in the exports of all estate products during the past year is very striking.

TEA.—Over seven million pounds (7,170,329), or nearly double that for the previous one, were exported during the financial year; and an immense impetus to the demand at home has been given by the costly advertisement at the Colonial and Indian Exhibition in London, where Ceylon tea gained a very great popularity. Otherwise there is nothing in the position of this product that calls for any remark from me beyond what is contained in my last report. The amount of land now under tea is estimated at over 130,000 acres, but this is to be regarded only as an approximation.

As anything relating to this product, which has now stepped into the first rank of our exports, has become of interest, this is the proper place to put on record the facts with regard to the first introduction of Assam tea into this Colony. In December, 1839, Dr. Wallich, the eminent Indian botanist, at that time at the head of the Calcutta Botanic Gardens, sent to Peradeniya seeds of the then recently discovered "Indigenous Assam Tea"; and these were followed in February, 1840, by 205 plants. In May, the then Superintendent at Peradeniya, Mr. Normansell, sent several plants to Nuwara Eliya, and a man was supplied to look after them. This was after a representation to Government that tea was likely to prove a "new and profitable speculation" and a "valuable source of revenue." Again, in April 1842, another instalment of Assam plants was received from Dr. Wallich, and in October some

* Too bad.—ED.

of these were sent to Mr. Mooyart at Nuwara Eliya with directions for cultivating them. I had often wondered what became of these, and by accident in London I met the gentleman to whose care they were committed, the Rev. E. F. Gepp, at that time tutor to the son of Sir A. Oliphant, Chief Justice of Ceylon. He informed me that in October 1842, he received the plants from Mr. Mooyart at Nuwara Eliya, about thirty in number, and cleared a piece of jungle for them on Sir Anthony's land there; they were doing well when he left the Island a few years after. Mr. Gepp thinks the ground was somewhere in the neighbourhood of the present Queen's Cottage, and it will worth a search to discover whether some of the plants may not be still in existence.*

CINCHONA.—In spite of the low prices prevailing, the export of bark continues to increase, and the enormous quantity of over fifteen million pounds (15,364,912) was sent from the Colony during the year. This is the more surprising, as at present the margin of profit to the producer of bark must be very small, especially as there are scarcely any choice varieties in cultivation here. As regards the future, it appears impossible to form any trustworthy idea as to the amount remaining in Ceylon, but it must be greatly lessened by this vast export of late years, during which very little has been planted. As soon as shipments from Ceylon drop, as they must do, prices may be confidently expected to rise.

CACAO.—It is gratifying to see that the unnecessary check to this cultivation has been of every short duration. The export (15,347 cwt.) for last year is more than double that of the previous one (6,578 cwt.). The "Forastero" kinds (see last Report) appear to be increasing in favour with planters as being heavier croppers and hardier, notwithstanding the fact that they do not yield so fine a product as the old Red Caracas variety. Cacao cultivation, I regret to see, has taken little or no hold on the Sinhalese villagers. As often pointed out, it is not possible to conceive a more suitable plant than this for the villager's little garden, if only the owner will pay it a little attention for the first two years of its life. After that, no further trouble is necessary, and the plant takes care of itself. In past years large quantities of seed have been distributed to the villagers in the Central and Western Provinces, and in 1884 I circulated printed instructions for their cultivation, but no results are apparent. Injury from *Helopeltis* is no longer dreaded, though it is by no means infrequent. With regard to this insect, it appears from a paper by Mr. Waterhouse,† chiefly based on specimens I gave to the British Museum, that our Ceylon species, the original *H. Antonii*, is distinct from the Java Cinchona-bug, which he names *H. Bradyi*, as well as from *H. Theivora*, the destructive Tea-bug of Assam. This gives some explanation of the immunity of our tea and cinchona, for it is probable that these species, though so much like one another, are restricted as to food to particular plants. A large consignment of Forastero cacao seed was sent to the Queensland Acclimatisation Society, and it is satisfactory to learn that fully 90 per cent. were raised there.

INDIA-RUBBER TREES.—The Para rubbers (*Hevea brasiliensis*) are now over ten years old, and the largest tree has a girth of 49 in. at a yard from the ground. Some plants have been sent to Queensland.

The *Castilloa elastica* trees are the same age. They are not now growing so rapidly as at first; the largest is 38 in. in circumference at a yard from the ground. A Wardian case with 250 seed of this was sent in May to the Conservator of Forests, Tavoy, and fifty young trees have been planted at Kandy. The paper by Sir J. D. Hooker, referred to in my last report, has been published ‡ It is illustrated by a fine coloured plate of the tree cultivated here, drawn by W. De Alwis, the draughtsman of the gardens. Sir Joseph points out that our plant, which it will be remembered is the "Caucho" tree collected by Cross in Darien in 1875, differs slightly from the original *Castilloa elastica*, Cav. (the "Ulé" tree of Mexico and Central America), in having the leaves less hairy beneath, and the seeds of a somewhat different shape. He does not, however, apparently consider these differences sufficient to warrant another specific name, and our plant may continue to be called *C. elastica*.

Of the East African rubbers, the oldest plant of *Landolphia Kirkii*, the climbing stem of which is now about 10 in. in circumference, produced fruit this year for the first time. The seeds are few in number, and contained in a thin-coated globular berry, and each is covered with a sweet orange-coloured pulp.

GUTTA-PERCHA TREES.—The "Gutta Tabañ Patih" (*Dichopsis pustulata*) have attained 12 ft. in height at Peradeniya, and the "Gutta Sundek" (*Payena Leerii*), which does better at Henaratgoda, are now about 16 feet-high at that Garden.

NEW VEGETABLES.—The "Chocho" of the W. Indies (*Sechium edule*) has been widely distributed, and has rapidly become common in the country. It is liked both by Europeans and by natives, and its easy culture is especially appreciated by the latter by whom it is much esteemed for curries. I have noticed it for sale in the Kandy market at 1c. and 2 the fruit. The tree tomato (*Cyphomandra betacea*) has also spread rapidly through the hill-country. The fruit keeps well after being gathered, and as it has a tough skin, and travels well, it might be largely cultivated in the villages for sale in the towns. The Arracacha (*A. esculenta*) is not generally liked by Europeans (though some like it), but much enjoyed by all the natives who have tasted it. Mr. Nock reports a good stock at Hakgala, and I am prepared to distribute, through the Government Agents, small quantities to the headmen of villages at 2,000 feet or more elevation, in the hope of its culture being taken up by the villagers. Much interest has been excited in India by the successful introduction of this vegetable into Ceylon, and in answer to applications we have sent boxes of the roots to the Botanic Garden at Saharunpore, the Agri-Horticultural Society of Calcutta, and the Chief Commissioner of British Burmah.

ULLUCUS TUBEROSUS.—As recorded in my last Report, a few tubers of this vegetable—the "Oca-quina" of Peru and Bolivia—were received from Kew at the end of 1885. They were sent on to Hakgala, and Mr. Nock reports as follows:—

"Planted in a nursery bed they grew rapidly, and the tops did not die down till November. They were then taken up, and the crop produced weighed 11½ lb. The tubers from which these were produced could not have weighed more than an ounce, and they were all very small, the largest being scarcely the size of a hazelnut, whilst the average size of the crop produced here was about that of walnuts. The largest—shaped like a kidney potato— was 3¼ in. long by 3⅜ in. in circumference, or 1¼ in. in diameter in the middle."

These tubers are largely consumed in Peru, like potatoes. Judging from those produced here, I think them too "waxy" to suit English taste generally.

FRUITS.—The Cherimoyer (*Anona Cherimolia*) is now well established at Hakgala; there are numerous plants in perfect health, and likely to do well; the largest is as yet, however, only 4 ft. high.

Pineapples.—During my visit home I was successful in interesting the authorities at Kew in an attempt to obtain additional varieties of this favourite fruit, and they with some difficulty secured from private sources twenty-six shoots of the following well-known varieties:—"Black Jamaica," "Queen," "Lord Carrington," "Smooth Cayenne" (which is already well-known in Ceylon), "Black Prince," "Charlotte Rothschild," "Lady Beatrice Lambton," and "Enville Queen." The plant of the last named was dead, but the rest arrived in excellent order, and were planted at Peradeniya at the end of September.

* Since writing the above, I find that Mr. Gepp communicated these facts in a letter to the London *Times*, dated August 19. He is, however, mistaken in supposing the plants to have come from China.

† Trans. Entomolog. Soc., 1886, page 457.

‡ Trans. Linnean Soc., ser. 2, II., page 209.

Oranges.—In answer to request, a fine selection of choice grafted oranges, &c., of twenty-five kinds, was despatched from the Queensland Acclimatisation Society early in October. I regret to say, that in consequence of a series of careless blunders the cases containing these were twice carried past Colombo, first to Aden and then to Calcutta. On finally arriving at Peradeniya (on January 2nd) they were, it is needless to say, all dead from drought. These were intended for the new Garden at Badulla. Another collection has been applied for.

Jamaica Billberry (*Vaccinium meridionale*).—On this plant Mr. Nock has the following:—A few plants of this fruit were raised three years ago, but until this year they remained almost stationary. They have, however, now made a start, and look as though they will yet do well. This plant in the mountains of Jamaica grows into quite a big tree; the wood is very hard and durable, and one of the very best for posts. It bears heavy crops of fruit, which is very good cooked, at elevations from 2,000 ft. to 6,000 ft.

Eucalyptus Plantation.—Mr. Nock reports:—The high winds at the end of May did much damage to the plants in this plantation. Some of them were blown clean out of the ground, and many others lost their heads. The trees are now nearly five years old from seed, and the following measurements of the fifteen kinds selected for measuring in 1884 will show the rate of growth for four years:—

Names	1884 Height ft.	1884 Girth in.	1885 Ht. ft.	1885 Gth. in.	1886 Height ft.	1886 Gth. in.	1887 Height ft.	1887 Gth in.
E. robusta	14	0 8	24	15	30	0 22	39	0 30
longifolia	14	0 6	24	14	35	0 19	43	0 26

hæmastoma	7	2 5	15	12	23	0 18	27	6 25
Lehmanniana	6	5 4	12	9	21	6 13	29	0 18
alpina	2	8 3	5	5	12	6 9	15	0 12

Eucalyptus acmenoides has commenced to grow rapidly during the last two years. It stands the wind well, and the growth is as straight as an arrow. At five years old from the seed it is 32 ft. high and 28 in. in circumference at the ground. *E. alpina* has a curious swelling at the base, which seems to be natural, as all the plants have it. Close to the ground it measures 25 in. round the stem, and 6 in. higher up only 12 in. This and a few of the other species are now flowering.

Conifers at Hakgala.—Though several species of *Thuja*, *Cupressus*, *Juniperus*, *Araucaria*, *Frenela*, *Cryptomeria*, &c., grow well in the hills (as also lower down), nearly all the pines and firs that have been tried have been more or less failures, and I believe very few will succeed in our climate. There is, however, a large tree of *Pinus longifolia*, which must be of some age, by the Office, 40 ft. high, with a girth, close to the ground, of 6 ft. 4 in. It has produced cones freely during the year, but none of the seeds were fertile. Some other young plants of this species, raised from Indian seed and planted in good soil in the Garden, are doing well, but those in the old cinchona plot have not come on at all well.

Seed of *Pinus sinensis* was obtained in 1884. The largest plant in the garden is 11 ft. high, but one left in the nursery bed, where there is probably better soil, is 20 ft. high and 10 in. round the stem at base. The plant evidently requires rich soil, as others of the same age in other parts of the grounds are not more than 18 in. high.

Receipts from Sales.

The commencement of more prosperous times is indicated by somewhat improved returns from sales, especially at Hakgala, where the dealings are mainly with the planting community. At Peradeniya the principal purchasers are still travellers, and the chief thing purchased are Wardian cases or boxes of orchids, &c., for taking away from Ceylon. No less than thirty-four of these were supplied in 1886.

The following are the receipts for the year:—

	R.	c.
From Peradeniya	2,136	99
Hakgala	877	68
Henaratgoda	191	82
Anuradhapura	34	44
Badulla	24	16
Total	3,265	9

[For parts omitted here, see further on.]

THE KANDY AGRI-HORTICUTURAL SHOW.

6th May, 1887.

The second Agri-Horticultural Exhibition of Kandy was opened today. The arrangements for the public were in many respects better than the former Show: there was more room and consequently less crowding. The buildings—mere sheds—lacked the artistic beauty or finish of those of two years ago—doubtless the effect of the hurry-scurry at the end—nevertheless to have got such houses up in so short a time, and decorated them as they were decorated said much for the energy of all concerned, and reflected considerable credit on the Committee.

There is so much floral wealth in Ceylon which even in inartistic hands readily lends itself to decorating a building that we are all more or less accustomed to seeing the effects in some style or another. But I do not remember to have seen anything so perfect in form, colour, and lightness, as a kind of canopy over some splendid ferns. It was, indeed, "a thing of beauty" apt, however, to be missed by the sight-seer owing to its height.

Perhaps the best Court in the Show was the one at the East-end, filled without art treasures. Here there were collections of native jewels of untold value; fine displays of moonstones; ivory carvings to please the eye of the connoisseur; samples of Kandyan painted pottery, the usually too glaring colours considerably toned down. Heaps of embossed silver work, for which some districts of Ceylon are so famed, and a fine silver salver, made in the Kegalle district, and lent to the exhibition by His Excellency. There were also rich cloths embroidered with gold, furniture, brass work, paintings, photographs, and a book of great beauty, gorgeously illuminated, and written in clear characters, a gift from the King of Siam to some of the Buddhist temples.

This Court was always crowded, it had colour and glitter in it, and had evidently attractions which were not present anywhere else within the walls of the Show.

There was a fine display of Ferns of all kinds and the cut flowers were in greater plenty and variety than formerly. Some of the flowers too in pots were pretty, and told of care, but there was much in this division of the Exhibition unworthy of a place.

As to the new feature—the Cattle—there is nothing special that lives in one's memory. You saw a notice "gold medal," "silver medal" tied on the forehead of very ordinary animals, the owners of which must have been more astonished than the public, at their being deemed so highly worthy of honour. It evidently did not want very many high points to get a first position on the list of prize cattle.

The Fruit and Vegetables were poor as compared with what might have been. They were only a shade better than the Estate Products, which may be pronounced all but a failure. It was almost laughable, the meagre display. Whatever product you were interested in, the poverty of the show was sickening. As to tea, the competitors were so few that the day before the Exhibition, frantic efforts were made to get *any*

body to exhibit, and it was quite pathetic to see how miserably those efforts had been responded to and how poorly our rising product was represented. People who had hunted round the place in search of the tea exhibits were often like the ships that tried to find St. Helena and couldn't. "But where *is* the tea?" they would ask you and would find it at last in a corner of a bench! I fancy a cooly could have cleared the Show of all the tea on exhibition and had a light load. The other products were not a whit better.

ARTS AND MANUFACTURES.

Jewelry exhibited by C. B. Nugawella, R.M. of Udanuwara; Ancient Kandyan sword (short) with elaborate ivory handle and sheath; Fret-work, ebony bracket by A. C. Lawrie; Porcupine quill work-box, price R200 by D. F. de Silva & Co.; Porcupine quill writing-desk, by D. F. de Silva & Co.; Porcupine quill inkstand, by D. F. de Silva & Co.; Kandyan pottery (20 pieces), K. Artwork Aassociation. One pair chair designed by H. Fraser, l Matale, and made by Thomas Fernando, Moratuva; Ebony chair mounted with ivory from Asgiriya Vihare; Turkish modelled Mattress and cushions, by Bunder Saibo (with cushions); Kandyan embroidery work (1 lady's jacket and 1 gentleman's belt), T. B. Banabokka; Old Kandyan cloth, by Rambukwelle R.M.; Nilgarunda cup, salven and plate, by T. B. D.; 2 Brass chembuws, by V. Valoo; Betel stand &c. by V. Valoo; 2 Large brass trays, by V. Valoo; Silver trays, chembuw bowls, jewel cases, &c., copper, ebony, brass, cases, by K. A Association; Map of Ceylon shewing some of the principal animals and natural products drawn by W. Francis Magnes Perera; one pair Indian Orchids from G. S. Saxton; a Centenerian, a Talipot Palm in blossom, by E. F. VanDort; an Elk Hunt, by E. F. VanDort; a Tropical Nocturne, by E. F. VanDort; Watercolour Pictures by Miss Mary F. A. Tench Glentilt, Maskeliya; Two Glasses with Water-colour painting, by Mrs. F. Braine; Moonstones from Attaragalla, Kandy, by Sinne Marikar Madar Saibo including the best and biggest moonstone ever confound in Ceylon; two Ivofy Scent Bottles, by Utumana Mulacharige Muhandirum; Ivory Chessmen K. A. Association; Chessmen, by K. A. Association; Ornamental Coconut Ladle, by T. B. Panabokke; 13 Clay Plates illustrating Perehera; Fretwork, by Mr. Wood; Revolving cannon in miniature by U. B. Dehigama; Ancient Iron Artistic Adze by Kotmale Ratamahatmaya; Collection of Brass articles from Mr. F. R. Ellis.

Native plough, by Uudawella Arachchi; Native plough, by Rambukwella R. M., of Uda Dumbara; Native kake, by Rambukwella R M.; Various instruments of husbandry by Rambukwella R. M. of Uda Dumbara; Aloe fibre rope from Kadawella estate (25 fathoms); Collection of paddy (native varieties) exhibited by S. Ratwatte, Lower Dumbara; Paddy (native, 4 varieties) T. B. Dimbulana R. M.; Paddy (native, 7 varieties) by C. B. Nugawela R. M.; Arecanuts (2 varieties) by L. B. Yatiwara; Arecanuts (4 varieties) by S. Weerakody Mudaliyar; Indian corn by L. B. Yatiwara; Indian corn by Dimbulana R. M.; Indian corn by Rambukwella R. M.; Small grain (8 varieties) by T. B. D.; Small grain (5 varieties) by H. Abyegoonasekara Korale Upper Hewahetta; Cotton, sample of crop grown in the Government Experimental Garden, Kegalla, exhibited by S. Weerakody; Tree and American cotton from J. P. Cotton; West Indian arrowroot from J. P. Cotton; Marketable leaf tobacco by Panabokke R. M.; Honeycombs with living bees by Yatiwara R. M.; Jaggery (6 varieties) by L. B. Nugawela; Jaggery by M. B. Nugawela (6 varieties); Ginger by L. B. Yatiwara; Ginger by S. Ratwatte R. M. of Uda Nuwara.

7th May, 1887.

The tea contest, as between Blackstone and Agar's Land, was said to have been very close. The matter of two points or so, so fine a thing indeed, that only a highly educated palate would pretend to distinguish the difference. Still there *was* the difference, and to Mr. Barber fell for a second time the much-coveted gold medal. Mr. Barber may be proud of the high place he has taken, and few, I think, will grudge him this honest congratulation. At the final testings, I believe, the tasters were quite in the dark as to what was what, or which was which. So few teas were offered, that a race was nowhere except between the two well-known brands, and then it was neck to neck, till the peculiarly fruity flavour of Ceylon teas which Blackstone possessed in a slightly higher degree than Agar's Land landed the formed with "the blue ribbon." What we want now is trial in the Colombo or London sale rooms, to test how the tea buyers regard the award. If each estate were to offer at the same time a break of 3,000 lb. or so, there would be a considerable public extremely interested in the result.

Those who have tasted the two teas, will bear me out that for strength they are very remarkable. It is when you try to describe such teas that you are impressed with the necessity of cultivating the jargon of the tea taster and you produced a result like the following:—"Strong, little, thick, deep, rasping, brisk, full rich powerful liquor, with great character and fine flavour." There is in that sentence a vocabulary enough for any man to set up as a Colombo tea broker—and as for its hidden wisdom goodness only knows all it means or if it has any meaning.

To supply omissions in my last I may say that as to Estate Products, fancy tea was very poorly represented. The commercial tea samples shewn were said not to be equal to the best that could be produced, but the average quality was good. The first and second estate teas which secured prizes far surpassed all the others and fairly represent the highest class of commercial tea being good in every part. Riverside would seem to be a bad third. Kandenuwara estate cardamoms presented a very fine appearance, but unfortunately the box in which they were contained could not be opened, and was thus out of competition. There was a disarrangement of words in the telegrams as to prize winners in this class which has been since rectified as follows: Mr Tatham silver medal, Cinchona bark. Mr. Milne, Liberian coffee. Mr. E. Anderson, Cardamoms. Waterantenne, Cacao. Roseneath, Nutneys Chocolate, L d'Espagnac. The rest were correct. A complete list is sent. The chief prizes for "Cut Flowers" were given to 1st A. Tabor, 2nd J. F. Hadden, 3rd A. Whyte. The up-country flowers were worth looking at. The roses raised by Mr. Whyte in Kandy were not so good when compared with those from the higher districts, nor could this be expected, and some distinction must be drawn in future Shows between Kandy and up-country flowers. Mr. Whyte's vegetables got mixed up with others and could not get a prize on the first day, but on Saturday the mistake was rectified, and a silver medal was awarded to him. Salem estate got silver medal for some excellent pine-apples which many visitors were tempted to taste on the spot. Some rare king coconuts were sent by Mr. J. G. de Silva; best mangoes silver medal same exhibitor, who exhibited also limes and other fruits. Mr. W. V. Woutersz shewed "silver cotton" preserves, jaggery &c. The pomegranates came from Morupola estate, Heneratgoda, J. G. de Silva. As will be seen, there was very little shown under Class S. (preserved fruits.)

The collection of Cut Flowers were added to by the contribution of bouquets on second day. Mr. A Whyte, Waller and De Livera and others got silver medals for these. Mr. Whyte's table bouquet was in the form of a pyramid terminated with fine variegated plants with graceful hanging palm-like leaves, and very much admired. Miss C. Reimers well deserved the prize she got for the show of flowers and Miss Kelly received also a silver medal for her beautiful bouquet. Under the head Live Stock were exhibited devil bird by Dr. E. Fitzgerald, M.D.; bear, jackal and porcupine (exhibitor not named); three elks by Girihagama R. M.,

"baby elephant by J. H. Girihagama; best Coast bull gold medal,) two bulls by G. Ross, Le Vallon gold medal, he buffalo by L. B. Nugawela.

Mr. Alfred Ambrose exhibited a fine pair of sky tumblers and pair fantails; Mr. Austen game-cock and two dorking game. Mr. Woth of Kandy sent the best pair rabbits, Mr. F. Ondartje three monkeys, some one sent two squirrels, Mrs. Alexander of Anuradhapura exhibited ducks, and Mr. W. R. Waller pair of fat geese. Mr. Vollar's English bull attracted attention (gold medal) as well as Mr. F. W. Gray's boar (gold medal). Best Coast bull (gold medal) belonged to Mr. A. Silva. Mrs. Shelly sent some good fowls as also Mr. Austen.

Amongst the Art collection His Excellency the Governor sent a large silver dish, lent for the occasion. Ratnapura District was to the front with a splendid casket which was much admired, as also was "bronze mould for silver ornaments for the King's feet" and "mould for silver ornaments" by Nelawala Muhandiram. Some one sent ancient Siamese Buddha excavated among the old ruins of a large Wihara at Thiriyawa, near Trincomalee. "The Taj in marble" with cover was also admired. It was of solid marble representing the burial place of the King and Queen of Agra, near the town of Agra; and an ornamental flower vase, Kandyan workmanship, with 15 cobra-images around it. The jewellery was contributed by Messrs. L. B. Nugawela and Panabokka. "Paiistana" was contributed by Tikiribanda Paranatalle. A beautiful ebony box by L. B. Nugawela, native clay, (native preparation). "Hand-cut" wood carving cut by Mr. W. G. Wood, Bogambera, Kandy. Models of ships also by same gentleman. Some excellent drawings and plans by Mr. F. W. Thomson, Surveyor. The Artwork Association sent silver-work and painted pottery. There was a large collection of old books.

Another correspondent writes :—Two pictures of two large groups of orchids carried the silver medal for paintings—but no ticket seemed to be attached, so that the exhibitor remained unknown. This we believe is contrary to the rule which required the name of the exhibitor to be attached. These drawings are admittedly copies and have been accepted by the judges and prepared to original designs by native artists. We have heard it said that the copyists are some ladies in England. There were besides, about half-a-dozen water colour paintings of local scenes. "The talipot palm in blossom" with the lights of early morning on the distant hills being particularly effective and a sea-scape "Crossing the Surf" deserves much attention. We were surprised to notice that a series of etchings of much merit sent in by the same artist was passed over, and it is not understood why the prize for this section was withdrawn. This seems a queer and novel way of encouraging native talent. It was a pity that the refreshment stall was so placed that the Arts department was at a disadvantage for the best light, it being in deep shadow towards the latter part of the afternoon. There was a large exhibit of Kandyan pottery in native lacquer work which carried the prize although the exhibitor did not profess that he did them. It was all the work of native (Kandyan) artists whose names even did not transpire. There was also a group of hand-painted pottery of very original design, but these were scarcely seen to advantage owing to their being sealed up with other exhibits on shelves behind a glass case. We have reason to know that they however attracted the attention of the Governor. Did the judges take the trouble to examine the details of the work and thus find out its merits? The representations of the Sinhalese in childhood, youth, manhood, and old age, and the four principal products of the island viz: tea, cinnamon, coconut and paddy were most original in design, and very well carried out, and it was explained to us that even the conventional designs were taken from leaves and flowers native to the island. It is very much to be regretted that there was no recognition of the merits of this original exhibit, nor of the beautiful fret-work exhibited by an Industrial School boy and Mr. Wood of the Garl,

LIST OF PRIZES PRESENTED BY LADY GORDON.

CLASS I: GARDEN PERENNIALS, in pots:—Roses, best collection of not less than 18 different varieties, Silver Medal, Mr. A Whyte; Begonias, best collection of not less than 12 different varieties, Silver Medal, Mr J D Jonklaas; C. H. Pate bronze special award; Begonias, best collection of not less than 6 different varieties, Bronze Medal, Mr. A. C. Lawrie, D J Kandy; Best Geraniums, collection of not less than 6 different varieties, Silver Medal, Mr J V H Owen; Pelargoniums, Silver Medal, Mr E J Thwaites; Gloxinia, Silver Medal, J V H Owen; Amaryllids and Lilies, Silver Medal, E J Thwaites, Bronze; Orchids in flower, Silver Medal, J Fenton Wingate, Bramley estate; Fuchsias, Silver Medal, J V H Owen; Achimenes, best collection of not less than 3 varieties, Bronze Medal, J V H Owen; Primulas, Silver Medal, E J Thwaites.

CLASS II: GARDEN ANNUALS, in Pots.—Best Balsams, Silver Medal, A Whyte; Phlox, Bronze Medal, Mrs E R Whitfield; Violets, Silver Medal, Mrs T G Baker; Violet, second best, Bronze Medal, Mr E J Thwaites; Mignonette, Bronze Medal, 'no exhibit'; Calceolarias, Silver Medal, Mr E J Thwaites; Cinerarias, Silver Medal, Mr A Whyte;

CLASS I: SPECIAL PRIZES.—Cyclamen, Mr E J Thwaites, Bronze; Tuberous Begonias, Mr E J Thwaites, Silver; Best Geranium plant in class, Mrs J G Baker, Silver; Spinosa, Mr A Whyte, Bronze.

CLASS III: FERNS, in pots.—Best general collection of not less than 18 different kinds, Gold Medal, Mr C H Pate; Best collection of Adiantums, Silver Medal, C H Pate, A R Lewis, Bronze, special award; Best single Fern, Silver Medal, J D Jonklaas; Second best Fern, Bronze Medal, C H Pate.

CLASS IV: FOLIAGE PLANTS, in pots.—Crotons, best collection of not less than 12 varieties, Silver Medal, Major Byrde; Dracænans of not less than 6 varieties, Bronze Medal, Mr H Neville; Palms, Cycads, &c. not less than 6 varieties, Silver Medal, Major Byrde; Caladiums not less than 6 varieties, Silver Medal, J D Jonklaas; Marantas not less than 6 varieties, Silver Medal, T C Huxley; D F de Silva, Silver, special award; Alocasias of not less than 3 varieties, Silver Medal, J D Jonklaas; Cleus. best collection of not less than 18, Silver Medal, J D Jonklaas; Cleus. best collection of not less than 9, Bronze Silver, Mrs Jeffries.

CLASS V: CUT FLOWERS.—Roses, best collection of not less than 24 different varieties, Gold Medal, Mr A Tabor; Roses, best collection of not less than 18 different varieties, Silver Medal, Mr F Hadden; Roses, best collection of not less than 6 different varieties, Bronze Medal, Mr. A Whyte; Roses, best three blooms of a white rose, Certificate of Merit, Mr R A Ferdinands; Roses, best three blooms of a yellow rose, Certificate of Merit, Mr R A Ferdinands; Roses, best three blooms of a pink rose, Certificate of Merit, Mr A Tabor; Roses, best three blooms of a dark-red rose, Certificate of Merit, Mr R A Ferdinands; Best Dahlias, double, Silver Medal, Mr L H Kelly; Geraniums, in trusses of three, Silver Medal, Mrs J G Baker; Geraniums, in trusses of three, second best, Bronze Medal, Mr T C Huxley; Pelargoniums, in trusses of three, Silver Medal, Mr E J Thwaites; Pelargoniums, in trusses of three, second best, Bronze Medal, Mrs J G Baker; Hibiscus, best collection of not less than six, Silver Medal, D F De Silva; Hibiscus, best collection of not less than three, Bronze Medal, Mr A Whyte; Carnations, Silver Medal, Dr E Livera; Carnations second best, Bronze Medal, Mrs Baker; Phlox Perennials, Silver Medal, Mr T C Huxley; Phlox Drummondii, Bronze Medal, Dr E Livera; Chrysanthemums, Silver Medal, Mr T C Huxley; Verbenas, Silver Medal, Dr E Livera; Pansies, Silver Medal, Mr E J Thwaites; Violets, Silver Medal, Mrs E G Hardinge; Violet, second best, Bronze Medal. Mr A. Tabor; Best arranged table bouquet, Silver Medal, Miss Constance Reimers, Mr L D'Espagnac, Silver extra; Best arranged hand bouquet, Silver Medal, Miss Kelly; Best arranged 3 button-hole bouquets, Bronze Medal, Mr A Whyte;

Best arranged collection of native flowers, Silver Medal, D Wijeyerame; Bouquets on second Six day, Silver Medals, Messrs A Whyte, W R Waller, Dr, Livera, D F De Silva and Gabriel Perera

CLASS III: SPECIAL PRIZES.—Single Fern, extra, Silver, Mr E F Wingate; Single Fern, extra, Silver, Mr A C Lawrie.

CLASS IV.—Miscellaneous collection of plants, extra, Silver, Mrs W G Wood.

CLASS V.—Pinks, extra, Silver, Mr T C Huxley.

CLASS VI: Vegetables.—Best collection of English vegetables grown upcountry, not less than 6 different sorts as below, Silver Medal, H Young and A Whyte; Best collection of native vegetables, as below, Silver Madal, Nugawela, R M; Best potatoes, 12 tubers, Silver Medal, D W Perera, Nuwara Eliya; Carrots, 6, Bronze Medal: R N Knight; Turnips, 6, Bronze Medal, H Young, Nuwara Eliya; Cabbage, 2 heads, Bronze Medal, H Young; Beet Root, 3 roots, Brone Medall, R N Knight; Clery, 2 roots, Bronze Medal, A Whyte Cauliflower, 2 heads, Silver Medal, E G Hardinge: Cauliflower, second best, Bronze Medal E J Thwaites; Lettuces, 3 heads, Bronze Medal H Young; Vegetable Marrows, 2, Bronze Medal R M Kmght; Raddishes, 18, Bronze Medal, H Young Cucumbers second best, Bronze Medal, M Badar Deen, Arachchi; Knol-kohl, 6, Bronze Medal, R N Knight; Yams, Silver Medal, J P Cotton, Watarantenne; Sweet Potatoes Bronze Medal, Proctor Girihagama; Pumpkins, 2, Bronze Medal, M Badar Deen; Breadfruit, 2, Silver Medal, M Badar Deen; Breadfruit, second best, Bronze Medal, Nugawela R.M.; Cho cho, 3, Silver Medal, Mrs. W G Wood; Cho cho second best, Bronze Medal, D F de Silva; Bringals, 6, Bronze Medal, J R Greve, Matale; Pot-herbs, Mint, Sage, Basil, Parsley, Marjoram, fennel, &c., Silver Medal, H. Young; Salad-herbs, Cress, Endive, Lettuce, Beet, Watercress, Onion, &c., Silver Medal, H. Young; Curry-vegetables, Murunga, Karavila, Podivilanga, &c., Silver Medal, Ratwatte, R.M.

Best general collection of plants and flowers in classes, 1, 2, 4, 5 and 6 excluding roses, Gold Medal, J V H Owen.

CLASS VII: FRUIT.—Mangoes, best general collection of not less than 6 different varieties, named, Silver Medal, J G de Silva, Colombo; Mangoes, best general collection of not less than 3 different varieties, Bronze Medal, D J Perera; Mangoes, second best, collection of not less than 3 different varieties Bronze Medal, Mrs. Poloris; Plaintains, best general collection of not less than 4 different kinds, named, of which Suwandel shall be one Silver Medal, A L J L Marikar; Plantains best Hanbanpuwalu, Bronze Medal, J G de Silva; Best Pineapples, 3, Silver Medal, Salem estate, W H Newman; Finest "Kew" Pineapple, Bronze Medal, Mrs. Jeffries; Best Oranges, 12, Silver Medal, Hanga Duriya; Best Oranges, second best, Bronze Medal, Mrs. Jeffries; Limes, 2 measures, Silver Medal, J G de Silva; Lovi-lovi, 2 measures, Bronze Medal, Major Byrde; Granadillas, 6, Bronze Medal, Mrs. W G Wood; Jaks, 2, Bronze Medal, P B Dassanayake; Rhubarb, 6 sticks, Silver Medal, R M Knight; Rhubarb, 6 sticks, second best, Bronze Medal, E J Thwaites; Tree Tomato, 12, Silver Medal, E J Thwaites; Tree Tomato second best, Bronze Medal, D H Perera, Nuwara Eliya; Grapes, best bunch, Silver Medal, W J F Soyza.

