It is certainly difficult to draw a hard and fast line between these two organs, especially when in so many of our best text-books of systematic botany we read of "roots," and find such able to produce leaf-buds plentifully under certain favourable conditions. I think, however, that the greater number of botanists will look upon roots and stems both as complex structures having similar rudimentary structures (in the thin-walled cell), although these may be developed differently according to their functions.—*Gardeners' Chronicle.*

Rubber in Brazil.—The Pará statistics not having come to hand, only those for Amazonas are published, viz.:—

	weight.	value.
1882-83....	718,137 kilos.	2,253,369$
1883-84....	1,040,358 ,,	2,564,431
1884-85....	1,412,407 ,,	2,505,580

The minister suggests that the municipalities and provincial legislatures should take steps to replant the tree, in the proper situations, near villages, not only to prevent the destruction of this source of wealth, but also by reducing the cost of harvesting to place the article on a better footing as regards foreign rubber.—*Rio News.*

GAMBOGE OF BURMA.

Although various varieties of gamboge-bearing trees have for many years past been known to exist in different parts of the province, notably in the Tenasserim division, it was not until comparatively recently that the subject was brought specially under the notice of the local Government. Writing more than 30 years ago, Mr. Simmonds, in his work entitled *Commercial Products of the Vegetable Kingdom*, says: "The *Garcinia elliptica* of Tavoy and Moulmein affords gamboge and approaches very closely in its character to Graham's *Hebrodendron*;" and he adds that it affords "a fine pigment." Dr. Mason also, in his work on Burma, remarks that "the best gamboge is produced by *Garcinia elliptica* but an inferior article is produced by *G. cornea*, *G. anomala*, *G. cowa*, *G. kydia*, *G. succifolia*, *G. xanthochymus*, and *G.* (*Hebrodendron*) *morella*. *Garcinia Cambogia* yields a pleasant fruit and a gamboge quite insoluble in water, and it is the complete solubility of the best gamboge that distinguishes it from inferior sorts, but it is probable that, when fully investigated, these insoluble gamboges will be found of service in the arts."

In 1875 Mr. Whittall, of the Forest Department, drew attention to three different species of trees, belonging to the genus *Garcinia*, growing in the districts of Southern Tenasserim. These were known to the natives as *Tawmengoot*, *Parawah*, and *Parajay*. The two last named Mr. Wittall did not consider of much account. The *Parawah* yields an exudation of a white colour, which changes to a reddish yellow on exposure to the atmosphere, and is scarcely at all soluble in water, but yields to alcohol. The *Parajay* yields a rather copious exudation which when dissolved in spirits of turpentine, affords a beautiful, permanent, yellow varnish for metallic surfaces, and on this account has been called the gamboge tree as well as the yellow varnish tree; but its exudation does not form an emulsion with water, and, for this and other reasons, Mr. Whittall considered it had no claim to be considered a real gamboge tree. The *Tawmengoot* was, in Mr. Wittall's opinion, the gamboge tree of the South Tenasserim forests. He says: "The gum resin is larger in quantity and darker and of a more glossy colour than the others: neither wet nor dry is it so sticky, and so readily does it form an emulsion with water that the exudation on the outer bark is completely washed away by the rains." This tree he believed to be the same as that which Dr. Mason calls *Thanataw* (*Garcinia elliptica*) [*G. heterandra*], and he adds that it was supposed to be the same as that which yields the gum resin exported from Siam. But Mr. Hill, Officiating Conservator of Forests, Pegu Circle, thinks the *Tawmengoot* is probably the *G. morella* or *pictura*, or *gutta*, the true gamboge tree, which does not grow all over Burma like *G. elliptica* or *G. cowa*, which latter are common trees throughout the province.

In May 1884 the Commissioner of Tenasserim, drew the attention of District Officers to the trees called *Thaungthaleh* (*G. kydia*) and *Thanataw* (*G. elliptica*) found growing in the tropical forests of Martabau and Tenasserim with the view, if possible, of developing a new industry for the people. Of the former Mr. Hill says: "It yields a yellow substance of a bright colour, but paler than the gamboge of Siam. It is scarcely soluble in water, but dissolves in spirits of turpentine and affords a beautiful, permanent, yellow varnish for metallic surfaces. As the substance is very resinous and will not dissolve in water, it is valueless as a pigment." Of the latter he remarks: "The product known as *Thanataw* is obtained from *G. elliptica* or *heterandra*. It is called a superior gamboge, but in all probability merits the name almost as little as *Thaungthaleh* owing to its only partial solubility in water. It is found throughout the province and is darker in colour than *Thaungthaleh*." A sample of *Thanataw* obtained from Tavoy was found upon analysis to contain—

Resin, ...	76·5
Gum, ...	23·5

This sample was sent to Calcutta for valuation, where it was declared to be gamboge, but unsalable in an unrefined state. In August of the same year samples of gum produced from two other kinds of trees called *Palagyi* and *Tawmengoot* were also obtained and submitted for analysis. They were found to contain—

	Palagyi.	Tawmengoot.
Resin, ...	58·82	53·20
Gum, ...	9·54	20·30
Water, ...	32·66	25·60

In his report on these samples Dr. Romanis, the Chemical Examiner, says the yellow kind (*Tawmengoot*) makes a very fair paint, but the other is of no use. If the gum is extracted it makes a spirit varnish, but when warm it melts and gets sticky.

According to the broker's report, to whom the sample of *Thanataw* referred to above was submitted for valuation, gamboge in its refined state sells in the Calcutta Market at from R2 to R2-8 per seer. It arrives there freely from June to August, usually packed in cases of from three to four maunds, and it is chiefly used in French polish and paint. In Burma the cost of collection alone is estimated by the deputy Commissioner, Tavoy, at R25 per viss (3·65 lbs). That is to say, the cost of collection amounts to nearly R7 per lb., while the market value of the product is only R1-4 per lb., and that too when it is in a refined state. It does not appear why the cost of collection is so great. In Ceylon the process of collection is very simple. There the gamboge is usually collected by cutting a thin slice of the bark of the tree here and there of the size of the palm of the hand. On the flat space thus exposed the gum collects and is scraped off when sufficiently dried. It may be possible perhaps to reduce the cost of collection. Unless it can be reduced very considerably, we cannot hope to introduce the Burma product into the market. From the enquiries made, then, it would appear that the *Tawmengoot* alone yields good gamboge, and that the only obstacle in the way of the gamboge succeeding as a commercial product is the high cost of collecting it. The products of the other trees mentioned are not promising because of their comparative insolubility in water.—R. A. Mack, of the Agricultural Department, Rangoon 22nd April, 1885.—*Indian Forester.*

PSEUDO-GUTTA-PERCHAS, OR SUBSTANCES SUPPLEMENTARY TO GUTTA-PERCHA.

From time to time numerous substances have been recommended as substitutes for, or supplementary to, gutta-percha. That a substance answering these purposes has not yet been introduced lies, I think, more in the fact that these substances have not yet been properly treated, or such a substance has yet to be discovered, than that such substance or substances do not exist. As to the method of preparation of these proposed substances, I have pointed out, in an article on gutta-percha,* the rapid oxidation of that substance if it be not prepared immediately after collection. This applies even more strongly to subjects of the present article. Balata gum has an assured value of its own, and with regard to the rest they may yet be utilised if their rapid resinification can be arrested.

In the following remarks but a brief *resume* is given, and the subject geographically treated. In view, too, of the various names which have been given to these plants in various botanical works I also append the synonyms.

I.—AMERICAN SOURCES OF SUPPLY.

(1) BALATA GUM. (2) MIMUSOPS BALATA, GAERTNER. (3) Natural Order—SAPOTACEÆ.

SYNONYMS.—*Sapota Mulleri*, Bleekrod; *Mimusops Kauki*, *L*; *M. dissecta*, Hooker; *M. Hookeri*, A.D.C., *M. Manilkara*, Don; *M. Ballota*, Blume; *Achras balata*, Aublet; *Lucuma mammosa*. De Vriese.

VERNACULAR NAMES.—Paarden vleesh (Dutch), Horse-flesh; Bullet tree; Bolletrie and Boerowé by the Arrawak Indians.

GEOGRAPHICAL DISTRIBUTION.—Demerara; Berbice; British Guiana; Antilles; Jamaica and Surinam.

* Encyclop. Britann.: Article "Gutta-percha."

One of the first writers on this substance was Professor Bleekrod, who communicated some information as to the plant and its product to the Society of Arts, in 1857.* He also described and named the plant as *Sapota Mulleri*. In 1860 Mr. Walker † communicated samples, &c., received by him from Dr. Van Holst, of Berbice, to the same Society; and in 1864 Sir William Holmes also drew attention to the same subject.‡

The tree is a large one, with a trunk of about 6 feet in diameter, and furnishing a wood much sought after as a building material. The Dutch name, Paardenoleesch, is given on account of the wood being of the colour and having the appearance of horseflesh. The bark is thick and rough, and the fruit is of the size of a coffee berry, sweet, like a plum, and with a hard white kernal, which yields an oil bitter in taste. The leaves are glossy, oval, and acuminated. The milk is drunk by the natives, and when diluted with water, used as cow's milk. The trees grow in groups, and in alluvial soil.

The "Balata" gum is of a character somewhat betweeu caoutchouc and gutta-percha, combining in some degree the elasticity of the one with the ductility of the other, freely softening and becoming plastic, and easily moulded under the influence of hot water.

What small parcels were sent to this country met with a ready sale, and were remarkably free from adulteration. But, unfortunately, through the difficulty of collection, the undertaking being so dangerous and unhealthy, the supply of this excellent and most desirable article has fallen off.

Balata is collected by making incisions in the bark about 7 feet from the ground, and a ring of clay placed round the tree to catch the milk as it exudes. The yield is said to be in profusion, especially at the time of the full moon—a statement with regard to milky juices which is adhered to by natives in all parts of the world—and the operation can be repeated every two months in the rainy season. It takes six hours to bring about coalescene by simple atmospheric influe ce, but very quickly by boiling in water. A lar.e tree is said to yield as much as 45 lb. of dry gum.§

II.—INDIAN SOURCES OF SUPPLY.

PAUCHONTEE, OR INDIAN GUTTA TREE.

Dichopsis elliptica, BENTHAM.

Natural Order—*Sapotaceæ*.

SYNONYMS.—*Bassia elliptica*, Dalzell; *Isonandraacuminata*, Lindley.‖

VERNACULAR NAMES.—Indian Gutta Tree; Pauchontee, Pauchoontee or Pashonti; Pauley or Pali Tree.

GEOGRAPHICAL DISTRIBUTION.—Wynaad; Coorg; Travancore; Anamally and Neilgherry Hills; Sholah Forest; Cochin; Sichar; and according to General Cullen, "appears to be common in all the forest tracts at all within the influence of the south-west rains."

This tree, which is now placed in the same *genus* as the true gutta-percha, is a large one, from 80 to 100 feet high, was first met with by Mr. Dalzell in North Canara, near the falls of Goirsuppah, in 1849. Since that date, General Cullen and Dr. Hugh Cleghorn have used every exertion to bring the substance prominently forward. The gum is obtained by tapping, a pound and a half being obtained from one tree by five or six incisions, a large tree yielding as much as 20 to 40 lb. of sap. Many experiments have been made with specimens of the raw milk, *i.e.*, milk simply dried after taken from the tree. The result of these experiments have shown that for telegraphic purposes it is wanting in some essential qualities, but it has been recommended as a sub-aqueous cement or glue. When dissolved in ordinary gutta-percha solvents, it, after the evaporation of the solvent, remains for some time soft and viscid, and partakes somewhat of the characteristics of birdlime. When cold it is hard and brittle. Without wishing in the slightest degree to throw doubt or discredit on the many and valuable experiments made, I would suggest that good samples be collected. I have not the slightest doubt, from the scientific aspect of the case, as well as from practical experience and experiments at home and abroad, that many a parcel of what would otherwise be good gutta-percha is spoilt through not being *well boiled immediately* after collection from the tree. At present, this is the only way in which I can see a possibility of ascertaining whether this product can be utilised, and I have the more hope that it can, from the fact that its structural character has led the plant to be placed in the same *genus* as the gutta-percha tree: structural affinity being a wonderfully safe index in numerous instances to chemical affinity also. There are in India various species of *Isonandræ* and other closely allied sapotaceous *genera*, but I have found no mention nor heard of their yielding any milky juices likely to prove of commercial value. It would be well if experiments were tried with the products of these trees.

* Jour. Soc. Arts, London, Oct. 8, 1857.
† *Ib.* Aug. 24, 1860.
‡ *Ib.* March 4th, 1864.
§ *Trinidad Chronicle*, September 2, 1873.
‖ Under this name, Dr. Hugh Cleghorn wrote a very valuable report in 1858.

CATTIMANDU AND OTHER EUPHORBIUM GUMS.

Euphorbia cattimandoo, and other species.

Natural Order—*Euphorbiaceæ*.

Euphorbia cattimandoo, of W. Elliot, is found in Vizagapatam, and is variously known under the vernacular names of Cattimandoo, Catemandoo, or Kattimundoo.

The product of this tree was first brought to notice by the Hon. W. Elliot, and a prize medal was awarded for the substance by the jurors of the Exhibition of 1851. This Euphorbia grows to the size of a shrub or small tree, and the milk flows out freely when a branch is cut. The natives use the milk as a cement to fasten knives in handles, &c. Under the influence of heat it becomes soft and viscid, and when dry it becomes very brittle. The same remarks as to the probable utility of "Pauchontee," apply also to this and following substances, although in a somewhat limited degree.

Euphorbia tirucalli, of Linnæus, known vernacularly as the Milk hedge or Indian tree spurge, tirucalli and the Lunka sij, is found in the Coromandel, Malabar, Bengal, and is, in fact, a very common plant in various parts of India.

This succulent unarmed plant often attains a height of 20 feet, and its inspissated milk is used for various purposes, chiefly medicinal, in India, and has been recommended as a substitute for gutta-percha; but like Gum Euphorbium, it has a very acrid character, and the collection of it is a very dangerous operation to the eyes. When dry it becomes very brittle, but when warmed in water has a certain amount of plasticity.

ALSTONIA OR PALA GUM.

Alastonia scholaris, ROBERT BROWN.

Natural Order—*Apocynaceæ*.

SYNONYMS.—*Alstonia oleandrifolia*; *Loddidge*; *Echites scholaris*, LINNÆUS.

VERNACULAR NAMES.—Mookum pala; Pala; Chatinn; Eerellay-palay; Ezhilaip-palai; Edakulapala; Edakulatariti; Edakula-ponna.

GEOGRAPHICAL DISTRIBUTION.—Travancore, Coromandel, Assam, and Ceylon.

This tree attains a height of 50 feet, and its wood and bark are much valued in India for their medicinal qualities. The tree yields an abundant milky juice, which was recommended as a substitute for gutta-percha, amongst others, by Mr. Ondaartjee, who brought the substance before the notice of the Society of Arts in 1864.* It is stated to readily soften in hot water, take impressions readily, and to retain these impressions when cold. I have only had very small specimens in my possession, so am unable to form any decided opinion. Good specimens of this and other like substances would be acceptable.

* Jour. Soc. Arts, London, vol. xii. 39., Feb., 1864.

MUDAR GUM.

Calatropis gigantea, ROBERT BROWN.

Natural Order.—*Asclepiadaceæ*.

This plant, known also under the name of *Asclepias gigantea*, of Willdenow, was very early described by Rheede in his Malabar Plants, under the name of Erica.

VERNACULAR NAMES.—Gigantic swallow-wort; Yercum; Yerica; Nella-jilledoo; Akund; Mudah; Ark.

GEOGRAPHICAL DISTRIBUTION.—throughout the peninsula and Southern Provinces of India.

This shrub is found in waste places, and grows to a height of from six to ten feet. Ten average shrubs are said to yield one pound of a gutta-like substance, which becomes plastic in hot water, and other ways behaves like gutta-percha. There is also another species said to yield the same characteristic milk, viz., *C. procera*, but I have not been able to procure specimens.

III.—CEYLON SOURCES OF SUPPLY.

In Ceylon there are species of *Dichopsis*, *Isonandra*, and other allied *genera* belonging to the natural order: *Sapotaceæ*. Specimens of their inspissated juices I have not seen. When I passed through Point de Galle, in 1874, I wrote to the late Dr. Thwaites, the talented Director of the Government Gardens at Peradeniya, with regard to the question of gutta-percha, and received a quick and courteous reply, by which it appears that the natives do not collect any of the gutta, even if the trees yield it in appreciable quantities. This agrees, too, with information I have received from native and other sources of information. Dr. Thwaites also remarked that some years ago he sent the inspissated juice of one species to Sir W. J. Hooker, but that the report on it was unfavourable.

Certain parts of Ceylon having a climate,* so similar to that of the Malayan Peninsula and Archipelago, it seems probable that here would be found the best localities for the acclimation and cultivation of the true gutta-percha tree. I have recommended the adoption of this course, and sincerely trust that efforts will be made in that direction. It is also probable that the island contains many indigenous pseudo-guttas, which might be made use of.

IV.—AFRICAN SOURCES OF SUPPLY.

At the Cape of Good Hope there are many species of Euphorbias which are said to yield a substance very similar to Cattimandoo, but hitherto I have only been able to see fragments, and thus have been precluded from making any experiments. Like the *Euphorbia officinalis*, the juice is so acrid as to give intense pain and irritation to any part of the body with which it may come in contact, especially the eyes and nostrils. Dr. J. Crombie Brown, whilst holding the post of Government Botanist at the Cape, paid much attention to the subject, and favoured me with much correspondence upon it. Our united efforts bore no fruit. The substance has been well spoken of as an anti-fouling dressing for ship's bottoms.

Mr. Baxter, whilst on the Niger Expedition, collected a specimen of *Chrysophyllum* (Sapotaceæ) yielding a substance like gutta-percha, but no specimen seems to exist. Tropical Africa should indeed be rich in such substances, and doubtless such will prove to be the case when careful search and enquiry is made.

With regard to the whole question of the Pseudo-Guttas, Balata should most certainly receive attention, and efforts should be made by the Government to introduce it into Ceylon and elsewhere. Pauchontee, too, should receive attention, and the possibility of the utilization of the rest of the group not denied till further trial has been made.—J. C.—*Indiarubber and Guttapercha Journal.*

SQUIRRELS AT WORK ON NORWAY SPRUCE.—In the August *American Gardener's Monthly*, Professor W. A Buckhout attributes the broken branchlets found under the Norway spruces in the spring, referred to in the previous number of the periodical, to squirrels. These branchlets usually lie among the clumps of trees near where these rodents may be seen feeding on seeds and cones. Isolated trees do not thus suffer; though native Pines (*P. rigida*) do. The editor admits that the Professor's specimens show distinct marks of gnawing; but specimens from New Hampshire appear broken off at a bud—disarticulated as it were—which a squirrel could not to do. Such disarticulation may have begun by drying commencing after the rodent had cut the branch.—*Journal of Forestry.* [We in Ceylon know what our "rodents" the coffee rats can do in the way of branch cutting.—ED.]

ARABIAN DATE TREE.—At the suggestion of Mr. Cameron, of the Lal Bagh, the Dewan has sanctioned the introduction of the Arabian date tree, which is to be cultivated as an experimental measure in the province. Steps have been taken, through the British Consul in the Persian Gulf, to obtain a supply of the proper variety of the date palm and it is expected that 400 or 500 young shoots will arrive shortly. The date palm which grows luxuriantly in localities that have a scantly rainfall, will, it is hoped do well in the Chitaldroog and Kolar Districts and part of Tumkur where the rainfall is precarious and far below the proviucial average and should the experiments turn out a success, and if the cultivation is largely extended, it will prove a stand by in the shape of a large yield of dates, as food for the people in times of scarcity. We believe that after careful enquiries and an examination of all records, it was found that some plants of Arabian date flourished in the Lal Bagh may years ago, but being lost sight of probably in the rush that set in for flowers and fallals the trees were either cut down or allowed to perish from neglect. B. S.—*Madras Mail.*

CHINA TEAS *vs.* INDIAN AND CEYLON TEAS.—The first crop from China is larger than that of last year. This has now been all shipped, or very nearly so. The quality of the second and third pickings is determined to a great extent by the prices obtainable by the growers, and when the demand is good, fourth and even fifth pickings are made, so that practically the supply from China may be said to be almost unlimited, or at any rate limited only by the fact of the value declining so as to render it unremunerative to pluck. We are inclined to think that a favorable spring, after and unusually hard winter, and fine weather for drying the leaf, have had more to do in determining the quality of this years' crop of China tea (which is undoubtedly above the average) than the Government edict, though this may have brought the desirability of making good tea prominently to the notice of the factors. The Chinese are eminently a practical people, and are shrewd enough to take care of their own interests. The course of the London market is not such as to induce them to make much really fine tea, and as the Russians also, who used to take most of their finest crops either direct or through their agents in London, appear now to be turning their attention largely to the medium and common grades, it seems doubtful whether it will pay the Chinese to expend time and labor in the manufacture of choice parcels when they can obtain a good average price with less care. While, therefore, we believe that the resources of China in regard to the production of tea are almost unlimited, and that she possesses many advantages, not the least being an abundance of cheap labor, we do not think that the outlook need cause alarm to Indian or Ceylon planters. The question to them to a great extent is the cost of production. If by the use of improved machinery they can keep this sufficiently low to make tea planting remunerative in the altered condition of the market, and maintain a high standard so far as quality is concerned, they will hold their own. They have no native tea-drinking population to fall back upon like China, and the greater portion of their produce must find its way to this market. The taste of the British public is what they have to cater for, and that demands for the most part a good strong tea at as low a price as possible. There is also an outlet for the finer grades, if they *are* fine to a certain extent, but the bulk required must consist of Pekoes and Pekoe Souchongs, and moderately fine Broken Pekoes."—Cor. Local "Times" quoting London Brokers.

* *Vide* Thwaite's *Flora Zeylanica*. (Preface).

CINCHONA BARK AND QUININE SUBSTITUTES.

Another scare has just been started, this time in London, which, did it contain the elements of success in it should indeed cause uneasiness in the minds of cinchona planters, not only here, but all over the world. The following paragraph appeared in the *Morning Post* of Monday, 23rd August:—

REMARKABLE DISCOVERY.—A correspondent says:—Dr. Cresswell Hewett, of Lincoln's Inn Fields, has discovered the synthetical or artificial mode of making quinine, by which the price of that drug will be reduced to something like 3d. per ounce. The importance of this discovery (which was made two or three weeks ago through the accidental breaking of a medicine bottle) is rendered greater by the fact that while hitherto we have been depending for our quinine on the cultivation of the cinchona tree, from whose bark only about 2 per cent. of good quinine can be extracted, 98 per cent. being valueless, the drug can now be manufactured without limit by a very simple process from an article which can always be got in abundance in any part of the world. A few days ago Dr. Hewett submitted a sample of his preparation to Messrs. Howard and Sons, quinine manufacturers, Stratford, who have expressed surprise at the result of their analysis the sample being equal to the best quinine in the market. The discoverer is about to communicate with the Government, who annually spend in India alone about £60,000 in the cultivation of the cinchona tree.

This was followed by the publication of the following letter in the *Lancet*;—

TO THE EDITOR OF THE *Lancet*.

"Sir,—In answer to your note of yesterday's date, I beg to inform you that the enclosed paragraph is in substance correct, with the exception that the process referred to was not accidental as described, but was first suggested to me by the late Dr. Matheson, of St. Bartholomew's Hospital, in 1869, while assisting him in experiments regarding apomorphine. Subsequently Professor Parkes, of Netly, aided me with his advice. To these gentlemen rather than to myself the process is due.—I have, &c.,

"CRESSWELL HEWETT,"

From Messrs. Wilson, Smithett's circular, appearing in our last issue, it will be seen that this correspondence, which appears to have gone the round of the daily papers in London created some excitement in the quinine trade, but the value set upon the announcement, as the above firm of brokers state, may be very fairly gauged by the better result of the bark sales which took place shortly afterwards; whilst Messrs. Howard & Sons state that Mr. Cresswell Hewett had no authority to use their names in connection with his discovery. The same sort of "discovery" has been so often repeated before, that planters are likely, we fancy, to be scared as little as the quinine manufacturers appear to be. Threepence an oz, is certainly a low price for quinine, but the news is, we fancy, too good to be true. There will be found, we think, to be just one little thing wanting to complete the success of Mr. Hewett's "discovery."—Local "Times."

THE ALLEGED DISCOVERY OF ARTIFICIAL QUININE.

Our readers interested in cinchona bark may make their minds easy about the alleged discovery of Dr. Cresswell Hewett, who is so unscrupulous in his statements that the only excuse that can be offered for him is mental aberration. His assertion that the Howards had endorsed his invention is disposed of by a letter which Messrs. Howard & Sons sent to the *Chemist and Druggist* to the following effect:—

"*Artificial Quinine*—The alleged discovery of the above was brought under our notice, the supposed inventor entirely failed to satisfy us of its synthetic formation."

The account given by the representative of the *Chemist and Druggist* of an interview with the alleged discoverer, will afford our readers amusement, even if it leaves them in doubt whether Dr. Cresswell Hewett is more humbug than madman. It is natural to incline to the latter conclusion when we find the man talking of manufacturing 90,000 tons of an article of which only 150 tons are at present consumed annually in the whole world! Here is the amusing account of the interview with the eccentric doctor who had purchased 180,000 gunpowder tins to hold his synthetically formed quinine:—

THE ALLEGED DISCOVERY OF ARTIFICIAL QUININE.

INTERVIEW WITH DR. CRESSWELL HEWETT.

That eminently respectable and aristocratic organ, the *Morning Post*, created quite a sensation on 'Change last Monday, when, in a somewhat obscure corner of its columns, as though the editor were not quite certain whether he was announcing a discovery of the utmost importance or communicating a joke, there appeared the following paragraph "from a correspondent":—"Dr. Cresswell Hewett, of Lincoln's Inn Fields, has discovered the synthetical or artificial mode of making quinine, by which the price of that drug will be reduced to something like 3d per oz. The importance of this discovery (which was made two or three weeks ago through the accidental breaking of a medicine bottle), is rendered greater by the fact that, while hitherto we have been depending for our quinine on the cultivation of the cinchona tree, from whose bark only about 2 per cent of good quinine can be extracted, 98 per cent being valueless, the drug can now be manufactured without limit by a very simple process from an article which can always be got in abundance in any part of the world. A few days ago Dr. Hewett submitted a sample of his preparation to Messrs. Howard & Sons, quinine manufacturers, Stratford, who have expressed surprise at the result of their analysis, the sample being equal to the best quinine in the market.* The discoverer is about to communicate with the Government, who annually spend in India alone about 60,000*l.* in the cultivation of the cinchona tree."

From these statements it would appear to be probable that the anonymous correspondent is but imperfectly acquainted with the properties of cinchona bark, but nevertheless the information conveyed by him was sufficiently startling to cause a sensation among the large number of persons interested in its preparations. Mr. David Howard no sooner appeared on 'Change than he was besieged by eager inquirers, desiring to have his view of the matter. Mr. Howard stated that his firm had actually received from Dr. Cresswell Hewett a sample of quinine sulphate, which was found to be in every respect equal to the commercial article, but they had no means of knowing how the article was obtained. The mention of their firm in the *Morning Post* was entirely unauthorised.

Desirous of obtaining some information from the alledged discoverer in person, a member of our staff set out in search of that gentleman, who figures in the Medical Register as Frederick Charles Cresswell Hewett, Member of the Royal College of Surgeons (England), and Licentiate of the Society of Apothecaries (London). Mr. Hewett's address in the Medical Register being inaccurate, and that in the *Morning Post* vague, the discovery of him was a matter of some little difficulty, but was overcome after some perseverance.

After stating our business to the attendant we were admitted into the Doctor's parlour, where we found him apparently engaged in "coaching" a couple of medical students.

Dr. Hewett commenced by inquiring whether we had come provided with a cheque for 20,000*l.*, which amount he named as the price for his secret, and upon

* The explanation being that the sample was ordinary quinine, probably Howards' own.—ED.

being answered in the negative, jovially responded, "That settles it, my boy; then you will not get it out of me."

We stated that we had not the remotest intention to deprive him of the secret of his invention, but merely desired to hear something concerning the manner of the discovery, and the use he intended to make of it.

"Ah!" said the Doctor, "that's another matter. Let me first tell you that the communication to the *Morning Post* was entirely unauthorised by me. I don't know who can have put the thing in, and I didn't want it to appear. I wanted to keep the matter quiet until I should have manufactured *ninety thousand tons* of the article, when I would suddenly have swamped the market. Did you see those tins outside?" (Referring to some granulated gunpowder tins piled against his door.) "Yes? well, I have bought up 180,000 of them, sir. The cellar down below is chokefull of them; and the lot you saw in the passage only cost me a shilling. I am interested in this granulated gunpowder; it is made by an old friend of of mine in the neighbourhood of Hamburg, and I am going to put up my artificial quinine in these empty tins. As I say, I want £20,000 for my invention, and I think I shall get it too. I am now in communication with the Government, and I think I ought to get part of the annual subsidy they give towards the cinchona plantations in India. Bless you, sir!" Dr. Hewett excitedly exclaimed, applying vigorous slaps to the seat of the sofa upon which he was reclining, "I have had Mr. Howard in this room, sir! sitting on this identical sofa! He wasn't a bit surprised when I told him of my discovery, but said he expected it all along, and knew it must come."

Dr. Hewett did not appear willing to give any further account of his alleged negotiations with Messrs. Howard & Sons. He mentioned, indeed, that he had a letter from that firm which he would like to show us but, upon looking for it the document could not at that moment be found. He thought, however, that he would be able to produce it later on, if we would pay him another visit, to which we agreed.

Calling again later in the afternoon, we found the Doctor enjoying a peaceful slumber on his sofa. He had, he said on awaking, received no end of calls from people anxious to know all about his invention and felt very fatigued. Again adverting to the question of his discovery he stated that he actually, at that moment, was in possession of an offer from a German firm, a member of which was a personal friend of his, the acquaintance having sprung up during the Franco-German War, in which Dr. Hewett was engaged as a member of the Red Cross Society.

As to the statement that the discovery was made through the accidental breaking of a medicine-bottle, that was quite incorrect. He, Dr. Hewett, was not in medical practice, and had never used a medicine-bottle in his life. The fact was he had during the last eleven years devoted his energy to the discovery of artificial quinine, and it was at last found by him in connection with the action of salicylic acid on urea, with which he was temporariiy occupying himself.

The Doctor declined to answer our question whether he obtained his artificial quinine from a mineral or a vegetable matter, but admitted the correctness of the statement that the material from which it is manufactured is obtainable in abundance in every part of the world. He distinctly stated that it was prepared by a synthetical process, and was nothing in the way of conversion of amorphous quinine as had been suggested in some quarters.

Dr. Hewett claims to be able to make either hydrochlorate or sulphate of quinine, and maintains that the article can be turned out by him even at a cost of twopence per ounce, if the manufacture takes place on a sufficiently large scale.

He states that he has actually sold some of his quinine, not, however, in wholesale quantities, his laboratory at the present moment not being sufficiently extensive to enable him to do so.

We requested the Doctor to provide us with an ounce of his artificial quinine, observing that of course we expected it at the new rate of 3d per oz. This the Doctor could not agree to. He was quite willing to make some quinine for us—would we have sulphate or hydrochlorate?—but he would have to charge us the present market price for Howard's quinine.

To this arrangement we raised no objection, and it was agreed that on the morning following our interview the Doctor should send us a sample of his preparation for inspection. But, remembering that his time was very limited that evening, and having, he said, no artificial quinine whatever in stock, he asked us to be satisfied with the delivery of ½ oz. next morning, that being as much as he could turn out that night. By way of explanation, he added that the drying process of the quinine in the water-bath was a slow one.

Adverting again to the commercial aspect of the question, we wished to be informed in what manner the Doctor purposed working his invention commercially. "Would he take out a patent?"

This inquiry, natural and harmless though it seems, appeared to rouse Dr. Hewett's anger, and in stentorian tones he desired us to say whether we thought he looked like a fool or an old woman. He knew very well what he was going to do, the principal and first step being the puttiug of money into his own pocket! Then, as if regretting his momentary ebullition of temper, the Doctor assured us that he had carefully made his plan. His idea is to start a company; a sum of about 2,000*l.* being, he thought, all that was required for building purposes and to set the concern going. He will be glad to hear of anyone willing to co-operate with him.

Our representative then pointed out to the doctor that the present annual consumption of quinine in the entire world is stated to amount to some 150 tons only and suggested that the quantities mentioned in the earlier interview as intended to be placed on the market by the doctor were out of proportion to all possible requirements. But Dr. Hewett firmly adhered to his determination to swamp the market in the manner indicated. It might be that no sufficient demand for the artificial quinine would be found in Europe, but he was quite sure that the inhabitants of other parts, particularly North and South America, only required to have the drug put before them at a "popular" price, in order to swallow it in quantities undreamed of hitherto.

We regret that up to the time of going to press the promised ½-oz. sample of the artificial quinine has not been received by us.

ASBESTOS *VERSUS* INDIARUBBER.

Our naval authorities appear to be showing a praiseworthy activity in the study of the problems which anticipation of the maritime warfare of the future suggests to them. How quickly ships become obsolete nowadays is demonstrated remarkably by the fact that the target for the guns of the "Blazer" and the "Pincher" yesterday was the "Resistance," an ironclad designed by Sir Edward Reed, soon after he had done the same creative work for the "Warrior." The object of the experiments was to test the merits of indiarubber and asbestos fibre as a means of plugging short holes, preventing the inflow of water into a vessel after performation by shot, and minimising the damage from shell fire below decks. The indiarubber inserted in the skin of the ship seems to have failed altogether. It was lacerated and scattered, and was manifestly not to be relied upon. Reports differ as to the results of the trial on the asbestos, but it would appear to have carried off the palm from its rival, though it won its victory in an unexpected fashion. It was supposed that it would keep out water by swelling, and through its elastic power generally. This was not the case, however. It achieved the desired end by changing its substance, after perforation by the shot, having been converted into a sort of paste or putty by means of absorption. When the ship was heeled over so as to bring this paste below the level of the waters of the "Solent," it was found that it

fully answered the purpose for which it was intended. The importance of the discovery of these qualities of asbestos cannot be over-estimated. It will raise our confidence in those of our fighting ships which have unarmoured ends, and many prevent them from becoming practically waterlogged in action. Indeed, it would appear that a most invaluable addition has been made to the defensive properties of war ships.—*Globe.*

NOTES ON POPULAR SCIENCE.

By Dr. J. E. Taylor, F.L.S., F.G.S., &c., Editor of "Science Gossip."

Most of my readers are aware that the edible swallow's nests, which form the acme of Chinese gastronomy, are composed of semi-digested seaweed disgorged for the purpose of constructing those curious dwellings. They may be also further aware that many fishes build nests, some of a highly artistic character. Amongst these nest-building fishes the sticklebacks, marine as well as freshwater species, are most distinguished. Our marine stickleback constructs a nest of various available materials, which latter he binds together by curious mucous filaments. Professor Moebious, the distinguished Danish naturalist, has recently shown that these mucous filaments are formed from the epithalial cells of the fishes' kidneys. Moreover, he formulates the possible means by which this curious habit has come into play. First, the kidneys are hypertrophied; their enlargement causes an abnormal pressure, from which the stickle-back tries to relieve itself by rubbing against foreign objects, to which the squeezed-out mucin adheres. But at such time he is in close company with his mate, and near to the bunches of eggs which the latter has fastened to the water plants. Among the latter he finds the nearest and most convenient place for getting rid of the troublesome mucin, and thus he becomes an unconscious nest-spinner.

Everybody is acquainted with the fact that after the leaves of trees and shrubs fall the wound closes up again. Otherwise the places would "bleed," and the sap or vegetable blood would ooze away. The healing of these vegetable wounds is not a matter of accident, nor is it always effected in the same way. Professor Haby has been carefully studying the subject, and he finds that the closing of the scars after the falling of the leaves takes place in at least four different ways. First, by the drying up of the surface of the wound, as in tree ferns; second, by the formation of reticulated cells, as among the orchids; third by the formation of a special skin or periderm (which is by far the commonest method); and, fourth by the wounds being closed by the exudation of gum. The latter process is also very common in nature, and it suggests an artificial means by which we may heal any accident to the shrubs and trees of our gardens.

A very suggestive and possibly important discovery to winegrowers has been made by Signor Cuboni, an Italian scientist. He shows that the sap which flows from the Italian grape vine stem in March and April contains numerous germs or microscopical organisms which he holds to be identical with Saccharomyces. When these germs are placed in sterilised must they rapidly produce vinous fermentation. A still closer examination has proved that the "germs" are merely buddings from the fruit-bearing (hypha) branches of a fungus which grows parasitically upon the bark of the vine, and which is known to botanists as Cladosporium herbarum. These buds get into the gum which exudes from the cut surfaces of the old branches, or into the sap which flows out. They then put on all the appearance of, and are possibly actually identical with, the ferment fungus Saccharomyces. Thus it may happen that we are indebted for the fermentation, ripening, and bouquet of our wines to the apparently accidental wanderings and ramblings of fungus spores, which have no botanical business to be where we find them.

It has been shown that the quality of yeast depends very greatly upon the absence of Bacteria. The vinegar-plant' (as it is called) builds up a tissue of true cellulose; but the real yeast plant develops a modified cellulose structure resembling that produced by Bacillus aceti, quite different in its reactions to the other. I don't know whether the little creature haunts Australian houses, but I have a strong opinion that I saw it in Melbourne—the "fish-moth," "silverfish," &c., as it is popularly called, but more correctly known to entomologists as Lepisma domestica, one of the Thysanuridæ, whose scales have long been favourite objects with microscopists. It haunts damp cup-boards, and glides about like a fish, and yet its body is silvery and moth-like—whence its popular name. It is very common in all old houses here. These insects are very fond of paper, and their chief delight is to devour the labels in museums. It has just been found that they are also partial to silk dresses (*always black ones*) and even woolen garments, Curators of museums, &c., are recommended to steep their labels in corrosive sublimate. Ladies cannot adopt the same precaution with their black silk dresses, so they will have to hang them in very dry wardrobes instead.

An important paper by Dr. Kelner has recently been published, in which many of the facts menioned will be familiar to horticulturists and agriculturists. The subject of the paper was the influence of urea upon soils, with special reference to the well-known methods of employing it in China and Japan. It is proved that the application of fresh excreta is actually injurious to crops, and that in such a state a great deal of the most valuable nitrogenous compounds of the manure are lost by the rain carrying them into the deep subsoils beyond the reach of the roots of plants. Japanese farmers never employ either urine or manure except when it is in a highly decomposed state, and the urea has been converted into carbonate of ammonia.—*Australasian.*

LABOUR IN FIJI.

(*From the "Handbook to Fiji" for the "Colind" Exhibition.*)

The chapter on "Labor" notices the subject under its three phases, Indian, Polynesian, and Fijian, and gives prominence to the leading facts in each case. Among other matters having respect to Indians it is observed:—"The quality of the coolies imported into Fiji has varied with each vessel. Some ships have brought a fine working lot of men; others appear to have successfully relieved India of a surplus gaol population. No doubt the past experience of Fiji planters, confined to quiet and more easily managed Polynesians and Fijians, has not been good training for the working of Indians. The notorious litigiousness of these people has been a source of great annoyance to planters in Fiji and has multiplied by ten the work in the district courts.' It may be hoped, however, that as time passes by, both Indians and their employers will become better able to form working traditions which will bind both sides by the bond of mutual advantage." It is generally understood that Mr. Anson will shortly return to the colony, and the resumption of his rule at the Immigration Office affords the very best possible guarantee for the realisation of the hope above expressed. Further it is remarked:—"That Indian immigration to Fiji has on the whole been a success admits of no question; without coolies none of the large companies could carry on work." It may here be interjected by way of comment that the full list of employers is under thirty; that almost half the coolies are under engagement to one leviathan company, and that when four others have been reckoned with, out of a total of about 6,000 there are not more than 600 or at the outside 700 in the employ of the rest. But to proceed; it is stated:—"Several indeed (of the large companies) have discarded Fijian and Polynesians entirely and work with Indians alone, from whom Europeans can obtain ordinary and extraordinary work by the inducement of money, which offers few temptations to the unsophisticated Polynesian, but which appeals with annually increasing force to the Fijian." This statement contrasts strangely with the following, taken from that section of the chapter devoted to Fijian labor.—"At the present time (Feb. 1886) there are 600 native laborers engaged for a term of a year beyond their home districts at rates of wages

varying from £5 to £8 per annum." The cost of Indian introduction per caput is £21 16s 5d exclusive of £7 10s for return passage money; the cash inducement is annually appealing with increasing force to the Fijian; yet out of a population of 114,000, but 600 are engaged as yearly laborers. The explanation given is that:—"This state of things has been contributed to by the Fijian's high idea of his own importance as a laborer and his exorbitant demands at a time when they had to be conceded." This of course supplies the fullest explanation which could possibly be required. But reverting again to the coolie; it is remarked that "constitutionally the Indian coolie seems to adapt himself to whatever colony he emigrates to. The climate of Fiji appears to be admirably adapted to him and unlike the Polynesian he has always formed one of the healthiest factors in the population of Fiji. They are, however, by no means such good workers as the Polynesian; while it would hardly be an exaggeration to say that the criminal statistics of the colony date their existence from the arrival of the coolies. It cannot but be regretted that while due recognition is given to the value of the work performed by the coolies, both on and off estates, the necessities of the colony no less than the crying calls of humanity called for the substitution of Indian for Polynesian and Fijian labor." Concluding this subject the followinn may be quoted from the section devoted to Polynesian labor and it may be read in conjunction with the above statement that the Indians are "by no means such good workers as the Polynesians."—"It cannot be said that Polynesian labor is really cheaper than that of the Indian immigrants, but being more docile and more trustworthy the Polynesian is preferred to the Indian by most planters who have had experience in working them. It has been found that the Polynesians are not sufficiently strong to undergo constant work in the sugarcane fields and the Government have therefore discouraged their employment by large sugar planters. On the coconut and fruit plantations on the other hand these people are quite at home, and are generally preferred to any other class of laborers. Of the Fijian it is further remarked:—"It may be said that his occupation is gone. Eminently fitted for such work as clearing a plantation his services were, on plantations being opened up, eagerly sought; but now that work of this nature has for the most part been completed the supply of native labor exceeds the demand." There is in the whole of the remarks on the labor question a great deal that is undeniably true, but there is also a great deal which will afford Fijian planters food for reflection and comment.—*Fiji Times*, July 21st.

HOMING PIGEONS.

Sir,—I noticed in your issue of the 28th August last an article on homing pigeons, by "Homer." Allow me to point out that, not only in this country but in Europe also, the carrier pigeon has been immortalized by poets and historians as the messenger pigeon sent out to friends at a distance from beleagured cities with written messages, and in such instances the preference has always been given to the carrier. But in this country, from the manner in which these birds are reared, they are not equal to sustained flight, and from the want of practice often grow too heavy for the purpose. For homing pigeons, carriers should be selected when about two months old, and they should be flown morning and evening for an hour or two, with the double object of allowing them to exercise their wings, and to acquire powers of sustained flight, as also to make themselves familiar with the surrounding country in which their home lies, after which they should be taken out either daily or two or three times a week to a certain distance, which should be gradually prolonged, and then let loose, to find their way home. When they can in time accomplish distances of one or two hundred miles they may be considered fully trained. I have said carriers are the best kind of birds to form homing pigeons, but I have been in the habit of crossing carriers with the wild blue or rock pigeon, and their young make excellent homing pigeons, as they do not grow so large as the carrier, and they have the vigour of great sustained flight, which they inherit from the wild bird. I have now some kind of carriers as well as crosses with the wild birds that would make excellent homers.

Yercaud, 8th September. John Shortt.

—*Madras Mail*, Sept. 10th.

THE ORIENTAL BANK ESTATES' COMPANY.

It must be remembered that there were no less than nineteen Ceylon and four Mauritius estates to be taken over *en bloc*, comprising in the former over 10,000 acres, and in the latter over 11,000 acres. Though the Ceylon estates as a whole left a margin of profits, and were certainly far more saleable than two years ago, yet it is fair to assume that they are not all equally remunerative, and indeed, that some of them being in the trantision state, between coffee and tea or other new products, are not at present paying their way. The subjoined schedule will enable our readers to form an independent judgment on the question:—

Estates.	Total.	Acreage. Cultivated.	Coffee.	Coffee & Cin.	Cinchona.	Tea.	Tea & Coffee.	Cardamoms.	Coffee & Cocoa.	Grass.
Looleondura and	1,130	594		296	100	108	89	1		40
Waloya	301	185	60			176				14
Kudaoya	754	170		59		79	62			30
Wattewelle	690	690		250		375				40
Darawella	492	492		359		133				
Craigie Lea	253	158		128						
Dodangalla	517	210	30			35		35	140	
Kondesille	490	155		85		175	54			154
Daug Kande	311	272		151	26	227	146			
Glendevon	986	612		209	179	249				
Nilloomally	299	474		50						
Forest Creek	158	88	88			250		23		30
Donoughmore	511	430		67	228			10		50
Havilland	700	488	60	140		190				
Naranghena	587	190			140	75				
Simnapitiya	178	140			22	157				
Summer Hill	165	165		40	91	104				
Stellenberg	352	591	213	183						
Delmar	1,382									
	10,245	5,929	151	2,017	786	2,533	351	69	140	358

Note.—The figures for tea in the above table represent the acreage under this cultivation on 30th of June last, but the figures in the other columns are taken from Ferguson's Directory for the current year, probably corrected to 30th of June 1885, and some little alteration has taken place since then. Thus there was an increase during that interval of about 600 acres under Tea, part of which is taken from the land previously under coffee and cinchona.

The amount of cash payable to the liquidator, on account of these properties was £87,600 which is equivalent to an average of about £8 10s per acre or considerably less than the current price of the primeval forest fifteen years ago. But if we now

estimate the forest reserve and grass land on these estates at £4 per acre, or about £20,000, there remains only a balance of £67 to be spread over close upon 6,000 acres under various forms of cultivation, or just £11 per acre, which is, of course, a very low average value. Or, if we put it in another way, there are, roughly speaking, 2,300 acres of tea, which certainly ought to be worth £30 per acre, or £69,000, so that the Company obtains the coffee, cinchona, cocoa, and cardamoms for nothing! There can be no question that the Company enters on possession under most favourable circumstances. Ceylon has now passed through the crisis which coffee-leaf disease involved her European enterprise, and capital is once more seeking investment there in the new industries created by the indomitable pluck and preseverance of planters, combined with great natural resources. Every year the value of the estates will steadily improve under judicious management, and the Company will presently be able either to sell them outright at a handsome profit, or to continue working them on its own account, and we have no doubt that the result to the shareholders will be highly satisfactory, whichever course is adopted.

The Mauritius properties acquired by the Company are so circumstanced that it is impossible for us to give particulars, consisting, as they do, of claims and charges upon different estates, shares in estate companies, &c.: but we are assured, by those who have gone through the calculations, that the purchase consideration, viz., £65,350 in cash, besides a proportion of the Deferred Stock of the Company was very moderate, and that this part of the bargain ought to turn out quite as profitable to the Company as the other.—*Planters' Gazette.*

COFFEE AND ARECA IN MYSORE.

From a Correspondent.

From the official report of the Kadur district for the year 1885-86—one of the best coffee-growing parts of Mysore, we note that the total number of plantations are reckoned at 23,238, comprising an area of 138,185 acres, of which coffee covers 136,439 acres, cardamom 1,646 and cinchona 100 acres. The cultivation of cardamoms is much on the increase, while cinchona is also finding favour with the planters.

The Arecanut is grown very extensively in the Kadur district of Mysore and is almost entirely in the hands of natives. The total receipts by the Durbar on the tax from the arecanut produce was R95,000 in 1885-86, being an increase of over R23,000 on the preceding year. The increase was due to a good crop consequent on a favourable season and an almost complete absence of "rot" to which this produce is so subject. The arecanut sold at R10-8-0 per maund of 80 lb. locally; much of the produce is exported into the neighbouring districts of the Madras Presidency. Still more largely is arecanut cultivation carried on in the Shemoyah district, which lies to the N.W. of Kadur. The amount of tax collected in this district for 1885-86 was close upon R2,10,000 being an increase of nearly R50,000 on the previous year.

INDIAN MACADAMIZED ROADS.

[In copying the following article from the *Indian Engineer*, it may be well to mention that *Kunker* or *Kankar* is an impure nodular limestone common in many parts of India where siliceous rocks do not exist.—Ed.]

Macadamized roads in India are of two sorts—(1) kunker roads, and (2) stone roads. It is by no means a very easy thing to produce a good metalled road. It is considered by most people that all that is necessary is to "shove in the metal and ram it down." If well rammed, this method will, of course, produce a hard surface; but unless an ordinary "pucca" road even is made on scientific principle, the *traction* can never be reduced to a minimum, which is the object to be aimed at in the construction of macadamized lines of communication.

1. Kunker Roads.—The existing practice is to break up the metal to 2" cubes and to consolidate it with iron or wooden "door-mats" or rammers.

2. Stone Roads.—The present plan is to break up the stone to pass through a 1½" ring and to consolidate it with rammers. In some parts of India ordinary iron rollers are used, and in some places steam rollers. In consolidating stone, "mooram" (decayed rock) is freely used as a binding agent, and also for dressing the surface after consolidation.

4. Now, this practice appears to be defective If a kunker road is dug up after consolidation according to method (2), it will be found that the 2" cubes have been crushed and reduced to ¼" and ½" cubes, thus reducing fearfully its power of resistance. Hence it is that (1) the top layer of kunker does not last long, and (2) the cost of maintenance is greatly enhanced, and (3) the surface of roads is never *even* and *smooth*, thus increasing the traction. On stone roads the surface is so very rough that the greater number of country carts pass along the earthen siding during the dry months of the year.

5. The writer ventures to offer the following suggestions, which if adopted in constructing metalled roads, will, he is sure, produce profitable results.

6. Kunker roads.—Kunker should be of hard texture and broken to 1½" cubes. Consolidation to be done with lots of water and one of Aveling and Porter's steam rollers of 15 tons. The advisability of using a roller is obvious. The gradual pressure will *not break up the kunker into small particles*, but jam it together, leaving the original nodules practically intact, but closely knit together.

7. Stone Road.—Stone (granite, quartz or other hard stone) should be broken up as small as practicable, but certainly larger than 1" cubes should never be used; ½" and ¾" cubes would be better. It should be closely packed and rolled with one of Aveling and Porter's steam rollers of 15 tons. "Mooram" should not be used, and the *first* rolling should be done quite dry until the layer of metal is firmly compressed. The surface should now be freely sprinkled with a mixture of "mooram" and water, or a layer of ¼" mooram spread over the surface, well watered, and the road rolled thoroughly over again until the surface becomes perfectly smooth.

The last process is to lay a *thin skin* of mooram, say ¼", dry over the surface and the traffic allowed to pass over it.

It is obvious that, unless the stone is broken up *small* and to a *uniform size as practicable*, (1) a smooth surface will never be obtained, and (2) the cubes will *never bind* and *hold together as a solid mass*. "Mooram," or any other binding agent should never be used with the stone *before the first rolling*, as it absorbs moisture and the road would break up during the rainy season.

R.

The Soap Tree.—The soap tree grows freely in Tallahassee. This tree bears a large number of berries, which are about the size of an ordinary marble, having a yellowish, soapy appearance, with a hard, black seed, from which the plant is propagated. Sometimes the soap is obtained by boiling the berries, but in Japan, and other tropical countries, the berries are used as a substitute for soap just as they are taken from the tree.—*Burgoyne, &c.'s Monthly Export Price Current.*

Acid (Boracic).—The experiments to preserve fish by curing it with this acid (to which attention was called in the *Chemist and Druggist* sometime ago) are, we hear, proving remarkably successful, some fish having recently been inspected in London which had under the boracic acid treatment retained all its original freshness. We hear that the idea is entertained in some quarters to introduce the boracic acid treatment of fish to Ireland. It is thought that fish so cured would command a ready sale in England and contribute to the revival of a drooping Irish industry.—*Chemist and Druggist.*

Artificial Diamonds.—A correspondent of *Inventions* (Mr. J. Palmer) states that he obtains crystallised carbon in the following manner :—Carbonic acid gas is liquefied by pressure in a strong wrought-iron cylinder, which has an insulated carbon rod fixed at each side of the lower end. The end of each carbon rod projects into the vessel about an inch. A current of electricity (about E.M.F. 30 volts and 15 ampères) is then passed through the liquid gas, by means of the ends of the carbon rods, outside the cylinder, being connected to an electric battery. Electrolytic action then takes place on the liquid gas, and pure crystals of carbon are gradually deposited on the carbon points. What becomes of the liberated oxygen, the iron vessel, and the operator is not stated.—*Chemist and Druggist.*

Cocoa Drying &c. in Matale.—What has become of those perfections of drying apparatus—the American evaporators? Is cocoa still stewed and desiccated in these machines? I hear that on one large estate a tea drier is being utilized as a cocoa-drier also. The drying of cocoa artificially is not by any means simple affair. I have seen a small room economically arranged with stove and fan turn out very efficacious and a more ambitious scheme of Clerihew (with no limit of care and thought and expenditure) yet turn out a failure. There is no doubt but that cocoa suffered terribly from the drought of 1883-84, and that even old trees in the open were not able to recover for a long time. The bark seemed black and "bound." I may mention an experiment made upon trees to effect some relief to this. They were cut as deep as was safe (the bark merely) along the older branches, but chiefly on the stems, straight down, in four lines so as to allow the tree to expand more freely. They all appeared to derive much advantage from this, and there is one tree at the Peradeniya Gardens which was so treated that it is literally crowded with fruit upon all its branches, as if the cutting had somehow made the sap fly to the branches in superabundance.—Local "Times."

Agriculture in the Southern Province of Ceylon.—Mr. Wm. Jansz, the retired head clerk of the Batticaloa Kachcheri, who has had 15 years' experience of Agricultural operations in the Eastern Province, has indented fot a supply of seed paddy from Batticaloa with the objec of introducing it into the Galle district. He is so convinced that before a good crop can be got, the seed must be brought from some distant place (which it appears the Sinhalese cultivator does not recognise), that he is desirous of experimenting with the Batticaloa seed paddy. The field selected is at Ganegama in the Gangaboda Pattu, and three kinds of seed, maturing in three, four and six months will be used. We trust that Mr. Jansz's efforts on behalf of the agriculturists of the South will meet with all the success which such a public-spirited attempt deserves. According to Mr. Green (Agricultural Primer) "the Sinhalese cultivator recognises this principle of rotation without knowing it when he tries one kind of paddy seed for one crop, and another kind for the next crop." In case the present scheme result satisfactorily, we shall be curious to know if the native cultivators will adopt the experiment. Mr Jansz's opinion is shared by an experienced European planter, who states that the present meagre yield can be quadrupled by employing imported seed.

The "furious" Ceylon Cinchona Planters.—Such is the way in which the *Chemist and Druggist* in reviewing proceedings of the Pharmaceutical Conference refers to our cinchona cultivators. An interesting reference is also made to the Nilgiri Gardens and to the scientific work going on there :—

Last year Mr. David Hooper gave good indication in a paper read at Aberdeen that there is good stuff in him, and that he is a worthy successor of Broughton. The importance of the Government cinchona plantations has, from a commercial point of view, diminished considerably since Ceylon planters have gone in for cinchona so furiously; but for that very reason the Government venture has increased in scientific importance. The work of a quinologist in a cinchona plantation is in the highest degree interesting, and of great practical value to the cultivator, since it reveals the effect on the bark of the various artificial means which are adopted to improve the drug in quantity and quality. Naturally, such a paper as Mr, Hooper's may be little discussed, but that is no reason why it should not get a good place in the programme.

Cinchona and Tea in Java.—From translations in *Straits Times* received today we learn :—"The Planters' Association at Sukabumie in Java has taken steps to test a newly invented process found out by Dr. Eydman for cheaply extracting medicinal alkaloids from *cinchona* barks. Should the experiments result satisfactorily, a problem of the utmost weight to cinchona planters in that island will be solved. Dr. Eydman is fully confident and sure of success so that there is every prospect of arriving at a solution favourable to the interests of cinchona growers there. Another welcome bit of news to them is the assurance on good authority that, in Ceylon, the export of cinchona bark has reached its utmost limits, attended by a heavy increase in that of root bark, one consignment of which was secured by digging up about fifty thousand trees. Bark exports show such evident signs of approaching decrease that one out of three agents of European firms buying up that article at Colombo is said to have made up his mind to settle down in Java. His coming thither is only deferred until that island produces cinchona bark enough to admit of his establishing himself permanently there.—Tea growing in Java as pointed out by an expert in the *Bode* has a bright future before it. Yet capitalists, for some reason or other, shrink from embarking money in this line of business. As matters now stand, of all the kinds of cultivation carried on in Java, that of tea is certainly by far the most remunerative. Should seasonable rains continue to fall, the dividends of many tea companies will assuredly prove this at the end of the year."

Water Purification.—At a recent meeting of the Institution of Civil Engineers, the paper read was on "Water Purification: Its Biological and Chemical Basis," by Percy F. Frankland, Ph. D., B. S. C., F. C. S. The earliest attempts to purify water dealt simply with the removal of visible suspended particles ; but later chemists turned their attention to the matters present in solution in water. Since the advance of the germ theory of disease, and the known fact that living organisms were the cause of some, and probably of all, zymotic diseases, the demand for a test which should recognize the absence or presence of micro-organisms in water had become imperative. It was, however, only during the last few years that any such test had been set forth, and this was owing to Dr. Koch, of Berlin. By this means the only great step which had been made since the last Rivers Pollution Commission had been achieved. It had been supposed that most filtering materials offered little or no barries to micro-organisms ; but it was now known that many substances had this power to a greater or less degree. It had also been found that, in order to continue their efficiency, frequent renewal of the filtering material was necessary. Vegetable carbon employed in the form of charcoal or coke was found to occupy a high place as a biological filter, although previously, owing to its chemical inactivity, it had been disregarded. Being an inexpensive material, and easily renewed, it was destined to be of great service in the purification of water. Experiments were also made by the agitation of water with solid particles. It was found that very porous substances like coke, animal and vegetable charcoal, were highly efficient in removing organized matter from water when the latter came in contact with them in this manner. Also, it was found that the well-known precipitation process, introduced by Dr. Clark, for softening water with lime, had a most marked effect in removing micro-organisms from water.—*Indian Engineer.*

Correspondence.

To the Editor of the "Ceylon Observer."

LIGHTNING AND COCONUT PALMS.—No. 1.

Colombo, 23rd August 1886.

Sir,—"Fact" has gone beyond facts when he does not doubt that it was the Telephone wires that attracted lightning. How does he account for the lightning ferreting out the few Telephone wires passing under the cornice of Messrs. Aitken, Spence & Co.'s office and not being *attracted* by the massive 30-feet iron post with its greater number of wires and brackets only a few yards off?

I think "Fact" may with advantage learn a few electrical facts especially with regard to Telephone and its wires.

Fact No. 1.—If the Telephone wires had attracted the lightning, they would naturally have received at least the greater portion if not the whole of the discharge, which was not the fact.

Fact No. 2.—The Telephone wires are so constructed, that, should they receive a discharge of lightning, they will be fused and cut off the further progress of the fluid, which fact did not happen.

Fact No. 3.—All the Telephone instruments are protected by very sensitive lightning protectors which act by fusion, and so sensitive are they that a discharge several hundred yards away from the lines causes them to act. In the thunderstorms of the 3rd and 4th May last over 80 of these were destroyed, in fact every Telephone Office was cut off.

Fact No. 4.—So small was the quantity of electricity taken up by the wires passing A. S. & Co.'s office that only their lightning protectors at one end were affected and the annunciator coils on the switch boards were not in the least injured.

Fact No. 5—Is that if the Telephone wires had the propensity of attracting lightning as "Fact" *no doubt* believes, I should certainly not expose myself in a Telephone Exchange from which so many wires radiate, whereas the fact is that since the Telephone was worked in 1877 there has not been an accident in the thousands and thousands of offices over all parts of the globe.

I will not take up more of your space, but if "Fact" wishes to learn some more facts I will be happy if he call round at the Telephone Exchange to show him all the precautions to guard against accidents taken by THE MANAGER, O. T. C. Ltd.

Colombo, 23rd August 1886.

Dear Sir,—I must thank "Fact" for correcting me as to the effect of lightning on the whole tree in front of Messrs. Aitken, Spence & Co.'s office, but what about the branches killed on the N. W. corner of the tree? For the information of the Manager of Ice Manufacturing Company, and others who should require t, I shall describe the way to put up a good ightning protector on a chimney; those for other buildings vary only as to size, quantity and position, according to the bulk and shape of the building. First, starting from the top it should consist of a copper rod from ¾ in. to 1 in. in diameter divided at its upper end into three or more points which should all be well electroplated or heavily tinned to keep them from oxidising; next, the rod should be about 5 feet above the top of the chimney; then it should be attached to a ribbon of copper 2 in. by ⅛ in. running down the whole length of the shaft, it must be attached directly, to the masonry by copper staples, it must be buried in the ground (or down a well preferably) to water-level in dry weather, on reaching which it should be cut in two equal strips and attached to a copper plate 6 feet by 3 feet by 1-16th in., each of the strips being attached 2 feet from either end and down the whole breadth of the plate. The plate should be brightened up and buried perpendicularly with 6 in. of charcoal pressed down well all round it. The plate should be well below dry weather water-level. A most important point is to have all joints screwed or riveted *and soldered*. It should when finished, be, if possible, electrically tested. The use of two metals is decidedly bad, and it must be remembered that a bad lightning protector is worse than no protector at all—Yours faithfully, Q. E. D.

THE DOUBLE COCONUT AND VARIETIES GROWING IN CEYLON.

Central Province, 25th August 1886.

Sir,—Does the Coco-de-mer or double coconut grow in Ceylon? It is said to grow luxuriantly in the Seychelles Islands. If we have none in Ceylon, perhaps Mr. E. H. Edwards who is down in those Islands will send up a few young plants in the shell. It would also be well to ascertain if the common coconut grown in those islands and in South Africa are the same as those we have in Ceylon. It is only lately I became aware of the several varieties there are among the coconuts grown here: the only difference seems to be in the size of the nuts. I am told some trees never yield large nuts, however good the soil may be. I should like much to know where the best and largest grow, in what part of the island.—Yours faithfully, LATCH.

[Our correspondent will find a good deal of the information he wants in our publication, "All about the Coconut.]" Dr. Trimen says of the *Coco-de-mer*:—

Coco de-mer.—In response to an application made in 1882, I have received from the Chief Civil Commissioner of the Seychelles, through His Excellency the Governor of Mauritius, 10 seeds of this rare and magnificent palm. They arrived in April (1884) and were at once planted 7 at Henaratgoda and 3 at Peradeniya. As yet there are no signs of germination, but the usual period occupied in this process is from 18 to 30 months, so that this is not to be expected. Peradeniya already possesses two beautiful specimens of this unique Palm, about 30 years old, but in the case of so extremely local a plant as this and one of such peculiar interest to naturalists, it is much to be desired that a larger stock should be in existence, so that in time it may be possible to propagate by seed from another centre. This palm, being, like the Palmyra, dioecious, it is necessary to have sufficient plants to make it probable that both sexes will be represented among them.

Mr. E. H. Edwards sees the *Tropical Agriculturist* regularly in which this letter will appear, and he may perhaps respond. We have no doubt our Hapitgam Korale correspondent will have something to say about where the largest nuts are found in Ceylon.—Ed.]

THE CROTON-CATERPILLAR ATTACKING TEA.

Dear Sir,—You will be sorry to hear that the croton-caterpillar does eat tea leaves, baring the bushes rapidly when there is no more suitable food for it to devour. Of course it prefers croton, but when that is exhausted it takes readily to tea and even Liberian coffee. The ravages of this pest have not been at all exaggerated, and those who have both tea and croton will find it desirable to decide which to keep, for if tea is held by, then the presence of croton becomes dangerous as tempting the pest to settle, The Madatiya (*i. e.* the wild charcoal-tree) also affords a tempting feeding-ground for the grub. NEW PRODUCTS.

[It must then be a case of '*Delenda est Carthago*' croton-oil trees taking the place of Carthage. "Out with them" will be the cry of our tea-planters, and the only question will be that of compensation to the croton-oil tree cultivators.—Ed.

Charcoal of the coconut shell is specially used by native goldsmiths in melting gold and silver. Why? Is it that it yields more intense heat? Charcoal is variously used in electric lighting. Professional or scientific men might try different kinds of Indian charcoal and ascertain if any of it is specially fitted for the purpose. There is the *yercum* charcoal, that of the coconut shell, that of *oomi*, the husk of rice, and the arecanut, and so on. If I remember aright, charcoal is also used in forming galvanic batteries. Trials might result in some useful discovery which might yield a little fortune to the discoverer!—*Madras Mail.*

Gutta-Percha.—Sir John Kirk, writing in December last, forwarded a sample of native African gutta-percha, the produce of a yet unknown tree which he found at Mombasa. From the papers now published, it would appear that after examination of the specimen there remained no doubt that the substance would prove an acceptable addition to the present supplies, its value being about 10*d.* per lb. At the same time Sir John Kirk also forwarded specimens of some Indiarubber taken from plants supplied from Kew Gardens about five years ago, these having flourished and propagated freely at Zanzibar. The report on this specimen valued it, if taken from the trunk of the tree, at about 1*s.* 9*d.* to 2*s.* per lb as Sir Joseph Hooker, late Director of the Royal Gardens at Kew, remarks, "the attention of Her Majesty's Consular officers in these countries (India-rubber producing states) cannot be too closely addressed to matters of this kind, which are not merely of great scientific interest, but may from the basis of a lucrative and beneficial trade."—*Indian Agriculturist.*

Planting Prospects in St. Lucia.—A. St. Lucia correspondent thinks King Sugar is dead, and blames, the Government and the planters for not initiating other industries which it will pay to cultivate. This is all very well, but it is very difficult to get out of an old groove. It cannot be done in a day, neither can it be done without money. Still, if there be no prospect of reviving King Sugar, then, obivously, something will have to be done if the estates are not to run to seed. From the market returns it will be seen that tamarinds, turmeric coconut oil, cinchona bark, chillies, cloves, ginger, and mace sell at rates which would pay for the trouble and expense of their cultivation. Now, as it is well known that the soil of St. Lucia is friendly to the cultivation of all these articles, might it not be as well if the good people there were to give some of them a trial.—*Planters' Gazette.*

Ceylon Tea Gardens.—Messrs. Rucker and Boncraft, the well known brokers, of 37 Mincing Lane, have just published a second list of Ceylon Tea Gardens, shewing the names, districts, and acreage, of about 900 different properties arranged in alphabetical order of districts.* In presenting this list to their clients they remark:—"When our first list was published in November, 1885, about 13,000 acres were under Tea. Now, including as Tea Gardens those estates which are growing tea among coffee and cinchona, the figures approximate 120,000 acres, or nearly three times as much. We have written so fully from time to time to urge upon Planters the great necessity of striving after quality, that we risk appearing wearisome by reminding them that very strong brisk flavory China Tea, with a fair leaf, can be bought at from 7d to 8d per lb. in this market, and that if Ceylon Tea is not kept away above this class in quality, the results must be simply disastrous. It must be borne in mind that such a list as this is necessarily incomplete, as fresh ground is being broken every day, but it may be of some use if only to signal 'Caution' in view of what must be regarded as a certain over production of Tea."—*Planters' Gazette.*

* Made up from our Directory.—Ed.

Making Tea in Japan.—The Japanese host never intrusts the making of tea to his servants on high occasions, and the fine art of the process was fully shown us in the dainty management of every article of the service before the host. The teapot was a little jewel-like thing that could be set—handle, spout and all—inside of one of the common-sized coffee cups that a foreigner draws once or twice at a breakfast, and the cups were of fine cloisonné, with plain enamelled linings, each no larger round than the circle of a tulip's petals could inclose. With them was a small pear-shaped pitcher, a beautifully wrought bronze teapot in which the boiling water was brought, and a lacquer box containing the caddy of the choicest leaves from the fine tea gardens of Uji district—a tea so rare and expensive that none of it is ever exported or known abroad, and only the wealthiest Japanese can afford to buy the precious leaves. Our host, taking an ivory scoop carved in the shape of a large tea leaf, filled the little teapot full of loosely heaped leaves, and then having poured the hot water into the pitcher that it might cool a little, poured it into the teapot. That part of the tea-making was most puzzling to us of the Occident, who had been taught, as the first principle of tea-making, that the water must be boiling at the minute it touches the leaves, and that unless at boiling-point, tea made with it is flat and unprofitable. Our Japanese friend explained to us that to the most critical and epicurean tea-drinkers of his country boiling water was an abomination, as it scorched hte leaves, drove out the fine fragrance in the first cloud of steam, and extracted all the bitterness instead of the first sweet taste of the young leaf. "It may be all well enough for the coarse black tea of China to pour boiling water on it," said this most delightful Japanese, "but the delicate leaf of our cultivated tea plant does not need it." And we bowed submissively and promised never more to apply Chinese processes to Japanese tea-leaves.—*Miss Scidmore's Kioto Letter in the Grocer.*

Tea Coffee, and Sugar in the United States.—The other day, says the *Pall Mall*, we printed statistics showing a great increase in the consumption of beer and tobacco in the United States during the past financial year. As the *New York Tribune* points out, a still better test of the condition of the entire population, however, is the consumption of tea, coffee, and sugar. Well, the consumption of sugar last year was 10 per cent. greater than the previous year, which means a consumption of more than 50 lb. for every inhabitant yearly, a quantity that has never been used except in one year in the entire history of the country. Twenty years ago the people used only 30 lb. each. The consumption of tea was over 1.27 per capita, as against 1.17 lb. in the previous year. This is a consumption less than was recorded in the years 1881-83. But in 1866 the consumption was scarcely more than a pound for every person. The quantity of coffee consumed last year was probably 9.17 lb. per capita. But that is more than was ever consumed in any previous year. It is nearly 1 lb. more than was consumed in 1881, a year of great prosperity, and 2 lb. more than was consumed in 1876, ten years ago, and more than double the quantity consumed in 1866, twenty years ago, when the consumption was only 4.37 lb. per capita. Surely, says the *Tribune*, these are not evidences of starvation. If the people drink two cups of coffee where they needed one in other years when general prosperity prevailed; if they take more cups of tea, at least four where they formerly used three; and if they use for sweetening the tea and coffee five pounds of sugar where they used to be content with three, if is safe to say that they are not in absolute want of the necessaries of life.

A CINCHONA SYNDICATE FOR CEYLON.

We have to call attention to the letter of Mr. James Sinclair on page, 276, a subject of very great importance to cultivators of Cinchona in Ceylon. It strikes us that one of the indispensable preliminaries to the successful working of the scheme proposed would be the acquirement of reliable and full information as to the exact position of the Cinchona enterprise not only in India and Java, but in the States of Central and South America where systematic cultivation has been attempted, and also the conditions under which the further exploitation of the native cinchona forests would be permanently discontinued. In this connection we may quote the summary in the *Pharmaceutical Journal* of a paper read by Mr. David Howard at the British Pharmaceutical Conference:—

"Cinchona Cultivation in South America was the title of a paper by Mr. David Howard, who belives that it is to other countries than Ceylon, which occupies at present the most prominent position of all the countries where cinchonas have been cultivated, that we must look for the solution of the scientific points involved in the cultivation of cinchonas, owing to the little care that has been taken in Ceylon to avoid the danger of hybridization. Unfortunately, very little scientific information can be obtained from South America, the natural home of the cinchonas, except what little can be derived from the study of the cultivated bark which reaches us from that country. Among the cinchonas under cultivation in South America are two new species, *C. Thomsoniana*, named after Mr. Thomson, who discovered it in the Central Cordilleras, the home of the well-known *C. lancifolia*, and another discovered by Senor Pombo in Ecuador. *C. Thomsoniana* gave on analysis of the bark of a two-year old tree 3·3 per cent. quinine sulphate, trace of cinchonidine, and 0·55 per cent. cinchonine. The bark from the other species of the same age gave 5·7 per cent. quinine sulphate, 0·43 per cent. cinchonidine, with no cinchonine or quinidine. The improvement brought about by the successful cultivation of the cinchonas is further shown by the results obtained from the same plantations in 1872 and 1881 of the several kinds of cinchonas grown in Jamaica and these results were even more favourable in the cultivation in Columbia of descendants from the Jamaica plantations. In the case of a succirubra cultivation in Columbia from a Jamaica plant the bark yielded as much as 7·0 per cent. quinine sulphate, with only 1·9 per cent. cinchonidine, and 0·67 per cent. cinchonine and Mr. Howard remarks that this succirubra is one of the finest he has tested. In Mr. Howard's opinion it cannot be too clearly borne in mind that the prospect of future profits in the cultivation of cinchonas depends entirely on the cultivation of high testing bark, for in the face of the importation of such highly valuable cultivated bark from Bolivia, as well as from Java, the profitable growing of inferior bark is impossible."

If the Ceylon Syndicate were fully supported, a special agent might be employed to collect information in the several countries, and if in addition the gentlemen in Colombo named by Mr. Sinclair in a private letter as likely to give their services, took a managing interest in the Syndicate we should be very hopeful of success. Of course there are other difficulties in the way, many of which are detailed in the letter under notice; but probably all could, by persevering and united endeavour, be overcome.

LETTERS FROM JAMAICA.—NO. XIII.

A STORM AFTER A CONTINUANCE OF UNSETTLED WEATHER —COFFEE CROPS—THE ANNUAL FLOWER SHOW IN KINGSTON—JAMAICA FRUIT TRADE—PROTECTION OF PRODUCTS AND MANUFACTURES.

Blue Mountain District, Jamaica, July 1886.

Since I last addressed you about the 20th ult., we have had a continuance of very unsettled weather. Sunday night, the 27th June, we had a storm which most people believe to have been the tail-end of a hurricane, for more mischief was then done in that one night, than had been caused by the previous fortnight's bad weather: not only was the rain heavy, but the gusts of wind were fields have suffered much; some estates worse than others, and it is strange that the wind from the Northward which usually does us most damage most severe. It is pitiful to see how it has blown off the leaves in all unsheltered places, all high this time was not the evil-doer, but S. and S. E., so that fields facing West have not suffered so much. In the lowcountry, especially the central part of the island, St. Mary's, Clarendon, Manchester, and St. Ann's, the floods were very heavy; cane fields were turned into lakes, boats had to be sent to rescue the settlers, and those living at the estates works, and great houses; several deaths took place from people being washed away and drowned. As to the Railway, especially the two new extensions to "Porns" and "Ewarton," it suffered very severely: bridges, walls, embankments being carried away, proving the contractor Mr. David Reid, our old Ceylon friend and his Manager Mr. G. M. Campbell, with their Ceylon experience, were right in protesting that the work as specified to be done by the Government Engineers was not sufficiently substantial, and it will no doubt be a cause of great expense to the Jamaica Government, for I cannot see it would be fair to make the contractor suffer for damage done by such very exceptional weather during their term of upkeep, especially after he had pointed out to the Government Official Engineers, and Public Works Department they did not consider the works sufficiently strong to stand against tropical floods: it would be injustice to make the contractor a sufferer under such circumstances.

As to coffee crops, last year's have not quite equalled expectations. I have only heard of one Blue Mountain Estate that exceeded its estimate and that was a very low one, and only exceeded by some 8 tierces; many others were short. No doubt some coffee was lost during the continued gales and winds in June; there seems also to be loss from rats and birds; then there are so many vacancies to the acre that it is very difficult to make correct estimates, even old stagers are often out in their calculations; the quality, however, of the 1886 crop is excellent, and there not being so much as was expected should cause prices to be all the higher. As to next year's (1887) crops, the settlers' coffee and lower fields will do well, as there has been so much rain, but I fear all upper fields will be short as the wind has cut them up so much; yet the coffee is so healthy and vigorous (like Ceylon, Udapussellawa and Haputale) that they are doing their utmost to put out blossom, and already producing a mass of young shoots.

The Annual Flower Show took place in Kingston a few days ago and it was not considered equal to other years,—no doubt the bad weather of the previous six weeks had something to do with it. It is not unlikely this Society will suffer from the absence of Mr. D. Morris, whose experience as a scientific

botanist, good taste in arrangements, and happy way of putting matters *en train* will be sadly missed. This reminds me to mention that Mr. Hart has been appointed *pro tem* superintendent of the Cinchona Plantation. What the council will decide as to the future management of the place will not be known till next session, it is to be hoped, they will not abandon the place, or let it be sold below its value. Mr. Morris' former residence would make a very good Government sanatarium: there is no such place in the Jamaica Mountains where officials can go to for change, when laid aside by sickness.

Our Jamaica fruit trade flourishes best during the winter and spring months before the American fruits are ripe; just now is a dull time and prices low. In January, £12 is given per 100 bunches bananas ready for shipment, now prices are down to £6 and £7; this added to the number of trees blown down during the gales and damaged by the floods, will cause considerable loss to growers. Cacao, and coconut trees must also have suffered from the late stormy weather.

The *Gleaner* newspaper has lately published several leaders on the subject of protection, pointing to the decadence of agriculture and manufactures in England as compared with America advocating the levying of heavy dues locally on all goods that can either be grown or manufactured in the island; this is no doubt a very wise advice *if* it can be carried out, but at present there would be a sad lack of experienced hands, so protection would only tend to a large increase in prices. It does seem an anomaly that Jamaica with hundreds of acres of fine land lying idle should have to import corn from America, also ice which can and is by one company manufactured cheaply at Kingston. Thousands of pigs could be raised here, and fed on sweet potatoes and turned into pork. Ham and bacon, milk and butter, could be got in quantities from the cattle pens; boots and shoes, furniture, clothing, &c., &c., might be made in the Island, and import duties saved and the money kept circulating in the island employing men, who, because our colonies, our sugar, coffee and other products are not protected, have to go to that deadly climate on the Isthmus for employment. I have always thought free trade a mistake, unless it was generally adopted; England cannot alone fight the battle of free trade and ruin her colonies and farmers, and manufacturers. This fact must at length be dawning on such men as Mr. Bright and his school and may reconcile them to a policy of reciprocity: allowing all colonial goods duty free except those necessarily taxed for purposes of revenue, and on these the import dues should be double to foreign countries that tax our products and manufactures. W. S.

COFFEE IN THE S. STATES' CONFEDERACY.

Coffee had been almost the sole table beverage of the South, and no privation caused more actual discomfort among the people at large than the want of it. There was nothing for which they strove so eagerly and unceasingly to procure a substitute. Few, indeed, were the substances which did not first and last find their way into the coffee pot. Wheat, rye, corn, sweet potatoes, peanuts, dandelion seed, okra seed, persimmon seed, melon seed, are but a few of the substitutes which had their turn and their day. "A fig for the difference between Ri-o and ry-e," said the wits. "Eureka!" cried an enthusiastic newspaper correspondent. "Another of the shackles which holds the South the commercial thrall of the world is severed. Let South America keep her Rio and the antipodes its Java. It is discovered to be true beyond peradventure that as a beverage the seed of the sea-island cotton cannot be distinguished from the best Java unless by its superiority; while the seed of the ordinary variety is found to be not a whit behind the best Rio."

What a flutter of excitement and joy it raisd in many a household—and doubtless the scene in ours was typical—to find that the great national plant, the very symbol of the Confederacy, was indeed was so many-sided! It gave us greater confidence, if it were possible to have greater, in the power and possibilities of the South, now that cotton, the great king, had had another crown laid on his brow. So opportune was the discovery, too, that it struck us as almost a divine revelation, indicating the interpositon of Providence in our favor. So eager were we to test it—or rather to confirm it, for it was too good, not to be true—that we could not await meal-time. Residing in North Carolina and up the country, we had never seen any sea-island cotton, but the prospect of being confined to Rio was by no means appalling. A pickaninny was forthwith hurried off to the cotton patch, then sparsely flecked with newly opened boles. The apronful of precious stuff, now a veritable manna, was hardly indoors before a dozen hands, of all sizes and colors, were tearing, picking at the discredited fibre, in quest of the more priceless seed. The Rio was made and drunk. Despite the sorghum sweetening, the verdict was unanimous in its favor.

I hope that the communication of this stupendous discovery to our neighbors added as immensely to our happiness as to our self-importance. But if in the last respect we sinned, retribution could not have been laggard. For although, owing to the fact that happily the recollection of disappointments and humiliations is less abiding than the opposite feelings, I am unable to tell exactly why and when we returned to parched bran, it is nevertheless true that we did.

Recipes for making "coffee without coffee" (when the real article was alluded to strong emphasis on the word left no doubt as to which kind was meant) were extensively advertised in the newspapers, and in some instances sold by canvassing agents. But rye, okra seed, and meal or bran held in the long run the popular favor. Those who could afford an infinitesimal quantity of the real article counted out by the grain, to flavor the substitute, were the envy of the neighborhood. A cup of pure and genuine coffee would in the eyes of many have been an extravagance akin to Cleopatra's famous draught itself. The contents of a small gourd, which held our entire stock of the genuine article for many months before the close of the war, must have gone towards the making of an incredible lake of coffee.—*David Dodge, in the "Atlantic."*

PETROLEUM AS FUEL.

In several issues of the *Journal of the Society of Arts*, a lecture on Petroleum has been published of an exhaustive nature. The latest portion deals with petroleum as a fuel, and we extract as follows:—

The "pulverisers" of Artemeff, of Brandt, of Nobel (which is a modification of Brandt's), and others, will be found fully described and illustrated in *Engineering*, vol. 35 (1883), by Mr. Thomas Urquhart, Locomotive Superintendent of the Griazi-Tsaritsin Railway of Southern Russia. The burner which is stated to have given the best results in use on the locomotives of that railway company, is Karapetoff's; and that which has been adopted by the Russian Government as best adapted for use in torpedo vessels is Kaufmann's. All these pulverisers depend for their action upon the

principle illustrated in the description of the Lentz apparatus, and differ only from that burner in details of construction and in the shape of the flame produced. They are all, in fact, similar to the apparatus patented by Messrs. Wise, Field, and Aydon, in 1867, and used at the works of Messrs. J. C. and J. Field, of Lambeth. In a valuable paper, which will be found in the "proceedings of the Institute of Mechanical Engineers" for 1884, Mr. Urquhart gives the results obtained in the practical use of petroleum residuum on the railway already referred to. Comparative trials, made in winter, showed that the economy of petroleum, as compared with anthracite, was 41 per cent. in weight and 55 per cent. in cost; and, as compared with bituminous coal, 49 per cent. in weight and 61 per cent in cost. As compared with wood, petroleum was 50 per cent. cheaper. At a speed of 14 miles an hour up an incline of 1 in 125 the steam pressure was easily kept up at a pressure of 8 to 8½ atmospheres, with a No. 9 injector feeding the boiler continuously. In summer the mean evaporation per lb. of fuel was 11·35 lb. of water from an initial temperature of about 55° Fahr., the theoretical evaporative power being 16·2. The useful effect was, therefore, 70 per cent. The comparative trials in summer gave a difference of 56 per cent. in weight and 66 per cent. in cost in favour of petroleum as compared with bituminous coal, and 52 per cent. in weight and 63 per cent. in cost as compared with anthracite. The results for the entire year gave for petroleum, as compared with the mixture of half bituminous and half anthracite coal used, an advantage of 38 per cent. in weight, and 46 per cent. in cost in the case of the goods trains, and 25 per cent. in weight, and 33 per cent in cost in the case of the passenger trains. Mr. Urquhart remarks that he has successfully used petroleum as an anti-incrustator, and also finds that the presence of oil in the boiler tends to reduce the tendency to priming, unless too much is employed. Petroleum is more difficult to use in a locomotive boiler than in a marine or stationary boiler, and at first it was found impossible to prevent leakage of tubes, accumulation of soot, and inequalities of heating of the fire-box; but by the use of properly arranged brickwork inside the fire-box these difficulties have been overcome.

Petroleum residuum is the only fuel employed for steam generating purposes in the steam-ships on the Caspian Sea, and I observed that, both in the case of these vessels and of the locomotives on the trans-Caucasian Railway, the combustion was smokeless, though occasionally a slight odour of imperfectly consumed oil was perceptible.

It is reported that the Central Pacific Railway Company have recently commenced the use of liquid fuel on their steam-ships, and have obtained results which show the cost of the oil to be 56 per cent. of that of the coal previously employed.

In this country experiments are now being made at Portsmouth with the object of determining the relative economy of liquid fuel and coal for use in the belligerent navy. At the end of last year the cargo steamer *Himalaya*, of 800 tons burden and 100 horse-power nominal, which had been fitted with Mr. Percy P. Tarbutt's oil-burning apparatus, made a successful trial trip to Leith and back, making 8¾ knots per hour under disadvantageous circumstances, her mean speed when fired with coal having been 6½ to 7 knots. The boilers in this vessel have three furnaces, each of which is lined with fire-brick and provided with a fire-brick baffle, and a combustion chamber beyond. Within the chamber is a coil of pipe to superheat the steam used in spraying the oil. Messrs. Tarbutt and Quentin, the managers of Tarbutt's Liquid Fuel Company, inform me that experiments made by two engineers of the Compagnie Francaise des Diamants du Cap, at the works of Messrs Oliver and Company, Chesterfield, with a Robey boiler fitted with the Tarbutt burner, showed a mean evaporation of 16·3 lb. of water per lb. of oil, the highest result obtained being 17·2 lb. Another test made by Oliver and Company gave the relative efficiency of coal and oil as 1: 2·6. In a marine boiler fitted with the same apparatus, the engineer of Messrs. Wigham, Richardson, and Company is stated to have obtained an evaporation of 15·57 lb. of water per lb. of oil. The liquid fuel which has been employed by Mr. Tarbutt in this country is the residual product known as "dead oil." In the use of the various steam-spraying apparatus it is necessary first to raise steam in the boiler by the use of some other fuel, or to employ an independent steam-generating appliance until the boiler has been sufficiently heated.

It is well known that Admiral Selwyn claims to have obtained in the use of liquid fuel far more satisfactory results than those which I have given. Liquid fuel occupies only slightly less space than coal, but its greater steam-generating power obviously enables a steamer to make a much longer voyage without taking in a further supply. Liquid fuel can also be placed on board far more quickly and with far less annoyance to passengers, advantages which will be appreciated by those who have made a long sea voyage in a steam-ship. Besides which, nearly the whole of the labour expended in trimming the coal and stoking is saved; and in the case of ships of war the smokeless character of the combustion is a feature of no small importance.

Cooking Gorakas.—The following extract is from the proceedings of the Horticultural Society of India:—From Mr. J. Buckingham, Amgoorie, Assam, presenting some plants of the "Rupi tikora," a shrub which he describes as "growing into a very pretty plant; the fruit also adds much to its appearance, and is, when cooked, extremely palatable. I think the plant is a species of *Garcinia*." Mr. Buckingham, in a later letter says: "We have three or four species of *Garcinia* up here. *First*, Garcinia pedunculata (Tikur, or Tikul, as you say); it is called by the Assamese, *Bor Tikora*. Second *Garcinia cowa*, called by the Assamese *Koojee Tikora*. Third, a *Garcinia sp*, called by the Assamese *Moh Tikora*. Fourth, the plant I sent you called by the Assamese *Rupi Tikora*, not identified by any one yet that I know of. The first three are trees, the last is a very handsome shrub about 10 or 12 feet high if allowed to grow."—Query, whether the last mentioned may not be what is known in Ceylon as the *Ratu Goroka*, of foreign origin and with foliage akin to that of the mangosteen, which the fruit so closely resembles?

The Natural Beauty of Burma is thus described in a letter to the *Times of India*:—Coming down the river from Bhamo, one is struck with the natural beauties of the country and the promising future still before it. More especially beautiful is the second defile, a score of miles south of Bhamo, but to me the first defile already mentioned in this letter is the grander of the two. Going down the river through the defile, the ship swishes along gaily at the rate of thirteen or fourteen knots an hour, and when the river is rising there are regular maelstroms in which the ship dips her bows in homage to the river nymphs and gods; and then it requires steady steering and hard going to keep her head from swerving, for nymphs of all sorts are famous for making heads to swerve. And coming along you get a good view of the rest of the surrounding country and see how beautiful Burmah is, perhaps all in all the most beautiful country in the world, more especially the portion of it lately annexed to the British Empire. Nothing, however, appears to be perfect and without blemish, and you think, with reluctance, that the very characteristics that largely impart to Burmah its beauty, also imparts to her bane, such as the rich alluvial soil, the swamp from the stately river, and the profuse vegetation, all more or less associated with sickness. No doubt cultivation, sanitation, &c., &c., will do much to diminish these spots on beauty or beauty spots. The majestic river, dotted over with island gems, the wooded plains and the tall blue hills in the distance are well worth a long, long lingering look. Not a river in India, if any in the world, can touch the Irrawaddy in its grand magnificence at this time of year. Neither the holy Ganges of the east nor the "Indus" of the west can at all approach this noble current.

Correspondence.

To the Editor of the "Ceylon Observer."

A CINCHONA SYNDICATE FOR CEYLON PROPOSED. IN ORDER TO REGULATE THE EXPORTS OF BARK.

Bearwell, 20th Sept. 1886.

Dear Sir,—"The price of Cinchona depends entirely on the shipments from Ceylon" is the remark of a leading firm of London brokers in a recent Fortnightly Report. This being so, surely a combination of those interested here for the purpose of regulating the supply which shall be sent from the island, is far from impracticable. Self-interest in this instance, would, I think, serve to bring the grower and his agent into harmonious action, and thus secure probably double the present price of the unit of quinine to those who so much require it. Judging from the ready way in which sales for the past year have gone off, notwithstanding the fact, that the most sanguine estimates of exports will nearly be doubled before the year is out, I take it that it is not so much the enormous increase which continues to depress prices, as the feeling that we may not yet have reached the highest point and that next year may see this year's exports once more doubled. Hence if a Syndicate could be formed having for its objects the storing of bark, and the regulating of shipments, in such a way that the unit of quinine could be kept at sixpence instead of about threepence, surely there are but few, be he mortgagee, agent, or planter, who would not give it his support.

I think I am not far out in saying that one and all of us have the idea that if we could keep up our bark for a year or two, very much enhanced prices would be obtainable.

With your permission, sir, I shall as briefly as I can lay before you the outline of a scheme, which I think would prove at once practical and economical, and to some extent, if not entirely participate in the better prices that will doubtless be ruling some time hence. Let everyone in the island who has an acre of cinchona form a Syndicate, and rent one or more of the many unoccupied coffee stores in Colombo, to which, all bark would be sent from the baling press (having been previously analysed) to be stored there until its turn come for shipment.

On the bales being handed over to the Syndicate storekeeper, a warrant—on which the variety, weight and analysis of the bark taken in would be marked—would be handed to the owner or agent, which warrant would be a document on which dealings might take place similar to those in respect of Pig-iron on the Glasgow exchange, by which the grower would get his money at once, or the Syndicate itself or one of our local branches might arrange to advance up to fully half the value of the bark, charging a low rate of interest.

The Syndicate would keep itself well-advised as to the trade requirements, and would have the entire control and regulating of shipments; not however to the extent of depriving the Colombo Agent of his commissions or charges in any way, but it would fall on those managing the Syndicate to say how much should be shipped during any one month.

I by no means underrate the difficulties that would have to be overcome before the scheme would prove a success, and I shall enumerate some of the more prominent ones, and endeavour to show how they could be met:—

1. I am assuming that self-interest would serve to rally the planting body to a scheme which can e shown to be of so much immediate benefit to them,

2. The fact that a considerable portion of the bark is hypothecated to people out of the island, who might be averse to even a temporary alienation of their security which storing with the Syndicate would imply. Even if self-interest did not induce their support, their agents in Colombo could hold the warrants until the bark was released or in other ways procure their sanction to a scheme which they could not fail to see would be of immense service to their constituents.

3. The fact that most planters require the full value of every harvesting, the moment the article is ready for the market, and that no bank or syndicate could with safety give an advance of much over half the actual value. For this difficulty, I would merely point out that if the operations of the Syndicate raised the price to 6d per unit an advance of fully the present quotation would be procurable, so that besides the ultimate advantage of getting 6d per unit, they would receive as an advance as much as the bark would sell for with no regulating Syndicate.

4. That of making a selection of bark for shipment would probably give rise to more discontent than any of the other difficulties, and yet I think a method at once fair and just could be devised. For example, suppose the stored bark consisted of that from 100 different estates, each proprietor, mortgagee, or agent more anxious for a realization than the other Directorate would proceed to select the barks that arrived up to a certain date of the previous month, and in the event of that being insufficient for the market requirements then take the next in order and so on; and on the other hand in the event of their being unable to send all the bark to the date mentioned, a proportion of each could be taken and the balance held up, and so on.

5. Then comes the possibility of Java, India, or South America, stepping in to upset our scheme, I would remark with reference to this that our object is a perfectly legitimate one; we seek only to get a fair value for an article which another combination, composed of canker and hard times, has unduly depressed, a value probably which may be raised even another 100 per cent the moment our extensive fields become exhausted as they assuredly will before many years pass over. We do not seek to operate to the extent of raising the fever powder up to, far less over its proportionate retail value, nor do I think that the extent we purpose, manipulating for, would cause shipments to be resumed from South America or more to be harvested from India or Java.

But even in that case, according to Messrs. Brookes & Green "the price of cinchona depends entirely on the extent of shipment from Ceylon," hence the Syndicate could at once render abortive any outside attempt to upset their aims. I trust that you will be willing to give your support to this, or some such Scheme, the outline of which I have sketched. There are gentlemen in Colombo I could name, who, were they to take the matter up, could work it out in all its details to a perfectly successful issue. I trust therefore, you will find space for my proposal so that the subject may at all events get ventilated.

Unless we again take to planting cinchona a very few years will exhaust the existing fields; we shall then feel similar chagrin to that most of us must at the moment be experiencing, now that coffee is fairly on its way to the three figures. That, most men could not help; but I maintain that we have it within ourselves to prevent our remaining cinchonas, from which so much was expected, from being sacrificed.—Yours faithfully,

JAMES SINCLAIR.

BEST SEASON FOR PRUNING TEA?

21st September 1886.

Dear Sir—The question, "What is the best month in which to prune tea on estates exposed to the south-west monsoon" is often asked and various answers with reasons which appear conclusive to each advocate, are given making the matter rather confusing to a new hand at the work. One man will advise a commencement in June, another in July, others at different dates up to October; a few preferring the north-east monsoon to prune in.

Judging from the growth on coffee and other plants throughout the south-west monsoon together with the short experience we have of tea, June and July pruning is I think a mistake, except on places under 2,000 feet. In these months there is a good yield of leaf and what is of great importance, the tea made—where the withering accommodation is sufficient—is of finer quality than is made earlier in the season. On the other hand, nothing appears to be gained by this early pruning, unless when the bushes require a lengthened rest after pruning.

To make the most of the bushes, I would prefer doing this work from middle of August to middle of September: the first plucking would thus fall to be taken in the first half of October and would escape injury from the burst of the north-east monsoon which usually comes on about 20th October. The second growth would start in November and the tea afterwards be in fine bearing condition for the best plucking months—March to June. Later pruning than this would shorten the yield from the small surface there would be to pluck from in the best months.

On estates approaching sea-level where in the wet season there is sufficient heat to induce the bushes to flush, pruning might with advantage be done in the dry season, but perhaps the prolonged drought immediately after pruning would have a damaging effect on the tree and probably cause a portion of the wood to die back. Has pruning been tried at this season in low-lying districts?

ALFYSO.

Indian and Kaffir Labour in Natal are thus noticed in the London letter of the *Indian Planters' Gazette*:—

The following information *re* Indian labour in Natal will not come amiss after what has already been sent you in reference to Natal. The necessities of the Coast plantations have led to the introduction of East Indian or coolies labourers in considerable numbers by Government agency, chiefly at the employers' expense. Several laws have been passed to regulate terms of payment, and to provide for the due care and protection of the immigrant. Indians are engaged to their employers for the term of five years, after which they are free to engage in any occupation they choose, and at the end of ten years from their first coming to the Colony they can claim to be returned to their country by the Government or to have an equivalent in land to the amount of their passage money. A sum of £10,000 is annually set aside as a Government contribution to the expenses of this immigration. The interests of the coolies thus imported are looked after by an officer specially appointed ("the Protector of Immigrants," a familiar term to your readers) and a complete medical and general staff. From the 17th November 1860 to the end of 1885, there arrived in the Colony 34,582 Indian immigrants including men, women, and children, of these nearly 5,000 have returned to India, on completion of term of service, or have left for elsewhere by license. Of indentured Indians, there are now, including women and children, about 10,000 in the Colony; and of "free" Indians, about 19,000 Indians are now to some extent employed in the midlands and up-country. Considerable numbers of the "free" Indians are at work on their own account as farmers, market-gardeners, traders, and hawkers. As a rule, all the Indians adhere to their old habits in diet, dress, social customs, and religious observances. Hence an old *cha sahib* going to Natal would, so far as he employed Indian labourers, feel quite at home. The native population I have already alluded to in a former letter; it comprises various tribes, but all of the Zulu type, and all use Zulu language, with slight dialectic differences. The experience of 50 years shows an unbroken record, except in a few unimportant instances, of submission to law and order and of good social relationships with their white neighbours and employers. Naturally good tempered, docile and honest, they appreciate just and fair treatment and many friendships have been formed between the two races. The Government of this large population (361,766) has been carried on with scarcely a disturbance and taxes amounting to a considerable sum have been collected from them year by year without friction or serious difficulty.

"Artificial Quinine."—Here is how the *British Trade Journal* deals with this subject:—

No sooner does the "silly season" set in than the daily press astonishes its readers by announcements of "remarkable discoveries" which are to "revolutionise" either this or that particular industry. Last autumn a London journal published the startling intelligence that the present sugar industry—beet as well as cane—was to be annihilated by the wonderful returns of sugar which it claimed could be obtained from the *Mahwa* or *Mowra* tree of Hindostan. As was pointed out shortly afterwards, this was nothing but a Munchausen story, since the flowers in question contain only 1·04 per cent of saccharine matter, and even that small quantity is fit for nothing but brewing and distilling purposes. We believe it was the same morning journal that reproduced the American hoax of the new species of cotton tree with pods weighing each from 2 to 3 lb., by which the cotton trade was to be "revolutionised." This year the same newspaper brings forward a "remarkable discovery" of the artificial mode of making quinine, which will, we are seriously told, bring down the price of that drug to something like 3d per oz. We are also told that this important discovery "was made by the accidental breaking of a medicine bottle." But, as we are well aware that all great discoveries are usually the result of accident, this need not surprise any one. The really extraordinary part of the story is that good quinine "can now be manufactured without limit by a very simple process from an article which can always be got in abundance in any part of the World." In order to round off the story it should have been stated that the artificially-made drug had been administered in cases of fever with the most satisfactory results; but to this extreme the inventor, doubtless with a discreet regard for his patients, appears not to have gone. We have the best authority for stating that the announcement that an eminent firm of manufacturing chemists has expressed itself favourably with regard to the alleged discovery is entirely false. It has yet to be proved that anyone has really succeeded in producing so complex a body as quinine synthetically; and it is extremely improbable that even if produced at all it could be made at any very low price. Before such statements are accepted and published by any newspaper it would be strongly advisable to have certain evidence of their correctness

Still more interesting is it to learn from *Chemist and Druggist*:—

Artificial Quinine.—Referring to the alleged discovery of artificial quinine Mr. J. C. B. Moens writes from Haarlem:—"The French chemist who in 1882 claimed to have discovered a synthetical process of quinine manufacture was so confident of his discovery that he actually submitted samples of his preparation to the Academy of Sciences for inspection. The almost incredible fact was then revealed that the so-called sulphate of quinine was nothing but sulphate of ammonia."

NEW RAW ARTICLES OF COMMERCE:—KAPOK.

(Australian Report.)

Pursuing the course adopted some time ago in publishing a series of articles on some "New Raw Articles of Commerce" we thought that a brief review and history of a commodity, which, from its importance in Australian commerce, must be classed among its most staple imports, may not be without general interest. Possessed of the knowledge of its origin and sources of supply, about which there is almost comparative ignorance, a few observations thrown together on the subject may serve a useful purpose in the encouragement of so important a trade, and may possibly suggest some means of attempting to meet at least a part of the enormous demand there is in these Colonies for it.

Kapok is both a Malayan and Java term for the *Eriodendrom Anfractuosum* and *Gossampinus Alba*. It belongs to the *Bombaceæ* family, of which there are several allied orders known botanically as *Byttneriaceæ*, *Chlenaceæ* and *Ternstræmiaceæ*, of which latter family the *Bombax Gossipinum* belongs. Amongst the most remarkable of the *Bombaceæ* family is the Baobab, the largest known tree in the world, whose trunk measures 90 feet in circumference and the Durian of the Indian Archipelago, the most delicious of all fruits, also the Ouatier (*Bombax Malabaricum*) so extensively planted in India as a shade tree. In their growth and products there is very little difference, all are intertropical and exogenous, perhaps no trees in the world have a more lofty and imposing appearance, the untutored children of Africa are so struck with the majesty of their appearance, that they designate them the god-tree, and account it sacrilege to injure them with the axe, they are also remarkable for their splendid inflorescence, their capsules on bursting display a flocculent substance often mistaken by travellers for cotton, and the tree hence called Cotton Tree, but as the substance is more silky than cotton, it has been distinguished by the name of Silk Cotton, or as more generally known in Eastern and Australian commerce, Kapok.

The fibre most imported here is of moderate length, although some varieties are short, remarkably elastic but unfortunately so very tender that it may be said not to possess any staple. It was first brought into notice in Europe on the occasion of the Great Exhibition of 1851, beyond being recommended for upholstery purposes, and in combination with other substances in the manufacture of mixed fabrics, to which there were many practical obstacles, it was generally considered as possessing little or no value, consequently it was looked on with distrust, "it was not in the market," "Brokers did not know it," no pains were taken with it, and from want of attention the article never gained more than notice. In Holland it grew rapidly into favor, and until the Australian Colonies became a customer, that country was the only market for it. At the late Amsterdam Exhibition it shared a much better fate than when exhibited in 1851, it was described as "vegetable wool," commanded considerable notice from all classes, and was valued at a very high figure. The effect of this exhibition was to excite the attention of merchants in Java, India and Ceylon to the article, for almost up to this time its qualities and capabilities remained unknown or so badly neglected that little or no progress was made in it, large consignments were made to Europe and to these Colonies, but the result so far as Europe is concerned, placing Holland aside, seems not to have been encouraging.

The extraordinary success which has attended its introduction, or literally speaking its establishment into Australian commerce, is, perhaps, without saying too much, without a parallel, for only those who have tried it know the difficulties of introducing a new article of trade however good, traders and manufacturers cling with tenacity to old customs and practices, and have almost a thorough disinclination to entertain new substances or new processes, hence the rapid and increasing demand for the product is unmistakable evidence of the favourable manner it has been received by merchants, the furniture trades and the general public.

It is now about fifteen years ago since the first shipment of Java kapok came to this market; but in consequence of the trade in it at Java being confined to Dutch and native hands, regular shipments were not kept up, and, when they did arrive, it was only in small lots; consequently, the trade was so unimportant as not to deserve more than notice here, except a passing reference to one or two eventful facts in connection with it. The price which it fetched in those days must have been different from now, for it is said that the purchasers of the first consignment netted a profit of £7,000 on the transaction. So firmly did it establish itself with the trade on its introduction, that when supplies were not regularly forthcoming they sought out a substitute. Various fibres were experimented upon, and much valuable information obtained, till, at last the trade settled down to the use of "Pulu," from the Sandwich Islands, which grew rapidly into favor; but after a few years' trial, though not until the trade had assumed considerable dimensions, was it found to be totally unfit for bedding and upholstery purposes. In a very short time it went to dust; in fact it possessed a peculiar property of dry decomposition until nothing was left, thus pulu had a short but curious history, being of a fibrous silky substance. It was thought to be of the same order as kapok; but an examination of the plant proved it to be of the *Cibotium* species, a quite distinct family altogether from the *Bombax*, and possessing none of its elasticity and durability. In proof of the lasting qualities of kapok, we have to relate that recently a pillow was shown us by a gentleman in this city, who was a non-commissioned officer in the imperial service engaged in the Mahratta war of 1843, who on noticing the tree, picked sufficient of the fibre to fill a pillow-case, which has been in constant use ever since (43 years), and still retains its elasticity and fulness, and who assures us he has found nothing so cool or healthful to sleep on in warm climates as this article. Such testimony is most valuable. It was not until the year of the Melbourne Exhibition (1881) that the first shipments arrived from India and Ceylon. It is difficult to obtain reliable statistics concerning the trade, for there appears to have been a determination, which by some houses is maintained to this day, on the part of shippers and local merchants to keep the whole thing a secret. We find it entered at the local Customs under all manner of names, such as "vegetable fibre," "vegetable wool," "silk cotton," "tree cotton," "raw cotton," and "Simool cotton." Even now, all the imports from India and Ceylon are entered at the Customs either as raw or Simool cotton; only the Java imports are described as kapok.

Tabulating all the values described under the above headings passed through the Customs in 1881-2-3 the trade seems not to have been followed up or prosecuted to any great measure of success, it may be said that no decisive and important progress was made with it until the year 1884, when the firm of Messrs. Catherwood, Welsby and Co. of this city went largely and solely into the trade, Mr. F. A. Catherwood when passing through Ceylon in 1883 became attracted by the article, and at once perceived its economic uses, and the future there must be for it. On returning to Victoria his firm entered with zeal upon the trade, and it is due to Mr. Catherwood's foresight and tenacity of purpose, as well, perhaps, to his firm's enterprising and venturous spirit for the wonderful development by leaps and bounds the trade has assumed today. Not only may it be said with truth that Messrs. Catherwood, Welsby and Co. control the market throughout Australia and New Zealand, but also the Java market their large purchases abroad are not only felt on the spot, but have a corresponding effect on the market in Holland. Had it not been for the heavy purchases of this Melbourne firm, it would have been a sorry time for both Java and Holland, at the opening of the last season December 1884, Holland had stored up in its warehouses 12,000 bales with a strong "ring" formed by dealers to bear

down the market, both merchants and dealers remained firm; as the season advanced the latter hoped, in fact expected, shipments would arrive when merchants would be bound to ease down stocks. They had reckoned without their host, their action, as is too often the case, was the result of a miscalculation, other competitors had entered the field abroad, Messrs. Catherwood, Welsby and Co.'s orders alone for the Australian market amounted to three-fourths of the entire crop. What a relief this must have been to the Dutch merchants who through the operations on this side of the globe were put in a position to withstand the tactics of the "ring." Some small consignments were made to Holland from Java towards the close of the season, stocks by our last advices from Holland dated April 27th had worked down to 2,000 bales, so that next season at Java a rise may be looked for, the crop will be keenly competed for by Dutch and Australian houses.

Satistics show that Messrs. Catherwood, Welsby and Co. imported duting the season now closed 7,815 Java bales; we notice some very large parcels arriving in one bottom, the S.S. "Khandalla" bringing 1375 bales; the S.S. "Tanmadice" 1442, both within a fortnight of each other; in January and February. The bark "Rachel" arrived in May with 1320 bales, the first vessel that has ever carried a full cargo of this product.

The following comparative tables containing statistics for the past three seasons will be found interesting to this part of our subject:—

Importation (in bales) of Kapok into Melbourne.

Country.	1884	1885	1886
Java	500	1300	7,995
Ceylon	86	150	200
India...	450	900	650

Note.—A bale of Java kapok average weight is about 80 lb.; a bale of Ceylon about 200 lb.: a bale of Indian about 400 lb.

Value of Entire Produce.

Country.	1884	1885	1886
	£	£	£
Java	1400	3700	22,600
Ceylon	430	700	1000
India...	3750	6000	3250

While values have been comparatively steady for the past three seasons, for both the Java and Ceylon article, viz., 8½d. and 6d. per lb., free Melbourne, there has been a gradual and serious decline in the value of Indian kapok, receding from 5d. in 1884 to 3d. today. It is understood, we only allude to merchants' parcels in original bales, the retail trade has not been affected much by the fall. Even at the low price Indian kapok is today, the trade find it to their interest to pay 8½d. and higher for Java, than 3d. for the former. The Indian is frequently received in such a filthy condition as to be almost unusable, more than 40 per cent of the whole being waste—composed of sand, dirt, seeds, &c., which necessitates the bales being sent to a kapok mill to be cleaned and teased, for which the cost of milling is 1d. per lb. on the gross weight put through. On working out the relative values of the Java and Indian article at current market prices, in original bales as above quoted, basing our calculations on the experience of experts, we find that 21 lb. of the Java fill as well as 29 lb. of the Indian in its teased and prepared state, the filling being the true test of respective values, resulting in a percentage of 38 in favor of Java. Therefore manufactured articles of this commodity, filled with the Java, are much lighter and more easy to handle, which is a great desideratum for bedding in warm climates, for which purpose this product, at the present period, is almost solely imported.

This notice treats it only as an article of commerce; in some future paper we hope to review it in its sanitary aspect.

We have not gone minutely into the Ceylon product, as the imports are so small as to be almost inappreciable.

The Indian product in its present state is thoroughly objectionable. First, as regards staple on fibre, it is both short and inferior in other respects to the produce of Java. Second, the inequalities of the stuff found in each bale, good and bad mixed together, added to which is the too frequent fraudulent practice of water packing, putting seeds, sand, and other foreign substances in the interior, in a manner not to be detected without opening the bale. Third, the form of packing is not the least obstacle which has so far acted detrimentally upon the quality. Hydraulic or steam-press packing of bales totally destroys that peculiar elasticty to which kapok may be said to owe its value—without this springy nature it is unsuitable as a stuffing material. Moreover, it is found by hard packing uncleaned stuff a dark-coloured oil is expressed from the seeds which is suffused over the kapok, and consequently stains it, hence the noticeable difference in colour between the Indian and beautifully white Java product. We might go on multiplying facts in support of the position we have asssumed, but we think sufficient has been said to satisfy the reader that when merchants complain of the inactivity and declension of the Indian kapok trade as compared with the rapid progress of its great rival of Java, they should at least remember that a portion of that declension is traceable to their own sins of omission. Of the causes which have brought it about, we have the opinion and experience of a gentleman who has been connected with the trade in Ceylon and India from its inception. We give it in his own words. Speaking of buying at Calcutta, he says:—"The crop begins to come in about May. Dealers go to the boats that bring it from the interior, and bargain. They screw the boatmen down to the lowest possible figure, stipulating for quantity rather than quality, and as it is generally disposed of before it is seperated from the seed, the boatmen gets much the same price for it, no matter in what condition it may be. They have no inducement to pick it more carefully; so that the truth is, the "middlemen" are more to blame than the natives for the filthy condition in which it reaches here. Little encouragement is given to them. So badly thus it pay that during June, July, and August there is always a cessation of deliveries at Calcutta, on account of the natives turning to more profitable work, being busy with their mango season."

At Java the trade has assumed a uniform practice. No unclean stuff is shipped, but the different grades of cleaning denote standard of quality; the first, "extra cleaned," being cleaned by machinery and the first picking of the crop; the second, denoted as "best cleaned picked," being all hand-picked and free from seeds, except an odd one here and there; the third is simply designated "*cleaned*." It contains a few seeds, together with the "slubs," or little knotty, curly lumps, which are cast aside from the higher grades. Quality of any one class is found most uniform throughout the bales. Packing is all done in straw mats, and never tight pressed; the first quality "extra cleaned," weighing about 65 lb.; the second and third, from 75 lb to 90 lb. Bales over 90 lb. to 95 lb., on account of having to be dumped by machinery, destroying the elasticity of the fibre, are reckoned not to be worth within ½d. to 1d. per lb. in value of bales of lesser weight.

In fact, it is a peculiar feature of the Java trade that weight of bales from an essential condition of price—the lighter the highest, and *vice versa*.

The article is of a kind that admits of a deal of speculation. Its unparallelled development and firm hold on Australian commerce hazards the belief that it will take many a season before supply overlaps demand.

The price of any raw article, especially one of this nature, never remains long at one fixed rate. In kapok, much depends on the season. If wet, the crop is small and poor. Again, with the fact that the demand more than keeps pace with the increased

supplies, and others, entering the market with orders for Europe, make prices fluctuate from day to day. The history of the late rise in value at Java and Ceylon was solely and sudden and unexpected enquiry from these parts for a product that no previous attention had been paid to.

Like most articles, kapok is not without its adulterations, imitations, and frauds. The practice recently brought to our notice of mixing "cotton fly," the refuse of cotton with it, which is worth in this market only from 1d. to 1½d. per lb., is a gross fraud upon the trade and consumers. Two lb. of the mixture is not equal in filling to ¾lb. of the true article, besides being devoid of its elasticity, for no vegetable substance is so dead and hard as cotton fly. We have been shown the ordinary Hessian bags filled with kapok, as used by the trade. We notice the bags of Indian and Ceylon were alike, 48 lb. A bag was then filled of the Java, especially for us, as the latter is only sold in "the original" straw bales—this weighed 30 lb. Then we were shown a bag of the spurious stuff, which had not even the appearance of fulness as the others we examined, but this to our surprise weighed 72 lb.—it was merely an illustration of weight between kapok and the refuse of cotton mixture. We asked the firm showing it to us how it could be detected. Were the trade aware of the fraud? They replied, very few; they only knew it did not fill so well, meaning it required more to do the same work, and as a consequence some would take nothing but the Java, but its real defects was its deadness and lumpy nature.

Underselling and cheapness being the mother of this nefarious device, we can only characterise such counterfeits as the surest means of killing a promising trade, like other modes of adulteration, in becoming established and universal, they cease to be profitable to anyone. Once the more honest trader commences to find he stands alone in selling an apparently similar article at a higher price, and that his customers as a consequence are going elsewhere, he will soon begin to furnish a like substitution to cope with competitors, till quality and price becomes so diminished that the trade succumbs to its own vices and follies. Let us hope the kapok trade will not meet this fate.

The following method will enable one to discover whether kapok is mixed with cotton fly or other substances of its kind:—The principal feature of kapok is the total want of strength of the fibre, being soft almost like eider-down, brittle and elastic—the fibre of the cotton fly on the other hand is broad and harsh, possessing great strength, with a tendency to twist. In examining a small sample where a mixture is suspected, it should be drawn out slowly between the fore-fingers and thumbs of the two hands, observe how on the slightest pressure the kapok fibre easily separates, if mixed with cotton fly, the latter will be detected by its strength in resisting this pressure, then by drawing the staple in the other direction and thus alternately from hand to hand, the kapok successively escaping pressure leaves the cotton fly exposed and intact. This is merely a rough and ready test, but examining the sample through a microscope, the difference between kapok fibre and the staple of cotton fly is observed without difficulty. We might animadvert on this subject further, but we have called attention to the iniquity, and we hope our remarks may be felt in the proper quarter. To speak mildly, it is most unfair to those houses who have won a justly earned reputation in the trade for honest dealing. We could wish that our calling attention, not only to the unfairness of such competition, but to the dishonesty of such action would lead to its being totally discontinued. Those, however, adopting such means have not usually any compunctions of conscience, and appeals to their commercial morality seldom leads to satisfactory results; however, we can but do our best in the matter, and that is to caution the trade and general public to exercise care in buying, and pay attention to the few hints we have thrown out.

It has a bright future before it, and we have little doubt that, with the invention of proper carding and spinning machinery, it will be used in the fabrication of articles of clothing, and prove a formidable rival to its allied substances. It has already been used for making gun-cotton, a substitute for beaver fur, converted into half-stuff for paper-making, making silk buttons and fringes, and by the Indians, who make beautiful fabrics of it. In Bombay, the fibre of the bark is used as a substitute for flax, and in Bengal the natives collect the milky juice as a substitute for shellac and gutta-percha. The seeds have almost the same value as cotton seeds, being exported to Europe to extract the oil, and fetch from £3 to £5 per ton.

A kapok mill has been erected by Messrs. Lynas and Gwynne on the Sandridge road, in this city, which is kept constantly going. To these gentlemen we are much indebted for being allowed to inspect the process of cleaning and teasing the article, and for their lucid explanation of trade matters.

In our next we shall give an account of another new fibre, the Dook of the Areng-tree, which Messrs. Catherwood, Welsby, and Co. have introduced here as a substitute for curled hair, the coarser fibres being employed for cordage and brushware.—*Buchanan's Monthly Register.*

Acorn Coffee.—In Germany "acorn coffee" is used, and greatly, liked, as a substitute for ordinary coffee, and is considered to be very strengthening for consumptive people and delicate children. The acorns are gathered in autumn, when they are ripe, shelled, and, after being cut into pieces of the size of coffee berries, they are thoroughly dried in front of the fire, or in a cool oven. They are then roasted like ordinary coffee, until they become a cinnamon-brown colour. Immediately after roasting, the acorns are ground or pounded in a mortar, to prevent there becoming tough. Whilst the coffee is being ground or pounded, a very light butter is added, and the coffee is then placed in air tight bottles. For children, prepare in the same way as ordinary coffee, using a quarter of an ounce to a pint of water, adding milk and sugar to taste. Young children should take it with two or three parts of milk. For adults, half an ounce of the coffee may be used to a pint of water. Acorn coffee and ordinary coffee are frequently mixed, and the decoction is found very palatable. In their raw state, acorns are known to be powerfully astringent, but they lose this quality in the process of roasting. In some respects acorn coffee is preferable to coffee proper, having none of the drying properties attributed to the latter.—*Cassell's Dictionary of Cookery.*

The Wedding-Flower.—This is what is known botanically as Iris or Morxa Robinsoniana, the giant Iris of Lord Howe's Island, and one of the most disappointing garden plants even introduced into English collections. Many have tried, and perhaps a few are even yet trying to induce it to flower, but, so far, no one in Europe has yet succeeded. We began to suspect that there was some condition peculiar to Lord Howe's Island and essential to the flowering of this Iris, till we learned that in the Hakgala experimental gardens in Ceylon plants of it had been raised and flowered in about a year from seeds produced from Australia. This is what Mr. Nock says of the Hakgala plants:—"Planted round a pond are several interesting plants, among them being the Wedding-flower, a gigantic Iris. One flower-spike contains from 120 to 200 blooms, which come out a few at a time, but only last 24 hours: the plant is in flower for several months." Hakgala is at a high elevation in Ceylon, the temperature being perhaps somewhat similar to that of Italy. Many interesting plants are growing there, amongst them being the splendid Tree Fern found only in Ceylon, viz: Alsophila Crinita, of which several fine specimens may be seen at Kew. In Ceylon, however, high-up the sunlight must be much more intense than anything we get, still the Wedding-flower may not really require all this light to make it flower. What does it want that we fail to give it here.—*The Garden.*

INVESTING IN PRECIOUS STONES.

ALL ABOUT THE FIVE PRIMARY STONES.

Collectors of stones are apt to have their nerves agitated by rumours of new mines, or threats that the market will be deluged from the looted treasury of King Thebaw, or destroyed altogether by some discovery of how to make one ruby worth 10,000 fr. out of ten worth 1 fr. each; but I have never found persons who may perhaps have from £100,000 to £200,000 worth of the stock so threatened to be in the least disturbed by these alarms. Even the astonishing increase which has taken place of late years in the supply of diamonds seems only to have increased, in still greater proportion, the demand for them. Good stones are as dear as ever they were, and really first-class stones dearer. Nor is there the remotest chance that "real," though "non-natural," rubies will ever be produced by any process of fusion, welding together, or otherwise. The products would not be ruby, though, chemically, exactly the same substance. Crystalline formation is of the essence of the ruby, sapphire, emerald, and diamond; and though exceedingly minute diamonds—less than the one-hundred-and-fiftieth part of a grain—appear to have been produced by allowing the vapour of carbon to cool under enormous pressure, it seem practically certain that large crystals have been the product of extinct telluric forces operating through enormous spaces of time, the effects of which art will never be able to copy.

Crystalline constitution is the condition of the dischroism or double colour, and the power of dispersion of light, which make all the difference between the mystic and ever-varying beauty of a true stone and a piece of white or coloured glass. The ruby may be softened by heat, and small rubies may perhaps be thus welded together, as they are said lately to have been by some cunning persons at Geneva; but in this process the crystalline character of even the welded bits would be destroyed, and much less would the whole have any such formation. Again, the ruby seems to owe much of its extreme beauty and variety of colour to a fact which has not been sufficiently dwelt upon in this connection. The ruby and the sapphire are chemically the same substance, or very nearly the same. Alternate layers of sapphire and ruby are even sometimes found in the same stone; and erroneous cutting has been known to damage immensely an inestimable ruby by "bringing out the sapphire"—that is, by bringing out a third and distinctly blue tint in the "table" over and above the twin colours of the pure ruby. Now it seems to me that some unequal mixture of the colour of the sapphire in the body of a fine ruby may account for one of the most inimitable beauties of very fine rubies—namely, an exceedingly slight and changeful inequality, or sort of smeariness in the deep carmine of the lower facets, as seen through the "table" and upper surfaces of the stone; a quality which gives to its colour the same kind of mystery and animation as is given to a space of blue sky by the ever-present but all but invisible and ever-changing shreds of white mist, with which the clearest sky is always covered and without which the blue would be as dead and hard, however bright, as the splendid red of the imitation rubies now manufactured in Paris: specimens of which may be seen in a jeweller's shop where Piccadilly joins the Regent's-circus. This effect must for ever remain beyond the power of art to copy; as also must another with which a great expert has told me that he considers the colour of the ruby to be somehow connected.

Very beautiful pink-rose-coloured rubies of great size, four to six carats or more, are sometimes absolutely flawless; but no ruby of the true deep and glowning carmine and of more than three carats in weight has probably ever been seen without flaws. Even in very fine and valuable rubies such flaws are perfectly visible at the first glance of the naked eye: but the most perfect "specimen ruby" ever known as far as I have been able to ascertain, though "perfect" in the sense that it is perfect to the unassisted vision, will reveal, under a strong magnifier, at least one or two such little points or planes of irregular reflection in its substance as those which quite fill the body of a fine opal and cause its many-coloured iridescence. It is a most curious fact that similar "flaws" seem to be similarly connected with splendid colour in the emerald though not so invariably as with the ruby. Large, light-coloured, and flawless emeralds are so common as to be comparatively worthless; and "aquam, arine," which is nothing but a very light emerald is found in absolutely faultless mass weighing pounds, or even hundreds of pounds. Fine sapphires, like emeralds, have usually some flaw or "feather" in them; but, like emeralds and unlike rubies, are sometimes to all appearance absolutely perfect. These characteristic flaws of fine stones are imitated by fraudulent manufacturers, but in vain. The cracks which they produce in their silicious or aluminous glass are too gross to escape detection as the work of artifice, and they do not affect the colour. But, while these imitated flaws are quite unlike those of real stones, the substance of the imitation stone, produced by fusion of alumina and other earths by great heat, has unavoidable flaws of its own, which easily distinguish it. On the whole, it may be safely assumed that the chances of any imitation or "production" ever endangering the value of natural stones is so small that it need not be taken into account by investors in them.

Pearls, though inferior in indestructibility to any of the precious or semi-precious stones, have at all times, on account of their extreme beauty ranked with rubies, sapphires, emeralds, and diamonds in value. They are subject to various kinds of injury, none of which affect the four primary gems, which are practically indestructible. They are easily scratched, are subject to discoloration by absorption of effluvia, and to actual and sudden decomposition by the presence of acids, even in the atmosphere. An instance came under my own observation in which some lustrous pearls were changed in the course of a few days, into things just like the eyes of boiled cod-fish, by the accident of a vinaigrette having been placed in the jewel-case with them. Notwithstanding this serious drawback, their beauty is so surpassing that a fine pearl of large size exceeds in value every other gem except the ruby. A short time ago I had the pleasure of being shown at Messrs. Garrard's a necklace of forty spherical pearls, not at all so large as to look vulgar and ostentatious, the largest being only forty grains. The price was £14,000; and the other day I saw two pearls, one of fifty-four and the other of about ninety grains, which were respectively valued at £1,600 and £4,000: that is to say, at about £140 and £180 a carat of four grains. Black and pink pearls are just now of even greater value; but this is rather on account of their singularity than their beauty, which is incomparably inferior to that of the pure white pearl, with its faint and changeful "photosphere" of all hues.

The pearl is even less capable of being successfully imitated than the ruby or the emerald. In a fine pearl, though there is not the slightest transparency or translucence, you seem somehow to see substance and not superficies. It is an organic surface, and cannot be copied by art. So with the forms of pearls, which, though often mathematically perfect, have a vitality and character of growth from within which, though easily felt by the practised eye, is not so easy to account for. The parabolic and hyperbolic curves of fine pendant and egg-shaped pearls seem somehow to be incapable of being copied. I have one of about the shape and size of the egg of the golden-crested wren; and the beauty of its form is a feast of which my eye is never weary. Science is quite as much at a loss to account for the formation of these exquisite gems in the pearl oyster as it is to account for the hues of the finest-coloured stones. Mr. Church, in his scientific little tract, says: "That there are small quantities of magnesia, oxide of iron, and silica in rubies and sapphires of all hues has been ascertained; but this

fact does not furnish the clue to the cause of the blue of the sapphire or the red of the ruby." Similarly though it has been sought to explain the formation of the pearl by the irritation caused by a foreign substance, "there are many pearls which betray no sign of such origin."

A fact of which the amateur investor should not be ignorant is that the carat by which the weight of all precious stones is reckoned is a variable quantity, as is therefore the "grain," four of which go to make the carat. There are only 3·17 grains of troy weight in the English carat, and Mr Jackson, in his "Modern Metrology" (quoted by Mr. Church) gives a list of sixteen different carat weights for different parts of the world. These weights range between ·2135 and ·1886 of a French *gramme*. There is an understanding between the merchants of London, Paris, and Amsterdam to use the carat of ·205 of a *gramme*; but it is not at all an inconceivable case that the amateur investor should be buying or selling very different weights. He ought therefore to possess a pocket set of diamond scales and weights of the London standard, and to use them when he conceives that there is ground for doing so.

The amateur who invests primarily for the pleasure of possessing a collection of the most precious and beautiful objects in nature, and to whom their character as safe and portable property is only a secondary consideration though a necessary condition in so laying out his money, must of course cut his coat according to his cloth; but, whatever may be the amount of money to be spent—two thusand or two hundred thousand—he ought to have definite views of what he proposes to do. Though he may lay out a regular forty thousand a year on his hobby (as a dealer lately told me that a client of his was in the practice of doing), if he be a true amateur there will be no superfluous repetition, no heaping up of treasure upon treasure merely because it is treasure. If his tastes are simple, he may easily spend a hundred thousand pounds upon a dozen specimens of the five primary gems—ruby, emerald, sapphire, diamond, and pearl; and a few thousands more would buy corresponding examples of all the quasi-precious stones—spinel, tourmaline, peridot, cat's eye, opal, etc. If he goes in for variety in each kind, he may easily spend any sum he pleases; for the individuality of character in precious stones is far greater than is commonly supposed. I was once examining some rubies in company with an uninitiated friend, at the house of a City broker, and my companion inquired how one was to be sure that a stone deposited for sale was not changed? "Surely a man would know his own ruby!" answered the broker, with such a look as one might cast on a man who should suggest a similar difficulty in identifying his wife. The aurora red and the carmine of the fine ruby exist in so many shades and proportions, that it would take many specimens to illustrate the various beauty of which the stone is capable: and it is so with the emerald and, in a less degree, with the sapphire. Several pearls—spherical, "button," pendant, and egg-shaped—would be required to show off these mere varieties of pure form, and several more the differences of colour. Cutting introduces another source of variety in precious stones.

The first thing to be attended to, in choosing stones for a specimen collection, is the colour; the second their interior soundness; and the third their cutting. The power of appreciating their colour can only come from practice, which, however, may be assisted by such hints as I have already given concerning the colour of rubies. The darker an emerald is, the better, provided it is perfectly clear; but to be a fine dark green is not enough. It must have a peculiar oily play of colour, which many have tried but none have succeeded in describing. Isodorus, Bishop of Seville (quoted by Strecter), says, "It surpasses in its greenness all green stones, and even the leaves of plants, and it imparts to the air around it a green shimmer; its colour is most soothing to the eyes." Pliny says: "If the sight hath been wearied and dimmed by intently poring on anything else, the beholding of this stone doth refresh and restore it again." Dante, describing the grass in a pleasant spot of Purgatory, says it was "as green as broken emeralds." Psellos (eleventh century) says it is "leek-green, playing easily into gold and blue." Heliodorus speaks of emeralds as "gems green as a meadow in spring, but illumined with a certain oily lustre." Another ancient writer describes them as "playing with a quivering green." This peculiar and indescribable beauty is owing to their strong dichroism; the double colour showing some different shade or mixture of shades at every slightest change of position, and, even when the eye and the stone are fixed, filling the different "steps" or facets of the stone with indefinable animation.