CLASS VIII: PRESERVED FRUITS, VEGETABLES, &c.—Jellies, fruit, &c., Silver Medal, A Alwis.

CLASS VII: Special Prizes.—Pomagranates, Extra Bronze Medal, J. G de Silva; Pears, Extra, Silver Medal, S Weerakod Mudaliyar

CLASS IX.—NATIVE PRODUCTS.—Best general collection of native products grown by one Exhibitor, Gold Medal, J F Soyza; Paddy, best collection of the following sorts:—Hatiyal, Mawl, Hondarawala, Hinati, Elwi, balwi, ¼ bushel of each, Gold Medal, C B Nugawala R.M.; Paddy, best collection of the following sorts:—Muttu-samba, Kaivra Samba, Sulai, Carolina, or any of them, ¼ bushel of each or any, Silver Medal, L B Yatiwara, R.M.; Indian Corn, Eringu, Silver Medal, Dimbulana R.M.; Cholum: Karal Eringu, Silver Medal, Rambukwella, R.M.; Kurakkan, Silver, Medal, Rambukwella R.M.; Small Grains: Amu Meneri, Tana-hai, &c., Silver Medal, L B Yatiwara, R.M.; Arrowroot, Silver Medal, J P Cotton, Watarantenne; Jaggery, Silver Medal, M B Nugawela R.M.; Tobacco, cured, Siaer Medal, Panabokka, R.M.; Cotton, Silver Medial, S. Weerackody Mudaliyar; Tree Cotton, Pulun, Silver Medal, A. L. J. L. Marikar; Ginger Silver Medal S. Ratwatta, R. M; Areca Nuts Silver Medal, Crystal Hill, Matale; Betel Leaves, Silver Medal; T. B. Panabokke R M; Honey, Silver Medal, T. B. Panabokke, R. M; Jungle Seeds, Resins, Silver Medal, M B Nugawela R M; Cocoanuts, Silver Medal, J G de Silva; Native Ploughs and other Instruments of Husbandry, Silver Medal, T B Rambukwelle R M.

LIVE STOCK.—Ceylon-bred Buffalo, best, Gold Medal, S Ratwatte R M; Ceylon-bred Buffalo second best, Silver Medal, Punchi Rala Korale; Native Bull best, Silver Medal, L B Nugawela R M; Native Cow best, Silver Medal, L B Nugawela Junior.

CLASS X: ESTATE PRODUCTS.—Best general collection of Estate Products from one estate, Gold Medal, Kandenuwara estate, Hugh Fraser; Tea: best set of samples of *bona fide* commercial teas, broken pekoe, pekoe and pekoe souchong, from one estate 5 lb. of each grade, Gold Medal Blackstone estate; Tea second best set of similar samples, Silver Medal Agar's Land; Tea: third best set of similar samples, Bronze Medal, Riverside; Tea: best set of samples of fancy Teas; 2 lb. of each grade, Silver Medal, Castlereagh estate; Liberian Coffee accompanied by one bushel in parchment, Silver Medal, Wm. Milne, North Matale. Cacao second best of commercial Cacao 28 lb., Silver Medal J P Cotton Watarantenne; Cardamons 5 lb. Silver Medal, Eric S Anderson, Loloowatte estate; "Mysore" Cardamoms 5 lb. Silver Medal, Eric S Anderson, Kobonella estate.

SPECIAL PRIZE.—Native Bull, extra William Dullewe; Paddy, extra, Gold Medal, L B Nugawela R. M. Paddy plants, extra, Silver Medal, A Ratwatta.

CLASS XI: TEA MACHINERY.—For the best individual machine used in the manufacture of Tea including motors, see rule 10, Gold Medal, Messrs. John Walker & Co., for Jackson's Excelsior Tea Roller: For the second best, see rule 10, Silver Medal, Messrs. Mackwood and Co., for Davidson's Sirocco. For the best collection of a complete set of machinery, with or without motors, in position as in factory, machines need not necessarily be by the same patentee, Gold Medal, Messrs. John Walker and Co.

CLASS XII: LIVE STOCK.—Best Coast Bull, Gold Medal, A de Silva; Best English or Australian Bull, Gold Medal, H J Vollar, Pallikelly; Best pair of cart Bullocks, Gold Medal, G Ross, Le'Vallon estate, Best Coast Cow in or out of milk, Silver Medal, J R Greve Matale; Best Native Cow in or out of milk, Silver Medal, Jacob Ambrose; Best English or Australian Cow Silver Medal, R E Waller; Best Boar, any breed, Gold Medal, F W Gray, Kondesalle; Best Sow; with or without litter, Silver Medal, F W Gray, Kondesalle; Poultry, best pen cock and 2 hens, Fowls any pure breed, Silver Medal, S Shelly; Poultry, best pen cock and 2 hens, Fowls any cross breed, Silver Medal, G M Austen; Poultry, best pen cock and 2 hens, Turkeys, Silver Medal, W R Waller; Poultry, best pen cock and 2 hens, Geese, Silver Medal, Mrs. Alexander; Poultry, best pen cock and 2 hens, Ducks, Silver Medal, W R Waller; Rabbits best pair, Silver Medal, W Woth; Pigeons, best pair, Silver Medal, Alfred Ambrose; Cream Cheese, best 1 lb., Silver Medal, no exhibit; Fresh butter best 2 lb., Silver Medal, Mrs. Forbes-Robertson; Fresh butter second best, Bronze Medal, R E Waller.

Cinchona, best collection of Barks grown by the Exhibitor, 20 lb. in all, Gold Medal, Frederick Tatham Yarrow estate; Cinchona, natural Ledgeriana Bark, 2 lb., Silver Medal, Frederick Tatham, Yarrow estate; Cinchona, natural, Robusta (hybrid) Bark, 2 lb. Bronze Medal, J Fenton Wingate; Cinchona, natural Succirubra, Bark 2 lb., Bronze Medal, J G Macfarlane; Cinchona, Renewed Succirubra Bark, 2 lb., Bronze Medal, J G Macfarlane; Vanilla, 3 lb., Bronze Medal, H J Vollar, Pallikelley; India-rubber ½ lb,

Silver Medal, H Fraser; Cinnamon, 25 lb., J F Drieberg; Nutmegs, 12 lb. Silver Medal, Mrs. J. L. Dewar, Roseneath; Cloves 5 lb. Silver Medal, L. B. Yatiwara, R.M; Pepper 3 lb, Silver Medal, L. B. Yatiwara R. M; Cuca, Silver Medal, no exhibit; Tobacco best selection of marketable leaf under same rules as Tea samples, Gold Medal, J. K. Ingleton, Rajawella; Cigars, Best 100, Silver Medal, J K. Ingleton, Rajawalla; Best collection of Medicinal Plants Kapok, Annatto Dye, Croton Seed, Kola Nut, Sapanwood, &c. &c., Silver Medal, W.F. Gomesz Kandy.

CLASS X. SPECIAL PRIZE.—Ceylon Chocolate, Extra, Silver Medal, L. d'Espagnac.

This special Medal was awarded, the Judges being of opinion that the Exhibit was worthy of special notice.

XI. CLASS.—Concentric Tea Roller, extra Silver Medal.

CLASS XII: WILD ANIMALS, extra, Silver, W. R. Waller.

DR. TRIMEN'S REPORT ON THE ROYAL BOTANIC AND ECONOMIC GARDENS.

The most important document in our present issue is the Annual Report of Dr. Trimen, Director of our Royal Botanic and Economic Gardens and of his trusty practical lieutenant Mr. Nock of the Hakgalla Garden. Dr. Trimen's Reports are always models of excellence, of scientific accuracy combined with practical and popular instruction. He writes with admirable precision, and he does not (like his predecessor) allow his love of science predominate to the exclusion of adequate interest in the everyday work and requirements of the planter and native agriculturist. In the latter department as well as in the management of the old and new Gardens, Dr. Trimen is faithfully seconded by his Assistants, Mr. Nock (who acted as Director part of last year, and who has simply revolutionised Hakgalla and all for the better), by Mr. Clark and by that fine specimen of an intelligent, unobtrusive Sinhalese gentleman, Mr. Ferdinandus who will one of these days well deserve to be made a "Maha Mudaliyar." It is particularly encouraging to learn of the progress and good prospects before the new Experimental and Economic Gardens started at Anuradhapura and Badulla, and that although the Railway Department did their best to "boycott" the Heneratgoda branch Garden, the persevering Sinhalese Manager has done his best to keep up the status of his charge. Under new train arrangements we have no doubt the encouragement of visitors will once more be afforded to the Heneratgoda staff, while Colombo residents and their guests will be able to revive the pleasure, picnic and other trips to Heneratgoda have so often afforded. It is particularly unfortunate that Dr. Trimen's Report did not see the light a little earlier, in order that the press and the public might have energetically backed up his enlightened, public-spirited suggestion that a station for the chief Gardens (and for the general convenience of the neighbourhood as well) should be opened at the Deltotte Crossing. We feel sure that the Hon. the Acting General Manager would do what he could to meet this suggestion had it come before him during the recent revision of train services. But perhaps it is not too late now; for, very clearly such a station would be an additional source of profit to the Government, while one calculated greatly to benefit the poeple who would be enabled so readily to visit the Royal Botanic Garden near by, of which it may be more forcibly said than of most applications of the line,—that it is

A thing of beauty and
a joy for ever.

As regards Experimental, Economic Gardens, we trust the Government will enable Dr. Trimen to open two or three more branches:—Ratnapura, for instance, the capital of the far-reaching and important Sabaragamuwa district, deserves to have a Garden of its own; so with Galle, or perhaps better, Matara for the Southern Province; nor should the East and North be forgotten. We should like very much too, to see a closer alliance promoted by Government between the Agricultural branch of the Educational Department and the Botanic-Economic Department. No two officers in the Ceylon Service have a more single eye to the good of the island and its people in performing their duties than Mr. Green and Dr. Trimen, the respective Directors, and we have no doubt that they would be exceedingly ready to co-operate in promoting agricultural knowledge and improvements in every way possible. One way might be by taking advantage of the Gardens to train some of Mr. Green's Agricultural students in practical Horticulture. Mr. Nock would no doubt, do full justice to a class of such lads and the healthy bracing climate of Hakgala, ought to put new life into Sinhalese and Tamil youths.

We have so far dealt with matters rather outside the scope of Dr. Trimen's Report; but we must call attention to its substance (see pages 420-422) and especially to the remarks on our staple products—Coffee (markedly encourging), Tea (with a suitable warning), Cacao (thoroughly satisfactory) and Cinchona, &c. In reference to bark Dr. Trimen judges—and his opinion ought to carry much weight in the local as well as home bark markets,—that the quantity to go forward from Ceylon cannot be kept up to recent exports, but must soon fall off, the reserves being largely encroached upon. What is said about Coffee ought certainly to encourage every man with living coffee trees to do his best to conserve, cultivate and strengthen them. We have no doubt this is being done on all sides. When R62·50 to R65 per cwt. for high-grown coffee is the current rate, it requires no urging on outsiders to get our planters to do their level best for coffee. Indeed there is the risk of their going a little too far in new born-zeal. Meantime we commend Dr. Trimen's wise and suggestive words to all interested in the prosperity of Ceylon.

DELI PLANTING.

(*Translated for the Straits Times.*)

The *Java Bode* calls attention to the contest between planters and brokers in Deli regarding coolie prices, now in full swing. To planters just embarking in business, who find now that, under these circumstances, labour costs twice as much as formerly, this is a matter of the highest importance. This unfortunate result is due to want of unanimity among the planters. Owing to some of them falling away, they could not present a united front to the broker's ring. Those who stood out against the brokers to the last, are now casting about for means to remedy the evil. This can only be done by combined action against the Penang and Singapore brokers, who have become emboldened by their triumph. The planters who will not bow the knee to them, will have themselves to see to the importing of coolies direct from China and the Straits Settlements. By striking into this course they would save a large sum of money which, now, the brokers appropriate as advances and charges.

CUBEBS IN THE GALLE DISTRICT.

Our correspondent at Galle forwarded us the other day a small tin containing a sample of cubeb pepper gathered wild in the Galle district, and asked us to obtain a report upon it. We at once forwarded the sample to Dr. Trimen, who writes as follows:—

"I opened the box accompanying your letter and found within a small kind of pepper in fruit. This is not cubeb pepper, and bears indeed no resemblance to it. True cubebs are not found wild in Ceylon, and is a plant about which very little is known though the medicinal product has been common in trade since the 10th century, I believe it is cultivated in the south of Java only for commercial purposes."

The sample sent us, therefore, must be a species of wild pepper, and not cubebs at all. We should much like to be informed as to where it was found, and whether it is to be obtained in any quantity. The following particulars as to the production of cubebs, taken from the Pharmacographia, are of interest:—

Cultivation and Production.—Cubebs are cultivated in small special plantations, and also in coffee plantations, in the district of Bangoemas, in the south of Java. The fruits are bought by Chinese, who carry them to Batavia. They are likewise produced in Eastern Java, and about Bantane, in the north-west; and extensively in the Lampong country, in Sumatra. There has of late been a large distribution of plants among the European coffee planters. The cultivation of cubebs is easy. In the coffee estates certain trees are required for shade. Against these *piper cubeba* is planted, and climbing to a height of 18 to 20 ft., forms a large bush.

Description.—The cubebs of commerce consist of the dry globose fruits, gathered when full grown, but before they have arrived maturity. The fruit is about 1-5th inch in diameter when very young sessile, but subsequently elevated on a straight thin stalk. By this stalk the fruit is attached in considerable numbers (sometimes more than 50) to a common thickened stalk or rachis, about 1½ inch long.

Commercial cubebs are spherical, sometimes depressed at the base, very slightly pointed at the apex, strongly wrinkled by the shrinking of the fleshy pericarp; they are of a greyish brown or blackish hue, frequently covered with an ashy grey bloom. The stalk is the elongated base of the fruit, and remains permanently attached. The common axis or rachis, which is almost devoid of essential oil, is also frequently used with the drug.

Cubebs have a strong, aromatic, persistent taste with some bitterness and acridity. There smell is highly aromatic, and by no means disagreeable.—Local "Times"

TRADE OF THE PHILIPPINES.

MANILA.

The report of Mr. Alex. Gollan on the consular district of the Philippines for the year 1886 states:—

I had occasion to point out in my report for 1885 that the official statistics are never published here until about a year after the period to which they relate. I am, therefore, only able to give the full figures, in the form prescribed by the recent instructions, for the year 1885; but through the courtesy of some of the leading merchants I am enabled to give the following particulars of the export trade for the year ending Dec. 31, 1886.

The receipts of hemp from the districts where it is grown have been:—

	In 1886. Bales.	In 1885. Bales.
At Manila	342,015	362,024
„ Cebu	60,693	61,051
Total ...	402,708	423,075

or a falling off of about 20,000 bales. The shipments during 1886 have been:—To United States, 186,211 bales; to Great Britain, 164,148 bales; to other countries, 21,323 bales; total, 371,682 bales.

The local consumption of hemp in 1886 is estimated at 5,000 bales, and the stock afloat and in store on Jan. 1, 1887, at 26,363 bales, while 21,500 bales are on their way to the consuming markets. The market value of hemp at the end of the year was about $16 per bale. The total value of the shipments during 1886 amounted to about $6,000,000, or at an average rate of exchange of 3s. 10d. per dol. (£1,150,000).

Coffee.—Exports have been about 7,500 tons in 1886, as against 5,000 tons in 1885, and as the price steadily advanced during the year from about £37 per ton in January, 1886, to about double that figure in December, 1886, it is to be supposed that a considerable impetus will have been given to the further cultivation and development of the article.

Other articles of export in 1886 are:—

Articles.		Quantity.
Cigars	Number ...	103,000,000
Leaf tobacco ...	Quintals ...	183,943
Indigo	„ ...	1,284
Sapanwood ...	Piculs ...	70,748

IMPORTS, 1886.

I am sorry to say that I have found it quite impossible to obtain the necessary data for 1886.

CEBU.

Mr. Vice-Consul Cadell writes as follows:—The value of the exports from this district during 1886 shows a marked falling off as compared with the figures for the preceding year, the decrease being due mainly to the smaller shipments of sugar. Prices of this commodity have ruled on the whole low throughout the year, and consequently less cane has been planted than in former years, whilst a good deal of sugar is no doubt being held back in the provinces by those whose means permit of their waiting for an improvement in prices. The coming crop of cane, however, promises to be a good one.

Return of principal exports for 1885-84:—

	1885. kilos.	1885. £	1884. kilos.	1884. £
Hemp ...	53,330,554	1,244,000	51,085,027	1,441,000
Sugar ...	204,222,480	1,936,000	122,128,325	1,375,400
Coffee ...	5,467,830	183,800	7,529,564	254,000
Cigars ...	972,975	226,000	800,093	252,000
Unmanufactd. tobacco	5,831,379	290,000	1,246,470	110,000

—*London and China Express.*

THE INDIAN CONSERVATORY.

[BY A PRACTICAL GARDENER.]

Of recent years, amateur gardening in India has become a very popular amusement. Many of our compounds are gay with flowers, and our verandahs with pot plants and foliage shrubs, but the general tendency of Europeans in India is to cultivate our home species, and the wide and interesting field of tropical flower gardening is considerably neglected. At a little cost, however, the amateur gardener could add to his collection many a "thing of beauty" from the plant world of India, and so enrich his collection. I have managed an Indian conservatory, or, as it is called a Betel House, for several years, and my experience may be of some value to others. The site for the building should be in the open and not underneath trees, as the drip from the branches in the rains, and the falling of dead leaves in the dry season, are objectionable. The size and shape of the structure must be regulated by taste and condition; and the material used for the framework of building, iron, wood, or bamboo, is a question of cost and durability. Many of us are not permanently placed in India, and it would often be folly to erect a heavy structure at considerable expense. To birds of passage, I would recommend a bamboo house, say 18 or 20 feet long, by 14 or 16 feet wide. The roof should be sloping, the ridge being 14 or 15 feet from the ground, sloping down on each side to nine or ten feet. Care should be taken to procure strong seasoned bamboos; those used for the posts and for the ridge of the roof should be stout, and those for the framework of the roof much lighter. If the posts and the framework of the roof are given a couple of coverings of coal tar, the house will last

well for three years. The walls should be made of bamboo trellis, openings for doorways being left at convenient places. The trellised sides should be clear of the ground by six inches, and also clear of the top, where the side joins the roof by six inches. Creeping plants should be grown on the trellis, but they should never be allowed to surmount the trellis and climb on the roof. In selecting the creepers, do not choose grass and rampant varieties. Among the most suitable are the Hoyas (nox plants), Stephanotis, Cissus discolor, the smaller varieties of Passifloras (passion flower), the climbing fern and some of the smaller spomoeas. The best, most durable, and neatest material for roofing is a coarse netting made of coir twine; this is much in vogue on the Bombay side though scarcely known elsewhere.

The next best thing for roofing is long elephant or Moonj grass, which must be thinly spread over the frame, so as to admit a checkered sunlight and a modified rain; it must be tied on with laths of bamboo. The leaves of the cocoa or of the toddy palm may also be used, of course tied on in such a way as to admit partial sun or rain, but they are not tidy. Grass or palm leaves will want renewing at the beginning of each monsoon, whereas the coir netting is calculated to last for at least three years. In tying on the trellis, &c., only use split cane, or coir twine as these two materials stand the monsoon without rotting. The floor of the house should be raised a few, say six inches; and the best material for the floor is a depth of three or four inches of coal ashes, which material never gets sloppy in the rains, and if thoroughly watered once or twice a day in the dry season, keeps the atmosphere in the house cool and moist. If these ashes or cinders cannot be procured, broken brick is the next best thing, and then gravel or small *kunkur*. Take care to have a drain round the house outside.

Rockeries are a favourite embellishment to an Indian conservatory. They may be made of rough stones and rocks where procurable, but fused bricks, which can be got anywhere, answer admirably. Having selected the place where it is intended to make the rockery, mark it out and remove the soil to the depth of one-and-a-half inch, and fill up the space with slaked lime; the object of this is to keep white ants away. The best soil for the rockery is a mixture of two parts leaf mould, one part common loam, one part coarse sand. The same soil is suitable for ferns, begonias, and other delicate plants grown in pots. As you build up the rockery, fill in the spaces between the stones with the above soil, and water freely as you fill in, so as to consolidate the soil, and completely fill in the spaces. Take care that your rockery is clear of the woodwork and trellis of the house.

In spite of every care and cleanliness, white ants will at times appear; but the best preventative is *kerosine oil*, prepared and applied in the following manner, the discovery of which is due to Mr. Ridly, of the Lucknow Gardens. Take a quart bottle and fill it one-third with milk, let it stand till the milk turns sour; then nearly fill the bottle with kerosine; let a cooly churn the mixture as cream is cuhrned for butter; it will form a thick, white emulsion which mixes freely when stirred into water. Use a sherry glassful of this emulsion to a kerosine tinful of water. Stir well and water the whole of your conservatory freely with it out of a rose waterpot. It will not harm the most delicate plants. The floor and rockery should be saturated with this effective insecticide; and if this process be adopted every two months, white ants and other pests will give your conservatory a wide berth. The only plants likely to be injuriously affected by this kerosine compound are *orchids*, but as they are usually mounted on hanging blocks they are not likely to come in the way of the *mallee* in his general watering of the house.

Stands for pot plants should be made of wood and painted green. Tubs and large flowerpots should not be placed directly in contact with the ground but should stand on inverted bottles sunk to half their height in the soil. Having described the manner of constructing the conservatory, the next thing is a list of some of the most suitable plants with which to stock it. Among the best are orchids, marantas, ferns, palms, canes, begonias, dracoenas, dieffenbachias, selaginellas, alocasias, anthuriums, caladiums, colei, crotons, fittonias, poffmanias, nepenthes, (pitcher plants), peperomias. In the North, West Provinces, the Punjab, and other localities where extreme heat prevails in the hot season, and frost at night in the cold season, matting should be used on the roof in the day time as a protection against the heat and at night against the cold. —*Englishman.*

HORTICULTURE IN NATAL.

The Colony of Natal, though younger considerably than the *Gardeners' Chronicle*, has had a chequered history. Our concern with it arises chiefly from the development therein of cultural enterprise, which may be expected to increase if the unhealthy excitement of the gold fever do not afford a check to it. By opening up new districts and making their resources known the search for gold may, however, effect much indicate good, which will remain after the gold fever has subsided. The late Indo-Colonial Exhibition served to indicate the resources of the colony so far as timber and sugar are concerned. Coffee, Tea, fibre plants, Tobacco, Arrowroot, Maize (Mealies), drugs, and fruits were also exhibited. But we are more especially concerned here with the growth of plants for horticultural purposes. The exports of plants and bulbs in 1885 comprised 845 packages, valued at £911. This is no doubt not a large sum, but one which serves to show how much it is likely to be increased in the future.

"The suitability of this colony," we cite from the official catalogue," for the growth of many plants and bulbs in demand abroad, and especially those required for the perfumery trade, has lately received attention. The double-flowering Tuberose is now cultivated on aconsiderable scale, and tubers have become an article of export. It has been stated by a local florist that the following plants would pay to grow in quantity if appliances were also provided for extracting the perfume, viz.:—Gardenia, Rose, Jasmine, Violet, Patchouli, Verbena, Geranium, Vetivert, Iris, Carraway, and Anise; and that there is every reason to believe that flower farming will become a profitable, as it is a pleasant pursuit. The export of plants and bulbs averaged only about £30 per annum till 1881; since then it has advanced considerably, and for the last three years has averaged £900 per annum."

As an illustration of horticultural enterprise we append, by the courtesy of Mr. Adlam, a list of plants shown at a resent flower show at Maritzburg. All the plants named are worth cultivation, and, with few exceptions, are found within a radius of 20 miles from the town, at elevations of from 2000 to 4500 feet. We heartily congratulate the promoters of this show, who seem to have done what we have so frequently urged our colonial friends to do, viz., to promote a knowledge of their own native flora and its capabilities rather than to attempt a servile copy of a European flower show. How rich in garden plants the Natal flora is, is shown in a letter from Mr. Adlam, in which he says that:—

"Owing to the' gold fever, which has seized so many in South-east Africa the country has been hunted over by prospectors with an eye to goldbearing quartz, and many a solitary mountain has been surmounted, many dense forests penetrated, and rivers forded in places in which, till now no white man has ever set foot. Thus from time to time I have received fragmentary imformation regarding new plants seen, and fresh localities for old ones, lighted on.

"Very recently some dried specimens were brought me from the Zululand border. A showy terrrestrial Orchid, bearing a spike of thirty-six spreading light purple flowers, each an inch across. The two lateral sepals are narrow and spreading; the upper sepal, which has a long spur, bends with the two upper petals over the minute column, which was too decayed for examination. The lip is remarkable, long, narrow,

thread-like, upright. We have reveral good Streptocarpi, but one from the same locality as above surpasses all hitherto seen. About a foot high, flowers very many, a deep intense blue; leaves unknown—in fact only a scrap was given me.

"Cymbidium Sandersoni was first sent to Harvey by the late Mr. Sanderson in 1860. In habit it is most distinct from any other epiphytic Orchid we have. Long spindle-shaped pseudobulbs, evidently tending to a true stem, 1½—2 feet long, covered by a tuft of robust two-ranked leaves. A tall scape ending in a panicle of pale yellow flowers. I am told of a forest where it was seen growing in abundance on trees. It is a plant I have often searched for, but hitherto it has never been my luck to come across it.

"*Disa macrantha, or crassicornis.*—I have seen this very fine plant in the same locality from whence Mr. Sanderson obtained his specimens, now in the Kew Herbarium, and can confirm Mr. N. E. Brown's remark, that it runs D. grandiflora very close. It is rare, and affects deep black, rich loam on sloping hillsides fully exposed to the sun. It has been found recently close to town at an elevation of 2200 feet, and also 20 miles from here; elevation, 4000 feet."

The following is the list of the native plants exhibited at the Maritzburg flower show in January of this year:—

Aristea Eckloni
Anemone Fannini
Agapanthus umbellatus
Aloe sp.
Begonia dregei
„ natalensis
Burchellia capensis
Bauhinia natalensis
Brunsvigia multiflora
Clerodendron glabrum
Calodendron capense
Cyrtanthus Mackeni
„ collinus (?)
Chlorophytum Bowkeri
Cymbidium Sandersoni (?)
„ Buchanani
Calhurnia lasiogyne
Crotalaria globifera
„ capensis
Duranta sp., white flowers, doubtful native
Disa polygonoides
„ sp., white and green flowers
Dais cotinifolia
Dianthus sp.
Disperis Fanniniæ
„ Cooperi
Eulophia ensata
„ Dregei
„ sp., yellow and maroon flowers
Erythrina Humei
Eucomis punctata
Gomphocarpus albens
„ sp., brown and yellow flowers
Gerbera aurantiaca
Gloriosa virescens
Galtonia candicans
„ princeps
Habenaria sp.
Hæmanthus natalensis
„ Baurii
Hypoxis latifolia
„ elata
Kalanchoe crenata
Lasosiphon sp.
Lissochilus Krebsii
Littonia modesta
Montbretia Pottsii
Moræa bicolor
„ iridioides
„ „ sp., large pale yellow flowers
Nycterinia nataleusis
Nerine flexuosa
„ pudica
Nymphæa stellata
Osbeckia Umhlasiana
Pavetta assimilis
„ Bowkeri
Phygelius capensis
Plumbago capensis
Polygala virgata
Protea sp.
Richardia africana
„ hastata
Satyrium sp., orange flowers
„ „ sp. white and pink flowers
Sandersonia aurantiaca
Tritoma natalensis
Tritonia aurea
Vernonia mespilifolia
Watsonia meriana
„ densiflora
„ „ alba

—*Gardeners' Chronicle.*

THE DRUGS OF MAURITIUS.

Medicinal plants have been but little studied in Mauritius. A remedy for dysentery is sought in the *ipica sauvage* or *ipica du pays* (*Tylophora asthmatica*). A decoction of the slender thread-like stem of the parasitic *tsihitrafototra* (*Cassytha filiformis*) is given for intestinal derangement, and as a tonic for scrofulous and rachitic infants. An oleoresin resembling elemi, probably produced by *Canarium Colophania*, is employed in the form of plaster as a detersive. The yellow juice which flows from the incised stems of the guava (*Psidium pomiferum*) is used as an application to ringworm, and a skin disease called *tampane*. The wood of the shrub *liane poilly* (*Embelia micrantha* is administered as a tonic, and given in decoction for nephritis. The leaves and seed of the *sogar gota* or *cadoque* (*Cæsal-pinia Bonducella*) are used for certain diseases, and the seeds, powdered and mixed with pepper, constitute a febrifuge. Small senna (*Cassia occidentalis*) is used in asthma, and as a fomentation in some skin diseases. A decoction of the root possesses diuretic properties, and the leaves are used by the negroes, when smeared with a little candle grease, as a substitute for adhesive plaister.—*Journal of the Society of Arts.*

THE CLOVE TREE.

The clove tree (*caryophulus aromaticus*) says Rumphius "appears to me the most beautiful, the most elegant, and the most precious of all known trees." In form, it commonly resembles the laurel, and sometimes the beech. Generally of the height of an ordinary cherry tree, its trunk is straight, and rises to four or five feet before it throws out branches. The bark is smooth, thin, and adheres closely to the wood, which is hard and strong, but of an ugly grey colour, and, therefore, not suited for cabinet work. In the commencement of the wet season, which is the month of May in the native country of the clove, the tree throws out a profusion of new leaves. Soon after, the germs of the fruit are discovered at the extremities of the young shoots, and in the four following months the cloves are completely formed. The fruit, at first of a green colour, assumes in time a pale yellow, and then becomes of a blood-red colour, if of the most ordinary variety. It is at this period that the clove is fit to be used as a spice, and of course, this is the period of the clove harvest. It is not, however, the period of the full maturity of the fruit, which requires three weeks longer to perfect itself, and serve for the purposes of propagation. In this short period the fruit swells to an extraordinary size, loses much of its spicy quality, and contains a hard nucleus like the seed of the bay. This state of the fruit is what Europeans call the mother clove, and the natives *poleng*.

There appears to be five varieties of the clove, *viz* the ordinary cultivated clove, the clove called the female clove by the natives, which has a pale stem—the keri, or loory clove, the royal clove, which is very scarce, and the wild clove. The three first are equally valuable, as spices, the female being considered fittest for the distillation of essential oil. The wild clove has hardly any aromatic flavour, and is, of course, of no value.

Of all useful plants the clove has perhaps the most limited geographical distribution. It was originally confined to the five Mollucas islands, and chiefly to Machian. From these places it was conveyed to Amboyna a very short time only before the arrival of the Portuguese. The portion of Amboyna called Leytimeer, and the Uliasser islands, produced no cloves until the arrival of the Dutch, by whom the cultivation was restricted to Amboyna, every effort being made to extirpate the plant elsewhere. To what distance from the parent country the culture might be successfully extended, there has been no opportunity of ascertaining.

Rumphius informs us, that the plant is not partial to large islands, and does not answer well in Gilolo, Ceram, Beuroe, or Celebes. It is probable that Beuroe and the Xula isles are the utmost western limit of the successful culture of the clove. The same writer adds that the Javanese and Maccassars, when they were the carriers in the spice trade to the western emporia of the Archipelago, conveyed to their own country, with great care, young clove plants and mother cloves, from which trees were reared that produced no fruit. Through the speculative enterprise of Europeans the clove has in latter times been cultivated so as to bear fruit in some of the western parts of the Archipelago, in the Mauritius, and in the West Indies. They have been cultivated for nearly fifty years in the Mauritius, where they bear fruit, of inferior quality and high price. The fact sems to be, that like the grape, but in a much higher degree, the clove may be raised at a heavy expense, and of inferior quality, in soils and climate little suited to it. How wonderfully restricted

the soil and climate of the clove is may be gathered from this well-known fact, that, in the parent islands, the tree yields fruit in the seventh and eight year of its growth, and grows almost spontaneously without care or culture, whereas, at Ambonya, where it is an exotic, it does not bear until the tenth and twelfth year, and demands very considerable attention.

The clove neither thrives well near the sea, where it suffers from the spray, nor in the higher mountains, where it suffers from the cold. The soil which suits it, is a dark loam, having underneath a layer of dusky yellow earth, intermixed with gravel. A sandy soil, a hardy clay, and the wet ground in which sedges grow are to be avoided. The tree may be propagated either directly from the mother cloves, or by transplanting the young plants found in the clove gradens from the natural propagation of the seed. The plants raised by the first method grow luxuriantly, but are alleged to yield more leaves than fruit, and growing remarkably straight, to be difficult to climb for the purpose of reaping the harvest. The trees propagated by the latter method are prefferred, but the culture is laborious, and the success of the operation uncertain until the plants have attained the heigh of five or six feet. The young plants at first require the shade of other trees, and must therefore be planted among them. As they grow up the other plants must be removed, leaving here and there a few fruit trees, such as the Kanari and the coconut, &c.; the neighbourhood of which, it has been discovered, is favourable to the clove. The clove trees must themselves be kept pruned, and care be taken that they are not choked with weeds, or by too many of the fruit trees just mentioned, in failure of which attention the plants will languish, or degenerate into wild cloves.

Such is the culture requisite in Amboyna, a soil and climate foreign to the plant, where comparatively much care and attention are required. In its native country, on the contrary the clove grows luxuriantly and almost spontaneously, being propagated and coming to perfection with hardly any culture. In its native country, the clove tree as already mentioned begins to yield fruit in the seventh or eighth year, but at Amboyna not until the tenth or twelfth.

Examples are given of clove trees living to the age of one hundred and thirty years, but the ordinary duration of its life in Amboyna does not average above seventy five. Much depends upon the nature of the soil and ground in which the tree has taken root.

The clove, though generally a hardy plant, suffers from excessive drought, and is apt to be destroyed by the depredations of a worm which insinuates itself into the wood and kills the tree. In particular seasons thousands perish from this cause.

The reaping of the clove harvest is perfectly simple. When the fruit begins to grow red, the reaping is begun. The ground underneath the tree is clean swept. The nearest clusters are taken off with the hand, and the more distant with the assistance of crooked sticks. Great care is necessary that the trees, in this operation, should not be rudely handled, as an injury offered to them in this way, would prevent them from bearing for years. The curing of the cloves consists in placing them for some days on hurdles, where they are smoked by a slow wood fire, which gives them a brown colour, and afterwards drying them in the sun, when they turn black, as we see them, in the article of commerce. In some places they are scalded in hot water before being smoked, but this practice is not common. Such cloves as casually fall on the ground, and are picked up in small quantities, the cultivators do not think it worth while to subject to the process of smoking, and they are merely dried in the sun; they are discoverable by their shrivelled apperance, and are of inferior value. The period of harvest is from October to December.

Of the fecundity of the clove it is not very easy to speak distinctly. The produce from one year to another is very unequal. At intervals of from three to six years they usually yield one extraordinary crop, but then a year now and then intervenes when they do not bear at all. At other times, again, they will give a double harvest. Some extraordinary instances of fecundity in particular trees are quoted. Rumphius and Valentyn speak of a remarkable tree, a hundred and thirty years old, which one year gave the enormous crop of eleven hundred pounds and another year half this quantity. About the propotion of two-thirds of a clove cultivation is considered to be bearing trees, the remaining third being allowed for barren and young trees. According to the present mode of culture, perhaps, it would not be safe to average the production of all trees at above five pounds.

According to the data, the produce of an acre will be 375 lb. avoirdupois, and deducting one-eighth for young trees under ten years, 328 lb. By a free culture, as in the case of pepper, a much larger produce than is here stated would, no doubt, be obtained.—*Indian Agriculturist.*

NEW YORK EXPERIMENTAL STATION.—The fifth annual report is now before us, comprising a record of the work done at the station, meteorological details, results of experiments, &c. The object of the station is to ascertain and apply the principles of natural history to the profitable cultivation of plants or the mainteuance of animals. Passing the experiments on cattle feeding as not coming within our scope, we may mention a few of the more important matters discussed, such, for instance, as the relation of soil temperature to produce, in which it is shown that for the cultivation of Potatoes a relatively cool soil is favourable. In the case of Lettuces, a cross between the Red-edged Victoria and the Deer-tongue, thel atter yielding the pollen, resulted in the production of seedlings referable to seven differnt types, the most interesting being one which reproduced the characters of the wild Lettuce, Lactuca scariola. Mr. C. S. Plumb gives a summary of his efforts to classify and arrange the synonymy of a large number of varieties of Wheat and Oats. A curious corelation is mentioned between the number of rows in the ear of Barley and the tendency to tiller; thus in the two-rowed varieties the maximum number of plants that tillered was 28·00, while in the six-rowed varieties the tendency to tiller was less, *i.e.*, 18·00; so the open-panicled Oat averages more fruitful culms per plant than the side panicled variety. The winter Oats tiller far more than the summer varieties. Mr. Goff, the horticulturist, reports on Potatoes, root growth orchards, Grapes, Tomatoes, insects, the influence of foreign pollen on fruit, &c. A Potato known as "Buffalo Bill" was found to be the most productive. It is calculated that this variety yielded at the rate of 275 bushels per acre. As regards the question of the relative produce of cut sets or whole tubers for planting, the difference was markedly in favour of the latter. With a view of testing whether regularity of form can be secured by careful selection of tubers, eyes were taken from the most ill-shaped tubers that could be got, and others from the most symmetrical tubers. It was found, however, in the result, that there was no material difference either one way or the other in the character of the produce. The observations on root growth have been continued, some interesting details being given as to the length, ramification, depth below the surface, &c. A root of Vegetable Marrow was measured to a horizontal length of 10 feet when it was unfortunately broken, evidently at a long distance from its extremity. The chief feeding ground for the roots seems to be between 3 and 10 inches below the surface, though others go much deeper; the plants that make the largest development of stem or foliage during the summer are those of which the feeding ground is shallowest in the soil. Experiments made to determine what, if any, influence on the fruit is caused by the application of stranger pollen, led, as in former years, to no definite result. Mr. Arthur's report on the Bean blight (Micrococcus amylovorus) has already been mentioned in our columns. The report concludes with the record of the work done by the chemists.—*Gardeners' Chronicle.*

ENGLISH TOBACCO.—The following is a letter which appeared in the *Times*, and which we reproduce as being of interest to our readers:—"It may be of benefit to intending planters of British Tobacco this year to learn that a parcel was exposed for sale by public auction in the City yesterday. It is described in the catalogue of the selling brokers, Messrs. Grant, Chambers & Co., as seven drums of English leaf Tobacco, per railway from Wittersham, warehoused at Haydon Square December 2, 1886. The first four lots sold at one half-penny per pound, and there were no bids for the other three. The attendance of the trade was a little below the average, and as to the Tobacco, I think if it had come from any foreign country it would not have fatched the price it did as it was unfit for trade purposes.—J. J. JONAS, 51 and 52, Fenchurch Street, E. C., April 7."—*Gardeners' Chronicle.*

THE KEW "BULLETIN".—The April number contains articles on Manilla Hemp (Musa textilis), which yields an excellent fibre, the supply being derived from the Philippine Islands. It may be grown where and in the same way as the common Banana, and its cultivation should therefore be taken into consideration in our tropical colonies, but only where labour is cheap and abundant, and where the best methods of preparation can be carried out. Mr. Morris gives details as to the best method of culture and preparation, but, on the whole, the culture does not seem to be very promising, although the price per ton of fibre is as high as £36, or even £45 - two-thirds more than the price of ordinary Plantain fibre, which also receives attention in this *Bulletin*. Plantain-fibre might be utilised for paper-making. The fibre of the Pine-apple plant is stated to have a future of considerable importance before it.—*Gardeners' Chronicle.*

"A SIGN OF THE TIMES" may be found in a letter from a China tea merchant received by us by a recent mail, from which we quote as follows:—"As regards trade, India and your rapidly developing tea trade has knocked poor old China about sadly and it seems to me nowadays that a China Chaasze's (or tea taster) life somewhat resembles that of a 'frozen-out gardener!' and scented Canton teas especially are bound to give way (as gracefully as they can) year by year to your deliciously flavoury and pungent pekoe and pekoe souchongs. As I could not help seeing this about June 1885 after I had been at home 6 months, I resolved to give up Canton, and to ally myself with some friends—tea brokers—here, who besides the waning China trade are cultivating the Ceylon tea trade." Any Ceylon tea planters in want of good London Brokers can have the name of our China friend's firm on application.

INDIAN AND CEYLON TEA.—The Indian Tea market remains generally firm, and the smaller supplies offered have met with a fairly active demand. The finest Teas, owing to the small quantities offered, have sold more readily than other grades, and at rather higher prices. There appears every prospect of the comparative scarcity of these sorts increasing until the new Teas come to hand, as from the last Calcutta advices very few lots of fine Tea appear to have been cleared from thence of late, and the range of prices paid at the Calcutta sales was exceedingly low. On the other hand, it is obvious that any material rise in the value of fine Teas would have the effect of curtailing the already limited demand for them, and this is the more probable as the new Ceylon crop, of which the first arrivals are now in the market will continue to be brought forward freely. Buyers of fine Tea, who are not in a hurry to purchase, will naturally be disposed to wait and see what Ceylon sends, as the improvement in the quality of last season's Ceylon crop was very encouraging, and the finest parcels are now often substituted for the finer kinds of Indian Tea, the value of which is not likely to advance much if the Ceylon crop turns out well. The market has also been strong for the medium descriptions, particularly for good Pekoes and Pekoe Souchongs, for which there has been a brisk inquiry at rather firmer rates. For the cheaper kinds values have been comparatively steady, although some common Broken Teas have sold at very low prices. Any reaction in the values of the latter sorts could only be brought about by a curtailment in the supplies, and this at present does not seem at all probable. All the better descriptions of Ceylon Tea have been in good demand at steady prices, but commoner parcels have sold at slightly reduced quotations. For the higher grades of Java Tea there has been an improved inquiry at better rates, but common sorts are less firm. —*Produce Markets' Review*, April 2nd.

USEFUL PLANTS.—There are one or two plants which Mr. R. Harding, of the Botanic Gardens, Toowoomba, strongly recommends as likely to prove useful to settlers. One is the *Phyllaria augustifolia*, which, for hedge purposes, on the Downs is unsurpassed by any other plant. A hedge of this shrub can be seen near the entrance gates of the gardens, where it has been one of the ornaments of the grounds for several years past. It grows dense and tall, and is admirably suited for planting as a break-wind to any garden situated upon a bleak plain. The only bamboo he has found to withstand the cold climate is the variegated species, which is very ornamental but does not attain to the height of the common kind. It is easily propagated by cuttings. For fodder purposes specially suited for the cultivator in the interior, he recommends the "Tonga" bean. Two seeds received by him from Mr. J. H. Young, Toowoomba, have made such marvellous growth that they cover the ground for an area of 20ft. square as completely as it could be done by sweet-potato vines, and the plants are loaded with pods, although it is only three months since the seeds were sown. This plant would take possession of the garden if allowed. These beans have a special aptitude for leaving behind them when cleared away a good bed of leaf mould.—*Queenslander.*

THE INFLUENCE OF FORESTS UPON rainfall is said to be now quite observable in the Hawaiian islands. It is recognised, according to a paper upon the subject in an American exchange, that since the plain and town site of Honolulu have been covered with trees the rainfall on that side of the island of Oahu has sensibly increased. The same observation has been made on the island of Hawaii under similar conditions. This may be so, but we are inclined to think the time required for observations in this case is too brief for correct deductions to be drawn from it, and that the conclusion as just stated does not cover what may be more than an ordinary recurrence of wet seasons after a period of dryness. Some twenty-five years ago the forests trees upon a large area of that good land which lies north of Belfast, and south of Hamilton, in Victoria, all died and the whole country was "sailing under bare poles." It looked very dreary, but the fattening properties of the grass increased and the residents became reconciled. However, the common remark at the time was that the climate would deteriorate to a dry one. About eight years after the commencement of the trouble a series of dry seasons did come round, and every one said it was the result of the forest denudation and would be permanent; indeed that henceforth they must expect a climate similar to their northern neighbours on the Wimmera. The supposition proved wrong, for the dry seasons were followed by wet ones with such a vengeance that fluke ran its ravages through the flocks to an alarming extent. That the destruction of forest trees, which by attracting and entangling clouuds would naturally produce rain, may undoubtedly alter a climate few will dispute, but a longer time is required to establish the fact than a five years' obsevation in a newly inhabited country. We are glad to see that our neighbours on the Hawaiian islands are continuing their experiments and planting extensively Australian varieties of trees, for certainly no forest growth is so suitable for the purpose aimed at, inasmuch as once get them established it will probably prove, as in the case of the coast districts of Queensland, almost impossible ever again to denude the hills.—*Queenslander,*

ROYAL BOTANIC GARDENS: CEYLON.
REPORT OF DR. HENRY TRIMEN, DIRECTOR, FOR THE YEAR 1886.

(*Continued from page* 815.)

Roads and Paths.—A large number of new paths, 4 ft. wide, have been formed during the year, the total length of such being 423 yards; 332 yards of old paths were gravelled.

The steep and unsightly path at the south end of the old ornamental pond has been done away with, and the space planted up with shrubs. A stone culvert was built in the gully between the plant sheds and nurseries, and a wooden bridge made across the gully in the new road to the fernery; also one by the carriage shed, and another leading over the water-course by the foreman's quarters. Retaining walls were built—one to support the road leading into the nursery, and one just below the carriage turn.

Turf verges, 12 in. wide, were laid down on each side of the new drive and on the sides of portions of the new paths, the total length being 840 yards; 338 cart loads of turf were required for this and the turfing of the banks. Most of this was obtained from the public roadsides, and the rest was kindly given by Mr. W. I. Cotton, from his property opposite the Garden. The turf laid on the banks measures 1,417 yards.

All the paths have been repaired and gravelled, and most of the beds have been dug up and mulched with surface soil from the jungle. A light top dressing of lime was forked in about May, the benefit of which was soon seen in the general healthy appearance of the plants where it was applied.

The scrub and jungle on the north side of the lower entrance to the fernery has been grubbed up for a distance of 108 ft. long and 12 ft. broad. A rockery bank has been formed here to correspond with that on the opposite side. This has been planted with mixed ferns and begonias.

A path has been opened from the corner of the flower garden leading past the thermometer shed, and winding through the jungle into the fernery on its upper side. The undergrowth only has been cut away, leaving all the jungle trees; and 1,250 plants of ferns and begonias have been planted out under the trees. This path not only gives a new access to the fenery, but affords an opportunity to visitors for seeing something of the hill-jungle and its native trees.

Borders and Shrubberies.—The chief work done during the year has been the digging up of the soil among the plants to let in light and air, manuring, staking, and pruning and thinning out the trees and shrubs; 53,900 plants were set out during the year, the greater part of these, as usual, being showy garden plants and annuals.

I may mention that hares have this year been most destructive to young plants. All efforts to get good beds of such things as verbenas, carnations, lobelias, &c., have been of no avail, for as soon as they begin to strike into healthy growth, they are eaten off and destroyed. The hares have become so bold that one night they came to a border within nine yards of the bungalow door, and 170 plants of choice poppies, which had been planted out some time, and had put on three or four inches of healthy growth, were eaten off close to the ground.

At different times during the year much pruning and thinning out of trees has been done. A good many of the casuarina trees near the gates died during the year from the effects of a little borer. These have been cut down and removed to the wood pile. Fifty-nine cart loads of timber for the stoke hole fire were cut out of the Garden from the thinnings and prunings of the trees. From the entrance gates to the old China tea plot, and running parallel with the public road for 80 yards, a hedge of *Duranta Plumieri* has been planted. No alterations were made in the arrangements of the beds, and they were filled with similar plants to those of last year. The only improvement to the flower garden was the building of a retaining wall and culvert at the north-west corner, and making a path across the drain there.

Rose Garden.—For the first-half of the year this garden was very attractive. The gladiolus, pansies, and portulacas bloomed remarkably well, and continued in flower for a long time. Some of the pansies attained 2½ in. in diameter.

The rose plants for the latter part of the year have not done well, and though they have received every attention in the way of manuring, &c., they have made but very little growth, and I fear the whole lot must be taken up and new plants put in.

Herbaceous Garden.—The beds at the lower end of this garden have been completed. A few plants have been set out in their places, in the orders to which they belong. The monocotyledons planted last year have done very well indeed, and have flowered freely. The planting here requires to be done personally, and I have had little time during the year.

Weather.—The weather in January was remarkable for wet, foggy, misty days and rainy nights, and up to the 29th of the month, the sun was but rarely seen. February, March, and April were fine, rain scracely ever falling before 2 P.M. During May the weather was variable, but up to the 16th the mornings were generally fine, and the afternoons more or less cloudy and rainy. From the 16th to the 28th it was very wet, though heavy rain only fell on one day, the 24th. The first half of June was fine, followed by ten days very wet rough weather. The weather in July was most unusual, being generally wet and foggy, with very high winds, and certainly the roughest month in the year. August was also very wet and cloudy for the first nineteen days. The rest of the month was fine and bright and very hot, the thermometer in the shade rising to 75·0 on the 21st, 22nd, and 29th. and on the 25th the thermometer in the sun went up to 142·0. In September rain was registered on twenty-three days, heavy rain falling on the 24th and 29th. From the 14th to the 23rd it was very fine and bright. October gave much the same sort of weather as September, heavy rain falling on the 2nd, 12th, and 25th. November was remarkable for the absence of the dense fogs which usually prevail during this month. From the 15th to the 25th the days were very fine and bright, and the nights cold, more like February than November. Though it was dull and wet in December up to the 22nd, the rainfall was not heavy. The temperature was very low several times during the month, and on the 8th and 9th a very strong cold wind passed over.

The following table will show the monthly rainfall from July 1, 1883, and the number of days on which rain fell during the last five years:—

Month.	1886. Rainfall.	1886. No. of Days.	1885. Rainfall.	1885. No. of Days	1884. Rainfall.	1884. No. of Days.	1883. Rainfall.	1883. No. of Days.	1882. No. of Days.
January	11·30	21	5·56	24	4·07	17	—	22	10
February	2·66	9	2·42	5	1·85	7	—	11	16
March	3·28	9	3·12	12	3·90	9	—	8	6
April	3·43	15	4·16	12	3·02	12	—	18	12
May	9·13	18	8·52	19	4·48	12	—	18	15
June	7·60	17	15·57	26	2·23	11	—	23	18
July	8·18	24	4·77	18	3·09	17	11·96	22	31
August	8·45	19	3·47	11	4·33	22	7·96	25	31
September	6·79	20	4·21	14	8·32	20	3·27	14	27
October	9·61	21	10·60	26	14·07	25	6·80	22	27
November	6·97	18	8·03	23	9·81	19	9·24	21	20
December	9·03	20	12·71	25	15·47	25	7·83	19	22
Total...	86·43	211	83·14	215	75·24	196	47·06	226	235

The average number of days on which rain fell during the five years is 216·6, and the average monthly rainfall for three and half years is 6·95 in. nearly.

The wind was light or moderate until May 20, and the direction was pretty steady from the S.E. It then turned to N.W. and blew very strong and steady from that quarter until June 22. From this to July 8 it was unsettled, sometimes going round to S.E., and the force was light or moderate during that time. It then settled, down to N.W., and continued to blow from that quarter till October 21, being at times very strong. From then till November 22 it was very variable, and light or moderate in force. On 22nd it settled down to S.E., and continued so till the end of the year, and the force was generally light, with the exception of December 8, 9, and 10. On these three days it blew very strong from the N.W.

The greatest pressure per square foot registered during any 24 hours was 8·333 lb., equal to 4·80 miles an hour, on June 16. This is the highest recorded during the three and half years the observations have been taken.

The mean daily horizontal movement of the air for the year was 207·49 miles. The most windy month was July, with a mean daily horizontal movement of 349·31 miles. The calmest month was February, with a daily mean of 106·15 miles.

The barometic pressure and the temperature of the air was as follows:—

BAROMETIC PRESSURE. 5,581 (ft.)

1886.	Mean.	Range.
January ...	24·547 ...	·275
February ...	24·556 ...	·233
March ...	24·557 ...	·208
April ...	24·541 ...	·171
May ...	24·480 ...	·239
June ...	24·474 ...	·209

October ...	62·4 ...	21·0
November ...	64·3 ...	26·0
December ...	59·1 ...	25·0
The 12 months	63·0 ...	36·0

Maximum temperature of air, 78·0 on March 23-24.

Minimum temperature of air, 42·0 on December 25.

The highest temperature during the year in the sun's rays was 145·0, on April 20 and June 27, and the lowest on grass was 38·0 on December 25.

The mean amount of cloud for the year was 7·05. The cloudiest months were January and November, with a mean of 8·1. The brightest month was March, with 4·7

6.—INTERCHANGE OF PLANTS AND SEEDS.

My absence from the Colony during the greater part of the year interfered to some extent with the exchanges with British and Foreign Gardens, but Mr. Clark has kept up most of our relations, and initiated a few new ones.

During the year we received Wardian cases and boxes of living plants from the Botanic Gardens of Kew (2), Calcutta (2), Madras, Singapore (4), Penang, Buitenzorg (Java) (2), and British Guiana; also from Colonel Berkeley (Rangoon), R. B. White, Esq. (Scotland), and Messrs. Weigandt, of Dusseldorff.

Packets of seeds were received from the following places and persons.—The Botanic Gardens of Kew, Cambridge, Calcutta, Buitenzorg, Melbourne, Mauritius, Hongkong, Natal, Jamaica, and British Guiana; the Agri-Horticultural Society of Madras, the Queensland Acclimatisation Society, Baron von Mueller (Melbourne), T. Hanbury, Esq. (Ventimeglia), E. M. Holmes, Esq., F. L. S. (London), H. Travers, Esq. (New Zealand), Adam & Sons (New Zealand), Dr. Henderson (Jamaica) T. Christy, Esq. (London), Messrs. Linden (Ghent) and Messrs. Haage & Schmidt (Erfurt). I have also to thank the following donors in the Colony:—Lady Hamilton Gordon, Mrs. Baker, Mrs. Grinlinton, Mrs. Jeffries, Rev. G. W. R. Mackenize, Captain F. Bayley, and Messrs. C. Badger, P. Bois, D. F. Browne, W.J. Cotton, W. Ferguson, F.L.S., T. C. Huxley, J. D. Jonklaas, W. Jordan, A. C. Lawrie, A. G. Kellow J. Kelley, H. Nevill, C.C.S., C. Strachan, A. Tatham, J. Wickwar, A. Whyte, G. W. Wood, and J. H. Wright.

The Parcel Post now affords great facilities for the carriage of many sorts of plants, and a box of *Cattleya superba* arrived in November in excellent order from so great a distance as Demerara by this means.

We have despatched Wardian cases and boxes of plants in exchange to the following:—The Botanic Gardens of Kew (3), Singapore (5), Penang, Saharunpore, Buitenzorg (2), and British Guiana; to the Conservators of Forests, Rangoon and Tavoy, to Colonel Berkeley (Rangoon), R. A. White, Esq. (Scotland) and Messrs. Weigandt, of Dusseldorff.

Seeds, &c., have been supplied to the Botaic Gardens of Kew, Glasgow, Calcutta, Singapore, Penang, Hongkong, Buitenzorg, Jamaica, and British Guiana, to the Acclimatisation Society of Queensland, to Messrs. Haage & Schmidt (Erfurt), and to Messrs. Veitch (Chelsea).

It may be worth putting on record here that thirteen stems of our mountain tree-fern (*Alsophila crinita*), sent home at the end of 1885, with the view of using them as decorative plants in the Ceylon Court of the Exhibition in London, all, with one exception, survived the voyage and recovered their health in the houses of the Royal Horticultural Society at Chiswick. This is, I believe, the first successful attempt to introduce this beautiful species into England. Four of the plants are now at Kew, two at Glasgow, and one at Glasnevin, Dublin.

We have made the customary *gratis* distribution of plants and seeds on application to public officials and places within the Colony. The Government Agents and Assistants at Anuradhapura, Badulla, Ratnapura, Hambantota, and Kegalla; the Museum Ground, Colombo; the Director of Public Instruction; the Forester, North Central Province; the Municipality of Kandy; the Local Board of Nuwara Eliya; the Superintendent of Police, Galle; and the Stationmasters at Matale and Rambukkana.

7.—PRINCIPAL ADDITIONS TO THE COLLECTIONS.

The following list, in continuation of those of previous years, contains the names of such of the freign plants received during 1886 as are additional to those already in the Gardens, and seem likely to succeed here. There are not among them many plants of economic value, but a considerable number of ornamental ones especially among the orchids, are included, as well as some species of great botanical interest.

I hope this year to find time to complete a Catalogue of the present contents of the Gardens, which is greatly needed.

(A)—PERADENIYA, &c., GARDENS.

DICOTYLEDONS.

Hibiscus liliiflorus, Cav. Mascarene Islands. (T. Hanbury.)

Sterculia quadrifida, Br. Queensland. (F. v. Mueller.

Theobroma bicolor, Humb. and Bonpl. New Grenada, &c. A wild chocolate, cultivated and used on a small scale by the Indians of Central America. (Buitenzorg.)

Grewia caffra, Meisn. Natal. (Natal)

Vepris lanceolata, A. Juss. S. Africa, Mauritius. (Natal.)

Canarium strictum, Roxb. S. India. Affords black dammar resin. Madras.
C. Mehebethene. Gaertn. Moluccas. (Buitenzorg.)
Dalbergia armata, E. Mey. Natal. (Natal).
Erythrina caffra, Thunb. S. Africa. (Natal.)
Millettia caffra, Meisn. Natal. Wood very hard. (Natal.)
Calpurnia sylvatica, E. Mey. S. Africa. (Natal.)
Ormosia coccinea, Jacks. Trop. S. America. (Kew.)
Colvillea, sp. (Calcutta.)
Maniltoa gemmipara, Scheff. New Guinea. (Buitenzorg.)
Acacia Kraussiana, Meisn. Natal. (Natal.)
Acacia, sp. "Black Boy." (Kew.)
Mouriria guianensis, Aublet. Guiana. (British Guiana.)
Combretum erythrophyllum, Sond. S. Africa. A handsome tree. (Natal.)
Trevesia palmata, Vis. Nepal, Malay Peninsula, (Singapore.)
Burchellia capensis, Br. The "Buffeldoorn" of S. Africa. (Natal)
Exostemma caribbæum, R. & S. West Indies. The "Jamaica Bark," a substitute for cinchona (Jamaica.)
Oxyanthus natalensis, Sond. Natal. (Natal.)
Pavetta lanceolata. Ecklon. S. Africa. (Natal.)
Gardenia globosa, Hochst. Natal. (Natal.)
Ardisia Oliveri. (Kew.)
Mimusops Kauki, L. Malaya, Trop. Australia. Fruit edible. (Buitenzorg.)
Willughbeia edulis, Roxb. (W. martabanica, Wall.) Assam to Malacca. A large climber yielding abundant caoutchouc. (Singapore.)
Jacaranda mimosæfolia, Don. Brazil. A beautiful flowering tree. (British Guiana.)
Aphelandra, sp. (Calcutta.)
Coleus. Many Garden varieties. (Calcutta.)
Lagetta lintearia, Lam. The lace-bark tree. W. Indies. (Kew.)
Piper, sp. Malaya. (Calcutta.)
Artauthe Veitchii. (Kew.)
Nepenthes marginata. (Penang.)
Artocarpus, rigidus, Bl. Java, &c. (Penang.)
Podocarpus, sp. (Singapore.)
Dacrydium elatum, Wall. Malay Peninsula, Sumatra, and Borneo. A handsome pyramidal coniferous tree. (Penang.)
Cycas tonkinensis. (Haage & Schmidt.)
Stangeria paradoxa, T. Moore. S. E. Africa. A very singular fern-like cycad. (Kew.)

MONOCOTYLEDONS.

Orchideæ.

Dendrobium Bensoniæ, Rchb. f. Moulmein. (Col. Berkeley.)
D. Brymerianum, Rchb. f. Burmah. Col. Berkeley.)

B. olens. }
Moræa iridioides, L. (Dietes. Sal.) S. Africa. (Natal.)
Eucharis pumila. (Calcutta.)
Asparagus virgatus, Baker. S. Africa. (Natal.)
Forrestia, sp. Malaya. (Calcutta.)

Palmæ.

Pinanga coronata, Bl. Java. (Buitenzorg.)
P. disticha Miq. (sub. Ptychosperma.) Sumatra. (Buitenzorg.)
P. paradoxa, Scheff. New Guinea. (Ptychococcus Becc.) (Buitenzorg.)
Drymophlœus ceramensis, Miq. Ceram. (Buitenzorg.)
Ptychandra glauca, Scheff. Malay Islands. (Buitenzorg.)
Arenga obtusifolia, Mart. Java, Sumatra. (Buitenzog.)
Caryota furfuracea, Bl. Java. (Buitenzorg.)
Sabal Ghiesbrechtii (Buitenzorg.)
S. glaucescens, Lodd. Trinidad. (Buitenzorg.)
Nannorrhops Ritchieana, W. & D. Afghanistan, &c. A desert palm. (Kew.)
Livistona humilis, Br. Trop. Australia (Buitenzorg.)
L. subglobosa, Mart. Java. (Buitenzorg.)
Calamus, sp. Demerara. (Calcutta.)
Korthalsia Junghuhniana, Miq. Java. (Buitenzorg)
Plectocomia elongata, Bl. Malaya. (Buitenzorg.)
Martinezia Lindeniana, Wendl. New Grenada, (Buitenzorg.)
Attalea Guichire, Karst. Trop. America. (Buitenzorg.)

Philodendrum gloriosum, André. New Grenada (Calcutta.)
Aglaonema, sp. Malaya, (Calcutta.)
Sagittaria montevidensis, Cham. & Schlecht. S. America and W. Indies. A beautiful water-plant. Fig. in Bot. Mag. t. 6755. (Kew.)

FERNS.

Dipteris Horsfieldii, Br. Polynesian Islands, Moluccas, (Penang.)
Niphobolus Penangianus, Hk. Malay Peninsula (Penang.)

(b)—Hakgala Garden.

DICOTYLEDONS.

Alyssum saxatile. Eastern Europe. (Cambridge.)
Pittosporum, revolutum, Aiton. N. Zealand. (H. Travers.)
P. tenuifolium, Banks & Sol. N. Zealand. (H. Travers.)
Viscaria corymbosa. Europe. (Cambridge.)
Herniaria hirsuta, L. S. Europe. (Mrs. Baker.)
Hibiscus africanus. (G. H. H. Austen.)
Elæocarpus oblongus, Gaertn. India, Malaya (Madras.)
Lagunaria Patersoni, Don. Norfolk Island. (Melbourne.)
Nephelium leiocarpum, F. Muell. N. S. W. (J. P. William Bros.)
Hardenbergia monophylla, Benth., alba. Australia. (Melbourne.)
Rosa Banksiæ. (A. Tatham.)

Saxifraga Aizoon, L. Europe. (Cambridge.)
S. sarmentosa, L. China and Japan. (A. O. Lawrie.)
Echeveria, sp. (Capt. Bayley.)
Melaleuca parviflora, Lindl. W. Australia. (J. P. William Bros.)
Cuphea miniata (Lady Gordon and Mrs. Baker.)
Eucalyptus crebra, F. Muell. Australia. (Kew.)
E. resinifera, Sm. N. S. Wales, Queensland. (Kew.)
E. regnans. (Melbourne.)
Begonia Rex, several vars. (T. C. Huxley.)
Epiphyllum, sp. (Mrs. Grinlinton.)
Cereus, sp. (Mrs. Grinlinton.)
Mesembryanthemum crystallinum, L. Mediterranean. (G. W. Wood.)
Cornus capitata, Wall. (Benthamia fragifera Lindl.) Himalaya. (Kew.)
Scabiosa columbaria, L. Europe. (Cambridge.)
Bellis perennis, L. Common Daisy. Europe. (C. Badger.)
Antennaria Leontopodium, G. "Edelweiss." European Alps. (Mrs. Baker.)
Centaurea macrophylla. (Cambridge.)
C. nigra, L. Knapweed. Europe (Cambridge.)
Chrysanthemum indicum, several vars. (T. C. Huxley.)
Clintonia pulchella, Lindl. California. (Lady Gordon.)
Specularia Speculum, DC. Europe. (Cambridge.)
Erica ventricosa (?) (T. Hanbury.)
Azalea, sp. (Capt. Bayley.)
Primula sinensis, var. splendens. (T. Hanbury.)
Primula sinensis, var. rubro-tigrinum. (T. Hanbury.)
Myrsine variabilis, R. Br. E. Australia.) (J. P. William Bros.)
Phlox speciosa, several vars. (T. C. Huxley and A. White.)
Anchusa italica, Retz. S. Europe. (Lady Gardon and Mrs. Baker.)
Solanum aviculare, Guill. New Zealand, Tasmania, S. Australia. (H. Travers.)
Schizanthus papilionaceus, Hort. Chili. (Cambridge.)
Verbascum olympicum. (Cambridge.)
Linaria purpurea, Will. Italy. (J. Gray.)
Pentstemon ovatus, Doug. N. America. (Cambridge.)
Collinsia bicolor, Benth. Calcutta. (Cambridge.)
Veronica longifolia, Linn. S. Europe. (Cambridge.)
Achimenes. sp. (Mrs. Jeffreys.)
Achimenes, sp., double. (Capt. Bayley.)
Gesnera bulbosa (?) (Mrs. Jeffreys.)
Catalpa Kæmpferi, S. & Z. Japan. (T. Hanbury.)
Salvia camphorata. (T. Hanbury.)
S. hispanica, L. America. (T. Hanbury.)
S. interrupta. (T. Hanbury.)
S. canariensis, Linn. Canary Islands. (T. Hanbury.)
Coleus, several garden vars. (A. C. Lawrie.)
Cryptocarya glaucescens, R. Br. Queensland, N. S. Wales. (J. P. William Bros.)
Nesodaphne Tawa, Hk. f. New Zealand. (H. Travers.)
Araucaria imbricata, Pav. "Puzzle Monkey." S. Chili (Haage & Schmidt.)
Picea Fraseri, Loud. Carolina. (Kew.)
Abies Smithiana, Forbes. W. Himalaya. (Kew.)
Pinus Strobus, Linn. N. America. (Kew.)

MONOCOTYLEDONS.

Dendrobium nobile, Lindl. China (T. C. Huxley.)
D., sp. (T. C. Huxley.)
Phalænopsis grandiflora, Lindl. Java. (A. C. Lawrie.)
Freesia Leichtlini, Klatt. Cape. (T. C. Huxley.)
Crinum, sp. (W. J. Cotton.)
Agave Xalaapensis. (T. Hanbury.)
A. xylinacantha, var. univitatta (T. Hambury.)
Commelyna cœlestis. (Mrs. Baker.)
Also bulbs of Hyacinths, Tulips, Crocus, &c., from W. Jordan.

9.—HERBARIUM AND LIBRARY.

Herbarium.—During my absence the opportunity was taken of going through, cleaning and sorting all the duplicate specimens of the "C. P." (Ceylon Plants) series, and re-arranging them under covers for easy access, in accordance with my new Catalogue of the Ceylon Flora. This has been completed during the year by the draughtsman, who acts also as keeper of the herbarium. Twelve new cabinets have been set up, and the duplicates accommodated in them; it is a great convenience to have them thus readily accessible, and in a parallel series with the herbarium itself. As time serves I am incorporating with these the numerous duplicates which have accumulated since I took charge of the Department, hitherto separately arranged.

The late Muhamdiram made several collecting expeditions in the earlier half of the year, and on two occasions was accompanied by the draughtsman several interesting and a few new plants were discovered, preserved, and sketched on these excursions.

In all, the draughtsman completed fifty-eight drawings of plants during the year, in addition to seven arge drawings of estate products, which were exhibited at the Exhibition in London, and subsequently presented to the Museum of Economic Botany at Kew.

The additions to the General Herbarium have been:—

From the Kew Herbarium:—(1) A collection of plants from Penang, collected by Curtis; (2) miscellaneous plants from the East.

From Dr. G. Watt, Calcutta, a collection of plants fron Munipur.

From Dr. G. King, Calcutta, a valuable serious of named specimens of *Ficus*.

From Dr. Engler, Breslau, Nos. 1 to 200 of his "Araceæ exsiccatæ."