Sapphires of a bright, dark, and hard blue should be avoided, as well as those which show a pale strawish tint at the thinner edges. The right colour is the dark and soft ultramarine of the cornflower; but this hue is rarely, according to my experience, found without some "silkiness." Clear stones of this colour and without a flaw fetch very high prices; but those of the harsher blue of ninety-nine sapphires in a hundred can be got for £10 or £12 a carat.

An emerald or sapphire of very fine colour may have several internal cracks or "feathers," and still be of great value. Yet flawless emeralds and sapphires are not so extremely rare as to justify a collector of first-class stones in putting up with flawed examples; but he may have to wait for ten or twenty years, if he cannot put up with a ruby which does not, by some obvious irregularity in the reflection from the lower through the upper facets, indicate the existence of interior unsoundness. He may be well satisfied if he is lucky enough to obtain a ruby of three or four carats of the true colour, without any brown or grey "marks" in it or serious chips or chasms in its surface.

A stone may be of the best colour and perfectly sound and yet be worth only half the value of another stone of like constitution and colour, because the cutting and shape are not so good. The "steps" and lower facets should be in such numbers and at such angles as to send their reflected sheets of light through all portions of the upper part of the stone, especially the table. If the stone is too deep or too shallow the table will be lustreless, showing only a dull transmitted light instead of bright reflected planes. It is the fashion now, and is likely to remain so, to give the "girdle" of the brilliant a circular form. This is certainly more beautiful than the old brilliant shape, which was a compromise between a circle and a square. It requires sixty-six facets, instead of the fifty-eight of the old brilliant. A fine large stone thus cut is worth some pounds more per carat than another of the same weight and quality of the old shape.

The value of all first-class specimens of precious stones has greatly risen and is still rapidly rising, on account mainly of the eagerness with which they are bought up by wealthy Americans for their collections. Unless you get the first offer of an as yet uncut ruby promised to you, on the chance of its turning out a "specimen," you are scarcely likely ever to get a faultless stone of even one carat, and for that you will have to pay at least £100. Should a three-carat ruby of such character turn up, you may be asked, or you may ask, almost any price for it. Eleven hundred pounds has been given for such a stone—that is, nearly £400 a carat.—*St. James's Budget.*

Vegetable Cultivation near Colombo.—We have to thank Mr. Atapattu, "Agriculturist," for an excellent basket of vegetables, the products of his garden at Dehiwala—comprising five specimens of the famous snake gourd, brinjal, and chillies &c. The radishes are somewhat large for ordinary use, but doubtless would have been very tender and palatable a fortnight ago. Let us recommend to the notice of this enterprising gardener, the choo-choo gourd introduced by Mr. Nock, also the tree tomatoes, both of which would probably succeed under his care and prove a great acquisition to our country gardens.

PLANTERS' ASSOCIATION, TRAVANCORE.

To the Editor *of the* "*Tropical Agriculturist*," *Colombo.*

1st September, 1886.

Sir,—The members of our Association have drawn my attention to the misleading nature of the statements in regard to Travancore which appear from time to time in your paper and the "Observer." While entirely agreeing with you that Ceylon has little to fear from Travancore, I hardly see for instance the necessity for the deliberate perversion of facts to which the *Tropical Agriculturist* for April last, pages 704 and 712 gives currency. Only two Estates Penshurst and Nagamally were at that time sufficiently far advanced to export Tea, which teas, unassorted sold @ 1/6½d., Pekoe @ 2 2½d. and averages of 1/6J. and 1 8d. for shipments, prices with which we, in our humility are satisfied although you may not consider them to compare favourably with Ceylon.—I am, Sir, Yours faithfully, Robert T. Miller, *Chairman.*

[This is the most extraordinary letter we have received for a long time, and we should be inclined to treat it as a hoax played off on the Travancore P. A.; for on referring to pages 704 and 712 of our *T. A.* for our "*deliberate* perversion of facts," we cannot on page 712 find Travancore mentioned at all in the only paragraph that can be pointed to, and this paragraph is not ours but the Calcutta *Englishman's*! So again, on page 704, the extract is from the *Grocer*" and all that is said is "In Madras and Travancore the plantations remain much the same as before!" This is based on the *official* figures and report. We recommend Mr. Chairman Miller to send us a report of the facts as they stand in place of accusing us or the editors we quoted of deliberate perversion. How are the facts to be known if the Travancore planters do not report them?—Ed.]

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

BEET CULTURE—CHEAP CORN—SUGAR IN BEET—CLOVER FUNGI.

Paris, Sept. 4.

Today beet replaces colza, and autumn sown wheats are the most productive. Lucerne is followed by two consecutive wheat crops, then succeeds oats, and next wheat again. This wheat crop suffers from the excess of nitrogen left in the soil, so the straw has to be stiffened by doses of potash or phosphate manures, which impart rigidity to the stems and corrects lodging. Red are generally found to be stronger in stalk than white wheats. Cultivating in drills, weeding and hoeing, produce the largest yields of wheat. It is thus that Messrs. Nicolas and Raimon reap 35 to 40 bushels of wheat, and 60 to 70 of oats per acre. Their soils are analysed before being cropped, and when they indicate a provision of 4,000 to 5,000 kilog. of nitrogen per acre, no nitrogenous manures are given, such as sulphate of ammonia and nitrate of soda. About 10 fr. per acre is expended on mineral manurings. The chief varieties of wheat grown are the blue and white Bordeaux. Victoria, Autumn red, Chiddham, golden drop, and Australian poulard. The above gentlemen cultivate a mixture of wheats, the Bordeaux and Chiddham, which gives three rows of ears of different heights, a plan they assert, which secures them 4 bushels more of grain per acre. The Chiddham, Victoria and Dattel wheats are remarkable for being exempt from the attacks of rust.

At the French Association for the advancement of Science, just held at Nancy, the chief subject of interest was the condition of French, indeed one might say, of European agriculture, in presence of the augmenting competition with the products of the United States, India, Australia, and South America. The concensus of the meeting inclined to the belief that the future of French farming depended not on fiscal measures, but in the augmentation of yield, and in the adoption to culture of scientific methods, parallel with such as have benefited industry. The freight per hundredweight of corn has fallen since some years from 5. to 1 fr. for United States, and 10 to 4 for India. This reduction is due to the general employment of, and improvements in steamers to the Suez Canal route, the ameliorations in harbors, the machinery for the loading and unloading of cargoes, and the multiplication of railways. These facilities cannot be undone, so lower prices must be expected in the case of grain, as in every other industrial product, Russia, at Odessa has tried the half-and-half-plan. On the quays of that port the railway waggons can shoot the grain direct into the holds of the ships; but in order to conciliate the prejudices of the porters, the lifting machinery is put aside, so that porters may carry the grain on board. In the employment of improved implements of cultivation, much remains to be done in the reduction of expenses. The old plough, still so general, only performs in the day of ten hours one-fourth of the work that a modernised plough easily accomplishes. Sowing grain in lines permits the use of the scarifier or hoeing machine to stir the soil and cut down the weeds, which, like parasites, appropriate the nutrition destined for other plants. Nearly one-half the quantity of seed is saved by machine as compared with hand sowing. Similar economy is to be obtained in harvesting; one man will mow say two-thirds of an acre of corn daily, while a reaper will cut down 12 to 13 acres. In threshing with the flail too, a laborer can beat out 4 to 5 cwt. of grain per day, while a machine does its 550 bushels. Large and small proprietors can alike benefit by these economic processes; the first, by his large capital or his credit, and the others by grouping themselves into co-operative societies to obtain the best and cheapest goods that certain payments and independence of sellers always command. France has plenty of home wealth to develop yet; she has 6 millions of acres to bring under irrigation; she has 80,000 to enclose from the sea, and 2½ millions to break up and reclaim. M. Benoit, of Bousquet, has practically tested several of these guiding ideas by furnishing precise information to wheat-growers—a grain occupying one-seventh of the cultivated surface of France. Now several reasons concur that France must rely on wheat as her staple, her national crop; hence the necessity to raise it better for the future by the choice of the best seed and the application to the soil of phosphate and nitrogen, wherever these indispensable agents are wanting. And these essential conditions are limited neither by climate nor soil. Where they have been applied, the yield of wheat per acre has risen from 15 to 35 bushels per acre. M. Benoit's soil is a calcareous—clay, poor in all the elements of plant-food, save lime. He tried no less than 17 different varieties of wheat to ascertain which suited his district best. He prepared the soil by four ploughings and two harrowings; sowed in autumn with an application of phosphates, and in spring top-dressed with 130 lb. of nitrate of soda per acre. The average yield of wheat in the neighbourhood of Bousquet is only 13 bushels per acre. M. Benoit obtained by improved processes 28 bushels with the Dattel, Blood red, and Bordeaux varieties of wheat; while the White Hunter, Square head, and Chiddam yielded only 12 to 15 bushels per acre. Now in other regions these varieties have given as high as 40 bushels per acre! Hence, the importance of selecting the appropriate seed grain for a locality. By employing natural phosphate in powder, the phosphoric acid will not cost more than seven sous per lb.; and the nitric acid about fourteen sous. It is only natural from these facts that the French government is fully justified in organising, as in Germany, a corps of ambulatory farming instructors, to impress on agriculturists to prepare the land well for wheat, to choose the best and most appropriate seed, and advance to the land phosphates and nitrates. At the same time, the banks will stretch many points in favor of small proprietors uniting themselves into syndicates for the purchase of the best materials for their industry.

M. Aime Girard continues his experiments relative to the formation of sugar in the beet. He concludes that the pivot and radicals of the bulbs only serve to pump up and convey to the organism the min-

eral matters required for the development of the plant—and which can convey during a season of 120 days, a total of two-thirds of an ounce per plant—this is in the ratio of 2 grammes of mineral food for the formation of one gramme of sugar. M. Girard demonstrates that the formation of the sugar takes place in the aerial part of the plant, that is to say, through the medium of the leaves; that it is in the veins of the leaves, not in the stalks, and under the direct action of light, that the saccharine phenomena take place. Supposing a tuft of leaves to weigh 20 ounces, and these represent 66 per cent of stalks and 33 per cent of veins; and that the latter contains 2 grammes of saccharine matter during the day, of which the half disappears during the night, the bulb can thus receive daily one gramme of formed sugar, pending 100 days. One hundred grammes, over 3 ounces of sugar, is thus stored up, which means for a root weighing 26 ounces, a richness of 13 per cent.

About twelve years ago clover was attacked by a parasitic fungi which seemed to cut the stem close to the surface of the soil, when the stalk blackened and the leaves yellowed. It is complained that lucerne presents similar symptoms in the east of France, and is more general where rye is cultivated. Could it be ergot? And are vegetable diseases contagious?

THE CACTI OR "PRICKLY PEARS" OF SOUTHERN INDIA

are thus noticed in the proceedings of the Agri-Horticultural Society of Madras:—

Read the following extract from a letter from the Honorary Secretary, dated Madras, 23rd June 1886, to the Director, Royal Gardens, Kew:—

"Your reference to the *Cactaceæ* brings me naturally to a subject which has been interesting me greatly for some time. Dr. Bonavia wrote to this Government some time ago, and advised the introduction of "the prickly pear" of Malta and that it should be grafted on "the prickly pear" of India. In previous years, suggestions had been made by others, to get rid of prickly pear, which intrudes on cultivable land, by the introduction of the Cochineal insect to eat it; while many attempts have been made to introduce Cochineal for its own value. In some cases it was asserted that *the* prickly pear was so and so, and "varieties" were spoken of by writers who should have known better, so when Dr. Bonavia's letter was referred to me, I set to work to study the subject. I first satisfied myself that most writers and authorities speak of *Opuntia Dillenii* as, or as if it was *the* prickly pear of India, or at least the only one of any importance. See Hooker's Flora of British India, Roxburgh Flora Indica, Wight and Arnott Prod., p. 363, Wight's Illustrations, fig. 114, and innumerable Proceedings of the Government of Madras, the Board of Revenue, Madras, and this Society. "I knew we had about a dozen species in the Gardens, and I knew where to find clumps of at least four species wild and used as hedge plants in Madras; but being here in the last hot season when the plants flower most abundantly, I undertook a series of long rides to inspect all thickets of prickly pear of which I knew or heard, 10 or 15 miles from these Gardens in all directions. "I found at once that the species, which appropriates whole fields and village sites near Madras, is not *O. Dillenii*, that *O. Dillenii* is comparatively rare, and that there is a third distinct species nearly as common as *O. Dillenii*. "I have little doubt that *the* plant in and round Madras is *O. spinosissima* Haw. mentioned in Brown's Hand-book of trees, &c., in Madras, Voigt's Hort. Sub. Cal. p. 62, Dons, Miller's Gardeners Dictionary, Vol III, p. 172 and Grisebach's W. Ind. Fl. p. 302. It is a very distinct plant. It grows *erect* ten to fifteen feet, often assuming quite a tree-like character, with a thick woody stem. Its colour is *blue* green. Its long *grey* spines are very numerous, and they and the small thorns surrounding them so easily detached that they stick and work into every thing that touches them. The flower before it opens is a beautiful rose colour, when fully open almost orange from the quantity of yellow intermingled. The fruit is oval; pulp very rich in colour and probably sweet, as though thickly studded with thorns, birds and beasts eat it greedily.

"What I take to be the true *O. Dillenii* though not in all particulars agreeing with the figure in Wight's Illustrations, Vol. 2, is over the considerable tract of country through which I have specially looked for it, comparatively rare—probably not found once for the other's hundred. It is a *prostrate* shrub, rarely struggling up four or five feet by resting its upper branches on those below. Its colour is *pale* or *bright* green. "Where clumps of the two species stand out on a bare plain, side by side, as I have found them, you can tell which is which, a couple of hundred yards off by the colour as well as by their different habits of growth. Its thorns are far less numerous, two or three in each cluster, yellow and generally *curved*. The flowers before they expand are straw-coloured, when open the most exquisite and intensest, clear, bright yellow. The fruit is nearly the shape of a jargonelle pear, and usually eaten by animals before it is ripe. The shape of the fruit is well shown in Wight's plate. "The third species is rarer than the last; in colour and habit of growth it is similar, but perhaps its green is brighter, and I think I have seen it grow higher. It grows in the hedges in Madras; but I have found it outside 15 miles from these Gardens, and far from native houses or cultivation, where there could have been no object in planting it, so it probably grew from seed. The thorns are few, growing generally *single*, and *grey*; the unopened flowers are rosy; when open, yellow, streaked or suffused with rose. The fruit is somewhat the shape of a swan egg pear. "The flowers and fruits of the three species are about the same size and the pulp of fruits much the same colour. "We have unfortunately no work yet in our Library which enables us to identify the plants here, so are sending you in a box, specimens numbered in the above order—flowers of each carefully dried in sand, and a branch or two of each which will, I hope, reach you in good enough order to grow if the matter interests you. We sent you seed of the first two some months ago.

"Several of the species we have in the Gardens do not flower, including a spineless one (possibly degenerate *O. Cochinellifera*) which is not uncommon in Madras, but we are making a new rock-work in a sunny corner for them and hope to indentify them all in time."

Read the following extract from letter, from the Honorary Secretary, dated 8th February 1886, to W. T. Thiselton Dyer, Director, Royal Gardens, Kew:—

"I was amongst the Prickly Pear again yesterday, and find my account of the fruit not quite accurate. No. 1, *O. spinosissima* gets purple all over and has pulp of the deepest of purple magenta or scarlet; No. 2, *O. Dillenii*, the fruit, from many opened yesterday, is often ripe when quite green *outside*, and usually seems to have only a pink or rosy cheek, while the pulp is the same rich colour, hard to describe—purple scarlet; No. 3, which I think must be *O. Cochinellifera* degenerate, has sometimes a pink cheek, but seems to be usually yellow, with green pulp I was surprised by this, and felt rather confused over it as to how I before concluded the pulp was purple. I could not find a good ripe fruit yesterday, but ordered a look out for one for me. "There is a very striking difference in the unopen flower buds of Nos. 2 and 3. "Yesterday I found flowers of No. 2, streaked and strained with crimson or rose, nearly as much as those of No. 3."

Read the following extract from a letter, from W. T. Thiselton Dyer, Esq., dated Kew, 31st March 1886, in reply:—I have your letters of January 23 and February 8. The box of *Opuntia* specimens has arrived in good order. "My colleague, Professor Oliver has been so good as to report upon them. He says that they are plants of unusual difficulty from the muddle in their literature. He identifies your No. 1, as *O. vulgaris*, Haw.—very nearly allied to *O. Tuna* (=*Cactus Tuna*, L.) and to *O Elatior*, Mill.; No. 2, is *O. Dillenii*, Haw.; No. 3, is *O. monocantha*, Haw. (=*Cactus indicus*, Roxb.). You will

observe that Professor Oliver does not agree with the synonymus of C. B. Clarke, in Fl. Brit. Ind."

The Honorary Secretary observed on a recent journey from Bombay that the *Opuntia* Professor Oliver names *O. nigricans* was the common species all along the railway after ascending the Bhore Ghaut, and possibly all the way from Bombay to Madras. Recorded with thanks to Mr. thiselton Dyer and Professor Oliver, for their assistance. Read the following letter from J. T. Ward, Esq., dated Nellore, 5th June 1886:—"I find from the report of the Committee of the Madras Agri-Horticultural Society of last year, that allusion is made to the seedless Bread-fruit (*Artocarpus incisus*) and the Tree Tomato (*Cyphomandra betacea*). May I enquire whether you can furnish me with root cuttings of the former and a few seeds of the letter. Also a few seeds of the Cherimoya (*Anona cherimolia*). They could be sent by post, and I would like to know their cost including postage." "I have found the thornless Prickly Pear in some hedges here. I have fed Cattle, Buffaloes, and on it Pigs relish it very much. Cattle refuse it at first, but if made to fast for a day, take to it and relish it afterwards. Buffaloes take to it easier than cattle. When cut up and thrown into a tub of water, the water becomes very glutinous, and is much relished by cattle. Can this plant be the "Kew Nopal" which was introduced in the Northern Circars and in Tinnevelly in the year 1792, and was even eaten by the people of latter place in that year's famine. It was introduced from Kew Gardens to St. Helena in 1807 for the nourishment of the Cochineal insect. It is said to cure and even prevent scurvy and to be excellent forage for cattle, &c." "The Mangrove plant grows luxuriantly on the Coast, and by the banks of salt streams. Buffaloes are very fond of the leaf. I believe a revenue is derived from the cuttings of this plant for fuel in Masulipatam." Resolved that Mr. Ward be thanked for his interesting communication and asked to be so good as to send to the Society specimens of the thornless Prickly Pear and Mangrove to which he refers.

ROOTS AND THEIR WORK.

Applications to Methods of Cultivation.

Seeds and seedlings.—We have seen how delicate is the structure of roots after first being developed. The soil must be light, easily penetrated, and damp at the surface, for all plants whatever their habitat may be when fully grown. Air must have access to soil—it must not "cake," as stiff clayey soil is apt to do—the mere shaking of soil down in the seed-pot is sufficient for the purpose, except just a little pressure after sowing to flatter the surface.

Branching.—The branching rootlets are apt to get broken, they should be removed from the seed-pot before of much length, and in pricking in the seed it is easily seen that a displacement of the soil to one side instead of boring a hole and shoving the roots in, is the preferable plan.

Potting.—At potting, if we cannot indeed judge from the seedling what is the habit of the plant, we can at least see of what nature the perfect plant is, and act accordingly. Had the plant a creeping habit, easily rooting from the stem, what folly it would be to press the soil firmly around the seedling. Were the roots very smooth and fibrous, plentifully produced, we should judge that the plant wanted plenty of water and a moisture-retaining soil. If our root branched readily we might judge that it liked a fairly loose damp soil. If there were naturally delicate long hairs and a hard root, stony places would be likely enough its natural home, and we should pot it firmly. As to wedging plants (alpines) between stones, there is the danger of drying them to death—the stones and small pots if not plunged becoming soon very dry. It is an excellent help in cases where there is no danger of this drought.

Repotting.—In repotting plants great care should be taken to get the old and new soil of the same density, else if the new is looser the water passes through it when watered and leaves the original ball dry. Some potters slope the surface of the soil from the centre to the circumference, considering that the roots are mostly formed at the edge of the pot, or on the further side of the old ball, therefore it is best to send the water to the side. Others prefer that the soil should be quite even, so as to secure an equal distribution of the water. This seems reasonable when it is considered that the slope of the pot will cause the outside to get most after all. It is, however, very objectionable indeed to see a hole in the surface of the soil into which the water always runs, and so goes only through one part of the "ball" thoroughly. If the ball be dusty it should be shaken out or else water never penetrates it, although as a rule there is not much root in the centre of the ball of pot plants. In cases where the roots are very fine indeed and make but slow growth the roots penetrate right through the ball. The best known case of this is to be met with in the Cape Heaths. Where the growth is so, it stands to reason that the "shift" in potting on should not be great, and where the root is very fine it may be taken for granted that it naturally grows in a hard, somewhat dry place. These fine roots and long root-hairs need the more careful treatment. In repotting also, except among coarse, easily branching roots (those of not too hard texture), care should be taken not to break the "ball," or the chances are that the greater part of fibrous growths of the root are broken away, when the shock caused by evaporation subsequently is too much for the plant. Nor in slowly growing hard roots, which do not give off branch roots, as Heaths, should the fibre be disturbed more than possible, certainly not broken by poking among them with pointed sticks.

Watering.—Watering is considered about the most difficult part of plant-culture to manage well. That the soil shall not be too much saturated with water is quite as important as that it shall not be too dry: in the latter case the flagging is readily seen. Where saturated with water the soil is cold—if not decaying—and the needful warmth is absent which causes the delicate growing roots to develop. Especially should this be taken care about where a plant is newly "potted on." The larger mass of soil retains the water more readily, and the roots cannot take it up quickly enough; and similarly, if a "ball" is not fairly well covered with roots, it is hurtful to water it much even if the leaves are large and appear as though they would draw water up quickly.

Drainage.—As to the drainage in pots, it is well to have a considerable amount where the roots do not—as, for instance, in Gleichenia—penetrate deeply. The plant may like a great amount of water about it, but it does not want stagnant acid-generating soil, which if the drainage is clogged is apt to occur. To pour water on freely and left it pass off freely is a better plan. For the same reason it is well to have the soil porous, not to allow too much fine soil to remain in the potting mixture, though among common plants—and coarsely rooting plants especially—it of course is not worth while to riddle the fine away. We may notice that when the drainage is blocked up the roots have a tendency to grow to the surface again. At times we may see pots well filled with roots at the surface, and roots absent entirely from lower down the pot. This shows that the roots object to a water clogged soil. A considerable length of root, as in Imantophyllum, indicates great capabilities for absorbing water. In many cases one is tempted to moisten the surface only of the soil in small pots. This, though beneficial, on account of the damp, to the leaves, is likely, unless very carefully managed, to be productive of harm. The bottom of the "ball" may be dry whilst damp at the surface—a most ruinous state of things, quite contrary to Nature. Top-dressing is very much to be deprecated also, for a somewhat similar reason—the fresh soil looks dry, and water is given, saturating to a hurtful extent the old soil of the ball below. It is much more advisable where possible to plunge all small pots in

sand, which keeps them uniformly damp throughout, and is more natural as ensuring that the dampest part shall be at the base of the pots.

Syringing.—Syringing, though invaluable in many respects, has just this drawback, that the surface is damped, the base of the ball not; if well managed, however, it is a most necessary aid, especially just after potting plants, where, through the roots being broken, and the leaves continually evaporating, there would not be a sufficient amount of water in the tissues, did not syringing allow of its entering largely by the leaves.

Planting.—In planting care should be paid to the physical nature of the soil especially. For example, there can be little pleasure in seeing a creeping plant growing on a dry sunny place. Wherever roots grow freely from the prostrate stems there must be a fair amount of moisture in the very surface soil which will attract them and admit them readily into the surface. Trees moved should be as little injured in the fibrous part of the root as can be; and it has again and again been pointed out, that as the ascent of the sap is more vigorous in the Spring and Summer months, when also evaporation is excessive from the leaves, transplanting should be done in Winter or Autumn, when there is no great amount of leaf in deciduous trees, or less evaporation.

Roots moving before Leaves.—Many plants make vigorous roots and do not produce leaves until later. I remember lifting in some rare plants (Ranunculus Lyalli) growing in a boggy place because the leaves were poor, and as winter was coming on it was thought as well to take the plants under glass. After having dug them up we noticed how vigorous and strong the roots were. The planting and lifting in such conditions ruined the plants. It would have been much better to have slightly protected them in the open place where they grew, had we judged from examination of roots as well as leaves before disturbing them. Roots of many rhizomes, as in Anemone fulgens, A. nemorosa, &c., move before the leaves do; therefore it is well to plant or pot these in the Autumn, that growth of root may have taken place before the conditions favourable to leaf growth are present in the spring time. An example of the dependence of root and leaf was given me the other day by one who had grown Vines. They made leaves vigorously the first year, and were not cut back until late; the grower knew that whilst making leaves they were also developing strong roots, which would be of great help the next year after the stem had been cut back. This was an example of thoughtful pruning. The grower allowed all the leaves to be developed fully before cutting back his stem, which is generally the case in pruning, I believe.

Pruning.—In cutting stems either for pruning or grafting great attention should be paid to the strong ascent of the sap before noticed. In one plant the time for the strongest ascent differs somewhat from the time for it in others. I am told that this bleeding from a tree has been known to continue even after the cut end had been painted and treated in many ways, the ground just under the branch being continually moist from the sap exuding. Early or late pruning would either be preferable to pruning in the middle of the growing season, but where possible late pruning seems to me the most recommendable as regards the callusing of the place cut, whilst early pruning is better where the parts left are wanted to "break" or make buds quickly. Illustrating the dependence of leaf and root, an old story is told by one of our nurserymen to the effect that he once was growing Asparagus a long time ago, and having to keep a walk clear through the bed he tied string on either side of it, which string supported the stems. The leaves or finely branching stem were produced more profusely, and the roots of the tied up plants were as a result by far the best in the plot. Those which had bent down had stopped the circulation of the sap, and therefore prevented the full development of the parts of the plants. Asparagus is now often grown against string supports.

Shifting Plants.—It is said to be well for [some] plants to be pretty frequently transplanted. Bulbs growing together and dividing, are of course enabled to swell to large sizes if shifted, and the soil below them has much of its nutrient properties extracted. All soil has a tendency to become close also, and this is hurtful, as the air so necessary to sweeten it does not have access to the particles of soil. It is harder for many plants to root if the soil be very close.

Manures.—In applying manures also, it is well to consider their effect upon the physical condition of the soil. Farmyard manure contains matter which has to decompose, and its effect is to split up the soil and keep it "lighter" for some time. When the roots are consequently benefited by these as well as by the chemical properties of the manure. No such effect is produced by the smaller quantity of phosphates, or the like artificial manures. A surface soil if well manured, should not be dug into a considerable depth; unless the soil is very light and poor, this trenching is not advisable to prevent it becoming too stiff. It is but a poor remedy, some very light sandy or rubbley material should be added.

Lengths of Roots.—Roots descend to different lengths; this fact is made use of by farmers on laying down grass land. It would be useful in our lawns, and I should think that a deeply rooting grass, for instance, would have a better chance of growing well in a place which was likely to be baked in hot summers.

Soils.—Also if roots thrive particularly in special soils, they should have some attention where possible given them in the way of supplying them with similar constituents. But far more important to my mind than supplying plants with soils of different chemical composition, is to give them those which retain more or less moisture in accordance with the positions in which the plant has grown. It is of no use to give a plant a peaty soil of a loose nature, and then expose it to the fullest sun. Peat and excessive moisture are generally associated in Nature, and we should not disassociate the two in practice. This is but one example out of many. Plants with running roots, too, should, of course, have a light soil, through which they will be able to easily send their shoots, and by way of practical advice I may say that peat, unless very sandy, or with leaf-mould, does not form the most easy substance for roots or runners to pierce; especially in pots it is apt to make a very tenacious "ball." Plunging in sand is a capital attempt to remedy the artificial isolation with which we visit plants when potted.

Growth.—I have thought that perhaps plants in pots, as is the case with many trees grown especially for fruit, did not at times produce roots vigorously at the expense of the rest of the plant. I have seen a Dactylis hanging over a bank, and sending out 15 inches of fibrous root without seemingly contributing any fresh leaves to its parent plant. In hoeing, we should not just cut off the tops of such roots as Dandelion and polygonum; we find that they grow again. The plant should be taken quite out of the soil, or at least the root cut well down, so that the greater part of the thicker tap-root is pulled out. We often ask, "What time should cuttings be put in, or grafts made?" We should look to the structures of the tissue, and see when such are fairly ripe, and not too woody. Where Orchids are grown in the air they should, of course, have a damp atmosphere kept up, and many of our pot plants would be better grown if we sprinkled water oftener on stands and about the pots. I have not been able in this essay to give any definite ideas as to how to judge from roots as to whether they should be placed in one place or another—whether, for instance, they are damp-loving or the reverse. This has been hinted at, but time has forbidden any minute examination as to these and similar suggestive questions. [This may often be seen from an examination of the microscopic structure of leaves and roots.—Ed.] We can all tell, for instance, if we see a root growing in moss at the surface rather than in the soil below

that such a plant likes open damp compounds of a light nature to grow in. Such facts and observations we can continually turn to account. In conclusion, however, I would say that we must not be too ready to throw over all "rules of thumb" because they are old and we are new, and cannot see reasons for them at first. We have many times in the investigations required for this essay been unable to find any reason, much less the right one, for various results we have met with: how important is it, then, that in our own practice that we should be reasonable enough to accept all rules of thumb when we see them producing good results, only breaking such rules when we can better the result. Our reasoning as to cause and effect should not be with the object of breaking down these old traditions of experience, but in the honour of our noble profession to show the common and resonable sense which underlies them.—P. Sewell.—*Gardeners' Chronicle.*

TALC IN CEYLON.

Talc is found in abundance in Ceylon and is very widely distributed. It is a component part of most of the primitive rocks and is found in all the crystaline limestone or dalamite of the country. Very beautiful and perfect specimens are found in the pure white limestone of the higher ranges of the mountains. This limestone is perfectly snow white and so compact it hardly shows a crystal in fracture. In this are found perfect cubes of talc, black in colour, sharp on the edges without sign of decay, in part bedded in its natural matrix; the cubes are small. I have never seen them larger than an inch and a half square. They separate perfectly clean and sharp on the edge from the lime rock and can be split into infinitesimally fine flakes.

Talc in larger quantities is found all over the country, generallyg in proximity to Plumbago, and like that mineral, to which it is nearly allied, is found in pockets, and is soon worked out. Ceylon talc is usually black in the block, but when split into flakes gives a neutral tint or a rich brown yellow. This talc is commercially inferior, but might be used by photographers as producing a subdued yellow light, and not easily broken in a travelling outfit. All Ceylon talc which I have seen is more or less broken and twisted in the strata in which it had originally been imbedded an thrown up. Talc near the surface is usually so decayed as to be worthless, and the deeper the deposit the better and more perfect it is. The best specimens I have seen are from near Haldamulle. They were pure, almost free from faults and nearly white, appproaching closely to what in commerce is called ruby talc, which is silver white with a faint pink tinge, and when split fine very transparent, giving to fire light or lamp light a bright warm ruddy glow in passing through it.

Talc is largely used in India and China for decorative purposes in Temples, for fans, screens, paintings, spangles on embroidery, and for lanterns &c., &c., In England and America, especially the latter country, it is principally and very largely used for light in an hracite stoves, lamp shades, and similar purposes. Like plumbago it is alsost indestructible by heat. Although the "waste" produced in dressing is now being used as a lubricator ground to an impalpable powder, talc is only valuable when got in good sized sheets free from faults and of good colour but there is an unlimited market for good qualities, and if attention were once directed to talc mining a very valuable native industry may spring up. I see no reason why finely ground talc should not be largely used in the manufacture of crucibles, either as an admixture with plumbago or free. It is far more pure and free from quartz and grit than our best plumbago.—James Irvine. [We have some samples from Haldummulle from 3 to 4 in. square. We can find a ready market for sizes from 4 to 9 in. square, packed in 1 lb. packets containing pieces of only one size.—Ed.]—"Ceylon Advertiser."

Coffee.—It is always a pleasure to chronicle really successful coffee planting. The *Daily Post* writes thus of a veteran planter of Kadur in the Mysore Territory. "The twelfth of this month will have completed a quarter of a century since Mr. Henry Courpalais set foot on the Sumpagay Estate, in the Terekere taluk. During this long term of a planter's life he has had what seemed to be, almost insurmountable difficulties to contend with; but he faced them like a man and his perseverance has been crowned with success. Few, if any, can boast of having been as prosperous as he has been; and now, at the end of a quarter of a century, he can point to estates in as flourishing a condition as it is possible to get them. He goes in largely for shade and abundant manure, but, better than al this, he superintends every thing himself. Herein lies the secret of his success." We congratulate Mr. Courpalais on his enterprise and success.—*Nilgri Express.*

Coconuts and Rice.—To return from controversy to my subject, the rainfall has been such as to delight the soul of every Coconut Planter, and where plantations are in proper cultivation and in good heart, the prospects for "next year" are cheering, always provided that drought does not destroy what the rain has helped to put on. Our *Yala* crops are fast ripening and becoming fit to be harvested. I do not think they will be large, as heavy rain at the time of sowing helped to wash away the thin coat of mud overlying fields, which helps to give the young blades a start. Fields generally are free from insect pests, though my field happening to seed early had all the flies concentrated on them. Through the courtesy of Messrs. Brown & Co., of Colombo, I received a small quantity of carbolic powder to be used as a remedy against the fly plague. Unfortunately it reached me too late to be of use, and the villagers prefer charming their fields and watching for results, to being daily engaged in dusting their fields with the powder. The one requires the expenditure of a few cents, and the other of a littleof their latent energy. I need not say they choose the former as least troublesome expedient. I shall give the powder a fair trial next season. Local "Examiner."

The Tea Question.—Arthur Young, the famous and most able writer on farming of the last century, hald very strong views about the tea question. Oddry enough they bear a curious resemblance to the waonings now being issued by various doctors and food reformers both in America and England. The following words were written more than 100 years ago by Arthur Young in the eighth of his "Farmer's Letters to the People of England":—"I therefore, am tempted to think that the present laws relative to the support of the poor are universal encouragers of idleness, drunkenness, and tea-drinking, and that as such they are highly pernicious to the welfare of the Kingdom, and here I cannot but observe that as low a figure as tea-drinking may make in this trio, it is, nevertheless, of wonderful extent and consequence. As much superfluous money is expended on tea and Sugar as would maintain 4,000,000 more subjects in bread. If it is considered what a fatal enemy excessive tea-drinking is to the human body, how much it impairs the vigour of the constitution and debilitates the mind, the pernicious influence of it will be apparent. It has been asserted that excessive tea-drinkmg is of more fatal consequence to the increase of the human speciesthan even the immoderate use of spirituous liquors, nor should it be forgotten that the trade we carry on for tea is totally against us in the balance. It is a branch of commerce by which we perpetually lose; thus burying our money in an unfathomable gulf for a pernicious commodity that tends to our very ruin. Our legislature taxes every necessary of life: surely this vile superfluity calls aloud in its abuse for greater restrictions. But what are we to think of a conduct, diametrically opposite, of lowering the duty upon this pernicious drug, that the people may be able so much the easier to consume their health, their time, and their money! To enable them universally to drink it twice instead of once a day. What wretched politics! Such an idea is congenial alone with the last ruin of the state!—*Agriculture.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, September 9th, 1886.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White, per cwt.	Slightly softish to good hard bright	£6 a £7
Yellow	Do. drossy & dark ditto	£4 10s a £6
CINCHONA BARK—Crown per lb.	Renewed	1s a 3s
	Medium to fine Quill	1s 4d a 2s 6d

CEYLON UPCOUNTRY PLANTING REPORT.

BLACK OR GREEN BUG ON THE TEA—THE "MONARCH" TEA MACHINE—"ANOTHER RICHARD IN THE FIELD."

27th September, 1886.

Most planters have seen a tea plant here and there, especially when growing in the vicinity of coffee, covered with black or green bug, and have set the same down to evil companionship. There is always the fear, however, that the pest may spread, and that tea may suffer as the coffee has done. I was sorry to hear that in the Pussellawa district a considerable extent of tea can be seen now blackened with this plague. The effect on the tea is not such as it was on our weakened coffee trees, but if the bug follows the nation, and takes a liking to our new product he may be rather hard to satisfy. The effect of the bug in the meantime is that all flushing is stopped. I have seen a memorandum which Mr. William Gow has put out regarding his "Monarch" Tea Leaf Withering and Fermenting Machine, and which is about to be introduced into Ceylon. This machine, it seems, tries to do mechanically what the Chinese accomplish by hand when they toss and beat the leaf about. But it does more than this; it withers and ferments by means of a current of hot-air circulating through a rotating drum of special construction. It is self-acting, requiring only coolies to feed, and a man to watch the fire. By its means the leaf is oxydised and fermented *before rolling*, and can be kept for a time—some hours—without deteriorating. It is maintained that leaf withered by this machine rolls well, and when fired is handsome and wiry showing the requisite bloom, and being of a good bright black colour. It further multiplies the pekoe ends, by the convoluted leaf-buds opening out. The rolled leaf is said to take a shorter time to fire than is usually necessary and the expenditure on fuel is small. Extensive withering space is rendered unnecessary, and a machine 8′×8′ at a trial on Mohurgong estate, Sukna, prepared fourteen maunds of withered leaf and six maunds of 'cutcha' leaf per hour, and did its work to the satisfaction of some eight managers of tea gardens who had come to see it working. A fill of the machine is six maunds of unwithered leaf, and the time occupied to complete the operation depends altogether on the quality and state of the leaf operated on. From the above particulars it will be seen that the "Monarch" promises much, and we will be all interested in comparing the result of the coming trial in Ceylon, with what took place in India. This is how the planters there put it:—"The meeting found that all these conditions were fulfilled, and that a great pull was obtained, namely, that oxydization and fermentation were fully and chemically perfected before rolling: that extensive withering space was rendered unnecessary; that tea made from even coarse leaf gave a good black appearance and that generally it was most favourably affected. The meeting further found that a good twist was given to the leaf, and that all superfluous moisture having been removed the process of firing was much more speedily carried out."

The "Monarch" is however not be "monarch of all he surveys," for I hear that there is already "another Richard in the field," and that a pushing upcountry firm is soon about to launch another Witherer. But I have not heard any particulars regarding it, except that the price was to be moderate, which is a comfort.

PEPPERCORN.

BRAZIL'S COFFEE EXPORTS.

In the year 1722* the first coffee plant was brought into Brazil, in the Amazon district. The cultivation of the plant did not commence until 1761, extending to Maranhao in 1774, from which province some plants were introduced in Rio in a private garden. In 1820 the export of coffee was 97,500 bags of 162 pounds. Its cultivation rapidly expanded, as the following table of exports from Rio at intervals of ten years will show:

	Bags of 162 lb		Bags of 162 lb.
1830.....	391,785	1860.....	2,127,219
1840.....	1,068,418	1870.....	2,209,456
1850.....	1,343,484	1880.....	2,799,791

In 1874 bags to hold 132 pounds were substituted, and therefore we make the figures of 1880 to correspond with those used at earlier comparative dates. The civil war disturbed seriously the relation of supply to demand, and as the United States was the chief market, very naturally its trouble discouraged production in Brazil. The yearly average exports from 1861 to 1870 were, 138,537 tons, advancing to 155,912 tons per annum from 1871 to 1875.

For the seven years 1874-1880 the annual average shipments from Rio and Santos were 229,149 tons, of which 48⅔ per cent. came to the United States and 51⅓ per cent to Europe. Adding local consumption in Brazil, we had what was then considered by the author of "Coffee from Plantation to Cup" the "stupendous" average annual production of 558,093,760 pounds, or 249,149 tons.

Since then we have had a period of low prices, and it still continues. The natural tendency of such a state of affairs would be to check production; that such has not occurred is evident from the foliowing statement:

EXPORTS RIO AND SANTOS COFFEE CROP YEAR ENDING JUNE 30.

	To United States.	To Europe.	Total.
1882.....	2,536,457	2,774,008	5,310,465
1883.....	2,950,121	3,325,178	6,275,302
1884.....	2,447,759	2,558,180	5,006,239
1885.....	3,138,251	3,131,262	6,269,516
1886.....	2,952,322	2,350,049	5,302,371
Total, five years	14,024,916	14,138,977	28,163,893
Annual average	2,804,983	2,827,795	5,632,778

This represents, allowing 30,000 tons for home consumption and exports from Bahia, an average annual supply of 360,752 tons, or 818,081,180 pounds, against an annual average of 558,093,760 pounds for the period 1874-80.

Therein lies the sequel of cheap coffee. It is claimed that planters, whose plantations are free from encumbrance, can profitably raise coffee on the basis of prices ruling during the past three years. Unfortunately many planters are paying heavy interest on mortgages, and these have become more or less discouraged.

It is noticeable that stocks have been growing smaller for two years, giving strength to the belief that new plantations are not being set out in Brazil, and a survey in detail of the above table rather supports that idea. The 1883 crop was about equal to that of 1885; that of 1882 was abreast of 1886, and making allowance for the variation in crops, the indications point to the Brazil production having reached a maximum until some new stimulant is given the industry. If this proves to be true we must, with a steady

* One hundred and sixtyfour years ago.—ED.

increase in the annual consumption, conclude that production is beginning to fall behind consumption, and unless Mexico and Central America rapidly increase their supply, coffee must sell on a higher average basis.—*American Grocer*, Aug. 18th.

COFFEE IN VICTORIA.

(Duty. 3d. per lb.)

	1882.	1883.	1884.	1885.
	lb.	lb.	lb.	lb.
Imports	1,836,033	1,289,666	1,189,010	1,656,403
Exports	494,408	418,408	397,348	414,626

—*Australian Trade Review.*

[In round numbers a consumption of 7 millions of pounds by 1 million of a population, or 7 lb. *per caput*, against nearly 5 lb. in Britain.—Ed.]

Mangosteens and Litchis on the Nilgiris.—In the annual report on the Barliyar Gardens, which are somewhat over 2,000 feet above sea-level, it is stated that mangosteen and litchi trees have fruited well and it is added:—"It is odd that there should be so little demand for these trees, for, after the mango, they are by far the best fruits we have in Southern India, and I believe they would thrive and grow rapidly in almost any part of the country." There is no limit as to altitude here and we should like to know up to what altitude the mangosteen can be grown. We once tried plants at 4,700, but they failed. No doubt the depressed state of the planting interest accounts largely for the decreased demand for plants. As plants are plentiful and probably cheap, some of our local readers may be led to indent on Mr. Lawson for some Wardian cases.

Malaria Altitudes.—While malaria usually has its ordinary habitat in low-lying regions, it may, under favorable conditions, exist at great elevations. On the Tuscan Apennines it is found at a height of 1,100 feet above the sea; on the Pyrenees and Mexican Cordilleras, 5,000 feet; on the Himalayas, 6,400 feet; on the island of Ceylon, 6,500 feet;* and on the Andes, 11,000 feet. At present the elevation of entire security has been thus approximated for various places: in Italy, from 400 to 500 feet; in California, 1,000 feet; along the Appalachian chain of the United States, 300 feet; in the West Indies, 1,400 to 1,800 feet. In any of these regions, however, malaria may drift up ravines to an indefinite height.—*Indian Engineer.*

* This is entirely new to us. Is there a case on record of malarious fever *contracted* at such an elevation? Of course persons who have malarious poisons in their systems are liable to recurrence of fever at any elevation.—Ed.

Coffee-planters in Southern India who have been complaining of a lack of matter bearing on their staple in the *Tropical Agriculturist* will be gratified to find a series of reviews of the various branches of a coffee planter's work by an old Ceylon hand is now being published in the *T. A.* They were written some years ago but are revised to date.

Pinus Insignis for Nuwara Eliya.—*Cryptomeria Japonica* promises to grow well at Nuwara Eliya, but what about *Pinus insignis*? It ought to be largely planted at once, for Mr. Lawson reports that this conifer is established on the Nilgiris, trees of six years old being sixty feet in height (10 feet per annum), while trees fifteen years old yield an abundance of excellent timber. If Mr. Nock has not already got nurseries, he will no doubt at once procure seed in quantity of this pine which equals *E. globulus* in rapidity of growth and quality of timber at an early age. Our forest department ought also to pay attention to this tree. With proper seasoning the timber would doubtless be suitable for tea chests.

Can Artesian Wells be sunk in Jaffna?—Probably not:—Two conditions are necessary for artesian wells. There must be three layers of earth or rocks, the upper and lower impervious to water, the middle, pervious. If water can pass through the upper it will come out in springs when the middle layer is full. If it can pass through the lower it will sink. But if these layers are level, no water can of course either get into or out of the middle layer. The layers must be shaped like one side of a cup at the bottom of which the well must be placed. The top of the layer must be higher than the top of the well, else the water will no more come out of the well than it will out of our ordinary Jaffna wells. But Jaffna is on a bank of coral. If this coral rock could be bored through the rock beneath would in all probability be like that of South Ceylon and South India—not in layers. There is hardly a possibility that artesian wells could be sunk in Jaffna.—*Ed. M. S.*—"Morning Star."

Ceylon v. Indian Teas.—The latest *Produce Market Review* has the following pointed remarks:—

Although the market for Indian and Ceylon Teas continues to be liberally supplied, the demand has sufficiently improved to maintain prices. Some of the last arrivals of Indian Tea are of distinctly better quality, and there has been a general improvement in the Teas from most districts. This may indicate that as the year advances better Teas will arrive than has been the case, until quite recently, since the opening of the season. At any rate, it is to be hoped that the improvement in quality will increase, as, unless this is the case, the general position of Indian Teas in the London market may be less favourable than it has been of late years. There is every probability of a lower range of prices this season for the very finest grades, in consequence of the gradually diminishing demand for high priced Teas. This is a consideration equally applicable to all fine Tea coming from any country, but to give less attention to quality in consequence must prove prejudicial to the interests of Importers, and Ceylon Teas have been recently substituted for Indian Teas, simply owing to their superior manufacture and strength. If Indian Teas are to hold their own in competition here, it can only be by careful attention to the requirements of the market, and by supplying Teas sufficiently marked by the well-known characteristics looked for in these growths. Ceylon Teas were some time ago very disappointing in quality; but they have much improved of late, and buyers have not been slow to recognise the fact, as evidenced by the brisk competition for them now. With the increasing production, it was thought probable that the quality of Ceylon Teas would not be maintained, and it certainly appeared so a few weeks ago, but recent shipments have quite dissipated this idea, and most of the fresh supplies are quite up to the average of former years.

THE TEA LEAF.

Sir,—In these days of small things (so far as our knowledge of tea manufacture is concerned) the most insignificant hint is not to be dispised. I need not, therefore, apologise to my brother planters in inviting their attention to the following small items of information. In the young leaf of the tea bushes, when picked, a chemical change is faciliated by the "withering" process, which goes on throughout the twelve hours of darkness, whereby (in technical phrase) the proteids are coverted into peptones. The nutritive extractives, which give flavour and strength to tea, exist, primarily, in the young leaf as insoluble grains (proteids). Whilst the young leaf remains unpicked upon the bush these proteids slowly become soluble, but as fast as any portion becomes soluble (peptones) such portions are at once drafted away (into some other portion of the plant) and are lost to the leaf. The "withering" process not only hastens, but also artificially completes this solvent transformanion, and therefore the hint we have to bear in mind is that the more thoroughly our tea leaf is withered (not dried), the larger will be the proportion of the nutritive ingredients of the leaf which become soluble, hence the greater flavour and strength in the resulting tea. We have conjectured frequently the ultimate purpose that the large proportion of oil contained in the seed subserves. Analyses of seed and seedlings seem to intimate that this oil furnishes the extractive "theine" in addition to increasing percentage of albuminoids and cellulose.—Naduvatum, September 13.—Novice.—*Madras Mail.*

TEAK-WOOD AND PAPER-MAKING IN SIAM.

Referring to Teak-wood, in his report on the trade of Bangkok for the past year, Mr. Consul French says :—

Throughout the year the prices offered for Teak in Europe and China were good, and the export from Bangkok was, although below that of the two previous years, above the average of the preceding five years. The rivers have now for two years past been very low, and consequently much of the wood could not be floated down. There is now a considerable quantity of logs upcountry, the accumulation resulting from two bad seasons, awaiting favourable floods to get down. More European capital is now being invested in the working of the Teak forests, and it is to be hoped that the experiment will result successfully. Hitherto the forests have been leased chiefly to Burmese, very few of whom have sufficient capital. The result has been that the forests have been worked in a meagre and unsatisfactory fashion, and litigation between the foresters and the persons advancing their money has been bitter and constant. The export of Teak may be said to almost entirely depend upon the ship building business in Europe, and as long as the present stagnation in that trade continues the prospect before Teak merchants will not be encouraging.

Native paper, it is said, is manufactured from the bark of a tree called "Toukoi," the process of which is a simple one, described as follows:—The smaller branches of the tree are cut and steeped in water for two or three days. The bark is then stripped off, and brought in bundles and sold to persons who make the paper. The bundles of bark are put in water for two or three days by the paper-maker, and having been cleansed from dirt, are taken out and steamed over a slow fire for two days, a little clean stone-lime being sprinkled through the bark. It is then steeped in water in earthern jars, and more lime is added. After a few days it is taken out of the jars, and having been well washed, to free it from the lime, it is beaten with a wooden mallet until it becomes a mass of soft pulp. A frame of netting about 6½ feet long, and of width varying from 18 to 5 inches, is set afloat in water, and the pulp, having first been again mixed up with water, is skilfully poured out on to the frame, so as to be equally distributed over it The frame is then lifted out of the water, and a small wooden roller is run over the surface of the pulp. By this process the water is squeezed out and the pulp pressed together. The frame with the pulp on it is then set to dry in the sun. In the course of some ten hours it is quite dry, and the sheet of paper can be lifted off the frame. It now only remains to smooth the surface; this is done by applying a thin paste of rice-flour to the surface, and then rubbing it down with a smooth stone. A black paper, which is written upon with a slate or steatite pencil, is made by colouring the surface with a mixture of charcoal. The paper here described is made from the bark of Broussonetia papyrifera.—J. R. J.—*Gardeners' Chronicle.*

TEA DRIERS.

* * * * * *

Davidson made a rapid stride with his "Sirocco," which has served us very well, and from the number now in use, he must have had a good time of it since he started. Still he seems to have had steadily before him the old "chulah" system in designing his machines and this is very apparent when the T Sirocco is closely examined. I have often wondered why Davidson did not work out an automatic machine like some of those now in use. We hear less of Kinmond's and the Gibbs and Barry machines now. I daresay the letter would have a better run but for its requiring coke as fuel. It is a costly item unless one is situated near a "ghât" or railway, and we do not seem to be favoured with any of a superior quality, though we pay very dearly for it. Our wants seem to be met in the Jackson's new Victoria which burns any kind of fuel or rubbish. It is a machine that will suit the requirements of many who are short-handed, and have difficulty in getting either coke or charcoal. When one of the large machines now at work in Assam is compared with the number of "chulahs" and coolies required to keep pace with it, I can only say, that it is a happy deliverance from the olden days when we had to pass through the rows of perspiring "batty wallahs" and getting half roasted before reaching the end of the factory. Note also the number of men it sets at liberty for much needed cultivation outside. Three men with one of these machines will do as much work as thirty "batty wallahs" in the old days, and last, but not least, note the saving in fuel. I am not an expert at describing machinery, though I am very fond of it, so I had better not get beyond my depth in giving details. But I was greatly taken with the description of this machine given in the papers last year, and a recent visit to Gainsborough has shown me that they justly merit all that has been said on their behalf. It appears the first Victoria machine was sent out to the Jorehaut Company in 1884 and since then they have three more at work, and in addition a Venetian or small-sized machine has been sent to one of the small divisions of the Company. I was surprised to learn that altogether 50 of Jackson's Dryers (Victorias and Venetians) are at work this season and I was struck with the following novel features in them. The leaf is fed into a hopper, or well, and nothing more is seen of it until it emerges underneath from a fluted roller which delivers the dry tea. Although turned over for times in its course from tray to tray it is not crushed or broken and not a particle of "goorie" is lost. Now with the utmost care in working trays in any machine of the drawer tray kind one cannot overlook the fact, that from day to day a large quantity of good tea is trampled under the coolies' feet, which if seen at the end of the season in a heap would make him stare. And if this tea can be preserved and its approximate value put past at the end of every season one would be able in a few years to write off a considerable part of the cost of machine saved in "goorie" alone. As I have mentioned before I am not an engineer or know much about machine construction, but I think Jackson must have taken a leaf out of the book of the manufacturer of the potato dryers sent to Assam many years ago with

a view of their being capable of drying tea. The furnace pipes in Jackson's are very like the latter mentioned, and if they last as long without renewal they will not cost much to keep up. The reason why I confined my remarks to drying machinery is, that we are quite pleased with our rollers and sifters and I do not think they can be much improved upon. In concluding these I would recommend all Assam planters who would economise labour and fuel to have a good look at Jackson's Victoria and Venetian dryers before deciding to go in for new machinery of a like nature.—On "Chootee."—*Indian Planters' Gazette.*

THE CULTIVATION OF THE RAMIE IN FRANCE.

An article recently published by Mons. M. E. Fremy in the *Comptes-Rendus* must be anything but pleasant reading for our cousins across the water. A solitary Frenchman in some part of Egypt is said to have accidentally dropped a cotton seed in his garden, and thus has been the means of introducing the cotton plant into Egypt; and now M. Fremy, after devoting a number of years to the investigation of the nature and character of vegetable textile fibres, has come to the conclusion that Chinese ramie can be cultivated in France as a substitute for imported cotton. In view of the importance of M. Fremy's assertions, it may be as well if we give our readers a few particulars of this plant. The ramie of China is grown to the natives under the name of Tchonma; to botanists as the *Böhmeria nivea*; and more popularly in England as the grass-cloth plant. The genus is of the order of nettleworts, *Urticaceæ*, and allied to true nettles, *Urtica*. There are several species found also in Assam, Nepaul, the Sandwich Islands, and Brazil; and in each country excepting the latter, where it has a medicinal use, it is employed in the manufacture of textile fabrics. The Chinese plant reaches a height of about 3ft. or 4ft. Its leaves, growing on long hairy footstalks, are heart shaped, have serrated edges, and are about 6in. long and 4in. broad. They are green on the upper side, and covered on the under side with white down. The Chinese obtain three crops of stems annually. The second is judged to be the best. The fibre is procured by stripping off the bark in two long pieces, which are carefully scraped with a knife to get rid of the useless matter. These are then divided into fine filaments by steeping them in hot water or holding them over steam.

In the researches made by M. Fremy into the chemical composition of the skeletons of vegetables, his attention has been principally directed to the bodies which weld the fibres together, and which oppose their separation. He has known that the cement of the fibres and cells is chiefly formed of three substances, which he has studied under the names of *pectose*, *cutose*, and *vesculose*, or pectin, cuticle, and vesicle. Knowing that these can be destroyed and the fibres separated from them, he has tried to complete his researches by applying himself to the separation of the fibres which are found in the principal textile plants, such as the ramie, flax, hemp, and jute. The ramie was cultivated in France, for the first time, says M. Fremy, at the Natural History Museum, by the late M. Decaisne, and yields an abundance of fibres of an extraordinary tenacity, often possessing the appearance of silk. The ramie thus presents for France, in which utilisation of vegetable textile fabrics is perhaps the most important industry of the country a particular interest, and may one day become, says, the investigator, our French cotton.

France, he points out, buys enormous quantities of vegetable textile fibres from the foreigner, as is shown by the fact that the value of the cotton imports into France in 1885, was about 7,200,000 fr. The cultivation of the ramie would, M. Fremy is persuaded, relieve the country of the necessity of purchasing from the foreigner. It would also mitigate the depression caused in French agriculture, by the relinquishment of madder cultivation, and might be introduced into their colonies, to the assistance of their threatened sugar cane industry. M. Fremy's method of separating the fibres is to eliminate the objectionable elements by the ordinary reactive action of chemicals, the Chinese, as we have already described, accomplishing this by mechanical means. M. Fremy has laid before the French Academy samples of the ramie fibres thus treated, to prove that the process of elimination is successfully completed, and he expresses the hope that French agriculturists will not hesitate to undertake the cultivation of the ramie on a large scale, that French spinners will utilise the fibres, and thus afford a fresh example of the services which science is able to render when allied to agriculture and industry.—*Industries.*

REPORT ON THE HORTICULTURAL GARDENS, LUCKNOW, DURING THE YEAR ENDING 31st MARCH, 1886.

Financial.—Despite the forebodings of lasst year in regard to the effects of the hailstorm of January, 1865 on the income of the year under review, receipts exceeded those of last year and were R202-9-11 in excess of the budget-estimate of R10,000. Expenditure amounted to R14,454-5-5, or R454-5-5 in excess of the estimate of R14,000, leaving the net cost at R4,251-11-6; from this deduct R822-4-0, which represent the cash loss on plants, &c., sent out at reduced prices to public institutions, and we have actual net cost R3,429-8-4.

Fruit Culture.—The fruit crop was, with a few exceptions, poor, as had been anticipated would be the case. Great attention is being devoted towards forming a good representative collection of the orange family and success in introducing the blood orange of Malta seems at last in view. The yellow Almorah plum has been found to fruit freely, and more plants of it have been laid down. Of grafted carob plants only a few are left, but these are healthy. The Arabian date-palms fruited freely, but, as in former years a difficulty was found in preserving the fruit till it had reached full maturity. Date seedlings have been raised in good numbers, including some from a successful cross between the Arabian and the wild date; a difference in the time of flowering limits free crossing of the two varieties. An instructive table of profit and loss on the various crops shows how pine-apples grown in mango groves may redeem the loss on a poor crop of mangoes by fruiting abundantly. Of new kinds introduced, Barries' fig, tree tomato, mountain papaya, quinces, the edible prickly-pear of Malta, and a few American vines were raised with success.

Vegetable and farm culture.—Following past experience, more space was given this year to planting for seed rather than for market sale. Cos-lettuce, for which the gardens have always had a great demand, proved a failure. Hybrid Nankin cotton is pronounced to be of no importance, and its cultivation will be discontinued. Muzaffarnagar white wheat, grown as an experiment after cotton, proved very successful both as to yield and as to quality of seed. In country vegetables improvement by selection is being preserved with and time must be allowed for effect. Belgian carrot (white) proved, as it has done elsewhere, to be inferior in yield to the country variety, but to have advantages as a late variety. Of new kinds under trial, salt-bush (*Atriplex nummularia*) continues to do well, and Saintfoin, from seed received through the Government of India, gave a fair crop. *Withania coagulans*, prickly comfrey, hard white wheat from America, and *Shafdar*, a forage plant from Persia, have been proved unsuitable for these provinces. On the other hand, good new varieties of maize, tobacco, and early-maturing vegetables of various kinds were tried with more or less success. Distribution was much the same as to acclimatized seeds as last year, save in regard to silver-skinned onion and cos-lettuce, for which the demand was abnormal. For imported seeds the demand slightly increased.

Flower culture.—A good demand for acclimatized seeds exists. The improvement of Hippeastrums by hybridizing is being carried on with continued success. A large number of the best kinds of annuals were imported and grown with satisfactory results. Of new introductions may be named *Erythroxylon coca* and a timber tree (unnamed) from Bhutan. Distribution was nearly equal to that of the previous year.

Arboriculture.—Owing to the ravages of the hailstorm distribution was limited. A large number of young trees (23,700) were raised during the year, and the stock now in hand will admit of extensive distribution in the rains.

Exotic plantation.—The acre of *divi-divi* planted as a test for profits continues to flourish and a few trees have begun to pod. No irrigation was given and cultivation was continued in the open spaces; though, owing to the heavy rains, there was not much of a crop. There is no tree more suitable than this for covering the waste soil on lines of railway. Its low growth obviates all the disadvantages to be found in higher timber in regard to obstruction of air and danger from windfalls to passing trains; its dense shade kills down the coarse grass and lessens to danger to villages and stackyards from fire; and lastly, there is the profit, which is known to be good. We have large numbers of young trees in the nursery.

The paper mulberry (*Broussonetia papyrifera*) is likewise being planted out on a scale sufficient to test its potentiality for profit. It appears to grow freely and is well worth attention. As lately stated at the Society of Arts by Mr. Baden-Powell, C. I. E., this plant seems likely to become one of the best sources of paper-making material in India and can be commended for waste lands.

Date plantation.—In this plantation *Eucalyptus citriodora* and date-palm are being reared intermixed on Dr. Bonavia's plan. The date-palms are flourishing, but the Eucalyptus plants are proving difficult to rear owing to the persistent attacks on them by white ants.

Annual flower show.—As the weather for the year had been on the whole favourable for gardening, the flower show, which had been stopped in the previous year, was held as usual. In exhibits the results were not so satisfactory as they usually are, but the show was managed with economy and success.

Apprentices and applications for malis.—Eight applications were received for trained *malis*, and, from amongst the apprentices, one has found a good post at Ghâzipur. This branch of the garden work, *viz.* training boys, is a very useful one.

Mr. Ridley remained in charge of the garden throughout the year and has had very hard work to restore order after the damage caused in January, 1885. It is submitted that the results as now reported are most satisfactory and creditable to his management.

From the detailed report we copy the paragraph regarding the attacks of white ants on *Eucalyptus Citriodora*:—"I greatly regret having to record very limited success with Eucalyptus citriodora. Out of 2,350 seedlings planted out only 380 have survived, or, more correctly, escaped the ravages of white ants. The tree appears to have peculiar attraction for this pest, as I have never known any other plant so persistently preyed upon as these Eucalyptus trees have been, both in small and advanced stages of growth, and all efforts to find a remedy or protective have equally failed. Kerosine and soap emulsion, phenyle, decoction of madar leaves and asafœtida were all tried as remedies, but without success. Other substances are being experimented with in the hope of finding a protective". There must be something very attractive to the *termites* in the Australian tree, and the tenacity if life in the insects seems marvellous.

THE MADRAS GOVERNMENT CENTRAL MUSEUM,

which under Dr. Bidie became so complete and interesting, continues, under Mr. Thurston's supervision to be attractive, over 25,000 persons having visited the building in one day. We quote as follows from Mr Thurston's report:—

Museum Grounds.—The Mhoganies mentioned in the last annual report were planted out, and the experiment is being tried of planting the faster-growing rain tree *Pithecolobium saman* by the side of them to act as nurses of the tender seedlings. Some seedlings of the giant *Bambusa katang*, *Bixa orellana* and *Erythroxylon coca* were also planted, but the last are not thriving. The *Naudea cadamba* which was planted in 1881 flowered for the first time, but bore no fruit. Several of the palms which were set down a few years ago also flowered. The Andaman trees, presented by Captain Torrie, are all making satisfactory progress. I purpose planting some fruit trees—mango, jack and coconut—in the grounds over several barren areas, which are not pleasant to look on.

Artist.—The artist was mainly occupied with making a series of drawings of impressions of seals attached to copper grants. These he did neatly and accurately.

Ethnology and Antiquities.—Some Buddhist sculptures (174 pieces) were presented to the Museum through Major H. H. Cole, being a portion of the sculptures discovered at two small Buddhist topes near Mian Khan, Eusofzai. The excavations were made for the Punjab Government. The sculptures were conveyed by rail to Madras at the rate of 6 pies a mile per truck and some of the finer pieces will be set up in the sculpture gallery of the Museum.

It having been desirable to make a collection as complete as possible of impressions of the seals of the South Indian dynasties, an appeal was made to the various Collectors for copies of any which are to be found in their districts. In response to this appeal a number of copies in wax, and other material, were received and have been figured by the artist.

The Museum is indebted to His Excellency the Governor for the donation of an old Dutch manuscript and His Highness the Maharajah of Travancore for four shields. Herbarium.—The Herbarium was repeatedly visited in the early morning by His Excellency the Governor between the months of November and March. The work of the Herbarium-keeper, Mr. T. Abboy Naidu, was retarded by the collection of raw products for the Indian and Colonial Exhibition. He, however, systematically arranged, according to Hooker's Flora of British India, natural order Acanthaceæ to Amaranthaceæ and natural order Ranunculaceæ to Labiatæ (extra Indian plants) according to the Genera Plantarum. In addition sixty-one plants were collected in Vellore, 59 plants mounted, and 150 Indian and 220 British Plants poisoned.

Library.—The total number of visitors who came to consult books was 5,563 against 5,172 in the preceding year, being a monthly average of 463. That, if their duties allowed it, many more would use the books is shown by the greater number of visitors during the Christmas holidays than at any other time.