Library.—The following books have been added during the year, many of which I purchased, cheaply during my stay in London:—

Clarke, B., New Arrangement of Phanerogamous Plants, third ed., 1886.

Miquel, De vero Pipere Cubeba, 1839

Regel, Monogr. gen. Eremostachys, 1886. (*Presented.*)

Trimen, Systematic Catalogue of Plants of Ceylon 1885. (*Presented.*)

Hooker, J. D., flora of British India, pt. 13, 1886. (*Presented.*)

Hollingsworth, Lists of Plants found in Guindy Park and in the Grounds of Government House, Madras 1886. (*Presented.*)

Seemann, Flora Vitiensis, 1865—73.

Lunan, Hortus Jamaicensis, 2 vols., 1814.

De Candolle, A., Origin of Cultivated Plants. English Edition. 1884.

Church, A. H., The Food Grains of India, 1886.

Acta Hort. Petropolitani, vol. IX., pt. 2, 1886. (*Presented.*)

Icones Plantarum, Ser. 3, vol. VI, pt. 2, and vol. VII, pts. 1, 2, and 3.

Thompson's Gardener's Assistant, edited by T. Moore 1884.

Vilmorin-Andrieux, The Vegetable Garden. English Edition, 1885.

Williams, Orchid Grower's Manual, edition 6, 1885.

Bull, W., A set of his Annual Retail Lists from 1870 to 1885, wanting 1871 and 1874. (*Presented.*)

Plukenet, Opera omnia, 4 vols., reprint, 1769.

Dillenius Hortus Elthamensis, 2 vols., 1732.

Hart, Botanist's Ramble in Central America, 1886. (*Presented.*)

Moore, Lepidoptera of Ceylon, pts. 11 and 12 (*Presented.*)

Museum.—I was much occupied in the early months of the year with the formation of a set of wood specimens for the Colonial and Indian Exhibition. The actual number ultimately selected and exhibited was 243, no duplicates or doubtfully identified specimens being sent home. As I anticipated, I was also able to supply a set of 126 numbered specimens in the rough to the Colombo Museum, which were sent there in September, and I have left a somewhat larger series—many of which are, however, duplicates of one another, or doubtfully determined—at Peradeniya. I purpose at once to arrange these here as a nucleus of the long-contemplated economic museum. They will form a good substantial commencement, and can be set up without much expense, but nothing can be done for the conservation of more perishable objects until some expenditure can be sanctioned for glass-fronted, well-made cabinets and glass-stoppered bottles.

And the following the number of purchasers:—

At Peradeniya	...	438
Hakgala	...	166
Henaratgoda	...	46
Anuradhapura	...	37
Badulla	...	32
Total	...	719

11.—EXPENDITURE.

The cost of the Botanic Gardens Department for the year has been as follows:—

		R.	c.	R.	c.
Salaries		—		18,342	78
Gardeners' and Labourers' wages:—					
Peradeniya	...	8,189	58		
Hakgala	...	3,000	0		
Henaratgoda	...	1,999	58		
Anuradhapura	...	999	75

HENRY TRIMEN, M.B.
Director.

Peradeniya, February 28, 1887.

PLANTING IN BRAZIL:

COFFEE—CINCHONA—TEA—SUGAR—COTTON—JUTE —LABOUR.

[I enclose you part of a letter I received from Mr. A. Scott Blacklaw, Brazil—by last mail. You will see by it that he gives some interesting facts in connection with agriculture and the labour question there.—*Cor.*]

I hope Ceylon has a good coffee crop this year, for the price is to be high. Brazil is to give a small one. The planters have no expectation of getting even half an average crop. This is proved to a good extent by the reports of those who sell imported articles, machinery &c., to planters, all complaining they can do nothing and the promised orders have been postponed for a year. There has been little coffee blossom. The great blossom of October did not make its appearance owing to drought in some parts and cold and frosts in others. A few blossoms showed themselves in January and February but they were like those that appear out of season in Ceylon; if they come to anything like fruit they do not pay for picking.

Coffee is selling in Rio at present some 10 per cent more than the prices of same quality in New York: you know of course the market at the latter place rules the price of Brazilian coffee.

There is a talk of growing cinchona here, but they want Government to take the initiative.

Tea has been tried, but the sample was rather gross and wanting in flavour, but as a proof that it will grow I may mention that I pass on the railway a piece of an old tea plantation which was abandoned some fifteen years ago and left for cattle to graze on, in spite of the neglect the bushes are standing up in beautiful line, and would well repay being taken care of again.

We are an enterprizing people but at the same time a great protectionist people, and our enterprise often goes in the direction of developing industries which are protected by heavy import duties. Large Cotton Mills have sprung up in all directions and owing to the heavy duties on manufactured goods these mills pay and are expected to pay even with the prospect of having to import the raw material. There is now a rage for Jute Mills and already machinery from a Dundee firm (Parker's) is being put up for a number of rooms. These machines are made and worked by British people at first. Cotton cultivation is not extending and as these industries look for their profit in manufacture only protected by import duty, we are not to suppose that jute cultivation will extend beyond the experimental process. Coffee and cane are the two products that can profitably employ the agricultural labourer in this country and will continue to be so. Ceylon and India need not fear competition in the cultivation of cotton and jute. Coffee will hold its own for a long time here, and were it not for the large export duty cane sugar from this country need not fear the great beet-root competition in Europe.

The labour question is in the way of being solved by the introduction of European families of the country labouring class. Government pay the passage from their homes to the place they choose to settle.

The doom of slavery is now fixed and it will be at an end by the advent of the Twentieth Century. Benevolent people are anticipating it by liberating their slaves on condition of working for a few years, say from three to five. Almost every newspaper contains some paragraph notifying such charitable intention. Our Emperor has been very sick for the last two or three weeks, but has now happily recovered. The addresses which have been presented to him since his convalescence from all classes, both Brazilians and foreigners, show how well he is liked and how much he would be missed. A. S. B.

TEA IN CEYLON.

In a recent article we discussed the probable future of Indian tea, a future which must be greatly influenced by the yield of Ceylon, and we now propose to specially consider the prospects of the industry in that island. Some marvellous results have undoubtedly been attained in the way of made tea per acre, notably from Mariawatte, but there are many reasons for thinking, it unlikely that the average yield per acre of the future, when Ceylon has settled down with its permanent area in full bearing, will exceed that of India. Much tea has been put down on old coffee land, and on poor soil, and though the tea plant is far more hardy than its rivals, coffee and cinchona, yet it cannot for long give paying results except in good soil, or unless it is well manured. Also, though as good land can probably be shewn in Ceylon as in India, yet on the whole, it is the opinion of such Indian planters as have been over Ceylon tea districts, and of not a few Ceylon planters, who have visited Indian plantations and are therefore in a position to form an opinion, that the average Ceylon soil is poorer than that on which Indian planters work. The size of the tea trees and their leaf bearing surface at Mariawatte probably the best known of Ceylon tea estates, compare unfavourably with the aspect of the tea on some of the Nilgiri plantations, though the yield of the latter is far inferior to that of the former. The explanation of this and of the strength and flavour of Ceylon tea seems to be that the climate there is perfection, as far as the tea plant is concerned. But climate, though it will induce a large yield to begin with, will not keep tea going for long, and the poorer the soil the sooner will exhaustion take place, so that it seems likely that, without heavy manuring, involving proportionate expense, many Ceylon tea estates will be early worked out. Of course this is only theory at present, and we have no desire to see it practically proved, as if ever a community set an example of pluck and enterprise under difficulties it was the Ceylon planters when their coffee was devastated by leaf disease and they turned to tea. Still, there must be a reason for abnormal yields from

comparatively poor soil, and as far as can be seen at present that reason is a forcing and, consequently, an exhausting climate.

It is difficult, then to believe that tea will pay in Ceylon to the extent that some of its sanguine supporters imagine, though, given proper cultivation, the Ceylon planter should in no way be worse off than the best of his Indian brethren. He has had a good start which is a great thing. Partly through judicious advertising and partly through its own merits Ceylon tea has taken the fancy of consumers, and is steadily making its way on the Continent, a noteworthy point. True, its average price has fallen to 1s 1d. per lb. from the 1s 3½d of 1885, but, considering the increased supply, this is only in fair proportion to the fall in other teas, and the highest average price on the London market is still held by a Ceylon estate, Blackstone, which obtained an average of 1s 9¼d per lb. for 20,000 lb. sent home during 1886. The group of estates represented by the K.A.W. mark realized 1s 3½d per lb. for 300,000 lb. the largest quantity sent home under one brand, and Mariawatte obtained 1s 2½d per lb. for 137,000 lb. shipped during the same period. As to the acreage now under tea in Ceylon, planters themselves seem to have but little idea of what it is, and extensions are still the order of the day. No deduction can be drawn from the export of tea, as might be done were the plantations in full bearing, for the greater portion is still immature, so there is nothing to go by except Ceylon estimates of future yield, (and how these are arrived at it is hard to say), bearing in mind that of two estimates it is safest to take the lower. This brings us to the figures given in our recent article on India tea as to the probable yield of Ceylon,—35 millions in 1890, and beyond this it is idle to look at present. With a poorer soil than India, a forcing climate, and no annual period of rest, such as the old season ensures in the north, cultivation expenses must be increased if the trees are to live and thrive, and unless this is speedily recognised by those who are rushing into tea in Ceylon they will have to face, later on a congested market and lower prices, both of which may be expected, with a reduced yield resulting from exhausted trees.—*Madras Mail.*

COFFEE AND GREEN BUG—AND THE NEED FOR LOOKING AHEAD.

We publish elsewhere three letters on this subject from planters of very long experience in the colony. The fact that these letters have reached us almost together within the past few days is a simple coincidence; for, even if known to each other, the writers, one in the Northern, one in Uva and the other in Colombo, could have had no knowledge, each of what the others were doing. This preliminary remark may be needful, because a reader of the letters would suppose that the Uva and Colombo correspondents had sat down to dispose of some of the very sweeping statements of "An Experienced One." This gentleman's "experience" has, we believe, been confined to districts north of Kandy, where, undoubtedly "green bug" has done all the mischief he specifies; but we do not see sufficient warranty for this very decided pessimist going on to generalize, that, as it has been in Matale, Kelebokka and the Knuckles, so must it be in Bogawantalawa, Agrapatana and the Uva districts. As a matter of fact, we believe, the comparison or generalization has failed already. We think that the period which was sufficient for green bug to practically kill out what coffee, leaf-disease had left in the Northern districts, has already been exceeded in reference to the other districts with green bug from time to time, visible, and yet no such "killing-out," so far as our information goes, has been experienced in any of the divisions we have specified? We are by no means preaching the permanency of "coffee," nor have we based a single argument for railway extension or any other work on such an idea. We have said and repeated it again and again, that, for every acre of coffee that may disappear in Uva for instance, the full equivalent—and more than the equivalent—will come into cultivation of other products suitable to the climate, soil and other conditions. Whatever value may be attached to our Northern correspondent's views regarding coffee, there is absolutely no justification for his closing paragraph, seeing that the success of tea in the great and fertile districts of Uva is now an assured success, and that to make it fully and financially successful, the Uva planters just want the railway facilities which the cisalpine districts enjoy. The one great railway blunder of the Ceylon Government was the making of the Matale line *before* the extension to Haputale. The latter would have paid handsomely all through the bad years and would now be affording an increasingly handsome income, rising year by year, as all the Uva traffic was gradually absorbed by it, and as the hidden valleys and resources of this most fertile province became more fully developed,—whereas the poor results of the Matale branch and of the abortive Nanuoya section have done much to damage the credit of the colony. We are free of responsibility for this result, for we preached in and out of season, to show where the really profitable traffic lay. But this is all by the way. It is a fine commentary on the pessimist letter before us that the writer should stand in the way of Uva having a railway after seeing his own district served, and at a time when Railway progress in the rule in nearly every British Dependency—in Dependencies even from whence old Ceylon planters are returning, for the reason that there is more life and activity here—more prospect of prosperous times than in the very countries where railways are going ahead at a rate which covers with shame the Downing Street autocrats who have stopped the completion of our main line all these years.

To return to green bug and coffee, it is absurd to tell planters with fine fields of the staple product which is becoming so increasingly valuable—and in a year when good crops are the rule,—that if green bug is seen on their bushes, they are do nothing, save to grin and look on until their coffee is swept out of existence, meantime putting in the fitting substitute. "One Experienced" laughs at the idea of "lime" being of use, or indeed anything else. Now we stated the other day, on the authority of a proprietor (name given)—a gentleman who is not in the habits of making rash statements, —that on his estate caustic lime had been proved to be very effectual in checking and driving away green bug. This was in Uva. Is our correspondent prepared to say that what did not do with him north of Kandy, is to prove equally useless in a different climate with soil and coffee trees it may be very superior to the best even under his observation? As regards Uva generally, we believe green bug was noticed on several estates both in Haputale and Badulla more than a year ago. Has it then killed out coffee there? Was it not rather seen on some estates which last season gave one of the heaviest crops they ever bore? If so, there is this characteristic about green bug in Uva which, we believe, was not observable in the old Northern districts, namely that the attack comes and goes—it does not, in Uva, as in the North when once it has appeared, march steadily on, killing out all before it. There is therefore not only room, but much reason for en-

couragement, to experiment, to cultivate, to fight the enemy wherever it shews itself with all available forces. A reprieve of even a few years would suffice, where there is any sign of the enemy finally conquering, to bring the substitute into full flush. But meantime we need scarcely say that with Ceylon coffee nearly touching the 100s per cwt., there is no Uva, Udapusellawa, Bogawantalawa or Agrapatena planter who will not make sure of doing justice to all the coffee that remains to him, before he decides to plant up his whole property with tea or some other substitute.

PLANTING LETTERS FROM JAMAICA—NO. XVII.

WEATHER AND CROPS—LEAF-DISEASE—LABOUR.

Blue Mountain District, 25th March 1887.

DEAR SIR,—The crops in the lower elevations are now well over, that in the Top Mountain District is just commencing. All low-lying coffee, as I have mentioned in a previous letter has done well this 1886-87 season, as it escaped the worst of the awful storms of June and August; prices also have been very good, so the settlers must have made money. Planters were willing to buy the cherry at a fair price, but "Quashie" to a great extent thought it better to pulp and cure it himself in his own rough way, fancying he could realize more money for it in Kingston. I have been told that the dealers in Kingston who have got orders from America, and a limit as to price, do not look so much to the quality, as long as they get the quantity. This accounts for the settlers getting a good price for their coffee though it must be far worse cured than the coffee prepared on the estates, with all the necessary and proper appliances. Crop of the real Blue Mountain berry will be very short this year, so prices should range higher than last year; in fact coffee prospects for planters seem to be brightening up, for if it be true that some disease has shown itself in Brazil in the Brazilian coffee fields which must prevent the increase of yield in that immense country, (added to yearly increasing difficulties as to labour,) and keep the production within certain bounds, and cause consumption to overtake production: then may we West Indian and Central American coffee planters be thankful that "it is an ill wind that blows no one any good." I am glad to see that improved prices have stimulated the efforts of the Ceylon planters to keep up in a high state of cultivation, the coffee still left in several of the high districts estates, and that many of them were rejoicing they had not entirely sacrificed their coffee-fields to tea. The Rev. Mr. Abbay's words have come wonderfully true, though I could hardly believe at the time leaf-disease would become so destructive and cause the commercial ruin of so many old and tried Ceylon men, for I hoped and believed it would pass away after a time as did black bug, and other enemies of the coffee tree. Mr. Abbay said, the oldest, poorest, and low-lying estates would first succumb, but that in the higher and younger districts with good soil, on the western, and specially the eastern side of the island as Haputale, Udapussellawa and Uva generally would fight the battle longest, and so it has turned out, but his prophetic idea that coffee would ere this have been selling for 200s per cwt., has not as yet come to pass; he supposed the disease would soon get to Brazil, for a letter, a man's clothes, a parcel, or botanical specimen, a book-packet would be sufficent to spread the spores all over the country. God grant that this may be averted, for so far the West Indies and the Brazils have not been visited by the *Hemelia Vastatrix*, so every care should be taken by the Governments of the various countries on this side of the globe to keep it out. Of late the weather has been cool and pleasant, indeed too much so for coffee fields over 4,000 feet above the level of the sea. The "Northers" we experienced in January and February have a very baneful effect upon the coffee bushes especially young plants, they become dried up, withered and look as if they had been blasted by fire instead of cold. As my experience accumulates, I find it takes longer to raise and bring coffee into bearing in Jamaica than it did in Ceylon, for the winters are much more marked, and vegetation high up on the hills seems checked for quite three or four months. It is evident to me that Jamaica being as far north of the Equator as 17 degrees, the utmost limit for the planting of coffee should be 4,000 feet above sea-level; 3,000 to 3,500 being the best and safest elevation to select. As to labour, it may become more scarce, especially in the low-lands if it be true that labourers are, being offered a Columbian Dollar say 2s 6d a day and their food to work on the Costa Rica Railway the starting-point on the Atlantic being "Port Limon," which moreover is fast becoming a very influential port for the shipment of bananas, and so threatens to damage our Jamaica market in the United States, unless we ourselves extend our railway lines into the fruit-growing districts, and connect them with the chief shipping ports because the Port Limon fruit being carried by rail, is put on board fresh and in good condition, whereas the Jamaica fruit has to be carried in drays and on people's heads, and may have several moves before it finds its way on boardship. It is also said that labourers on the Costa Rica Railway can arrange to have a portion of their wages remitted to their families, this and the food to be provided by the Company, and the better climate will, in my humble opinion, draw many men away from the Panama Canal, which is getting a worse name than ever, as the agents for procuring labour, according to letters in the newspapers state, deceive the people by assurances of immediate employment, and free return passages, whereas it seems only the strong and hardy get employment from the contractors.

W. S.

COFFEE REDIVIVUS!—In our Overland Summary we allude to the special care, nay coddling now observed of every coffee tree with any life left in it, upcountry. A special case is brought to our notice referring to a proprietor in a district not a hundred miles from Adam's Peak who has been trying for two or three years to kill out his coffee generally to make room for the tea, and who nearly accomplished his end last year, but who has of late been anxiously inspecting the stumps with a view to revival! "Can these dry bones live" is the question asked. Apparently they can, for a single sucker is already appearing and with every attention paid to it and the parent stem, we daresay, a good few bushels at R15 per bushel! may yet be gathered even though it may be to the detriment of the tea simultaneously being plucked alongside. The moral is evidently "Never say die" even to a dried up Coffee stick; 'but oh!'—thinks this planter and many other men,—'if I had only not been in such a hurry to supersede the old berry, I might have got a big haul this season!'

CACAO IN BRAZIL.—A correspondent of the *Journal* at Ceará states that the cultivation of cacao is attracting considerable attention in that province, particularly in the Baturité district.—*Rio News.*

TEA PLUCKING EXTRAORDINARY.—From a medium elevation a planter reports that two of his coolies brought in 150 lb. of green leaf plucked between 6-30 a.m. and 3 p.m. The flush was an eight-day one on Jatinga-Manipura, indigenous tea, about three years old. Has this been beaten?

MORTGAGE SECURITIES.—*Public Opinion* has published the first of a series of monthly tables, showing the capital employed in landed securities in Trinidad, as also the fluctuations of the rate of interest as determined by a monthly average. The transactions in February, 1887, fairly indicate the ruling rates in the open market, as distinct from the Bank rate of 6 per cent. In the column of 5 per cent, the figures represent one single transaction between a cocoa firm there and suppliers in England; while in the column of 7 per cent, two large loans of $20,000 and $12,000 respectively make up the figure $32,000. Eliminating these exceptions, the ruling rates in the open market are 8 and 10 per cent., interest at 10 per cent. being readily paid on sums not exceeding 500*l.*, and at 8 per cent. on loans in excess of that amount.

THE VALUE OF SUGAR ESTATES IN BARBADOS.—Here is a chance for English investors. Amongst recent appraisements in Barbados has been the Redland estate, containing 204 acres of land well situated in the valley of St George, which has been valued at 10,958*l.*, and a correspondent of the local *Globe* suggests that it would afford a good opportunity for the organisation of a company to purchase the property and erect a factory thereon, as there is a surounding acreage which would yield about 1,000 tons of sugar, the canes being sent to Redland to be manufactured. Another authority thinks the experiment would be on too small a scale to pay the expense of erecting the necessary machinery; unless, of course, there was a prospect of other landowners being induced to send their canes to the factory to be made into sugar. The proposal, which is said to come from a practical planter, is, however, another indication that the idea is gaining ground amongst the planting body that improved systems of manufacture are indispensable if the Colony is to hold her own in the present struggle with competition.—*Colonies & India.*

DECLINE OF FARMING PROFITS IN BRITAIN.—Mr. Goschen in his Budget speech stated:—

The assessment of lands under Schedule A was £69,000,000 in 1877 and £63,000,000 in 1886. That was on lands alone. The assessment under Schedule B which relates to farming profits, was per penny £74,000 in 1876, £51,000 in 1886, and only £47,000 in 1887, being a fall of 36 per cent in ten years. This is a notable circumstance, and one which should be taken into the consideration of the Committee. (Hear, hear.) It is perhaps what I may call the distributing classes whose incomes are below £1,000 who have suffered least from the general depression. The commercial depression has struck at the top; it has struck the great manufacturers; it has also affected the wage-earning classes to a certain extent though they have been largely indemnified by the fall of prices; it has struck at the agricultural classes and the farmers; but the middleman has not suffered to the same extent. (Hear, hear.)

TEA: INDIAN AND CEYLON.—There was good competition for the small quantity of Indian tea brought forward on Thursday, and slightly advanced rates were in most instances paid. As the available stocks of the past season's crop, held by importers, are now becoming comparatively small, the market for the next few months will probably be more moderately supplied, as is usually the case at this period; the advance in the value of the better grades from the lowest point, which was touched towards the close of last January, is in some cases considerable, but it seems probable from the gradual contraction of their supply, that these kinds will remain firm, at any rate until the new teas are in the market. The tendency of values of the commoner, sorts is also towards greater firmness, but if the proportion of the supply of these grades continues on the same large scale as hitherto, any actual advance in their value does not appear probable. The future course of values, however, must depend on the demand, and if the consumption continues on the present satisfactory scale, prices are less likely to prove more favourable to buyers.—*Produce Market Review*, April 16th.

THE OBSTACLE TO AGRICULTURE.—It is often said that the real obstacle to agricultural improvement in India is the obstinate conservatism of the agriculturists. The *Hindu Patriot* in an article upon the last Report of the Agricultural Department of these Provinces laudably endeavours to strengthen this feeling. It says:—"We have over and over again shewn in these columns that many of the experiments conducted in the model farm relate to matters which can have no real bearing, direct or indirect, on agricultural improvements, and can certainly convey no lesson to the agricultural community. It cannot be too carefully borne in mind that the ordinary ryot cannot be expected to practise the transcendental agriculture of our model farms. We used to hear much of the famous plough invented by the North-West Department in the time of Mr. Buck; but we are now told that 'the initial obstacle to improved ploughs in many places is that the starveling bullocks are unequal to the slightly increased draught.' Did not Mr. Buck assure us that the improved plough patronised by him was admirably suited to the weak cattle of the country? From what we have said above it is clear that although the North-West Agricultural Department costs R70,000 a year, it has nothing to shew in return for this expenditure."—*Pioneer*, May 5th.

"THE TEA-PLANTER'S MANUAL."—By T. C. Owen. (Colombo: A. M. & J. Ferguson.)—Tea-planting is yet in its infancy in Ceylon, and this little book is probably the first treatise that has been written on the subject with special reference to that colony. Mr. Owen, although a practical planter himself, does not profess to speak only from his own experience—and, indeed, it may almost be said that there is as yet no man in Ceylon whose personal experience of tea-planting there would invest a work on the subject with any very commanding authority. But the author expressly premises in his preface that his manual is rather a compilation of the opinions of others, and the results they have arrived at. It is this which gives the book its special value as a practical treatise for practical men in Ceylon, and even perhaps in the older tea districts of India, for, indeed, it is a valuable contribution to the library of tea. Mr. Owen has made his selections from the recorded experiences and deductions of others with great judgment, and addressing as he does, practical planters, who will not be likely to quarrel with a degree of detail, perhaps not always necessary, he has preferred rather to risk erring on the side of prolixity than to sacrifice any of the original authority of the opinions he quotes by condensation. He supplements these opinions, however, by valuable comments derived from his own experience and that of other Ceylon planters. The book also contains plans and specifications of buildings required on a tea garden, which will, no doubt, have their value to the practical planter; although the erection of such buildings is far too important a matter to be materially influenced by hard and fast generalities. To the general reader, however, by far the most interesting portion of the book will undoubtedly be the "Introduction," which is devoted mainly to a narrative of the growth of the industry in Ceylon, and a wonderful story it is. Ceylon therefore, promises to become a serious competitor with India and China; but there is room for all, and cheap tea undoubtedly means increased consumption. There are better days in store, then, for a colony which has suffered so much through the decay of coffee planting. —*Glasgow Herald*, April 11th.

Correspondence.

To the Editor of the "Ceylon Observer."

CINCHONA "THATCHED" AND "UNTHATCHED—AS TO QUANTITY?

Badulla, 2nd April 1887.

DEAR SIR,—A late correspondent, in asking Mr. Esdaile for explanations regarding thatched and unthatched trees, omitted one question, perhaps the most important, viz.: Did the *unthatched* trees produce as much bark as the *thatched*? If Mr. Esdaile can save us the expense of thatching, I am sure we shall all be very much obliged to him. Hoping you can find space for this enquiry.—I remain, &c., A PLANTER.

CACTUS AS A FORAGE PLANT FOR THE NORTH-EAST OF THE ISLAND.

Mullaitivu Agri:-School, 5th May 1887.

DEAR SIR,—In the March number of the *Tropical Agriculturist* (page 586,) I came across an extract about a thornless species of cactus introduced as a forage plant into the eastern districts of the Cape by Mr. J. B. Hellier. I doubt not that, as you remark, the plant will be found useful in the north and east of Ceylon. It will especially be a source of great relief here at Mullaitivu where most of the cattle actually starve during the greater part of the dry season. Anyone, therefore, who will take the trouble to introduce the plant here will deserve our best thanks. One great drawback in cattle rearing here is bad feeding. Country cattle, I need hardly say, would be in a much better condition were they well fed; and any superior new breed introduced here would soon degenerate so long as the present bad feed continues.—Yours respectfully,
E. T. HOOLE.

SERICULTURE.

Colombo, 7th May.

SIR,—Sometime ago I had a few hundred eggs of silkworm sent me by an up-country gentleman. I had according to his directions kept them in a tray, and gave their young, tender leaves of the mulberry tree at first, and larger leaves as they grew older. I had also to take care that no mice, birds or insects got at them and to feed them as regularly as possible three times a day, or four times in hot weather. The result was that after the lapse of about a month, I had cocoons from which I gathered a small quantity of floss silk say about one or one-half lb. But as I did not know how to comb it and put it to some use, nor get further information on the matter, I left off making further experiments. Also, I have not been able to preserve the eggs yet the butter-flies laid. I could not make provision for a further supply of these worms. There is, however one thought that struck me forcibly and that was that if proper and systematic efforts were made in the rearing of silkworms in Ceylon, silk could be easily manufactured here as well as is done in other parts of the world. The following passage which I lately read in a book confirms me on this opinion:—"The countries most noted for their silk manufactures are China, Japan, Italy, France and England. The rearing of silk worms enables many persons to earn a livelihood. Old people and children unfit for hard-labour can tend silkworms."

I have seen a large number of mulberry trees growing freely in and around Colombo, and with their leaves, these worms could easily be fed, and, if needed, more trees might be grown for this particular purpose. As the silkworms or eggs are not procurable here, I think it would be well if Government would order out a supply for gratuitous distribution among the people, and they will, no doubt, give an impetus to a new industry in Ceylon. And if eventually the rearing of the silkworms succeeds, a person could be ordered out in order to teach the further process of combing &c. to the people.—Yours faithfully, A WELL-WISHER.

[We fear suitable labour is too expensive in Ceylon, and the Sinhalese too apathetic, apart from questions of climate. The most promising experiment we ever saw in the colony was at Kowdapallella, somewhat over two years ago, with eggs brought by Mr. Robt. Fraser from Japan. It threatened to break down and probably did so (?) from the difficulty of supplying the voracious worms with a sufficient quantity of mulberry leaves.—ED.]

PECULIAR TEA LEAVES.

Kalutara, 8th May 1887.

DEAR SIR,—I enclose some tea leaves with a peculiar rib running on each side of the mid-rib. This peculiarity is common over hundreds of acres in the district. Can you explain the cause of the appearance? No evil effect whatsoever appears to accompany it, but it would be interesting to know the cause.—Yours faithfully, R. MORISON.

[We referred the leaves to Dr. Trimen, who has been good enough to give the following interesting explanation:—

"The markings on the leaf are not ribs or veins, but linear scars or bruises. The cause of their formation would, in all probability, be found by examining them when in the bud, before expansion. Normally the young tea-leaves in that stage are rolled in from both sides on the upper surface, a condition technically known as 'involute;' but it would appear that in those before us there has been a *folding* inwards instead of or besides the rolling, (accompanied with some pressure) along the lines so clearly marked. These lines thus produced, though not normal in the leaves of tea are always found in those of *Erythroxylon coca* and give them a very characteristic appearance."

COFFEE AND GREEN BUG:—No. I.

9th May, 1887.

SIR,—*Re* the green bug question, people are too apt to catch at straws of hope, instead of utilizing the short time left them to rapidly replace coffee by substitutes, and we are often airily told, in planting notes, that "bug has been about, but has gone again." *Has it*?

It is perfectly characteristic of it to depart for a short season, but the instances when it has not returned again and again while a coffee tree was left, are so very rare, that they are not worth counting. Another straw is, that any coffee which has been actually killed, was it not, perhaps, due more to exhaustion than to bug? And a correspondent wants to know whether any large acreage being killed by it is upon record?

THOUSANDS OF ACRES have been killed in one and two seasons by bug, and bug alone, and as cleanly as if they never existed; while, in many instances, the best coffee (such as one sees round cooly lines) made the poorest fight, caving in in one season only. The great and only hope for such districts now experiencing the bug for the first time, is that some climatic influence, such as higher elevation affords, may obviate much destruction by the pest; but, if the climate fails then the fact is no secret, which every one with experience will maintain, that before two years have elapsed, there will be

but a few desultory fragments of coffee left to Ceylon.

There are no known remedies, and those who are squandering money upon experiments, may just as reasonably drop their coin into the depths of the Indian Ocean. As for *lime*, it is exactly the luxury this bug most dearly loves. To the "nauseous gases" theory and digging round the roots to enable their escape, I say "rubbish and fiddlesticks."

Coffee does not produce 6 to 8 cwt. per acre with nauseous gases at its roots, but fields with fine healthy crops upon them have been, nevertheless, attacked and killed in one season by bug.

The immediate starting of substitutes for coffee is the remedy, solely, for properties where coffee is attacked, but where it is still "The King" fragile monarch tho' he be.

And *until* such remedy be *largely* applied and with every prospect of success proved, were a Governor of Ceylon to give even a passing thought as to Railway Extension beyond Nanuoya, be the gauge broad or narrow, it should entitle him to consignment to some such establishment as Bedlam.

ONE EXPERIENCED.

GREEN BUG IN UVA:—No. II.

DEAR SIR,—Yes, we have green bug here and have had it for some time, longer than we ourselves know, for it is so like the old black bug which never did us any harm to speak of and never spread over an entire estate as it did in wet districts. Green bug, so far as I have been able to judge, is very similar in its action, that is to say, whilst it has diffused itself rapidly over a large extent of country in a short time, nowhere that I know of in Uva has it affected more than a few isolated patches on estates and in no case that I know of has it killed the coffee. Weak, sickly coffee or sickly plants of any kind are always more liable to disease and more severely affected than healthy plants. It would be folly altogether to ignore and shut one's eyes to the fact that green bug is on our coffee, but I would ask the Uva planter to look back on the past and "seeing take heart again." Green bug, serious as the evil may prove, will no more kill our coffee than has leaf-disease or black bug. Let Mr. Deaker continue to cultivate well, keep his trees well open to sun and light, prune judiciously when his "powder will be dry" and he may "trust in Providence" and a good soil.

OLD UVA PLANTER*.

COFFEE AND GREEN BUG:—No. III.

DEAR SIR,—Having been challenged as it were to say something about green bug and having been accorded the privilege of being allowed to stand-by—and watch a considerable part of Mr. Green's operations in working out the life-history of the insect, I venture on making a few observations. The discussion which has arisen about the *Lecanium viride* may be considered by many to be rather late in the day—when about two-thirds of the acreage of coffee in the island has been destroyed by it. However, "better late than never" may I think be exemplified here, as I hope to be able to show that there are several reasons why attempts to destroy the pest in certain situations are more likely to be successful now than they have been in the past. The principal reason which gives planters hopes of eventually overcoming the enemy is the very characteristic which first drew my attention to the fact of its being a new species of coccus—even before I had seen it,—the fact that it flourished most and was more destructive on dry low-lying estates than on high, wet and exposed fields. The year 1860 was a very dry one in the Central Province until crop time, and then it commenced to rain, and continued doing so more or less for about two-and-a-half years on end. In Rambodde—and similarly situated districts—black bug literally smothered certain fields and estates and did immense damage. On Weddamulle estate where I was then stationed, there was a young field at an elevation of about 4,300 feet, bearing a fine crop when the bug got a grip on it, and the green berries—rolled off—might have been swept off the ground literally by the bushel. I don't suppose a tenth part of the crop ever came to maturity, and that small portion was wretched, small, deformed stuff. The bug in some stage was always present for years after, though the black fungus was not always prominent. The young bushes were growing fast, and a day or two's sunshine was sufficient to enable the leaf to throw off the covering of black, but as soon as the wet set in again, a black wave swept over the surface in a very few days, and the result was very disheartening. The new bug on the other hand seemed at one time likely to absolutely annihilate the trees on the hotter and drier fields and only to partially affect those at higher elevations. The new bug was at one time said to absolutely destroy the vitality of the trees, but I am told that many fields, given up as totally gone, have come round again. The old bug, however much it damaged the crop, and the foliage never got so far as to destroy the life of the tree, nor did I ever see in the case of black bug, what I have seen in green bug, and that is the ground below and around the trees covered with the black fungus which accompanies the attacks of both varieties. When the green bug had advanced to where I was residing it was evident that in long spells of wet weather, a very large proportion of them turned mouldy and died, and I learn that the cold this last dry season has caused an immense destruction amongst them especially where there has been a touch of frost on the trees. This is the point where Dimbula and Dickoya planters, and the men of upper parts of Uva may hope to make a successful stand. As far as I can learn, the bug has not spread evenly and badly over large areas, but has appeared in patches larger or smaller as circumstances have been favourable, and these patches are at a comparatively high elevation. The enemy is neither so numerous nor so vigorous as it was when the good folks of Matale and Elkaduwa and neighbouring districts, had to retire from the contest baffled and disheartened. The climate of the higher districts is in their favour, and they have gained the experience which was wanting in the early days of the contest. If our old friend Holloway could do so much in the way of a remedy at Wattagama, the men who enjoy the advantage of higher elevation and more favourable climate as well as being subject to less vigorous attacks of the pest may well hope that their labour may not be in vain. In regard to treatment, Mr. Holloway only repeats what is well-known to all agriculturists when he points out that rendering the trees as healthy and vigorous as possible, enables them the better to withstand the attacks of insects, fungus and all the other ills of vegetable life, such as too much drought, too much rain; and, on the other hand, everyone who has lived on an estate cannot but see that weakly tress first fall victims to such attacks, sooner or later, according to their condition. This, however, is no argument against the late Mr. Nietner's theory. He used to argue—and at the time being merely

*Not a proprietor we may add.—ED.

a listener without experience I saw no reason to disagree with him—that the effect of manuring a tree was practically produced by supplying it with certain matter which was taken up by the roots and absorbed into the sap of the tree. Taking this as the basis of the argument—why should it be impossible—to salivate—so to say—a tree by manuring it with some substance which, when absorbed into the sap, should be inimical to the disease which it is intended to combat, or the insect feeding on that sap. This is a matter which must be decided by scientific botanists. I cannot pretend to say more than that I have always favoured the idea, and in spite of Mr. Holloway's dogmatical assertion to the contrary still imagine it to be quite feasible. I have used Little's Liquid Phenyle to a considerable extent both as a disinfectant and an insecticide, and the successful experiments with it on leaf-disease were made on properties then mine. When properly used, Phenyle is a most valuable adjunct to nurseries for such small light seeds as cinchona and seed-beds carefully prepared can be kept free of insects in a marvellous way. I imagine Phenyle would be very deadly to green bug—even if it were only from the scent so freely evolved from its use—and within the last few days I have learnt that Mr. Green's experimental tree, still remains free of bug when the surrounding bushes are affected in the usual way. As Phenyle can be obtained tolerably cheap if taken in large quantities, I should say that experiments on a larger scale are well worth trying. In fact, I happen to know that they are being tried at the present moment. Perhaps Mr. Holloway may explain why he asserts so positively that green bug was not brought over on the Liberian plants in wardian cases; this is the very point I want to see elucidated, as my idea is that it did come over in that way. EDMUND WOODHOUSE.

TEAS FROM UDUGAMA DISTRICT, GALLE.

Daphne estate, Udugama, 10th May 1887.

DEAR SIR,—Having seen one or two notices lately in the *Observer* anent Udugama, I take the liberty of forwarding for your inspection and taste three small samples of tea from Riseland estate.

You will doubtless not fail to note the absence of strength and presence of flavour as compared to the average of low-country teas. The sample sent has been handrolled and chulafired—and represents tea made from a *first year's plucking*. If this does not speak well of Udugama, I am sorry I troubled you with these remarks. PLANTER.

On the samples, Messrs. Somerville have been good enough to report as follows:—

Samples No	Description	London Value	Colombo Equivalent at Exch.	Remarks
1	Broken Pekoe	1/4, 5 for leaf	86 cts.	Blackish well made semi Bro. Pekoe leaf with tips, strong dark liquor, *burnt*.
2	Pekoe	1/1 for leaf	65 cts.	Blackish fairly made Pekoe leaf with tips, strong pungent liquor. *burnt*.
3	Souchong	9d	41 cts.	Blackish irregular bold Souch. leaf plain burnt liquor.

p. p. SOMERVILLE & Co.
A. H. THOMPSON.

N.B.—These teas would be worth nearly 2d a pound more money if they had not *been burnt* in the manufacture. They possess very fair strength.

CINCHONA HARVESTING: RESULTS FROM UNCOVERED TREES.

Verellapatna, Lunugalla, 10th May 1887.

DEAR MR. EDITOR,—For the information of enquiring correspondents, let me reiterate in part: "The bark was taken from off trees growing together *in lines*, shaved at the same time," these lines were not six feet apart, and were of a field of 50 acres in extent and of same age, say rising seven years, consequently pretty well sheltered. I perceived no difference in appearance of trees after shaving. As to quantity, I operated on 40 trees of each *i.e.*, 40 thatched and 40 unthatched, and on weighing found the difference so infinitesimal that I took no entry of it. I think from 1 oz. to over 1½ oz. in favour of the thatched. So on the whole my endeavours point in favour of: do not thatch—which would be a grand thing for all concerned in "cinchona;" but my advice is, do not act on results as I have shown them or rather let "E. F. T." and "A Planter" and others experiment a little for themselves, and in comparison, we might arrive at some definite and reliable facts which would save thousands in the way of thatching.—Yours faithfully,

CHANNING ESDAILE.

P.S.—I may mention that I only got 10 lb. renewed bark from off the 40 trees. *N.B.*—And further, I may mention that the "Cannaverella" bark which fetched such a handsome figure the other day was from trees that had not been thatched.—C. E.

UDAGAMA TEAS:—BURNT!

15th May 1887.

SIR,—Almost enough to make one feel sort of planted "at stake." My good friend, down at Daphne, I may say, though no sanction needed, acted without my inspiration in sending you on those tea samples for public disrobing. However ruthless a little personal firing, I have no bones to pick, as the report you have kindly published, and by Somerville & Co. furnished, will suffice to help your readers to form their judgment as to the possibilities of the district in regard to the eventual standard of the teas from hence, and which may fairly be put down as information likely to be wished for, and wanted generally of any locality where a special cultivation is still young.

As for the overfiring to the teas, I may not as an excuse, but in apology as still in petticoats in the mysteries of tea-making, say my instructions were to "fire high"—as that is what is liked in the *Lane*! To find oneself at 2 a.m. pacing upt and down a shut up tea-house with the thermometer at 90°, imaginatively watching half-a-dozen perspiring niggers—Indo-Aryan, or Dravidian—squdging green leaf, demands a high figure *sans* any additional roasting.

Apropos of "yield," my last flush here from old bushes pruned down this season for the first time was, at an average of 3 flushes a month, and 10 months to the year, at the rate of 1,260 lb. of made tea per acre annually. To which you may be disposed to add "it might be better and might be worse!" Worse or better, tea is going to pay here." SUPERINTENDENT, RISELAND.

THE COFFEE PLANTERS of Mysore, Coorg and Southern India generally are rejoicing in the prospect of high prices for their staple and they have generally good crops coming in.

"WHITE" COCONUT OIL is being prepared and shipped from Ceylon; but it is not colour alone that renders the Cochin oil superior. There is a difference in the substance of the Cochin coast Oil as compared with the Ceylon—something which mere manufacture cannot get over.—*Com.*

GRUB *v.* GREEN BUG.—The question is started as to whether green bug has not got the merit or demerit of killing out coffee, when probably grub was the chief offender? The two are not uncommonly found together.

CAUSTIC LIME is said to have cleared out green bug wherever it has been applied on certain coffee Uva estates.

A PLANTER informs us that the condition of the coffee in the Coonoor Ravine is simply splendid. The trees appear to be in good heart, and a fine blossom has set. With coffee at 95, this means something. If it isn't the great bumper, it is very near it. The same favourable prospects attend the tea, which has thrown out a fine flush.—*Nilgiri Express*, 7th May.

COFFEE IN SOUTHERN INDIA.—The weather at Seegoor and Mussanagudi is said to be simply intolerable. The recent showers have brought out a fine coffee blossom and the intense heat is burning off at least 20 per cent. Many of the estates in this locality possess facilities for irrigation. One property brings its water by a channel which cost R15,000, from the Pykara river but does not regret the outlay, as since the channel was made irrigation has rendered the crops more certain. If irrigation could be more generally adopted on the Nilgiris, the doubts and fears of planters considerably relieved.—*Nilgiri Express*. [We should doubt the success of coffee where it has to be irrigated.—ED.]

TEA: Mr. WHITTALL, representative of Messrs. Matheson & Co., London, left today by the B. I. S. S. "Chyebassa" for Madras *en route* to visit Coorg and the adjacent planting districts. Mr. Whittall who had long experience of tea in China, and who some years ago did not, we believe, regard the Ceylon tea enterprise very favourably, is now inclined, we learn, to anticipate an export within a few years far in excess of any figurewe have yet ventured to put forward. Seventy to eighty millions lb. of Ceylon tea exported in a year, say about 1891-2, would certainly bring this colony into prominent notice, and, if Uva is to have her due share in making up this quantity, how in the world is she to manage for transport is a question which may well be asked on her behalf and dinned again and again into Downing Street ears. A gentleman of much experience in India, in tea and other products, tells us that he has never seen tea anywhere, for growth at its age, to equal that which he saw in Udapussellawa, and that he recognised at once beyond Nuwara Eliya, the climate and fine soil peculiar to the very best Indian planting districts. Of course, it remains to be seen who are to consume the 80,000,000 lb. Ceylon tea, and whether they will pay for it at a remunerative rate. Much depends on new fields being opened, and it is satisfactory to learn that steady progress is making in America, Italy and France in the sale of good teas.

TEA.—Mr. Joshua Whitworth writing on the subject of tea, says:—"Why should the great socialising beverage be made the target for catch-price adventurers? Tea is now being distributed and advertised in countless mediums and forms. There is the would-be benefactor or compound dealer in tea and dispenser of presents? in the shape of toys, china, metal, earthenware, and other devices. The system (I will not say principle) to my mind is utterly un-English and un-businesslike. I cannot conceive any wife or housekeeper, with ordinary intelligence, purchasing tea with the primary object of obtaining a bonus in the form of a present. She need only ask herself who pays for such gifts. As a matter of course she herself does in the inferior value of the tea she buys. If I go to my tailor and purchase a suit, I neither receive nor expect to be presented with a hat, or even a pair of gloves. The two cases are parallel. Tea is no longer considered a luxury, but a necessary of life, as the increased rate of consumption abundantly testifies. The figures stand thus—the home consumption for 1882 was 164,958,000lb for 1886, 178,891,000lb,—and I am of opinion that if better grades of tea had been sold by the retailers, the increase in consumption would have been still greate

Tea is variously and industriously advertised—notably by London dealers or retailers who offer to deliver a given quantity free of carriage by parcel post. Now, I contend the provincial grocer or tea dealer can do better than this. He gets his tea direct in bulk from the London Bonded Tea Warehouses at about one farthing per pound carriage, while the cost by parcel post will add pence per pound. The natural inference is obvious. To ensure good and nourishing tea, my advice to all consumers is do not pay less than 2s 6d to 3s per pound, and this rule will be found wise and economical. Statistics show that the working classes are the largest *pro rata* consumers; then how desirable it is that the sons of toil should have as a sequel to the day's work an enjoyable cup of tea—tea that must soothe, sustain, and cheer. In this question there is a large field for the exercise of women's right; they should one and all denounce the questionable decoction, and in asserting their rights demand pure tea. In conclusion, there is another aspect to this contention—viz., if people would buy better-class teas, I am morally certain that it would prove a further auxiliary in the spread of temperance principles, irrespective of its health-giving qualities."—*H. & C. Mail.*

TOBACCO AND COFFEE: THE DIFFERENCE OF POLICY.—The following extract from Mr. Goschen's speech shows that although the British Government still apparently refuse to prohibit the adulteration of coffee with chicory and worse, they mean to prohibit the adulteration of tobacco with water:—

There is one error which all parties admit to have been made in the fiscal legislation of late years—viz., the rising of the tobacco duties by 4d. The tobacco duties were raised from 3s 2d to 3s 6d in 1878, and the fiscal result of that has been most unsatisfactory. The first year under the higher duty was expected to yield an increased revenue of £750,000, but it only yielded £500,000 additional, and in consequent years the result has been still more unfavourable. The increase in the consumption of tobacco, which was 11 per cent during the five years between 1872 and 1876, fell to 5 per cent in the period between 1877 and 1881. We checked the consumption of tobacco; and what was the effect upon the quality of the tobacco and upon the smokers? It will be seen that the consumption has not increased in the ratio of the population. The increase in the consumption of tobacco before the duty was raised was twice as fast as the increase of population, but since that time the consumption has not increased as fast as the population. The consumption per head is now less than it was. But there is this most curious fact. It is not quite so certain that people have smoked less pipes or fewer cigars than before. The same thing has occurred with tobacco as with beer. There has been an admixture of water to increase the weight. The workman pays 3d per ounce for his tobacco. When the duty was increased it was supposed that he would pay 3¼d and that in that way the dealers and manufactures would be able to recoup themselves. But that is not what has happened. He does not pay more than 3d per ounce; therefore, tobacco had to be produced at 3d. How is this done? It is done by increasing the amount of water. The purchaser buys a nominal ounce as before, but he really buys less tobacco and more water, and in that way the revenue loses and the smoker loses, because he does not get the amount of tobacco to which he is entitled. The price of 3d is too small to enable the manufacturer to produce the tobacco at a duty of 3s 6d, and I propose to reduce the duty from 3s 6d to 3s 2d. (Hear hear.) That I trust will be a considerable boon to the working classes, and although it will not affect their pockets they will get a better article. For we propose to prohibit by law the watering process by which at present the dealer recoups himself for the extra duty. The natural moisture of tobacco is 15 to 17 per cent, and it is increased to 30 per cent in the process of manufacture. I was not aware that 30 per cent of water was necessary for that process. (A laugh.) But now tobacco is often sold containing 40 or 45 per cent of water. In future we intend to make it illegal to sell tobacco containing more than 35 per cent of water.

A REMEDY FOR BORERS.

TO THE EDITOR OF THE "AUSTRALASIAN."

Sir,—*Apropos* of your remarks in *The Australasian* of last week's concerning the boring grub, permit me to say I have found the following remedy for its attacks upon fruit trees as successful as it is simple.

Take a piece of soap somewhat rounded by use, and force as much of it into the hole made by the grub as you can by pressing the soap on or by rubbing it backwards and forwards over the aperture several times.

Since I tried the above plan about six years ago I have not lost a branch through decay caused by the efforts of the grub in question. I have had occasion to apply the remedy to many limbs on all the kinds of fruit trees in my garden—apples and pears as well as stone fruits, &c. I used the soap with the idea of suffocating the grub by hermetically sealing it up—Yours, &c., J. S. P.

FORESTRY IN THE STRAITS SETTLEMENTS.

It may not be known to many of the ladies and gentlemen who lend life and animation to our Gardens in the cool of the evening, that the pleasure grounds in question form but a small part of a very important system of arboriculture, agriculture, and horticulture, extending over all three of our settlements. The Forest Department has demarcated wide stretching areas, opened up many miles of boundary paths, and planted thousands of valuable trees in waste lands. Excellent work has been done in the new reserves at Bukit Timah Jurong, and Bukit Mandai, where mahogany, teak, and other costly timbers may be seen springing up with every promise of developing into tall and stately trees. We think however that a good policy has been adopted in planting a very large number of native trees of rapid growth, such as serayah, casuarina, bintangor, &c.; these will "form the forest floor," and after they have been cut down and converted into money, they will leave the land in a much better condition than it is at present, to be re-stocked with the more valuable varieties. The young plants appear to be quite able to bid defiance to the *lalang*;* their stems soon overtop this troublesome grass and overshadow it with their leaves; indeed it is rather curious to note that some plants which have been grown on a patch cleared as an experiment in the Bukit Timah reserve, do not look so well as the others which have been left to take their chance among the *lalang*. No manures are used, and as the trees are flourishing it would appear that the soil of Singapore is not quite so poor as is usually supposed, but of course much depends upon the situations in which the different varieties are grown. Thus teak and rubber trees, of which a large number may be seen in the reserve near Cluny road, love low lying and moist lands, while serayah, meranti, kelat, etc., prefer the hill tops and slopes. Some kinds will not grow on laterite, in fact a systematic chain of experiments, (during the course of which the influence of different elevations should be especially studied) must be carried out throughout the Settlements before we can form any real idea of the agricultural possibilities of the Colony.

In the meantime it is gratifying to find such notable progress being made with the afforestation of waste lands. During the year 1885 over one hundred thousand trees were planted in Singapore alone. It is not too much to hope, therefore, that if this good work is carried on with sufficient energy, that we may live to see unproductive and hideous wastes of *lalang* replaced by beautiful and valuable forests.

The different reserves have been demarcated chiefly by means of boundary paths eight feet in width, bordered for the most part by young fast growing trees, amongst which a great number of casuarinas may be noticed. These paths, which in Singapore are about thirteen miles in extent, are much used by the natives as roads, and must be of very great use to them. One of these boundary paths was the means of stopping the further progress of a jungle fire which raged for a distance of two miles along the eight foot way without being able to cross it. The importance of having such "fire-breaks" in a jungle or forest country is very great.

The annual expenditure of the Forest Department amounts to about $20,000 per annum which does not appear to be a large sum when the work done in the three Settlements during the years 1884 and 1885 is considered. During this time about 22,000 acres have been demarcated, 109 acres planted, and 107 miles of the eight foot boundary lines opened; thus it will be seen that although the department is quite in its infancy, it has already accomplished a formidable task, and has so far achieved all the success which can be reasonably expected of it. The enterprise is one that the Government alone is in a position to attempt, and as the Forest Department has really been created by H. E. Sir Frederick Weld, it should meet with adequate support and encouragement. Within a few years these modest nursling forests will be considered as being amongst the most valued of the Colony's possessions, and will be a noble and lasting memorial of Sir Frederick Weld's enlightened administration.—*Straits Times.*

* Our *Illuppi*.—ED.

THE VEGETABLE PRODUCTS OF THE STRAITS SETTLEMENTS.

Besides the many native trees which afford excellent timber, there are other trees and plants cultivated by the Superintendent of the Forest Department which possess an especial interest, these are the varieties which swell our export returns by providing us with rubbers, gums, oils, spices, and other descriptions of produce.

Rubbers are probably attracting a good deal of attention just now in certain quarters; the prospectus is out of a company which intend to spend half a million sterling on a submarine telegraph cable, and if the capital is subscribed it is probable enough that the malodorous and dreadfully adulterated article known as "gutta" may give rise to a certain amount of speculation.

The Department makes a very good show of Rubbers; Panama, Ceara, Madagascar and African kinds are all represented, the native guttas however are growing so well, that the exotics do not after all possess a very absorbing interest.

But another imported plant the Australian Wattle, looks as if it would grow very well in this climate, the bark of the tree is getting into favour with English tanners, and fast coming to the front as an Australian export.

The specimens in the Experimental Garden are of a most varied description; nutmegs, cardamoms, vanilla, cocoa, sugar, tea and coffee are all to be seen growing within a small radius. At one moment the visitor may examine the famous coca leaf *(Erythroxylon Coca)* and at the next, rejoice his eyes with the sight of some tiny English strawberries, peeping in all their scarlet glory from beneath their protecting leaves. And there is a splendid logwood hedge with small delicate leaves which remind the exile of hawthorn sprays and distant landscapes; the many shades of green which it possesses contrasted in the happiest manner possible with a delicate light brown tinge make its colouring as beautiful as its foliage; as this is a rapidly growing plant it might easily be used to replace coarse bamboo hedges in grounds where much attention is paid to effect.

The Superintendent has been working up yet another question, of great interest to ladies who are gifted with a domestic turn of mind, and that is our supply of vegetables of which there are about eighty different kids more or less known in our bazaars. This appears to be a very fair assortment, but unfortunately many of them are scarce, others again are not very attractive to European palates, and nearly all are badly grown because our Chinese market gardeners believing that it pays them best to produce the greatest possible quantity, leave their crops in the ground until the beans, lettuces, cucumbers or whatever they

may be, degenerate into aged, coarse and melancholy caricatures of the young and delicate vegetables which would appear on our tables, but for this deplorable system or sacrificing quality to weight. We hope that the attention which is being drawn to the unsatisfactory nature of this pleasant and wholesome article of food, so necessary in a climate like ours, will lead to good results, although it will need some little energy and skill to overcome the obstacles which lie on the way of a practical solution of the difficulty.

Considerable success has rewarded the trials which were made both in Penang and Singapore of European fruits and vegetables; asparagus, green peas, lettuces, tomatoes, turnips, carrots, leeks, pot-herbs, &c., have turned out well, the superior elevation attainable in Penang of course giving our sister settlement a great advantage in these experiments. The peaches, apples, and vegetables exhibited at the recent flower show, were very pleasant to look upon, and it is somewhat surprising that such a fine display did not attract more general attention, especially as the excellent condition in which these delicacies were shown go far to prove that Singapore tables might be easily supplied from Penang Hill.

The Botanic and Experimental Gardens will be incomplete until they possess a small but well arranged Economic Museum specially designed for the produce of this colony, and the plan adopted by many other colonial gardens, might well be imitated here. Nothing could be more convenient than to have the museum in the gardens so that the plant and its manufactured product might be compared on the spot. Thus the gambier plant having been examined, a few minutes' walk should bring the person interested to the museum, where he might be left to inspect the different kinds of bale and cube gambier at his leisure. In such a building the visitor, after having admired the full, well grown, clustering berries of the pepper vine in the open air, would see a specimen of Singapore "sun-dried," the ideal pepper, than which nothing can be finer, being far superior to anything that comes from Cochin China, Siam, or the West Coast; this being a most desirable commodity, in the nature of things here below, non-existent in our market; then besides the usual "smoked" sorts, there should be good large sample of the stewed, smoked, fermented, uripe pepper, which loses in weight to the extent of 15 per cent by steamer shipment to London. This particular kind is becoming too well known in our market and is much appreciated by the Chinese sellers thereof, but with the European buyers transactions in such a quality are apt to end like the marriage service, that is to say, in "amazement."

In such a way an Economic Museum could be made to fulfil its real functions, and the establishment could not be in better hands than those of the Superintendent of the Forest Department, who, besides having considerable knowledge of the subjects to be dealt with, seems to possess the very useful qualification of producing excellent results with the means at his disposal.—*Straits Times.*

ESTATE COMPANIES FOR CEYLON.

There are few residents in Ceylon who have not at some period found it a difficult matter to invest small sums of money. The purchase of estates, or even of a share in an estate, requires a very considerable amount of capital. There are in Ceylon, and most tropical countries dependent upon agricultural or planting industries, few or no opportunities for small investments. This is a more serious matter for the poorer members of the community than appears at first sight, as it is opposed to those habits of thrift and frugality which go far to enrich any country.

If we look back for some ten or fifteen years to those days when salaries were high, and remember how few estate superintendents, dependent upon their own exertions, really saved money, how many there were who lived up to the last rupee of thir income, it may occur to us to consider why this was the case, why there was such general extravagence, not confined to planters only, but to all other classes of the community. There is but one reason to give—the difficulty of investing savings. In those piping days of prosperity, when A, who had no capital, saw his neighbour B. who had two or three thousand pounds, buy a block of land in one of the new districts and double his capital year after year, poor A. felt himself unable to participate in the good things going. He grew despondent at first, then reckless, and probably ended by having a burst of extravagance, scattering his savings with the prodigality of an Australian digger. When there is no other outlet for small capitalists than the deposit receipt accounts in a Bank, is it to be wondered that few are content with this one form of investment and have the patience to wait till old age to save sufficient to keep them from want? Just consider how much greater interest A would have in his work could he from time to time invest his hundred rupees in business he understood; how he would strain himself to increase his funds and look out for fresh opportunities for investment!

One has not to look far for a remedy for the existing state of matters. There is an excellent old saying "Union is strength," and, were the capitalists of Ceylon, both small and great, to bear this in mind, the prosperity of the colony might be raised to a pitch such as it has never yet attained.

Tropical agriculture, as we all have too good cause to know, is subject to great vicissitudes; so is mining. When a mine is opened in one of the Australasian colonies it is seldom worked at the undivided risk of one individual. When the scheme is matured it becomes a company. The chances of a large fortune may be less for the original proprietor, but the chances of great loss or ruin are proportionately diminished. The prosperity of our Australasian Colonies is greatly owing to the facilities for investment afforded by companies, the original capital of which is subscribed for in shares of from £1 to £10 each. This gives the small capitalist a chance, and minimizes the risk of the richer investor. These companies are not formed for mining investments only: banks, saw mills, manufactories, shops, &c., are among the number.

I cannot help thinking that were more estates turned into companies in Ceylon it would have a great influence in re-establishing the prosperity of the colony. Large companies are not required; small companies, with capitals of from £5,000 to £20,000, are. At first these would have to be commenced in Ceylon itself, but they would soon attract capital from England. At the present time, were any good tea estates to be offered as limited liability companies, I believe London capital would not be wanting. But the greatest benefit such companies might confer upon Ceylon would probably arise from the opportunity it would give to small investors; they would utilize what is now the idle capital of the island, the savings of members of the Civil Service, mercantile and planting communities, &c. But the advantage of forming estates into companies would not be confined to the utilization of capital only, an equally strong argument in favor of such a system of working would be in the diminution of risk. It is well known how variable the returns are from adjacent estates. On estate would pay handsomely while the next estate would seldom give a crop; this I have noticed in different cultivations in widely separated countries. Were estates cultivated by a co-operative system the loss of the bad estate would not fall alone on some unlucky investors, but would be borne by others as well, and the consequences lessened. By not putting all the "eggs" in "one basket" planting would become a much safer investment. Instead of each individual who wished to cultivate cacao, cinchona, tea, spices or coconuts having to open up clearings for the same, in different parts of the country, would it not be more to his advantage to be able to buy shares in estates cultivating the product he fancied? The special cultivation would be on a larger scale and most likely under better management than the single investor, on a small scale, could afford.

Times, I believe, are hard in Colombo, and estate stock-broking might in time become a persuit of considerable advantage to members of the mercantile world in Ceylon.

To recapitulate: I again say "Union is strength," divide the risk, instead of being dependent upon one crop in one district let the planter consider whether his capital would not be better laid out in various crops in different parts of the country. The cost of management may be slightly increased, but the results will be safer and planting investments less speculative. H.

London, April 10th, 1887.—Local "Times."

SILK IN INDIA.

The Indian silk industry is the subject of more attention now than it has been since the days of its greatest importance. Sericulture received a great impulse from the European early settlers, who built factories for the production of the raw material. These factories were large massive buildings erected in wide enclosures and protected by high walls. The residence and factory buildings were generally laid out in such a manner that the whole enclosure could be turned into a fortress if necessary. As the country became more settled, European capitalists stepped in, and travellers passing through the silk districts at the present time will observe standing monuments of the period of keen competition. It appears to have been the custom in those days to erect princely mansions with imposing gateways to prove to the rearers of the worms and to the country in general the wealth and greatness of the owners. But there was a business idea underlying this display of ostentation in the jungle. The substantial show was meant to attract the rearers of cocoons on the look out for good prices. If one of these mansions secured the title of "Burra Koti," the monopoly was secured to the fortunate owner, and other competitors had to retire from the scene, leaving piles of masonry as monuments of the fruitless contest. This process practically left the monopoly of the silk industry in Bengal in the hands of a small group of capitalists, carrying on operations in widely separated districts. As the industry prospered, operations were extended, out-factories were built, and the old contest was renewed. At the time of this revival Cora silk was greatly in demand for export, thus causing a local demand for raw material for the native looms, and the inferior native reeled silk commanded almost as good prices as the finer quality reeled by European filatures. The native was thus able to raise his prices for cocoons, and the market was immediately affected.

The European owners of filatures agreed not to outbid each other, but to purchase cocoons at market rates. This, however, led to no improvement, and the manufacture of fine raw silk for export rapidly changed from an important industry into a mere commercial speculation, such as it is to a large extent at the present day. Rightly or wrongly, Bengal silk has always had a bad name, but it would appear from the prices now ruling that it is in every way as good as Italian, if not superior. All that can be urged against Bengal silk is that, owing to a certain want of firmness in the cocoon, the result of reeling is not all that might, perhaps, be desired. The producer of the Indian cocoon is in some important respects like his brother, the cultivator of the soil. You may point out to the latter how he may grow the best wheat in the world, but unless you can prove to him that the result will place more rupees to his credit, your teaching will be utterly disregarded. But the moment you show him that it is to his personal profit to use improved seed or better methods, the cultivator is surprisingly ready to take advantage of any counsel. In the same way the rearer of cocoons has found from practical experience the quantity of mulberry leaf it pays him best to allow his worms to consume in order to give him a certain gain, and to this present day it has been found impossible to convince him that it would pay to rear cocoons of the Italian quality. When he once sees this he will change his traditional tactics, but not till then. At present, the rearer finds it pays him best to half starve his worms; his father did so before him, and he will continue to do so as long as it pays. He is quite content with the result, and it is not yet ascertained by his teacher that the delicacy of Bengal silk may not after all be due to the process of feeding and forcing in vogue. As a matter of fact the various worms to be seen in Bengal are of a very mongrel description. Some rearers attempt to classify and keep the breeds separate, and succeed partially in doing so, but the difficulties in the way are enormous. In this matter the native would appreciate help and advice from Europeans, but unfortunately the Europeans most capable of aiding him have no time to devote to the subject, and still less to give to the somewhat delicate task of popular instruction.

During the past few years, however, a very considerable amount of attention has been directed to the study of silk, and it may be hoped that the movement—for it is nothing less—will not be without its effect on the practical working of the industry. In England quite a host of men are interested in the future of Indian silk; Mr. Rondot, on behalf of the French Government, has been making a searching study of Eastern silks and dyes; and not many months ago Mr. Thomas Wardle, of Leek, who visited India in connection with the silk collection for the London Exhibition, gave a new and more serious turn to the industrial phase of the enquiry. The Revenue and Agricultural Department has given some attention to the matter, but it may be worth while to consider whether Government might not with advantage make silk the subject of a special enquiry, and do what it can to turn the present movement to account. The time is distinctly favourable for some such action, and there can be no doubt that for want of a fixed central agency a great deal of valuable information is lost, and the development of the industry is retarded. It would be important if a public Association could be formed for the purpose of fostering the study of the special subject, and in these days the manifold difficulties and discoveries in the silk world are adequate to the sustenance of such an Association, and its necessary pendant, a monthly periodical. We understand that a laboratory for the study of Indian silk producers is to be established at the Imperial Museum Calcutta, and that Mr. Wood Mason, the Superintendent of the institution, is already engaged in the work of studying and classifying the worms, and in making accurate drawings of them in the various stages of their development. He has succeeded in rearing some very shapely cocoons, in spite of many drawbacks, and the further results of the work will be looked forward to with great interest by all who have given any attention to the subject. It is by means of such an enquiry, carried out to its logical sequence, and aided by a strong alliance of fellow-workers, that we may yet hope to see a languishing industry revived, and the Government freed from the reproach of neglecting one of the commercial resources of the country.—*Indian Daily News.*

[What about the promising experiment by Mr. Ross of Kowdapellella with silkworms brought from China or Japan and by Mr. Robert Fraser of Waripolla?—ED.]

COMPOSTS FOR POT PLANTS.

One of the most important matters connected with the cultivation of imported or acclimatised plants,—which have in this country to be cultivated mainly in pots or restricted borders, frequently under glass or carefully shaded houses, and have, as a consequence, to be constantly supplied with water by artificial means—must always be the constituents of the soil in which they are potted or planted. Although certain plants—the Croton for instance—appear to be not over particular as to what description of soil is used as a basis for a compost, yet even such plants attain to different degrees of health and vigour when the soil most suited to their nature preponderates. Good culture in all other respects lessons the evils arising from a misapplication of soils; but when a plant finds its element in this respect, and is otherwise

properly cared for, its character is developed with more freshness and vigour.

We believe it is correct to say that the chief features of the horticulture of the present, as compared with that of the past, is that complicated mixtures of soils and manures are less used and believed in as "the secret" of successful culture, and that the tendency is still in the direction of simplicity in this respect. Mixtures when compounded from fancy, and with little knowledge of the elements of chemistry, may or may not be compounds of evil. After many years of extensive practice we are thoroughly convinced that the mixing of different sorts of soils and manures for potting plants in general is an evil to be avoided, and feel certain that a plant that thrives in loam will thrive better in it ultimately—make a more healthy and robust plant—if there are no animal or organic manures mixed with the turfy loam. We of course mean all organic manures of a rapidly changing character which putrifies, even though in that process the substances formed are highly important to plant life. All such, and humus of every description, are best left out of the soil in which all the slower growing and more hard wooded plants are potted, if they are to be healthy, floriferous and long lived. By so doing the soil runs far less risk of becoming what is well understood by the term soured, and, of course, unhealthy. It may be asked, are the excrements of animals and decaying vegetation not beneficial to such plants? Undoubtedly they are; but not mixed in with the soil in a narrow, deep vessel like a flower-pot. Such highly stimulating, and more or less fermenting, substances are best applied as a top dressing when the plants require it. The turfy loam generally used for potting possesses, at first, much organic matter, of a less rapidly changing (because to some extent differently incorporated with the soil) as well as of a more natural character; and as a rule no other manure need be mixed with the ball of earth in the pots, unless it be of a less rapidly changing character, such as ground bones. Take for instance a Croton and a Dracæna—plants of very diverse characters. They thrive splendidly in light turfy loam, and require nothing else till their pots get pretty well filled with roots. Then a top dressing of rich manure is of immense benefit to them, which if mixed with the soil at the time of potting, is not only unnecessary but positively injurious. The roots which these two plants make in the loam pure and simple, with perhaps the addition of some charcoal and bones, are far more numerous, and of a different character to those produced in soil made rich and soft with rapidly decaying manure, in which the roots are long and less twiggy, escaping more rapidly down among the drainage into simpler and sweeter fare.