Madras Harbour and Beach.—Through the kindness of F. N. Thorowgood, Esq., Superintendent of Harbour Works, I have received many interesting specimens which were picked up during the diving operations. These include a red incrusting sponge, two other sponges, a zoanthus, several species of coral (gargonidæ) and a holothurian (sea cucumber). I have also obtained from the surface water in the harbour specimens of Salpa, Velella and Physalia (Portugese man-of-war) and from the beach a shell of Ostræa perforated by a boring sponge (cliona), a shell of Pinna Japanica with hydroids attached to it, and various other molluscan shells. Pieces of pumice stone have been repeatedly picked up on the shore, and I incline to the theory that they have drifted hither from Krakatoa. Similar pieces have been sent to me during the year, picked up on the shore of the West Coast at Calicut and Tellicherry.

Numismatics.—Through a catalogue of the Gold coins in the Museum collection had been issued, the arrangement of a great mass of silver and copper coins remained to be taken in hand. My first endeavour in this direction was to collect them all together and distribute them roughly into dynasties. This work was completed with the assistance of Captain R. H. C. Tufnell, who from his experience in Indian Numismatics was able to identify many issues to which I should have myself been unable to assign a place. The same gentleman then gave me great help in the arrangement of the different dynasties, and the Roman and Indo-Greek series are already completed. Among the former several coins of very considerable interest and value have come to light, notably an issue of Plautilla, wife of Caracalla, with Latin inscription PLAUTILLA AUGUSTA, and a fine green copper coin of Constantinus Magnus struck in London. The collection of Indo-Greek and Bactrian coins is not very rich, but I am in correspondence with a view to making it more complete. As the coins of each dynasty are arranged, I am compiling a manuscript catalogue, with a view to future publication, in which all issues, gold, silver, copper, &c., will find a place, but I propose to keep the gold coins, as at present, in the Museum strong box, and display the coins in silver and the baser metals in the body of the Museum, so that they may be seen by visitors without any special application.

As usual a large number of coins, amounting in all to 1,411 has been presented to the Museum during the year either by various societies or by private individuals. Among these I may specially mention a gold coin of the Gupta era presented through the Honorary Secretary of the Madras Literary Society, and a fine Rama Tanka presented by T. M. Scott, Esq., of Madura.

Natural History.—(1). *Arachnida.*—A large living spider (Mygale fasciata) was forwarded to the Museum from Hoonsoor where it was supposed to be causing death among the flocks. An experiment was made on a living sheep to see if the spider would produce any ill-effect on it, but the result proved negative, and the untimely death of the spider stopped any further experiments. I wrote requesting that some living specimens should be sent to me, but at the end of the year none had arrived. Mention was made in last year's annual report of a scorpion sent by H. R. P. Carter, Esq., living by preference in water. During the latter end of the year. I kept specimens of two other species of scorpion from Madras in jars containing some water, and though the animals were often seen above water on some stones which I placed in the jar, it frequently happened that they remained for long periods submerged beneath the surface of the water, so that our common scorpions may be considered amphibious in their habits. The subject is one which is worthy of study on the animals in their natural conditions.

Insects.—A large number of insects were sent to the Museum, among the most interesting of which were one which was proving destructive to the sugar-canes in North Arcot, and another which was inflicting its ravages on the cinchona leaves in the Wynaad, and of which specimens were sent, together with some of the affected leaves, by Messrs. Arbuthnot and Co., to whom I made a report suggesting certain precautions to be adopted and certain remedial agents to be tried, while pointing out that the expense of applying chemical re-agents where the infested area is a large one is often greater than the loss of money caused by the ravages of the insect pests, and further that in the interest of the planter, a prolonged and careful study in a practical manner, not only of the life history and habits of the parasites, but also of the cheapest and at the same time most effective means of exterminating them is much needed. I am much indebted to H. S. Thomas, Esq., for giving me specimens of the shells of *Avicula vexillum* and *Avicula fucata* in various stages of growth in illustration of his report on Pearl Fisheries.

The Order of Government on the Report stated:—Dr. Bidie gave over charge of the office of Superintendent to Dr. Thurston on October 12th, 1885, and His Excellency the Governor in Council took an opportunity of expressing his appreciation of the former officer's valuable services, in reviewing the report for 1884-85. The number of visitors to the Museum during the year again shows an advance, being 311,462 as against 272,968 in the previous year. The Government observe with satisfaction that there was an increase in the number of gosha ladies who visited the Museum on the days reserved for them. There was also a considerable increase in the number of books consulted during the year. The position of the staff has been recently much improved and the Government notice with pleasure the interest which the various assistants take in their work. His Excellency the Governor in Council is much indebted to the various gentlemen who contributed to the Museum during the year. In conclusion, His Excellency in Council desires to notice the evident zeal and interest of Dr. Thurston in his work.

REPORT OF THE DIRECTOR, GOVERNMENT BOTANICAL GARDENS AND PARKS, NILGIRIS, FOR 1885-86.

By M. A. Lawson, Esq.,

Government Botanist and Director of Cinchona Plantations, Nilgiris.

I. Season.—The weather during the past year was all that could be desired for carrying on horticultural operations. The amount of rain registered was 52·48 inches, spread over 142 days. The early part of the season was dry, but the monsoon broke unusually early, after which the rain was light and continuous. The frost during January was severe, but owing to the dryness of the weather, little harm was done.

II. General Conditions of the Gardens and Parks and improvements which have been made in them during the year—(1)—Ootacamund—(*a*)*Government Gardens.*—These gardens have improved in appearance during the past year, the lawns were kept constantly mown and are in good order. The trees and shrubs which had been planted during the two previous years are doing well, and are beginning to make a show. The ground at the entrance of the gardens has been laid out and shrubs and flowers beds have been planted with the view of improving this formerly unsightly piece of land. The ravine above the Doctor's house has been cleared of brambles and brushwood and will be planted up with shola trees as soon as the monsoon rains begin. The rest of the upper part of the gardens was planted up during the past year with a large variety of ornamental shrubs and trees. A considerable portion, however, of this land is still very rough and untidy, but I expect to be able during the next dry season to put this in order at a small cost. The ground lying around the old Cinchona laboratory has been levelled and sown with different kinds of grasses, the seed of which was presented to the gardens by His Excellency the Commander-in-Chief with a view to experimentation upon their value as fodder. Next year this ground will be laid down in permanent grass and form part of the gardens. The roads and walks in the lower part of the gardens are in fairly good order but want re-gravelling; some of the paths also in the other part of the gardens have been re-made or improved, but there is still a good deal wanting before they can be said to be in a satisfactory state. A tank to supply water for the fountain which it is proposed to place in the pond opposite the band-stand has been made, and pipes laid down to the pond; but, owing to the great difficulty of getting a proper jet, the fountain has not yet been started.

Kitchen Garden.—During the past winter, I converted one of the terraces in the upper part of the gardens into a kitchen garden which has been sown with all the more common kinds of European vegetables, and I shall report upon them next year. The vegetables obtainable in Ootacamund are very good, and I do not expect that they will be much improved upon. There is, however, room for improvement in our fruit

trees, especially the Native ones. The European kinds as a rule do not thrive.

Garden for Herbaceous Plants.—On another terrace adjoining the kitchen garden, I began an herbaceous botanical garden, but the plants have not done well, owing I think chiefly to its very exposed situation.

Nurseries.—The old nurseries having become overcrowded with plants, I am converting the remainder of the terraces into new ones, and these will be completed during the present season. Our stock of plants has increased enormously both as regards variety and numbers, as will be seen from a perusal of the price list which was printed for distribution last spring.

The witty practice of destroying labels or of changing their places is not confined to public gardens in England, as it has been manifested during the last year in these gardens.

(*b*) *Government House Gardens.*—These are in a better state than they have been hitherto. The lawns about the place are in fair order, flower beds and shrubberies have been planted, which make the place look less bare, and now that proper spouting has been put up around the roof of Government House and that of the Private Secretary it will be possible to plant creepers up the walls. In my last year's report I stated that many of the trees in front of Government House were in a bad condition, and that I thought they would not last many years longer, and I regret to say that my prognostication has only been too fully verified. Several scores of big trees have been cut down during the year, and as many more will, I am afraid, have to be removed during the present one. The green house which was put up last season has proved to be a good one for growing plants in.

The blue-gums which are in close proximity to the servants' houses ought to be removed as, in my opinion, they are dangerous. The trees are one hundred and fifty feet in height, and if during one of our high winds any were to be blown down and fall over these houses serious damage and even loss of life might be the result.

(*c*) *Stonehouse Park.*—The trees which were planted out on this estate the year before last are doing well. A little planting was done during the past year, and a little more which will be carried out during the present season will complete all that is wanted. Barbed wire for fencing this estate has been ordered from England, and will be put up as soon as it arrives.

(*d*) *Church Hill Park.*—The usual upkeep has been maintained.

(*e*) *Crewe and Ottley Hall Estates and adjoining ground.*—These estates were kept weeded during the year and portions of them planted with trees and shrubs. The land lying between Crewe Hall and Stonehouse was fenced to keep out cattle. This bit of ground is in a very rough state, and I propose digging or ploughing it up during winter and planting it perhaps with potatoes or some other such crop for one season with a view of cleaning it, after which it will be put down in grass.

(2) Coonoor—(*f*) *Sim's Park.*—The condition of this park is good. Several of the bridges have been substantially repaired, and the roads and paths have all been maintained in good order. The bridle road through the new shola has been finished at a total cost, including the bridge, of R842-9-1. This road is much frequented and is, I think, a great addition to the park.

Nurseries.—These have been established and are being gradually stocked with the indigenous plants of the neighbourhood.

(3). Barliyar—(*g*) *Experimental Garden.*—Things are looking well in these gardens. Several new plants have been put out here during the year, but damage was done to some of them by wild pig. Of the old plants, the Mangosteen and Litchi produced a quantity of fruit. It is odd that there should be so little demand for these trees, for, after the mango, they are by far the best fruits which we have in Southern India, and, I believe, that they would thrive and grow rapidly in almost any part of the country.

III. Proposed Museum of Natural History in Ootacamund.—In reviewing my report of last year, I was desired to obtain and submit plans and estimates for the building suggested by me. This has been done.

IV. Herbarium.—The number of dried plants collected during the last few years had accumulated to such an extent that the old office at the entrance of the gardens was inadequate for the purpose of properly storing them, and I therefore asked to be allowed to convert the old Cinchona laboratory into a new repository for the collection. This alternation Government sanctioned, and the herbarium is now housed in its new house. The building is roomy and all that I can desire.

V. Library.—R590-4-1 were spent during the year on books, R365-14-3 being spent on botanical works, and R224-5-10 on chemical works for the use of the Quinologist; the balance of the allotment of R1,200, or R609-11-11, was unexpended because it was not known what botanical works might be eventually obtainable from the library of the Central Museum, Madras. This will now shortly be determined, as I propose during the coming autumn to visit the Museum with the view of arranging for the transfer of the herbarium to this Department.

VI. Notes on some of the more interesting Plants which have been introduced or grown in the Gardens during the year.

1. *Erythroxylon coca.*—This plant grows very rapidly from seed and cuttings, and a large number were raised in the green houses at Ootacamund, but the demand for it has ceased, and I think wisely, for although there can be no doubt but that the plant would grow well in many parts of Southern India, it would not be likely to compete profitably with the vast tracts of country in South America where it is already so largely cultivated.

2. *Eucalyptus.*—Major A. C. Smith, R.E., Executive Engineer, Public Works Department, has frequently spoken and written to me about the desirability of growing the better sorts of Eucalyptus in this country for the purposes of timber. The following species flourish on these Hills:—

E. marginatus, E. sideraphloia, E. calophylla, E. piperita, E. obliqua.—All these are reckoned admirable as timber trees in Australia, and in the course of a few weeks I could supply the Conservator of Forests with seed of all of them.

3. *Castilloa elastica.*—Colonel Campbell-Walker in a letter to the Board of Revenue, No. 2,156, of the 27th January 1886, embodied in G.O., No. 231, of the 24th March 1886, Revenue, states that this valuable *Indian rubber* producing tree has at last been finally established by Mr. T. J. Ferguson at Calicut. I saw Mr. Ferguson's trees 18 months ago, and they were growing magnificently, and as it has at last been found easy to raise these trees from cuttings, I hope they will in the future form no unimportant item in the forestry of this place. The other rubber-producing plants have so far been a failure, either through their not yielding as much rubber as they do in America, or because we have not yet learnt how to tap the trees properly.

4. *Mahogany.*—In my last year's report I stated that I had received two casks of the seed of this plant from Mr. Thiselton Dyer. The seed arrived in magnificent order and was distributed chiefly to Colonel Campbell-Walker and Mr. Gamble of the Forest Department and to the Agri-Horticultural Society in Madras. Almost every seed germinated and tens of thousands of plants must have been raised. From a single pound sown in the green houses at Ootacamund between three and four thousand plants were obtained, some of these have been sold and the remainder will be handed over to Mr. Gamble.

I had the pleasure of visiting last autumn the teak forest in charge of Mr. G. Hadfield, Deputy Conservator of Forests, Nilambur. It was a treat to see the grand growth which the teak trees had made during the last 40 years. In the forest were many fine specimens of young Mahogany trees, but

they were suffering from the ravages of a grub which attacks the buds of all the leading shoots. In other situations the Mahogany might not suffer from these pests.

5. *Quilaja saponaria.*—This plant thrives well in Ootacamund and it is found that it can readily be propagated by means of cuttings, so that if it proves to be a tree of any value, it can be increased to any extent.

6. *Kumera.*—The tubers of this plant have been raised, and on being eaten, proved palatable.

7. *Ullucus tuberosus.*—I received this plant from Mr. Thiselton Dyer. It grows freely in the open air at Ootacamund, and it would seem likely to yield a heavy crop of small tubers. Its name is derived from the river Ullucus, a river in the north-west of South America, in the neighbourhood of which it is found growing wild.

8. *Arracacia and the Cochin tuberous-rooted Vine.*—On neither of these am I able this year to report, as the former has not yet produced any tubers, and the second, although it flowered at Barliyar, for the first time this spring, has borne no fruit.

9. *Hop.*—I am indebted to Mr. J. L. Holland, the Manager of the Nilgiri Brewery, for some cuttings of the hop, from which I purpose raising a large stock. I fear that the climate of these Hills is not likely to suit the plant, but I shall at any rate give it a fair trial.

10. *Ipecacuanha.*—In my last year's report I was obliged to confess that I had lost a large number of these plants, but during the past year, Mr. Jamieson, who has paid particular attention to again getting up our stock, has now about 200 plants. I saw a bed of Ipecacuanha growing very vigorously in the teak forest at Nilambur, the climate of which seems to suit it much better than that of Barliyar.

11. *Pteroxylon utile.*—Mr. Gamble gave me a considerable amount of the seed of this valuable timber tree, which is a native of South Africa. On dissecting the seed it appeared to be perfectly sound, but on attempting to germinate it in the green houses at Ootacamund, I failed completely notwithstanding that it was sown under several different conditions. I am glad to hear from Mr. Gamble that he has been more successful, so that this tree will, I hope, be added the long list of timbers which will in future years adorn our Hills.

12. *Mr. J. Gammie, Superintendent of the Cinchona Plantations, Darjeeling.*—To this gentleman I am indebted for the seeds of several useful or ornamental plants growing in the neighbourhood of Darjeeling. The chief of which are *Phœnix rupicola, Areca gracilis, Wallichia disticha, Calamus flagellum, Hollbellia latifolia.*

13. *Miss Baker of Peermaad, Travancore.*—To this lady the gardens are indebted for sundry *Impatiens* and *Souerilas* collected on the mountains of Travancore. None of them has yet flowered, but to judge from their leaves and their habit of growth, they appear to be different species to those which we get here, and as such will be of much interest.

Mr. T. Hanbury.—From the magnificent donation of seeds which we received from this gentleman through His Excellency the Governor last year, a very large number of plants have been raised in the green houses. Among the most interesting of the plants are the Acacias, many of which are new to the gardens, and bid fair to be very ornamental. *Fuchsia procumbens* also promises to make a fine basket plant.

15. *Coinferæ.*—Several of the Coinferæ grow magnificently on the Nilgiris. (1) *Pinus insignis.*—Trees of six years old are sixty feet in height, and those of fifteen years of age yield an abundance of excellent timber. (2) *Cupressus torulosa.*—Though not nearly so rapid in its growth as the former, this flourishes well, and at the end of twenty-five years makes a massive tree of sixty to seventy feet in height. (3) *Cupressus macrocarpa and its varieties* grows with surprising rapidity, but from their branching character are more suited for the purposes as fuel than for timber. (4) *Cryptomeria Japonica* grows well while young, and will, I have no doubt, grow into a fine tree, but there are none of any great age on the Nilgiris.

16. *Tristania conferta, Syncarpia, Laurifolia Angophora, subvelutina and Grevillea robusta.*—All grow rapidly and make fine trees. I was told that in the Wynaad there were *Grevilleas* which had been planted out only eighteen months, that were five and twenty feet in height. It ought, however, never to have been called *Grevillea robusta*, for it has in its living state the most brittle wood I know. The branches are always snapping off with the slightest breeze; * but grown in sheltered places, it becomes a noble tree. Its wood is beautifully grained and is well adapted for all the purposes of the cabinet-maker.

From the remarks of Government on Mr. Lawson's report we quote as follows:—

8. *Exotics.*—The Government approve of the proposal to grow the better sorts of Eucalyptus for purposes of timber, and the attention of the Conservator of Forests, Northern Division, will be drawn to the subject. The *Quilaja saponaria* thrives well in the climate of Ootacamund and can be readily propagated by means of cuttings. It still remains to be seen, however, whether the tree will prove as valuable here as in its native country, Chili. Tubers, of the *Kumera* (*Convolvulus chrysorhizus, Soland.*) have been raised and were found palatable. The Director does not say whether these tubers were grown at Ootacamund or, as purposed in his report for 1883-84, at Coonoor and Barliyar; nor does he give any information regarding their probable value as an article of diet for the people of this country. A new tuber (*Ullucus tuberosus*) a native of South America, which was received from Mr. Thiselton Dyer, has been found to grow freely in the open air at Ootacamund. The Government await further report on its properties and value. The director is not able to report upon the Arracacha (*Arracacia esculenta*) or the Cochin-China tuberous-rooted vine, as the former has not yet produced any tubers or the latter any fruit. Experiments in the culture of hops have been commenced; the Government await the results with much interest, for the successful cultivation of this product would probably prove of great advantage to the ryots of the Nilgiri Hills. The failure in the stock of Ipecacuanha plants which was reported last year has been effectually remedied, but Mr. Lawson thinks that the climate of Nilambur is more suited to this plant than that of Barliyar. The remarks on the successful growth of certain *Coniferæ* on the Nilgiris are interesting and will be communicated to the Forest Department. The Director has omitted to report the results of his experiments with the Medicinal Rhubarb plant, referred to in his report for 1884-85.

Ploughing and Manuring.—One of the most interesting results of the agricultural experiments carried out during the past two years at the Cawnpore experimental farm is the establishment of the use of woollen refuse as a manure. This refuse is turned out of the Cawnpore mills in large quantities, and great difficulty is experienced in getting rid of it on any terms. Recent experiments, however, have shown that as a manure for wheat it produces results only second to saltpetre. As saltpetre is an expensive manure, and the woollen refuse costs next to nothing, the discovery ought to be of some value to cultivators. Another point brought out is the importance of deep ploughing. The average for all the experiments showed that deep ploughing gave an increase over ordinary shallow ploughing of 53·5 per cent. when the land was ploughed 9 inches deep, and 43·5 per cent, when ploughed 5 inches deep, although the number of shallow ploughings was twice as many as of the deep.—*Bombay Gazette.*

---

* The tree grown in Ceylon as *Grevillea robusta* must surely be a different variety, as it stands wind without the snapping of the twig.—Ed.

STRAY BOTANICAL NOTES FROM A VISITOR TO THE SOUTHERN PROVINCE, CEYLON.

Galle, 27th Sept. 1886.

At about 12-30 yesterday a strong South-West '*blowing*,' accompanied by rain, began at Kalutara. The rain soon ceased, but the monsoon blew steadily and strongly nearly all the rest of the day till about 8 p.m., when the mail coach arrived at Galle. "Brucea Sumatrana" which the late Dr. Gardener found common on the Hantane range as an escape from the Royal Gardens of Peradeniya, is become a very common plant about Kalutara, and the "Scoparia dulcis," a West Indian plant, and known as a "ballest plant" which the writer of this first found growing at Galle when on a visit in 1871, has now spread in some mysterious way over considerable portions of Ceylon. It was very conspicuous at Kalutara and Galle, and whole fields of it were observed near some of the tea estates at Awissawella some years ago. The "Turnera ulmifolia,' with its conspicuous light, yellow colored flowers, is a roadside plant all over the Western and Southern Provinces, whilst the lantana of several hues seems to have taken complete possession of tracts of the country from Mount Lavinia to Galle. The fact that the portion of Ceylon from Kalutara to Bentota is the most exposed to the force of the S.-W. monsoon rains, is amply exemplified in the luxuriance of the bread-fruit trees growing here, some of which must be fully 60 to 70 feet in height, and coconut trees upwards of 100, and other plants and trees in proportion. In the Kachcheri grounds here, I noticed a solitary old tree of "Dalbergia Sissoo," which you will recollect, was introduced by the late Mr. Anstruther from India as a timber tree that would come to perfection in 20 years, and of which several hundreds were planted as avenue trees in Colombo and elsewhere about 30 to 35 years ago, but which have all died out and I do not now recollect where anyone in the Western Province exists. The late Dr. Boake is my authority for stating that in the seeds of this tree sown in the avenue of Queen's College it was that the now common "Lucœna glauca" first sprung up. This is the white-flowered Acacia-like plant now so common in and around Colombo with flat brown pods, the seeds of which are strung together for necklaces &c. I saw today at "Closenberg' where Mr. Scott now lives, the Doum palms planted by Captain Bayley some years ago, 3 or 4 of them in full fruit and a younger one just beginning to bifurcate. This is the famous "Hyphæne thebaica' of upper Egypt and is remarkable for the fact that it is a branching palm always divided into two. There are two of these which have divided four different times, so that each of these have 16 different heads bearing fruits, instead of the original single head. There are two of these singular palms in the Queen's House grounds in Colombo, one of which has begun to flower and bifurcate, and another at Temple Trees, the residence of the Messrs. Green, Kollupitiya. With the exception of the bifurcations, this palm is so like the palmyra, that it may be easily mistaken for this common palm.—About 28 people drowned here in the late storm.

The "Treasury of Botany" says:—

Hyphæne. A small genus of African palms confined to and widely distributed throughout that continent, more particularly upon the eastern side, extending from Egypt as far south as Natal. The genus is remarkable for having the stem branched, a peculiarity not frequent among palms, each branch terminating in a tuft of large fan-shaped leaves, from amongst which the branching catkin-like spikes of flowers are produced, the different sexes being borne on separate trees. The fruit is about the size of an apple, and has a thick mealy fibrous rind with a smooth polished skin, enclosing a single hollow seed of a horny consistency. *H. thebaica*, the Doum or Doom Palm, or Ginger-bread tree of Egypt, grows also in Nubia, Abyssinia and Arabia. It seldom exceeds twenty-five or thirty feet in height, and its stem is frequently three or four times forked or branched in old trees, though when young it is always simple. The fruits, which are produced in long clusters, each containing between one and two hundred, are beautifully polished, of a rich yellowish-brown colour, and of irregular form. In Upper Egypt they form part of the food of the poorer classes of inhabitants, the part eaten being the fibrous mealy husk, which tastes almost exactly like gingerbread, but its dry husky nature renders it unpalatable. The hard tough wood is used for making various domestic utensils; and rosaries are cut out of the horny seed. See Plate 18. The doom-palm of Egypt (*Hyphœne Thebaica*) has a trunk which divides in a dichotomous manner; its pericarp is used as food, and has a taste of gingerbread. In the parched districts between the rivers Dande and Zenza, in tropical Africa, Welwitsch came upon a palm forest five leagues in length, which consisted exclusively of the crowded stems of a branched palm belonging probably to *Hyphœne*. Like most African palms, this yields an excellent wine.

COLONIAL AND INDIAN EXHIBITION: BRITISH NORTH BORNEO.

North Borneo is a British colony unattached, in this respect occupying a position the converse of that of Cyprus, but similar to that of the Niger districts. It is a part of the British Empire by virtue of the charter granted to the company which owns it and governs it, and is on a similar footing to that of many of our colonies when first we began to expand beyond the seas, and indeed, to India in the early days of "John Company." But we have long ceased to make colonies after this fashion, and it might be well to put an end to the anomalous position of North Borneo by according to it the dignity, rights and privileges of the other members of our great colonial family. As it is, though only a company's property, it has all the paraphernalia of a Crown colony. It has its Governor, styled "Excellency by his subordinates, its colonial secretary and treasurer, its residents and sub-residents, and all the other officials whose designations form so prominent a feature in the Colonial Office List. Its interesting and well-stocked little court forms a continuation of that of the Straits Settlements. From a commercial point of view timber is the most prominent and most important exhibit. Like many of the other colonies in the Exhibition, North Borneo regards itself as the great timberyard of the world. Timber it certainly has in abundance; it is one vast forest, and of its timber there are several kinds of great economical value. One of the principal woods shown in the court is known as billian, a timber that sinks in water, is very hard and durable, and is already being exported in considerable quantities to Australia. Other timbers are exported to China and the Straits Settlements as well as Australia. North Borneo has a considerable number of other woods which are said to be of great utility where strength and durability are required, such as russak, tapang, paluwan, greeting camphor, sereah or Borneo cedar (used in Australia), &c. There are also several good furniture woods to be seen in the Exhibition, of fine grain and capable of beautiful polish, resembling mahogany and walnut. The Borneo forests are still practically virgin, and no doubt the company will take warning from other colonies that now lament the reckless destruction of their forests. Timber does not as yet figure largely among the exports of the embryo colony, but with its many converging streams, giving facilities for floating down logs, and its really fine harbours, much might be made of it in supplying some of the comparatively timberless countries of the Far East. So far as Europe

is concerned, there is so much timber of every description within easy reach that we doubt if Borneo can ever expect to do a large business in that direction. Another natural product found in considerable quantities, and figuring largely among exports, is a kind of native gutta-percha of several kinds, specimens of which may be seen in the court. There are also specimens of indiarubber in the court, and it also is stated to be found in abundance. We have also that rare Chinese luxury, edible birds' nests, which are found in enormous quantities and of various qualities, some of the finer kinds fetching very large prices. A considerable export trade is done in this product. Rattans, of course, grow in profusion, and they form one of the most important items of export. Tortoise-shell, bees-wax, vegetable tallow, gums, and beche-de-mer are other products to be seen in the court that can be turned to considerable commercial account. Of minerals, coal and gold are shown; and these and other minerals, —tin, antimony, iron, copper, and cinnabar, are said to exist in abundance. This is probably true with reference to coal, as the testimony of explorers proves, and, if so, the company will certainly be fortunate. But the interest and duty of the company at present are to demonstrate in a manner satisfactory to practical men and possible settlers that these and other resources do exist in the abundance conjectured. No mere vague statements will produce much effect.

As to cultivated products, there seems little doubt that the soil of North Borneo is well adapted for nearly all tropical cultures. Tobacco, sago, pepper, gambier, Manila hemp, sugar are shown in this court; while the natives largely cultivate rice. A German company has entered on the cultivation of tobacco, and a report we have seen speaks well of the results. It compares the Borneo tobacco to that of Sumatra, and we believe Sumatra tobacco has actually been introduced. No doubt the tobacco is good enough, and its culture deserves encouragement; but it seems to us premature to bring it forward as something exceptionally superior. The company certainly offer liberal terms to planters and settlers, and even advance money to those in want of capital, under certain conditions. We believe a Chinese company are at work with capital partly advanced by the company. It is doubtful whether the natives themselves will ever be of much service in developing the colony, and it would certainly be a good thing for the company if they could induce Chinese to immigrate in large numbers.

The court abounds in "curios" and in articles of native manufacture and ethnological interest. The clothes and apparel used by the Dusuns, the principal tribe of the colony, are abundantly represented, as well as implements and weapons and ornaments. There are a Dusun winnowing machine, plough, rice decorticator, harrow, reaping knife, distaff; a bamboo lyre, knives, war apparel, shields, a curious coat of mail, swords, kris, a pongun used in producing fire, and other such articles, interesting to compare with similar exhibits in other courts in which semi-barbarous features are prominent. The Malay execution kris is an ugly looking weapon; while we are glad to see the last pirate flag, taken in Darvel Bay in April, 1885, and a model of a pirate boat.

The company have certainly acquired one of the choicest bits of a fine island, including an area of 31,000 square miles, with a coast-line of 600 miles, containing several magnificent harbours. One of the best of these is Sandakan Bay, in which stands the chief settlement, Sandakan. On this area the estimated population is only 150,000.—Mahomedan Malays with an infusion of Chinese and Arab blood on the coast, and various aboriginal tribes, mainly Dusuns, in the interior. The country is well watered, some of the rivers being navigable for small craft for a considerable distance. There are picturesque mountain ranges averaging 6,000 ft., rising in Kina Balu to 13,700 ft., a picture of which forms one of the decorations of the court. Elephants, rhinoceroses, buffaloes, and other large game are found, and will doubtless afford fair sport for some time to come. The territory was ceded to Mr. Dent and others in 1877-87 by the Sultans of Brunei and Sulu, and the company, was formed, and chartered in 1882. The company, we understand, act only as administrators, preferring to rent the land to settlers able to develop it. The ports are free, but a royalty of 10 per cent is charged on the export of jungle produce; the bulk of the revenue, however, is derived from farming the right to sell opium, tobacco, and spirits. During the short time the company have been in possession of the territory the progress has been marked. The revenue has increased from $20,297 in 1881 to $106,190 in 1885, and is estimated at $127,886 for 1886. The expenditure has not increased in anything like the same proportion; in 1881 it was $108,294; in 1885, $202,075. The exports, again, have advanced from $145,443 in 1881 to $387,757 in 1885. To illustrate the hopeful prospects of this infant colony, the rapid progress of the commerce of Hongkong and the Straits Settlements is adduced. But it seems to be forgotten that this progress is almost entirely due to the importance of these two colonies as emporia for the trade of the Far East, and not to any great extent to the development of native resources, of which Hongkong has none. We doubt if there is room for a third *entrepot* so near to Singapore as North Borneo is. Let the company by all means endeavour to attract trade to its harbours, but it seems to us that the prosperity of the colony must depend mainly on the development of its natural resources, and the culture of the tropical products for which its soil and climate are so well adapted. As to climate, it seems fairly well fitted for European residence, under the precautions which should be taken in every tropical country.

It is to be expected that the colony will soon become an Imperial possession. And, if so, it might be advisable to consider whether an arrangement could not be made by which for administrative purposes it might be combined with Sarawak and Brunei; for we believe it would not be difficult to persuade the Sultan of the latter to part with his rights for a moderate consideration, while Rajah Brooke, of Sarawak, might not object to be placed under Imperial protection. The North Borneo Company certainly deserve credit for the very effective steps they have taken to explore their territory and take stock of its resources; and if they could only succeed in attracting capital and labour probably much could be made of it. They have had several zealous and competent officials, who have done good work for science as well as for the company. Among the names that ought to be mentioned in connexion with this court are those of the Executive Commissioner, Sir Rutherford Alcock, chairman of the company; Mr. Alfred Dent and Mr. William Kidner, Commissioners, and Mr. W. M. Crocker, Assistant Commissioner.—London *Times*.

TEA AS AN INVESTMENT FOR CAPITAL.

The *Statist*, in a recent article, called attention to the favourable prospects of Tea cultivation in India and Ceylon, stating that "The profits of the Indian Tea Companies," where there has been the combination of careful management and freedom from debt, have been very satisfactory in several instances. The Assam, the Darjeeling, and the Lebong Companies have yielded good dividends in face of claiming prices of the produce. The dividends paid are set out below for reference, and we add the price per lb. realised for the tea sent home for sale:—

"Dividends at per cent. per annum, and price per lb. realised (exclusive of exchange) for Tea sold by undermentioned Indian Tea Companies:—

Assam.	1884.	1883.	1882.	1881.	1880.
Dividends..	11	14	10	25	7
Price of Tea	11¾d	1s 1d	1s 1 7-16d	1s 1½d	1s 1½d
Darjeeling.					
Dividends..	7	7½	6	8	7½
Price of Tea	1s 5½d	1s 6½d	1s 3⅜d	1s 7¾d	1s 5⅜d
Lebong.					
Dividends..	9	9	6	7	6
Price of Tea	1s 4 1-5d	1s 5 2-5d	1s 5d	1s 6½d	1s 1½d

"Provided, then, that estates are acquired at reasonable prices, that able management is secured, and that

the capital raised is in the form of shares and no powers are given to mortgage estates, there ought to be some chances for the legitimate Company-promoter."

To the above list may be added the Brahmapootra Company :—

Brahmapootra	1884	1883	1882	1881	1880
Dividends	15	12½	9	11	7
Price of Tea	1s 2.9d	1s 1.5d	1s 3.62d	1s 4.77d	1s 1.94d

All these Companies fulfill the conditions laid down by the writer in the *Statist* as necessary for success, being ably managed, free from debt, and having their capital raised in the form of shares.

Since the above was written, three of the four Companies named have declared improved dividends, the Lebong Company remaining at 9 o/o, viz :—

	Assam Co.	Darjeeling Co.	Lebong Co.	Brahmapootra Co.
Dividend for 1885	20 o/o	8 o/o	9 o/o	16 o/o
Amount paid per Share	£20	£20	£10	£25
Approximate Selling Price	£42	£24	£12	£46

Yielding at these selling prices, and at the average rates of dividend for the two years 1884 and 1885, the following percentages, viz. :—

	Assam Co.	Darjeeling Co.	Lebong Co.	Brahmapootra Co.
	£8 1s 10d	£6 5s	£7 10s	£8 8s 6d
Equal to years' purchase	12⅜ yrs.	16 yrs.	13¼ yrs.	11½ yrs.

There is a liability on the shares of the Assam Company for a further call of £10 a share.

The Jorehaut Company have declared a dividend at the rate of 15 per cent, and their £20 shares are quoted at £42, thus showing a return of £7 2s 10d per cent on that selling price, or fourteen years' purchase.

The *Home and Colonial Mail* of the 16th July, in an article on Tea as an investment, remarks : "It is somewhat surprising that with such handsome results Tea is not a more favourite investment among English people. The shares it is true are not quoted on the Stock Exchange, and for this reason probably little is known among the general public of the advantages of Tea as an investment." August, 1886.

THE PROSPECTS OF CINCHONA BARK.

The most interesting Report we have seen for some time on the condition and prospects of the Cinchona Bark market is that of Messrs. Lewis and Peat received by last mail. It affords a very fair summary of the latest information from the different cinchona-growing countries and we learn from it for the first time, the important fact that Java shipped 1½ million lb. of bark in the 12 months ending 30th June last, while larger quantities are expected in the future. We give the report here in full:—

CINCHONA BARK.

CEYLON, INDIA, JAVA &C.

Mincing Lane, London, E. C., Sept. 17th, 1886.

The extraordinary and continuous increase in the supply from *Ceylon* shows no abatement, and has baffled the calculations of those who relied on previous experience, and on the information circulated from Ceylon itself, especially in the early part of this last year's harvestings.

Quantity (in pounds) offered since 1st January to date:—

	Ceylon	East India	Java	Total
1886	9,457,762	702.614	301,477	10,461,853
1885	7,890,702	495,738	95,659	8,482,099
1884	6,214,686	404,000	86,144	6,704,830

We expect the shipments from Ceylon from Sept. 1885 to Oct. 1886 will total 15½ million pounds.

Hence the greatly reduced price (about 3d per lb. per unit) which is today's value.

The range of future values will, as in the past, depend more on the supply than anything else ; for as we have frequently observed, the capacity of this trade, the greatly increased actual consumption of bark and its products, is shown by the facts of deliveries and stocks to be far in excess of the ideas of those new to the trade, few of whom have had, as we have had, the privilege of dealing personally for half a century in the disposal of a large part of this article. But so overwhelming and rapid an increase in the supply,—at a time when serious depreciation in the values of all produce was the order of the day, though startling and fatal perhaps to the prospects of many of our Eastern planters and friends,—has not resulted in anything approaching hopeless views for the future, as the manufacturers have adapted themselves to the altered state of things, and the novel mode of handling this article (too abundant supplies being forced on the market each fortnight) with wonderful composure and cleverness.

We think it apparent, however, that the limit for the present has been reached, and that *any further material increase of supply* would be disastrous to the trade and reduce values possibly considerably. No great war has occurred during the last year to increase largely the consumption of Sulphate Quinine, but the opening of Burmah to British rule, the settlements in Central Africa, specially on the Congo, and the new awakening of China, and consequent intercourse and sojourn in these countries of Europeans and Americans, will tend to greater demands in the future for this invaluable medicine, now so universally prescribed. The manufacture of the Sulphate the past year or two has, however, been excessive, and stocks of this too are large.

The imports from Ceylon have fairly maintained their quality, and the packing and condition of the Bark has left little to be desired. Spokeshavings and stem chips have formed a large and valuable bulk of our imports, and have met a ready sale, bright clean bold lots often realising high figures for other medicinal purposes besides quinine making. Of renewed Bark the proportion has been good. Root has sold well, especially Crown. Quills, when fresh silvery, of even lengths, *in cases* of 100 to 120 lbs. weight, have sold at high rates: press-packed, broken and ragged immature lots have sold very badly. Young branch and twigs have come in large quantities, and have sold at low prices, helping to swell the supply and our stocks ; and some of scarcely any value to Quinine manufacturers. It is said the great increase in supply is largely owing to the cutting down and pulling up of so many Cinchona trees for Tea planting, and that we shall see a great reduction consequently in the future supply ; time alone will shew.

The supply from *Java* shews a steady increase, but as yet nothing alarming, total shipments from Java 1st July 1885 to 30th June 1886, 1½ million pounds. The richness of quality, however, of much of it, will make this a very important factor in our supply, and we are told we may expect large quantities in future years. The general condition of mercantile affairs in that Island, mainly owing to the depreciation of the sugar industry, and consequently the reduced credits from Holland may help to retard the otherwise probable excessive outlay in this industry.

Our supplies from Central America have continued insignificant, and the great cost of transit from the interior (and according to their previous experience), the ruinous rates now ruling for Bark render it unlikely that we shall receive any appreciable quantities for a long time thence. The Bark is there, it must be remembered, in enormous forests of various descriptions, and when prices allow, and collection and transit are cheaper and easier, we may expect the United States of Columbia, Ecuador and New Granada to obtain once more a place of great importance in our supply of this product.

Bolivia continues her average supply, and of rich quality of quill bark, much being from cultivated plantations.

India, Darjeeling, and the Wynaad and Neilgherries are making still further developments, but current low values will not encourage them in great outlay for the present.

West Indies, Africa (St. Thomas), which has sent small poor lots, shews little prospect of becoming an important source of supply.

It must be remembered that it is more true today than ever, that the stocks for the world are in London, and the fortnightly regular auctions held here are the guide and controlling influence of values, and of supply and demand. Both New York and Paris hold greatly reduced stocks of Bark as compared with former years.

The consumption of Sulphate of Quinine in America is enormous and progressive.

The Statistics on the other side will be of interest, and we beg reference to our regular fortnightly Prices Current on this article.—Your obedient servants, LEWIS & PEAT, Brokers.

We cannot find room for the valuable statistics appended to this Report, but these will be given in our *Tropical Agriculturist*. We may mention however, that out of 12,241,600 lb. total deliveries of bark in 1883-4, as many as 5,320,000 lb. were of South and Central American barks; while in 1884-5 the proportions were 4,101,720 lb. out of 14,186,720 lb.; and in 1885-6, only 2,900,000 lb. of American bark out of 14,900,000 lb. delivered. As to Stock, the estimate is for 1st September, Ceylon, Indian and Java barks 2,229,840 lb. against 7,980,000 lb. American, doubtless being held for prices. But the total stock is only about the same as 1st September 1885 and 20 per cent less than on 1st September 1884.

As regards the prospects in Java, we have had the following placed at our disposal :—

Extract from Mr. G. Tolson's letter of 24th August 1886:—"We certainly shall be shipping more and more cinchona every year from Java, but nothing like what Ceylon has done. If we ship one million lb. during the next two years it will be A 1. But we don't expect higher prices so long as Ceylon sends such a lot forward.

We may also quote from the private reports of merchants in London as follows:—

"We have 250,000 lb. of real good stem and plenty more to come, and I am much interested in the future of bark. The stock here is not considered excessive, 60,000 bales, one year's consumption. They know more about Java in London than we do in Ceylon. Van Goorkem the man who has written about cinchona in Java estimates the acreage of that island at 20,000 acres and the production during the next 5 years at 1,000,000 to 5,000,000 lb. per annum. The exports from Java this year are 1½ million pounds and this is excessive as they have peeled up a lot of inferior to make room for Ledgers instead. I wrote to a reliable person in India:—"What is the probable production of Southern India, during next three years." He replied: 1, 1½, and 2½ millions per annum.

It is most difficult to learn anything satisfactory about cinchona. The Mincing Lane Brokers declare we have driven S. America out of the market and hardly any comes from there now. The production in 1880 and 1881 when 2½ per cent and 3 per cent stuff was worth 2s 6d and 3s, was 24,000,000 lb per annum and now it is not much in excess of that, yet price has gone down to 3½d a unit. Howard says that the price entirely depends on Ceylon exports.

"Cinchona.—Sales advertised for next week comprise some 2,200 lb. Ceylon, which is a large supply. The market for Quinine has developed further weakness and sales of German have been made at 1s 10d per oz. We fear this will affect the price of bark to some extent and we anxiously look for a material decline in shipments from your side."

From all this it may readily be judged how much depends on the outturn and distribution of the Ceylon Cinchona Bark exports and this brings us back to the proposed Syndicate, regarding which we shall have more to say in an early issue.

FROST ON THE NILGIRIS.—The *South of India Observer* of 18th September states :—The fall of frost at this time of the year is unprecedented. Not even in the recollection of that ubiquitous animal, the oldest resident, can such a circumstance be called to memory, yet we have to record a small fall of frost on the morning of Friday and again today.

RHEA.—The secrecy observed in connection with the cultivation and manipulation of Rhea fibre is causing great harm. It is strengthening the impression that the whole thing is a failure and a delusion. If the machinery is refractory, the fact should be known with a view to stimulate enquiry and inventive genius. If Mr. Minchin is now on the steaming and chemical processes, we presume, it is because the Death and Ellwood machines have not turned out according to expectation.—*Nilgiri Express.*

THE GOVERNMENT of Trinidad has taken a wise step to encourage local industry in forwarding $40 to each of the District Agricultural Boards. It is not a very large sum, to be sure, but it will encourage those boards to make an effort to develop the minor industries in their several districts. If good results should follow the action of the Governor, he may perhaps be disposed to make a further and still larger grant. Anyway, it is a step in the right direction, and ought to be the means of doing much good among the agricultural classes.—*Colonies and India.*

CACTUS EDGING is finding favor in Bombay. In an economical point of view it is an extremely cheap undertaking, and as a safe-guard and preventive against the inroads of animals or intruders, it is unparalleled. It is an erroneous idea that long rested in the public mind, that this genus of succulent plants afford harbourage for snakes. We should prefer *Aloe* fencing. [On the above, from the *Indian Engineer*, we would remark that cactus has an inconvenient tendency to spread laterally. Aloes, on the other hand, will, in about a score of years, or less, flower and die down.—ED.]

ALOES AND WHITE ANTS: IS IT TRUE? A recent traveller states :—I noticed that for the most part the hedges of the Madras Railway were composed of the common aloe plant. It is still a conundrum in my mind from which of two causes this came about. It may be that aloes form a good fence to keep cattle off the line. Possibly it originated from a knowledge of the fact that white ants will at once leave any place if you take aloe leaves and bruise them and place the bruised leaves on or near their runs as I know from experience, or as I have heard, if you mix aloe juice with the mortar when building a house, the white ants will never come near it. So it may be a well considered design to protect the sleepers of the railway.—*South of India Observer.*

EFFECT OF LONG-CONTINUED VEGETABLE DEPOSIT ON SOIL.—The following extract from an article in the *Indian Forester* on deterioration and recovery of forest soils, has a good deal of bearing, probably, on the history of some of our Ceylon patenas:—"Over large extents of Motipur and Chakia, the soil, now supporting vigorous sál growth, would be undoubtedly very stiff in quality, but for the large admixture, in its substance, of vegetable manure. It is my opinion, therefore, that we have in Bhinga nothing more than an instance of soil deterioration on a gigantic scale, a deterioration that has progressed slowly through generations of time, the inevitable consequence of unceasing destruction by man, of pasture, fires, exposure to sun and air, and the resulting exhaustion of *that only element of original fertility in this otherwise purely argillaceous soil.* Restore this vegetable manure, and, in my opinion, you restore the forest at one and the same time. But this restoration signifies no more fires, no more pasture, no more fellings, no more removal of produce—not even grass—for two score of years." If a tract of patena were enclosed and treated as a forest reserve, suitable trees being planted in succession as the soil was improved by the fallen leaves, in half a century we should probably have not only fine forest trees but land eminently suited for tea culture. Such an experiment ought to be made.

Correspondence.

To the Editor of the "Ceylon Observer."

WASHING COLOURED COTTONS SO AS TO RETAIN THEIR COLOUR.

Matale, 20th Sept. 1886.

SIR,—In reply to "Outstation" 's letter in your issue of 19th instant I beg to say that coloured cotton frocks may be frequently washed and their good looks retained by attention to a few simple precautions. A small bag of bran (1 lb. will be sufficient) should be left for some hours in the water (cold) in which they are to be washed. Very little soap should be used, and that little ought to be white curd soap, not the dhoby's inevitable "salt soap," which contains much free alkali and various crudities most destructive to delicate colors. A large handful of table salt should be dissolved in the water in which the frocks are finally rinsed, previous to the application of "congee". The salt "sets" the colours if there be more than one in the dress and prevents their "running into each other." The frocks should at once be put to dry in a shady place, if possible in a current of air. It is important that drying be accomplished with all speed. Any intelligent dhoby will carry out these directions, especially if he knows a "*santosum*" is forthcoming to reward his extra trouble. At the same time, from sad experience, I would remind "outstation" that many of the pretty, inexpensive cottons cannot be washed successfully, as in nearly every instance they derive their colours from aniline dyes. In this category may be classed almost all pale blues, creams, greys, fawns, and those delicate "tertiary" shades now so much worn, and if striped or spotted with a different colour, or colours, the dyes are pretty sure to amalgamate very inartistically in the wash-tub. Most shades of cardinal, strawberry, navy, or indigo, and notably pink zephyr may be said to be "die hard" colours, as with careful washing they retain their freshness till the last. I may add, that a pretty shade of cream may be communicated to lace and cotton frocks, etc., by substituting for the usual laundry blue a little of the liquid from a few bruised arnatto seeds.

VANITY FAIR.

INSECT PESTS.

Haddington, Hatton, 5th Oct. 1886.

DEAR SIR,—I am sending you by this day's post two caterpillars or grubs, which I found this morning on a tea bush in a 15 months' old clearing, on Kudaoya estate. The bush was entirely stripped of its leaves. The grubs seemed to have worked their way steadily upwards from the bottom of the bush, eating the leaves, old and young, as they happened to come across them. There were six of them on the bush. I send the twig also on which the grubs were. I have never seen anything like them in the course of my tea experience, and it will be most interesting to know what they really are.—Yours faithfully, T. J. TORRIE.

[Larva of Stauropus Alternus (grey coloured moth); family Notodontidæ: (pretty common and not much to be feared.)—*Entomological referee.*]

ON THE DESTRUCTION OF SMALL BIRDS, AND ON FEATHERS AND POOCHIES.

DEAR SIR,—In the May number of the *Tropical Agriculturist*, there is a long statistical article on the "Trade in Feathers," see vol. V. No. 11, page 782, from the *Journal of the Society of Arts*. The figures given are probably far below the actual amount both as to the money value of the trade, and the number of birds slaughtered, and it may be fairly stated that for every bird's skin which finds its way to market, four birds have been destroyed and that frequently or mostly in the breeding season. Many skins are rendered useless by being shot to pieces, many are spoiled by "bird lime," many are rendered useless in skinning and many more are spoiled for want of skill or the proper means of preparing them, so that they will keep. I quote from the article in question: "The average annual importation into this country and France of small foreign birds of bright plumage is no less than a million and-a-half. They come mainly to England for distribution. We import about quarter-a-million Humming-birds yearly. At a public sale in the Autumn of last year, besides the loose feathers, 147,386 bird's skins were disposed of during the two days sale among which were no less than 44,381 green or Amazon parrots and other species." Is not this wanton destruction? My poor little Humming-birds that used to nest every Spring in the yellow-scented flowering currant "Ribes Aureum," at my bed room window. I know not which was the most beautiful and pleasant after the long American winter, the beautiful little bird or the sweet scented shrubs they frequented. I consider the Humming-bird, perhaps, the most perfect and beautiful of all the feathered tribe. I will not even except the great bird of Paradise and the Lyre bird in their native habitat in the Malay Islands. The article and statistics I have alluded to, are well-worth the attention and careful perusal of all who take an intelligent interest in Agriculture, Horticulture and Arboriculture. It is useless to recapitulate the figures already published, but I may quote again as to the value of the birds and feathers imported. "In 1883 the import of birds was £155,240 stg., ornamental feathers £2,011,926." This seems an enormous sum to be derived from such a source, no wonder that our rice fields and our wheat fields are being destroyed by insects when we are ruthlessly destroying our natural protectors. How many of our Government officials or planters know that in Ceylon, there is a considerable trade in bird skins to India? In Badulla, often when coolies are sick or not to be found they are bird catching in the chenas or lowcountry. Where they sell the skins I do not know, probably to the Moor traders in the lowcountry. "Civilized" man is the most ruthless destroyer of all animals: the wild beast kills that he may eat and live, the savage Indian will not wantonly destroy game, but the sportsman will kill for the sheer love of slaughter and excitement. No wild beast of the forest will do this, but what is to be said of the gentler sex, the better-half of mankind, when a quarter of a million multiplied by four for those that are spoiled or wasted, say a million poor little Humming-birds are slaughtered every year to be worn as ornaments for the person. Adding the above figures together for value of bird's feathers and skins imported, we have £2,167,166 stg., a trade not to be lightly sacrificed, but it is not necessary that this trade should be entirely sacrificed. The ostrich producing the most valuable of all feathers is now domesticated, peafowl are domesticated, pheasants are domesticated, all the Heron tribe are easily domesticated and many other feather-producing birds may be domesticated profitably for their feathers. The Astecs of Mexico and the Incas of Peru kept their most beautiful birds in aviaries to obtain uninjured the feathers with which they produced their most exquisite feather work, but to return to figures as above, £2,167,166 is a large sum, but at what cost is it obtained; the destruction of birds has cost the world in grain and fruit-yielding plants more than this many hundred times over. Take the Genesie valley in the State of New York, long considered the garden of the Northern States, it produced the finest wheat and the largest yield per acre of all the wheat fields of America, where is the wheat now?—utterly ruined and gone; destroyed by insects because there were no birds to keep them within bounds, I have no statistics, but can put it this way. The Rochester flour mills, long said to be the largest and finest in the world, turning out the finest flour on the American continent, the capacity of one mill alone was, I believe, said to be 1,000 brls. (one thousand barrels) in the 24 hours or say 300,000 brls. per annum, value say $7 per brl—$2,100,000. I do not claim accu-

racy for these figures for the value of flour like every thing else, fluctuates and few or no mills are run to their full capacity night and day all the year round; still my figures are not far wrong and I would ask where is the profit in destroying our small birds? First the Hessian fly attacked the wheat, a small insect which deposited its eggs in the first joint of the straw above ground and just as the wheat began to ripen, the larvæ cut the joint and the crop was ruined and the remnant of grain left uninjured could hardly be cradled or cut owing to the straggling straws; then came the midge, a small fly which deposited its eggs in the ear of the grain, just after it had blossomed and the wheat was destroyed in the milk; and what to all appearance seemed a magnificient field of wheat on examination was found to contain not wheat, but millions of little red maggots. The cultivation of wheat has had to be abandoned in the Genesee valley, this is the result of destroying the equilibrium of Nature by felling all the forest and killing all the birds. The Hessian fly is said to have found its way to England, but fortunately England may still be called a "sylvan" country, and we are too fond of our feathered songsters to destroy them. The destruction of insectivorous birds is to Ceylon a very serious one; this season in Uva has been most favourable for paddy, yet the crop reaped has been very light, all caused by "poochies," but what I plead most for are my pet humming-birds, my swallows, my cocos and my sparrows. The humming-bird is found only in America, and in no other part of the world; there are a great many varieties and all are birds of passage; they are found from Terra del Fuego to Hudson's Bay, to the very utmost limit of flowering shrubs and from the Atlantic to the Pacific. Humbodt in his "Travels in South America," mentions having seen the humming-bird in some of the highest passes of the Chilian or Peruvian Andes: they flit with the flowers, and their favourite food is in the earliest Spring blossoms. I knew so soon as I saw the first blossom open on the Miserion, the Pinus Japonica, and the sweet scented currant, that my little birds were not far off. I do not think any lady would ever again wear a humming-bird in her hat or as ornament had she seen them, as I have done in Canada, after the long cold winter flitting from flower to flower, fearlessly entering the breakfast room, flashing about brilliant as emeralds and rubies set in burnished gold, sipping the honey from the hyacinth or Spring-flowers on the breakfast table; constantly returning to their tiny nest under the window to feed their two little fledgelings, for they lay but two eggs and if the present ruthless slaughter is to be continued it will not take long to exterminate them. It is a mistake to suppose that the humming-bird lives entirely on honey, they are also insectivorous, and as such most valuable in a flower garden, but the destruction of the swallows is worse than all the others. They are entirely insectivorous and do no harm to anything. Look at the swallow skimming a paddy-field or a wheat field, the swallow is the salvation of our crops. In America they have been nearly exterminated to supply the Paris market, the color of the common American swallow having been found to match admirably some new colour or "Mode." It used to be a sight worth seeing in American autumn when the swallows were preparing for their flight southwards, the old birds had probably had two broods of little ones, during the summer. Old and young in the autumn would collect on the ridges of houses and barns but their favourite place of resting was the telegraph wires, where they congregated in vast numbers, taking occasional flights to see if the young birds were strong enough on the wing to take their southern flight; in one day they disappeared how, when, or where, or if in the night no one knows. The Americans blame the introduction of the English sparrow for driving away the native birds and also say the sparrow destroys the blossom buds of the orchard in Spring and the fiat has gone forth that jack sparrow is to be exterminated, (if they can). Fools, it is their own insatiable greed and the law which is no law at all and protects nothing, but allows everyone to do as he pleases. You might as well tell one, it is the English sparrow has exterminated the Salmon from every river and the trout from nearly every stream and river in New England and New York. Mr. Downall should and must see to our Ceylon birds. A Sinhalese goya will plough all day in his muddy paddy-field and the coco is his companion like the rook following the plough picking up the grubs and slugs which would otherwise destroy his crops. The goya may be and often is hungry, but he will not kill his coco birds either to eat them or sell their feathers, and why should the stranger or others be allowed to do so for any purpose whatever, Here is an extract from the *Sunday Magazine* of June last: "In the State of Maine the sparrows were ordered to be destroyed; the order was carried into effect, next year the crops and even green trees were destroyed by caterpillars. At Auxeria a similar order was given with precisely the same effect; in the County of Oxford the farmers clubbed and destroyed all the sparrows and small birds on account of the grain they destroyed, the clergyman alone protected them in his garden and encouraged them; he had that season the only fruit crop in the parish and it was unusually large, caterpillars and other pests literally swarmed elsewhere." My friend, I ask, sparrow is an impudent bird and will steal from my breakfast table, but he is not particular; he will also eat cockroaches, in the early Spring; in cold countries he will feed on the buds of trees in the garden or the orchard, but he much prefers the buds on the trips of succulent shoots to the blossom buds on the dry fruit spurs of an apple tree. Our birds must be protected or we will suffer serious injury; that they destroy or live on grain and young plants is to a certain extent true, but they do infinitely more good than harm and I can plead for my feathered friends as Burns did for the field-mouse in his well known lines:

"A daiman icker in a thrave
'S a sma request
I'll get a blessin wi' the lave
And never miss't.

JAMES IRVINE.

Ventnor, Isle of Wight.—At Steephill Cattle, an *Araucaria imbricata*, about 40 feet high, has had nearly 40 cones, each twice the size of ordinary coconuts, this season. A *Chamærops Fortunii*, one of Robert Fortune's palms introduced from China, has been in full bloom throughout the season at East Dene, near Ventnor.—*Journal of Forestry.*

Future Cinchona Bark Supplies.—Mr. John Hamilton who is a very good authority on the cinchona market, writing to us from London, says:—"I quite agree with you that Ceylon people have more to fear from themselves than from any bark shipments that Java may send for the next four years. In view of the great fall in the value of bark, Ceylon men should decide only to send their good barks home, and keep their common kinds and twigs packed away on the estates for shipment nine months hence, or perhaps a year. It will all be wanted some day, but a combined effort is necessary to relieve the present tension." This again would seem to point to some such combination as is indicated in the Syndicate.

Jaffna Coconut Planting.—If coconut planting were not a success, and a decided success, we would really be unable to account for the fact of the Catholic Mission taking to it in right good earnest. We know of one coconut planter, the owner of almost half a dozen Pachchilapallai estates, whose views about coconut planting are not very encouraging and whose faith as to the productiveness of existing estates on an appreciably remunerative scale is rather shaky. But he is possibly mistaken. It is a conviction that coconut planting on an extensive scale is a safe and profitable investment and not one in which money is thrown away, that has induced the local head of the Catholic Mission to devote a large sum out of his private means, as we are told, to the purchase of a coconut estate and of 300 acres of Crown land, part of which has been already cleared and planted.—"Ceylon Patriot."

THE COLONIAL AND INDIAN EXHIBITION: TRINIDAD.

The cocoa or cacao of Trinidad has a greater name than its sugar. The value of the quantity exported was 421,974*l.* in 1885, as against 684,675*l.* for sugar. In 1829 the export was scarcely 3,000,000 lb.; in 1885 it was nearly 14,000,000; an increase of 433 per cent in less than fifty years. Coconuts are the only other native export of importance. The cocoa palm grows luxuriantly along the sandy shores of the southern and eastern coasts of the island, and, although the simplest, it is far from being the least profitable of the agricultural industries of the colony. The number of coconuts exported, which has risen from 4,450,846 in 1876 to 11,276,339 in 1884 proves that it is a paying and a progressive one, and it is stated to be well suited to capitalists who can afford to wait for a return. Beyond the purchase money of the land and the expense of putting in the plan but little expenditure is necessary, and when fully established, say at the end of eight years, it will give regularly a net income of from 80 cents to $1 (3s. 4d. to 4s. 2d.) per tree. In Trinidad the cocoa palm has been known to flower when only three years old, and generally bears at between five and six years; but it does not bear fully until eight years, old. To a limited extent there is a manufacture of coconut oil, and that industry has recently shown signs of revival. Hitherto about 45,000 gallons have been manufactured annually. Amongst the products which thrive well in the colony, though they have not been extensively cultivated so far, are coffee (for which a ready sale can always be found in the local market), tea, nutmegs, ground nuts, tobacco and lime tree.

Grenada.—The chief product of Grenada is cocoa (or cacao) for the production of which the soil and climate of the island appear to be peculiarly adapted. The consumption of chocolate has increased so largely in late years that considerable lands have been cleared and planted with cocoa trees with great advantage to the island. Last year about 5,500,000 lb. of the product was exported (this figure being below that of recent years), but the falling off was due to unfavourable weather during the bearing season, and the consequent lateness of the crop. Besides cocoa many other economic plants have been cultivated with success, such as nutmegs, cloves, vanilla, cardamoms, coconuts, &c. Attention is also being shown to Kola-nut—an African fruit said to contain a large proportion of caffeine, and some enterprising agriculturists are attempting to cultivate the tea plant in the island. Tropical fruits of the finest quality are always abundant, and the principal vegetable food resources include ground provisions (yams, sweet potatoes, tanias, Kushkush), pigeon peas, plantains, Indian corn, cassava, bread fruit, &c.—*Chamber of Commerce Journal.*

INDIA—(*Continued*).

Next to the native shops referred to in our last notice the seed and grain trophy is perhaps the most popular; standing, as it does, in the centre of the court, it cannot fail to be seen, if not actually admired by all. The seeds used in the decoration of the trophy are very varied, and they are here arranged more for effect than actual use, patterns being worked out according to colour. As this aspect of the trophy, however, is not within our province to criticise we will briefly notice some of the seeds used in carrying out the design, and this may be the more interesting, as the seeds are not named, and, indeed, from the nature of the design, it would be impossible to do so. The following are amongst the seeds used:—The Physic Nut (Jatropha curcas), the oil of which is a powerful purgative. The plant is a bush or shrub, native of tropical America, but introduced and now grown in most tropical countries. These seeds are about three-quarters of an inch long, and of a dirty black colour. Here are also the seed of the Gingelly, Benne, or Teel (Sesamum indicum the oil of which is very extensively used in Ind for culinary and a variety of other purposes. The oil is brought to this country in very large quantities, and used as a lamp oil, in soap making, and for mixing with Olive oil. Cold drawn Sesamum oil is used in France and Italy for salads, and the lamp-black used in China and Japan for making the best Chinese ink is procured by burning Sesamum oil. The seeds are small, somewhat flattened, and Pear-shaped, and vary considerably in colour, from a dingy white through various shades of brown to black. The combined violet and green tints of the Pistachio-nut (Pistacia vera) causes it to be distinct in appearance from its neighbours. In consequence of its pleasant taste the Pistachio-nut is eaten in large quantities, not only in India but on the shores of the Mediterranean. Sometimes they are cooked and eaten with salt and pepper. The oil has a very agreeable smell, and is occasionally used in perfumery, or for scenting soaps. Pistachio-nuts can be obtained in this country, but are not so well known as they deserve to be.

Another well-known oil-seed, which is in itself edible, is the Ground-nut or Monkey-nut, as it is sometimes called (Arachis hypogæa), an annual herb, probably of American origin, but now grown very largely in all warm climates, both as a food and for the sake of the oil contained in the seed, but more especially for the latter purpose. The oil is of a sweet limpid character, and is much used as a substitute for or mixing with Olive-oil, and also for making pomades, soaps, burning in lamps, and for various other uses. The Ground-nut is well known for its habit of pushing its young fruit under the surface of the soil and there ripening, from which habit its common name is derived.

In the genus Bassia the best known species are B. latifolia and B. longifolia; both of these have shiny brown seeds, with a broad rough scar on one side running the entire length of the seed, which averages from 1 to 1¼ inch. The former species is a large deciduous tree, common in the forests of Central India, and cultivated and self-sown throughout India generally. Gamble describes the oil obtained from this species as having a greenish-yellow colour, and, says it "is eaten by the Gonds and other Central Indian tribes, and is now used to adulterate glue, and in soap-making. It solidifies at a low temperature but melts at a temperature of 110°, and though it keeps well in a cold climate, in a hot one it soon becomes rancid, and seperates into two parts—a clear fluid oil above, and a thick brown substance below. One seer of oil is obtained from four seers of kernels." The tree is generally known as the Mahwa, and is celebrated for the fleshy flowers or corollas, which are eaten as food, or distilled for the spirit which is obtained from them.

Bassia longifolia is a large evergreen tree growing in South India and Ceylon, and known in each country respectively as Illupi and Mee. From the seeds an oil is expressed which is used for similar purposes to the last named, as are also the flowers. Amongst other oil seeds shown in the trophy are the Castor (Ricinus communis), the varieties of which are very numerous, some of the seeds being of a reddish or chocolate-brown colour, while others are nearly black. They also vary much in size, from a quarter to half an inch or even five-eighth inch long. The castor oil of commerce is obtained either by simple expression or by expression with a certain amount of heat; that obtained by the first process, known as cold-drawn castor oil, is the best. The Castor-oil plant is originally a native of India, but is now widely dispersed through tropical and warm countries, in the former of which it grows to a height of about 40 feet, becoming much smaller in warm climates while in colder climes it is known as an annual.