As a rule we neglect far too much of nature's rule of potting and nourishing her children. We put manure of a too gross nature *into* the soil; Nature lays it on the surface. We give narrow, deep body of soil, with comparatively little surface exposed to the air, and that little is far too often a mass of gangrene and slime: on the other hand nature, as a rule, gives a shallow body of earth with a great wealth of surface clothed with living verdure of some sort. In all these respects we cannot in small gardens or houses follow the lead of nature in the culture of plants in pots. But the further the departure from her ways, the more likely we are to be in error. We can however top dress more and mix less humus *in* our soils. Who will say that flower-pots would not be better if made a little shallower and a little wider? With regard to the mixing of stones or charcoal, or clean broken potsherd, this can be followed without any offence to the eye, or any extra space. This we have come to regard as a cardinal point in the pot culture of nearly all plants that are not of the grossest and most ephemeral kind. Who that has had much to do with plant growing and potting has not noticed that a plant that has clean crocks, or, best of all, charcoal mixed to a liberal extent, with the soil in which it has been potted, has always been in a more satisfactory condition the next time it required a shift, than when these substances finds no place in the soil? Take any hard-wooded flowering or ornamental foliage plant, and in potting it fill one side of the pot with soil in which charcoal is liberally mixed, and the other with soil devoid of that substance, and in twelve months, when the plant needs another shift, it will be found that there are double the number of rootlets on the side of the charcoal to what there is on the other. Wherever a few pieces of broken pot or charcoal are found in the ball of a plant, there the roots are found to muster in greatest numbers and health.

The mixing of these substances, in imitation of nature's prodigality, is not practised to the hundredth part in plant culture that its good effects demand. Charcoal has a wondrous charm for roots, and is of the very foremost importance in the soil of nearly all pot-grown plants. It has a beneficial mechanical effect; has a sweetening tendency; is highly useful, absorbing ammonia and other plant food from air and water and from all decaying substances in its vicinity; while its own character is most unchangeable. It prevents stagnant water; and being such a store-house, is a safeguard against extreme drought. In the case of nine plants out of every ten, it would be well if charcoal formed a fifth part of the whole compost in which they are potted.—*Indian Gardener.*

BRAZILIAN FLOWERS.—Travellers in Brazil speak of Fuchsias 50 ft. and 60 ft. in height, blooming from top to bottom; of large bushes of Abutilon venosum, bearing a profusion of orange bells streaked with crimson; of huge Daturas, with hundreds of white trumpet-shaped and sweet-scented blossoms, some 16 in. in length; of Orchids and Ferns; huge Arums with shield-like leaves, large enough to cover a man; brilliant red and yellow Bromelias and Tillandsias; epiphytes and parasites of all descriptions; Camelias large enough to climb into to pluck the topmost blossoms.—*Indian Gardener.*

TOBACCO.—In France, in the Pas de Calais, large tobacco crops are reared. All about douai the plants may be seen reaching up to between five and six feet high, and the cultivation, treatment, and manufacture form quite an industry of the place. But the Pas de Calais is appreciably colder than the South or even the Midland parts of England. The snow rests there in winter when our landscape is clear of it. It is true the tobacco grown is but of a coarse kind. Still, its cultivation gives employment and brings in revenue. In Canada the revenue authorities are less strict. Tobacco is viewed in that colony not as a luxury but as a necessity. Every farmer is allowed to plant one-eighth of an acre with the plant, and whatever that plot produces is his own, for his own consumption. Beyond that limit he comes under the rigid laws and prohibitory penalties of the Custom-house, but so far he may go with impunity. The 5th of May, 1886, may be an important date in the future history of English revenue; but, if great results should be attained, they will certainly have sprung from very modest commencements.—*Pall Mall Gazette.*

PLANTS IN LIVING ROOMS—There was once, still is, perhaps, a superstition that plants in rooms are unwholesome. Setting aside special cases it may be said that as a general rule, plants in a living room, if they have any, perceptible effected at all, are benefical rather than otherwise. We are glad to see the Faculty taking this view of the subject. An American physician has, it seems, pointed out that by their powers of transpiring moist vapour plants render great service in rooms warmed by dry air. The value of plants and flowers as *dèlassement* for the weak and weary is acknowledged on all hands. Dr. Anders, according to the *British Medical Journal*, goes further and states that the pursuit of gardening, though naturally it favours rheumatism, appears to arrest consumption in persons of phthisical tendency, while the abandonment of the pursuit in other cases led to the development of the disease. Dr. Anders recomends a room well stocked with plants as a complete and agreeable health-resort free from the inconveniences of travelling and the anxiety of separation from home. We coucur with our contemporary in the opinion that the Doctor has opened up a most interesting subject for investigation.—*Gardeners' Chronicle.*

THE PAPER MAKING INDUSTRY OF INDIA.

India is very backward in the paper-making industry, although it abounds with fibre producing plants of all descriptions; and there are perhaps few countries in the world richer in these than India. Many of these fibrous plants have been experimented upon by competent men and found capable of yielding a very abundant and never failing supply of sufficiently cheap and excellent materials for paper-making of all kinds. The following is a list of some of the most important indigenous plants in India which produce fibres most useful for paper-making :—

Venday or Bhendicai (Abelmoscus esculentus)
Toothee nar (Abutilon indicum)
Kasini or Pulchi nar (Hibiscus cannabinus)
Janapa nar (Crotalaria juncia)
Yercum, Mudar (Calotropis gigantica)
Ganja plant (Cannabis sativa)
Coconut fibre from leaf stalks, (Cocos nucifera)
Palmyra tree fibre from leaf stalks (Borassus flabelliformis)
Country date palm (Phœnix sylvestris)
Betelnut palm, fibre covering the nut (Areca Catechu)
Screw-pine fibrous leaves (Pondanus Odoratissimus)
Pine-apple leaves (ananas) (Bromelia ananas)
Common plantain (Musa paradisiacia)
Marool or bowstring hemp (Sansiveera zeylanica)
American aloe (Agave Americana)
Various kinds of Bamboos,
Rattan canes,
Sugar cane refuse,
Arrowroot, Turmeric and Ginger stalks and leaves, Rice and other straws.
Grasses, various kinds.

There is in different parts of the country an abundant supply of certain products known to be well suited for paper-making purposes, such as sugarcane refuse, the common plantain leaf stalks, stems, &c., all which, owing to the fact of there being no demand for the purchase of such materials are allowed either to rot on the ground, or are burnt as fuel or are simply used as manuring substances for the land. Suitable pulp may be manufactured in this country from these or other materials which are at present almost wasted and rendered useless to the country; and such manufactured pulp may be used in this country for making paper of various kinds required for consumption in the country, and the surplus of pulp may be exported to European markets and sold there for profit.

It should be noted that enormous means by which wealth may be increased and the condition of the cultivators improved is lost, and vast quantities of products are allowed yearly to be wasted and treated as useless and undeveloped substances in this country. For instance, thousands of plantain trees on an average are cut down for the sake of fruit every day throughout the year. Each root-stock throws up from six to eight stems, each of which must be yearly cut down, and will yield from three or four pounds of very good fibre fit for texile fabrics, for rope-making, or for the manufacture of paper. Some very useful and tough kinds of paper have been made in India from the fibres of the plantain and paper of finer quality from the same material in France and in England. We can easily see that an enormous quantity of valuable produce is annually lost in this country through the mere want of knowledge and attention, and requisite facilities to turn it to utility.

There is an abundance of some kinds of grasses which readily grow in different parts of the country which yield materials both cheap and well suited for paper-making purposes in this country. The American aloe can be grown to almost any extent and at very slight expense in this country. It will apparently grow on the roughest and coarsest soil and needs little attention or care after it has once sprung up. We have the bamboo growing in the greatest abundance, which yields material for paper manufacture superior to any other vegetable product which has as yet been discovered. Thus we have the most valuable fibre-yielding plants such as the plantain, aloe, and bamboo in sufficient quantities to produce abundant materials for the pape trade. It is hoped that this subject will soon engage the attention of those interested in such matters, and result in the creation of new industries and the development of a large new trade which will add materially to the wealth and prosperity of the country.

Paper pulp is at present not only used for paper making purposes, but it is put to innumerable other and abundant uses in various arts and manufactures. It is employed in the construction of even such things as railway carriage wheels.

It was therefore justly remarked that the real wealth of this country had yet to be found " in its fibrous plants and many valuable vegetable products, as compared to which in value the grain produce of the country will in time be nothing." India abounds in innumerable kinds of fibres most valuable and best suited for paper-making, and as these fibres are procurable at a comparatively very small cost, there ought to be no reason, physical or economical, why paper should not, with suitable machinery, be made at a much cheaper rate than it can be imported from Europe where the raw materials are daily becoming more and more costly. One Mr. Henley, who was evidently in search for materials for paper manufacture in his country, observed that " the east coast of the Bay of Bengal, as well as Malabar on the West coast of India, are the places where the growth of suitable materials from the warmth and moisture of the climate, is most abundant, and the conveyance by sea is at the same time most easy. It is to India we must look for extensive and cheap supplies, for it is there alone we find the necessary conditions of very low priced and intelligent labour, with an abundance of elementary suitable materials."—*Friendly Visitor.*

VARNISH RESINS.

BY P. LUND SIMMONDS.

The number of substances suitable for coarse varnishes has lately become very numerous in Europe. Common resin is now purified by a patent process consisting of distillation with superheated steam, by which it is obtained nearly transparent and colourless as glass. Resins suited, however, for the preparation of the finer descriptions of varnish are still very limited. All plants produce, indeed, resins in a greater or less degree, but the trees which produce them in sufficient quantities to be of commercial value are to be found principally in South America, India, Africa, and New Zealand. These belong principally to the pine tribe, the *Dipteraceae* (only found in India and the Eastern Archipelago) and the *Leguminosae.*

Of the latter, the *Hymenaea* seem to be the trees from which the resins most nearly akin to the true hard, or fossil copals, are mostly derived. The copal of Africa and the dammar of New Zealand (known in commerce as kowrie gum), are the best known and most esteemed.

The word Varnish covers a very wide field, as the term in its fullest sense, can embrace all the thousand and one preparations compounded for as many different purposes. An essential quality of varnish is that it must harden without losing its transparency, as it must not change the colours it is intended to preserve. It must exclude the action of air, because wood and metals are varnished to protect them from rust and decay. It must also be waterproof, else the effect of the varnish would not be permanent. And a point of primary importance is that it must possess durability. New uses are constantly being found for varnish, by which it embellishes the article to which it is applied, affording satisfaction to the buyer and profit to the manufacturer. A few notes on the chief varnish resins may therefore be acceptable.

East Indian dammar is the name applied by varnish makers to the resin of *Dammara orientalis*, imported chiefly from Singapore, which is strawcoloured, or, like pale amber, very clear or transparent. It is easily and entirely soluble in benzole, ether, or chloroform, less rapidly so in turpentine, forming a clear, nearly colour-

less varnish, which dries rapidly on exposure to the air. Dammar comes principally from the Lampong islands and Sumatra, and the yearly receipts may be given at about 32,000 cwt. This resin is produced by many kinds of trees in the State of Perak. The principal are *Dammar mata kutching D. Meranti D. Lant, D. Degon*, and *Dammar Bulk*. It is the sap which exudes spontaneously, and being exposed to the air, acquires a flinty hardness, from which the epithet batu, or stone, is given, to distinguish it from the softer resins. The dammar is found either in large masses, at the foot of trees which yield it, or floating in rivers, drifted to them by the floods of the rainy season. The natives apply it to most of the uses to which we put tar, pitch, and resin. Most of the family of *Dipterocarpeæ* yield balsamic, resinous juices, those of the genus *Dipterocarpus* the wood oils, and of *Vateria* indurated dammar. The natural order abounds in Sumatra, Java, and Borneo, which are the chief sources of the dammar of commerce. In Borneo, dammar is generally found in the ground below the trees, but may occasionally be seen in huge masses, not unlike icicles, hanging from the sides of the trees. A single piece weighing 6 cwt. has been found on one tree, but necessarily these large masses get broken in collection. The value of the dammar found in the Sandakan district, North Borneo, is rarely over 10s. per cwt. Further to the north much better sorts are found, the dammar mata kutching (or cat's-eye), of Palaman, brings £2 per cwt. Of resins, chiefly dammars, we import 20,000 cwt. from Singapore, and 6,000 cwt. from Java. Two or three species of dammars are met with in British India, but are of no great commercial value. *Canarium strictum* is known in Malabar under the name of the black dammar tree, in contradiction to the *Vateria indica*, known as the white dammar tree.

The Sal tree (*Shorea robusta*) furnishes also a dammar, which dissolves much more freely and speedily in benzole than in spirits of turpentine. The resin is usually of a pale, creamy colour, nearly opaque. *Shorea sericea* yields a kind of dammar which closely resembles the Indian kind.

Hopea odorata, of Burma and Pegu, yields the rock dammar of commerce, a yellow resin which dissolves readily. The trunk of *Hopea Mingarawan* furnishes a white dammar of a superior quality. The resin yielded by *Hopea Micrantha* in Borneo, Sumatara, and Malacca is not so good, but that obtained from Belambang is much sought after for the lustre it gives. This resin is of a yellowish colour, and exudes in large lumps from the trunk and branches. It is soluble in turpentine or benzole, and forms a clear limpid varnish.

The Kauri gum of commerce is the produce of *Dammara Australis*, a coniferous tree, which occurs only in the north island of New Zealand, over a large area of land which has been exhausted by forests in past ages, and is now barren. The turpentine that has exuded from the dead trees is found at a depth of from 2 ft. to 3 ft. The export of this fossil resin has been steadily increasing the last thirty years. In 1855 only 355 tons were shipped, whilst in 1883, 1884, and 1885 the annual shipments were over 6,000 tons, valued at £320,000. We received in 1885, 81,000 cwt., valued at £254,000. This fossil resin is often found in immense masses, larger than those of any other known resin. Fine Blocks were shown in the New Zealand Court at South Kensington last year, as well as large collections of trade samples of the different commercial varieties.

Copal of Zanzibar.—This, sometimes called Indian Animé, has been found to be the produce of *Hymenaea Mosambicensis*, or *Trachylobium mosambicense*. The South American species *Hymenaea courbaril* also yield a good deal of resin. The true, or ripe copal, is the product of vast extinct forests overthrown in former ages. The export from Zanzibar averages about 1,000,000 pounds annually. The raw, or true copal, is called Chackaze, corrupted by the Zanzibar merchant to jackass copal. Copal, it may be remarked, is the Mexican generic name for all resins. Manila copal derive its name from the port from which it is shippe there are two varieties known as hard and soft Manila the hard resembles kowrie in appearance, but is inferior in quality; the soft is a pale yellow kind resembling dammar. From *Hymenæa courbaril*, the soft resin known in commerce as American copal, is obtained. The tree is very extensively diffused over the West Indies, British Guiana, Venezuela, Mexico, and in almost all the provinces of Brazil, though some other species of *Hymenæa* probably furnish the resin. It is found in many localities in a semi-fossil state, and is obtained by digging in the vicinity of the roots of the tree. The masses seem to have the appearance of a stalagmitic formation, arising from exudations from the branches of the tree dropping in the soil below. *Guibourtea copallifera* is the principal, if not the sole, source of the copal resin of Sierra Leone. All the resin exported under the name of West African copal, may be looked upon as a fossil resin, produced in times past by trees which, at present, are extinct, or exist only in a dwarfed posterity. The origin of the kind of copal known as Angola, is at present undetermined. Considerable quantities of copal are washed down during the rainy season from the slopes of the mountains. The natives subject the copal to a rude washing in lixiviated ashes, whereby the outer crust and its impurities are partly removed. It has, on arrival to be further cleansed for the trade with extreme care, and without the use of acids, which are very detrimental to varnishes in causing them to run "pin-holey." The flat Angola copal is sometimes called red animi, as it somewhat resembles it in appearance and quality. It is principally sent from here to Europe and America. The rounded water nodules, known as "pebble copal," assume this form, from the abrasion consequent on their being washed down by the rapid mountain currents, from the beds of which they are obtained.

The animé of commerce is a resin of great value to the varnish maker, but it is now largely replaced by copal. The best is obtained from Zanzibar, and is derived originally from *Trachylobium mosambicense*. The finer qualities come from the northern districts of Wande. The imports are never very large, seldom amounting to 3,000 cwt. Of copal, the imports occasionally reach 20,000 cwt. but the imports from West Africa are only about 7,000 cwt. Of dammar the imports range from 3,000 to 7,000 cwt. and of kowrie gum, 70,000 cwt. to 80,000 cwt. annually.—*Journal of the Society of Arts.*

ON THE USE OF SOOT.

As an April top-dressing for wheat, soot has been applied in certain districts for very many years, with most satisfactory results. Indeed, before the introduction of Peruvian guano and nitrate of soda, it was probably the only spring top-dressing employed; while its use on certain soils was regarded more as a preventive against fungoid and insect attacks than as a source of plant food. Doubtless it is owing to this preventive property that soot has retained its position as a favourite dressing with many practical farmers, so that its cost has rather increased than decreased.

If we compare the relative amount of available nitrogen compounds supplied by soot and by nitrate of soda respectively at the same cost, the economy is certainly largely in favour of the latter; for not only is the nitrate, on account of its richness in nitrogen, much less bulky, and therefore less costly in the matter of carriage and subsequent distribution, but there is the advantage that it can be purchased with a definite guarantee as to its chemical composition; whereas soot is subject to all kinds of adulteration, and its quality, moreover, must necessarily vary with the character of the coal consumed in different localities so that it is quite impossible to get any quantity at a uniform standard of purity. The only ready test of quality is its weight per bushel, for the less the weight the richer in ammonia-salts, and, consequently, the more valuable the soot. As we shall presently see, upon making a careful comparison of the chemical composition of the best qualities of soot with ordinary nitrate of soda, the latter is the more valuable of the two if we consider it simply as a

source of manure; and, further, this opinion has been borne out by actual field experiments. If, therefore, soot is to be preferred in certain localities, it must be on account of properties other than those of a manure pure and simple. From a number of analyses it will be sufficient to select the two following ones as fairly representative of average good commercial soot, which are placed by the side of a very poor sample for better comparison.

	Good soot.		Bad.
	No. 1.	No. 2.	No. 3.
Water	4·90	2·37	2·40
*Carbonaceous matters	33·01	49·01	41·86
Tar and hydrocarbons	27·42	15·83	·30
† Chloride of ammonium	5·69	7·49	trace
† Sulphate of ammonia	4·09	·81	·89
Oxides of iron and alumina	7·48	7·70	14·16
Sulphate of lime	4·49	2·72	5·36
Sulphate of Magnesia	·50	·86	·18
Siliceous matters	12·41	13·21	34·85
	100·00	100·00	100·00
*Containing nitrogen (insoluble form)	1·66	1·24	1·25
Equal to ammonia	2·03	1·50	1·51
†Containing available ammonia	2·85	2·59	·23
Total ammonia	4·88	4·09	1·74
Matters insoluble in water	74·60	82·20	91·75
Matters insoluble in spirit	57·90	73·70	96·90

From the above results it will be seen that good soot should contain at least 4 per cent of ammonia, and not more than 20 to 21 per cent of mineral impurities, such as sand, oxides of iron, and alumina. No. 3 shows us the composition of a very inferior quality, there being nearly half its weight of mineral matters, while the total ammonia is not more than 1·74 per cent. It is important also to notice that of this 1·74 there is only ·23 present in the form of available ammonia, as compared with 2·85 in No. 1, and 2·59 in No. 2, samples. This comparison leads further to the observation that even in No. 1, the best sample, there is only 2·85 of the ammonia present in a form available as plant food, the remainder 2·03 existing in a condition insoluble in water, and probably of very little practical use to the growing crop.

Indeed, a glance at the above analytical results will at once show that, so far as a source of fertilising matter is concerned, it is only the available ammonia that is of any manurial value in the soot. This ammonia is in fact, present in the form of an ammoniacal salt, sometimes in union with chlorine, and sometimes—perhaps more frequently—in combination with sulphuric acid, which latter is produced from the sulphur present in the original coal.

It will be further noticed what a large proportion of the three samples is insoluble in cold water; thus, in No. 3 there is nearly 92 per cent., in No. 2 as much as 82, and in No. 1 there is still 74 out of 100 that is of no use as a soluble manure.

It is therefore worth while, in these days of agricultural depression to ascertain whether it is possible that good soot will be an economical source of soluble nitrogen as compared with nitrate of soda. For this purpose we will assume that commercial soot of good quality, representing the mean analysis of Nos. 1 and 2, can be obtained at 6d. per bushel weighing 28 lb. Also, that good nitrate of soda, testing 95 per cent purity, can be obtained at 12s per cwt.

Nitrate of soda compared with ordinary soot.

	Nitrate of soda.	Soot.
	1½ cwt,	36 bushels,
Quantity of manure per acre	168 lb.	=1008 lb.
Cost of manure	18s.	18s.
Soluble nitrogen	26 2/5 lb.	22 3/5 lb.
Equal to ammonia	32 lb.	27½ lb.

From these figures it will be seen that, with the expenditure of the same money, the nitrate gives nearly 5 lb. more of available ammonia, and that, in order to make the quantities equal, it would be necessary to apply 42 bushels of soot, costing 21s., as against 18s. for the nitrate of soda.

In other words, the latter would appear to be quite 16 per cent cheaper than soot at 6d. per bushel, and that unless the price is 4½d., the farmer had far better use nitrate of soda as a top dressing for his wheat. Moreover, in these calculations only the original cost of the manures has been considered; but if we compared the extra cost for carriage and distribution caused by the increased bulk of the soot, the difference in the expense would be still greater. Thus, 42 bushels of soot at 28 lb. each, would represent 10½ cwt. as against 1½ cwt. nitrate of soda.

Let us next ascertain how far these chemical calculations have been borne out by actual field experiments, and we cannot do better than refer to a most exhaustive paper, "On Experiments with Different Top Dressings upon Wheat," by the late Dr. Voelcker, which was published in the Journal of the Royal Agricultural Society in 1862.

The experiments, which were carried out on the College farm at Cirencester, include a number of different kinds of manure; but for our immediate purpose it will only be necessary to refer to those we are now comparing, namely: a dressing of 1½ cwt. nitrate of soda gave an increase over the unmanured plot of 10¾ bushels of corn and 10½ cwt. of straw, while 32 bushels of soot gave only an increase of 7⅝ bushels of corn and 6¼ cwt. of straw, the nitrate thus giving an increase of nearly 25 per cent more corn and 35 per cent more straw than the soot. Both manures were carefully analysed, and found to be of good quality.

These results, therefore, fully confirm the previous calculations respecting the agricultural value of the two dressings, and it seems therefore desirable, at present market prices, to confine the use of soot to those districts where it can be obtained for about 4½d. per bushel, and also to certain cold damp clays, specially liable to produce mildew, but upon which soot seems to exercise its popular property of averting this disease. Indeed, if we refer to the analysis of No. 1 sample it will be seen what a much larger proportion of tar and hydrocarbons there is, as compared with No. 2 sample, there being 27·42 in one case, and only 15·83 per cent in the other; while in No. 3 there is only a mere trace.

It is therefore important to have as much of these compounds in the soot as possible; and the extent to which a sample is soluble in spirits of wine will be a useful indication of its quality as a preventive of fungoid disease, as well as against the attacks of insects.

In regard to this latter point there can be no doubt that it must be most effective, acting both mechanically and chemically. Further when applied in large quantities, such as forty bushels per acre, soot must supply a warm covering and protection from cold wind to the young plants, and its dark colour favours the increased absorption of the sun's heat rays.

In conclusion, it may be repeated that as a simple manurial top-dressing soot cannot be economically compared with nitrate of soda, except in those districts where it can be purchased at 4½d. per bushel; but as a useful preventive against fungoid and insect attacks it is likely to be still employed with marked advantage, even when the price is as much as 6d. per bushel, provided it is of really good quality.—JOHN HUGHES, F.C.S., Consulting Chemist to the Planters' Association of Ceylon, 79, Mark-lane, E.C.—*Field.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, April 16.

An experienced authority asserts that he has increased by five per cent the yield of milk from his cows, and which his neighbours admit, by attending to the following simple rules:—Never worry the cows on their going or returning between the field

and the dairy; milk them at uniform and unchangeable intervals, say five in the morning and six in the evening; let the operation of milking be performed as gently and silently as possible; and to remember that passion and threats will not win the confidence of cows, nor will a blow in their flank be the means for dispelling their fear.

The only grain which succeeds in all soils is oats, due to the great development of its roots and leaves, that is, its organs of development. For spring oats, as well as for barley and maize, the most economic and efficacious sources of azote, phosphoric acid and potash are nitrate of soda, the salts of Strassfurt; and the dephosphoration-clinkers and phosphate of lime nodules reduced to powder. The collective dose to apply depends on the richness of the soil and the wants of the plant to be cultivated; the expenditure should, under the head of fertilizers for top-dressing spring cereals, be about fr. 40 per acre.

For barley, the Chevalier is the pet variety; for oats, the Canadian or the Hallet Tartary. The practice of farmers, residing in different and distant districts, exchanging grains for sowing, cannot be too highly encouraged. The vigour of a plant at its first stages depends uniquely on the reserve of aliment contained in the grain. This magazined food is destined to furnish the plant with all its nutrition, till the moment where the development of its roots and stem permits it to rely on the air and soil. Hence, the importance of seed being dense, plump, flat and heavy, and the utility of sifting out of cereals intended for sowing all seeds either light, small or shrivelled. In the case of oats 75 per cent of the grains germinate, for barley 88, and maize 70. To germinate, oats must swell to the extent of 60 to 70 per cent of their weight of water, and which is absorbed in soils of ordinary humidity in twelve or twenty-four hours. When the soil has a temperature of 65 or 66 degrees, germination will take place in the course of two days, but not till eight days if the temperature be as low as 39 degrees. Above 86 degrees the grain will not germinate at all. On an average the germination is effected within six to seven days.

These conditions are modified by the depth to which the seed is buried; in compact clays one inch of covering will suffice; for soils of average consistency 2½ inches in depth, while in light sandy land a covering of 3 to 3½ inches will be required. The growth of the plant commences by the development of three rootlets; next, by the first leaf. With a soil of 65 degrees temperature, the daily increase of the stem is less than half an inch. Oats require a larger sum of heat to mature than barley, and the average period of maturation may vary from 134 days as in England to 100 round Paris, and only 88 at Kœnigsberg in Prussia. Oats should be sown in 6 inch rows. Barley possesses the faculty to germinate at a soil-temperature of 97 degrees, while oats can only sustain that of 85; this explains why in warm latitudes barley replaces oats in the alimentation of stock. Barley will germinate after absorbing 55 per cent of its weight of water. Around Paris it ripens in 96 days, while in England it takes 127. Maize exacts only 44 to 50 per cent of water to germinate; from its appearance above ground, till coming into flower, 45 to 105 days are required; 15 to 18 more for fecundation, and 40 to 80 days to mature. In France, the total mean time from the sowing of maize to its reaping 104 to 130 days, and even more are necessary.

Since ten years a professional agricultural school has been established at Haroué, in Lorrain, by Monsieur l'abbé Harmand for orphan girls, and which is conducted by the Sisters of Charity. The area of land attached to the institution is 35 acres; it is worked almost exclusively by the pupils and their mistresses. Practical everyday instruction is not only given in household management and the elements of ordinary education, but in kitchen gardening, floriculture, small farming; the culture of fruit trees, vines, hops, tobacco, &c.; dairy management, poultry, and the rearing of cattle. The school is a success, and the girls are eagerly sought as servants and wives. Would it not be time to make farmers' daughters at least as well-informed as their helps?

In Belgium, farmers are compelled by law to keep down weeds on their holdings, so as not to allow propagation by the wind carrying away the seeds. The farmers have petitioned that the State should take the beam out of its own eye, by ordering that all the vacant land it owns be kept clear of weeds, and that the roadsides especially be maintained as a model in the way of freedom from weed propagation.

The truth is now making way that meadow lands require their fertility to be as much studied as tilled soils. Indeed, when the grasses commence to get thin and dwarfish, when irrigation too fails, something is wrong with the soil. It wants potash and nitrogen, or, it may in addition be sour. If the latter, commence by drainage and fresh limings; next apply fertilizers, such as potash or bone dust singly, or in the proportion of two of kanite and one of bone powder. This dosing will not only augment the yield, but the quality of the grass. There was a time when potash alone was relied on as a sufficient top-dressing for pastures; it was concluded, meadows contained a sufficiency of the other elements of plant nutrition. This belief has been of late shaken by the failure of potash to act as a heal-all, because when phosphates are added the efficacy of potash becomes developed, proof that phosphoric acid was wanting, and when co-operating with an alkali, the best action of both stimulants were obtained.

Tobacco culture is making rapid strides. The secret of success perhaps lies in the preparation of good compost or mould-manure to form the nursery beds. The compost should be prepared twelve months in advance, and blood and urine will form excellent ingredients. The site for the beds should be such as to secure sunshine from nine in the morning till four in the afternoon. Many enclose the beds with bricks or boards, so as to keep the farm-yard manure, which ought to be two feet thick, and the compost well together to produce heat—it is in March the seed is sown—for the young sprouting plants against the chance rigors of spring. Over the trampled-down manure the compost should be placed, the first layer three inches, and also trampled, but the next left loose. Mix the seed with ashes and a little of the compost, sow broadcast, rake in, cover with matting, and regulate air and light, till the young plants are able to hold their own. If watering be necessary, leave the water in the pot exposed to the sun a day before being employed.

In planting out, care must be taken to water liberally, so that the rootlets can readily take up sap when dibbled in the field. Water after dibbling. Good black calcareous soil suits tobacco best. And the soil must be kept rich by winter manurings, and not too often stirred, as this might induce excessive porosity, and hence dryness. The soil before planting out cannot be rendered too friable by skim-plough, harrow and roller. In soils not the best for tobacco culture, such should be well dosed with sulphates of potash and lime. Bad land produces a tobacco without much flavour, and which burns badly. Dibble the young plant in firmly 24 by 16 inches in straight lines.

If after some days any of the plants fade replace them. Hoeing, earthing, stripping off the lower leaves, and nipping the top shoot of the plant, so as to leave 8 to 10 leaves, is all that is necessary. The tobacco raised on plains is more aromatic than that grown in a garden, while that produced on some southern slopes is superior to both. Tobacco succeeds all crops in a rotation if the soil be rich. In Alsace it follows best after maize and beet. Both the large and narrow-leaved varieties of tobacco are cultivated. In France the revenue officers insist upon the plants being spaced at fixed distances according to defined regions. In the south 4,000 plants per acre is the government number, while in the north it is 20,000. In Alsace 12,000 plants are limited to an acre.

The harvest generally takes place at the end of August, and the plant is considered ripe, when on cutting the stem a reddish circle appears. After

being cut some leave the plant a few days to fade, others transport it under sheds to dry, and later, roll the leaves in linen cloths or press them between bundles of oaten straw. The object is to obtain a leaf that will be at once aromatic and burn well. From 5 to 15 cwt. is the average yield per acre in southern and northern regions respectively. The question may fairly be raised, is tobacco culture profitable? Many farmers will not hesitate to say directly it is not, but indirectly it is the best preparation for any succeeding crop.

Dr. Hector George, Professor of Hygiène in the Agronomical Institute of this city, draws attention to the sanitary influence of light in favouring the formation of blood globules, and aiding all the functions of life to their fullest extent and intensity. Light revives and stimulates energy in the animal economy, assists to purify air by destroying malaria germs. Light is salutary for the young by aiding growth, and for the aged by filliping sluggish nerve-organs.

It may be useful to dwellers in the bush to known that carpenters frequently cut rafters according to this rule: Multiply the span in feet by 6, and point off one right hand figure, as in decimals. The left-hand figures are feet and the other inches; thus, for a roof of 28ft. span x 6=16·8, or 16ft. 8in. This is not quite one-third pitch, and makes a good roof.—*Queenslander.*

Benjamin Hepburn, of Ballarat, Victoria, makes known in the *Australasian* the following antidote to strychnine:—The remedy is salad oil first, and afterwards castor oil. In three cases of his own stud greyhounds he has proved its efficacy, even although convulsions had already commenced. He gives a small bottleful of salad oil at one dose, and in about an hour's time a large dose of castor oil.—*Queenslander.*

Local Manufacture of Quinine.—A London correspondent interested in Ceylon writes:—"I have been making some experiments upon the extraction of quinine from cinchona bark and shall hope to write you shortly on same. I have extracted the quinine without using *sulphuric* or hydrochloric acid. I am surprized that no Ceylon firm has yet taken up this important matter of local extraction. Sending low quality of bark home cannot possibly pay at present prices."

The following remedy might perhaps be effective in destroying the cabbage caterpillar. It is used for the destruction of the gooseberry and currant caterpillar:—If 5 oz. of alum be dissolved in boiling water, and this mixture afterwards mixed with cold water so as to make about 18 quarts, and the fluid be applied to the bushes when attacked, the caterpillar will entirely disappear. It is a good assistaance also against the attacks of other species of caterpillar, the American blight, and aphides.—*Queenslander.*

The following letter from Baron von Mueller on the transport of cuttings is published in the *Gardeners' Chronicle*:—"To show the facility with which cuttings also of rather hard-wooded plants can be sent to very long distances, I may mention that an experiment lately instituted by me in sending cuttings of Buddleia Madagascariensis and B. globosa simply packed in wax-cloth, by post, all the way to Madras, proved perfectly successful, as stated by Mr. Lawson and Mr. Gamble, while cuttings of the large-flowered Hypericum shrubs of Upper India, and of some other kinds of plants, reached me in return also quite safely by the same simple process. The time required for the sending of these cuttings was four to five weeks."—*Queenslander.*

The diamond drill has led to a valuable discovery in South Australia. Around the township of Hammond hitherto the water found in any wells that have been sunk has invariably been too salt for use, and very frequently the residents were put to great straits when their surface supply was exhausted. The diamond drill has discovered beautiful fresh water at a depth of 230ft., which immediately rose to within 60ft. of the surface. There are many spots in Queensland where salt water only is to be got in the shallow wells already sunk, and we mention this success of the drill to encourage settlers here to bore down below the salt stratum. It is a trouble sinking a well through strata containing salt water, but with any of the water augers or earth borers this trouble is reduced to a minimum, for the salt water can be easily kept back by piping the bore.—*Queenslander.*

Tea Flushing and Sinhalese Pluckers.—While in the higher districts there has actually been a check of flushing from the drought which followed the little monsoon, in the medium districts like Dolosbage there has been steady continuous flushing keeping all hands so fully employed, that extra pay to the amount of 3d per day is being freely earned—a circumstance sure to gratify Ramasami and which will erelong induce a big inflow of coolies to share in the rupee harvest. Meantime many estates are able to get help from Sinhalese, who in some cases are glad to work along with the Tamils on day's pay. Mr. Blackett especially has quite a large force and he finds the Sinhalese boys and lads very useful as pluckers. Some of the 8-year old tea in this district is simply magnificent. Mr. Blackett had the 'flush' on one or two bushes carefully plucked and weighed the other day, resulting in 9 ounces of leaf per tree; equal to about 400 lb. made tea per acre for the one plucking! or at the rate of 4,000 lb per annum!! 'What do these planters do for the country and its people?' is a question sometimes thoughtlessly asked by a young Civilian or other newcomer. Perhaps if they saw Mr. Blackett's force of 1,200 men, women and children (Sinhalese and Tamils) and his monthly indent for 1,000 bushels of rice to feed them, the thoughtless querist might feel he had his answer.