Sunflower (Helianthus annuus), and Linseed (Linum usitatissimum), both of the brown and white varieties, are here shown; besides many varieties of food seeds and grains, such as Lentils (Lens esculenta), Dolichos Lablab, green grain (Phaseolus mungo), ordinary grain (Cicer arieinum, Job's Tears (Coix lachryma), Maize (Zea Mays) &c.)

Of the very extensive collection of fibres, which has attracted a considerable amount of attention amongst specialists, it would be difficult to speak without a very extended notice; it will, therefore, suffice to draw attention to the Glenrock company's exhibits of China-grass (Boehmeria nivea), and fabrics made of the fibre, showing what can be done with this useful Nettle. The leaves of Puya fibre from Maoutia Puya, will also attract attention, indicating as it does what might prove to be an excellent paper material, if not a textile. In India it is used for making cloths and fishing-nets. Close to this are fine samples of Bhabar-grass (Pollinia eriopoda), a very strong grass, much used for ropes and cordage. Dr. Watt says it is "largely used in the tract between the Jumna and the Sarda, and is particularly abundant in the Garwhall Himalaya."

Amongst products interesting to the pharmacist, some fine samples of Cinchona bark will attract attention, especially one of Cinchona Ledgeriana, from a seven years' old plant, and some stems with moss-renewed bark.

Dye products, and the method of their manufacture or preparation, are well illustrated in the Indian Court. Amongst the products themselves the samples of Annatto (Bixa Orellana) will be noticed for the brightness of the colour, and the large size of the seeds. This product is well represented amongst the Ceylon and West Indian exhibits, and is referred to under those heads. Here are also large samples of Tissoo or Pulas flowers (Buttea frondosa), of a bright fresh yellow colour, used for dyeing yellow and orangered. The tree is one of those which yield a variety of products. The root-bark gives a good fibre used for coarse cordage, also for making slow matches, and for caulking the seams of boats. The gum or resin, under the name of Bengal Kino, is astringent, and is used in medicine, while the seeds are used as a purgative and vermifuge, and the leaves are employed as plates. Here are pods of Acacia concinna, which contain a quantity of saponaceous matter, and are used as soap, especially for washing the hair. The leaves of this species are eaten on account of the acid flavour they possess. Of indigo the exhibits are both good and numerous, and the model of an indigo factory will not fail to attract the attention of all visitors, so accurate is it in detail and so perfect in finish. The model shows the process of steeping the plants and pressing them in the vats or divisions, from which the water runs by a kind of pan into a large receptacle below, in which the workmen stand up to their middles in indigo, stirring it with long poles, and in a room behind is seen wire or wicker frames on which the cakes of indigo are placed to dry. The model gives a very good idea of the preparation of an important article of commerce about which but little is popularly known.

The other models illustrating Indian industries are oil pressing, Sugar-cane pressing, and the preparation of sugar from the Date Palm, in which the collector of the toddy is represented in the crown of leaves drawing the juice from the freshly cut spathe.

In the matter of direct forest produce, such as timbers and Bamboos, many excellent examples are shown. The timber trophy or screen at the entrance of the Economic Court is composed of small specimens of a great variety of useful timbers, the most striking specimens, however, are the large planks and blocks of Padonk (Pterocarpus indicus), of which also an enormous squared trunk lies outside in the adjoining promenade. The Padonk, or as it is sometimes called Andaman Red-wood, is a lofty tree of Burmah and the Andaman Islands. The wood is fairly hard, even grained, and easily worked, and is well known for its deep red colour, which darkens or becomes brown on exposure to the light. It is a very useful wood, and is much used for furniture as well as for cabinet work, carriage wheels, and similar purposes in India.

Another wood that will no doubt attract considerable attention amongst cabinet makers, is the Andaman marble wood (Diospyros Kurzii), an evergreen, the native of the Andaman Islands, as its common name indicates. The wood is very hard, irregularly blotched with black markings upon a greyish ground, usually arranged in alternate streaks of grey and black, but in the plank exhibited at Kensington, the figuring resembles as near as possible what might be effected by the casual upsetting of an ink-bottle, an appearance not to be found in any other wood. The smaller specimens of woods are too numerous and too well-known to claim any special notice, notwithstanding that many of them are of excellent quality, both on the score of durability and for their fine markings or figure, and ought to be better known amongst English hard wood dealers.

In the matter of Bamboos, the well-known bridge in the centre of the Court will be remembered as an excellent illustration of what these gigantic grasses can be applied to, besides which the numerous uses to which they are put in India are well shown in the couches, chairs, baskets, &c., which surround the bridge, some excellent photographs of Bamboo bridges spanning the Sutlej, are also shown in close proximity. A stem of species of Calamus, a slender of climbing Palm, often popularly confounded with the Bamboos, is shown under the roof of the court, and reaches almost its entire length. This, though a fine specimen, is not however, so long as one contained in the No. 2 Museum at Kew, which measures over 400 feet, or about the height of the dome of St. Paul's Cathedral. These stems are very pliable, and some of the more slender species are known as canes and are used when split for the bottoms of chairs. Another Palm product which will attract attention is a dug-out or canoe, such as is ordinarily used in India, consisting of the hollowed stem of a Palm from which one side has been cut away and the central, cellular portion removed. The bottom of the canoe has therefore no approach to a keel, but is simply rounded—the shape or from of the trunk.—JOHN R. JACKSON, Curator Museums, Royal Gardens, Kew.—*Gardeners' Chronicle*'

TEA ADULTERATION.—Mr. E. Collin contributes to the August number of the *Journ. de Pharmacie d' Anvers* a valuable paper on the means of detecting by the microscope the adulteration of tea and mate, and also points out the features by which coca leaves may be recognized under the microscope. The most frequent adulterations of tea leaves, according to Mr. Collin, are the leaves of *Epilobium angustifolium*, *Fraxinus excelsior*, *Sambucus nigra*, *Laurus nobilis*, *Prunus spinosa*, *Salix alba*, and *Populus nigra*, none of which, however, present the numerous sclereuchymatous phytocysts which are present in the tea leaf. The leaves of mate are said to be often adulterated with those of *Myrcia acris*, which are easily recognized by the presence of pellucid oil clots in the leaves.—*Pharmaceutical Journal*.

PROLONGED VITALITY OF SEED.—From the garden at Glen Grant we have received two joints of the pod of Entada scandens. The pods of this plant are very large and woody, each joint containing a single large seed. We have heard of these pods being made to serve the purpose of door knockers in the West Indies, and this use suggests another, viz., that they might be used as rattles to keep the birds off fruit trees. If we remember rightly, seeds of this plant have been washed up in a germinating condition on our western coast, but this is of minor importance as compared with the story told in the following letter:—"The enclosed are two Beans from the joint of a pod 2 feet in length, and containing ten Beans. This pod was brought home from India over forty years ago by the late Dr. TAYLOR, of Elgin. Two months ago I put several of the Beans in a pot in our stove, and to my surprise two of them have germinated and thrown up stalks which are now over a foot in height. The Beans have not been preserved in any special way, so that under these circumstances and after so long a lapse of time it is strange to see vitality so stronge in them. Perhaps you could tell me what is the name of the plant from which the enclosed has been taken off.—GLEN GRANT."—*Gardeners' Chronicle*.

THE USES OF COTTON-SEED.

From the Monograph on cotton cultivation in the Punjab, recently issued, it appears that 84 per cent of the whole yield of the province is locally consumed. Taking this as a basis for calculation we arrive at the conclusion that the quantity of cotton exported only averages 16 per cent of the total yield of the entire peninsula, including British Burmah. Assuming therefore that 84 per cent of the seed yielded is retained for local consumption, and taking the calculation given in the Monograph referred to above, that the proportion of seed to cotton is two-thirds, we have for disposal 506,604 tons of cotton-seed. The quantity of seed annually crushed in the United States averages about 420,000 tons, which yields a revenue of 8,000,000 dollars, or 3 per cent of the cotton crop. Therefore 506,604 tons of seed would represent 9,649,600 dollars, or reckoning at the rate of R2-8 to the dollar, we should have a revenue from cotton-seed alone of R24,123,800 which at present entirely lost to the country. In making these calculations, we have taken only 16 per cent of the yield of the country, taking the yield and consumption in the Punjab as a basis for the whole of India. It may, however, be stated, without fear of being contradicted, that this represents a very small proportion; as it is not to be supposed that 84 per cent of the seed is actually retained for local consumption and sowing. Our estimate may therefore be regarded as very low.

In no trade returns of India have we come across cotton-seed as forming an item of export or import, nor have we seen any allusion to it as an article of commerce. In the Punjab cotton Monograph referred to in this paper, it is stated that the labourer employed to separate the cotton from the seed, "is commonly paid by receiving the cotton-seed which he extracts:" and the only use to which the seed is put would appear to be the feeding of goats and buffaloes, and this, so far as we are aware, only to a limited extent. We have sometimes seen the seed used for illumination purposes. Earthen pans, 4 to 6 inches in diameter, are filled with the seed; a little common "sweet" oil is poured over it, and the whole ignited, burns with a fitful sort of blaze for a couple of hours or so.

That cotton-seed opens a wide field for the development of a profitable industry in India must be admitted. It is therefore to the owners of oil-presses and capitalists in particular that we address ourselves. We see no reason why it should not prove as profitable in India as it has in America. The Government of India have turned their attention to the development of various industries in this country—fibre, wheat, cotton, ensilage, &c. We hope they will add another to the list—the extended use of cotton-seed.—*Indian Agriculturist.*

RHEA (FIBRE).

By Samuel Jennings, f. l. s.,
Corresponding Member of the Agri-Horticultural Society of India.

The publication of Mr. Cogswell's useful Review of the History and Prospects of Rhea in a recent number of the *Journal* of the Agri-Horticultural Society of India, Vol. VII, Part II, may be considered to mark the period at which this valuable fibre ceased to be merely the admiration and the despair of experts, and definitely passed within the range of practical enterprise. Thirty years ago the excellent qualities of the fibre obtained from the stems of the Rhea plant, *Boehmeria nivea*, were recognised by the Society, and strenuous efforts were made from time to time to encourage the efforts of inventors, to provide some method of treatment under which the fibre could be produced at a cost that would bring it into general use, but no completely satisfactory results were obtained, and all that Mr. Cogswell could say was that he had hope that the problem would soon be solved. Agriculturists were naturally reluctant to risk their capital in a new cultivation, with but slender prospects of an adequate return, and consequently but little has been done to encourage the cultivation of Rhea except upon an experimental scale.

Since the middle of the year 1884, however, a considerable advance has been made in our knowledge of the best methods of preparing this fibre for the manufacturer, and it may now be definitely stated that all difficulties have been surmounted, and wherever Rhea can be grown, it can also be prepared for market in such a form that it will at once command a remunerative sale. It is well known that the fibre of Rhea is contained in that part of the stem of the plant which lies between the wood and the outer bark, to both of which it adheres tenaciously, embedded in a mass of glutinous, resinous matter, from which it is most difficult to free it. In China this is accomplished by hand-stripping and washing, an expensive process which involves a serious loss of good fibre. M. Favier has invented a process of decortication by steam, which so loosens the bark together with the whole of the fibre from the wood, that it can instantly be stripped off without damage to the fibre.

I have before me stalks of Indian grown Rhea which have been thus stripped, and similar stalks that have been decorticated by hand without the use of steam, the contrast is remarkable and quite conclusive. In the former case the wood is perfectly clean, and the stalks can be broken short like biscuit, but on the latter there still remains a considerable quantity of fibre adhering to the wood, which of course would be lost, and when it is considered that no more than five per cent of fibre is contained in the green stems, it is a matter of consequence that the whole be secured. This is accomplished by the steaming process, and the ribbons so obtained may be dried, packed and shipped to England for subsequent treatment.

I have also the ribbons which have been removed from the stalks to which I have referred, and comparison indicates a further superiority of those decorticated by steam, the inner surface being smooth and even, whilst in the case of those which have been stripped without the use of steam the fibre appears much lacerated, and this would involve a still further loss of fibre when the ungummed filasse is converted into slivers in the carding machine, or rather I should say the percentage of noils or short filaments will be considerably greater from the unsteamed ribbons than from those prepared by Favier's method, and the value to the manufacturer will be proportionately less. It will be the aim of producers to furnish a staple which will compete for use in the manufacture of the most expensive fibres, because such a staple will command the highest range of prices, and it cannot sufficiently be impressed upon cultivators that whether their produce will compete in the market with hemp, with flax, or with silk, depends almost entirely upon the method they adopt for the production of fibre in the first instance. Although the fibre of Rhea is exceedingly stroug, it is easily bruised and injured in the process of separating it from the stem, and the severe treatment to which it is subjected in the best machine yet introduced cannot fail to affect its ultimate value considerably.

I have recently sent some machine-prepared Rhea for conversion into filasse, and the result is deserving of note. When carded the proportion of Slivers—*i.e.*, long filaments—was considerably smaller than it should have been, this was attributed to the bruised condition of the fibre in the first instance. It must, however, be remembered that the Fremy process is specially adapted to de-gum steamed ribbons, and may not therefore have been the best chemical process for machined fibre. I do not mean to say that a machine may not yet be produced, which will be a great improvement upon anything at present before the public. A machine that will remove the fibre from the stem and clean it at a small cost, and yield a product that will command a ready sale for many purposes, I have, indeed, already seen a sample

produced by Mr. Death's recently invented machine, which appears to be vastly superior to any Rhea produced by mechanical means that had previously come under my observation. What this new machine may do yet remains to be seen, but until it is shown that any machine can produce the fibre without more or less bruising it, the trade will probably always give the preference to filasse from steamed ribbons. It is not alleged even on behalf of Mr. Death's new machine that it can entirely remove all the resinous matter from the fibre. The machine of Death and Ellwood recently exhibited in Calcutta leaves about 15 per cent of foreign matter still adhering to the fibre, possibly Mr. Death may have now succeeded in reducing that percentage, but some still remains which can only be removed by chemical treatment. So that after all, whether machined or not, the ultimate success of Rhea will depend on the completeness of the process by which it is rendered fit for the spinner.

This subject has long occupied the close attention of the distinguished French Chemist and Botanist, Professor Fremy, whose scientific works have obtained for him a European reputation. M. Fremy and his associate M. Urbain have now brought their system of de-gumming Rhea to great perfection. Within the past three or four months important discoveries have been made respecting the chemical properties of the glutinous matter of the Rhea plant, which have enabled them to simplify and cheapen their process very considerably. But as it is well known that laboratory experiments, however successful, are apt to disappoint when applied in practical operations on a large scale, M. Fremy and his associate have established a Factory at Louviere, near Rouen, where many tons of Rhea ribbons have been treated and the filasse worked up into yarn, in which form it is eagerly purchased by French manufacturers, who thoroughly appreciate its valuable qualities. A regular business has thus been created, which is only limited by the very small supplies obtainable of the raw material. In the meanwhile English manufacturers are by no means indifferent at the appearance of a staple that threatens to be a serious rival to silk and flax, and ultimately, perhaps, even to cotton, and before very long arrangements will doubtless be made to carry out the Fremy-Urbain process in this country. I recently visited the Factory at Souviers in company with several gentlemen interested in the subject, and for the first time the full details of the entire process were explained, and we were enabled to verify by personal observation every step in the treatment of the ribbons. The result of our visit was thoroughly satisfactory, we not only saw the filasse produced, but some of it was carded and manufactured into yarn in our presence, we were also shown yarn dyed in various colours which were remarkably brilliant, some that had been passed between hot steel rollers were as glossy as the richest silk, plainly indicating the high class of fabrics for which this fibre will be employed.

A manufacturer (English) who had worked Rhea into dress material, remarked to me recently that it had only one serious disadvantage, and that was, that it would never wear out. He had presented his wife with a dress of Rhea fabric, it had been washed several times without in the least impairing its beauty. "Good," he said, "for the husbands, but bad for the wives, who would get tired of their dresses before they could make them shabby." When in Paris I was shown some very handsome curtains having the appearance of heavy silk damask, delightfully soft, and rich and pleasing in colour. I was surprised to hear that they were made of Rhea. Excellent results have also been obtained with the same material in the manufacture of damask table cloths, napkins, bed linen, and such like fabrics indicating a wide range of uses to which this fibre may be applied, so that all fear of over-production may be dismissed for a long time to come. But apart from European demand, when it is remembered that thousands of tons of China grass are annually manufactured into fabrics in China, Hankow exporting 8,000 tons per annum for local consumption, it becomes a question whether the same result will not follow in India, if the cultivation of Rhea should be taken up on a large scale, what an immense gain this would be to the country in every way, and I do not know any reason why the Fremy-Urbain process of de-gumming the Favier ribbons should not be as successful, and managed as easily in Bengal as at Louviers. I saw nothing in the way of manipulation that Bengalee women and children could not do with these. A superintendent with some knowledge of chemistry, and a man to look after the boiler would be necessary. The chief requisite seems to be a plentiful supply of soft water, and the means of getting rid of it; when charged with colouring matter it becomes as black as bottled stout. This last is a difficulty where the water-supply is precious, and rivers may not be contaminated. In preparing ribbons for the Fremy-Urbain process, they may be greatly improved in value by removing as much as possible of the outer brown cuticle, this is effected by wiping th stems with some pressure with a rough cloth, while hot from the steaming chest.

In China this has been done with so much success that the ribbons thus prepared have yielded from 75 to 80 per cent of fine filasse. Ribbons not so treated yield from 45 to 55 per cent. of filasse. This means that freight has to be paid on at least 40 per cent of useless material which might be saved by the removal of the cuticle before decortication. It will also probably cheapen the chemical treatment by saving the expense of one boiling. Whether the extra cost of handling on the field will be less than the percentage saved in carriage and freight, will, of course, depend on circumstances of time and place. Cheap labour and high freight would be in favour of hand-cleaning. Dear labour and low freights might turn the scale the other way. Suppose 100 tons weight of Favier ribbons have been obtained, and the filasse contained therein amounts to 45 per cent, then—

	Tons.
The weight of filasse produced will be ...	45
And the weight of the waste will be ...	55
Total ...	100

But if these same ribbons had been thoroughly cleaned when removed from the steam chest, so that when converted into filasse, the yield would be 75 per cent instead of 45 per cent, the actual weight of fibre would not be increased, but the bulk of useless waste would be greatly reduced, thus—

	Tons.
Weight of filasse	45
Weight of waste	15
Total ...	60

Or a saving of 40 tons in every 100. It is obvious, however that the value of this deduction will depend on the percentage of fibre in the ribbons, which may be greater in China than in India, and may, in fact, vary in different parts of India. It having now been proved that Rhea can be converted into a highly remunerative staple for textile manufactures, there will soon be enquiry as to the best methods of cultivating the plant. Up to the present there has been a great deal of talk about the subject, but scarcely anything has been done. Garden experiments are almost as unreliable for planters as Laboratory experiments are to the practical manufacturer. I am not aware that any attempt has yet been made in India to grow Rhea upon an extensive scale elsewhere than on the estates of the Glenrock Company in the South-East Wynaad, where some 250 acres are now fully planted. Mrs. Montgomery has an estate at Kangra, where the cultivation of Rhea has been carried on for several years, but I do not know to what extent, the produce, I believe, is locally consumed. In Algiers the French have been growing the Rhea with considerable success, and also in Egypt, and the earliest information on the subject has been derived from these sources, but their statistics do not seem to apply in Southern India where the conditions are so different. There is not, therfore, a great deal

of experience available for the benefit of would-be Rhea planters, and what there is must be studied in view of the circumstances under which it has been obtained. Every planter will have to find out for himself what treatment is best adapted for his own climate, soil and other conditions.

The experiment at Glenrock has excited considerable local interest not only amongst the neighbouring planters, but also (*mirabile dictu* at this stage) amongst native cultivators as well; it is only the difficulty of obtaining plant that has hindered them from already beginning on their own account. I am quite satisfied that before another year has passed, the cultivation of Rhea will be vigorously taken up by the natives, especially in the Coimbatore District. Plants and seed have been promised already to several of the headman of the villages, who have asked to be supplied.

I am indebted to Mr. J. W. Minchin, the able Manager of the Glenrock Estates, for a vast amount of useful information, the result of his own careful observation and experience during the past 18 months. Mr. Minchin was sent out to India early in 1884 for the special purpose of introducing the cultivation of Rhea. On his voyage out he obtained la small supply of plants from Algiers, these were dug up and roughly packed in boxes, and after a long and trying voyage at the hottest season of the year, were delivered at Glenrock in the month of May. The roots were at once planted, and from them about 2,500 plants were obtained to start with. In the following November 200,000 plants had been obtained from the original stock by cuttings, layers, and root divisions. These were again, taken up and divided, and in June last the number of plants had been increased to above two millions. A remarkable example of arithmetical progression applied to agriculture deserves to be recorded. From one root planted in January seven stems were cut, each divided into five cuttings, three eyes to each cutting, most began to grow in a week; from the roots bulbous tubers formed nearly filling up all the space between the roots at 18 inches apart. From this one plant 57 strong root cuttings were taken, making in all 83 plants, from one root not five months in the ground, and that under unfavourable circumstances, poor soil, and no water or shade. Again, a single root left undisturbed for a year had so increased in size that 42 stems were counted in various stages of growth.

The plants require to be left a whole year before they should be cut for fibre. During the second year only half a crop should be expected, the yield of the third year will be greater, and from the fourth year full crops be cut. This is Algerian experience, but it remains to be seen if the rule holds good in India. In Algiers they reckon the average weight of each stem when ready to cut to be 1½ oz., and they obtain ribbons to the weight of 10 per cent of the green stems. Mr. Minchin states that the average weight of Glenrock green stems when mature is 3 ounces, but he has not hitherto obtained more than 7½ per cent of ribbons. There can be no doubt that the growth is far more robust in India than in Algiers, and the plants too carry far more moisture, and this may account for the smaller percentage of ribbons to the green stuff cut. The season of cutting may also make a considerable difference. Then again all the French calculations are based on the results obtained from *Urtica tenacissima*, *Roxb.*, whilst Mr. Minchin's refer to *Urtica Nivea*. He has both species in cultivation at Glenrock, and remarks on the great difference between them. The latter being far more robust in habit and quicker in growth, though it may be that experience will prove that the former will yield as good a crop when thoroughly established, and the smaller weight of stem may yield a higher percentage of ribbons. During the wet seasons the stems will certainly contain a far greater waste of moisture than at other times, and this is the case with *Urtica Nivea*, with stems 7 to 8 feet long, and weighing over 6 ounces each. It does not, however, follow that the actual weight of fibre will be less, neither can it be said that the same results would follow in different parts of India under different conditions of soil, temperature, rainfall, &c. These are points that each planter must find out from his own experience, and doubtless we shall all be very much wiser a few years hence. A gentleman told me a few days ago that he had seen *Urtica Nivea* growing in Italy with stems from 10 to 12 feet high, but he could not tell me what percentage of fibre it yielded, which after all is the important point. I should recommend planters to try any species they can get, for they all yield excellent fibre in remunerative quantity.

Urtica candicans is also grown at Glenrock, but I have no information about it. *Urtica Nivea* may be known by its leaves, the undersurface of which is silvery-white. In *Urtica tenacissima* the undersurface of the leaf is green.

I have already referred to the extraordinary rapidity with which the varieties of Urtica can be propagated by cuttings and root division, plants raised in this manner make new growth very quickly. In one month new shoots appear, in three months the shoots will be four feet high, and in six months there will be five or six strong stems. Separations of the tubers are, however, much slower in growth than cuttings, and in hot dry weather the best mode of propagation is by layering without complete separation. Mr. Minchin sowed 2 lb. weight of seed on the 27th March occupying an area of 1,400 square feet, germination took place on the 3rd April. Much trouble was at first experienced with ants, but a little kerosine oil mixed with the water successfully kept off the depredators. In four months the seedlings were 18 inches high and strongly rooted, both cuttings and seedlings require partial shade till they well established. I am inclined to think that for most districts in India seedlings will ultimately prove to be the most satistactory, because the roots of plants raised from cuttings seem to have a tendency to spread laterally, and do not strike deeply into the ground, these will be sure to suffer more or less in long continued drought. On the other hand, the tap root of seedling penetrates vertically, and seek moisture at a considerable depth. The French recommend their own system of planting out at 18 inches apart, so that each acre will contain 16,000 plants. This, no doubt, applies to the less vigorous species *Urtica tenacissima*, and in a climateless forcing than that of India. At Glenrock Mr. Minchin has put in his plants in six-feet beds, separated by a one-foot drain, two rows in each bed 3 feet apart, and 18 inches between the plants on the row, so that in Glenrock 7,000 plants occupy an acre. He finds that the space between the plants quickly fill up with new growth, and the ground soon becomes quite covered. Irrigation is a matter of considerable importance, as it will probably make a difference of one crop in the year. A portion of the Glenrock plantings was left without any artificial watering, in order to observe the result. It was found that although root growth was not materially checked, there was scarcely any movement above ground between the months of February and May. On the irrigated fields the dry heat did not seem to affect the development of the shoots in the least, in eleven days stems were observed to have grown 15 inches. Growth is more vigorous on the hollows than on ridges, or on level ground. At Glenrock the altitude above the sea is about 2,000 feet, and the rainfall is exceedingly heavy during the monsoon. Rhea is also being grown in the Bhowani Valley at the foot of the Neilgherrie Hills, in the Coimbatore district. Here, where the soil is rich and the climate very forcing, the development of the plant appears to be much more rapid and the growth more uniform and vigorous than at the greater altitude of the Wynaad. Close planting is strongly advocated in order to induce tall, straight growth and check the formation of side branches, it is also said to be a great protection from the ravages of caterpillars and other insect pests which devour the leaves, and so cause side growth. As regards shading, the practice varies considerably in

different countries. In the Indian Archipelago Rhea is planted under the shade of forest trees. In Algeria and in Egypt it is grown in the open field entirely exposed to the sun. Mr. Minchin advocates partial shade, and in clearing his forest land he has left some of the larger trees for this purpose. Manure can scarcely be despensed with, but the plant gratefully responds to every attention paid to it.

No crop for the purpose of fibre extraction should be expected until after the plants have been left undisturbed in the ground for at least 12 months, during which time the fields must be kept free from weeds, an expense that will not recur when the Rhea has thoroughly established itself. The cost of upkeep after the first year will, therefore, be light in comparison with most other crops. When in full vigour, Rhea should afford in India from four to five crops in each year according to locality. The stems are said to be in their best condition for cutting when they begin to ripen, which may be known by their commencing to turn brown at the butt. An interesting account has recently appeared in one of the Manchester papers of a visit to the Rhea plantation near Zagazig, on the Suez Railway, where there are over 300 acres of Rhea under cultivation, the property of the Ramie Company of Egypt. Here it is said that no shade is necessary, and the fields are irrigated in the customary Egyptian manner. The treatment of the crop differs very materially from that recommended under the Favier system, and I am unable to say whether the introduction of decortication by steam would enable them to obtain better results than they have yet realised. It appears to be the practice in Egypt to cut the stems while still young and pale green in color, and they do this because they find that when the stem once begins to change colour, the bark hardens, and the resinous matter becomes stronger and decortication almost impossible. Of course this is so, and as the flowering stage approaches, the entire structure of the plant will be undergoing considerable changes, which, in all probability, will, to some extent, affect the character of the fibre, as well as the bark and the wood.

The steaming process enables the bark to be removed with all the fibre attached, at a much later period when the plant has reached its most perfect vigour, and when it is reasonable to assume that all its component parts are in their best possible condition. In Egypt the stems would then be 8 or 9 feet in length, but they cut them when from 4 to 5 feet long, and the delicate film of bark can then be easily stripped off the stalk by hand, and an hour's exposure to the sun is sufficient to dry it ready for packing. When removed from the half-matured stem, the bark is described as "a thin pellucid ribbon as translucent as green Persian silk when in a moist state." No doubt, in this condition the gum will be much less tenacious than at a later period, and therefore more easily treated, but on the other hand the weight of fibre lost by premature cutting must be very considerable, and the decision as to which of these two systems is the most advantageous will turn upon the relative qualities of the filasse so produced. If there is but trifling difference in the value of the fibres, the balance of advantage must rest with the system that affords the heaviest crop.

On this point I am not in a position to afford a decisive opinion, never having seen any of these delicate Egyptian ribbons, but of the fibre produced from the mature stems by Favier's steaming process, some of the leading flax spinners have spoken in the highest terms, describing the yarns made from it as possessing "quality and strength superior to other China grass yarns from other sources," and again "very superior to that which is obtained by the application of mechanical methods." The testimony is sufficiently conclusive as to the commercial value of the filasse from steamed ribbons, and is satisfactory evidence that the fibre is in no way injured either by the action of steam or by the subsequent chemical treatment by the Fremy-Urbain process. Some notion of the probable crop may be arrived at from an interesting observation of Mr. Minchin's, who selected three one-year old plants, and on the 6th March cut them down close to the ground. On the 6th May following he cut from these three plants 62 stems, weighing in the aggregate 8½lb., and on the 1st July he again cut from the same plants 83 stems weighing 11¼lb.

In April, stems 6 feet long when decorticated, yielded 7½ per cent of their weight in ribbons, but in the rains the green stuff contained more water, and the percentage of ribbons was somewhat less. In Algiers, where the ripe stems only averaged about an ounce and a half in weight, it is stated that an average yield of 10 per cent of ribbons is obtained, whereas in India, owing to the greater vigour of Indian grown Rhea, the stems of which averaged three ounces in weight, the percentage of ribbons to the weight of the bulk may very well be much less, whilst the actual yield of fibre per acre may be as much as, or even more than, in Algeria.

It will be seen that an enormous quantity of green stuff must be cut and handled for every ton of fibre that is produced. One hundred pounds weight of green stems, after the leaves have been removed, will not yield more than 3lb. of fibre, treated by the machine, the average will probably not exceed 2½lb. The same weight of stems, when decorticated by steam, will furnish 7½lb. of dry ribbons. The process of decortication can be carried out on the field by the use of light easily portable steam generators, and this will render the carriage of but seven and a half per cent of the gross weight necessary. Now the machines, I am speaking of Death and Ellwood's patent, require a strong pressure of water, and can only be used where there is an abundant supply of water, and either steam or water-power for driving. They must, therefore, be located where these requisites are available, and the entire weight of green stuff must be carried to the mills. Fancy carrying 35 to 40 tons of stems for any distance to produce a single ton of machined fibre. It is in this direction that the planter must exercise all his ingenuity and close supervision to effect economy in labour and carriage to prevent his profits from being eaten up at the very first stage of treatment.

With these figures before them will be possible for planters to draw up approximate estimates of cost of treatment according to the scales of charges current in their several localities. I will now proceed to furnish some idea of the probable crop to be expected. To obtain a ton of ribbons per acre, assuming the percentage obtained from the bulk to be 7 per cent, it will be necessary to cut 12,000 lb. weight of green stems, and assuming them to average eight stems to the pound, that will be 256,000 stems, so that if five crops are obtained in the year, it will be necessary to get 51,200 stems at each cutting from the acre, or per square yard (4,840 square yards=1 acre), say 10½ stems. To get two tons of ribbons per acre 21 stems must be cut from each square yard. At Glenrock, in many places, over 30 mature stems have been counted to the measured square yard. Two tons of ribbons per acre is not, therefore, an unreasonable estimate of the probable yield of established cultivation in favourable localities. I have already stated that the dry ribbons produced by the Favier system of steam decortication will yield at least 45 per cent of fine filasse when treated by the Fremy-Urbain process. If the yield per acre be two tons of ribbons, the produce in filasse will be 2,016 lb., the present market value of which is stated to be from seven pence to nine pence per lb. according to quality, the gross proceeds of the produce of one acre would therefore be £67-4, from which must be deducted the cost of cultivation, handling, treatment, carriage, drying, packing, freight, chemical treatment, commissions, &c., to ascertain nett results. I cannot, however, as yet say that there is a large present demand for the filasse of Rhea in England, for the simple reason that no considerable quantity has yet been offered in the market, and manufacturers naturally hesitate going to the expense of altering

their machinery to suit the new staple until they are relieved of uncertainty as to supply. The French manufacturers on the other hand will take as much as they can get at about the price I have quoted, and English and Irish manufacturers are ready to follow their example as soon as a definite and regular supply can be depended on. I have been personally assured by some that they are prepared to enter into contracts on a large scale, directly the supply can be guaranteed.

I do not, in the least, fear that Rhea coming to this market a couple of years hence will fail to find ready purchasers, because arrangements have already been made to obtain supplies from China and elsewhere, that will encourage the trade to expect regular shipments, and the present uncertainty will at once disappear, and as every one freely admits the valuable properties of the new staple, it will not be long before Rhea will take an important position amongst textile fabrics of British manufacture.

NOTE ON RAISING RHEA FROM SEED.

By Mr. J. W. Minchin, of Glenrock.

We have been fairly successful with Rhea Seed Nurseries, and have germinated and planted out seedlings from seed received from Paris and London and also two varieties of seed from plants on our own plantations. Generally speaking, the seed and seedlings must be treated in the same way as Cinchona Ledgeriana seed. The great difficulty is to protect the seed, which is exceedingly small, from ants. We tried soaking the seed and watering the seed in phenyle and in kerosine oil water, but found the best course was to sow the seed in boxes or raised beds supported on legs kept constantly tarred. We made long basket beds of bamboo lattice-work, raised about one foot from the ground on forked supports 5 feet apart, with 6 inch sides to hold in the earth; the earth was sifted as is usually done for Ledger nurseries; fresh jungle soil is sufficient: each basket bed was 3 feet wide, and over each bed was erected an ordinary sloping screen thatched sufficiently to keep out rain.

The beds should be made so that the slope of the screen should face south and west, which keeps out the sun for the greater part of the day and evening: before sowing the seed the earth in the basket beds should be well damped through a fine rose watering pot, the seed should be mixed with about 5 times its bulk of ashes, or fine sand, so that it may be sown more evenly; it can be sown rather thickly as the seedlings can be pricked out when about an inch high; after the seed is sown the beds should be gently pressed with a flat board, no earth is required to be sprinkled over them; they should be lightly watered with a fine rose every evening. Care should be taken to keep the supports fresh tarred, and that no grasses or straws hang to the ground by which ants, &c., could reach the seed beds. The seed will begin to germinate in from 6 to 10 days. In from two to three months some of the seedlings will be large enough to prick out, they will be about an inch high above ground, and will have radish-like roots, two to three inches long, they can then be carefully taken up with small bamboo, chop sticks, the seedlings being handled as little as possible, and can be planted out into ordinary nursery beds about 4 inches apart, and should be protected from the sun by bracken fern, stuck into the ground about them; in another three months they will be large enough to plant into the field, and I have found that in 12 months from the time the seed is sown, the plants will produce stems large enough for treatment. The seed should be sown between October and March; during the monsoon the seedlings are very liable to damp from some fungus growth, as in Ledger seedlings, although I have no doubt, with care, they can be grown at any season of the year; but I have not yet succeeded with young seedlings subjected to the early monsoon mists.

SUGAR AND "THE NEW SWEETNESS."

In these dull and prosaic times the following amusing article from the *Weekly Scotsman* will, we are sure, be read with some interest by Colonial sugar planters:—Persons who are so fond of sweet things that they have not the courage to practise the self-denial of the Banting system have good things in store for them. They have found a friend in Orthobenzoyl-sulphonimide, the new discovery of Dr. Constantine Fahlberg. Whether the makers of cane and beet sugars will have as much reason to be glad may be questioned, for in the near future they will probably find their occupation gone. What will become of the West Indies is, of course, a serious matter. The ruin they have suffered by the emancipation of slaves, and the ruin again suffered by the abolition of the "differential duties" about which Tom Dupuy waxes so savage in Mr. Grant Allen's current story, "In All Shades," will both be as child's play to the fate now in store for the cane-sugar growers. Their only consolation will be that the beet-sugar makers will share to some extent, in the same fate: and, of course, if there is one thing that sweetens one's own loss, it is the knowledge that one's rival is being overwhelmed in the same calamity. Dr. Fahlberg's great discovery has recently been brought before our scientific men in detail in Mr. Levenstein's paper before one of the learned societies, and by Sir Henry Roscoe before the Royal Institution, while incidentally it was mentioned by Professor Meldola in describing the progress of the coal-tar colour industry before the Society of Arts three months ago. For it is amongst the busy German workers amongst coal tar products that the great modern discovery is made, so that the country which has flooded us and ruined our native sugar industries with cheap sugar is to be hoist with its own petard, by making a discovery which is not only to spell ruin to Greenock and Bristol, but to render the cultivation of beet as unnecessary and unprofitable as the sugar cane seems likely soon to become.

The story of the progress of the investigation of coal-tar products is the scientific romance of our day. Since the sickly and somewhat fugitive colour, mauve, was discovered by Perkins thirty years ago, investigation has been carried on with indefatigable industry, till at the present moment the most brilliant dyes—scarlets, blues, greens, and yellows—can be drawn from the waste of our gasworks. And now a further stage of discovery has been made in the production of saccharine from the same source. In sweetening power the new product is stated to be 220 to 1 as compared with the best cane sugar. We give the Philistine or popular name to the new product rather than the appalling chemical title already quoted. For it is wise in those learned people to invent a simple as well as a scientific name for their products. It would be rather hard if our helpmeets at home had to ask, "Do you take cream and Orthobenzoyl-sulphonimide in your tea?" This, it is true, is not so formidable as some of the names in the new industry. Thus, Professor Meldola assured his hearers that "it appears flavenol is hydroxyphenyl-lepide," and that when pure orthoamidoacetophenone is treated in a certain way flavaniline is produced in small quantities, and that flavaniline is amicophenyl-lepidine. Truly, small quantities of such articles should only be made when their pronunciation is so difficult, and we may be glad that as sensible a word as "Saccharin" has been adopted for Dr. Fahlberg's popular invention. To an American interviewer the successful chemist has laid bare the entire process of extracting this new sugar, and given illustrations of how it may be used to drive other sugars out of use. It is not actually a sugar

but contains carbon hydrogen, sulphur, oxygen, and nitrogen in certain atomic relations. There are it appears, seven distinct steps in the course of obtaining it from the toluene of coal-tar, and the process is described by Sir Henry Roscoe as a triumph of synthetical chemistry, and perhaps the most remarkable of all the marvellous products of coal tar. Saccharin is not a nutriment or a poison. Where sugar is used as food the new invention cannot take its place ; but for all sweetening or flavouring purposes its use is certain to be great. It is so sweet, we are told, that a tea-spoonful will convert a barrel of water into syrup, while a small portion will convert the bitterest quinine solution into "a regular molasses." It is already being used by makers of biscuits and "wafers" in Germany. It will neither decay, mould, nor ferment, nor will it be attacked by bacteria. In sweetening power it is, as already mentioned, 220 times more powerful than cane sugar, and it is said that for food purposes a small fraction added to beet sugar makes that article equal to cane sugar in strength, as it is already superior in digestibility and wholesomeness. Another blow to the West Indies !

Dr. Fahlberg's story of how he made the discovery is hardly less sensational than the invention itself. The German chemists are constantly experimenting with the coal-tar products. It was stated by Professor Meldola that while in this country an experimental chemist can neither find encouragement nor employment—so much so that a young chemist here who wishes an opportunity goes over to Germany—one German colour work alone has fifty-four chemists at work. Labour of this kind goes on with complete indifference as to immediate "practical" results, and most of the concoctions go down the sink ; but one successful hit may enable the discoverer to throw a new and valuable dye upon the market, and so more than repay all the misses that may be made. Dr. Fahlberg was in his laboratory one evening, so much interested in some experiments that he forgot all about supper, till very late he rushed to his meal, without, as usual, washing his hands. Breaking a piece of bread and putting it to his lips, it tasted "inexpressibly sweet." Rinsing his mouth with water and drying it, the napkin with which he wiped his lips tasted sweeter still. Raising the glass of water to his lips, his mouth came where his fingers had previously touched it, and the water seemed like syrup. Then the truth began to dawn. He applied his thumb to his tongue, only to find it exceeding in sweetness any confectionery he had ever tasted ! The secret was out—he had discovered some coal-tar product which "out-sugared sugar." A rush back to the laboratory, a taste of every dish he had been working with, and some weeks of careful study and experiment with the stuff he found in one vessel, sufficed to trace out and fix the elements of this remarkable invention. Dr. Fahlberg says that when he first announced his discovery people treated it as a scientific jest, and he was laughed at in the press at home and abroad. But now the laugh is on the other side, and large works to produce Saccharine are already started in Germany. The price at present is from 40s to 48s per lb., but Dr. Fahlberg hopes to reduce this considerably soon. But even that is not dear for 220 lb. weight of sugar. And then the delight of having everything as sweet as you like, without the danger of growing fat !—*European Mail.*

[The discovery, we need hardly say, is not new. Dr. Fahlberg found it out in 1879, and it has been frequently referred to in these columns. Even the *Weekly Scotsman* admits that when sugar is used as food the new invention cannot take its place, and it is very questionable, owing to its enormous cost, whether "Saccharin" will ever be largely used for sweetening or flavouring purposes, even though its sweetening power may be 220 times that of cane sugar. As yet it is not certain whether its consumption would prove injurious or not, because although it and many other hydrocarbons do not act as poison, a long course of true hydrocarbons have an effect, more especially upon the liver. Experiments are still being made with this product from coal-tar, but even its discoverer, Dr. Fahlberg, hesitates to recommend its use at present.—Ed. *E. M.*]

CEYLON MINERAL EXHIBITS AT THE LONDON EXHIBITION.

The mineral resources of Ceylon comprise gold in small quantities, platinum, silver, tin, mercury, iron, and lead, graphite in large quantities, but no coal. The minerals exhibited are graphite, ironstone, talc, and building stones, with a very fine display of Gems, for which Ceylon has always been famous. The precious stones exhibited are, omitting the diamond from consideration, the finest display of the kind in the Exhibition.

The graphite of Ceylon is too well known to need any commendation. It is chiefly met with in the north-western and western provinces, and is an important article of export, the total quantity which left the island in 1883 amounting to 279,057 cwt. "The yearly value of the graphite exports now varies from one and a-half to two and a-half millions of rupees. . . . the finest bright silvery lumps ranging between 100 and 135 rupees per ton, and the lowest quality, in the form of dust, commanding a price of from 30 to 45 rupees per ton." Both the mining and trade are in the hands of the Sinhalese, and the mines vary in depth from 100 to 450 ft. The graphite exhibited appears to come from the Dematagolla mines at Kurunegala, the most important in Ceylon. Mr. de Mel's mine at this locality and from which samples are exhibited, has been carried to a depth of 450 ft., and yielding, according to Mr. A. M. Ferguson, at the rate of 800 tons per annum for 11 years. The graphite exists here generally in horizontal veins, "associated with beautiful snow-white transparent crystaline to semi-opaque quartz, the latter occasionally showing specks of garnet and bands of soapstone." A number of these small quartz crystals are exhibited by Mr. de Mel in illustration of this. Graphite is said generally to occur in Ceylon in "quartz gneiss'," embedded or diffused, but usually in long thin horizontal veins, the quality of the mineral always improving with depth. The term mine is hardly applicable to these openings, as they are in reality mere excavations or deep holes.

Some fine blocks of graphite of great purity are on view, the only associated minerals being little iron pyrites, and the before mentioned quartz. One block, forwarded by Mr. A. T. Fernando, weighs 3 cwt., 3 qr. 24 lb., another by Mr. W. A. Fernando, 3½ cwt., and a still larger of 4 cwt. by Mr. W. Gunasekara. Mr. Ferguson states that a block of Mr. de Mel's was exhibited in the Philadelphia Exhibitions only 14 lb. short of 6 cwt. probably the "largest mass of plumbago ever shown." Some of these masses present a coarsely laminar structure, the portions between the laminae having a prismatic appearance. There are also on a view number of trade samples, known as "ordinary." "chips," and "dust," but from a mineralogical point of view the silvery graphite in flakes, shown by Fernando & Co., is most interesting, each flake being in fact an hexagonal plate. A fibrous variety is also exhibited by the same exhibitor having much the appearance of radiating stibnite crystals. About one-third of the Ceylon graphite is used in the manufacture of crucibles, and the process is illustrated by Messrs. Morgan Brothers, of Battersea, who exhibit specimens showing the various stages in the manufacture. Several works of art demonstrating the adaptability of this mineral for ornamental carving and

turning are also on view—a carved elephant, an elephant hunting scene in a jungle by Morgan Brothers—a cashew tree with crows, a crab and lobster, by Mr. A. T. Fernando, a Buddhist Dagoba, by W. A. Fernando, and other articles including models of the sifter and tools employed in preparing the graphite after extraction. Nearly one-half the entire quantity produced in Ceylon is exported to the United States, the other moiety is distributed between this country, the Continent, and India.

The ironstone found largely in the southern provinces is of excellent quality. A true bog iron ore is exhibited from Kumilamzunai, in the Mullaitivoe district, by the Government of Ceylon. It is found as large boulders and gravel, and was formerly smelted by the Sinhalese and used for tools, weapons, and other articles. Although of a rude character, these have been found to possess a fine temper, and to be not inferior to those made of the finest Swedish metal. Talc has been found in the province of Uva, and specimen are on view. A few building stones are exhibited by the Government, including pedestals of a massive gneiss, both polished and unpolished from Mahara, Western Province, showing but little evidence of foliation. Gneiss appears to be the chief geological feature of the island, and is overlaid by a dolomitic limestone, hand specimens of which are also on view. A pedestal of a highly crystaline limestone from the Dolosbage district, and a coarse, gritty sandstone from the sea coast, in the neighbourhood of Colombo, are prominent stones in this collection. And this very interesting sandstone is also to be seen slashed with dark curving lines of foreign minerals, which seem to be small octohedral magnetite, and garnets in small grains. We again meet with laterite, or, as it is called in Ceylon, cabook, in masses of suitable size for building purposes. Some interesting blocks of coral-rock are also exhibited from the Peninsula of Jaffna, Northern Province, where it forms the principal rock of the country. Finally, Mr. A. M. Ferguson has a good red granite from Veyangoda, Western Province.

Ceylon produces almost every variety of gem commercially valuable, with the exception of the diamond; but the principal are rubies, the sapphire, cat's-eye, and the moonstone. The gems are chiefly obtained from the alluvial plains at the foot of the Saffragam Hills not, however, in the recent alluvium, but in an older and similar stratum, known as *nellan* usually at a depth of 10 ft. to 20 ft. from the surface. It is separated from the overlying recent alluvium by a hard crust called *Radua*, a few inches in thickness. The gem drift is composed of waterworn pebbles and blocks of granite embedded in clay. In 1884, 500 of these gem diggings existed. The chief producing district of sapphires and rubies is within a small radius around the town of Ratnapura (City of Gems), in the Western Province, and near Rakwana.

The Ceylon Government have been much assisted in their exhibit of the gems of the island, by the loan of some exceedingly fine examples and suites of stones by the following gentlemen, Messrs. C. H. de Soysa, J. P.; R. C. Nockold, E. W. Streeter, Hunt and Roskell; W. J. Tripp; O. L. M. Macan Marikar; A. L. Meera Ismail Lebbe; A. L. M. Mohamadu; Captain F. Bayley; and A. de Beer. The Sapphires of Ceylon are very variable in colour, which is by no means confined to shades of blue as is very generally supposed, but embraces all colours and their shades, until they approach that of the rose-red, when they are included under the ruby. The blue stones range from a pale azure blue, through deepening tints to inky black, when it is useless as a gem-stone, the most valuable of those tints being the velvety blue found in the district of Rakwana. Some very fine examples of these are shewn, also a very large suite illustrating their range of other colours besides blue. These form a large part of the contents of two cases lent by R. C. Nockold, each of which contains 221 facetted stones of high quality and beauty. Noteworthy also are the sapphire and ruby star stones, the characteristic feature of which however, is only well seen under direct instead of diffused light, as daylight. Like the other varieties of corundum, the star stone or "Asteria" varies much in colour, but is usually of shades of sapphire blue or of ruby red. These stones are almost most peculiar to Ceylon.

The Ceylon Ruby is usually of a rich rose, varying in intensity, and differs in this respect from the Burmah ruby, which is mostly of a pigeon-blood colour; it also differs in its brilliancy, and "has considerably more light and life." A peculiar kind of chatoyance or as some may express it, a "silkiness" is characteristic of most of the rubies of Ceylon. Of this stone a remarkably fine example is shown by Mr. de Soysa, valued at £450. With this may be coupled a fine exhibit of 49 unusually fine examples of this rare gem which are designated as "specimen rubies."

Some really magnificent examples of the true "cat's eye" which is a stone also peculiar to Ceylon are exhibited. One of those belongs to a "Moorman," and is valued by him at £3,000. This mineral is a chatoyant variety of the species chrysoberyl. The finest are found in the gem pits of Morowa Korle. Like the star stone these chatoyant stones require the aid of direct, instead of diffused light, to develope the characteristic band to which they owe their name.

Another variety of chrysoberyl is the "Alexandrite," which was first found in the emerald mines of Ekaterinburg, Government of Perm, Russia, where it occurred frequently in large twined crystals of the same type as those of the chrysoberyl of Brazil and Ceylon, but, rarely of sufficient transparency to admit being facetted as a gem. Its colour in daylight varies from that of a dark emerald-green to a smoky or sometimes bottle-green, but it possesses the peculiarity of exhibiting a raspberry to a columbine-red colour when exposed to artificial light. A stone weighing about 23 carats is one of (if not the most) beautiful example of this peculiar mineral we have yet had the pleasure of examining. Quite new to us is a single example of a chatoyant variety of this stone, designated as an "Alexandrite Cat's-Eye."

The moonstone, hitherto in our opinion a much neglected stone, is, we learn, meeting with a greater amount of favour. Numerous examples illustrating its adaptability for ornaments of personal decoration in the way of brooches, necklaces, scarfpins, &c., are shown. This variety of felspar is found in considerable quantities of varying quality in a pegmatite rock. The other gems shown are the varieties of zircon, (the jargoon and hyacinth or jacynth), the lustre of which approaches nearer to that of the diamond than any other known mineral; cinnamon stone, a variety of garnet often sold as jacynth, which, however, is an exceedingly rare mineral. Most of the above minerals are also represented in their natural state as found, both those fit and unfit for facetting purposes. Finally, a large crystal of quartz is shown enclosing numerous cavities (some of considerable dimensions), each of which contains a fluid and a moveable bubble, which recalls to mind the equally interesting example from Brazil preserved in the National Collection of Minerals in the Natural History Museum.—*Mining Journal.*

At the British Pharmaceutical Conference an interesting paper on the Correlation of Study in Botany and Materia Medica was admirably read by the author, Professor Hillhouse, of the Mason College. The arguments set forth were based in a great measure on the requirements of the medical student, but Professor Hillhouse struck a chord of sympathy with a section of his audience in declaring that pharmacy is a part of the medical profession. The paper was intended as the basis of an arrangement for future consideration, and the subjects advanced were (1) a thorough training in pharmacognosy, pharmacogenesis, pharmacy, posology, and therapeutics; and (2) a comprehensive course of histological work. The author regretted the abolition of botanical studies by some medical qualifying bodies, and this was taken as the key-note by some of the speakers who followed. Dr. Trimen—the well-known botanist—could not agree

with Mr. Hillhouse regarding medical botanical studies, and gave a forcible illustration of the inefficient manner in which botany was taught in London twenty years ago. It was pointed out in the course of the discussion that bad results hitherto were due to the want of systematic and practical teaching, pharmacy apparently being as bad in this respect as medicine. From what the chairman said, however, it appears that we shall by-and-by get all that is required in the research laboratory of the Pharmaceutical Society. —*Chemist and Druggist.*

The Falkland Isles.—There is certainly a remarkable contrast between this place and Seychelles in the way of vegetation. There the most redundant tropical growth, here all as bare as your hand. It is about this very bareness that I am going to trouble you. I am very anxious to try and grow some hardy bushes and shrubs here; and in sheltered spots they will grow I know, to a certain height, though I doubt if one could expect anything about 12 or 15 feet at most. Still this would be something better than "diddle dee" and Balsam Bog. Could you advice me what to try, and perhaps send me a few seeds or roots, with directions as to the best way of managing them. I have a good gardener here who was at Paul's Nursery Gardens, and will take pains with plants. The soil, as of course you know, is chiefly peat, and the winds are high and cold. The latter, I suppose, would always prevent trees of any size growing. But it is wonderful what can be done here in sheltered spots, and the flowers do capitally. I have never seen such Pansies, Pinks, Picotees, &c. as are grown here. Fruit seems to degenerate—Strawberries, Raspberries, and Currants, all get small by degrees and beautifully less, year by year. So far as I have yet seen, the climate has been too much abused, chiefly by people who, like Sir Wyville Thompson, happened to come here during bad weather. It is now over three months since my arrival, and I find from my journal that more than half the days have been fine and calm, and when it is fine it is lovely—like spring weather at home. To be sure it does blow "whiles," and snow, too; and, unluckily, visitors generlly arrive when it is doing one or the other, or both, and at its best it looks a little bare and dreary, but would be vastly improved if a few nice evergreen bushes and shrubs could be induced to grow here and there in sheltered places. About the town I do not see why Laurels, Hollies, &c., should not do, but I should be very glad of your advice and assistance to think of me.—Extract from letter from Hon. A. C. Barkley, late Commissioner at the Seychelles, now Acting Governor of the Falkland Islands, to Mr. W. T. Thiselton Dyer, F.R.S., C.M.G., Director, Royal Gardens, Kew.—*Gardeners' Chronicle.*

Effects of White Ants on Soil.—The opinion has been held and expressed that the white ants use the best particles of the soil in forming their pyramidal nests. A writer on a sál forest in the *Indian Forester* is of a very different opinion, thus expressed:—But if, in the Bhinga forest, fires have devoured the mould desiccated by exposure, and the free inlet of sun and air has made further accumulations of it impossible, if the hitherto highly impregnated soil has been bereft of all its remaining riches in the ordinary course of vegetable life, a most formidable agency of ruin and destruction remains to be described. I refer to the ever-busy colonies of white-ants, whose numerous hillocks—sometimes as many as fifteen to the acre—constitute one of the most conspicuous features of the Bhinga forest. Neglecting the almost certain fact that the termites consume a considerable quantity of the forming vegetable mould, these only too industrious insects are mischievous in quite another direction, and on a much more serious scale. Each one of these tiny Neuroptea is but a living pump, and by the united force of their myriad numbers, an immense quantity of unkindly subsoil is annually brought to the surface, to be there spread out, wherever the protection of the neighbouring trees is deficient, into even sheets of a plastic and impenetrable cement—a soil so inhospitable that, until much diffused in the progress of years, even the lowliest herbs cannot grow upon it. An observing visitor to the Bhinga forest will not fail to notice the many blanks, from a few hundred square feet to acres in extent, which characterize it. These void spaces bear many points of close resemblance to one another in the generally barren nature of the soil, its white coloration, and the numerous evidences of extinct and living ant-life—evidences that range from the not wholly demolished hillock to the white circular deposit of unusually cement-like earth. Before walking very far inside the Bhinga reserve, the observing stranger will descry this process of soil deterioration going on in all its different stages, from the truncated cone just attacked by the advancing monsoons to the three or four mounds littering with their detritus half an acre of ground. Wherever we proceed, we notice, at short intervals, either towering ant-hills, or the evidences of their past existence, and it is impossible for us to neglect the immense importance of the part played by termites in forest economy."

The Value of Fruit as a diet has often been insisted upon; but there seems to be a sort of prejudice to the use of fruit on a large scale, which may doubtless be traced to an ignorance of the laws of hygiene. The following remarks, which we extract from the *Journal of Health* will, we think, be read with interest. In a hot, enervating climate like that of India, fruit should form a very large proportion of our daily food:—

Of all the fruits with which we are blessed, the peach is the most delicious and digestible. There is nothing more palatable, wholesome, and medicinal than good ripe peaches. It is a mistaken idea that no fruit should be eaten at breakfast. It would be far better if our people would eat less bacon and grease at breakfast, and more fruits. In the morning there is an acrid state of the secretions, and nothing is so well calculated to correct this as cooling, sub-acid fruit, such as peaches, apples, etc. The apple is one of the best of fruits. Baked or stewed apples will generally agree with the most delicate stomach, and are an excellent medicine in many cases. Green or half-ripe apples stewed and sweetened are pleasant to the taste, cooling, nourishing, laxative, far superior, in many cases, to the abominable doses of salts and oil usually given in fever and other diseases. Raw apples stewed are better for constipation than some pills. Oranges are very acceptable to most stomachs, having all the advantages of the acid alluded to, but the orange juice alone should be taken, rejecting the pulp. The same may be said of lemons, pomegranates and all that class. Lemonade is the best drink in fevers, and when thickened with sugar it is better than syrup of squills and nauseants in many cases of cough. Tomatoes act on the liver and bowels, and are much more pleasant and safe than blue mass. The juice should be used alone, rejecting the skins. The small seeded fruits, such as black-berries, figs, currants and strawberries, may be classed among the best foods and medicines. The sugar in them is nutritious, the acid is cooling and purifying and the seeds are laxative. We would be much the gainers if we would look more to our orchards and gardens for our medicines and less to drug stores. To cure fever or act on the kidneys, no febrifuge or diuretic is superior to water-melon, which may, with very few exceptions, be taken in sickness and in health in almost unlimited quantities, with positive benefit. But in using them, juice should be taken, excluding the pulp, and then the melon should be fresh and ripe. It is true that we cannot procure apples in sufficient quantities, or at rates low enough to suit the pockets of the masses, but peaches, water-melons, oranges and figs are common enough, should be largely used. We have other fruits, such as plantains, mangoes, plums, papyas and pine-apples, custard apples, &c., which are are all good wholesome fruit, which ought to figure conspicuously on our tables. The tomato can be had nearly all the year round, and limes or lemons are plentiful in all seasons.—*Indian Agriculturist.*

MR. LESTER ARNOLD'S BOOK ON COFFEE-PLANTING.

Review of Coffee: its Cultivation and Profit, by E. Lester Arnold.*

Only twenty years ago, and coffee-planting was the best investment in Ceylon, the one grand product of the island; beside which, all its other exports were separately insignificant trifles; but the destroying demon came and marched in triumph through the land, leaving his mark everywhere, gradually feeding on the life blood of the plant, and extinguishing the hopes of the planter. The invisible germs of the destroyer floated in the air and attached themselves to every object, and were thus borne to other lands; it spread to the coffee regions of India, to Java, to the Straits Settlements, carrying ruin in its train, and it seems to be a work of time merely, for the same fungus to extinguish this industry, all over the world. We have no authentic information that this enemy has yet reached the coffee regions of the West, but we have clear proof now that coffee is nowhere a permanent industry. Within living memory, coffee was profitably grown on the sea shore in Brazil; it has now receded far into the interior, and still marches westward, leaving (so far as coffee is concerned) a barren exhausted soil behind. We were told long ago, that the Brazil system was unsound and must collapse; but since that theory was first broached, Brazil has doubled its exports and goes on increasing them, till the markets of the world are swamped and the profits of that industry, reduced to the vanishing point wherever it is grown, independent of the ravages of *Hemileia Vastatrix*. How long it may take Brazil to exhaust her resources, we have no means of estimating, but they are not inexhaustible and her onward career, may be checked by social or financial collapse, long before she has got to the end of her vast forests; in the meantime, we cannot credit with very deep wisdom the man, who goes into coffee planting in any part of the world, with perhaps one exception; the Blue Mountain coffee of Jamaica has never been affected by the fluctuations of the market, and probably never will, unless its production is increased beyond the wants of its own special market.

It is at such a time, and under such circumstances, that Mr. E. L. Arnold, an Indian planter, has given himself the tronble of writing a book on coffee. If the object of this work was to instruct those already engaged in administering diminishing crops in a falling market, he will probably be told to instruct a venerable ancestress, in the art of extracting food by means of suction. If on the other hand, the object is to draw fresh capital into the enterprise, there may be some chance of success. There are always plenty of English people ready to open their purses, for the support of any scheme that is plausibly invested with the promise of profit, but writing a book of technical instructions, is not the best way of reaching them.

Planters first and last, have learned very little from books: the new 'chum' who comes among them has only to open his eyes and his ears when he meets his neighbours, they talk little else than 'shop' and he sees around him daily the outcome of the accumulated experience of a long series of years; so that he has little need to turn to books on coffee for professional knowledge. There is only one possible case in which such books are useful, that is when new hands begin to plant in new countries, but such a case is not likely to occur in this century. The early Ceylon planters owed much to the old French refugee, Laborie, and all the books that have been since written, add little to the information, given by him.

As to the merits of Mr. Arnold's book, there is little to say. It gives a fair view of the life and work of a planter. His estimates are rather slovenly in details; and larger in the gross, than the Ceylon rate for the same works. One great slip is cutting pegs, lining, making holes two feet by eighteen inches, and filling them up with fresh surface soil for R25·80 per acre, and then charging R27 for removing the plants from the nursery to the field, setting them in the spots prepared for them and filling in any vacancies that may occur during the season.

A maiden crop of 4 cwt. per acre is more than the average Ceylon yield in our best days, and 70s is certainly above the average of present prices and no allowance is made for curing, packing, shipping, insurance, freight, and London charges; if the difference between ten rupees and twenty shillings was meant to cover those charges, it might have been so stated. With no guide but Mr. Arnold's figures, the investing capitalist can arrive at no other result than an excess of receipts over expenditure at the end of the fifth year of not less than R30,000 and the promise of R30,000 per annum for a long series of years. If something like this is the general experience of Indian coffee planters, nothing more can be said, but the capitalist who has learned what the coffee fungus has done in Ceylon and that it has a hold in India, will shake his head and button up his pocket.

CEYLON UPCOUNTRY PLANTING REPORT.

Dumbara with enough rain—Fine crops of cacao in prospect—Mangoes and cardamoms—Tea-sifter and tea-roller—Mother Seigel's syrup.

11th Oct. 1886.

This fine planting season still continues, and the south-west seems to be as boisterous as if it were but beginning to blow. That we have had more than enough of rain was manifested by the remark of a Dumbara man the other day, who said that they really were not wanting any more there! Fancy Dumbara in a state of saturation and the inhabitants thereof, calling out 'enough'! What fine crops of cacao may not be expected; in all likelihood, the best they ever have had if the present promise holds. But what suits one product does not suit another, and the tobacco enterprise of that rich valley has, I understand, not been quite such a mine, as it might otherwise have been had the usual weather obtained. Another season, let us hope may make up for this.

I suppose it is one effect of the abnormal weather that our mango trees are full of blossom which may mean another crop, whereas we usually have only one. In the old days a fine mango blossom was a pretty sure token that there was going to be a good coffee one: but then the mango flowered in the early months of the year, and to see it in bloom in October was not looked for. In a quiet way, there is going on at present a good deal of Cardamom planting, and those who are doing this are hopeful of reaping the reward of their faith in having a firm market to send to with good prices, when the time of harvest

comes. Most of the cardamoms now in fruit will be past by the time the bulbs now being put out are matured, and as there are not very many extending the cultivation of this product, there would seem to be ahead a good time for the knowing ones.

Messrs. Baillie and Thomson's patent Tea Sifter has been improved lately. The old style of wood in frame has given place to a wrought iron tubular end, which makes the machine look much smarter. With this improvement, the price has also advanced somewhat, whereas tea machinery in Ceylon might well afford to have a turn the other way.

Messrs. Law & Davidson's "Simplex Tea Roller" is quietly making a name for itself, and is said to do very good work. It takes 100 lb. of leaf at a fill and finishes this off in 30 or 40 minutes with six coolies.

One who has had practical experience of almost every hand-roller in the field, has now no hesitation in giving the palm to the "Simplex." He maintains that it is strongly and solidly built, is the lowest priced, has a better twisted leaf, gives a larger proportion of fine tea, than can be turned out by any other hand-machine. He further asserts that every leaf is thoroughly rolled. That is high praise, and if the "Simplex" comes up to it, it will be another example of the capability of Ceylon men to invent and manufacture their own machines. Certainly such a testimonial should fully satisfy the inventors, although in these days it is sometimes difficult to do this. Of course, in regard to the merits of tea-rollers, there will always be a variety of opinions, and as almost every other man you meet now is an authority on tea, there will be for every machine that does any kind of fair work, a number willing enough to supply the manufacturer with a sample of this literary composition, so treated or otherwise. Coffee, what at least of it is left, is beginning to ripen up, but the picking is a farce after all; you don't know very well how to do it, so as to secure the miserable harvest, at anything like a modest cost. If you try four coolies in the line, the tale at the close of the day is so poor as to make you regret the more: whereas by the picking, you may secure half or two-thirds of what is really there, and the rest drops. And then to read of the excitement and speculation in the American coffee market, and the brilliant prospects which lie before the cultivation of that fragrant bean, and to feel that we are all out of it or nearly so! It is rather tantalizing that this turn comes just as we are unable to avail ourselves of it. Had it been earlier, it would have suited Ceylon much better. I suppose it is because that we are now recognized all over the world as a sorely tried and suffering people that the proprietor of "Mother Siegel's Syrup" has of late inundated the island with an almanack, altogether given over to the extolation of this quack medicine. It is difficult, however, to understand why the Post Office officials should be mixed up with it—for the copy of the almanack which lies before me is from one of the outstation offices, and the name of the postmaster is printed thereon. It has a gay cover, and the outside is the best of it. One who was disappointed in love, and took to the "Syrup," says that its effects were wonderful. He at once recovered his spirits, was able to sleep, and ceased grinding his teeth. He hints that the official connection with the "Syrup" includes many in high places, that the Acting Postmaster-General is always at his worst when his supply is exhausted: that Mr. MacBride goes in for heroic doses, whenever Mr. Campbell writes a letter about the state of the roads; and that even His Excellency has of late been rather an extensive buyer, and as he has not been known to offer it to any one, it is conjectured that he uses it all himself. But in Ceylon, it is very hard to know what to believe, and this "gup" from the disappointed lover may be, after all, not a whit more reliable than much which we have formerly rejected.

PEPPERCORN.

HOOPER AND HOWARD ON CINCHONA BARK.

We copy from the *Pharmaceutical Journal* abstracts of papers read before the Pharmaceutical Congress. As regards Mr. David Howard's opinion regarding hybridization in Ceylon, it seems a pity he did not explain how hybridization can be prevented where different species are cultivated within reach of winds and insects:—

"Mr. David Hooper communicated some of the results obtained in the course of his quinological work in the Madras cinchona plantations. Shaving cinchona trees as a method of harvesting bark is now very general, but the question as to the limit to the constant and successful shaving of the tree is not yet fully understood. It has been found that when operating on trees of six years old the increase in the amount of quinine during the first and second renewal at intervals of twelve months was most satisfactory, but the increase was not so marked in the third year renewal, although the conclusion arrived at is that renewal by shaving might be permitted for at least four years. The beneficial effect of renewal by shaving was very marked in the case of a six-year old succirubra, which yielded twice as much quinine sulphate as from a natural succirubra of twice that age; but the operation was not satisfactory in its results when applied to trees of sixteen to twenty-one years, as such old trees will not bear the shaving treatment. The application of cattle manure to cinchonas seems, from the results of three sets of experiments on succirubra and magnifolia trees, to have the effect of increasing the amount of total alkaloids, and in two instances the amount of quinine, by 52 per cent. and 20 per cent. respectively; but the usefulness of the application of manure was not so marked in old trees, and it is believed that the effect of manuring would be more apparent in Crown and Ledger barks. It is also stated that the maximum yield of quinine in Ledger and succirubra barks seems to be attained when the trees are between the age of five and six years, as after that time there is no sensible increase in the amount of quinine. Another point ascertained was that bark which had been kept for ten months in a damp room, and had become mouldy in consequence, had not deteriorated as regards the amount and quality of the alkaloids."

Cinchona Cultivation in South America was the title of a paper by Mr. David Howard, who believes that it is to other countries than Ceylon, which occupies at present the most prominent position of all the countries where cinchonas have been cultivated, that we must look for the solution of the scientific points involved in the cultivation of cinchonas, owing to the little care that has been taken in Ceylon to avoid the danger of hybridization. Unfortunately, very little scientific information can be obtained from South America, the natural home of the cinchonas except what little can be derived from the study of the cultivated bark which reaches us from that country. Among the cinchonas under cultivation in South America are two new species, *C. Thomsoniana*, named after Mr. Thompson, who discovered it in the Central Cordilleras, the home of the well-known *C. lancifolia*, and another discovered by Señor Pombo in Ecuador. *C. Thomsoniana* gave on ana-

lysis of the bark of a two-year old tree 3·3 per cent quinine sulphate, trace of cinchonidine, and 0·55 per cent cinchonine. The bark from the other species of the same age gave 5·7 per cent quinine sulphate, 0·43 per cent cinchonidine, with no cinchonine or quinidine. The improvement brought about by the successful cultivation of the cinchonas is further shown by the results obtained from the same plantations in 1872 and 1881 of several kinds of cinchonas grown in Jamaica, and these results were even more favourable in the cultivation in Columbia of descendants from the Jamaica plantations. In the case of a succirubra cultivation in Columbia from a Jamaica plant the bark yielded as much as 7·0 per cent quinine sulphate, with only 1·9 per cent cinchonidine, and 0·67 per cent cinchonine and Mr. Howard remarks that this succirubra is one of the finest he has tested. In Mr. Howard's opinion it cannot be too clearly borne in mind that the prospect of future profits in the cultivation of cinchonas depends entirely on the cultivation of high testing bark, for in the face of the importation of such highly valuable cultivated bark from Bolivia, as well as from Java, the profitable growing of inferior bark is impossible.

THE KALUTARA TEA DISTRICT.

(From a Resident Planter.)

THE RUSH INTO AND COLLAPSE OF LIBERIAN COFFEE —THE SUCCESS OF TEA, YIELDING UP TO 1,000LB. PER ACRE—CHEAP SINHALESE LABOUR FOR TEA-PLUCKING—THE TEA DISTRICT PROPER NEARLY ROADLESS—THE TRAFFIC LOST BY THE RAILWAY—THE NEED FOR A VISIT FROM THE GOVERNOR.

A very few years ago it was doubted if tea would grow in this District, at all; and experiments on—— were tried, partly alone, and partly intermixed with coffee. I only know what crops two fields of this have given, but it all looks very fine indeed. The field you saw on——is giving 800 lb. per acre *this* season; and during the last 9 months the field you saw on—— has given 924 lb. of made tea per acre, with 3 months to run yet, during which time it will be pruned. I estimated some time ago that at least R800,000 had been invested in the District, mostly spent in Liberian Coffee cultivation, which has turned out a snare and a delusion, and of which there are only a few acres left now.

Perhaps never in the history of the Island, has so much capital been put into an industry, which, practically *before it gave any returns*, collapsed; and the perseverance of the planters under the heart-breaking circumstances, is beyond all praise. As much as R70 per acre was paid for some of the land, and most of it was planted with plants costing from 50 cents to 12½ cents each! so you can easily imagine what some of the capital accounts must have stood at, to start with. Then came the fact that it took 4 bushels of cherry to make 1 bushel of parchment, and when it became known that instead of being worth 50 per cent more than ordinary coffee in New York, it was worth much less the last straw was piled on "that broke the camel's back," or rather that decided the fate of Liberian coffee, and in the last 3 years a wonderful change has taken place in the District, as practically all the coffee has been replaced by tea, which is coming on remarkably well.

With Liberian coffee, everything was an experiment and the calculations of profits were built upon fables wafted over the sea, and pamphlets published by the sellers of seed; while the few trees in Ceylon at the time only served to confirm the exaggerated reports of its bearing capabilities, as they bore enormous crops simply, I suppose, through over-manuring. I know of one instance where eight experimental trees gave at least at the rate of 50 cwt. per acre; *one individual tree giving 2 bushels parchment in one year!* while the adjoining field never gave over 5 cwt. per acre, and this was very good for Liberian coffee. With tea, on the contrary the planting generally was gone about in a far more systematic manner,' and with previous experience before them in the fields first planted, and in estates in other districts, there have ensued the happiest results and I venture to assert that there has not been a single (or married either for that part) visitor to this district, who has not been surprised at the state of the tea industry and the wonderful growth of the plant in the district.

Tea planted in abandoned citronella land and in its 8th year giving over 1000 lb. per acre augurs well for the future of the district. The price that tea can be produced for in this district is another point, with scarcity of Tamil labour and reduced prices both looming ahead of us, this is an important factor, and we have cheap work in the shape of indigenous population, who will work more cheaply and quite as well as Tamils.

"I pick leaf regularly at 2½ cents per lb.,' said a superintendent to me lately, "I have a gang of 60 women (Sinhalese) always employed." If prices fall, and as the women get better up to the work, I have no doubt that leaf will be plucked all over the district at 2 cents per lb.; and even supposing half the plucking only is done in 1888 by Sinhalese, it will mean an income of about R50,000 (fifty thousand rupees) for this work *alone* to the local Sinhalese population.

It is clearly in the interest of Government to encourage planting in Kalutara as much as they can, for the very reason that it is employing a large population of hitherto idle people (in many cases idle, because except at seed time and harvest time, there was no work) and there is still an ample number of labourers of this description in this population of 270,000, many of them being on the verge of starvation before the approach of harvest.

The question of the value of low-grown tea at first caused some anxiety to the owners of tea gardens in the district, but the fallacy of the theory that low-grown tea means poor prices has long ago been proved; and in the last week's Sale List five Kalutara estates had tea sold; three of them realizing between 1/3 and 1/3½ sterling and two between 1/1 and 1/2d sterling, averages that will compare favorably with those of any district in the island.

The next question to be faced is how to get the crops despatched and food imported for the labourers. By their present policy Government are driving the traffic from the railway to the river and canal to Colombo.

Fancy what would be the action of a private Company if it owned 30,000 acres of available tea land, within 16 miles of a railway, and wheer useful cart roads could be cut for R3,000 per mile. Certainly not to refuse to cut absolutely necessary feeding roads, to its own direct loss.

In the year 1888 there will be made in Kalutara, tea	800,000 lb.
Say packages, tea-lead and up and down	300,000 ,,
Rice, (say 1 bushel per month per acre)	2,600,000 ,,
Sundries	780,000 ,,
	4,480,000 lb.

or 2,000 tons of traffic, and not a road through the district to take it to the railway, although this could be made for R30,000 at the outside.

Tea is an article which should be possible to dispatch direct to its destination without the delays

and damping it gets in river transport, and the only principal road to Kalutara now is flooded repeatedly during the year, and stops short seven miles from the railway. At this point a large cart bridge was put up some years ago at considerable expense (*and the road not continued a foot beyond it* ! !), so that carts come to the bridge and turn without crossing it, there being no road.

PLANTING IN NETHERLANDS INDIA.

(*From the Straits Times.*)

We understand that Mr. Teves, one of our townsmen, along with an experienced Deli planter, and on account of an enterprising tobacco grower in Mid Java, will proceed to British North Borneo to ascertain how matters stand there, and how far that article can be successfully cultivated there for the European market by the methods pursued on the East Coast of Sumatra. It is deplorable that enterprising Hollanders must look to British colonies for advancement in the cultivation line, notwithstanding the circumstance of Holland having magnificent colonial possessions. The British seem to have the knack of better knowing how to encourage private enterprise and backing it up than our Government. We look forwards with interest to further particulars of this undertaking owing to so little being known as yet of British North Borneo. *Samarang Locomotief.*

At Buleling in Bali so says a Surabaya newspaper, the tobacco hitherto grown was used only for native consumption. The quality, however, has proved so excellent and the leaf so choice that the article has some chance of being grown at a profit also for the European market. Bali may hence at some time become a rival to Deli. Experiments in this direction have not yet been made but no doubt will soon be, judging from appearances.

Dr. Bonavia, in a letter to the *Gardeners' Chronicle* (July 31, p. 147), gives a glowing account of the beauty of the *Cassia fistula* tree, or "amiltas," as he calls it. When in bloom he considers it to be one of the sights of the Indian flora. An avenue of the trees in bloom would, he says, be worth a trip from any part of the world to see. When in full flower it is a perfect cascade of canary-yellow spray. He remarks that there are two varieties, one with bright green leaves throughout, which has flowers of a pale yellow, and the other with fine maroon-bronze leaves when young, but turning green later on, and bright canary-yellow flowers.—*Pharmaceutical Journal.*

Experimental Tobacco Culture.—On some ground rented by Messrs. Carter & Co., at Plaistow in Kent, a number of varities of the Tobacco plant are now undergoing a course of trial, so as to ascertain the varities best sulted to our climate. The ground is so far suited to the growth of the plant it being well sheltered, but although its area does not exceed three-quarters of an acre, there appears to be considerable diversity in its fertility, as is shown by the varying heights and strength of the plants; and the lowest part of the ground is liable to be flooded by water from a neighbouring ditch. These drawbacks could be avoided by deep digging after an even distribution of homogeneous well-rotted manure, and by other obvious changes. The sorts grown are Havana, Spanish Seed-Leaf, Florida, Yellow Pryor, Hester Virginia, Pennsylvania, One Sucker, Kentucky, Virginian, Big Frederick, Maryland Broadleaf, Island Broadleaf, White Burley, White Stem, Yellow Oronoco, Connecticut, and Gasner. The most promising Tobaccos are those which are long jointed and broad-leaved. These carry their foliage clear of the soil, and are in consequence not disfigured by dirt or injured by worms and slugs; the air gets better amongst them than is the case with the short compact-habited sorts whose leaves, as in the case of Cann's Seed-Leaf, lie on the ground or nearly so. Glasner, Connecticut, Pennsylvania, and White Burley are each more or less, so far as could be seen now, of this close dwarf habit. The other kinds differ from these in being, as we have said, of an ascending habit, with long intervals between the leaves. Some have slender foliage, pendulous at the tips; other support the leaf horizontally, or nearly so; and in scarcely any of them are the various hues of green alike. The plants are now growing fast, and if the weather continues warm, without rain, great progress will be made before we get frost in that part of the country. The method of cultivation adopted is that generally advocated by men of experience in the United States of America. the plants being set out on light hillocks standing 3 feet apart in the row, and 4 feet between the rows, the greater space affording means of getting amongst the plants with the cultivator in the early stages, and with the hoe later. Topping the plants as they show the flower-buds and have developed nine leaves, without reckoning the bottom pair, and constantly removing laterals, requires the constant attention of the man in charge of the crop. If it should be found to answer, and our Government fix an Excise tax on each plant, as is done in Belgium, it would prove a source of revenue to our small farmers and cottagers, as the profits per acre are considerably higher than those from corn, &c.—*Gardeners' Chronicle.*

Tea Prospects in India.—From the Calcutta "Commercial Letter" in the latest *Pioneer* we take the following:—

The following are the figures published by the Calcutta Tea Association, giving correct estimates of the crop. The previous estimates of the Indian tea crop given in their Circular, dated 8th May last were:—

	Estimated crop of 1886. lb.
Assam	35,133,494
Cachar and Sylhet	22,908,180
Darjeeling, Terai, and Dooars.. ..	13,302,800
Chittagong and Chota Nagpore ..	1,346,800
Dehra Dun, Kumaon, and Kangra ..	3,250,000
Total ..	75,941,274

From figures since obtained, a revised estimate has been prepared based upon actual results up to 31st August, showing the following figures:—

Manufactured up to 31st August	1885. lb.	1886. lb.
Assam	16,520,520	18,910,054
Cachar and Sylhet ..	11,749,129	13,004,412
Darjeeling, Terai and Dooars	7,076,594	8,769,820
Chittagong and Chota Nagpore	589,154	651,057
Total ..	35,935,397	41,335,343

Revised estimate of crop, 1886:—

	lb.
Assam	32,584,466
Cachar and Sylhet	22,074,022
Darjeeling, Terai and Dooars.. ..	14,014,485
Chittagong and Chota Nagpore ..	1,316,596
Dehra Dun, Kumaon and Kangra ..	3,500,000
Private and Native Gardens (estimated)	2,000,000
Total ..	74,489,579

The consumption of Indian tea in India and the requirements of Government being estimated at 14 million lb., and the exports to the Australian Colonies and other places being calculated at 2 million lb., there should remain about 71 million lb. for shipment to Great Britain against 65¼ million lb. shipped during the season of 1885-86.

Adding 13 million lb. out of a total of 14 million exported from Ceylon, we get 84 million lb. of Indian and Ceylon tea for the United Kingdom in 1886-87. But the Indian and Ceylon seasons do not quite correspond.

MANURING TEA WITH COTTON-SEED.

Our readers will recollect that we quoted into the *Tropical Agriculturist* the results of experiments in the manuring of tea by Mr. F. McL. Carter of Chandpore Garden, Chittagong, with castor cake solely, and the same substance mixed with superphosphate. Mr. Carter has now published in the *Indian Tea Gazette*, the results of manuring with Cotton-seeds. Three pounds to a bush raised the yield to 831 lb. per acre as compared with 554 lb. on an unmanured plot and the profits in first and second years were good in proportion, though not quite equal to those resulting from the use of castor cake. There is no evidence that in this case the quality of the leaf was improved.

MEMORANDUM OF EXPERIMENTAL MANURING WITH COTTON-SEED ON CHANDPORE GARDEN, CHITTAGONG, IN SEASONS 1882 AND 1883.

Elevation of plateau 75 to 80 feet above the paddy lands; and soil, a sandy loam near surface, with a ferruginous clay and sand for subsoil. The bushes are of a fair Assam Hybrid variety, transplanted from nurseries in 1867, to 4'×4'=2722 per acre, and were pruned down to 18 inches on 5th, 6th and 7th January 1882.

SEASON 1882.

The experimental plots A, B. and C comprised ¼ acre, 680 bushes each manured with Cotton-seed, &c. and a similar area contiguous to each with no manure; all properly fenced in, and plucked by selected women throughout the season, the leaf being carefully weighed by beam scales. The style of plucking 2¾ leaves (the bud counted as one).

Plot A manured with Cotton-seed, @ 2 lb. per bush } equal 68 maunds per acre }
„ B Do. do @ 3 lb. per bush } equal 102 maunds per acre }
„ C Do. 1 lb. of Cotton-seed, mixed with 5 lb. of *gobar* per bush } equal to a combination of 204 maunds per acre. }

The manures were applied between the 7th and 10th March 1882.

RESULTS IN YIELD.

Plot A.

	lb.	oz.		lb.	
Manured ¼ acre	694	8	green leaf	=694	tea per acre.
Non-manured do.	564	5	„	=564	„
In favor of former by	130	3	„	=130	„

or an increase of 23 per cent.

Plot B.

	lb.	oz.		lb.	
Manured ¼ acre	831	11	green leaf	=831	tea per acre.
Non-manured do.	554	2	„	=554	„
In favor of former by	277	9	„	=277	„

or an increase of 50 per cent.

Plot C.

	lb.	oz.		lb.	
Manured ¼ acre	729	10	green leaf	=730	tea per acre.
Non-manured do.	632	10	„	=633	„
In favor of former by	97	0	„	= 97	„

or an increase of 15·3 per cent.

From the foregoing areas there were 27 flushes in the season, which commenced on 15th March, and terminated on 31st December.

The rainfall in 1882 was 102 inches and 21 cents, and number of days in which rain fell was 137.

The average rainfall for this garden in 15 years was 97 inches 70 cents.

The height of bushes at end of season was on plot A

Manured plot	...	...	36"
Non do.	...	...	30"
Do.	do.		Plot B
Manured	...	...	36"
Non do.	...	...	30"
Do.	do.		Plot C
Manured	...	...	36"
Non do.	...	...	30"

The mean average of Brokers' *three* valutations in 1st season was R0-8-5 per lb. from the manured areas, *viz.* 8th June, 5th August, and 17th November, and also R0-8-5 on non-manured area, no difference in fact, but plot B was the highest, being R0-8-7 per lb., the lowest being R0-8-2 per lb. on plot C.

The results are estimated as follows:—

Plot A.

		per acre
Manured plot lb. 694 tea *to* say		R0-8-0=R347-0
Non-manured do. „ 564	„	R0-8-0=R282-0
In favour of former by 130	„	=R65-0
Less the actual cost of the manure, including Freight, transport, and application &c., was on this plot R47-7-4 per acre		=R47-8
Amount in favour of manured plot	...	=R17-8

Therefore, the profits were 36¾ per cent per acre.

Results from Plot B.

			per acre.
Manured plot ...	lb. 831 say @	R0-8	=R415-8
Non do.	lb. 554 @	R0-8	=R277-0
In favour of former by	lb. 277	„	=R138-8
Less the actual cost of manuring, &c., this plot was	R71-3 per acre		=R71- 3
Amount in favour of manured plot			=R67 -5

Therefore, the profits were 94·3 per cent per acre.

Results from Plot C.

			per acre.
Manured plot ...	lb. 730 @	R0-8	=R365-0
Non do. ...	lb. 633 @	R0-8	=R316-8
In favour of former by	lb. 97	„	=R48 8
Less actual cost of manures on this plot	@ R 39-11-8 per acre		=R39-12
Amount in favour of manured plots	...		=R 8-12

Therefore, the profits equal 22 per cent per acre.

From the above it will be seen that plot B. manured with lb. 3 per bush=102 maunds, or about 3½ tons per acre, give the best returns.

This can be demonstrated in another way: for instance, the *cost* of manuring plot A is R 47-8, and plot B, R71-3 per acre, which is exactly 50 per cent more; whilst the profits on former were 36¾ per cent and on *latter* 94·3 *per cent per acre*, or "57·55" per cent greater, whereas in "theory" the profits ought not to have been in excess of 50 *per cent per acre above plot* A.

I should have stated that these areas were twice deep dug, and five times light hoed or weeded in the season, which is twice more than is the usual practice on this garden.

The foregoing experiments were carried on in 1883 also, being the second season, but no more cotton seed or other manure was applied to the plots, and the outturn from them is as follows:—

A

			per acre.
Manured area ...	lb. 470¾ green leaf	=lb. 471	tea
Non do. do. ...	lb. 457 „	=lb. 457	„
In favour of former by	lb. 13¾ „	=lb. 14	„
The increase therefore was	...= 3 per cent per acre.		
Add do 1st year	..=23 „	„	
Total increased yield in 2 seasons	=26 „	„	

The profits therefore will be

Manured plot ...	lb. 471 tea per acre @	R0 8	=R235 8
Non do. do. ...	lb. 457 „	R0 8	=R228 8
In favour of former by	lb. 14 „	R0 8	=R 7 0
Less cost of manure	„	nil.	
Therefore, net profits	... per acre		...R 7 0
Add profits 1st year	... „		...R 17 8
Total profits in two years	„		...R 24 8

or 51½ per cent.

			per acre.
Manured area ...	lb. 571 green leaf	=lb. 571	tea
Non do. do. ...	lb. 426¾ „	=lb. 427	„
In favour of former by	lb. 144¼ „	=lb. 144	„ .

		per acre.
The increased yield therefore was	=33¾	per cent ,,
Add do. 1st year	=50	per cent ,,
Total increased yield in two seasons	=83¾	per cent ,,

The profits consequently will be

Manured plot	...lb. 571 of tea per acre @ R0-8	= R285-8
Non do	...lb. 427 ,, @ R0-8	=R213-8
In favour of former by lb. 144	...	= R72-0
Less cost of manure	...	= nil
Therefore, net profit per acre ...	...	= R72-0
Add profits 1st year ... ,, ...	...	= R67-5
Total profits in two years ,, ...	...	=R139-5

		=100 per cent per acre.

In the second season the increased yield of C over plot A must be attributed to the *gobur* not having been in a soluble condition, and therefore not fit for assimilation by the rootlets of bushes until second year after application.

The plucking of 2¾ leaves (bud as one) commenced in 1883 on 16th March, and terminated on 29th December—and there were 25 flushes in the season—the rainfall being 112 inches 21 cents. The garden was deep dug once, and light hoed or weeded 2¼ times—total 3¼ times only this year, which is much less than usual. The bushes were pruned down to 18" on 11th and 12th January—and on plot B (the others were not recorded) the average height at end of season on manured area was 37 inches, and on non-manured area 33 inches. On a reference to my Castor Cake experiments published in *Tea Gazette* of 6th October 1885, it will be seen that better results are obtained on plot No. 3 where castor poonac alone was applied @ lb 1 per bush=24 cwts. per acre, although the cost in 1884 was R70 per acre, than on plot B manured with lb 3 per bush of cotton seed, and which cost R71-3: the profits in the *two* seasons of former being 245¾ per cent and from latter 195-4 per cent per acre.

The trials with cotton seed were not registered after the second season. but it was very noticeable that the bushes were benefited by the single application in the third year also.

I should have stated previously that the seed was purchased at Naraingunge near Dacca perfectly fresh at 6 as. per maund, and had to be transported from there about 170 miles to the Factory, *all the way by water* except the last 2 miles, on a level road, from the khal to garden. The seeds had then to be *heaped* in 50 or 100 maunds, the latter quantity the most desirable, moistened with cold water (hot water would have answered the purpose quicker) and then covered over with clods of earth to induce fermentation with the object of destroying its vitality; otherwise the seed when put into the soil would have germinated and produced plants.

I found this took from 5 to 8 days, which could be judged by the disagreeable sour odour emitted, and also the proper stage could be ascertained by the temperature of the heap, as the outside was very warm when felt by the hand. The entire charges for transport, fermentation, and application to the soil, cost R0-5-2 per maund, and including the purchase money of 6 As. per maund, the total cost per maund was R0-11-2. The former charges therefore nearly equalled the orginal cost.

I have been frequently asked if such and such a manure would pay if the transport charges were *higher* than yet cost to *this garden*; and to enable any one to ascertain the limit of expense under this head, beyond which there would be a loss, it will be necessary to make the following calculation. The average price the Tea *realizes per lb.*, is a principal factor in the estimation; another of considerable importance, also, will be the average yield per acre on a garden *in ordinary* seasons prior to any application of manures. If, as in the former case, the produce sells *below* a certain price per lb., taken in connection with the cost of manure there will be a loss; and in the later case loss will ensue likewise if the *yield per acre* is *below* a stated quantity; and on the other hand the converse will happen if the tea realizes high prices, &c. In this event the increased price will enable the planter to pay more for the cost of manure and transport, and still secure a good profit per acre. Most managers can tell fairly well what the ordinary yield per acre is on the different areas of a garden in full bearing, unless the season should turn out exceptional, and therefore there will be no difficulty, when the cost of manure and results obtained from it per acre is known, in ascertaining whether it will pay to apply a certain quantity or not on any particular area. As a general rule, poor lands that are incapable of producing more than about 2 maunds of tea per acre when in full bearing should be abandoned, as it would never pay to apply the large quantity of manure requisite per acre in order to ensure a remunerative yield of crop, unless of course the manure could be put late the soil for very much less than is possible at the present time.

Table I, is based on the supposition that the results obtained from plot B will be accepted as more satisfactory than either of the other experimental pieces. The plot C also shows well in second year, and probably would be preferable where *gobur* can be had in *large quantities*, and when cotton seed is expensive. I will assume that a garden's teas realize any of the prices from 8 As. to 10 As. per lb. inclusive as in column 2. Column 1 gives the increased yield of tea per acre due to manuring; col. 3, the gross receipts per acre; col. 4 the increased yield in 2nd season; col. 5 the total gross receipts per acre in 2nd season, *cost of manuring.*

*The *loss* per acre is written in black figures.

From the foregoing table any one can estimate whether there is gain or loss, and how much, in applying 102 maunds of cotton seed per acre to his tea cultivation, the profits being dependent upon the cost per maund to put it into the ground and the price obtained per lb. for tea. As to what amount may be considered *fair profit* per acre must be left to the decision of each planter who uses this manure, as circumstances differ so greatly that what would be deemed satisfactory by one person or garden might not turn out a profitable investment for others.

In the foregoing table the cost of cotton seed per maund includes *all* charges, *viz.*, the purchase money and the expense of transporting and application per acre. Finally, it must be remembered that the above quantity per acre extends its beneficial influence upon the cultivation during a portion of the *third* season, also, after application; and although there seems apparently to be no improvement in the strength and quality of the tea, judging from the few samples reported on by the Brokers, yet there is no doubt whatever that *suitable* manures when applied in *adequate quantity* per acre, must enhance the value of the produce in addition to increasing the outturn.—F. McL. Carter, *Manager.*

Chandpore Garden, Chittagong, 4th August, 1886.

P. S.—I have omitted to state that if the cotton seed could have been procured *fresh*, with the oil expressed, it would have been equally as valuable for manurial purposes, and the cost in consequence would have been less.

NOTE ON PAPER PLANT,

By J. S. Gamble, Conservator of Forests, Northern Circle, Madras.

The "paper mulberry" is very easy to grow when once one has a few plants to start from, for cuttings strike most freely. Before I left Bengal I planted a few acres (I forget how much) in the Terai. They were doing well when I left, but I have heard nothing of them since. The tree is indigenous in Tenasserim and wants a moist climate. It would not grow in the Ceded districts, but would do well enough, I think, in Goomsur, in Madras, and in, perhaps, the coast rice country, and, of course, in Malabar, &c. To be of any use as a fibre it should be grown near the port of shipment, for we have unfortunately no paper mills yet in this Presidency. I have no idea of what its value is. Plantain fibre (see also for this Dr. King's remarks) is purchased by the Bally Mills from Bengal ryots at R1 per maund of 80 lb. Babuli grass (Pollinia Euopoda) is worth R2 per maund, and is nearly equal to Esparto. Cleaned Broussonetia *might* be worth R4, so that it would not stand much railway freight to pay its expenses. Grown at Madras or near other coast ports it might be a good speculation if the land were not heavily assessed, and it were done on a large scale. But unless paper mills are started it is not worth growing inland. The Chingleput District Forest officer might try it on the old farm lands at Saidápet. If seed is wanted, it should be procured from Colonel Seaton, Conservator of Forests, Tenasserim Circle, British Burma. We have any number of indigenous fibre plants in the moist climates of the Presidency, and paper mulberry could be very easily grown if the paper stock would pay its expenses. In such climates, I have no more doubt of its success than of any of the common urticaceous plants which grow so easily from seed or cuttings. What we *want* are plants that will do to reafforest dry and poor soils and give sufficient wood or fibre or bark or something to pay expenses.

THE NORTHERN AUSTRALIAN TERRITORY YAM.

(To the Editor of the "Australasian.")

Sir—My attention has been drawn by the various accounts given in your paper of the prolific nature of what is now generally known as the Northern Territory yam, its extraordinary value as a fodder plant for all kinds of stock throughout the year, as well as its value to man as a substitute for potatoes. If all that is written about it be true, it will flourish under any climate and in any soil. Under these circumstances it ought to become when once located a great boon to both stockowners and farmers in the arid North, especially during the summer months and times of drought, when everything else is parched up, yet its usefulness, I think, can be still further extended. Might it not be planted with advantage through our scrub lands? I believe in a very few years it would be the means of enabling us to stock many square miles of useless scrub which will carry little or no stock at the present time. My idea is that it should be distributed among the leaseholders of these lands, with the request that it should be planted through the scrub. The same should be done on all unleased Crown lands by the Government. If successful and once firmly rooted the vines would soon spread over the ground, and would choke and destroy a great deal of the undergrowth and bushes which man or beast do not eat, and which prevents anything like grass growing. It would also spread and climb over the trees and entwine itself among the leaves and branches. The stock would help to destroy a great deal of scrub by constantly trampling and breaking it down in getting at the vine, whereas now they only make tracks or pads. I firmly believe its presence in these said scrubs would make them capable of carrying a certain amount of stock, and by so doing would place a value on the land which it has not now. Let it grow ever so thickly, a plant that will give food to both man and beast can never become a nuisance. There are scores of places where it might be tried with advantage that are now only refuges for bunny; for instace, through the Murray Scrub, and that long stretch of country between the Gawler Ranges and the West Coast—the *bete noir* of the Colton farmers. Provided bunny did not destroy the vine it might in time become bunny's greatest enemy, by drawing a population into the isolated portions of the country, and help in a measure to break up these great breeding-places. I should like to see it tried on this now despised Kangaroo Island. I believe its advent here would help more in its advancement than anything I know; there would be little or no trouble or expense in the experiment. The telegraph line runs through the centre from one end to the other. A parcel of tubers should be sent to each of the telegraph officers, and given by them to the line men, who could easily plant them on either side of the line about a mile apart on their travels up and down. The lighthouse-keepers ought to have some tubers sent to them, and be asked to plant them round about. I feel certain if the settlers and farmers were found in seed they would only be too glad to plant them about, as most of them leave home for a month or two every year and pretty well spread themselves all over the Island. It would be no trouble for each of them to take a few in their pockets, and plant them here and there as they go about. I myself could plant any quantity if I had the tubers over a large extent of country from West Bay down. Like the wallaby-hunters we could take some in our pockets and plant them when out mustering. By these means the whole of the Island might be thickly planted in one season, and the sooner the better. It will be to every islander's advantage to help in the cultivation of the yam here, for well he knows what a very great boon it would be even if it did nothing more than provide food for his horses when travelling. The want of grass has been the one great bar to all travelling here, and the principal cause of so little being known about this island. Kangaroo Island has been in the background long enough. It only wants a little energy and enterprise to bring it to the front. I am one of the few who believe that it is coming on slowly. I live in hopes of yet seeing the smoke of a thriving township curling over the waters of Vivonne Bay. Wool, timber, fruit, and minerals chief exports, not forgetting the wallabies—skins, tails, carcasses, and all.—I am, Sir, &c., Another Industry that will Yet be Added.

PLANTING PROSPECTS IN UDAPUSSELLAWA, CEYLON

COFFEE BEARING IN ITS OLD STYLE—CINCHONA KEEPING UP—TEA VERY FINE—ROADS.

Udapussellawa, 12th Oct. 1886.

The blossoming season is now well over and we are in a position to gauge our prospects for the coming year. Mid and Upper Udapussellawa will do very well, the eastern end of the district not so well, but even there crops will be better than some alarmists prognosticated some months ago. The truth is that the nerves of our planters have been in such a state of tension, that ill rumours are far too readily accepted and they err in good company, for the press and the Colombo agents too eagerly swallow any evil reports regarding our old staple. The season has not been a favorable one as regards weather and our good crops arise from the inherent strength and vigour of the *coffee*. Manured coffee is bearing in is old style, leaving nothing to be desired. We had our sharp attack of leaf-disease which did some damage, but it soon passed off, and we believe as the area under coffee contracts, this pest will diminish in virulence and strength.

Cinchona.—There is still a good area under cinchona, and this crop will not be reduced for several years. Some planters are rooting out when the trees arrive at four years old, that being the age, when the question arises which to sacrifice, the cinchona or the good coffee. Time has justified the warnings thrown out by many, years ago, that bark was only a drug and would be overproduced. Had we all looked upon it as simply an auxiliary, and planted it only along roadsides and in odd corners, we might have kept our export down to six million pounds and preserved paying prices. As it is, the cultivation will never be abandoned. It grows as well as ever with careful cultivation, and I do not believe that the output will fall below the six million lb., in a decade of years to come.

Tea is beginning to shew up and I feel sure that finer fields of tea, than are to be seen on Eskdale and Glendevon do not exist in the island. Most of the coffee estates are getting in an appreciable average of this product, as a secondary cultivation most useful in the assistance of our finances. The leaf will as a rule be sold to the tea estates, whose managers are rapidly providing themselves with the necessary machinery.

Roads.—Our road is beginning to cut up and wants immediate attention. I have not lost faith in the MacBride system as it was defined in the official instructions. Unfortunately, these instructions have never been carried out to the letter save for a short time in the face of district agitation. If Mr. MacBride would tell-off two men to each mile of road, to watch the first symptoms of breaking up and there and then to fill in and blind and pound, his system would yet commend itself to the public for the upkeep of grant-in-aid roads. As it is, all the work is done during three months of the year, the men then disappear from mortal ken, and the road is left to itself. For my part, I consider that the upkeep of all grant-in-aid district roads should be handed over to the care of a District Road Trust, consisting of the district engineer and two resident planters. The upkeep of roads, is no longer a branch of the engineering profession as in the days of Telford or MacAdam. All that is wanted is organization and persistent supervision. The work at present is done in a spasmodic fashion; under a Trust every mile would be in charge of a couple of men, whose work, under a properly organized system, would be seen every day, for every planter through whose estate the road passes, would have a personal interest in the continuity of the repairs. The old adage (a stitch in time) goes to the foundation of what is wanted for road upkeep.

Labour.—Many enquiries are being made for coolies and a good number have left the district, having received advances from other districts. Anyone can foresee further trouble on this head. I myself sent a European in 1862 to India to recruit for coolies. I got a mixture of engine-drivers, sepoys, sailors and riff-raff of the jails, at great expense and had to fall back on the old system of trusting the coolie and the kangani, and cannot say that I have been victimised; on the contrary, the honesty of Ramasamy as regards advances, has always seemed to be very remarkable.

I enclose rainfall statement—for the first nine months of the year from 1880-86.

INDIA AND CHINA TEAS.

The North China *Herald* in discussing this question says:—

People now in the tea trade must look back with regretful envy to the time when tea was synonymous with China and China with tea. Every year brings new competitors with what was always regarded as the birth-place of the tea-plant, and there are far-seeing tea-merchants in China now who believe than in three or at most five years more the tea-tasting profession will be extinct in China. The first blow was struck at China's pre-eminence in the production of tea when the tea-shrub was found to be indigenous in Assam: and there are not wanting botanists in India to declare that the tea-shrub was introduced into China from the slopes of the Himalayas. The second deadly blow was struck when American consumers found the Japan leaf

more to their taste than the China green teas. It is an old cry now how the competition of India with China grows stronger every year; the Chinaman, with the prestige of centuries of experience in the production and preparation of the tea leaf, cannot hold his own with any success against English energy and intelligence. Following in the steps of India come Ceylon and Java as competitors with China; and the first mutterings of the storm are beginning to be heard even in the Straits Settlements, and South Africa. The fact is that the tea-shrub is so hardy, and requires so little attention when it once takes kindly to the soil, that every continent must have districts suitable to its growth, and we shall by and by wonder not that successful competitors with China have arisen, but that China maintained the first place so long. There is evidently little hope, without vast reforms which we cannot expect to see realized, that she will keep it much longer.—It is not to be supposed however that tea will cease to be exported from China; a commodity of which the production is practically unlimited, and the first cost no more than the rent of the ground which the plants occupy, is not likely to be snuffed out altogether. It is the fine distinctions, the discovery and maintenance of which have been the occupation of chasees for decades, that will be swept away. Here and there no doubt a special market will still call for a special kind, and it is apparent that the Russians will still for some years prefer the fine teas of China; but the bulk of the China product will be lumped together, or divided into two or three broad classes, and used at home as the foundation of the grocer's shilling, or eighteen-penny or two-shilling canister, as they are called, the required flavour being given by the more carefully prepared growths of India and Ceylon. Foreigners in China have not to blame themselves for this degeneration in the Chinese leaf; they have preached to the Chinese year after year, that the trade must suffer unless more care were taken to make good tea, and not to hurry it to market before it was properly cured. Individual foreigners have tried in vain to get the midlemen—unfortunately they do not come in contact with the growers—to see the desirability of having foreign supervision over the manipulation and preparation of the tea. The Chinese have preferred to stand on their ancient ways, and the result will be the early extinction of the tea-trade in China in its present form, and the relegation of China tea, as an article of commerce, to a level with what has hitherto been contemptuously designated as "truck."

INDUSTRIAL ENTERPRISE IN SIAK.

The Native State of Siak on the east coast of Sumatra made over to the Netherlands along with Acheen by Mr. Gladstone's Sumatra treaty of 1871, is now attracting some attention in Java and Holland as a promising field for enterprise in the cultivation line. Several capitalists at Amsterdam have secured land there for opening out a tobacco plantation, and have actually set about operations by last advices. As will have been seen in our recent article on the productive resources of Siak, the waste land available is admirably adopted for tillage so that with common prudence, there is every prospect of success of rewarding the exertions of both planters and financiers. Among the productions which abound in the forests of Siak and have proved a spur to commercial enterprise are the trees yielding the prime trade articles styled Balan and Suntei. Under the name of Siak vegetable tallow, they are exported from Singapore, and have gained a high repute in the European market. Balam and Suntei trees are said to be found in any quantity in forest tracts, not only on the main land but also on the islands off the cost. The information available points to the likelihood of their being mostly met with in primary jungle on moist land near the coast The Balam tree is from 60 to 80 feet high. It also yields gutta of inferior quality used for adulterating superior kinds. The timber turnedout therefrom is white and not of a lasting nature. The Suntei tree is less big its measurement being 50 to 60 feet. The timber is reddish brown and in great demand. Seeds of both these kinds of trees have of late years been regularly collected and forwarded for the most part to Singapore, where, from their lobes, tallow is manufactured which is used for sundry purposes, and is in great demand throughout Europe. The collection of the fruit is an important item in the domestic finances of the people. From November 1884 to March 1885, no less than 200 coyans of tallow-yielding material were collected and disposed of at high but fluctuating prices. The usual price per coyans is from 60 to 100 dollars, rising sometimes to $120. The pulp is taken off by hand very easily. The seeds after being dried in the sun are then shipped off to Singapore. A few Chinese at Bengkalis have taken to the preparation of the tallow but in a very rough style indeed. The Balam tallow is yellowish in colour, rather bitter in taste, and as plastic as wax. It is used in sugar refining, in making artificial flowers, in preparing tapioca, and for other purposes. It is smeared on the pans heated to a high temperature upon which tapioca is dried. The larger portion of this kind of tallow prepared at Singapore is forwarded to Europe. The Suntei tallow is pure white in colour, has a sweetish taste, and is used by the natives for cooking purposes. In its extraction by the native method there is a good deal of waste. Prepared at Singapore the percentage of tallow is higher. The market price of both sorts varies from 7 to 15 dollars per picul. These rates are readily paid on shipments for Europe. It is evident that, gradually, this branch of industry will so increase in importance and extent, that research will lead to trees of the coveted kind being found in other localities throughout Siak. The trees do not need to be destroyed to secure the product so that they do not run the risk of dying out. Considering the important place taken by Siak vegetable tallow in the list of articles making up Straits Produce, the advantages attending the experimental cultivation of the trees yielding the article by our garden authorities are too obvious to need more than drawing attention to the subject. At present it is hard to tell whether growing them will prove profitable if taken in hand by private enterprise. The average yearly yield of dried seeds from a full grown tree is as yet an unascertained point. Any estimate so far of the pecuniary value of each tree in bearing is hence impracticable. Other trees of the same species take 20 to 25 years to attain full growth. Few private individuals would be at all inclined to take this branch of cultivation in hand at the risk of the capital sunk in the enterprise remaining unproductive for so many years. Planting it may however prove advisable for afforestation purposes. The importance of these trees to the people of Siak may be judged of from the fact that, though this branch of industry is still in its infancy, 600 coyans of seeds are, on an average, exported yearly, valued at 100,000 guilders. Several specimens of both these tallow yielding trees have reached the Government Botanical Gardens at Buitenzorg and more are expected shortly, besides consignments of seeds. We trust that the economic section of the Gardens here will soon be the richer by including samples of these valuable trees among its treasures.—*Straits Times, September 25.*

SPECULATIONS ON THE PHYSIOLOGY OF TEA

are indulged in by the London correspondent of the *Indian Tea Gazette* thus:—

Tea in Johore is still confined to two or three small experimental gardens, the largest not much exceeding, I believe, 35 acres of tea in full bearing. This Garden was started by the Maharajah (now sultan) of Johore as an experiment, and has since become private property. It is rumoured that a gentleman interested in the tea-trade of Formosa, is negotiating for a share in this property with a view to extending on a fairly large scales. The climate is a forcing one, rain falling regularly every afternoon, expections to this rule being considered quite of the nature of events. This

regular rainfall modifies the excessive temperature, and renders the climate not disagreeable (for the tropics). Chinese labour is chiefly relied upon. Hitherto the resemblance to Ceylon experience, of a temporary extraordinary yield in the cases of coffee, cinchona and spices, more particularly of the latter, only to be followed by disease and disaster, has marked the history of cultivation in the Straits, Malay Peninsular. It remains to be seen whether tea, as prophesied on a *quasi* scientific hypothesis, will follow the same course. For my own part there is a noteworthy difference between tea on the one hand and spices and coffee on the other, if we exclude cinnamon and roots. Thus tea is a *leaf* crop, the others for the sake of argument are *fruit* crops. Now, it is an accepted axiom that fruit is an effort of nature exerts herself in proportion to the danger which may be incurred by the species. For this reason we expose the roots of vines, peaches, &c., and produce temporary debility, so to speak, and this excites nature to put forth her utmost efforts to insure reproduction, which efforts once excited we feed and nourish with rich and suitable manures. In the case of the wonderful yield of coffee obtained in Ceylon in the palmy days, we may have had the best index that either the soil or the climate was not suited for the permanent endurance of the plant, inasmuch as nature made such extraordinary efforts towards reproduction, thereby under the above axiom telling us that the healthy appearance of the bushes was misleading, and that their vitality was low, just as a powerful man to all external appearance may have the seeds of death maturing within him. Now, the yield of tea in Ceylon bears on this line of reasoning no analogy to the past experience, *re* coffee and spices. Where, however, we may look for an index, if this mode of reasoning has anything in it, is in the yield of tea-seed per acre in Ceylon. It is not alone a matter of curiosity, but of great importance—as establishing a precedent for future guidance in respect of other crops—that planters in Ceylon should at this early stage compile statistics of the yield of tea-seed per acre in various localities, which statistics should be carefully filed by some record-office in Ceylon. These statistics should in the first instance be compared with the average yields of similar—*jat*—plants in Assam, and cases of excessive yield carefully noted and tabulated. Should a large excess be noted perennially, then, under above axiom, that excess should indicate the approach of disease, blight, &c., and efforts should be made to stave off the evil day by applying the particular manure which chemists should be able to recommend after comparative analyses of tea-soils and Ceylon soils. The vast difference in the seed yield of different *jats* in Assam is so remarkable as to make the insistence of special care in comparing the statistics of the greatest importance. The above axiom is borne out by these very differences of seed-yield in Assam. *Pure* indigenous bushes *under cultivation* and sickly old China bushes give the largest yield. Healthy hybrids give the lowest seed yield. The pure indigenous have not become habituated by "heredity" to exposure and to pruning and plucking and in fact to artificial living, and, "feeling," upset so to speak, in fear of death, seek to reproduce the species. The low, old Chinas found on some of the oldest gardens, come from a worn out stock deteriorated by centuries of artificial existence in China, and being old plants too in themselves, without a strain of the indigenous to reinvigorate their *effete* race, also, spend their strength in efforts after reproduction. The healthy hybrids, being the result of new life infused into stock already accustomed to abuse and unnatural usage, embrace many of the characteristics of mules; and being vigorous and hardy, under the conditions for which by descent on both sides they have been produced, they make but little effort to reproduce the species. This reasoning might be followed up in a search after the best crosses, as I by no means wish it to be supposed that I am here advocating a cross direct between a pure indigenous and a pure China. On the contrary, we want the smallest possible amount of the deteriorated China race which will suffice to infuse the asinine quality of long suffering under abuse and unnatural treatment into the more desirable qualities of the thorough-bred. Crosses are now so woefully mixed in Assam, that few gardens are suited for using as true tests, but there are many which would serve for all practical purposes. Were Ceylon planters to send a commission to those gardens from whence the seed used in Ceylon had been sent, to report upon each, with a view to comparing the *jat* conditions, and surrounding *jats* of the parent gardens with the progeny as visible in Ceylon, it might save vast sums being wasted in the future. The whole scope of the enquiry and comparison is too vast to enter into here, but if a botanist, who had made a special study of the laws of reproduction were to accompany the commission, its usefulness would be increased. Take one instance. An estate planted on shallow strong soil in Ceylon might have a dangerously high record in seed yield, yet the parent garden planted on deep, rich, forest soil in Assam might be all that could be wished. Its seed, however, would be totally unsuited for that particular Ceylon plantation. The way in which people have gone in blind-fold and purchased their seed merely because it was the "best"—for its own conditions—irrespective of all the teachings of science as to "heredity" and the laws of reproduction is staggering. They would not attempt to breed their racers by sending their Arab to a donkey to obtain produce qualified for weight carrying, why should they be less particular in a matter of vital consequence to the success of their plantations?—*Indian Planters' Gazette.*

ARNOLD'S COFFEE MANUAL.

As much literature has lately grown up about the cultivation of tea, we are glad to welcome a book.* that is likely to recall public attention to the advantages of the cultivation of coffee. Many excellent works on this subject already exist, but they are, in many cases, of a nature little calculated to attract the notice of any one contemplating opening a coffee estate in India, or to give him much useful information as to what he may expect during his first few years in this country. Some of these books are antiquated; some, and, perhaps, the best refer exclusively to Ceylon, where the conditions of life are somewhat different to what they are in India; while others diverge into questions interesting enough in themselves, but which have little to do with the matter in hand. Now Mr. Arnold's book gives a very fair idea of the work that has to be done in opening and managing an estate, and of the planter's life and surroundings. It does not make the mistake of representing the life in too enticing colours, but neither does it fail to show that the pursuit has many attractions for those who are suited for it. Readers of the author's former work will remember that his experience was principally gained as one of the first Europeans in the Neillampathy Hills, where the life was then about the roughest, and the difficulties of all kinds the greatest, that coffee planters have had to contend with in these latter days. His account of a beginner's troubles and of some items of expenditure must therefore be taken with a certain amount of qualification; but his book will be found eminently readable. It contains a great deal of useful information, and though some of his opinions are open to controversy, they are never put forward with the aggravating air of superiority found in some writers on kindred subjects.

Mr. Arnold commences with the inevitable historical retrospect, and briefly traces the history of the plant from its original home in Abyssinia, whence it appears to have been first introduced to Arabia in the 14th century. An enterprising Bishop attempted to grow it in England about 1796, and the Dutch have a tradition that all their Eastern plantations are from seed grown in Holland. The first planting in India

* *Coffee: Its Cultivation and Profit* By E. L. Arnold on don, Whittingham & Co., 1886.

was made in Wynaad, as an experiment, in 1822 by Major Bevan, and somewhat later Mr. Cannon opened his celebrated estates in Mysore. The various species of the plant are next enumerated, and a glowing account is quoted of that atrocious and unpronounceable fraud the "Maragogipe" coffee. Indeed, we are inclined to quarrel with Mr. Arnold for devoting two pages to an extract on this subject—which first appeared, if we are not mistaken, in a circular—and for apparently accepting the wild statements therein made about that variety of coffee as undoubted facts; if he had examined any of the beans he would have found them rather smaller than ordinary coffee instead of being "much larger," and any planter who had experimented with it, could have informed him of its worthlessness, in this country at least. We next have an account of the climate and soil most suitable for coffee, and may raise a casual objection to the statement that "the best zone of latitude for coffee is 15° on each side of the equator." As to soil, the recommendations on this point are, we think, good as far as they go, but the author himself remarks that it must be remembered by the intending planter, that "an estate may have everything to recommend it to the external view, and fulfil to a nicety all the conditions he has been taught to seek for, and yet disappoint when the crucial test of crop time comes." In fact, excellence of soil is one of the most deceptive of all tests on which to rely; negatively it may be a good guide, as there are classes of soil which no one with any experience would care to put coffee in; but affirmatively it is likely to be neutralised by many other considerations. The next chapter is devoted to an account of the means employed to get together a gang of coolies, and of the various races the beginner is likely to come in contact with. Some useful hints are given as to the best way of treating them, so as to gain their confidence, and induce them to remain on an estate; and the author then proceeds to give details of the various works that have to be undertaken in connection with opening. It is this part of the work that will probably be found most useful to the beginner. The question of cost is an important one, and Mr. Arnold thinks that nobody should attempt to open on his own account with a smaller capital than £5,000. We shall have occasion hereafter to analyse his "estimate for bringing 200 acres of forest land into bearing," but even if we adopt the somewhat lavish scale therein advocated, we find the planter who starts with £5,000, at the end of three years with his estate of 200 acres in bearing, all his buildings, except cattle sheds, complete, and about £2,600 in hand. Now this is a state of felicity which most men, and all coffee planters, would be glad to work a good deal longe for, and, as a matter of fact, comparatively few of those who have succeeded in coffee commenced with as much as this fortunate youth's balance.

The account of the numerous countries in which coffee can be grown is interesting. Burmah appears as likely to come to the front in this respect as any other place, for the authorities are anxious to establish the industry there, and have offered considerable advantages to planters. The first accounts received from the Tavoy district were rather encouraging, but we have not had much opportunity lately of judging how things are going on. So much depends upon the course of events in Brazil that we should have liked our author to have given more space to an account of the present state of the cultivation and prospects of coffee in that country. The information is to be found in Mr. Van Laerne's book, but this is not even referred to. There can be no doubt that the cultivation of coffee in Brazil is gradually declining; but it is dying very hard, and it would be difficult to say with certainty that the influence of Brazil coffee on the markets of the world is appreciably less than it was five years ago. The abolition of slavery, and the consequent inability of proprietors to work their estates as economically as they now do, are powerfully destructive agents, but absolute prediction on this matter is nearly useless. Of the other countries noticed as likely to compete with India and Java, little need be said here. Ceylon need not have been omitted by Mr. Arnold from his list, for the export is still large, though terribly decreased; in Natal, the attempt to grow coffee has been an utter failure and there does not appear to be much likelihood of estalishing it in Queensland. New Guinea appears to be adapted for ths purpose, but immigration to that great island is not yet encouraged. The West Indies, especially Jamaica, produce a limited quantity of very fine coffee, but on the whole "middling plantation" appears likely to decrease in quantity, and rise in value in the near future.—*Madras Mail*

Scientific Tea Manufacture.—"Another Old Planter," writing to the *Indian Daily News*, takes up this subject, and abuses all who differ from him in the necessity for a "scientific" knowledge of Tea-making in India. He states that he does not believe there is a man in India with the requisite scientific knowledge. As long as there are men with a *Practical* knowledge of Tea making, and who can succeed in making good Tea to fetch good prices, we should prefer them to any number of chemical experts. You may overdo even chemical analysis. We should have thought that if the cognomen "Old Planter" is a correct one, he might have told us something about the "science in Tea-making" of which he says all are ignorant; but although he claims to have age and experience, and presumedly therefore "scientific knowledge," he seems indisposed to part with any of the results of the latter for the benefit of his neighbours.—*Indian Tea Gazette.*

A Plague of Earwigs.—Earwigs are a perfect plague here; the place is swarming with them. They eat the hearts out of lettuces, injure fruit trees, and otherwise do harm in the garden. Is there any ready way of getting rid of them?—Hazelwood (King's Langley, Herts). [These destructive insects cannot be destroyed upon the plants they are devouring, but they can be trapped in several ways. The dahlia grower places small pots, partly filled with dry moss, upon the tops of the stakes, into which they gather for shelter and security through the day. These he examines every morning, and casts the occupants into hot water. The fruit grower places pieces of beanstalk 8in. or 9in. in length about his trees, and once at least every day blows the earwigs into a bottle of hot water. Earwig traps, too, can be obtained from dealers in horticultural requisites, but their superiority over the gardener's primitive contrivances is doubtful. The insects being so very numerous in your garden, get small pots 3in. diameter, by the score or the hundred, put a small piece of dry moss into each pot, place them on their sides in your lettuce beds, anywhere and everywhere about the garden, where they will be partially or entirely covered by the foliage or other shelter from rain. Equipped with a can of hot water, send a boy round every morning—the earlier the better after they have retired from their night's feed—and he will soon make a perceptible reduction in their number. Some put a piece of raw potato into each pot, but this is superfluous, as the earwigs go out to feed by night, and only require a dry shelter from rain and cold. This system of catching and killing is the best for the time being; but, to prevent a recurrence of the plague another year, dress your lettuce and other beds with gas lime as soon as the crop is off, and let it lie until the time arrives for winter digging. Scrape the surface soil away from nut bushes and other fruit trees, and let it be burned, but do not place the gas lime near the stems, as it is powerful and dangerous to the roots. Collect all the soapsuds from the laundry into tubs or tanks, and, so soon as the leaves have fallen from the trees, commence washing every twig and stem, also the old walls and trellises, with the garden engine or an old syringe. Repeat the washings throughout the winter as often as the supply of soapsuds will admit, and the earwigs will not again trouble you. The benefit will not, however, end here, as moss, lichen, and the larvæ of other insects will disappear.—*Field.*

CARDAMOMS IN SOUTHERN INDIA.

COORG, 28th Sept. 1886.

DEAR SIR,—I think if your correspondent "Aberdonensis" could give the nett price per lb. realized for the whole crop (refuse included) of the M.M.M. & C.C.C. estates, it would be a better comparison with Ceylon & other S. I. marks. I believe the above estates send only the *very finest* of their cardamoms to the London Market.

Though not up to all the "tricks of the trade" I managed to nett R1·6 per lb. for my crop this season, the whole of it being sold in the country. The fancy bleaching, which our Mysore friends think so profound a secret, is very generally known now. One of the firms on the Coast make cardamom, pepper and ginger curing a special branch of their business, and I hear a partner of the same firm is going in extensively for cardamoms in the Wynaad. It would be interesting to know if the Ceylon planters are still planting them to any extent; and if the estimated 250,000 lb. for this season is likely to be exceeded in the ensuing season.

The lease of cardamom jungles in Coorg having expired this year, the Commissioner invited tenders for their lease for any period not exceeding 21 years, subject to rather stringent rules. I enclose for your readers, benefit, a copy of the form of agreement the fortunate tenderer must enter into. Strange to say, notwithstanding the new rules and the heavy decline in the cardamom market, the rents in most cases have gone up considerably, clearly shewing that the natives at least consider it a paying spec.

The cardamom crop will be a mediume one. The rain in January forced the racemes out too early and not being followed by showers in March, the b ossom got burnt up. The monsoon has been light and enjoyable, the heaviest rain being in July. The weather for planting could not have been better,

Showers and sunshine. YELAKEE.

FORM OF AGREEMENT IN RESPECT OF LAND LET FOR THE CULTIVATION OF CARDAMOMS.

I son of of village Nad Taluk, being the successful tenderer for the lease, for the space of years from the 1886, of the Malle situated in the village of in nad of the Taluk, the estimated area of which is acres, and which is bounded as follows:—

North
South
East
West

do hereby agree and contract to abide by the following conditions:—

1. The sum of Rupees shall for the first 7 years be paid by me annually into the Government Treasury on account of the rent of the said malle on or before the 20th January of each year, commencing from January 1887. In the case of this lease being for 14 years or under, the amount of the aforesaid rent shall be subject to revision by the Deputy Conservator of Forests at the end of the 7th year from the date of the lease, according as circumstances and the ruling prices of Cardamoms may justify. In the case of this lease being for 12 years or under, the amount of rent as prescribed on revision at the end of the 7th year as aforesaid shall be similarly subject to revision at the end of the 14th year from the date of the lease. If the Commissioner require a fixed deposit on account of rent from me, I will comply with such requisition. For the due payment of rent as above provided for I name and as my securities.

2. If I fail to pay rent as above provided for on the appointed date the Commissioner shall be at liberty to cancel this lease and to grant it to some other person or persons or to dispose of it otherwise as may seem to him fit. Any loss accruing to Government from such cancelment and release shall be recoverable from me, together with interest and process charges, under the rules or existing practice for the recovery of land revenue. The Cardamom crop raised from the said malle will be held by me liable for the Government demand for rent as a first charge.

3. I will not cut any trees in the said malle except such as it is indispensable to cut for the purpose of making plots for the cultivation of cardamoms, or for erecting cooly lines or other buildings incidental to such cultivation. I will replace immediately every tree felled by two suitable saplings. If any tree be cut for other than the purposes above described I hold myself liable to pay the value of the trees as determined by the Deputy Conservator of Forests together with such penalty not exceeding R50, as may be fixed by the Commissioner, on each tree so cut down. No timber or produce, except cardamoms, pepper arekanut and resin on which assessment is paid as specified in the schedule hereto attached shall be taken from the jungle without the special permission of the Deputy Conservator of Forests.

4. (1) I will cultivate the malle according to the plot method; (2) no plot shall exceed in area more than one-sixth of an acre; (3) and I will leave a belt of Forest of at least 30 feet, round each plot.

5. Should I make any plot larger than one sixth of an acre, or by any means bring a plot into such a bad condition as to prevent its regrowth into forest, and to render it unfit for cardamom cultivation, I agree to pay in respect of every such plot a penalty of R100.

6. I engage to keep the boundary marks of the said malle clear and to show the boundaries of the said malle to the Deputy Conservator of Forests or to any Official whom he may depute to inspect the malle.

7. I will not cultivate cardamoms or fell trees or otherwise interfere with the forest or soil beyond the boundaries of the said malle.

8. If any above mentioned conditions be contravened, or if after being warned, I neglect to encourage the growth of young trees in the plots of the aforesaid malle the Commissioner shall be at liberty to cancel this lease, and to prosecute me under any Forest Rules for the time being in force.

Countersignature of Deputy Conservator of Forests.

THE ENGLISH TOBACCO CROP.

In reference to the British harvest, one has now to include a greater and a lesser novelty—namely, maize and tobacco. In April last, when Lord Harris found the Royal Agricultural Society considered the date too advanced to attempt the experiment of growing tobacco, he said, with some confidence, "But the Royal Horticultural Society will try a quarter of an acre at Chiswick." Whereon the writer of this article remarked, "But the public will not be satisfied with Royal societies or gardeners' experiments—*farmers must grow it themselves*, and by the acre." At this juncture the president and hon. secretary of the Ensilage Society, believing the attempt might yet be made in 1886, applied to and obtained from the Inland Revenue Department very prompt permission for several agriculturists to grow "the Indian weed." As a result, there are now at this date, growing and maturing, several acres of English tobacco. I visited two lots last week, and I have to record the first impression of seeing the crop—this was, that the dangers and difficulties said to be lying in wait for the British agriculturist in the cultivation of tobacco are ending, as difficulties often will end when they are met, in smoke. A farmer who is making the experiment, upon my asking him whether, if the crop would pay, he would hesitate to grow it, replied, he should willingly grow fifty acres next season, just as he might fifty acres of any other plant.

But, speaking with all reserve of what is only a beginning, and as referring only to two fields, I may mention that I have received from the Revenue Department a list which includes a score of growers,

who farm in Kent, Essex, Worcestershire, Devonshire, Suffolk, Norfolk. Lincolnshire, Lancashire, Scotland and Ireland.

Now, in July, at the Norwich Show, at the Ensilage Society's stand, were exhibited a few good and forward tobacco plants which had been grown in a garden (some chemists have supposed the silo may be seviceable in preserving the tobacco leaf, hence the special interest taken in the subject by the society); but it was quite a month later before field plants were of the same size as those exhibited at Norwich. Let me, then, speak of the first English field of tobacco visited on Tuesday Sept. 7, being grown at Holloway's Farm, at the foot of Bromley Hill, in Kent, for Messrs. Carter, of Holborn. When I was there, one of the friends we have always with us was also present —the supervisor from Gravesend, in whose excise district the ground was situated. He had watched the crop from the beginning, and expressed his surprise at the thriving state of the plants; they seemed acclimatised, and had nothing exotic or sickly-looking about them. I give this as a second opinion in support of my own. The soil of the field was a good but variable sandy loam, with a little slope to the north. The tobacco plants, of several varieties, were sheltered by hedgerows on two sides, a yard-high partition of matting from other crops on the third side, and open to the sun on the south side. The space covered was three-quarters of an acre, each plant being from the next a yard apart, and being earthed up on a hill. There was decidedly a noticeable difference in the sorts, some being better than others, whilst across the field itself the soil ran in belts—good, better, best the last being almost a black loam. For these reasons —difference of variety and difference of soil—the general surface of the plants was rather uneven. Many of the leaves measured 2ft. 6in. across, and as for the previous three weeks the plants had been pinched or topped, taking away the centre seed-bearing stem, the height was fairly regular. Each plant had seven to ten leaves left. The seed had been originally sown in a bed; next, on the 14th of May, pricked out in boxes; and finally planted out in the field on the 16th of June. The weather that followed for about a month was often ungenial. The varieties called Pennsylvania, Island Broad Leaf, Connecticut, Glassner, Hester, Virginia, Maryland Broad Leaf, appeared most thriving; the Havannah and Kentucky were least so. All the plants were of a good "stocky" character, and their pyramidal growth reduces to a minimum the effect of wind, which was considered as likely to be a great drawback to the cultivation. It is expected the crop will be cut in about a week. Visitors to the farm manifest by their attendance general public interest in the expriment. Insect pests were conspicuous by their absence. No coverings, glass or otherwise, had been used at any time. The leaves have that gummy stickiness which rightly pertains to the leaf. The ground had received farmyard manure in the proportion of twenty loads and 7cwt. of artificial dressing to the acre. In going to the nearest railway station, Plaistow, I observed a small field of inferior maize.