How Moisture in the Soil Behaves.—To many it appears inexplicable how our settlers can cry out for rain within a very few weeks of the time that the fall of perhaps several inches has been recorded. The fact is easily explained when the extreme desiccation of the subsoil and even the rocks is considered. Capillary-attraction is silently but constantly at work distributing to the most attenuated film the water in the ground, so that once a series of years of deficient rainfall has occurred nothing but prolonged rain will saturate the lower ground to the point of yielding moisture to the surface instead of drawing it downwards. When prolonged and heavy rain falls, the water descends by gravity and fills all the larger spaces in the ground, the cracks, and even the rocks; then this same law of capillary attraction comes to work for the benefit of vegetation. Instead of attenuating the only moisture in the soil and retaining it, as is now the case, it causes a constant film upwards to the roots of the plant from the store pools below. It is often a matter of surprise how the roots of a tree will discover a well or a drain many feet away from the parent tree. It seems inexplicable that there should be so much sense in the rootlet, but a little thought about the action of capillary attraction will explain the proceeding. From such a well or drain there is this constant film of water being spread out; no matter, though it is many feet off the root, yet the moist film touches it and the root follows the lead until the fountain's source is reached. Besides, while the lower ground is spreading out the moisture in the way just mentioned, it must be remembered that the young growth of succulent grass which has been started into to life by the rain falling upon the hot surface is a powerful evaporator of moisture; the water absolutely streams through the fresh young leaves into the hot dry air, and in order to keep this up the drain upon the moisture in the surface soil is very great, so that in a short time the supply is inefficient and the grass withers. Thus it is that the newspaper correspondents' reports of the "drought having broken up" is soon followed by the unexpected cry of "drought." Unfortunately nearly the whole of interior Queensland is in this desiccated state, and nothing but prolonged rains can possibly do any real good. Even a flood would not suffice unless it were followed by continuous rains, for flood waters rush away before they have time to penetrate deeply into the earth.—*Queenslander.*

INDIAN TEA COMPANIES.

(From the "*Pioneer's*" *Calcutta Commercial Reporter.*)
CALCUTTA, April-May 1887.

TEA.—The report of the Managing Agents of the Adulpore Terai Tea Company shows that the outturn was 684½ maunds, against an estimate of 700 maunds and an outturn in 1885 of 690 maunds. The price realized was As. 8-1 57 against As. 10-4 last season.

The report of the Managing Agents of the Bengal Tea Company shows that the yield was 3,605 maunds, against an estimate of 3,600 maunds and an outturn in 1885 of 2,795 maunds. The fine tea realized an average of As. 8½ per lb. against As. 10 1-6ths in 1885, and the coarse 5 5-12ths per lb. against As. 6⅝ in 1885. The gross revenue for the year was R1,37,172, and the expenditure R1,17,751, leaving a profit of R19,421, and, adding the balance brought forward from 1885, the amount at credit of Profit and Loss is R34,455. A dividend of 3 per cent will be paid and R6,000 will be carried forward. This is the first dividend for many years. The area of the gardens under plant is 1,292¾ acres. The estimate for 1887 are for a crop of 3,000 maunds fine, and 1,400 maunds coarse, tea at an outlay of R1,42,400. The Manager hopes to plant out 200 acres of flat land by next cold season.

The report of the Directors of the Bishnauth Tea Company discloses an outturn for the past year of 492,315 lb., against an estimate of 492,000 lb. and an outturn of 331,412 lb. last year. The teas have all been shipped, and so far have realized an average of 10d per lb. against 1s 3d per lb. last year. The revenue account shows estimated receipts of R2,82,842 and an expenditure of R2,49,582, leaving an estimated profit of R33,260, and, adding the balance from last year, the amount at Profit and Loss is expected to be R35,707, which would admit of a dividend of 4 per cent. The Directors propose to declare a dividend after realization of the crop. The estimates for the current season are for 7,650 maunds of tea at a cost of 3,05,700. The Calcutta expenditure will be exceptionally heavy as it includes some R45,000, cost of coolies. The area under tea is 1,556 acres. The dividend last year was 4 per cent. The block account stands at R8,47,010.

The report of the Directors of the Central Terai Tea Company shows that the outturn was 1,916 maunds, against an estimate of 1,850 maunds and a crop in 1885 of 1,577 maunds. The average price realized was As. 7-6·64 per lb. As. 9-4 last season.

The report of the Directors of the Cocheela Tea Company discloses an outturn of 93,455 lb., against an estimate of 90,000 lb. and an outturn in 1885 of 85,858 lb. The average price realized was As. 7 against As. 9½ for the previous year.

The report of the Directors of the Dehing Tea Company shows that the outturn was 5,196 maunds, against an estimate of 4,700 maunds, and an outturn in 1885 of 4,348¾ maunds. The average price realized was As. 7-11 against As. 9-5½ in 1885.

The report of the Managing Agents of the Dhunsiri Tea Company shows that the outturn was 1,005 maunds, against an estimate of 1,180 maunds and an outturn of 900 maunds in 1885, the average price realized being As. 9 7·29 net against As. 12½ per lb. last year. The receipts for the year were R52,010 and the expenditure R50,912, leaving a profit of R1,098, and, adding the balance from last season, the amount at credit of Profit and loss is R1,296, which will be placed to credit of new cultivation. The dividend last year was 5 per cent. The area now under plant is estimated at 300 acres, and some 25 acres, are already cleared for planting out. The estimates for 1887 are for a crop of 1,250 maunds of tea at a local cost of As. 5 per lb. The Company have ordered the necessary machinery for a saw mill to turn out 15,000 boxes a year, as a lot of fine timber is available from the clearances, and the Agents estimate a profit annually of at least R3,000 from this source. The block account now stands at R1,56,694.

The report of the Directors of the East India Tea Company shows that the crop was 310,250 lb., against an estimate of 304,000 lb. and an outturn in 1885 of 200,190 lb. The entire crop has been sold at an average of As. 8-0½ per lb. against As. 10-5¾ in 1885. The receipts for the year were R1,53,784 and the expenditure R1,70,482, leaving a loss on the working of R16,698, and the debit balance at Profit and Loss is R16,549. The dividend last year was 3½ per cent. The estimates for 1887 are for a crop of 4,782 maunds, at an outlay of R1,72,000, or 7¼ As. laid down in Calcutta. The area of the gardens under plant is 1,535 acres, and the block account stands in the books at R10,10,660.

The report of the Directors of the Majagram Tea Company shows that the outturn was 76,693 lb. against an estimate of 88,000 lb. and a crop of 84,883 lb. in 1885. Two severe hailstorms account for the deficiency. The bulk of the tea was sold in Calcutta at an average of As. 6-7 per lb. and 13,785 lb. in London at an equivalent of As. 7.

The report of the Directors of the Monacherra Tea Company shows an outturn of 2,039 maunds, against an estimate of 1,925 maunds and a crop in 1885 of 1,869 maunds. The average prices realized were:—

FINE TEA.	1886.	1885.
Monacherra per lb.	As. 8-4	As. 10-5
Julnacherra ,,	,, 7-7	,, 9-10
COARSE TEAS.		
Monacherra ,,	,, 5-8	,, 6-7
Julnacherra ,,	,, 3-10	,, 6-1

The report of the Directors of the Mothola Tea Company shows that the outturn was 1,470 4-5ths maunds, against an estimate of 1,400 maunds and a crop in 1885 of 1,351½ maunds, the average price realized being As. 10-2⅛ per lb. gross against As. 9-10 in 1885.

The report of the managing agents of the Pashok Tea Company shows that the outturn was 1,433 maunds, against an estimate of 1,450 maunds and a crop in 1885 of 1,369 maunds. The teas were nearly all disposed of in London, and the average realized for the whole crop was As. 7-10 net in Calcutta, against As. 10-4 obtained last year.

The report of the Director of the Runglee Rungliot Tea Company shows that the outturn was 1,400 maunds against an estimate of 1,250 maunds and a crop in 1885 of 1,250 maunds. The average price expected to be realized is As. 9-8 against As. 10-10 for the previous season.

The report of the Managing Agents of the Sapakati Tea Company shows that the crop was 107,145 lb. against an estimate of 96,000 lb., and an outturn in 1885 of 95,375 lb. Some 80,415 lb. were disposed of in London at 8¾d per lb., and sales in Calcutta realized As. 8-10 per lb. The average price last year was As. 9-2 per lb.

The report of the Managing Agents of the Shamshernugger Tea Company shows that the yield was 3,745 maunds, against an estimate of 2,800 maunds and an outturn in 1885 of 3,070 maunds, the average price realized being As. 7¾ against As. 10 last year.

TEA.—The report of the Managing Agents of the Bargang Tea Company shows that the outturn was 88,579 lb. against an estimate of 76,000 lb. The teas which were of fair quality were shipped to London and have almost all been disposed of at 1s per lb. which is equal to As. 10½ in Calcutta. The receipts are put down at R58,676 and the expenditure at R39,718, leaving a profit on the season's operations of R18,958, and adding the balance from 1885, the amount at credit of profit and loss is R19,947. A dividend of 10 per cent is recommended, and the transfer of R5,000 to a working capital account, carrying forward R397. The estimates for 1887 are for a crop of 1,100 maunds at an outlay of R13,000. The area of the gardens under plant is 271 acres and the Block Account stands at R1,48,500. The report is satisfactory.

The report of the Managing Agents of the Good Hope Tea Company is in accordance with its name; it discloses an outturn of 2,214 maunds against an estimate of 1,800, a crop in 1885 of 1,616 and in 1884 of 1,301 maunds a record of steady and substantial progress. The average prices realised were As 9⅜ against As 12½ in 1885 and As. 9¾ in 1884. Had prices kept up the results would have been truly magnificent. The revenue for the year was R1,03,986 and the expenditure R75,842

leaving a profit of R28,144, and adding the balance from 1885 the amount at credit of profit and loss is R34,745. Ad interim dividends of 20 per cent, exhausting R20,000 have already been declared, and a final dividend of 8 per cent. has now been paid, a balance of R6,745 being carried forward. The dividend last year was 40 per cent. The estimates for 1887 are for 2,200 maunds at an outlay of R74,456. The area under plant is 440 acres, and the Block Account R96,383.

The report of the Managing Agents of the Mohargong Tea Company shows that the outturn was 1,285 maunds against an estimate of 1,200 maunds and a crop in 1885 of 1,042 maunds. The average price realised was As.7-11 per lb. against As. 10-11 in 1885. The accounts show receipts of R50,995 and expenditure of R47,209, leaving a profit of R3,786 and adding the balance from last year the amount at credit of profit and loss will be R3,885. A dividend of 2 per cent. has been declared and R685 carried forward; the dividend last year was 5 per cent. The estimates for 1887 are for 1,300 maunds at an outlay of R44,652. The area of the Mohurgong garden is 215 acres and the Block Account R1,60,000.

The report of the Managing Agents of the Tezpore and Gogra Tea Company shows that the out-turn was 3,150 maunds against 2,318 in 1885 and 2,744 in 1884. The average price realized from both gardens was As. 7¾ per lb. against As. 10-11 for Tezpore and As. 11¼ for Gogra in 1885. The accounts show receipts of R1,21,764 and expenditure of R1,06,956, leaving a profit of R14,808 and adding the balance from 1885 the amount at credit of profit and loss is R18,272; a dividend of 4 per cent is declared on the A shares carrying forward a balance of R2,313. The estimates for 1887 are for a crop of 2,800 maunds at an outlay of R104,625. The area under plant is 667½ acres and the Block Account stands at R6,05,350. The dividend on the A shares last year was 7 per cent.

The report of the Directors of the Baintbaree Tea Company for the year 1886 shows that the out-turn was 133,653 lb. against an estimate of 128,000 lb. and a crop in 1885 of 124,480 lb. the average prize realized being As. 7½ against As. 9-5 last year. The revenue account shows receipts of R62,580 and expenditure of R57,362, leaving a profit on the season of R5,218, and adding the balance from 1885 the amount at credit of profit and loss is R7,355. The estimates for 1887 are for a crop of 2,000 maunds at local outlay of R45,000 which includes the cost of opening out and planting an additional 50 acres. The area under cultivation is 334 acres and the Block Account stands at R1,74,242. The capital of the Company is R1,60,000 and there is an over draft of R11,723 at the Agra Bank.

The report of the Managing Agents of the Ting Ling Tea Company shows that the out-turn was 862 maunds against an estimate of 900 maunds, and a crop of 794 maunds in 1885, the average price realized As. 10-10-22 against As. 14½ in 1885. The revenue account shows receipts of R51,481 and expenditure of R37,625, leaving a profit of R13,856 and adding the amount at credit of Profit and Loss from 1885, the available balance is R13,929. Dividends aggregating 8 per cent. have been declared, and R1,929 carried to new cultivation account. The dividend last year was 15 per cent. The estimates for 1887 are for a crop of 900 maunds of really fine tea at an expenditure of R40,090.

The report of the Directors of the Leesh River Tea Company shows that the outturn of the Kallagoitee Division was 1,629 maunds against an estimate of 1,500 maunds and a crop in 1885 of 1,412 maunds. The price obtained being As. 9-2 per lb. against 11-1 per lb. in 1885. The estimate for 1887 is for 1,700 maunds. The outturn of the Hope Division was 394 maunds against an estimate of 382 maunds and an outturn in 1885 of 290 maunds; the price realized being As. 7-7 per lb. against As. 9-1 last year. The prices realized are disappointing. The estimate for 1887 is 550 maunds. The accounts show receipts of £5,298 on account of Kallagoitee Division and an expenditure of £3,777, leaving a profit of £1,521 and deducting debenture interest and other charges and adding balance from last year the amount at credit of profit and loss is £955. The Hope Division shows a loss of £1,056 which has been added to Block. A dividend of 4 per cent has been paid, £250 taken to Reserve, which now stands at £1,000 and £105 carried forward.

The report of the Grob Tea Company shows that the outturn was 3,238 maunds against an estimate of 3,050 maunds, and a crop in 1885 of 2,878 maunds. The average price realized was As. 7-8 per lb. against As. 10-8 last year. The receipts for the year were R1,22,641, and the expenditure, including interest, &c. R1,34,487, leaving a loss on the working of R11,846 and the debit balance at profit and loss is swelled to R52,935. The estimates for 1887 are for a crop of 3,392 maunds at a cost of R1,15,867. The area of the gardens under plant is 798 acres and the Block Account stands at R5,59,020.

The report of the Desai and Parbutia Tea Company for the year 1886 shows that the yield of tea has been 136,226 lb. against an estimate of 136,000 lb. and an outturn in 1885 of 125,734 lb. The average prize realized was As. 9-3 16-25ths per lb. against As. 11-329-50ths in 1885. The revenue account shows receipts of R79,982 and an expenditure of R73,700 leaving a profit on the season of R6,282 and after writing off R1,416, for land purchased and adding R258 brought forward from 1885 the amount at credit of profit and loss is R5,124. A dividend of 2½ per cent has been declared and R624 carried forward; the dividend last year was 9 per cent. The estimates for 1887 are for a crop of 152,800 lb. from an area of 493 acres at a local coast of As. 5-10 per lb. which includes the upkeep of the young cultivation. The Block Account stands in the books at R1,50,433.

The report of the Managing Agents of the Phoolbarrie Tea Company shows that the outturn amounted to 239,374 lb. against an estimate of 273,000 lb and an outturn in 1885 of 247,774 lb. the average price obtained being slightly over As. 8¼ per lb. against As. 10⅞ per lb, last year. The Revenue Account shows receipts of R1,27,002 and an expenditure of R1,01,460—which includes interest on debentures, preliminary expenses, and amount written off Block, aggregating R9,393—the nett profit being R25,542, and adding the balance from 1885 the amount at credit of profit and loss is R25,647. A dividend of 5 per cent has been paid and R47 carried forward;—the dividend last year was 9 per cent. The estimates for 1887 are for an outturn of 3,550 maunds at an expenditure of R100,000, or a little under As. 5¾ per lb. The Company has suffered a loss in the death of its garden manager, Mr. C. H. Pillans. The Block Account stands at R5,26,036.

The report of the Managing Agents of the Washabarie Tea Company shows that the outturn was 2,724 maunds against an estimate of 2,200 maunds and a crop in 1885 of 1,686 maunds,—the average price realised being As. 8¼ per lb. against As. 11 1-6ths last year. The Revenue Account shows receipts of R1,10,287 and expenditure of R79,485, leaving a profit of R30,802 and adding the balance from last year, the amount at credit of profit and loss is R32,046. Dividends aggregating 10 per cent have been paid, R8,010 taken to extensions, R4,385 written off machinery and R4,651 carried forward, the estimates for 1887 are for a crop of 3,000 maunds at a total cost of R77,922. Proposals are in circulation to transfer the Company to London and to alter the capital to a sterling one of £25,000. The area under plant is 523 acres and the Block stands at R211,872.

A return of R16 per share has been made to the shareholders in the Gowhatty Tea Company.

TEA.—The first annual report of the Managing Agents of the Chapagurie, Tea Company for the season ended 31st December shows that the area under plant is 305 acres, of which 170 acres were planted in and before 1884, 50 acres in 1885 and 85 acres in 1886. The outturn for the year was 422 maunds, against an estimate of 340 maunds, and the average price realized, As. 6¼ per lb. The receipts were R14,456 and the expenditure R42,441, the balance being transferred to Block Account which stands at R94,686. The estimates for 1887 are

for 850 maunds of tea at a total cost of R58,261, which includes cost of boiler, engine and drying and rolling machines, as well as of putting out 55 acres more tea. There will probably therefore be a deficiency of R24,261 on this season's working, which can be added to Block.

PLANTING IN NETHERLANDS INDIA.

(Translated for the *Straits Times*, May 11th.)

In the province of Pasaruan, the Resident has forbidden the people to take away young bamboo shoots from clumps of that plant. These shoots are largely used by the natives as an article of food, and as such are sold in the markets in hundreds. Among the poorer classes, slices of bamboo shoots are the only relishes to rice. The prohibition has been promulgated to save the bamboos there from total extermination, but will be found hard to enforce.

In the Lampong districts, according to the Batavia *Nieuwsblad*, disease has broken out among the pepper plantations. The Resident of the province has forthwith repaired to the spot to make enquiries. His report on the subject is already in the hands of Government. The spread of the disease will prove detrimental to the wellbeing of the natives in that quarter. Experiments with tobacco growing there, have so far not led to any satisfactory results. Tin has also been sought for in the Lampong districts but hitherto without encouraging results.

CHINA TEAS GOING OUT OF CONSUMPTION.

The London Tea Broking Firm whose China tea circular we quoted lately, have since issued the following:—

DEAR SIRS,—Since we had the pleasure of writing you last week the position has become more acute. It is no use China buyers any longer living in a "Fools's Paradise," the fact staring them in the face is that China tea is going out of consumption with the most alarming rapidity. For example the delivery of congou last month (March) was 8 millions; if we allow 2½ millions for export, it leaves 5½ millions for Home consumption against 7¾ millions of Indian growths, and for the first three months of the year figures stand thus:—Congou deliveries 1885, 33,253,000 lb. 1886, 29,103,000 lb. 1887, 23,500,000 lb. If figures prove anything this should be tolerably convincing.

In former years when prices materially gave way, consumption quickly responded, but not so now. The trade find that they can get such value in Indians at 6d to 7d that common Chinas are dear at less than the cost of production, that is to say we take it that Shuntaams cannot be laid down here at 4½d, nor common whole leaf red at 5d with an export duty of Tls. 2-8 included.

At the opening of your markets it would seem that exchange would be lower than ever before known, freights may be, as well as Marine Insurance. If the differences on all these are to be calculated in the laying down cost and given to the Chinaman "the game is up." For there to be any safety in the trade, you must pay the teaman (and so the grower) a tael price that will not induce him to pluck for quantity.

We quote a few sales made in the auction room this week:—A choice Kintuck said to have cost 1s 8½d at 11d, a few sold on arrival at 1s 5d. Another bought on speculation by a well-known judge of fine tea at Messrs. Thorne's sale in June at 1s 6d resold at 11d, an Oonfaa counterpart sold at 1s 2d, at 9¾d, a choice Ningchow part sold at 1s 5d, at 11d. "Wing Mow" a contract Pekling per mail steamer at 11½d. A choice Paklum part sold last month at 1s 2d to 11¾d.

COCAO PLANTERS are in a fair way to be strongly congratulated in Ceylon: their product is equally with coffee, rapidly approaching the round 100s per cwt. and with the good crop prospects which Matale and Dumbara as well as other districts shew, the Ceylon owners of cacao may well be satisfied.

A TRIP THROUGH THE KELANI VALLEY.

(From a Correspondent.)

I have just returned from a visit to the Kelani Valley, one of the new and flourishing tea districts. The estates are a good deal scattered through this large Valley. Starting from Avisawella Rest-house, I visited some of the estates in the neighbourhood. On Atherfield, a few miles off, I met Mr. Ingles the Manager formerly of Mariawatte; this place was looking well and I was informed that 600 lb. per acre had been taken off this property. More land was being opened and the only complaint had reference to the risk of an insufficiency of labour.

On the properties managed by Mr. Byrde I found other products, such as coconut and cardamoms but the latter, I was informed, was not productive, the elevation being too low for this kind of cultivation. Arecanuts I found were planted everywhere, the profits from this cultivation being estimated at R50 per acre. Elston, a large and fine estate with a manager and assistant, and close by is Farnham, managed by Mr. Willisford; this property looked remarkably well cared for—even the surroundings of the buildings being all so neat and tidy.

On Doranakande I met Mr. Grigson, who was busy plucking, and found it, he said, hard to keep up with the flush as many of his coolies were down with fever. From Avisawella I proceeded to Dihawita; on the way I was ferried across at two places where bridges are being built. At Dihawita Messrs. Glenny, Fielder & Co., have a store and agency under the management of Mr. Ferguson-Jones. A cart road is in course of construction between this place and Veyangoda which is about 15 miles off, passing Springvale, Brazenose and Dewalakande—the latter has a fine large iron store and is a well cultivated property under the management of the popular Secretary of the Kelani Valley Planters' Association, Mr. H. V. Masefield. At Yatiyantotte I noticed a large quantity of machinery lying on the roadside which I was informed was for Polotagama, where a large store had just been completed. I also passed through Parusella and Kelani—all very fine tea estates. I passed through Ivies near the Yatiyantotte Rest-house and on the banks of the Kelani Ganga and went on to Balgownie, near by which is the Morton estate under the management of Mr. Hope who has also the opening of Eila—a new place. On my return I visited Lavant and Ekkioya both places being worked as one property under Mr. Wright: this was as fine a block of 250 acres of tea as you could wish to see. Before leaving this district, I went to Mipitiyakande, and also to the adjoining property (Dunedin) belonging to the Ceylon Tea Plantations Co. Here I spent some hours with the courteous manager, Mr. Turpin, who has just completed a fine store and was busy planting up more land. Opposite this estate and in sight of the Bungalow can be seen the Degalessa estate, a large new clearing of over 200 acres. From Yatiyantotte I proceeded to Ruanwella, the site of a former Military station and on to Veyangoda. I passed through Sunnycroft and some other places; on the last-named place a large force of coolies were busy planting. I also passed through several new places where planting had not commenced as yet, though the land had been cleared. As I passed through the villages, I heard bitter complaints of the ravages of fever and passed a number of huts that had been recently forsaken by the occupants. These huts are built alongside the roads recently opened to the tea estates in this district, and I suppose on the outbreak of fever which has been worse than usual this year, the Sinhalese must have cleared off. On enquiry I was told that at Karrawanella there was a Doctor and Assistant and an Out-door Dispensary. The hospital, I was told, was just being built.

[It is shameful that the Government have not been earlier with their hospital, and that, so far as we can find, no one was sent through the villages in the fever districts at the out-break, to distribute fever powders. —ED.]

DURATION OF AN ASSAM-HYBRID TEA-BUSH UNDER CULTIVATION.

The question raised by Mr. J. L. Anstruther, and to which we only very hurriedly responded in our last issue, is one of great practical importance. The fear evidently entertained is that subject to the heavy and continuous pruning which tea receives at the hands of the planter in Ceylon and India, can it be fairly expected to last beyond a very limited term of years. To any one who has seen a Tea Garden after the knife has been thoroughly applied, the doubt is not an unnatural one. The sight of the bushes cut down until not a single leaf is visible is not a very encouraging one. "Can these dry sticks live?" springs spontaneously to the mouth of the observer. Now we are not going to enter on the vexed question of "pruning," further than to say that a good deal has, no doubt, yet to be learned on the subject in Ceylon, and that it would be well for planters in different districts to initiate experiments on their own account, meantime, studying all the literature on the subject, including the thoughtful paper by Dr. George King of Calcutta on "tea pruning." Already, there is considerable division of opinion in Ceylon, some with experience averring that the "annual" pruning should rather be one of "eighteen months" interval, and that a slight pruning should often be sufficient. This, of course, apart altogether from the important question raised in our letter "From the Hills" on Saturday as to whether our bushes should not be left to grow much longer than is usual before the knife is put in at all. Such is undoubtedly the opinion of a good many of our Indian critics. Some have gone the length of saying that a very few years will show the wrong principle upon which we have been acting, and that our bushes will then need a long rest and do nothing or very little for two or three years. But we do not think such gentlemen make sufficient allowance for the wonderfully recuperative character of the Ceylon climate, especially in our moist region, so far as the tea-bush is concerned, nor for the hardy character of the plant itself as exhibited even in our poorest soils.

Then as regards the life of the bush, in Ceylon even, we have some data to supply for the reassurance of Mr. J. L. Anstruther and his "Job's comforters." The first clearing in Loolcondura—20 acres—was felled by Mr. Taylor we believe at the end of 1867 and has been cropped continuously we suppose, for about 17 years. We feel sure no objection will be offered to an inspection as to its condition today. Then again Mr. C. Shand reminds us that he has tea in Kakwana—on the Barra flat which was always considered as worthless by coffee planters—under regular cultivation and pruning from 19 to 20 years. We cannot go beyond this in Ceylon but the question is well asked whether the case of cinnamon should not afford some comfort to the dubious tea planter. The same cinnamon bushes are flourishing today that have had their main stems hacked and cut away periodically for over a hundred years back and still the process goes on with good results over the same roots and stumps.

But it is from Northern India and Assam mainly, that we must gain the information calculated to relieve the suspicion that the tea-bush under pruning is short-lived. One authority writing on tea either in Assam or China, speaks of 100 years as the life of a tea-bush; but we cannot recall where we read that statement whether in Fortune's or Colquhoun's book? Of more intimate bearing is the fact that the original Assam Company began operations in the "forties", their first shipment of tea being made in 1847. It will be of special interest to learn whether the clearing from which this was gathered is still in operation and if not, what is the age of the oldest garden in regular and full cultivation in Assam? This is a question which we hope to have answered in due course by one or other of the Ceylon men now in Northern India who get the *Overland Observer* or by an Assam planter who will read of this discussion in his *Tropical Agriculturist*.

THE LIFE OF THE ASSAM-HYBRID TEA TREE.

Pundaluoya, May 20th.

DEAR SIR,—Can you or any of your kind correspondents inform me of the "duration of life" in the Assam hybrid tea bush under cultivation and harvesting. I observe that "Fortune" in his book: "Tea countries of China," states "the length of time which a plantation will remain in full bearing depends of course on a variety of circumstances, but with the most careful treatment consistent with profit, the plants will not do much good after they are ten or twelve years old; they are often dug up, and the space replanted before that time." I trust for the sake of our industry, that with us the hybrid plant will live and give profit somewhat longer, although from a sympathetic point of view the poor plant having such a painful existence after we have once begun to operate upon it, it might not be desirable. While on this subject, I do not think that the mysterious mortality amongst apparently healthy bushes all through plantations, at various ages, has ever been satisfactorily explained. Can it be that the bushes lose heart at the terrible future before them, and prefer to succumb rather than brave it, or prefer death to existence under the circumstances.—Yours faithfully,

J. L. ANSTRUTHER.

[The existence of the "Symplocos" tree often accounts for dying out: see Tea Planter's Manual. As to the age of the Assam-Hybrid bush under cultivation, we do not see why it should not flourish and bear profitably for 30 to 40 years and there must be gardens of that age in Assam. We shall endeavour to make sure on this point.—ED.]

COFFEE, CACAO AND TEA PROSPECTS.

Our South-west monsoon, in the opinion of the most competent local authority, Master Attendant Donnan, may be considered to have fully set in at Colombo and the biggest thunderstorms of the season may be regarded, we fancy, as being over. But there will be some more rain yet to come, although April gave us nearly three times its average, and the total for the year is also above the average. Thus the average of 17 years' rainfall at Colombo for the first five months is almost exactly 32 inches, whereas to date (21st May) we have had over 35½ inches, of which no less than 23·80 inches fell in the one month of April. We have therefore no reason whatever to complain of our South-west monsoon allowance at Colombo. But the case is very different upcountry, where "a failure of monsoon" has already been an alarming note sounded from some districts. This cry is, however, premature; there is plenty of time yet for plenty of rain, and even now heavy clouds are moving on from the Indian Ocean across the lowcountry to the hill districts to gladden the hearts of the tea planters and render them as busy as possible

over the flushes. Already in the low and medium districts, planters have been crying out 'hold, enough' to the tea-flushes, which many of them have scarcely been able to overtake with their supply of plucking hands. Labour seems to be the only ticklish question in connection with the future of our great tea industry and even here, light is now breaking in from several sides; for, besides that coolies are reported to be coming in from the Coast far more freely than in previous years, in quite a number of districts, Sinhalese are coming to the rescue and showing themselves very ready to earn the tea-planters' money. Extra pay too in the busy flushing season is sure to be popular and must speedily attract the poor people of Southern India in large numbers. The difficulty of getting Tea machinery supplied and erected in time is said to be bothering the planters this season: every machinist in the island is reported to be as busy as he can be, while agents for home firms have also plenty of orders; and no wonder with the large area of tea coming into bearing erelong throughout the island.

New life has also been put into other staples. The high prices for coffee,—middling plantation Ceylon being reported from London at 100s per cwt.—have cheered planters with our old staple still on their estates, very greatly. This is especially the case in the Bogawantalawa and Agrapatana divisions of Dikoya and Dimbula, in Udapussellawa, and all through Uva. The greatest possible attention will now be paid to good coffee and every effort made to arrest any signs of the new visitant green bug. As for the leaf fungus, it is scarcely, if at all, heard of now-a-days, and even the native coffee along roadsides which for years has done nothing in crops, is this season reported to be improving and shewing berries. Cacao planters are much cheered by the good prices of their product "cocoa," no doubt caused by the anticipated great scarcity of coffee—a circumstance which may well be expected to benefit tea, since if there is no coffee to drink, tea as well as well as cocoa must be taken to as substitutes.

CEYLON UPCOUNTRY PLANTING REPORT.

HOW TO MAKE TEA PAY—TRANSPLANTER—TEA PRUNING FLUSHES GALORE.

23rd May, 1887.

In a late number of the *Indian Planters' Gazette* there is a communicated article on "How to make tea pay." The writer is treating of "plucking," and the following little extract may perhaps in part explain why so many Indian tea gardens lose money for their proprietors:—"A little rum goes a long way: it is well to celebrate the beginning of the season by giving the pluckers the first day a glass of rum each, and say a bottle to the *sirdar*"! We don't all think alike, but it seems to me that the writer of the article has a good deal to learn. I fancy this "rum" dodge of making tea pay, has never occurred to even the most imaginative mind in Ceylon, and I trust it never will.

It is like harking back to something old referring to the transplanter of Mr. Scowen. But it is a tool which only requires to be used, to know its value and it is but lately I have taken to use it. I had it highly recommended to me, and during the rains in April I put out with that tool as a trial about 500 tea plants as supplies a day or two after the dry weather set in, and there was more than a fortnight of it. The plants were left without any shade, and with the exception of two or three, they stood as well as if they had never been taken from the nursery. Those that failed were evidently damaged in some way independent of the transplanting. For Supplying, it evidently means certainty, that anyhow was the character I got of the work by one who used it all last season. The coolies get very expert in handling it, after working with it for a very short time and from 800 to 1,200 plants can be taken out in a day. The carrying out is where the expense is, but if the estate nurseries be at all central, even that does not cost so very much when it is remembered that the work once done, has not to be done again.

About tea pruning there is much to be learned. How often a bush should get the knife, and where, are questions which will be undecided for a long time. It looks like as if a yearly pruning were much too often, when you hear that "Rookwood" has not been pruned for two years, and they are getting over 800 lb. an acre now.

A visitor to the Kelani Valley was telling me of the wonderful character of the tea flushes lately to be seen there, and the more extraordinary ones of which he heard. I don't care to give the average pluckings—figures you gave as extraordinary the other day are nowhere near them—besides it might set every other district "envying and grieving," but they were piled on till at last the visitor was forced to suggest a new system of measuring, which he had often to adopt himself, he said, especially in a rush. He gave the wrinkle to a man who had not been able to get round half his place in a week, and the growth was so rapid that he had always had a difficulty in saying where the former day's work had ended! "Try our plan" said the visitor "give your pluckers grass knives, stack the leaf, and measure and pay for it like firewood"!! The visitor came from one of the old districts, the fame and knowledge of the ways of which had evidently never reached the benighted Valley of Kelani. There should be no flushes lost there in the future, and their Labour Difficulty ought to vanish.