On Thursday, the 9th, I saw more maize and more tobacco many miles from Kent—at the home from, Merton, Norfolk, where Lord Walsingham is making his tobacco experiment, and continuing the already successful cultivation of maize. Here I do not want any second opinion to support my own when I record that the fifteen acres of maize which I there saw is one of the grandest crops I have ever seen. I have seen maize growing in parts of France, Germany, and Spain, but have never seen a similar crop for bulk and beauty as that now standing seven feet high, in plants a foot apart in rows and about four inches in the drill line, each weighing some four pounds. Let the students of Cirencester and Downton reckon up the present weight per acre, and remember for about two weeks more the plant should grow one to two feet higher. Truly this was an English jungle, and I can only compare it to the seven foot high hemp crops I have seen growing on the best lands of th Loire valley. Of course the store for this harve e was the big excavated silo, of which a model was seen at the Royal Show. The maize was drilled 8th to 10th June, and followed an oat crop. Fifteen loads of farm muck and 5 cwt. rape cake per acre was the manure applied a few days before planting. This exuberant vegetation was not in tassel, and, as frosts injure it, the crop will be secured this month. Grass frosts often come in September, but seldom occur at seven feet from the ground.

I have purposely dwelt on the above particulars, because I think they indirectly infer that the last six weeks have favoured broad-leaved plants, and, therefore, tobacco. White turnips, mangolds, and swedes, especially, are looking remarkably well, and possibly, therefore, this first season has lately suited tobacco cultivation. Assuredly the plot of a rood on the Merton farm was in a most thriving condition, and more even, decidedly, than that seen on Tuesday. One reason for this would be in the fewer varieties grown. They are the Pennsylvanian, the Connecticut, the Big Frederick, and some Virginian. They form seven rows across a large field of about 20 acres. These rows are but 30 in. apart, and the plants are at the same distance from each other. The rows run east and west. The soil is a mixed, fairly good sandy loam, with clay subsoil, and had twenty loads of farm muck to the acre. The crop follows swedes. It is to be remarked that the plants took well, and only about a score of misses had to be made good. The plants, I believe, were from Messrs Carter's stock, and were set out on June 16, then being 3 in. to 5 in. high, with four leaves. They were constantly hand hoed, and now the surface soil is quite free from weeds. Since they started in growth they have gone on without check. The colour has always kept good. They are now about 4 ft. high, and some leaves 3 ft. by 16 in., with an average of nine leaves each. Here and there, where the seed stem has been allowed to flower, the leaves of the plant are much smaller than in the plants which have been carefully "topped." The stem circumference is 5½ in. They are entirely free from insect attacks, and to the eye form a beautiful crop in the evenness of colour and thriving appearance. It is expected to cut them in about a fortnight, and take them to dry in a sheep house admirably suited for the purpose, as moveable shutters extend along the sides, and allow the circulation of air in a direct current.

The morning of Friday, the 10th inst., was very unsettled in Norfolk, and much rain fell after midday. Leaving Thetford for Brightlingsea, Essex, to view Mr. John Bateman's experiment, I may note that weather could hardly be more adverse—a circumstance that confirmed my day's arrangements to see his tobacco growing, although under equally wind and flooding rain. Although I had but one object for this journey, to inspect the tobacco crops, there is no good reason I should not record, by the way, that a farmer at Thetford showed me how he utilised some of the headlands of his fields—by planting them with prickly comfrey, a plant much like tobacco; also where there was a long wall to one field, close to which usually nettles and other weeds abound, he had planted rhubarb, which, well manured, smothered all undergrowth, and produced a crop which, for several weeks in spring, brought a return of 12s. per week—a single row more than paying for the rent of the acre of land, which it only bounded on one side. The walk in the rain from Brightlingsea station to the "Hall" farm showed me Mr. Bateman's neighbours were following him in growing maize, and the crops looked generally well, being in tassell and about seven feet high. There are some 35 acres of maize on Mr. Bateman's farm, of whih 30 acres follow the crop of maize I saw last year on Oct. 1, when it was being cut and carried to the silo. This season's crop is heavier, probably 30 tons to the acre, and was manured with sprats 5d. per bushel and some 80 bushels per acre.

Although planted at the same date as that of Lord Walsingham, early in June, the Essex maize was quite ten days in advance of the Norfolk crop. My visit being without notice, it was by chance, that I found a party of a dozen gentleman already "prospecting" the tobacco crop! Amongst them were scientists and

manufacturers of cigars; also a gentleman now living in England, but formerly a tobacco planter and buyer in Virginia. The plot selected by Mr. Bateman for his experiment was a swampy piece of ground draining into a small lake, and with a moist, black soil which had been enriched with ashpit manure. Here were a dozen varieties of tobacco growing, and the plant stood up thick and well against the wind and rain. The seed had been planted in a cucumber frame and raised to the height of three to four inches by June 12, when they were successfully transplanted. They are now fairly ripe, and have remained free from insect pests. The English experiments are too new to have lured over the American worm, which, however, said the Virginian planter, would be sure to find out the tobacco plant, wherever it might be raised. The whole crop at Brightlingsea was in flower on the 10th, not having been budded or topped; so whilst it is tall and thriving the leaves are not equal in size to those I had seen in Kent and Norfolk. Our tobacco planter, philosopher, and friend from Virginia expressed his opinion that this Essex crop was as good as he had usually seen in the United States and Mexico, and he could confidently say the plants properly cured should make excellent cigars or smoking tobacco. He recommended the cutting should take place this week, and that the curing might be undertaken in a silo compartment, which would form temporarily a tobacco shed. The plants having a slit made in the base of their stem, will be speared throughout by oak laths, or threaded by cords, and then be suspended across the silo at some elevation from the basement. On the floor dry wood fires (beechwood preferred, as emitting but little odour) will be kept going for some eighty to ninety hours, to produce the necessary heat and dryness. Next the leaves should be stripped from the stems, and be allowed an amount of fermentation that only an expert could determine. The manufacture into cigars Mr. Phillips, of Colchester, would undertake.

The above remarks infer that English tobacco growing successfully is so far accepted as a general probability, failure not being apprehended; reckoning of course, always, that the drying and curing process of good product can be accomplished by Englishmen in the English climate.

On Thursday last I had expected to see the tobacco crop at Lynsted, in Kent, grown by Mr. Faunce de Lanne, but a letter from that gentleman defers my visit until next Monday, because on that day "he will be taking out one cured lot of tobacco, and be putting in a fresh lot of tobacco. Of the two kinds cured, one lot has come out in the finest yellow leaf, which has been inspected by one of the chief tobacco manufacturers in the country, who pronounces it to be of the best quality. Besides, on Monday I shall be filling my silos with buckwheat and hopbine." This extract carries the experiments a step further—the growing has been successful, and the drying also successful.

Whilst deferring further remarks until more visits have been made, it is desirable to state, as several growers are now wishing to cut their tobacco plants, that, whilst tobacco grown in hot climates is usually saved in the gross, by cutting the plant and drying it off, each separate plant suspended complete, in rows with others, yet in slower and more irregular climates, such as the British islands, it is best to select and pick off the leaves as they mature, and these may be threaded together on string, and be dried in succession.

First, should any grower be pleased with any special variety, and desire to save the selected seed, care must be taken that no frost has touched it, and impaired its vitality. When the seed pods blacken, the seed is ripe, and the heads are cut off below the forks of the plant, and are hung to dry. The seed is rubbed out by hand and winnowed, and if it crackles when thrown on to a hot stove, it is good. An ounce contains about 100,000 seeds; but as the percentage of vitality is low, half an ounce is usually saved to produce the plant required for an acre.

But probably most growers will seek to save only the leaves, and these are ripe when they assume a marbled and yellowish green colour—they increase in gumminess, and the tips bend downwards. The leaves should only be harvested after the dew is off the plant, and not upon a rainy day. When the leaves are gathered singly, the bottom leaves are the first taken. They should be taken to shelter—even a tree will serve the purpose; but commonly the grower will have some suitable shed, where the whole plant, or the strung leaves, may be suspended to dry. They must not be hung so close as to press each other. Usually a dry day is sufficient to "wilt" the plants, so as to allow them to be handled without breaking or tearing the leaves. They may then be dried, and below is given an illustration how tobacco plants are suspended for drying:

The drying shed should be ventilated so as to allow of regulation of the currents of air. Everyday the leaves must be carefully examined, as they dry unequally. Experts recommend that artificial heat should be supplied, and this should be conducted into the drying shed without the fire or the products of combustion being admitted; but, as stated above, many Americans light wood fires on the floor, and cure tobacco much as bacon is cured by smoke. Confirmation of this mode—referred to at Mr. Bateman's meeting—has been given to me by a former large grower of tobacco in America, who has had 100 acres in cultivation. One coloured workman was reckoned sufficient to look after four acres of tobacco. The arrangement of a tobacco-drying shed is much like that of a fish curer, the object in both being to keep the plants or fish close and yet apart. When the tobacco plants or leaves have become dried, and yet are pliable, the process of stripping commences, which is done in a moist atmosphere, and then the selected leaves are graded and made into hands, *i.e.*, ten to twenty leaves are tied together, and each day these "hands" of tobacco are "bulked" together in heaps 4 ft. to 8 ft. square (of course this refers to cultivation on a large scale, and experimenters can only reasonably follow the methods), with all the stalks outside, in order to ferment. The amount of fermentation can be controlled, as in the making of ensilage, and the process lasts an irregular time. The bulk is often pulled to pieces and rearranged through days and weeks. Some tobacco is fit for smoking a few weeks after drying, whilst it is usually some months before it becomes an article of commerce.

The above details, simplified and reduced as much as possible, may appear to claim great skill and trouble, but actual practice makes them easy and quite within the scope of ordinary farmers who may grow tobacco.—Invicta.—*Field*.

A Present of Coffee Leaf Disease from Cashmere.—We have just received a packet from Cashmere containing four or five coffee leaves more covered with leaf disease than any we have ever observed. The leaves are enclosed in a piece of paper, on which the following is written:—"Coals to Newcastle, or leaf disease (of sorts) from Cashmere." The present serves to show us that we are not the only ones troubled with *Hemeleia vastatrix*, though the number in this colony who now take much thought concerning this fell pest is getting fewer every day.—Local "Times."

At the British Pharmaceutical Conference were read two papers on quinological subjects. Mr. Hooper's paper dealt with experiments in Madras. He showed that renewal by shaving greatly increased the quinine value of the bark, and that manuring has a somewhat similar effect in a less degree. The paper also contained details of analyses of barks at different ages, and concluded with a reference to the effect of mould on bark, which is almost nil. Mr. Howard's paper was one of considerable interest, and contained the results of many analyses of various cinchona barks, all of which, contrasted with a review of what was being done in cultivation of the bark, led him to predict that profitable cultivation can only result from the propagation of the highest quinine-yielding trees.—*Chemist and Druggist*.

TEA MAKERS.—A writer in the *Indian Daily News* signing himself "Old Planter" declaims against the custom of employing native superintendents of Tea factories. He would have a "good, active, intelligent European" placed in charge of the Tea-house, who should be required to remain in the Tea-house from the commencement of manufacture till its finish, and on no consideration to leave the building—all his meals being brought there to him. "The Old Planter" must, we fancy, have had very limited experience, or he would know that on all large factories the Assistant in charge of the Tea-making is a European, and that he *does* remain in the factory during manufacture; sometimes half through the night.—*Indian Tea Gazette.*

JAPAN CLOVER (LESPEDEZA STRIATA, H. A.)—My attention, says Dr. Schomburgk, was directed to this valuable fodder plant by Mr. F. E. Schlegel, of Beachport, by his sending me a cutting from a Californian paper (the *Rural Californian*), which gives a glowing account of this remarkable plant. The extract runs as follows:—The perennial Clover, Lespedeza striata, is now covering thousands of acres where in 1886 it only covered 10 feet square. It grows in the plains, and at an altitude of 4000 feet, and stands well through the midsummer droughts, flowering and blooming until the frost comes, and living after most herbage is dead. It grows on every kind of soil—rich or poor, clay or sandy, dry or wet—and is deep-rooted and improving the soil. It never runs out, and can be fed off without injury. It is wonderfully fattening, and contains—

Nitrogen matter ...	16.60	Potash	0.88
Fat	1.10	Soda	0·51
Ash	5.92	Phosphoric acid ...	0.39
Lime	0.99	Sulphric acid ...	0.20
Magnesia	0.56		

—*Gardener's Chronicle.*

DEPENDENCE OF THE GROWTH OF WOOD UPON METEOROLOGICAL FACTORS.—A. Spamer communicates the following conclusions as to the dependence of the growth of wood upon meteorological factors:—1. Temperature and precipitation are the meteorological phenomena that affect the process of the formation of wood. 2. Of these two variable quantities during the principal period of growth, the rainfall diminishes the formation of wood while the heat increases it. 3. The principal period of wood growth is from July to October, at least for the plants which are very sensitive to frost. 4. The rainfall seems to influence growth more than the temperature. [Excess of rain diminishes growth more than excess of temperature increases it.] 5. The growth of different plants is not affected in the same degree by the rain; some are affected more by rain and others by the temperature. 6. In many periods only one of these factors appears to exert any influence, the other being inactive. 7. Possibly this anomaly may be explained by observations of the duration of insolation. 8. The increase of carbonaceous compounds goes parallel with the increase in the inorganic constituents of the wood. 9 The aqueous component of the wood dimnishes when the carbonaceous increases. 10. The so-called ripe wood [the heartwood] differs from that which is less ripe by a greater amount of ashes and carbon.—*Smithsonian Institute Report.*

CULTIVATING THE MAMMOTH SEQUOIA OF CALIFORNIA.—To the editor of this magazine one of the most interesting lessons learned in California was one which only one experienced in the culture of trees could learn; namely, that the Sequoia gigantea is by nature a swampy tree. The places where they grow now are comparatively dry; but two or three thousand years ago they followed the track of descending glaciers, and they received the melting snows from the tops of mountains that have no summer snows now. The ground on which these mammoth trees stand, once very wet, or even swampy, has become drier through the long ages. Horticulturists know that swamp trees generally grow very well in ground that is comparatively dry, but seeds of such trees will not sprout in anything but the moist oozy moss on the top of a swamp or damp ground. Hence the only young trees we find in the mammoth tree locations are where a chance seed happens to fall on a moist rock, or other damp situation. Young trees are common only in one location, where clouds condense against a mountain-side, and the whole situation abounds with springs and oozy spots. Here in the east hundreds of trees have been planted during the past quarter of a century, but rarely has one lived more than a few years. They do not mind the winters. We have known them stand 20° below zero uninjured, but some fungus, favoured by a dry atmosphere, carries them off gradually during the summer season. Profiting by these facts, the writer brought three strong plants from California and set them in a swamp. Usually when we set swamp trees in a swamp they will not grow unless they are suffered to grow into the swamp themselves. We make a mound and plant them in the mound, from whence they root down as suits themselves. These three plants have had two winters and one summer the past winter being a terribly severe one. Today they look perfectly sound and flourishing, and the editor believes that he has at last discovered how to make the great tree of California thrive in eastern gardens.—*Gardeners' Monthly.*

CINNAMON CULTIVATION IN CEYLON.—Cinnamon peeling is at a stand-still owing to a heavy bud being on, and will possibly not be resumed till this month is well nigh over. In the meantime the favourable weather is causing the bushes to grow apace. I have to congratulate you on a new departure, or rather on the resumption of an old practice, the making public the results of the Cinnamon sales. As the form in which you give it is open to improvement, I trust you will favourably entertain my suggestion to give the price each quality fetches, the same as is done with Tea. This will afford more information than simply giving the range of prices and the average. The average price any produce of more than one quality fetches, is a very misleading test to apply as to its excellence. The average price is lowered or raised according as lower or higher qualities predominate. The brand that heads the list, occupies that exalted position owing to its two first qualities only having been sold. The older Estates, where the soil is sandy and the growth not very vigorous, can as a matter of course make a larger percentage of the finer qualities of Cinnamon. The same with the Estates, that, in direct violation of the Resolution passed by the Agricultural Association, and by which they were bound, never gave up the short-sigted and pernicious practice of scraping Chips. Estates were, owing to the richness of the soil, the growth of the Cinnamon is vigorous, will have the bulk of the Cinnamon consist of the lower qualities, unless very tender Cinnamon is cut. One noticeable feature in the shipments from Mr. De Soysa's numerous Estates, is the absence of the 4th quality Cinnamon. Has he gone a step beyond the Resolution of the Association, or does he convert his 4th quality Cinnamon also into Chips for the still? The Lairds of Wester-Seaton asserts that if all Cinnamon Planters had followed his example, and scraped Chips only for the still, the price of Cinnamon was bound to rise. I go further than he, and say that if all Cinnamon Planter's had followed my, I believe, solitary example, and did not scrape Chips at all, the price of quilled Cinnamon was sure to have risen. Cinnamon oil is but a concentrated form of Cinnamon, and for some purpose can with advantage be substituted for it, under these circumstances it must be regarded as much a rival of quilled Cinnamon as Chips. But the respected Laird of Wester-Seaton so little believes this, that he consistently refuses to sell Chips except for the still, even though he receives a higher offer for them, and asserts that he will sooner bury their Chips, than sell them for export. Paddy-crops are being harvested everywhere, and the air resounds with the cheering strains of harvest songs. Except in a few favoured fields, crops are not above the average. —Local "Examiner."

THE PROSPECTS OF CEYLON CINCHONA BARK.

We call attention to the letter of Mr. John Hamilton on page 332, and feel sure it will be read with interest both by tea and cinchona planters. It is with reference to the latter portion of his remarks that we would wish once more to consider the position of the holders in this island of cinchona bark whether on the trees or in the stores. Mr. Hamilton, like so many other authorities, quotes with approval our remark that Ceylon cinchona planters have for several years to come, more to fear from themselves in the way of competition, than from any other quarter. The more information we receive and the more we study the subject, the clearer this becomes, at least so far as the course of supplies for the next four years is concerned. We do not see that the exports from Java, India or Bolivia can, up to 1890, seriously affect the position attained by Ceylon; although after that the case may be different.

But the question is, suppose Ceylon to go on for the next four years exporting 12 or 15, or even 10 millions lb. of bark per annum, in what position would our plantation clearings or bark supply be at the end of that period. This is a most important question to have answered, and we are glad to see that the Dimbula Planters' Association has taken steps to have the requisite information collected after a careful and authentic fashion, and we trust the example so set will be followed by other Associations in the cinchona growing districts. At the Dimbula meeting we learn Mr. James Sinclair called attention to the subject, disputing the accuracy of the statistics supplied or worked out for our Directory, and although the remarks he made could not be embodied in the Secretary's report we have received a copy to which we readily give a place:—

"Cinchona bark has fallen to such a low figure, that it has really become a question whether much of it is worth the expense of placing on the market. There is too, an idea prevalent, which speaking for myself, has assumed something more definite, and that is, that before long (but too late for most of us) a re-action is bound to set in; I mean, when the bulk of the article has been shipped from the island, and this date at the ratio of shipments for the past three years cannot be far off. Fairly accurate information on this point, gentlemen, is within our reach, if we will but set about it. I beg, therefore, to propose that this Association do communicate with the several District Associations interested, with a view to obtaining for each body the following information:—

I. The estimated acreage under cinchona.

II. The quantity to be harvested for the years ending Oct. 1887 and 1888.

If we can induce the other Associations to aid us, as I say, fairly accurate figures are possible, and we shall then know the *best* and *worst* of our position. If, unfortunately, it should be the latter, it might yet be one which some such regulating Syndicate as I propounded lately in the newspapers, (which some of you may have seen) would enable us to some extent at least to participate in the rise of value, which we all know *must* take place after our fields have become denuded. In the *Observer* of Friday and "Times" of Saturday much interesting information is given, also the opinion of the greatest living authority on bark (Mr. Howard), viz., "that the price of cinchona entirely depends on the exports from Ceylon." This coming from one, who has probably the greatest facilities of any one individual for acquiring information from cinchona-producing countries, may be accepted as true. Another no mean authority, Mr. John H. Hamilton, tells us that we have more to fear from our own exports than from those of any other country. With such testimoney to that effect before us, can we not go hand in hand in obtaining accurate figures of the total acreage now in the island? The following figures and conclusions being given only to illustrate our possible position regarding the product, I need not now take up your time by stating how I have arrived at them, but I may mention, in passing, that such an enquiry as I propose will probably prove them fairly correct. Let us take the whole area in Ceylon under cinchona at 20,000 acres with 1,200 trees per acre, which when all matured, say at 30th September 1888, would yield one pound of dry bark per tree, or twenty-four million pounds. Suppose we once more ship 15,000,000 lb. of which quite ⅔ds would be stem, branch and root bark, or say ten million pounds we have but fourteen million trees on which we can operate during 1888, by shaving or any other process. If therefore, gentlemen, my figures are nearly accurate, consider the re-action that would take place in the value; why, I believe we should see the unit at 1s again, and all our bark gone; surely this would be too tantalizing on the back of all we have had to bear these last eight years. I hope therefore, you will support this resolution; and when information is asked by our Secretary, that every care will be taken in framing estimates. I am aware there are many who do not belong to any Association and who may decline to furnish information, but there must be few who would wantonly throw obstacles in the way of such an enquiry, and if there are, their neighbours can generally give a rough estimate to make the return as accurate as possible."

We are as keenly anxious as any planter can be to give only fair and accurate returns of cinchona under cultivation as of all other products and we shall be much pleased to get the result of the Dimbula enquiry. We think it likely enough that our returns will be found above the mark, only it is possible that Mr. Sinclair forgot they were compiled before much of the past season's very heavy export was harvested. At the same time Mr. Sinclair's own figures must be decidedly below the mark: to say that Ceylon has only 20,000 acres with an average of 1,200 trees per acre, yielding about 24 million lb. in all by 1888 must be far below accuracy. Mr. Sinclair can have but a poor idea of the cinchona clearings and interspersed plantings in the several divisions of Uva. From the best authority in Udapussellawa we have a very interesting and able report in which Mr. Dick expresses the opinion that cinchona may be regarded as a permanent cultivation, and further that in a decade of years he does not believe our exports will fall below six million lb. From another reliable authority—a gentleman who we believe has been taking stock of the different districts,—we have estimates which we consider much nearer the mark than those of Mr. Sinclair. In estimating for next season's exports the correspondent we refer to, while venturing on 11 million lb. as a possible total of exports for 1886-7, adds that he thinks "40 million lb. of cinchona bark still remain in the country." This seems to us as a much more probable approximate estimate than 24 million lb. in 1888; but although the former may appear large, in reality—remembering to what a limited extent comparatively, cinchona is being planted in this tea era,—40 million lb. is by no means a formidable stock to place before the world. On the contrary if it could be shewn that were Ceylon to ship say 10 million lb. for four consecutive seasons, the export would then of necessity drop down to five to six millions, the effect would inevitably be to strengthen the position of our bark in the European market very considerably. It is the uncertainty that Ceylon may not go on pour-

ing in at the rate of 15 millions lb. (or even more) per annum for an indefinite period that has adversely affected prices. It therefore becomes a question of supreme practical importance to all interested in Ceylon cinchona to set a careful reliable enquiry afloat, and we know no better medium for obtaining the information than the several District Associations.

In this connection we would refer once more to the proposed Ceylon Cinchona Syndicate, regarding which a competent commercial authority offers the following remarks in a semi-private letter to us:—

"About the formation of a Syndicate for the purpose of helping planters who are obliged to crop their cinchonas (in order to meet their expenses of tea-planting), from glutting the market and thus reducing prices to a ruinous rate per unit, not alone for the poorer men, who are obliged to coppice and shave or uproot, but for men who are fairly well off, and whose cinchona is harvested in the ordinary course. In some cases to make room for tea, planters have only lost by rushing their crops into the market and obtaining prices barely sufficient, and in some cases not sufficient, to cover expenses. The matter lies in a nutshell, and all it wants is *cohesion* on the part of the growers of cinchona and if petty jealousy could be got rid of, the Colombo agent would really be as much benefited as the planter, as he would be saved from shipping cinchona when the market was overstocked and the crops could be shipped through his agency and the bills drawn on the London houses to whom he sent crops, just the same, without taking a cent from his pocket. In fact, he would be benefited by it as the prices would be higher and he would thus be in a position to *realize* his advances to the planter against crops. Planters must agree to be guided by advices from home and they would be subject to the control of a Committee of the Syndicate, as to when shipments should take place, the produce for shipment being taken in the order of dates of receipt at Colombo. The more I think of it, the more certain I am of the success of such a Syndicate, which really might be termed a Mutual Co-operative Society.

"We will assume that 100 planters joined (but of course the number ought to be greatly exceeded) and sent their cinchona to Colombo. On its receipt it would be baled by their own agents or by any one the planters pleased. Samples drawn for analysis and those who *required advances* on crops, would have a return sent to the banker or bankers who agreed to advance on such, setting forth *class*, *quantity*, and *analysis*. The advance made on it would be expressed on the warrant, which would be given to the Bank. As soon as the lots were shipped, the usual bill would be drawn by the planter or by his Colombo agent on the London House. The Bank which advanced money on the lot repaid and the warrant being returned cancelled, the matter would end. The Bank's security being the warrant, and *the signatures of the man or men selected in Colombo to manage the business*, such managers arranging *guarantees* with *the Banks*, so as to present any delay in shipping or drawing bills. The whole matter is so simple that there need not be the slightest hitch.

"Unless something like a Cinchona Syndicate be started and worked as suggested herein, the next half-penny or penny rise in cinchona will see millions of lb. shipped and down will come the prices to an amount which will simply ruin some poor deserving men, who are struggling to plant tea and to live on it."

Now it may be said that the collection and publication of reliable returns of the stock of bark (on the trees now growing) in the island would, of themselves, have much the same effect as is anticipated from the action of a Syndicate. We said that the latter would require to procure reliable information as to cultivation and stocks to guide its operations. On the other hand, already we have some wealthy and large owners of Ceylon cinchona playing the part of a Syndicate by holding their bark both in the island and in London off the market, waiting for the opportunity of a more restricted supply and a rise in prices. No doubt, this is what every Ceylon planter would like to do. Each one will say with reference to his harvesting prematurely and shipping hastily,—

My poverty and not my will consents!

But it is just to meet the case of such planters —gentlemen who must get money for their bark,— that a Syndicate is required and it should be the best means to help them, and we would ask our commercial authority whether it is necessary that there should be any general adhesion of all cinchona owners. Let those who do not need the aid of banker or merchant go on as at present shipping; but if a considerable number would prefer to get a moderate advance on their bark and to have it stored until the market rises, they should be able to make a considerable impression on the distribution of this staple from Ceylon. We do not see why it should need all our cinchona owners to form a Syndicate. Indeed, our correspondent supposes 100 planters joining together, and we think that if rules or articles of Association were drawn up and circulated, there would not be much difficulty in getting that number of cinchona planters to support a Syndicate. Meantime we trust the Planters' Association in Dimbula will prosecute their enquiry without loss of time and that their example will be followed in Dikoya, Maskeliya, and throughout Uva. For the rest of the country there ought not to be much difficulty in forming an approximate estimate of the cinchona trees and bark in the several districts.

THE OUTLOOK FOR INDIAN TEA.

Planters usually feel interested in what their candid friend the dealer thinks about them, and the following article from the *Grocer* indicates the prevailing views of members of the wholesale and retail tea trade concerning Indian tea trade concerning Indian tea and its prospects:

"The estimates of the tea crop for 1886, prepared by the General Committee of the Indian Tea Association a few months since, showed that there was likely to be a yield of nearly 76,000,000 lb., as compared with 68,735,000 lb., actually produced in 1885. This represents an increase of over 7,000,000 lb. for the season now commenced, and means a very considerable addition to the existing supply.

'These figures relating to the deliveries show a difference of 1,126,400 lb., and mark the first decided phase which has been witnessed in the rapid extension of Indian teas in this market during recent years. There can be no doubt that the trade experienced a severe check in the early part of this year through the disturbed state of Irish affairs, politically, socially, and commercially; and as our Hibernian brethren, who were previously free consumers of the strong and pungent teas that come from India, have since used them in a more stinted manner, the ground at first lost has not subsequently been recovered. To correspond with this modified taste in the consumption of tea there has also been a change in the character of the demand, which has of late run chiefly upon the commoner kinds, or, as we expressed it in our market report of Friday last, 'upon teas for price,' and at such prices too as are 2d to 3d per lb. lower than they were a twelvemonth ago. Whether this is the cause or the effect of the altered

style of the new season's imports, we cannot positively say, as both circumstances have happened simultaneously and as it by accident; but of this the dealers and those who daily inspect the teas are pretty sure, that the supplies of Indian descriptions now contain a larger proportion of inferior and badly made sorts than they did in either 1885 or 1884, with the natural consequence that both qualities and value are markedly below those in preceding years.

To what then shall we attribute the real cause of the deterioration of business in Indian teas? Is it from necessity or choice, and are the tea-planters in India sacrificing quality to quantity, by gathering the teas from their gardens before they have had proper time for becoming matured and full-conditioned? If so it may be a serious matter for them in after years, as they have powerful rivals against them in the growers of Ceylon tea, who are rapidly advancing in public estimation, and may wrest from the importers of Indian as well as China teas the special advantages of the market generally, which they are supposed to hold over and above all other competitors. India up to this time has successfully contended for the approbation and support of her tea industry in the British market, and for many years has displaced large quantities of China productions from the annual consumption of the country; but from the facts already stated, it can hardly be denied that at this moment Indian teas have not the same name and reputation for richness and strength which they had formerly. The home trade themselves, however are the final judges of what Indian, no less than other teas, are or should be in the cup, and as they determine by their rejection of, or preference for, this or that kind of tea, so will the planters everywhere shape their course and regulate the process of cultivation and the mode of preparation and manufacture from time to time. We believe that the question of profit is the secret of all the changes that are taking place in the tea trade just now, and not till this is fairly decided will it settle down into a steady and healthful condition throughout.

"In considering the position and prospects for Indian teas, it is also desirable to entertain a broader view of the whole situation of the tea trade in general, if only for the purpose of pointing out one great inconsistency which prevails therein at the present season more than at any other we can remember—that is, the outcry against rubbishing and ill-prepared teas being imported here, and the coolness and indifference of the reception which fine and superior qualities meet when they arrive. To illustrate our meaning more fully, we will remind our readers that in February last remonstrances and warnings were addressed to the Tea Guild of Shanghai, against the careless and imperfect preparation of China teas for the London market, and assurances were thereupon given that in future more attention should be bestowed upon the teas grown and shipped from the Celestial Empire; but with what result? The new season's teas, it is true, came to hand in all respects better than those in 1885, but, as we observed in the *Grocer* only a fortnight ago, 'tho dealers often will not look at them, and many highly respectable houses are beginning to consider whether it is not a complete farce to have choice teas to sell, when nobody appears inclined to purchase them at any price.' If preferable teas—whether from China, India, or Ceylon, does not signify in the least—are thus at a discount, what encouragement is there to make them and send them across the seas? And if the trade are supplied with the improved article which they ask for, why do they not patronise it when it is placed at their disposal? These are questions which the importers are almost sure to put to the trade the next time complaints are made of the inferiority of China or even other teas, and unless the wholesale dealers can answer them satisfactorily, it will be in vain to expect any but common and poor trashy teas to find their way to the United Kingdom one season more than another. To be quite consistent, if the trade cannot afford to pay the necessary price for good tea they should not order it: and if, instead of the desired article, they get a weak substitute, they must take it and say nothing." —*Home and Colonial Mail.*

THE subject of Balata Gum and its capabilities has been attracting increased attention of late, but wide differences of opinion exist as to the commercial value of this article. As regards the advantages of growing this product in the West Indies, Mr. James John Day, who claims to be the first European who systematically cultivated Balata, states that a company formed by him in 1874 to work it came to grief, because the gum was so unfavourably reported on by telegraph engineers as being quite unfit for insulating purposes. He warns West Indian planters, therefore, not to waste time and money on Balata.—*Indiarubber and Guttapercha Journal.*

NEW ZEALAND EDIBLE FUNGUS.—For the benefit of a correspondent who made enquiries of us lately we extract the following from the current number of that excellent periodical, the *Pharmaceutical Journal*:—"An edible fungus, which is shown in the New Zeland department of the Colonial Exhibition (Hirneola polytricha) forms an article of considerable export to China, where it is used largely as an ingredient in soups, &c., and also as a dye for silks. It is imported from New Zaland to the extent of about 100 tons per annum. This fact suggests that other objects of Chinese commerce might be worthy of cultivation in the colonies, such as the true Gingseng. It bears considerable resemblance to the Jew's-ear fungus of this country, which is common on Elder trees in damp shady places."—*Gardeners' Chronicle.*

VARIETIES OF GNEISS.—The protean structure and colouring of gneiss are well known and according to the *Madras Mail* are strikingly exemplified in the crystaline rocks of Vizigapatam district as described by Dr. King, the Indian Geological Survey:—The only original work previously published on the geology of the district was that of Dr. Benza, who in 1835 accompanied the Governor of Madras on a tour in the Northern Circars and published his diary in the Madras Journal of Literature and Science. His notes show the almost universal prevalence of crystaline rocks, but in some points he was mistaken, as when he supposed that the Bimlipatam hill was capped by coast laterite. As a matter of fact it has no capping at all, but consists throughout of quartzoze and garnetiferous gneiss is as a rule, a very uninteresting rock to the amateur geologist, who, unless he be skilled in petrography, sees little difference of importance between one gneiss and another. To those, however, who have spent years in the study of the geology of Madras this is far from being the case, and, just as Mr. Bruce Foote recently made the important discovery that nearly all the gold fields of the Presidency lie in a peculiar formation which he has named the Dharwar rocks, so Dr. King, when surveying the Kistna and Godavari districts some years ago, found in the neighbourhood of Bezwada a more decidedly bedded and presumably newer form of gneiss than is usually met with in Madras. He then named this rock Bezwada gneiss, but from the predominance of this form in the districts now surveyed he is inclined to speak rather of the Vizagapatam gneisses. Amongst the other geological features of the district may be mentioned the Waltair red sands. These consist of bright red deposits of a fine-grained clayey sand occurring over most of the northern half of the Waltair ridge. Besides its red colour this sand is notable on account of its isolation, there being no visible source from which it could have been derived. But in reality it is only a particularly highly coloured example of what is common over the coastal plains of Southern India. Similar deposits of red sand and gravel are common round the hilly regions of the Trichinopoly, Salem and South Arcot districts, and since they have yielded a number of palæolithic stone implements they probably ought to be classed amongst the post-pliocene alluviums. The most interesting geological features of the district are to be found in the bands of crystalline limestone, which occur in the gneiss of the hill-tract. This limestone may hereafter be found to have great economic value but at present the interest in it is chiefly due to the circumstance that it contains a number of swallow holes, or caverns, one of which is of considerable size and magnificence.

Correspondence.

To the Editor of the "Ceylon Observer."

QUERY AS TO ALLOWING SEVERAL STEMS OF CINCHONA TREES TO GROW.

DEAR SIR,—Can you or any of your numerous readers give me practical information on the advantages of allowing two or three stems to each cinchona tree? What will be the probable increase in weight of bark by following the system, and are there any known or probable drawbacks? —I am, dear sir, yours faithfully, SUBSCRIBER.

THE PACKING OF TEA IN CEYLON AND THE WEIGHING AT THE LONDON CUSTOMS; PROSPECTS OF CINCHONA.

12. Great Tower St., London, E. C.

DEAR SIR,—Although doubtless many in Ceylon are quite familiar with the peculiarities, of the "London Customs" in weighing tea, the following particulars may be of use to those who are on the point of sending their first breaks into the London market. In order to save loss in weight in making up packages, care should be taken not to exceed the round figure in lb. by too many oz. For instance, say a package weighing gross weight 90 lb. 14 oz. would be called by the Customs 90 lb., and a package weighing gross weight 90 lb. 4 oz. would also be called by the Customs 90 lb. the difference between these would therefore mean a loss per package of 10 oz. The same with the tare. A tare weighing 24 lb. 2 oz. would be called 25 lb., yet a tare weighing 24 lb. 14 oz. would also be called 25 lb., meaning a further loss to the shipper of 12 oz. (being the difference between 2 oz. and 14 oz). Therefore, to avoid loss in weight, let the gross weight be say 90 lb. (or any other unit of lb.) plus 4 oz. = 90 lb., and the tare of the package 23 lb., 14 oz. = 24 lb., which would be 90 lb. gross and the tare 24 lb.

Boxes should not exceed 28 lb. Customs gross and should be made up as under—gross 28 lbs. 2 oz., and the tare 6 lb. 14 oz. which would be called 28 lb. gross and 7 lb. tare. If the weight of a box is declared by the "Customs" to weigh 29 lb. gross, an allowance of *one lb.* draft has to be made to the trade. To give proper effect to this, great care must be taken in weighing up the tea before leaving the island, and the scales should be frequently balanced. The teas in London are weighed by a beam scale; and it is said weighing machines are frequently out of order, and not easily detected and should not properly be used in weighing tea for the London market. If packages run irregularly, they have to be bulked in London, which of course leads to loss in weight in addition to the trade allowance of 1 lb. Small lots of 5 packages and under are always weighed each separately.

It has been suggested to me that we should endeavour to do away with the trade allowance of 1 lb. Such an alteration would of course be of decided benefit to all the growers, but to bring about such an important change is a matter of such enormous magnitude, that in the present state of affairs it is quite hopeless. As I said in a former letter, the whole working of the tea business in London is conducted on a system laborious, expensive, and unsatisfactory to the new order of things now prevailing. The cumbersome "weight note" arrangement must be swept away, together with other obsolete forms and customs only suited to the old working of the China tea trade and its merchant princes. As I pointed out before, the Ceylon and Indian Tea Planters' Associations must unite against them and when sufficiently powerful to make their wishes felt, then and then only will this important article be dealt with on the inexpensive and easy system that all other articles of produce are bought and sold at in the London market. It is supposed that it would be no greater difficulty to sweep away these trade allowances in the tea trade, than it was in the bark trade, which is quite a mistake. In the bark trade a few wealthy buyers only had to be urged to acquiescence, and even in that trade, it took some years to bring about so important a change.

What was the result of the Ceylon Chamber of Commerce's cogitations on this matter? I have never seen the subject mooted since in your columns. Ceylon as a rising factor in the tea trade of the world cannot too soon take the matter up.

Regarding Cinchona, I fully endorse what you stated in one of your recent leaders, that the Ceylon growers have more to fear from themselves than from any other countries. Some of us are afraid of Java, whilst Java is afraid of what Bolivia can do. I don't think Ceylon has anything to fear from the cinchona productions either of Java, India or Bolivia. There is room enough for us all with proper care; and by proper care I mean estates should *not* send forward their very low class bark and twigs which can bring but little profit, if any, in the present unsatisfactory state of the market. Let all combine only to send forward fair 1½ per cent. barks and upwards for the next six months, and planters will benefit quite as much with far less cost to themselves, as if they threw in all their common barks to swell their shipments,—common barks can easily be stored on the estates, until they are wanted. Mr. Von Gorkom in a recent letter to me mentioned that the Java export is not likely to exceed 1¾ to 3½ million lb. per annum even by 1890. Nor does he think the acreage under bark now exceeds 20,000 acres. The heavy shipments lately received from Ceylon have by now been tolerably well discounted, and it will be a pity when the market does revive, as it promises shortly to do, to again crush it hopelessly with too eager shipments of twigs and low class barks which are only valuable with a steady unit considerably above late and present rates. Apologizing for trespassing so much on your valuable space, I am, yours faithfully. JOHN HAMILTON.

SHORT WEIGHTS IN TEA.

18th Oct. 1886.

DEAR SIR,—Mr. Hamilton's letter in your issue of the 16th inst. affords a means of gauging the difficulties which underlie a satisfactory settlement of the short-weight controversy; and his explanation of the manner in which the weights are taken in London goes far to exonerate planters from the unworthy suspicion of systematically putting less tea into their packages than they are invoiced to contain—nay more than this; for it seems to suggest, that if they managed *differently* there would be no complaints of short weight at the other end.

It may be that there is a clerical error in Mr. Hamilton's letter, but as I read it, it seems that whilst in taking the *gross* weight, fractions of ½ lb. and under are disregarded, and fractions of over ½ lb. are counted a full pound, it is not so with the tares; in the latter case *all* fractions, however

small, counting apparently as a full pound—and so, if the actual gross of a package was 114 lb. 8 oz., the actual tare 24 lb. 1 oz. and the actual nett 90 lb. 7 oz., yet when this package came to be weighed at the Customs, the gross would be returned as 114 lb., the tare 25 lb. and the net, weight 89 lb. This is doubtless an extreme caset in which the planter having ingenuously made a present to the buyer of 7 oz. tea in excess of his invoice weight, would be punished for his generosity by being mulcted in a further 16 oz. If, however, this be the system on which weights are taken in London, it is scarcely fair that buyers who—*prima facie*—must be admitted to be sufferers to an equal extent, should call on the *planter* for a further sacrifice to recoup them for the result of an inequitable system. Rather let it be an argument—if the system be unalterable—for an agitation to abolish additional trade allowances under the name of draft. In face of the loss due to such a system as the above, the trifling loss due to sampling in Colombo sinks into insignificance.

Planters will doubtless note the stress laid by Mr. Hamilton on regularity in the weight of packages. No doubt irregularity is often met with, but in my own experience, and dealing with my own standard chests, I have not found this difficulty at all insuperable. In the first place, care should be taken in making up a break to have packages of as nearly as possible the same weight, and this can as a rule only be secured by paying regard to the seasoning of the wood—and getting together packages so to speak of equal ages; which will in most cases ensure even weights. The next thing, as there will always be differences of ounces in the weight of shooks, is to sort out, after putting together, the chests according to weight. Thus in 100 chests it is possible that 25 might run to 22 lb. 25 to 22¼ lb. 25 to 22½ lb. and 25 to 22¾ lb. each. In making up a break take all 22¼ (quarters), or all of some other equal weight, but do not mix them—and still less do so if the difference in weight be greater. Then too in order to secure uniformity it is necessary to have a stock, and as the drier the wood gets, the more it loses in weight, it is advisable to check the marked tares on stock chests immediately before use. Uniformity of weight in lead linings is easy of attainment, but even here care should be taken to mould the linings, on a similar plan, so as to leave the same amount of flap in each. Much tea lead is wasted by inattention to this point, and lead cuttings can always be utilized. To show the need for greater attention in checking tares on the estates immediately before weighing, I may mention that I have known packages lose apparently as much as 2 lb. on the way down in the gross weight, leading to the belief that tea had been abstracted en route; but in nearly all cases I have found the discrepancy to be really due to inaccuracy in the tares, and the actual nett weight correct.—Yours faithfully. C. W. HORSFALL.

PADDY GROWING: CHANGE OF SEED—IRRIGATION.

15th Oct. 1886.

Dear Sir,—The Council will soon be voting away large sums of money for irrigation purposes which is unquestionably right if these are judiciously spent, which I think is open to question. Water is an essential element in paddy cultivation, good seed is equally so, and while our Government go on building bunds, erecting sluices, and cutting channels, the matter of seed is almost entirely neglected, hence the miserable returns for the large amounts spent on waterworks. The native cultivator goes on sowing successively—and has been doing so for how far back, no one knows—the seed his own field produces. Is it any wonder the grain is in so many cases miserably light and a great proportion of it simply 'husks'? In passing through a broad extent of paddy-fields, some months ago in lower Sabaragamuwa, with the owner—a native headman—I remarked, you have very good crops this year? "You would think so, sir," he replied, "but they are very poor. There is plenty straw, but the paddy is very light. We get no good heavy paddy as formerly." "What seed did you sow?" I asked. "The seed was all right," he replied, "we never sow any seed but our own." On my recommending a change of seed from a disance, he smiled, and no doubt pitying my ignorance—said, "We don't know why our grain does not fill, but we know there is no fault to the seed." Is it not surprising that this important matter has escaped the notice of our able Governor, whose mind is so much set on irrigation? and why does the Government Agents ignore it in their Administration reports? Probably some of these sapling A. G. A.'s promoted out of due time, neglect the matter in their reports through ignorance of agriculture? So it is time it were dealt with the the press and brought to the notice of the Council. —I am, sir, yours faithfully, LOOKER-ON.

The Great Value of Coffee is beginning to be properly estimated by the fortunate ones who still own an acreage with our old staple in good heart. We may be sure that full justice will be done to such, now that the prospect is of extreme high prices with a gradual falling-off in the production of Brazil. Every effort will be made in Ceylon to help the trees to throw off the effects of the leaf fungus, bug and grub. As illustrating one phase of the attention given to coffee in Uva, we may quote from a circular recently issued by a proprietor to his superintendents on the subject of "handling" coffee and its general treatment with a view to crop:—

"Now that the price of coffee at home promises to rule *very high*, and will probably continue to do so for some years to come, it becomes necessary to remind Superintendents that it is very desirable that the *fullest attention* should be paid to the condition of their trees. There can be no doubt that the seasons have changed and that no longer can periods of drought be counted upon with the same certainty as they could in the past. Such being the case, it seems more than ever necessary that the trees should be *constantly handled*. Where this system has been strictly carried on good coffee in Uva has, *today*, a fine crop on it. We know of an estate of about 3300 acres coffee that lately produced not more than 3 or 4 days ago a *fine healthy* blossom *adding* quite 2,000 bushels of parchment to the crop already set, and there is another in spike on th ehigher coffee; yet, close by, estates that have ignored this factor of *constant handling* have missed fire! No doubt had the anticipated drought been experienced in due season these estates might have had large crops too, but as they have comparatively nothing *they have suffered from the constant rain*, while *constantly handled estates have not*. Therefore act in future so that every advantage may be taken of whatever sun power you may get. *Handle out the trees well* and *constantly*, *keeping a supply of young wood* (nursery in fact) *always in readiness on the trees* and you will get good paying crops when others fail and work perhaps only to a loss, year after year.—This is proved by many estates we might mention. The net results of both systems have this year been invariably *the same*. Wherever poor cinchona interferes with *good coffee it* is a question if it shou notld now be *removed*."

THE MOUSE PLAGUE OF BRAZIL.

In the colony of Lourenço, Brazil, in the months of May and June, 1876, mice suddenly appeared in enormous numbers. They invaded the maize fields in such great numbers that the corn seemed literally alive with them, destroying in a few days everything that was edible; and where but a short time before bushels of grain might have been harvested, not an ear remained; and the noise produced by their nibbling and climbing was audible for a considerable distance. After the corn-fields were devastated the potatoes next received their attention. Only the largest were eaten in the ground, such as were transportable were carried away and hidden in hollow trees, or other retreats, for future use. Gourds and pumpkins, even the hardest, were gnawed through and eaten. Of green food, such as clover, oats, barley, not a leaf was left standing; even weeds were cut down and the inner parts eaten out. In the house the struggle for existence of these long-tailed invaders was truly amazing. In many of the dwellings hundreds were killed in a single day. The cats could contribute but little aid fighting such a plague, for not only were many of the mice so large that it would have been an unequal contest, but by their great number they drove the cats actually from the houses, not to return until the plague was passed. Nothing except what was composed of iron, stone, or glass, was spared from their destructiveness. Furniture, clothes, hats, boots—everything bore the traces of their teeth. They gnawed the hoofs of the cows and horses in the stables, literally ate up fatted hogs and often bit away the hair of persons during sleep. They penetrated all apartments, and gnawed, their way through boards and walls of houses. Ditches that were dug about granaries did not suffice; the mice would climb over each other in some corner or other and thus reach the top. The foregoing account of one occurence in Lourenço will suffice to show to what an extent the plague reached. The same province had suffered similary in 1843 and in 1863, and in all probability will again in 1889. Similar plagues, though far less in extent, have occured in Europe, in which the field-mice unaccountably appeared in greatly increased numbers. One may well think what would be the result were these little, almost insignificant creatures everywhere in such wise to take the ascendancy. When one considers that on an average of every one or two months from five to eight young are born, and that these young become mature in a few months themselves, he will not be surprised to know that a single pair of common field-mice, in the course of a single summer, would increase to 23,000 individuals. Could all the conditions which now keep them in check be removed, every living thing upon the earth would be consumed in a half-dozen years.—*Science.*

A NEW OPENING FOR THE UTILISATION OF THE SWEET POTATO AND YAM IN THE WEST INDIES.

The root crops, often termed "bread kind," associated with the above plants are largely used in the West Indies for food purposes. The sweet potato (*Batatas edulis*) is the main food crop at Barbados, where yam is little known, whereas at Jamaica the converse is the case, the yam (*Dioscorea*) being very largely grown all through the interior hills, while the cultivation of the sweet potato is confined to a few places in the lowlands. Since the large emigration of negroes to the Isthmus of Panama there has arisen a considerable trade in yams between Jamaica and Colon, to the manifest advantage, in present cash returns, of the former country. Unfortunately, the cultivation of yams entails the cutting down of forest year by year, as good yams seldom do well, in the manner cultivated at Jamaica, except by the "rotation of land"—a peculiar negro mode of interpreting the European idea of "rotation of crops." Hence it is not very desirable, from a general economic point of view, to extend or encourage the cultivation of yams. With the sweet potato, however, it is different. This tuber can be grown without the sacrifice year by year of valuable virgin forest, and it is, in many respects, a crop well adapted to all the lowlands, not only of Jamaica, but also of the West Indies generally.

Besides being utilised directly for food purposes, it would appear that a new demand is likely to arise for the tubers of the sweet potato in connection with the production of the alcohol. The first notice of the sweet potato being utilised in this manner appeared in a report to the Foreign Office given by Consul Hertslet on the trade and commerce of the Azores for the year 1884.

Owing to a variety of causes, it appears that cultivators at St. Michael's and other islands of the Azores, who had hitherto looked upon oranges as their staple production, were so disheartened by low prices and the diminished crops yielded by their trees, that they resolved to clear their land of everything and plant it afresh with sweet potatoes. The whole of the crop thus raised was used in the preparation of alcohol.

During the year 1884, 1,326 pipes of alcohol, of the value of £40,588, made from sweet potatoes, were exported from Azores to Lisbon; and, as will be incidentally shown later, the trade has assumed still larger proportions.

For the imformation contained in this article we would mention at the outset that we are indebted to Mr. D. Morris, late Director of public Gardens and Plantations, Jamaica, now of the Royal Gardens, Kew, who has obligingly placed it at our disposal for the use of West Indian planters.

Encouraged by the success of the enterprise at the Azores, it appears that an enterprising French chemist, Monsieur A. Ralu, having much experience in chemistry, as connected with distillation, and possessing extensive relations with the West Indies (Martinique), has taken out patents:—(1) For utilisiug as a commercial and industrial substance sweet potatoes and yams by means of desiccation and conversion into flour; and (2) for distilling alcohol from the above flour.

In relation to the ordinary or Irish potato, white beetroot, and maize flour, sweet potatoes possess an alcoholic richness of 15·50 per cent as compared with 8 and 9 per cent in the Irish potato, and 4 and 5 per cent in the beetroot. The value of raw sweet potato for distillation, and its superiority, both as to quantity and quality, over other substances, has been for some time known and recognised. The difficulty has been in extracting the alcohol on the spot; added to this, there is the danger attending its exportation, for it is impossible to prevent leakage, and the vapour of alcohol at 95° Fahr. in hot climates is said to be inflammable. Alcohol, therefore, is assumed to be a dangerous cargo. As alcohol cannot, it is supposed, be made on the spot and exported to Europe, M. Ralu's patents aim at the preparation of sweet potato flour in the West Indies, from which afterwards the alcohol may be distilled and utilised in Europe.

As already noted, one establishment for distilling alcohol from raw sweet potato exists at the Azores, and we gather that since it began work it has doubled its plant, and all the alcohol it produces is sold in advance at Lisbon, where it is used for the fortification of wines. M. Ralu says:—"The alcohol of which we have specimens is superior in quality to the best marks of France. The distillery obtains 12 per cent (*i.e.*, 12 litres of alcohol at 100° per 100 kilog. of sweet potato) of alcohol. We have experimented with the sweet potato of Algeria. They give 13 4-10 litres of alcohol per 100 kilog. The sweet potato of Martinique and Brazil have given 15 litres. There is here, therefore, a very rich material for distillation. Ordinary potatoes yield only 3 litres of alcohol per 100 kilog."

The objects sought by M. Ralu's patents involve the extensive cultivation of the sweet potato in the West Indian Islands, its desiccation by means of fruit driers, its reduction into a meal, and its export to Europe, where an almost unlimited demand exists for sweet potato meal for distilling purposes.

The alcoholic richness of sweet potato is unquestioned, and the following table will give its superiority over the cereals ordinary employed at present for distilling in Europe:—

	Francs	Litres
Wheat	19·75 to 21·50	28 to 30
Rye	15·50 to 16·25	22 to 23
Barley	17·75 to 20·00	24 to 25
Oats	17·25 to 19·50	20 to 21
Buck Wheat ...	16·00 to 17·00	24 to 25
Maize	14·00 to 14·50	28 to 30
Rice	18·00 to 19·00	32 to 33
Sweet Potato Flour	14·00 to 15·00	38 to 39

Maize, it will be seen, is the only cereal which is as cheap as the potato flour, but it requires 324 kilog. (714 lb.) of maize to make one hectolitre (22 gallons) of pure alcohol, whilst it requires only 235 kilog. (519 lb.) of the flour to make the same amount of alcohol. There is a great saving of time and combustibles when distilling from the flour, as compared with the maize. Alcohol from maize costs 10 f. per hectolitre more to make, and when made sells from 8 f. to 10 f. less than the alcohol made from the sweet potato flour.

The question for the planter, however, is, Will it pay to grow sweet potatoes and to prepare the flour for export purposes?

The sweet potato at present cultivated in Jamaica is mostly intermingled with other plants in the provision grounds of the negroes. Hardly any is cultivated by Europeans. No definite area is returned as exclusively devoted to this cultivation, and no returns or yield per acre are available from authentic sources. A negro in the same ground will have yam (*Dioscoreæ*), corn (maize), sugar-cane, and possibly, also, two or three other plants, such as bananas. plantains, cocos (*Colocasia*).

Sweet potatoes thrive best in rich friable soil free from clay.

At the foot of the Liguanea Hills, and, indeed, in most localities with the soil indicated above, they are found to thrive. They are easily propagated by slips or portions of the stem planted in rows or in hills. The roots come to maturity in three or four months, and the cultivation is continued by covering up the stems when digging up the more perfect roots for use. The crop comes in practically all the year round: there is no regular season for it, and hence it can be best harvested by examining the state of the roots, and taking out those that are found perfectly ripe. The crop may be gathered at least three or four times in the year; but as to the amount or value of each cropping, no data are immediately available.

If the cultivation were undertaken by sugar planters, and large areas were planted with sweet potatoes, there is no doubt that in Jamaica they might be grown as advantageously and as successfully as anywhere.

We apprehend that few of the West India Islands would care to grow sweet potatoes to be utilised simply in the manner indicated by M. Ralu. Why should they go to the trouble and expense of drying the tubers, reducing them to a meal and export the latter to Europe to be there converted into spirit? If the whole process can be accomplished at the Azores, there is no reason why it should not be also accomplished in the West Indies. We say this with due regard, of course, to any patent rights held by M. Ralu or his friends. At least, it is well worth trying; and the number of sugar planters now on the look-out for something to supplement the meagre profits (or something worse) of a West Indian sugar estate should lead to some concentrated and united action being taken to examine and test everything having the slightest hope of aiding them at the present juncture.

In relation to its size, Barbados at present grows sweet potatoes more extensively than other West Indian islands. They are grown as a catch-crop between the regular intervals of planting the sugar cane, and are generally sold as they stand, the purchaser harvesting them himself. Here there would be no difficulty in growing sweet potatoes on the most extensive scale commensurate with the size of the island; but there are no stills already in existence as in Jamaica, and both the plant and the knowledge of distilling would have to be introduced. Jamaica has the advantage in this respect, for every sugar estate there has its still-house, and when once the *modus operandi* is known has regards this special industry, it would be a very simple matter for the Jamaica planter to distil alcohal pure and simple from the sweet potato, as for him to distil rum from molasses. The Barbados planter at present ships his molasses either to Europe or America, or sells it to the distillers at Martinique, where it is used in the preparation of French rum.

It is not our intention to advocate, in any decided manner, the preparation of alcohol from sweet potatoes, or cypress a strong opinion either way. We only wish to point out the West Indian planter a possible means, in these hard times, of meeting a demand which evidently exists for a certain article, and to throw out suggestions which may be of ultimate benefit to him. At St. Vincent, for instance, where nothing at present appears to pay a well-established industry connected with this method of utilising sweet potatoes might give the initial start to local enterprise and lead to a more prosperous state of things. Or, again, there is Tobago, with its Métayer or *quasi* co-operative system, which might offer an excellent opening for and industry of this kind, provided, of course, it were taken up in a business-like and systematic manner, and adapted to the special circumstances of the island. In fine, this is essentially a matter which commends itself for consideration to West Indian planters in general. and they would do well to look carefully into it.—*European Mail.*

THE PLANTAIN AND THE HORSE-SHOE BAT IN BORNEO.

The plantain of Paradise obtains its name from a legend that Adam and Eve clothed themselves with its broad green leaves after they had eaten the forbidden fruit. In India, where it is indigenous, the plantain is termed *Pisang*; here, as elsewhere, it is cultivated as one of the principal sources of food. Jamaica, it is said, would be scarcely habitable without the plantain, as no species of flour or bread could supply its place to support health and strength in the negro. Bananas and plantains, when fully ripe, are eaten as fruit, but unripe are boiled as a vegetable, and eaten with meat or fish. In South America the ripe fruits of both plantain and banana are first dried, then pounded into flour, which is made into biscuits. One hundredweight of dried fruits yields forty pounds of dry meal; four hundred and fifty pounds yield a weight of meal (sic). A fermented liquor, also an excellent temperance drink, is made from both plantain and banana. The ripe fruit of either being pressed through a cane sieve, is first wrapped in the green leaves, and then dried in the sun for future use; one of these dried portions being dissolved in water, there results a pleasant, nourishing, and refreshing drink. The plants of all the tribe Musaceæ attains perfection in ten months from the first planting to the ripening of the fruit. The growth of the fruit, either banana or plantain, is peculiar and unlike any other. When the tree-stem is fully grown, spikes of flowers appear from the centre of the top; these spikes are from four to six feet long with knots of blossom on one side only; this is followed by the fruit, each being about twelve inches long, growing in green clusters, forming a bunch sometimes upwards of forty pounds in weight. The bulb at the end of the spike somewhat resembles in colour and shape a bullock's heart. The cluster of fruit is generally taken off before ripe, it mellows, turns yellow, and eatable. Sometimes it is left to ripen when it becomes a dainty to be stolen by animals. Bats are fond of bananas, particularly the horse-shoe bat, which has a dark projecting ridge over its upper lip, resembling a horse-shoe. These bats are precisely similar to those of Madagascar; there they are termed Rousettes. In Borneo this bat

is known as Melanopis. It is a formidable creature about four feet broad, and one foot long from the tip of the nose to its almost imperceptible tail, the form of its wings, in its manner of flying, and in its internal structure, is similar to our common English bat, but there the likeness ends. The large bats of Borneo and Madagascar resemble a fox in colour, and some of the specimens in the shape of the head and in their predaceous habits. These creatures are often seen darkening the air by day as well as night; they destroy the ripe fruits of the country, drink the juice of the palm trees, and devour indiscriminately fruits, insects and flesh, sometimes settling upon animals, and will attack a human being when sleeping. A portion of the tongue of the bat is constituted as an organ of suction. These bats at night make a noise that can be heard for two miles distance, but at daylight they generally retire to their caves or hollow trees, for they make no nest, but hang by the wing claws to the sides of the dark rock or hollow tree. They are singular creatures, being neither birds nor quadrupeds. They are never seen to walk. The feet resemble long fingers, but are webbed like a duck's feet, the membrane however, being thin. This serves to lift the body for flying, which soon tires it. In some places in South America the bats have a protuberance, resembing a horn between the long ears, and just above the nose. These generally keep to the forests and deserted places, but when they come into a village, as they sometimes will, they darken the air like a canopy, and become the dread of the villagers, as they attack and suck the blood of all domestic fowls, and if interrupted will fly at the face of the intruder doing serious injury.—*Ladies Treasury.*

PRESERVING FRUIT, FRUIT-JUICES, MUST, AND FRUIT WINE BY SALICYLIC ACID.

Dr. F. von Heyden's successor, manufacturer of salicylic acid at Radebent, near Dresden, writes as follows:—

Fruit and fruit juices can be preserved in a variety of ways by means of salicylic acid, and which permits of being employed in all the various methods, jam making and preserving, &c.

1. Cherries, Currents, Raspberries, Green Gage Plumps, common Plumps (*zwetschgen*), Peaches, Apricots, &c., are placed in wide-mouthed glass bottles holding about 1 kilo. (2 lb. English,) without water being added, putting alternately a layer of fruit and one of sugar. The upper layer must be of sugar. Above this last half a gramme about half a teaspoonful of dry crystallised salicylic acid is strewed. The bottles are then covered with parchment paper in the usual manner and placed in a water bath, and the water allowed to simmer for fifteen to thirty minutes, according to the size of the fruit—small fruit requiring less time than large; berries about thirteen minutes. When cool it is advantageous to cover with a piece of salicylic acid paper, and make fast. Fruits treated in this manner have and retain constantly the appearance of fresh fruit.

2. If it be desired to preserve large fruits, such as Quinces, Melons, Gourds, also Rose haws, in great earthen cooking vessels, put into the usual sugar and water syrup, half a gramme of salicylic acid per kilo. of fruit. When filling the bottles a good fitting piece of salicylic acid paper, which must be saturated with a concentrated solution of salicylic acid and rum, must be laid on the surface.

3. When preserving Melons, Gherkins, Pears, Plums &c., in vinegar, a little more than the proportion of salicylic acid given above can be added to the boiling vinegar and sugar, and the rum-paper can be omitted.

4. Russian rum compote.—The making of this is begun at the new year, and ends late in autumn, all sorts of fruit being placed in a large vessel as they come into season. The following is the process adopted in this kind of preserving:—Strawberries, for example, are placed in a layer, bestrewn with sugar, and a glass of rum is poured over the mass, and as this kind of compote easily ferments, half a gramme of salicylic acid per kilo. of fruit must be added each time anything is put in.

5 In making marmalade (must) and some other particular kinds of fruits, as well as the so-called *tutti frutti*, the salicylic acid is added towards the end of the operation, and preferably in the form of the rum solution.

6. Freshly pressed fruit juice, with or without sugar, are preserved in excellent condition in a cool place in resined bottles, by the addition of half a gramme of salicylic acid to 1-2 kilo. of juice. Such kinds of fruit juices, free from alcohol, and not oversweetened, make agreeable drinks, mixed with water, for children and convalescents. The raw juice of small fruits require in the warm season, when they are made, about 50 grammes per hectolitre put into the vessel when no spirits are added, so that fermentation be prevented. Complete exclusion of the air, and a cool storing place are absolutely necessary conditions of preservation in this case. Attention must be paid to the equal division and mixing; and if the acid be dissolved in spirits of wine, ten times the quantity of juice can be diluted, and then be well stirred about. In the wholesale manufacture, when a large addition of spirit is made with the intention of increasing the quantity, and therefore the use of salicylic acid does not appear to be necessary, the mash remains several days in the tubs before it is pressed, exposed to the risk of an injurious fermentation. This evil can be avoided, and the fine aroma preserved, by means of an addition of salicylic acid, dissolved in alcohol in the propotion of .5 to 10 grammes for every 50 kilos. of raw fruit as it is put into the vessel, or after the same is filled. By this means the juice will be more thoroughly and quicker clarified than by the usual method by means of spirit, because all kinds of fermenting organisms, owing to their absorption of the salicylic acid, remain inoperative.

7. Grape juice continues sweet and clear for a whole year, when 20 to 30 grammes of salicylic acid per hectolitre (=half a teaspoonful) per kilo. are mixed with some must into a sort of thin dough, free from lumps, and added to the unfermented must immediately after it has left the press. In fourteen days later the juice after becoming clear can be put into bottles. The latter must be washed out with a watery solution of the acid, and the corks should be boiled in the same.

8. Cyder and perry can be kept for long periods by the addition of 10 grammes per hectolitre. If the articles are preserved in casks, 5 grammes are given in the spring and 5 grammes in the summer. Complete exclusion of the air from the contents of the casks is essential, and by partial opening of the same the air should be passed through a cotton-wool plug saturated with salicylic acid, or, better, through prepared salicylic acid wadding.

Apples and Pears remain in good condition and can be layered in large quantities when each fruit is wrapped in paper impregnated with salicylic acid. This last is readily made by soaking blotting or tissue paper in a mixture of alcohol and acid and hanging it over a string to dry. The complete purity of the acid is essential to success. *Deutsche Garten Zeitung, Sept. 22.—Gardeners' Chronicle.*

Germination of Seeds of the Vine.—M. Nobbe has ascertained that the number of seeds which germinate is proportionately small, and that the process of germination occupies weeks and even months. The seeds of the best varieties germinate less freely than those of commoner kinds. Ripe seeds freshly taken from the berries germinate best: drying of the seed diminishes the germinating power. There is no advantage in heating the soil to 18° or 20° C. (68° F.) A slight fermentatin in the pulp acts favourably, but the same operation if continued for six days destroys the germinating power. The best temperature for germinating Grape seed lies between 12° and 15° C.—*Gardeners' Chronicle.*

PALM KERNELS.