The monsoon rains seem to be fairly in, and Planting will soon be in full swing.

PEPPERCORN.

THE PRICE OF COFFEE.

Nearly a year ago the *American Grocer* gave it as its opinion that Brazil had already reached its maximum of production, a bold prophecy, truly, concerning a country of 3,300,000 square miles, or nearly as large as Europe, having a large proportion of its area still virgin forest, and a population of little more than ten millions, including rather over a million slaves. Still, there are many things which seem to support the idea gathered by the *American Grocer*. Coffee planting in Brazil cannot be considered a success so far as the planters themselves are concerned when in the Provinces of Rio Janeiro, Unias, S. Pauls, and Espirito Santo nearly nineteen-twentieths of the plantations are mortgaged. Nor can low prices be pointed to as the cause of this state of things, most of the mortgages being of over twenty years standing, a magnificent fact when we recollect the price of coffee prior to the last few years of depression. The emancipation of slaves has equally little to do with the planter's embarrassments, as the law of free birth only came into force in 1871, and though it was estimated two years ago that the whole of the slaves in Brazil would be free by 1895, there have been few complaints of the great damages which it was at one time expected would be done to the coffee industry by emancipation. At the same time, if Brazilian planters, from whatever causes, could not keep out of difficulties when they had slave labour, it is unlikely that they will be able to do so without it, so that, on this account alone, it does not seem as if coffee cultivation will be extended, either by the original planters or by fresh settlers. Vast as the forests of Brazil are, they must remain practically untouched

for years to come, until the increase of the world's population provides a class of imported labour for Brazil as good and as cheap as that employed in the East Indies. With this probably somewhat distant period it is unnecessary to deal.

The 1887-88 crop is estimated as a very short one, and consequently, the price of coffee is likely to remain high until some idea, however vague, can be formed of the prospects of the 1888-89 crop. This, with a short yield the season previous, should be large, and, if a bumper one, the last Indian quotation would doubtless come down with a run, probably below 80s a cwt. But to forecast with any chance of success it is necessary to look to the causes of the expected shortfall of the 1887-88 crop. Various reasons are given. "Prolonged droughts, followed by severe frosts" would naturally have a bad effect, but we are also told that, in parts at least, "only the new coffee gives any hope, the old, though very green and fine, has not blossomed." This, taken in connection with the accounts of serious disease, not, apparently akin to our "leaf disease," but attacking the roots of the coffee tree, which shortly afterwards dies, seems to point to exhaustion of the soil, whether from want of cultivation of whatever cause, and if this is the true reason of Brazilian short crops then indeed the *American Grocer* is correct in saying that the maximum production has been reached, and the price of coffee is more likely to be doubled than to drop. In any case, as the time approaches for the 1888-89 blossom the reports of the sanguine ones are sure to cause a fall in the quotations, which will be confirmed in the event of their anticipations turning out correct. If there is another short crop East Indian planters may reasonably conclude that the presen Brazil plantations are past their prime, and that bum per crops from them and correspondingly low prices, are things of the past.—*Madras Mail*, May 16th.

PLANTING AND MINING IN SELANGOR (STRAITS SETTLEMENTS) IN 1886.

COFFEE—GAMBIER—PEPPER—TOBACCO—NATIVE CULTIVATION—MINING—RAILWAY—LABOUR.

It is satisfactory to find that the agricultural resources of the State are being put thoroughly to the test. Coffee-growing presents such a promising outlook that the cultivation of the Liberian variety has been taken in hand successfully by Javanese and Tamils in two districts. At Weld's Hill, fifty-seven acres under Liberian Coffee, yielded seven hundred piculs last year. Gambier and pepper are the articles that have been most productive in agriculture. Considerable areas have been taken up for growing them. At Klang Mr. Stephenson has already brought a considerable extent of land under pepper cultivation, with the result that the vines have come into full bearing. His example has been followed by Messrs. Hill and Rathbone at Weld's Hill; and by Captain Christiansen and Mr. Barugh at Batu Tiga. At Pataling, Mr. Bailey has taken up a wide stretch of land for the same purpose. Syed Zin has set to work growing gambier, and pepper at Klang. Several Chinese from the Straits Settlements, have started pepper and gambier plantations at Sepang in the Ulu Langat district. They have already cleared 2,000 acres and have 200 coolies in their employ. They have altogether secured 5,000 acres of land. Their success so far is said to augur well for the thorough realisation of their aims at no distant date. In these hard times, it is an encouraging sign to find Europeans taking up a line of plantation enterprise, so likely to yield remunerative returns as pepper growing. The field has too long been left to Chinese to profit by the steady and increasing demand for spice in Europe, and America. With European skill and business knowledge scientifically brought to bear upon pepper growing, the pioneer planters in Selangor may count upon a return handsome enough to satisfy reasonable expectations. Tobacco growers in Deli already alarmed and kept on the alert by competition looming in Siak and North Borneo, will have to keep an eye also to Selangor. Competition in their line of business in that quarter, has every prospect of becoming formidable erelong. With seeds from that Netherlands colony, tobacco plantations have been started by Messrs Hill and Rathbone at Batu under the supervision of Mr. Toynbee, a planter from Sumatra. In spite of planting operations having been set agoing late in the year the crop yielded proved highly satisfactory. The quantity and quality so answered expectations, that several European planters have applied for grants of land to be put under tobacco in the Klang district. It all depends upon the result of the first shipment of Selangor tobacco to Europe. Should the outcome prove satisfactory, tobacco cultivation in that Protected State will become an important branch of plantation enterprise.

The public interest has also been seen to by the passing of regulations checking the reckless felling of primeval forest. Measures have also been taken for putting a stop to the destructive native system of shifting the cultivation of hill paddy from place to place, as the soil becomes exhausted. Bringing the soil under cultivation permanently, has on the other hand, met with official encouragement by holding out hopes of Government aid in the opening out of land for growing swamp paddy, coconuts, and productive trees generally. Native cultivators in some cases have not been backward in taking action accordingly. In most of the districts, they have taken pains to improve their land, and to bring an increased acreage under tillage, with the gratifying result that swamp paddy has been more extensively cultivated. As must however be expected from the sparseness of the population, wide stretches of land available for the purpose far inland remain uncultivated. Malay indolence and stubborn attachment to old customs, will bar for a long while yet the march of improvement in the agricultural line. Soil and climate favour laziness among them. Paddy growing for their own immediate needs, just suits them. Plantains and a few other food articles enable them to eke out a subsistence till the following year. This easy-going system however readily it may meet the wants of the moment, runs so counter to the interests of the country, that we are glad to find the Sultan of Selangor setting a good example to his subjects by increasing the acreage he has under coffee and fruit. The path he has so far successfully trodden has been followed by his son, Rajah Kahal, and many other planters. The son of the late Rajah Muda of Selangor bears the palm for intelligently taking planting operations in hand. He has now about one thousand acres under sugar cane, coconuts, areca nuts, swamp paddy, &c. A high meed of praise is certainly due to him for showing his countrymen what businesslike enterprise can do. Another headman, Datu Dugang, has opened out in Klang, a plantation for growing areca nuts and swamp paddy on 600 acres of land, by means of Javanese labour with encouraging results hitherto. The fruit season did not turn out well, but the paddy crop proved satisfactory throughout the State. It was satisfactory doubtless as to yield, The trade returns show heavy importations of rice, the quantity required to meet local consumption aggregating upwards of 186,000 piculs, about two-fifths more than in 1885. The population in the interval barely increased by one-seventh. Evidently there is every ground for encouraging local agricultural enterprise in this direction.

Enterprise in mining affairs has made considerable head-way in 1886, judging from the tin exported totalling 99,073 piculs, an increase of about 16,000 compared with the quantity shipped in 1885. In the Kwala Lumpor district, Chinese management has again scored a success, where European methods broke down in the case of the Sunghy Puteh tin mines. These workings started by the Selangor Tin Mining Company of Shanghai, passed by purchase into the hands of Chinese in 1885. The latter have worked the mines so remuneratively ever since, by setting 1,800 men at work, that 6,120 piculs of tin

were exported therefrom last year. Profitable returns have been secured from deep as well as shallow workings. Three engines bought from the company have sufficed to keep the mines quite dry. Fresh mining land has been opened out near the railway line, and in many other localities. European tin mining enterprise in Selangor has yet a bright future before it. The Rawang mines have been kept thoroughly free of water, by a 42 horse power turbine and are susceptible of large extension. The result of mining operations on Mr. Cameron's concession at Ulu Kerling has not proved equally encouraging, owing to the ground having been only partially tested. Chinese miners have worked successfully on the adjoining land. There is no reason why Europeans, should not do well in the tin mining line provided local circumstances be duly taken into account.

The Selangor railway from Kwala Lumpor to Bukit Kuda has been so fruitful of controversy and difference of opinion, that it is satisfactory to find the Acting Assistant Resident affirming its practical success so far as local circumstances admitted. There is urgent need of extending the line either to Klang itself or to some point opposite. The latter site has the advantage from its admitting of extension to the seaboard. The railway taken altogether cost $721,473, or about $37,000 per mile. Considering the nature of the country traversed and the hindrances in the way of constructing a railway in an undeveloped country like Selangor, the Engineer in charge may be congratulated on having so creditably overcome these difficulties.

Of six weather stations, Ulu Selangor heads the list with a rainfall of nearly 286 inches last year. Kwala Selangor standing at the bottom with 67·41 inches.

The population of the State at the close of the year may be estimated at 60,000. Chinese immigration has helped materially to swell the number of inhabitants. No fewer than 8,000 new arrivals under contract from China entered Selangor in 1886. Chinese immigrants not bound by contract totalled 5,000. The aboriginal Sakei tribes have been brought under control of the district collectors, with such a marked improvement in their condition generally, that they have increased in number, owing, especially, to their immunity from small pox. Not only Chinese coolies, but also Chinese capitalists have set to work developing the mining resources of Selangor. They have so little to complain of there, that the Chinese Commissioners who recently visited the State found their condition satisfactory. With increased shipping facilities, the tide of Tamil immigration continues so to swell that the number of persons of that nationality already reaches one thousand who earn a living as coolies and bullock drivers. Messrs. Sword and Mullinghaus have secured a three years monopoly of the right to export tin ore from Selangor. They have set to work smelting tin with coal instead of charcoal, and anticipate great success from the enterprise on the score of saving of expense.—*Straits Times*, May 4th.

PLANTING INDUSTRY IN THE CAROLINES.

(Translated for the *Straits Times*, May 11th.)

The *Comercio* in giving particulars of the hoisting of the Spanish flag in the Eastern Carolins islands, so recently a cause of trouble with Germany, states that the Commander of the man-of-war, charged with this duty, has forwarded to the Minister for the Navy at Madrid, a despatch furnishing interesting details of the voyage. The first island group touched at was that of Raur composed of 17 or 18 coral islets with 600 inhabitants, the handsomest throughout the whole of the Carolines, living on breadfruits, coconuts, and fish. The only trade they carry on is in copra, in barter for tools, tobacco, and cloth. The king of the group readily submitted to Spanish rule.

The vessel then proceeded to Ifalik, a group of islets without any anchorage or inhabitants. Coconuts abound on them. After calling at other small islands, she anchored off the Hogoliu group made up of eight large islands and about two dozen smaller ones, the former mountainous and fertile, and abounding with water and fruit trees. The inhabitants, about 12,000 in number, are accounted downright savages, ugly and uncleanly. They go about dressed in skins, only those of high rank showing off in cloth. Their practice of smearing themselves with fishoil renders them disagreeable at close quarters. Being both warlike and cannibalistic, they are continually at strife with the neighbouring islanders. In the island of Mohen, a Methodist missionary named Logan is stationed. Native teachers under his supervision are labouring in the adjoining islands. The mission has been at work for three years with appreciable results. With the aid of Mr. Logan, no less than 16 chiefs were assembled together. They all signed a treaty accepting Spanish sovereignty. The man-of-war then proceeded to Jamestown on Ascension or Ponape island. It is the largest of the Carolines, and the most important from a commercial standpoint. Ascension is mountainous, abundantly watered, most fertile, and picturesque. Breadfruit abounds, and is the staple food of the inhabitants. The pine-apples grown there proved to be of highly superior quality. Of poultry and hogs, there is no lack. With hardly any tillage worth the name, the inhabitants grow sweet potatoes, sugar cane, and coffee. They are mild and gentle in disposition. The people wear European dress with neatness and elegance. The population muster from 4 to 5,000, mostly Methodists, residing chiefly on the coast. They go about in the neighbouring waters in neatly constructed canoes. The exports are copra, and vegetable marble. Their civilisation is due to the efforts of the American mission which has been established among them for more than 30 years, under the management of Mr. Dean. The weekday and Sunday schools are numerously attended. The missionaries weild great influence over the natives, who are too few in number to take full advantage of the fertility of the soil. About half-a-dozen European firms do the trading. Some two dozen Europeans, chiefly deserters or refugees, dwell on the island. The Spanish flag after being hoisted, was left in charge of a petty chief. On the island of Tomen, some ruins are met with. They consist of double walled square enclosures built up of basaltic stones. The outer wall is 8 feet high by 16 inches thick. It is as strong and as solid as ever, and can easily be turned into a fort. On leaving Ascension, the Spanish mission proceeded to the Pinguelap group, where the German flag had been formerly hoisted. Four closely adjoining islands form the group. About fifty inhabitants dwelt there. The sandy soil supported abundance of coconut trees. On the hoisting of the Spanish flag, the islanders tendered their submission. The natives are industrious after a fashion, by making hats and other articles of pandanus leaves. Their civilisation has reached the same height as on Ascension. The chief of Lela, the easternmost of the Caroline islands, signed a treaty, and agreed to hoist the Spanish flag. An American widow resides in Lela, where she carries on trade. She is the only foreigner settled there. The islanders are civilised, owing to missionary effort. The island is fertile and beautiful. The schools there supply masters for those in the Gilbert and Marshall Groups. The man-of-war after visiting also the Uluti Group, returned to her starting point.

TEA ROLLING.—We hear very good accounts of Messrs. Richardson & Kinmond's roller: the large quantity rolled with a moderate power to drive, seems to be the great recommendation.

NETHERLANDS INDIAN HORTICULTURAL SOCIETY.—The "Ind.-Mercuur" hears that preparations are being made to create under the superintendence of Mr. E. J. Voute of Zeist an establishment to foster agricultural interests in India and in Holland by way of mutual interchange of plants, &c. Accordingly a proof station (probably in the district of Mistengorg) will be founded in connection with the existing establishment of Mr. Voute at Zeist (Holland). The first effort to establish a horticultural garden in India deserves general encouragement and support. The Indian Establishment has in view to experiment with artificial manure, and the results of the same will be published.

PURIFICATION OF DRINKING WATER.

EDWIN J. HOWE, M. D.

The average healthy adult man takes into his system four and a half pounds of water daily, and with it too often a dangerous quantity of foreign matter and disease-producing germs. In very many homes during the summer months, water that otherwise would nauseate the drinker, is made cold by ice, and then is hastily swallowed, the coldness masking its offensiveness. Unfortunately for the health of the consumer, the addition of ice does not render the impurities in water innocuous, but often adds to it its own contribution of disease-germs. Those who have studied the subject are aware that impure drinking water is the cause of many of the most common diseases. No subject then is of greater importance to the public than how to purify our drinking water. Water, if drawn through lead and tin pipes, often becomes, contaminated with these metals to a dangerous extent. Where water remains in a lead pipe for twenty-four hours, and is then drawn off and drank, there is always danger of lead poisoning. It is always safer to let the water run for several minutes before using any for drinking purposes. Boiling the water destroys some germs, but does not remove impurities in solution. Analyses of water from city wells have frequently shown it to be so impure as to be utterly unfit for drinking purposes, and dangerous to health. The use of rain water caught in cisterns, with suitable precautions, will obviate most dangers from the present supplies of many cities, but unfortunately, few persons can take these "suitable precautions." A clean roof to collect the rain, clean pipe to transport, and a clean, well ventilated cistern to receive it, are essential. Water stored in a close cistern soon becomes unfit for use. Many waters that appear clear are full of impurities, and dangerous to health. Dr. Ezra Hunt says: There are many waters used for drinking, which, if kept a few days in a long glass tube, half full and corked, will, on opening, emit much odour from the change in the suspended or dissolved ingredients they contain." The large majority of people in cities must depend for water on the public supply, hence it is of the utmost importance to the public health that the purest water attainable be secured; this, unfortunately, is often very impure. The only safe-guard to the consumer is in giving his personal attention to the filtration of the water used in his household. Water slowly percolated through crushed vegetable charcoal will escape from it not only cleansed of particles held in suspension, but also of organic and other matter. The cheepness of charcoal is such that is obtainable by all classes, and when soiled, a fresh quantity can be substituted at trifling cost. The most effective filtration is obtained by placing crushed charcoal in an earthen vessel, so arranged as to compel the slow passage of the water through it, as all efforts at rapid filtration have proved inefficient. Only wooden spigots should be used in drawing of the water. A reservoir for the filtered water with a separate ice chamber, will permit the water to be sufficiently chilled and keep all ice impurities out. Such a contrivance requires but very little room, is easily cleaned, the coal renewed, and is efficient in freeing water from impurities.—*Indian Gardener.*

AMOUNT OF FAT IN FISH GUANO.

BY JOHN HUGHES, F. C. S., F. I. C.

Of late years finely ground dried fish, commonly known under the name of fish guano, has been extensively used as a separate manure, with very satisfactory results. On naturally poor sandy soils, as well as on the light chalk soils of Kent and Sussex, it makes a capital manure for potatoes, especially when used in conjunction with superphosphate and kainit salts. That fish should form a valuable fertiliser is not at all singular; indeed, its agricultural value has long been recognised by the farmers of the sea coast in all countries, but the peculiarly offensive character of decomposing fish has hitherto prevented its extensive use, and it is only of recent years, since attention has been directed to the removal of the greater portion of the natural moisture and the subsequent grinding into a fine powder that the article has become of commercial value.

The name of fish guano seems appropriate, inasmuch as there can be little doubt that fish was the original source of Peruvian guano, the latter consisting in fact of the dung of sea-fowl, whose only food was fish. In the one case we have the natural dried fish, and in the other we have the same material which, under a process of slow decomposition in vast heaps under the influence of a hot rainless climate, has been converted into the strong-smelling ammoniacal guano of Peru and Chili now, alas! becoming only too scarce.

It is well, however, to bear in mind that there are differences in the agricultural value of the new guano as there was and still exists in the cargoes of the old, and that not only do the proportions of phosphates and ammonia vary considerably in quantity, but that the rapidity with which these constituents can be rendered available as plant food is also likely to vary according to the special character of the prepared fish, and more particularly in relation to its freedom from fatty or oily matter. Fat, as we all know, is a great preservative o animal and vegetable substanc s, and therefore any large quantity of fat or oil is prejudicial to the natural decomposition of fish manure when applied to the soil, and it will be desirable to encourage the manufacturer to press out or extract by chemical means as much oil as possible.

It must be remembered that fat has no agricultural value in a manurial sense, and that its presence in close association with an organic material rich in nitrogen and phosphates tends very materially to retard the natural process of conversion of these ingredients into plant food.

With a view of showing clearly to what extent the proportion of oil varies in different samples of fish guano, some dozen specimens representing the average qualities prepared by different firms were carefully tested for the amount of oil or fat contained, and the results, with the relative amounts of nitrogen and phosphate of lime present in each, are set forth in the following table:—

Sample.	Oil.	Nitrogen	Equal to Ammonia.	Phosphate of Lime.
1	5·80	7·26	8·81	15·98
2	6·93	7·68	9·82	19·54
3	6·96	8·90	10·80	16·94
4	7·30	6·94	8·43	16·46
5	8·33	8·71	10·57	19·54
6	8·90	8·54	10·37	18·88
7	8·36	8·68	10·54	15·94
8	7·96	8·71	10·57	20·63
9	8·93	8·69	10·55	18·99
10	10·10	8·66	10·51	17·79
11	12·56	8·48	10·30	15·06
12	17·06	9·45	11·47	9·14

It will be seen that the oil varies from 5·80 in one sample to 17·06 in another, and that the specimens which show from 6 to 9 per cent, of oil are those which are the richest in nitrogen and phosphates combined.

In order, therefore, to keep down the proportion of oil in commercial samples, it is suggested that the amount of this constituent should be stated in the analysis in addition to the other items, and if this be asked for by buyers, the manufacturer will, no doubt, soon find means to reduce the fat in the best make of fish guano.—Analytical Laboratory, 79, Mark Lane, E.C. —*Agricultural Gazette.*

CULTIVATION OF CAOUTCHOUC-YIELDING PLANTS.

BY THOMAS T. F. BRUCE WARREN.

Looking at the increasing commercial importance of india-rubber, and the few fresh sources of supply which have been added to augment our stock of this substance, we are forced to admit that the activity of our experts have not been marked with that success which a manufacturer can wish for.

Caoutchouc is much more widely diffused in the vegetable kingdom than many are aware of. An idea exists that any plant which yields a lactescent juice contains caoutchouc. There is an error in such a proposition being too generally accepted, because of the disappointment which follows an unfavourable report; still, it would be very unwise to assume that any plant yielding a lactescent juice is unworthy of a careful examination for caoutchouc. There seems to me a great want of a reliable method for examining the juices of plants for caoutchouc. It cannot be too forcibly impressed upon those who are interested in this matter, that the recently-drawn sap of a plant should be examined, if possible; even experienced people consider that caoutchouc is too permanent in its character to alter. When caoutchouc is isolated from resins, oils, and similar principles, it may be kept for a long time, but it would be quite another matter if these were left together for some time. The elaboration of certain principles, or secretions, by *living* plants, points conclusively to an idiosyncrasy in plant life which we ought not to ignore. We know that vitality interferes with chemical affinity, by preventing changes due to mere chemical action.

A few years ago my attention was directed to the curious changes which took place in the medicinal activity of certain plants under cultivation, as compared with the same plant growing as it were on its own natural soil. Chemical analysis of the soil and plant revealed the fact that nitrogenous matter was wanting. The mineral ash of a plant gives a fair idea of what is required in the soil so as to be favourable for its growth, but we must look to the sap of the living plant to know how far climate and other meteorological surroundings are suitable for a healthy and vigorous growth. An abnormal development of any part of a plant must be avoided if we wish to maintain its original integrity.

Warm climates are more favourable to the production of milky juices than cold climates. From this we may conclude that, in order to arrest rapid evaporation from the plant, which would of course involve exhaustion, certain principles are developed whose function is by its emulsive action to retain the water, or to impede its evaporation, we must not overlook the fact that excessive evaporation, *per se*, is injurious to a plant, but the cooling action due to rapid evaporation, has the same influence as transferring a plant to a cooler region.

In such cases, currents of dry air are productive of much mischief; moist air has little or no effect on evaporation. When the cultivation of india-rubber plants was first mooted, the idea was to work on the plant yielding Para-rubber, and considering the state of our knowledge at that time, the error of judgment was pardonable, still it is by no means improbable that the effort to raise the Para-rubber yielding plant may be again attempted.

I have often been struck with Faraday's analysis of India-rubber juice, which was, I believe of Indian origin. The omission of ammonia, if present, could not have been passed over by such a careful observer. More recently, in examining india-rubber juices, I find that ammonia is by no means a constant ingredient in these juices. When a juice has been coagulated, the caoutchouc which separates out cannot be redissolved, but if ammonia be added previously, the caoutchouc remains blended in an emulsive form. If the juices become acid in anyway, the cautchouc separates out. The only juice I have examined which contains a large quantity of free ammonia is that obtained from the *Syphonia clastica*, grown in Para, and it would be extremely interesting to know whether, when the plant is raised elsewhere, this ammonia is present. The juice of the Masaranduba (Cow-tree), although as rich in caoutchouc as the *Syphonia elastica*, and quite as good as regards quality, is not only free from ammonia, but remained for some months quite fluid. This juice was also gathered at Para. A point of singular importance connected with the cultivation of the *Syphonia clastica*, is the fact of its juice being so rich in a nitrogen compound, when we know that the soil itself is neither manured nor supplied with nitrogen in any form, so far as we can tell. We are driven to the conclusion that the atmosphere contributes nitrogen to the plant.

This brings us to the consideration of the meteorological conditions under which the Para india-rubber plant grows, and will help us to explain why it is that this plant will not grow productive of caoutchouc, even when transplanted to the same parallel of latitude. During the evening, and greater part of the night, it is curious to note the vivid lightning which plays almost incessantly among the trees along the Para river; there is a decided absence of that violence which characterises a thunderstorm; in fact if rain sets in, it is almost invisible. Do these silent elective discharges in warm, damp air, assist in generating ammonia? If it is impossible to transplant the *Syphonia clastica* to a suitable climate, with the meteorological accompaniment as found at Para, we are certainly justified in trying an experiment by supplying it with ammonia in some form, so that under the influence of vegetation, it may approach the assimilative action of what nature supplies to the Para plant. I am comvinced that in some parts of our colonies, we may reasonably expect that rubber cultivation can be successfully carried out.

The Mangabeira (Mango-tree) and Masaranduba (Cow-tree), are worth experimenting on, as their cultivation do not require anything particularly special but what an ordinary grower can supply, of course a suitable climate being granted.

Analyses and general descriptions of the soils on which caoutchouc producing plants are grown, are indispensable, as from them any soil to which a plant may be transferred for cultivation, can be selected or made up so as to represent the natural soil on which it previously grew. This assistance would help to relieve an intending cultivator from the onus of delay in fruitless experimental trials and expense.

This would be a very simple matter, as our foreign Consuls would have no difficulty in procuring authentic samples of the soil and of the wood of the rubber plant raised on it.—*Journal of the Society of Arts.*

MOTHER-OF-PEARL FISHERIES IN THE RED SEA.

Consul Jago, of Jeddah, says that the mother-of-pearl fisheries extend the whole length of the Red Sea, from El Wedj on the North, to Aden on the South. The principal grounds are in the neighbourhood of Suakim, Massowah, and the Farsan Islands. About 300 boats are employed, the majority belonging to the Zobeid Bedouins, a tribe of Arabs inhabiting the coast line between Jeddah and Yambo. About fifty boats belong to Jeddah, and two or three to Confida, Cameran, and Loheiha. They are open, undecked boats of between eight and twenty tons burden, carrying a large lateen sail, manned by crews varying between five and twelve men, and each provided with a number of small canoes, which are imported specially from the coast of Malabar. There are two fishing seasons during the year, one of four months and one of eight months, during nearly the whole of which the boats keep the sea, the crews living on board, returning to their homes for short periods of two to four weeks. The crews, composed principally of black slaves, are paid by share of the produce of their fishing, the owner of the boat taking one-third, the remaining two-thirds being divided among the former, after deducting the cost of food consumed by them during the voyage, and which consists of dhourra, rice, and fish, with sometimes a little ghee and dates as a luxury. Fatal accidents are said to be unknown, and the men are remarkable for their strength and good health. They dive between the ages of ten and forty, and the practice is said to have no ill effects. The fishing takes place in the neighbourhood of reefs, the boat anchoring at a certain spot, whence the crew proceed

to fish in their canoes, in the vicinity. Operations are conducted only in calm weather, when the shell can be discovered by the eye at a depth varying between seven and fifteen fathoms. Of late years, to assist the eye, empty petroleum tins, with the ends knocked out, and a sheet of glass inserted in one end, have been used. The tin, with the glass end below, is submerged a little in the sea, and the discovery of the shell thereby facilitated. During the last ten years the find is said to have diminished ten to twenty per cent in quantity, owing to dearth of shells. The value of the total harvest is estimated at 120,000 to 170,000 dollars annually, the dollar varying in value between 3s. and 3s. 6d. The short season of four months, which used to average between 40,000 and 50,000 dollars, only realised in 1886, 25,000 dollars. Formerly, all the produce of the Red Sea was brought to Jeddah for sale and export, but recently, owing to fiscal and custom-house restrictions, only about one-fourth now goes there, the remainder going to Suakim and Massowah. Shells imported at Jeddah for sale are disposed of by public auction in heaps of about half a hundredweight each. As preliminary inspection is not allowed, the bidding is purely speculative, and bidders have to take account of dirt, corals excrescences, and inferior shells. Prior to exportation the shells are sometimes cleaned to remove the coral and dirt, and are then packed in barrels. Up to ten years ago all shells brought to Jeddah for sale were shipped by natives to Cairo to be sold there. Now, however, the bulk goes to Trieste, a small quantity to London, and a little to Havre; and a few of the finest and largest shells are purchased for exportation to Bethlehem, where they are engraved and sold to pilgrims. The Jeddah shell is considered in Europe inferior to that exported from Suakim and Massowah, owing, it is said in many instances, to the yellowish tint of the former, and the fact that many of the shells have a greenish tint round the edges. Some ascribe this to the excessive dampness of the climate of Jeddah. With regard to the origin of the shells, the following distinctions are made:—*Dah al ak-i* shells, found on the group of islands of this name, situated along she African side of the Red Sea; *Barr-adjem-i* shells, found along the same coast, north of the Khôr or inlet of Suakim; *Farsan* or *Yeman-i* shells, brought from the Farsan group of islands, on the Arabian side of the Red Sea; *Shebak-i* shells, from the banks between Confidah and Leet; *Sham-i* shells, from El Wedj down to Hassance Island on the Arabian side, and found in the neighbourhood of Kossaïr on the African side. Consul Jago says, in conclusion, that the *Sham-i* is the best, and the *Yeman-i* the most inferior quality.—*Journal of the Society of Arts.*

BRITISH NORTH BORNEO.

PROVINCE DENT, BUNDU.—Situated about 26 miles from the British Island of Labuan, the flourishing district of Bundu in Province Dent invites attention from its many peculiar and interesting characteristics. In no other part of British North Borneo have we met a community of descendents of Chinese, who whilst still wearing positive pig-tails have gradually abandoned the ancient teachings of Confucius and who now declare themselves to belong to native tribes. In some of their houses are still to be found altars, idols and pitcures of the Good and Evil Spirits which are peculiar to China. Most of them have discarded their Chinese names, and rejoice in Malay titles and names conferred on them and on former generations by the Sultan and chiefs of Brunei, and very few of them can speak any Chinese dialect. The chiefs were usually ennobled by the Sultan because they were the most wealthy and powerful cattle-thieves during this and the last centuries. In Great Britain the present bearers of titles in some of our highest aristocratic families are the descendents of the most notorious cattle-lifters on the Scotch Borders, and so history repeats itself in different countries. Whilst these descendents of a Chinese race were carrying on marauding pursuits, they were conscious that they had settled upon a fertile tract of country, and whilst they received empty titles of honor they had to pay heavy and irregular exactions to the Sultan of Brunei and to his chiefs, but still they held on with Chinese tenacity to their adopted country of Bundu. Besides, they were intermarried with Besayah, Dusun and Brunei tribes and their crops yielded remunerative returns. On the cession of Province Dent by the Sultan of Brunei to British North Borneo about eighteen months ago, the Bundu people, tried of the oppressions of Brunei rule, gladly welcomed the advent of the white man's administration and are new amongst the most royal of the population in the Province.—*British North Borneo Herald.*

KUS KUS TATTIES are made from a grass (*Andropogon maricatus*) which grows in abundance on sandy banks in Bengal, Upper India, the Coromandel Coast and Mysore, where it is commonly planted to divide fields. The roots when distilled with water yield a fragrant oil, which is used as a perfume. An infusion of the roots is also given as a febrifuge, and a powder in billious complaints. It is regarded as stimulant, diaphoretic, stomachic and refrigerant. The essence (or otto) is used as a tonic, and, finally, the grass itself when young affords good fodder.—*Madras Mail.*

SOLVENT POWERS OF EUCALYPTUS OIL.—The solvent power of eubalyptus oil on resins, etc., have been given in the following order:—Mastic, sandarac, elemi, xantorrhea, resin, benzoin, copal, amber, anime, shellac. cautchouc, and gutta-percha. The oil added to methylated spirit, in the propotion 10 ounces of the former to 1 gallon of the latter, is used to dissolve kauri resin, which will dissolve in this mixture without the aid of heat to the extent of 2 lb. out of every 2½ lb. used; the addition of a little colophony or Venice turpentine rendering the kauri resin completely soluble. It is also used to dissolve asphaltum for photograph varnish. In veterinary practice it is used in Australia as an embrocation for swellings, bruises, or stiff joints. In domestic practice it is employed for rehumatism. etc.—*Indiarubber and Guttapercha Journal.*

THE ORANGE OR CITRUS tribe of trees are somewhat delicate trees to transplant during the dry winter season peculiar to this colony. When once planted on well-drained porous soil they stand hardship in the way of neglect as well as, if not better than, any other tree, but care should be taken when transplanting. If a drying westerly wind is blowing defer planting out, and keep the trees well protected from it in some shed, but keep the roots moist. The best plan is to puddle them and then throw a big over them. If the young tree has only to be lifted from your own nursery bed to your own orchard, still this precaution of never allowing the just exhumed roots to be acted on by the wind or sun holds good, for nothing is more detrimental, and many trees and garden plants fail to grow simply owing to the omission of this precaution. All holes for the trees should be dug previously, or by a man in advance of the planter. Puddling is done by immersing the roots in a tub of liquid sludge of mud and water, so that every root gets a coating. This is a good plan to adopt with any trees, shrubs, or plants that have naked roots when taken up. The watercan should follow the planter immediately, indeed there should be several bucketfuls poured into the hole before putting in the tree and allowed to penetrate the soil; then when the tree is planted and the fine soil carefully pressed against the roots (not carelessly trodden so as to break off half of the small rootlets) one good watering should be given; afterwards rake back the dry soil on the top of the moist centre, drive three stakes in a triangular fashion round the tree, outside of the circle of roots, and from these stakes the strings to the stem of the tree not forgetting to put a piece of soft material to hinder friction of the bark by the strings. In a week's time remove the soil from round the stem so as to form a basin a few inches deep, pour in several buckets of water, and when this has disappeared rake back the soil again, or cover with a good mulch of dry grass or litter, but not of manure. Apply *no* manure at the time of transplanting any of the orange tribe, or most assuredly they will be killed.—*Queenslander.*

MARKET RATES FOR OLD AND NEW PRODUCTS.