A correspondent seems anxious to know if the importations of palm kernels from Africa which are recorded in the *Reporter* almost every week, go into consumption here. We have been asked before what disposition is made of them. Last week the receipts of palm kernels at this port were valued at $2,000 and a considerable quantity arrived previously. In making inquiry for our correspondent, we were informed that a New York drug house used the kernels in medicinal preparations, or the fatty substance as a base for ointments, salves, &c. If such is the case, the amount used is trifling compared to what is consumed by soap manufacturers. It is understood that nearly all the palm kernels imported into the United States are sent from here to Liverpool and elsewhere on the Continent to be crushed for the white soap stock which is sent to this and other markets. Some enterprising capitalists who understood the business and commanded a good trade for soap stocks, undertook to establish a factory in Boston for manufacturing palm kernel oil, but after all the plans were matured and the contract awarded for erecting suitable works, it was discovered that only sufficient kernels could be secured to run the factory three months in the year, and for this reason the scheme was abandoned. The same parties have since congratulated themselves on their narrow escape from a heavy loss, as since that time prices have declined to some extent and the Boston market has been burdened with heavy stocks of palm oil, up to the present period. Palm kernel oil bears no resemblance to palm oil, and is held at one-quarter and one-half a cent per pound above the latter. Its chief competitor is Ceylon coconut oil.—*Oil, Paint and Drug Reporter.*

GRAIN GROWING AND LABOUR IN INDIA.

The chief secret of India's ability to undersell her competitors is the nominal wage for which the ryot will work. Sir James Caird says that an Indian family of four can live comfortably on 5*l.* 6*s.* a year, and clothe themselves for 30*s.* more. An American, writing from India a month or two ago, said that twenty-five farm coolies cost no more for wages there than one farm hand does in the United States; in addition to which the Indian boards and lodges himself. The Chinaman has always seemed to the Yankee to have reached the lowest possible poin in cheap living, but this writer says that, as compared with the Hindoo, he cannot get a foothold. The tools used are of the cheapest and most primitive character. What passes for a plough is a rough wooden implement which simply tears up the ground. It costs 1*s.* 8*d.*, and is drawn by a pair of bullocks, the average cost of which is 32*s.* the two. The only other implement used is a cold-crusher, and this is merely an ordinary log of wood which is dragged by the bullocks sideways across the field. One of the most serious items in the cost of cultivation is watering the soil. This has to be done three times during the growth of a crop, and costs altogether about 10*s.* an acre. This is an item of cost which, with improved irrigation arrangements may be reduced. The total cost of cultivating an acre of wheat in the Punjab has been stated to be as follows:—

	£	s.	d.
Rent, per acre	0	14	6
Cartage of manure	0	4	10
150 lb. of seed	0	6	8½
Ploughing twenty times ...	0	3	1½
Sowing by hand	0	0	7½
Watering three times	0	10	0
Reaping and carrying	0	2	6
Threshing	0	1	5½
Winnowing	0	0	3½
Total	2	1	11½

On good irrigated land the crops average about 17 bushels per acre. On ordinary dry land 10 bushels is the average. Two crops are got in a year—one in October and the other in April. The North-West Province and Oude are the chief wheat-producing districts. They comprise an area of more than one hundred thousand square miles of excellent soil. Last year the total area devoted to growing wheat in the whole of India was 27,820,223 acres, which produced close upon 300,000,000 bushels. It has been contended in some quarters that as India has with full crops only been able to export about one-sixth or one-seventh of her production, she is not likely to glut the markets of the world to any serious extent. The fact, however, seems to be overlooked that India is only just developing facilities for getting its wheat away from some of the most productive districts. More wheat has not been exported simply because it could not be got to ports of shipment at a reansonable cost. In good years enormous quantities have been left to rot on the ground because there were not means of exportation. But once open up a market for the grain, and make it possible to reach it easily, and there is scarcely any limit to the quantity that can be produced.—*British Trade Journal.*

COCA CULTIVATION IN THE DUTCH INDIES.

The director of the National Botanic Gardens at Buitenzorg, near Batavia, in his report for 1885, states that in the gardens under his control extensive experiments have been made in the cultivation of coca. These attempts have invariably been attended with success: every seed sown has germinated, and the plants flourished with a minimum of care. Many inquiries for coca seed arrived from planters in all parts of the Dutch colonies, and they were in every instance responded to. But strange to say, though sound seed was supplied to every applicant, in most instances the attempts on the part of the latter to raise the coca plants were unsuccessful. The director gives particulars of eighteen attempts at cultivation, of which only five succeeded. The coca plantations which promise well are situated in the residences of Soekaboemi, Tjitjalengka, Malang, and Tjiandjoer. The report attributes most of the instances of failure in raising coca to the unsuitable or neglectful treatment of the seed by the applicants; but the director is of opinion that with ordinary attention the shrub may be successfully raised in different parts of Java. During the prevalence of the east monsoon the young plants suffer considerably from drought, and should be watered daily, and the soil around them covered with mould. The seed decomposes easily, and the application of moisture should therefore be a moderate one. The seeds generally germinate after forty or fifty days. They should then immediately be exposed to the light in order to prevent excessive elongation, which is generally followed by decay. Rats and insects are dangerous enemies to the seeds, especially before the proper development of the cotyledons. During protracted drought coca plants do, perhaps, require some shade, but this should be a light one in any case. In the Buitenzorg Botanic Gardens 1,116 coca plants were put in the ground last October between growing rows of *Eucalyptus pilularis*.—*Chemist and Druggist.*

TOBACCO.

The following extracts are taken from a pamphlet written by Sir William Robinson, K. C. M. G., the Governor of Trinidad.

CULTIVATION.—For general information and guidance I would state from my own experience the following facts:—

1. Any ground intended for the growth of Tobacco should be cleared of bush by the end of July at latest. The bush should be cut as low as possible, and the stumps extracted if practicable.

2. Seed should be sown in the middle of the month of August and not all the year round as is probably now the case.

3. Every plant before being transplanted must have six leaves on it, and those leaves should be as large as a half-dollar piece before it is removed from the nursery.

4. When transplanted, a distance of 18 inches should be allowed between each plant.

5. Tobacco plants are sometimes attacked by insects in November. This, however, depends upon the state of the weather. The plants should be carefully watched, and the insects, if any, picked off.

6. As soon as suckers present themselves they should be ripped off; they will be found between the stem and the leaves. By this operation the vigour of the plant, which should not be allowed to flower, is increased, and the condition of the leaf improved.

7. Tobacco flourishes best on level ground, and red or reddish soil is preferable to any other. If the spot where it is cultivated is at all hilly, the northern portion of the ground will be best, as in that position the plants will suffer less than in any other from the rays of the sun.

8. Vegetable manure will be found an admirable fertiliser, and it will be necessary to dress the ground every two years, as the plant exhausts the soil very rapidly.

9. Care should be taken, in sowing the seed for transplanting, not to sow too thickly.

Curing.—10. The curing of Tobacco—and everything depends upon the curing—is a very delicate operation, and one requiring great care and attention. The most common practice, when the leaves are fit for gathering, is to cut the stems of the plants close to the ground and lay them on beds to dry until the evening. They should then be carried to a drying-house, which should be thoroughly ventilated, laid in heaps to "sweat," covered with mats to keep in the heat, and left for several nights to soften and bleach. The leaves—and no more than twelve should be allowed to grow on each stem—should when supple be stripped from their stems, strung together on packthread and then hung across the drying-house: sufficient room for the air to circulate among them must be allowed. When dry the leaves should, in damp weather, be placed on hurdles in heaps and left for a week or two. During this time the leaves should be frequently examined and turned with a view of preventing undue fermentation. When fermentation is complete the leaves should be sorted according to their different qualities, redried, tied in bundles and pressed.

11. It is necessary in the case of those intended for export that the bundles should be compressed into a solid mass and the air excluded from them.

12. In Jamaica, Cuban, Chinese and native labour is employed in the cultivation of the plant, but Cuban and Chinese labour alone is employed in the manufacture of the leaf into cigars.

13. The cultivation of two acres of Tobacco should cost about £30 and the average produce should be worth £80, leaving a nett profit of £50.

The Director of Kew Gardens informed me for years ago that with "proper methods of cultivation and preparation Tobacco might become a very important article of export from the British West Indies."

If any one should doubt the correctness of my rules let me say, though it may appear egotistical, that Sir Joseph Hooker observed that "Governor Robinson's excellent despatch" (from which they are taken) "really leaves little room for further remark. It is of course desirable to obtain seed of good quality, though this is of less moment than careful attention to cultivation and preparation. Governor Robinson's statement that the finest Tobacco in the world may be spoiled by improper or inefficient curing cannot be too much emphasised." Looking to the fact that Spanish colonists in two distinct parts of the world, east and west, grow Tobacco with pre-eminent success, it certainly is difficult to understand why more should not have been done with it by British enterprise.—*Gardeners' Chronicle.*

THE ENGLISH TOBACCO CROP.

Of tobacco literature available for immediate assistance I would name as the best Spon's Encyclopædia of Commercial Products; the section therein is masterly and exhaustive, referring especially to cultivation and curing in the U.S. and India. Then a shilling pamphlet, "Why and How Tobacco should be Grown," published by Nichols and Sons, Parliament-street, contains much concise information, brought together by Mr. A. A. Erskine from numerous sources. The third edition of the pamphlet, "Cultivation of Tobacco in England," issued by Messrs Carter and Co., 237, High Holborn, contains, beside much general matter, a valuable and practical paper from an American publication lent by Lord Harris, wherein it is noted "five curings are spoilt by proceeding too fast to one failure from going too slow." This American authority recommends as a dry, curing heat that shall expel the sap from the leaves, stems, and stalks of the plants, and catch the colour—yellow, (next one to nature's colour, green)—and to fix this yellow colour indelibly, the employment of stone or brick flues, with furnace and pipes, and with fuel of old wood. As such flues do not exist in England, the nearest substitute should be attempted. In a medium sized tobacco plant is about one pound of water, and this has to be expelled in from eighty to one hundred hours. Thus:

About thirty hours at a temperature of 85° to 90°;
About four hours at a temperature of 100°
About four hours, advancing 2½° to 110°;
About four to eight hours, advancing regularly, 120°;
About six to eight hours maintained at 120°;

until the leaf appears to be cured and all sap expelled; then advance 5° every hour up to 170° to thoroughly cure the stalks and stems in those cases where the whole plant is hung. Of course, where only the leaves have to be cured, the treatment is completed earlier. When cured properly most of the leaf will be of a mahogany colour, the remainder of a bright dapple to a cherry red.

To me the whole of the inclosures (plots surrounded by a single line of hops at right angles) appeared to have been overfed with manure—the result of delay in permission for the experiment to be made. In another season due preparation of the ground by working and manuring should be made in time for the soil to get duly mixed with the fertilisers employed. Farmyard manures, wood ashes, and sheep droppings had been applied to the ground from which hops had been grubbed up. Mr. de Laune raised some of his plants from seed placed in a hotbed during May, and set out from June 10 to June 26. Other plots were from seedling plants reared by Messrs. Carter of Holborn. The distance of the plants apart is about a yard—as recommended by American practice—but the luxuriance of the English plants demands much more space for the large-leaved varieties, so as to allow room between the rows, to cultivate and clean the crop from rapidly-growing suckers, &c. During the past week this work could not possibly be accomplished without a greater evil following, through injury to the finely-grown and ripening leaves overlapping each other.

In reply to a schedule of questions, Mr. de Laune has favoured me with the following particulars:—

1. Names of varieties grown: Kentuky, Connecticut, Pennsylvania Island Broad Leaf, Hester, Virginia &c.

2. Prepared bed for plants with foot of farmyard manure and a few inches of loam on the top. Did not burn over the soil before planting out. Covered the seed plants with sheets on cold nights.

3. Set out plants (June 10 to 26) in hills made by hand.

4. Percentage of first planting which rooted and grew off. Very few died from natural causes, and none from insects or worms.

5. The soil is loamy (formerly a hop garden); last crop turnips, fed off by sheep.

6. Manures: Wood ashes, bats' guano, farmyard muck, &c. How applied: direct to the plant hills and broadcast.

8. Date of first topping—July 24. Average number of leaves left on each plant to mature—ten. I did not prime or pull off inferior leaves.

9. Did not see any horn worm.

10. Earwigs the only insects that preyed upon the plants.

11. Daily record of weather.—(Refer for this to district tables.)

12. Costs of producing crop.—Must have time to answer.

13. Date of cutting.—Commenced Sept. 3 and Sept. 22; am now proceeding. Mode of curing.—By fires in hop oasts.

14. Total yield in pounds of marketable tobacco per acre, and in what proportions of quality.—Answer must be postponed.

I may add that I saw, on Monday afternoon, the prompt enterprise which Mr. de Laune exhibits in all his agricultural undertakings. The tobacco leaves as they were cut were strung together in pairs, and at once suspend from a rod supported by a newly-made wooden horse of the right height. So the leaves, some nearly two feet broad and over a yard in length, cleared the ground, and when the rod was completed it was carried away to a framework on wheels, which latter when loaded was trundled off to the ample oast house. This picking off the leaves for curing, rather than struddle the whole plants in pairs, seemed to me decidedly the best practice, as the stalks require much more time and heat to dry than do the leaves.—*Field.*

PARAGUAYAN TEA.

From its earliest history, *yerba mate*, or Paraguay tea (botanical name *Ilex Paraguayensis*), has gained a greater notoriety than any other article produced in Paraguay, and has been the chief source of revenue. From it Francia and the two Lopezes gained their enormous wealth, as did the Jesuit fathers before them. Lopez I. annually exported about eight hundred thousand dollars worth. The last year of his life the export, of which he had the monopoly, amounted to more than twelve million pounds, of which the value was between five and six million dollars. The curing of *mate*, which like all other active industries, was almost wholly destroyed during the war, has revived with the return of peace and is regaining something of its former importance. Eleven million nine hundred thousand and twenty-four pounds were exported in 1881, of which the official value was $996,752. It was from the universal use of the leaves of this plant in what was then known as Peru that Europeans derived the custom of tea drinking. Paraguay tea was introduced into Europe fifty years before the Chinese herb was known there. It is said that the latter gained the precedence by an opinion which some physicians were hired to give by parties interested in the traffic, that the Paraguay tea was injurious to health. Quite as reasonable an explanation might be found in the different business methods of the parties engaged or interested in the traffic from the two sections of the globe. The plant is indigenous to the entire northern part of the La Plata basin, and grows spontaneously throughout a wider district than the combined areas of France and Germany. In no part, however, does it reach such perfection as in the locality from which it took its name. The finest species is said to be found only in a comparatively small district lying north of Asuncion and east of the Paraguay River. This variety would probably thrive under cultivation in all sections where any species of the plant is found growing wild. The increasing demand for it in European markets will eventually incite to its cultivation. Washburn thus describes a visit to the *yerbales*: "April 8. This morning the work of collecting the *yerba* commenced. The process of curing was as follows:—A dry, level place is selected and a circular spot some twenty-five feet in diameter made perfectly smooth and hard, and a layer of damp clay spread over it and stamped down till it becomes a hard and smooth floor. Within this space a number of small trees are set into the ground in circles of about eighteen feet in diameter. The tops of the trees are bent over and interwoven into each other so that an oval roof is formed. Then, commencing some three feet from the ground, long *withs* are woven in longitudinally with the upright poles, forming a sort of open basket-work at the top. The *peons* next go in search of the *yerba*, which they collect and bring to the camp. They take with them a sort of basket made of thongs of raw-hide, that they adjust on their shoulders and neck in such a manner that they carry enormous loads. Provided with this and a hatchet, the swarthy native plunges into the woods to look for the *yerba*. That most coveted is the bush from six to ten feet high, which he cuts down, and then, chipping off all the branches and leaves, whips them into his basket. It is the medium-sized shrub that is most sought. Sometimes the bush grows to a tree of twenty-five feet or more, but those are left unmolested when the smaller shrub can be found. So soon as the *peon* collects as much as he can carry he returns to the camp, and the branches, having the leaves still on them, are passed quickly through the blaze of a hot fire, and the leaves are stripped off and thrown upon the ground. When a sufficient quantity has been gathered in this way the leaves are all taken up and worked into the wicker-work of the oval structure before described. They are worked in with great care and so as to be of a uniform thickness over the whole surface. When this is finished the floor beneath is swept out, and a pile of wood that has long been cut and seasoned is placed underneath and a fire kindled. The heat soon becomes very great, and much care is taken that it reaches all parts overhead alike, so that none of the *yerba* is scorched and none that is not completely dried. To cure it thoroughly every particle of moisture must be driven away, and as there are always more or less of the stems of the wood of considerable thickness it is not considered safe to withdraw the fire until it has been in full flame for some thirty-six hours. When the roasting process is finished the fire and ashes are drawn out, the floor carefully swept, and the now cured *yerba* is shaken to the ground. It is then gathered up and placed under cover ready for packing.

"The packing process is not the least singular of the *yerba*-curing operation. First the green hide of a large ox is taken, and a strip about five feet by two and a half is taken and sewed up with thongs from the same hide in the form of a square pillowcase. It is then attached to strong stakes driven into the ground and a quantity of the *yerba* is put into it, when a couple of stout *peons* proceed to press it down with heavy sticks of wood in the form of hand-spikes. It is a very slow progress, as the *yerba* is beaten and hammered in until the mauls, though pointed at the ends, can hardly make an indentation. When as much has been forced in by this operation as possibly can be, the open sides are brought together and laced up with thongs of the green hide, and then it is left to harden in the sun. What with close packing and the contraction of the hide by exposure to the sun, it becomes almost as hard as a rock. The bales, called here *tercios*, usually weigh from one hundred and fifty to two hundred pounds each."

Numbers of these *tercios* may be seen at the various ports along the river and being unloaded before *almacens* in the towns. Small ones weighing an *aroba* (twenty-four pounds) are not uncommon, and those of a half or even a quarter *aroba* put up in the same way may sometimes be encountered. The pounding to which the *yerba* has been subjected to the process of packing has reduced the dry leaves and twigs to a fine powder of a pale-green color tinged with brown, which is highly aromatic. It is called *yerba mate* from the cup from which it is partaken of, and is more frequently simply called a *mate*.

To prepare the tea, which is the universal beverage of the La Plata countries and the unfailing token of hospitality, the cup is half filled with the powder, with or without sugar, the *bombilla* inserted and the cup filled with boiling water,—for which the

kettle is always in readiness,—and the hot liquid is sucked slowly through the tube.

Yerba mate is the one indispensable luxury of all classes throughout the La Plata countries. A cup of the tea is taken the first thing in the morning, and also after the midday siesta. It is presented to a visitor within a few minutes after entering a house, and is not infrequently tasted by the hostess before being passed the guest. The same cup passes from guest to guest and to the several members of the family, being refilled as required. Upon entering a house and finding the lady taking her *mate*, she has immediately withdrawn the *bombilla* from her lips and passed it to me. I have also frequently seen the servant trying the flavor through the *bombilla* while bringing in the mate.—From "La Plata Countries," by E. J. M. Clemens.—*American Grocer.*

Piper Betle Leaves.—According to Messrs. Gehe and Co. (*Handelsberichte*) a supply of the leaves of the *Piper Betle*, L., which are used in India for chewing with arekanut, has recently been imported for the first time into Germany. An essential oil obtained from the leaves by distillation at Samarang, by Herr Schmitz, has been credited by him with having given good results in the treatment of catarrhal disorders and as an antiseptic, and the claim has been confirmed in the experience of Dr. Kleinstück, of Jena. The oil, which seems to be of an aldehyd nature, is said to oxidize with extreme rapidity, losing at the same time its characteristic ethereal odour and therapeutic properties. Great care will therefore be required in the transit of the leaves, if the oil is to be distilled in Europe.—*Pharmaceutical Journal.*

Couch Grass.—In a season like the present one, when heavy rain falls about every fourteen days and showers still more frequently, it is almost useless for the cultivator to think that he can master couch grass. If it is ploughed over it grows as freely from the underside of the sod when inverted as it did before the ploughing, and the furrow slice soon has a sward on the two sides; if the scarifier is put through the inverted furrows it only tears them to pieces, and every joint of the grass grows. The consolation the farmer has is that his crop, owing to the favourable weather, grows equally well, and will repay a little energy bestowed in attempts at keeping down the couch, by a grand growth afterwards, and so will soon be beyond harm from these under-growing weeds. Couch is a good grazing grass, and apparently stands the worst treatment in the way of overstocking better than any grass in the country; it can be eaten down to the roots by sheep, and be none the worse for it; it can be kept thus bare for years, and yet when rain falls and the paddock is spelled the grass is as good as ever; all stok like it, fatten on it, and cows give nice sweet milk and butter when grazed on it. In fact but for couch (*Cynodon dactylis*) the commons, the road sides, the suburban paddocks, and much of the country where close settlement is would be useless for stock. One special feature about this grass that it follows settlement; no matter in what part of the unsettled interior man may elect to put up his house and live, before the year is out the couch will be there too. The grass likes a firm consolidated surface, and appears first in such places as by the roadside, stockyards, or round the house. It is indigenous to the country, but also it is largely spread by the minute seeds getting embedded in the mud by the wheels of vehicles and on the feet of animals, and also it is passed in their droppings. Notwithstanding its being so fatal a grass to all cultivated plants and crops it is powerless to master many weeds, such as sida retusa, catmint, thistles, cobblers' pegs, &c., and in this particular it differs materially from the buffalo grass, although both are creepers and joint rooters; indeed the buffalo does not spread by seed at all, so that the couch has the advantage over it; nevertheless the buffalo will smother it when the two are planted together. In the garden every rootlet of couch should this season be carefully picked out as the forkful of soil is overturned, for if left in the ground they are sure to grow again. —*Queenslander.*

Growth of Rootlets.—Messrs. Van Tieghem and Doubot have recently shown that rootlets, in making their way out from the interior of the axis of main roots, secrete a fluid which destroys the cells in their immediate nighbourhood by converting them into jelly and then dissolving, perhaps absorbing them, somewhat in the same manner that the embryo metamorphoses the albumen surrounding in it and then appropriates it as food.—*Pharmaceutical Journal.*

Vine Manures.—As a result of observations made in Germany, it appears that superphosphate of lime increases the yield, hastens the ripening of the Grapes, and facilitates the ripening of the wood. Nitrogenous manures are useful when the Vine lacks vigour, otherwise they do harm by stimulating growth rather than fructification and maturity. Potash by itself is of no value, but when conjoined with phosphates and nitrogenous manure it is very serviceable. —*Gardeners' Chronicle.*

Caucasus Boxwood.—Vice-Consul Gardner reporting from Poti, says, that the Boxwood forests in the vicinity of Poti are exhausted, and supplies are now drawn from Abkassia, which Province has lately been opened to cutters by the Russian Government. About 2,000 tons were cut and exported during the year 1885 to the United Kingdom. This wood is of fine clean growth, good colour, and great thickness, many pieces being 15 inches in diameter.—*Gardeners' Chronicle.*

Mandioca.—The numerous varieties of the mandioc or cassava plant (*Manihot spp.*) cultivated in Brazil, where, as is known, the roots are worked for the preparation of Brazilian arrowroot, or tapioca, forms, the subject of a lengthy and exhaustive paper by Dr. Peckolt, the chemical section of which (*Pharm. Rundschau*, iv., 148, 174, 201) presents several points of interest. Dr. Peckolt says that the occurrence of hydrocyanic acid is not limited to the bitter mandioca, but extends to all varieties, though it is present in smaller quantity in the sweet kinds. Hydrocyanic does not, however, exist as such in the root while in the earth, but is first formed on contact with atmospheric air, and its formation can be entirely prevented by immersing the freshly dug root in alcohol. The capability of forming hydrocyanic acid proved to correspond with a popular belief as to the time when the bitter mandioca is most poisonous, being greatest at the time of flowering. As a general rule it was found that the richer in juice the roots of a variety are, either sweet or bitter, the more poisonous they are, some of the sweet varieties containing only traces of milky juice. But Dr. Peckolt confirms previous suspicions that the toxicity of mandioca is not due wholly to hydrocyanic acid, for there exists in the juice, already formed, another volatile poison, which he has provisionally named "manihotoxin," as 5 milligrams of it killed a full-grown pigeon in five minutes. This he obtained from ether in stellate crystals, volatilizing completely at 60° C. Another substance, which is non-poisonous and occurs in the expressed juice from both bitter and sweet roots, but in greater proportion in that from the sweet, has been named "sepsicolytin," or "fermentation hinderer," on account of its remarkable antiseptic properties. It was obtained as a thickish light-brown extract, having a peculiar odour and a bitter pungent taste. It is insoluble in absolute ether, chloroform, petroleum spirit, carbon bisulphide and essential oils; freely soluble in ether and alcohol; less soluble in cold water, and only partially soluble in boiling water. Two drops of sepsicolytin mixed with fresh albumen (quantity not stated) are said to preserve it for upwards of six months without deterioration of any kind. It would seem therefore that the antiseptic properties that have been attributed to "cassareep" and the "pepper pot" of the West Indies, both of them prepared from mandioca or cassava juice, have some foundation in fact (see *Pharm. Journ.* [3], i., p. 274). Other compounds separated were "manihotin," a crystalline mannite-like substance, which is a decomposition product, since it does not exist already formed in the root, and Henry and Boutron's "manihotic acid," which has been ascertained to be a decomposition product of manihotin.—*Pharmaceutical Journal*

AGRICULTURE IN MYSORE.

(From a Correspondent.)

From Official Returns recently published by the Mysore Government, we gather that the total area cultivated in the Mysore provinces amounts to 43,54,006 acres. Of this 5,54,554 acres are cultivated with rice; 19,073 with wheat; 32,71,771 with food grains; 1,33,433 with oil seeds; 25,956 with sugar cane; 20,759 with cotton; 1,305 with fibres; 9,860 with tobacco; 1,40,501 with coffee; 32,032 with vegetables; 6,074 with mulberry; 1,38,264 with coconut and arecanut; 280 with pepper and 164 with lac. The Shiringeh District with its 2,07,598 acres takes the lead in rice, while the Kadur district with 91,784 acres takes the lead in coffee. The Tankar District takes the lead in coconut and arecanut, having 45,769 acres under cultivation, while the Kolar District leads in vegetable with 11,915 acres under culvation; the Chitaldoorg Disirict, which adjoins the Bellary Collectorate of the Madras Presidency has the greatest area under cotton. * *

The average rates of rent from cultivated lands in the Mysore province are as follows:—Per acre for rice R5 2 9; for wheat R4 6 9; for inferior grains R1 10 9; for cotton R1 13 7; for oil seed R1 10 1; for fibres R1 9 9; for sugarcane R6 1 4; and for tobacco R3 1 7. * *

The average produce of land per acre in pounds is: rice 1,069; wheat 661; inferior food grains 739; cotton 26; oil seeds 633; fibres 216; sugarcane 1,382; tobacco 379; coffee 501b. and silk 31. * *

The estimated value of manufactures in Mysore is returned at R53,91,946 for a whole year, of this silk realized R1,61,800, and here it may be mentioned that the Bangalore District, which is the great silk-growing district contributed R1,50,000 of the whole. Cotton R21,18,490; wool R2,66,525; other fibres R32,470: paper R400; iron R45,214; jaggery and sugar R8,44,175; coffee R11,14,488; oils R6,55,184; and brass and copper R1,54,500. * *

THE INDIAN TEXTILE INDUSTRIES.

The *Madras Times* has been directing attention to the condition of India's trade with Europe "Then and Now," or its position at the begining of the nineteenth century and the present day, and it occurs to me that as so many of your readers are interested in India, a few remarks on the subject suggested by the topic discussed in the aforesaid newspaper will be acceptable.

Sir Thomas Munro was a careful experienced observer of the state of trade in India sixty or seventy years ago. It was his opinion that European traders would not remain long in India, but from the operation of various obvious cause would be forced to the sea coast. So far as regards the coffee planters and indigo factors, this prediction has been realised. Indigo factors in India are now almost without exception natives, and the coffee plantations are rapidly passing into their hands. But with respect to the textile industries, the forecast made by Sir Thomas Munro was not correct. His words are the following:—"As to the exports (from England to India) it is not likely they will ever, unless very slowly, be extended; opposed by moral and physical obstacles, by religion, by civil institutions, by climate, and by the skill and ingenuity of the people of India. Some increase there undoubtedly will be, but such as will arise principally from the increase of European establishments, and of the mixed race which springs up in their chief settlements. No nation will take from another what it can furnish cheaper and better itself. In India almost every article which the inhabitants require is made cheaper and better than in Europe. Among these are all cotton and silk manufactures, leather, paper, domestic utensils of brass and iron, and implements of agriculture."

The use of machinery driven by steam has falsified this prediction. By its means Europe produces fabrics which only fall a very short way behind the finest hand-made fabrics of India, while the price is considerably lower, and the goods can be produced to any extent required in a very short period of time. Now this state of things has reduced the native Indian industry very low. When the best Indian hand-woven fabric is compared with the productions of English and Scotch looms and found to be as 10 in favour of the Indian, but at the same time the price is as 60 in favour of the British goods, it will be seen at once that the latter would command the native market over the former. This is the case now. The finest cotton fabrics from Indian looms, the admiration of the world, is a decaying industry, and it is difficult to find workmen suitable to produce them, while the coarser native cotton fabrics are subjected to a competition with European goods which prevents their proper development. It must not, however, be supposed that the Indian cotton industry is ruined, for the formation of new companies promoted to establish new mills at once refutes the notion, but at the present time the Indian cotton industry has not kept pace with the increase of the native population. Thanks to European manufacturers, who have sent to India fabrics which from their even threads, close weaving, and thickness look very strong, but are really very rotten, the natives who can afford to do so prefer Indian cotton fabrics to Europeans; still, owing to the cheapness of European goods, clothing is more extensively used among the lower orders than formerly. It may be that in the future, by more equitable modes of raising revenue than that now adopted by the Government, who have removed all duties on imported goods in the interests of European manufacturers, an obtaining an equivalent for the lapsed duties by laying a heavier burden of taxation upon the country, and by encouraging the growth of native manufactures, Indian productions may supplant European goods.—*Textile Recorder.*

THE BRITISH ASSOCIATION.

SECTION D.—BIOLOGY.—PAPERS BY PROFESSOR MARSHALL WARD AND DR. TRIMEN.

On the Germination of the Spores of "Phytophthora infestans," by Prof. Marshall Ward.—One of the objects of this communication was to bring before the meeting copies of some careful drawings of all the stages of germination. These were obtained by actually watching the development, escape and germination of the zoospores from the "conidia," following all the phases in *one* individual. The curious effects of light and of abnormal conditions upon the development of the zoospores were also pointed out, and the author showed diagrams of other forms of germination obtained by interfering with the conditions. In the short discussion which followed Prof. Marshall Ward referred to some points in the development and escape of the zoospores of the Saprolegnia.

On the Flora of Ceylon, especially as effected by Climate, by Henry Trimen, M. B., F. L. S.—Attention was first called to the fact that the Island of Ceylon was practically known to Europeans only by its south-west part, being about one-fifth of the whole area, but including the chief European centres, the planting districts of the hills, and the railway system. The remainder of the country is thickly covered with jungle, thinly inhabited, and rarely visited by Europeans, save Government officials and sportsmen. This difference was shown to be due to climate, especially to rainfall. The distribution of the rain, so far as is shown by annual amount, was exhibited by a map, in which the great advantage to the south-west of the lofty forest-clad escarpment of the central mountain-mass of over 7000 feet was exhibited. The south-west monsoon wind commencing at the end of May deposits an immense quantity of rain here, especially in the neighbourhood of Adam's Peak. In the rest of the island this wind becomes dry, and the country is parched and arid until the arrival of north-east monsoon, which commences in October. This wind brings rain to the whole island, and is the only rain which the dry districts get; in many places it all falls in a few weeks, when the country is completely under water, though parched with drought for the rest of the year. This is very different to the well-known south-west of Ceylon, where save in February or March, a fortnight's drought is a very

rare event. In some parts over 200 inches falls in the year. In these respects Ceylon is an epitome or continuation of the Southern Indian peninsula. The peculiarities of the flora were then gone through in some detail, taking first the low country of the wet districts up to 3,000 feet—in which the number of introduced tropical plants was commented upon; then of the lower hills, the principal home of the planting enterprise and tea and coffee estates; and next of the higher or true mountain districts above 5,000 feet. In the low country the forest has been much destroyed by the indolent and improvident native mode of cultivation called "chena," and but little virgin forest remains in this portion of Ceylon. From 3,000 to 5,000 feet the agent of destruction has been European planting, and the forest has almost wholly disappeared. Above 5,000 feet, land is no longer sold by Government. Attention was specially called to the concentration of endemic species in this wet district—over 800, or nearly 30 per cent of the whole flora—and to the strongly Malayan, as distinguished from Peninsular Indian type of these and of the whole flora. There are no Alpine plants in the Ceylon hills; dense forest covers their summits, but a number of temperate genera are represented. This flora is entirely Indian in type, with no *genus* represented which is not also found in the Nilghiris, but the number of endemic *species* is very remarkable, only about 200 being common to both mountain-ranges. A few remarks were then made upon the naturally open grass lands, called "patanas," in the hills, and their peculiar vegetation. The flora of the great dry tracts of Ceylon was then considered. It is completely distinct from that already considered, being mainly the same as that of the Carnatic or Coromandel coast of India, with no Malayan admixture, and very few endemic species. The whole country is covered with forest, apparently primæval; but in reality much of it is secondary, and not more than 800 or 1000 years old, as is reported by native tradition, and evidenced by the vast remains of temples, tanks, and ancient buildings now overgrown with trees. Most of the timbers of importance in trade are obtained in these districts, and, owing to a very faulty forest conservancy, there is now but little first-class timber remaining, save in very remote places. The botanical characters of this forest, which is everywhere evergreen, were given; and the paper concluded with a few remarks on the coast flora, which is very uniform throughout the tropical belt of the world.—*Nature.*

THE COLONIAL AND INDIAN EXHIBITION AT SOUTH KENSINGTON.

JAMAICA.—Several specimens of annatto are shown, all of which are of very good colour and appear to be the best in the Exhibition. A specimen of the colouring matter in the form of a dry red powder is worthy of notice as being likely to be useful for colouring oils, and as a paint. It is free from the peculiar and somewhat disagreeable odour possessed by the solid form usually met with. This specimen was prepared by the Government Chemist, Mr. J. J. Bowery. Allspice is shown by several exhibitors. The tree, which grows on warm limestone hills in the island at an elevation of 1,500 to 2,500 feet, appears not to flourish so well anywhere else, so that Jamaica practically supplies the whole world. According to the official catalogue the export of this spice from the island during the year 1885 was valued at £53,867; ginger being exported during the same period from Jamaica to the extent of £20,168. Several other spices are exhibited as produced in the island, including some fine nutmegs, also cardamoms, cinnamon, and cassia. The clove, black pepper, and vanilla are also established in the island.

The samples of cardamoms exhibited are small and not well filled with seeds.

Neither the cinnamon nor the cassia exhibited by the Botanical Department present the aspect of the commercial product; indeed it would be difficult to judge from the appearance alone which is cassia and which cinnamon. They are also very deficient in aroma. Unless the cinnamon could be obtained richer in essential oil and prepared in fine quills, as in Ceylon, it is hardly likely to be received in English commerce.

Dyewoods, including logwood, fustic and sapan wood, are exported from Jamaica to the extent of about £100,000 annually. The logwood tree was introduced from British Honduras in 1,715, and has spread spontaneously over the island to such an extent that the export of logwood now exceeds that from British Honduras.—*Pharmaceutical Journal.*

THE NORTHERN TERRITORY OF AUSTRALIA.

HALF-YEARLY REPORT BY GOVERNMENT RESIDENT.

Mining.—The discovery of an alluvial gold field in the Kimberley district of Western Australia has of course, had a sharp effect upon our gold returns for the half-year, which have fallen from 10,112 oz. from January 1 to June 30, 1885, to 6,610 oz. in the corresponding period this year.

Geological Examination and Prospecting Parties.—The Rev. J. E. Tenison Woods arrived here by H. M. S. "Flying Fish," after completing a three years' scientific tour in the East. He writes me from Burrundie:—"I am much pleased with the geological aspect of the country. It has the features of an auriferous district in a way that brings to my mind some of the best gold-bearing tracts I have seen in Australia, and one sees at a glance how little can have been done as yet to explore its deposits."

Agriculture.—The past wet season has not been a favourable one for sugar-cane. We had nearly the usual rainfall, but the rains came in heavy deluges, with somewhat long intervals of drought between. The rain, too, was unusually local. For example, in forty eight hours there was a difference of about 4 inches between the rainfall in Palmerston and at Fannie Bay, only 4 miles distant. On my return from the Katherine, when at Port Darwin Camp, I was shown some splendid bins of rice which had been grown on the Margaret River. The Chinaman who owned the rice informed me (and it was confirmed by Mr. M. D. Armstrong) that the Chinese give 2s. per bag more for this rice than for the rice imported from China. Originally 30 lb. were sown, and the first harvest yielded over 1 ton of fine sample rice. I thought the sample so fine that I purchased a 56-lb. bag for the Colonial and Indian Exhibition in London. At the same place I was shown some splendid cobs of maize. On suitable soil maize grows two crops in the year, and with fair seasons each crop yields 40 bushels to the acre. The prize of maize upcountry this year is £10 per ton. I have no doubt that one of the successes in tropical agriculture will be the growth of rice. I have again visited the Beatrice Hills plantation. The coffee plants were strong and healthy, and many of them bearing fine berries. The indiarubber trees had grown well and flourishing.

SUGAR FROM THE TERRITORY.

We have been shown by Mr. Otto Brandt, of the Shoal Bay Plantation, near Palmerston, Northern Territory, a parcel of sugar, being part of this season's, the first recrushing in our northern dependency. About three years ago there was a very small crushing of a few tons on Delissaville plantation, which is now abandoned, but this was not of very excellent quality. The sample sent to us by Mr. Brandt is an unrefined good white. Mr. Brandt opened his plantation in 1883, but this is the first year of crushing, except for a few tons of sugar made last year in testing the machinery. The operations were at that time affected by the fact that a fire burnt about 20 acres of cane, and the cane could not be put through the mill on account of the machinery having been received from the south and erected too late in the season. The plantation has an area of 761 acres of land selected by Mr. Brandt, and purchased under the 12s. 6d. an acre special survey laws. In addition to this the survey cost 2s. 6d. an acre.

The area under cane is about 200; the yield of sugar by single crushing is about 2 tons to the acre, or by double crushing considerably more. The Queensland average is about 1¼ tons. The cane grown is of three varieties. This season, though it was a miserably dry one, some of the plants gave 12 feet of crushable cane, with a circumference of 7 to 8 inches, running in density more than 15° Beaume, against about 9° in Queensland. Mr. Brandt is now so far the only plantation owner who has a chance of getting the bonus offered by the Government of £4 per ton for the first 1,250 tons of sugar grown in the Territory, and his energy will certainly entitle him to that well-earned reward. Mr. Brandt, from an intimate knowledge of the capabilities of Queensland as a sugar-growing country, points out that the Northern Territory has several advantages for the sugar-grower over Queensland. He remarks upon the absence in the Territory of the frost, which frequently will destroy a whole crop in one night. Another advantage is a certain dry season, which favours the maturing of the cane, rendering unnecessary, as in Queensland, occasional intervals in the crushing or complete stoppage, because if the cane is wet the density will go down. Consequently the Queenslanders sometimes get only one crop in two years, whilst in the Northern Territory one crop a year can always be depended upon. Mr. Brandt further testifies that in the Northern Territory there is an advantage in the labour, which is cheaper than in Queensland. A Chinaman (used in the Northern Territory) costs only 2s. a day, keeping himself, and they can be had at a moment's notice without any difficulty, and re-engaged again in the same way. In Queensland if the planter has say 100 kanakas on the plantation he has to keep them all the year round, whether he wants them or not. They cost the employer, moreover, about 15s. a week, counting everything. It should be added that with the residue of the crushing Mr. Brandt has made a number of casks of golden syrup treacle, which he is having brought down to Adelaide.—*South Australian Register.*

NOTES ON DRUGS IN THE COLONIAL EXHIBITION.

Medicinal Plants and Medicines of Ceylon.

Amongst the many and varied exhibits of drugs and medicinal substances from all parts of the British dominions now to be seen at South Kensington, none is so complete as that from Ceylon, and an excellent handbook accompanies the exhibits, the uses of each plant being given after the scientific and Sinhalese names. In an introduction to native medicinal plants and medicines, the writer points out that in Sinhalese medical practice disease is held to be a disturbance in the equilibrium of the three humours—air, bile, and phlegm—which pervade the human system. These agents preside over certain vital functions, and while susceptible of being affected by temperature, diet, drugs, habit, etc., react on the organs whose functions they control. Every individual is supposed to be born with a predisposition to some one of these humours, or to a modification of one of them in combination with some proximate principle corresponding with the nervous, bilious, phlegmatic, and sanguineous temperaments formerly recognised in the practice of Western medicine. Of the five or six hundred different causes of disease recognised in Sinhalese medicine, more than a fourth are ascribed to the abnormal conditions of the three humours, and the rest to to vitiation of the seven proximate principles of the human body, viz, blood, flesh, fat, etc. Hence, diseases are not classified by their symptoms so much as by their causes, and accidental symptoms are not only confounded with essential ones, but receive special treatment as distinct diseases. The treatment, accordingly, is more theoretical than empirical, every symptom being referred to some derange humour, which alone receives attention, and has to be rectified according to the rules laid down by the recognised authorities. A very common practice with native practitioners is to allow a disease to progress for some time with a view to "mature" it, or "to bring it to a head," before any attempt is made to remove it. A quick recovery, whether under European or native treatment, is deprecated, as likely to lead to a relapse, since sufficient time has not been allowed for the restoration of a permanent, healthy equilibrium between the contending humours. They have great faith in critical days, and in the influence of the different phases of the moon, each of which is supposed to preside over its own set of organs, so that purgatives, for instance, however much they may be needed in any given case, are never prescribed on the day on which the moon exercises its influence on the bowels, emetics on the day on which it presides over the stomach, etc. The Sinhalese seldom make use of powerful or hurtful remedies. In most cases the treatment only seems to change an acute disease into one of chronic character, while recovery from a simple affection is protracted, the patient being kept half-starved on gruel, and made to swallow huge quantities of infusions and decoctions of medicinal herbs, villainously compounded, the number of ingredients in each portion increasing in direct ratio with the continuance and severity of the disease. A mild form of fever, for instance, would be treated with a decoction of the "Five Minor Roots." *Desmodium gangeticum*, *Uraria lagopodioides*, *Solanum Jacquini*, *Solanum indicum*, and *Tribulus terrestris*, which are believed to cure fever due to deranged phlegm, catarrh, etc. A severer form would be ascribed, perhaps, to deranged air, requiring the use of the "Five Major Plants,"—*Ægle marmelos*, *Calosanthes indica*, *Gmelina arborea*, *Stereospermum suaveolens*, and *Premna speciosa*. In remittent fever, etc., all ten may be prescribed together, and in typhoid fever, with head symptoms, the same, with eight or ten other ingredients. When conducted by intelligent and skilful practitioners, native practice is not unlike the morden treatment of European Medicine, viz., that of trusting to nature for efforts to restore health, while placing the patient under the most favourable conditions for recovery by means of suitable diet and regimen, medicinal treatment being directed chiefly to the relief of the more urgent symptoms. It must be admitted, however, that the Materia Medica of the Sinhalese will compare favourably in many respects with the Pharmacopœia of the most enlightened countries of the West. Not only is every class of medicine well represented and supplied in profusion by the boundless prodigality of nature in Eastern tropical climes, but some of the vegetable productions are valuable enough to deserve a place in the medicinal resources of Western science.

The Ceylon Collection.

The collection exhibited in the Ceylon Court consists of 362 specimens, all of which are indigenous or wild Ceylon plants, and the uses of which, as, recorded, have been taken from the mouths of the village doctors themselves. The following is a selection of those drugs which appear to be the most important:—

Abrus precatorius (Olinda-wel).—The juice of the green leaves is used as a purifier of the blood, especially in females. The root, for sore throat, leprosy, stiffness of the joints, paralysis, and nervous diseases; externally it is applied to ulcers and sores. This plant is a common tropical weed, and is well known as the source of the jequirity seeds or crab's eyes, which are sometimes used as an article of food in Egypt, being harmless when eaten, but producing fatal effects when introduced beneath the skin. In India the roots are used as a substitute for liquorice.

Abutilon asiaticum (Anódá).—The root is used in mild fevers, and is considered tonic, diuretic, and stimulant. The water in which the leaves have been boiled is used as a wash for sore mouth, and for fomentation in piles. This is a malvaceous plant and like most of the order it has demulcent properties.

Acacia concinna (Hinguru).—The juice of the wood is used to cure murrain in cattle. The pods are very saponaceous, and are used as a substitute for soap.

Acalypha indica (Kuppa-méniya).—The whole plant is used in worm complaints, and to expel wind. The

juice of the leaves is emetic, and is applied externally to bad sores and ulcers.

Acorus calamus (Wada-kaha).—Used in bowel complaints in children as a stomachic and carminative. This plant is the sweet flag, and is very widely distributed, being found not only on the banks of rivers and other wet places in England, but also in the cooler parts of Europe, India, and North America. All parts of the plant, particularly the rhizome, have a strong aromatic and somewhat acrid taste, in consequence of which it has been used in European practice as a stimulant and tonic, especiall in cases of indigestion and ague. Candied, the rhizome forms a well-known confection, and it is also used in perfumery.

Acronychia laurifolia (Ankinda).—The bark is considered a good remedy for obstinate ulcers and indolent sores. The root, bark and leaves are applied to dislocations.—*Burgoyne, & Co.'s Monthly Export Prices Current.*

STRAY NOTES ON CACAO IN CEYLON.

(*From "Old Colonist."*)

My visit to Matale North greatly charmed and interested me. Twelve years ago, there was not a cacao plant in the district, now its cacao groves are amongst the finest sights in the island, and as Sir Henry Ward said:—"It is difficult to decide where there is so much of surpassing beauty." No longer is cacao a mere experiment, but in North Matale at least, it is assured, as much as any vegetable product can be. I am only sorry there are not, and never can be, 100 Kowdapelelas in Ceylon.

I have seen nothing of *Helopeltis*, and believe *Boreas* to be the only real enemy to cacao in good soil; as "R. B. T." long ago discovered. The lucky proprietors of North Matale are getting an excellent crop this year, and as far as man can judge, it is destined to go on rapidly increasing for many years to come. Warriapolla, also, is a fine picture, nothing could exceed the luxuriance of its healthy and heavy-laden cacao, nor the beauty of its well-trimmed shade trees. Dear old Dumbara, of course, still holds its own, and will probably this year give double the crop it has ever before given.

New Products in Mexico.—Among the most valuable fruits yielded by the Mexican flora is the vanilla, which has been in use in the country for ages as a flavouring for chocolate, the national beverage. Its use was made known in Europe by the Spaniards, and until comparatively recent times Mexico was the only source of supply of the fruit. Mauritius and other parts have since taken the lead in supplying the London market, but the true Mexican vanilla still remains the best of any. In the country itself it is cultivated more for home use than for export, the centres of the trade being the districts of Misantla and Papantla. A wild variety of vanilla is found abundantly in the virgin forests of the republic, but its fruits, not being aromatic, are not gathered. The value of the vanilla exports in 1884 is declared at 83,000*l.* Efforts are now being made by a German agriculturist in Mexico, Dr. Hugo Finck, of Cordoba, to grow the cinchona tree in that locality, one of the most favourable parts for the cultivation of new plants. According to official statements there were in 1884, 15,000 cinchona plants flourishing in Cordoba, and it is hoped that in a few years Mexico will be able to derive large profits from the export of cinchona. Commander Maury, who visited the country in 1868, was the first to suggest the introduction of the cinchona in Mexico, but his advice was not acted upon until several years later. Careful observations have shown that the climate and temperature of large tracts of Mexican territory correspond exactly with that of the Bolivian provinces where the cinchonas flourish most luxuriantly.—*Chemist and Druggist.*

Piperine in Ague.—Some cases of refractory intermittent fever, in which, after the failure of quinine, piperine has been administered with advantage, are reported by Dr. C. S. Taylor) *Brit. Med. Journ.*, Sept. 4, p. 449). In one case, immediately on the accession of an attack three grains of piperine were given every hour until eighteen grains had been taken, and on the following day, when the intermission was complete, the same dose was given every three hours. Dr. Taylor remarks also that piperine does not produce the unpleasant symptoms in the head that sometimes follow the use of quinine.—*Pharmaceutical Journal.*

Extract of Pomegranate Root Bark.—The official preparation of pomegranate bark is open to objection on account of its nauseousness, and three years since Mr. Siebold, in order to obviate this, suggested a process for removing the astringent principles (*Pharm. Journ.*, [3], xiv., 396). With a similar object Dr. von Schroeder has recommended the use of an extract free from tannic acid, but containing all the alkaloid of the bark (*Pharm. Zeit.*, Sept 18. p. 556). The extract is prepared by treating a decoction of the bark with milk of lime to remove the tannic acid, filtering, neutralizing the filtrate exactly with sulphuric acid, evaporating it on a water-bath almost to dryness, treating the residue with 70 per cent alcohol, and then driving off the alcohol from the extract obtained. The product is described as nearly entirely crystalline, and soluble in water with a slight turbidity. The yield is about one gram of extract from twenty grams of bark. In order to retard as much as possible the absorption of the pelletierine, which is present in the extract as a sulphate, it is recommended to add to this quantity one or two grams of tannic acid to convert the alkaloid into the difficulty soluble tannate. —*Pharmaceutical Journal.*

Vegetable Products in Tunis and Tripoli.—The export of Esparto-grass or Alfa, as it is locally termed, has been more active during the past year. This valuable fibre, nine-tenths of which is shipped to the United Kingdom for paper making, affords a livelihood to the Bedouin Arabs, who load their camels with it and bring it a distance of 100 miles from the interior. The Government has not relieved it from the oppressive duty which for the last nine years has weighed upon it, amounting in the northern districts of the Regency to 12*s.* 6*d.* a ton, and to 17*s.* further north at Susa. The largest shipments take place from Sfax. The Alfa from Susa commands somewhat higher prices than that farther south. The unusually large quantity of the fibre which was exported from the Regency in 1881 was owing to a failure of the grain crops in the south, which drove the Arabs to Esparto plucking as the almost sole means of obtaining a livelihood. In 1882 the Arab tribes in the south fled over the border to Tripoli to avoid the French, and that year showed the lowest point to which the export of this grass has sunk. In 1883 shipments of Esparto began to be made from another little port to the south of Sfax, called Skira, which would under ordinary circumstances have found an exit at Sfax. Skira has been selected as the port of exportation by the Franco-English Esparto Company, which has obtained a concession to export that fibre from a certain district inland from Sfax, and which began its operation in 1883. From Tripoli it is stated that business in Esparto, which had become very slack in 1884, had so far recovered itself as again to be in the position it occupied in more prosperous years. Notwithstanding the low range of prices—10*s.* to 15*s.* per ton below the usual rates of the last two years—the supply of this fibre has not diminished, but flowed steadily into market in even greater quantities than before. The quality of the grass is better, as would appear from the general satisfaction it has given in England; and it is anticipated that both the quality and quantity in 1886 will be above the average. Freights for Esparto kept low, ranging from 9*s.* to 12*s.* the ton for hydraulic pressed bales, and from 16*s.* to 20*s.* for those mechanically pressed.—*Gardeners' Chronicle.*

CULTIVATION OF THE ORANGE IN INDIA.

TO THE EDITOR OF THE "INDIAN AGRICULTURIST."

SIR,—I shall be much obliged if you can give me any hints on the cultivation of orange trees in India. I don't want to know about the climate, because no place is better adopted to growing oranges than the place I have selected. I wish to know what distance apart the trees ought to be planted, when they will fruit, and how much fruit they will yield; also what extent of land should be planted to yield a sufficient return to pay for superintendence and up-keep, with a profit of R6,000 annually.

If you could let me know whether there is a good market for oranges in Calcutta, and what prices they fetch, it would be an additional obligation. T.

The orange should be raised by budding on the common lime or lemon. The operation should be performed in February. In the December following, the young trees should be planted out at a distance of 20 feet apart, in large holes 3 feet deep and 3 feet diameter, filled with a rich soil composed of well-decayed cow-dung, night-soil, common black earth, and a small quantity of slaked lime. The trees blossom, as a rule, in February and March, and the fruit is ripe by November, and sometimes earlier. They last till the end of January, and sometimes February; but the fruit should, for the sake of the trees, be all removed by January, to allow the plants to rest a little before flowering again in February. The soil should have a top-dressing of manure every year just before the trees begin flowering. A well-grown tree, say about 3 or 4 years old, will yield from 200 to 500 fruits. We have known them to yield a great deal more. [We suspect orange trees in Ceylon do not bear under twice the age specified.—ED]

WOOD FOR CIGAR-BOXES, &c.

I have read the correspondence on this subject in recent numbers of the *Forester* with much interest. I entirely agree with Mr. S. E. Peal in considering that 'tun* or Poma' wood is the best we have in India for the purpose. There are of course others that will do, and among those referred to by "ex-Student" *Duabanga sonneratioides* and *Alnus nepalensis* might be used, but would not be nearly so good as several other woods that can be named, such as 'bakáyan,' *Melia Azedarach* (very like tun) and *Acrocarpus fraxinifolius*. To put down in a list such coarse woods as *Echinocarpus* and *Elæocarpus* is only to mislead.

The boxes in which Trichinopoly cheroots are usually packed are made of tun, those used in Coconada are made invariably of *Adina cordifolia*, but I doubt if that wood would be used if tun were easily procurable in the Godavari forests. I strongly advise those who want a good cigar-box wood to stick to tun, the Indian representative of the Spanish cedar, which I believe is *Cedrela odorata*.

It is worth noting here that according to the most recent determinations, neither the 'Lali' of Darjeeling nor the 'Súm' of Assam is *Machilus odoratissima*. The real *Machilus odoratissima* is the Punjab tree so common about Simla, the others will, I think, be found under other names, which I am sorry I do not yet know, when the next part of the 'Flora of British India' is published. The three trees of Darjeeling, known to the Nepalese coolies as 'Lali,' 'Kawala' and 'Jagrikat' respectively will probably be described as distinct species, instead of being all placed, as hitherto, under *Machilus odoratissima*. The 'Lepchaphal' has proved lately, from good flowers and fruit collected, to be not *Phœbe attenuata*, but a new species, to which Dr. King has given the provisional name of *Machilus edulis*. I expect "ex-Student" is mixing up cigar-box woods with those suitable for tea-boxes. It would be rather too much to expect Mr. Sutherland to go to Darjeeling for such woods, when he can get tun and bakayan from the N.-W. Provinces.—J. S. GAMBLE. —*Indian Forester.*

*Popular spelling *Toon*,—ED.

THE QUESTION OF MULCHING.

Mulching may serve to keep the surface moist, but it will be found that the portion in contact with the ground is apt to mildew and encourage fungus growth, which does not promote healthful vegetation. We are cautioned, therefore, against the use of easily decaying or fermenting substances. A careful examination of the under surface of most mulchings will develop the fact that it is a snug harbor for slugs, snails, worms and all minor sorts of vermin.

If the material used cannot be usefully or properly dug into the soil after its use as a mulch has ceased, as with tan, sand or sawdust upon light soils, then the labor of spreading and afterwards gathering it together again is by no means inconsiderable. A coating two inches thick on an acre amounts to about three hundred single loads of stuff, which must cost at least $50 to $60 to spread and remove. How many times could you go over an acre with a cultivator for $50? Certainly more than thirty.

Mulching induces a growth of fibrous roots to push up to the surface. It is not a little remarkable that none of those who have recorded this fact so repeatedly have noted that this is not a useful result.

How can temporary advantages of mulching be otherwise obtained permanently? In a well-cultivated field not more than from one-eighth to one-tenth of the rain that falls upon the soil finally passes off by percolation; the remainder is drawn to the surface and evaporated by the process described. Anything that breaks up the uniform continuity of the texture of the soil, by which atom after atom of water is brought to the surface, will accomplish the first step in retaining the natural moisture of the soil within it.

Now, mulching does not do this at all; it only checks or moderates the approach of the atmosphere to the moistened surface of the soil, and therefore retards evaporation to that extent; but the reason why there is so much moisture beneath the mulch is because the capillary action of the soil keeps on pumping up the water faster than it can evaporate.

Dry soil is an excellent non-conductor, made doubly so by being loosened and thus intermingled with air. This is precisely the condition of the soil after a thorough cultivation. When thus rendered fine and light the surface becomes truly a cushion of air and dry earth; the continuity of the insensible process of conviction of the water of the soil is broken, the point at which the upper passage of the water of the soil ceases is removed to the depth of the cultivation, the free access of the air to the continuously moist surface is hindered and you have accomplished all of the beneficial effects of mulching in a cheaper, more intelligent and scientific manner.—*Proceedings Massachusetts Horticultural Society.*

ANTS ON TREES AND PLANTS.

The ants so often found in great numbers upon plants and young fruit trees cause no injury. Their presence is due to plant lice, a very peculiar insect found upon nearly every part of plants, but usually in the greatest numbers upon young shoots, buds, and leaves. These parasites multiply with wonderful rapidity. It has been proved by Reaumur that a single individual is capable of becoming the progenitor of nearly six thousand millions of these pests in five generations. This accounts for the fact that the tender twigs and leaves of plants and small trees will often become completely covered with a living mass of these minute lice in a very short space of time. Most of these are females, destitute of wings. The winged individuals, according to Harris, "appear only at particular seasons, usually in the autumn, but sometimes in the spring, these being all small males and larger females. After pairing, the latter lay their eggs upon or near the leaf buds of the plants upon which they live, and together with the males soon afterwards perish." The genus to which plant lice belongs is called Aphis, from a Greek word signifying to exhaust. The eggs are hatched in the

spring and the young lice immediately begin to exhaust the vitality of the plants by sucking the sap from the twigs and leaves. They increase rapidly in size and soon mature, and it is a remarkable fact that the entire brood, without a single exception, are wingless females and in condition to propagate their species. Their young, however, are produced alive, and each female may be the mother of fifteen or twenty young lice in a single day. The second generation also consists of wingless females, which grow up and have their young in due time, and thus brood after brood is produced to the seventh generation, or even more, without the appearance of a single male, but the last brood in autumn consists of males and females, upon which wings are developed, the eggs being laid by the females as before mentioned, and remaining upon the twigs until the following spring, when they are hatched and their work of destruction begins. The leaves and bark of plants much infested by these insects are often completely sprinkled over by a sticky, sweetish fluid discharded by them, which upon drying turns dark, greatly disfiguring the foliage. This sweetish fluid is what attracts the ants, which are very fond of sweets of all kinds. The ants are very careful not to injure or disturb the lice, which they treat with remarkable gentleness. Probably the most effective remedy for plant lice is strong soapsuds, which can be applied in the same manner as for canker worms, by means of a garden pump. Some fruit growers use a decoction of tobacco with the soapsuds, which makes the remedy much mere effective. *American Cultivator.*

CURING A COLD IN THE HEAD.

The commonest type of cold is that called "cold in the head," to distinguish it from "cold on the chest." This "cold in the head" has certain well-marked symptoms, a feeling of general *malaise* is experienced, often accompanied by a slight feverish sickness. Then comes a sensation of fulness in the head, there is sneezing, a profuse flow of tears, an irritating and copious discharge from the nose. This means that the mucous membrane of the nose is inflamed, and if this spreads down the back of the throat the sufferer becomes hoarse. The best way to treat this troublesome complaint is to take a "hot drink." An orange sliced and put into a large cup with a little sugar sprinkled over it, and boiling water poured upon it, and then drunk as hot as possible, is both pleasant and beneficial. The feet should be put into hot water, with or without a little mustard. This foot bath should be taken at the bedside; the patient should be well wrapped up, and a blanket placed across his knees should be drawn outside the bath, so as to confine the steam. After keeping the feet in the water for from five to ten minutes, the patient should lose no time in getting into bed, where he will probably derive great benefit from the general feeling of warmth, and from the flow of perspiration which has been induced. If possible, at this stage, the patient should remain in bed for two days, with a fire in his room, which should be well made up at night, so as to keep alight till morning. But keeping in bed will do little good if the patient persists in holding a newspaper or a book to read, for thereby he is more dangerously exposed to cold then if he were up, dressed and going about as usual. The main point is to keep throughly wrapped up and constantly warm. Even an uncomfortable degree of heat may be beneficial.

A small piece of camphor chewed and sucked is very good. So is the inhalation of sulphuric acid gas—a remedy which was found to be in constant use by the weavers of Kircaldy, who had it among the materials of their work. Buy two ounces of sulphurous acid (dilute) from a chemist, and then take out the cork and inhale—through the nostrils only, of course—the pungent gas which is given off. Some use Ferrier's snuff, and find benefit therefrom; but it must be used cautiously, as it contains a powerful drug—to wit, morphia. Ten or twelve grains of Dover's powder taken in gruel at bed-time is good for an adult, but should not be administered to children, as it contains opium, which should never be given to them without a doctor's prescription. To avoid an unpleasant excoriation of the nose and upper lio during the course of a cold in the head, they should be often washe l thoroughly with soap and lukewarm water and a little vaseline should be applied. If the throat feels sore a chlorate of potash lozenge should be sucked ocasionally.—*Household Words.*

MEMORANDUM ON KILLING, PRESERVING AND TRANSPORTING INSECTS.

For killing insects, the best thing is a tin cylinder—say, an empty tobacco-tin—with a closely fitting removable cap lid at each end. The ordinary half-pound tobacco tin, which is about 6½ inches long with a circumference of 9¾ inches, is a convenient size for most insects. Into this a perforated tin diaphragm may be fixed, at about 1½ inch or 2 inches from one end of the cylinder. The larger chamber will contain the insects to be killed, while the smaller one will be used as a receptacle for poison.

The most effective poison against insects is cyanide of potassium, but its peculiar property of deliquescing with either heat or moisture renders it difficult to use. I have tried making up strong solutions of it with plaster-of-Paris (calcined gypsum), but I find the effect goes off too rapidly, and the hardened cake soon becomes perfectly innocuous. I have also tried enclosing solid pieces of cyanido of potassium in plaster-of-Paris, but I have not yet succeeded in getting the plaster to set properly. Should further experiments in this direction turn out better, I hope to be able to supply a convenient form of insect poison to any one who wishes to possess it.

Hitherto, I have employed essential oil of almonds, a drop or two of which on a small piece of sponge is quite enough to fill a tobacco tin with strong fumes of prussic acid. In place of the oil, ordinary flavouring essence of almond may be used, but its effect is not so good. The oil may be obtained from any chemist at every large station, while the flavouring essence is procurable from all provision dealers. Ordinary benzine is also very effective, and is easily obtained from any chemist. It has further the property of removing greasy stains from the wings of moths, when directly applied. Before being placed in a collection, the insect should be painted over with a fluid composed of:—

1 quart of methylated spirits.
1 oz. of mercuric chloride (corrosive sublimate).
1 oz. of carbolic acid.

This will preserve it from insects and mould.

Larvæ of insects—grubs of beetles, bees, wasps, &c., and caterpillars of butterflies and moths—may be preserved in spirits of wine.

For transmission by post, larvæ may be sent in bottles of methylated spirits. Beetles, grasshoppers, and hard-bodied insects generally, should be placed in tin-boxes with saw-dust, over which benzine should be liberally sprinkled.

The various species of insects in one box may be separated by layers of paper. Lepidoptera (butterflies and moths) should be packed, with their wings together, in pieces of paper folded into triangles with the edges overlapping. The specimens must not be left loose in the box, but so arranged that they cannot be shaken in transit. When packed with insects, the box should have all its interstices covered with gum paper carefully applied, so as to exclude all enemies.—M. H. Clifford.—*Indian Forester.*

Origin of the Blood Orange.—A correspondent sends us the following cutting from the *Tropical Agriculturist* respecting the origin of the Blood Orange in the hope that its appearance in our columns may lead to a discussion tending to confirm or refute the ideas suggested in it:—* * * (see page 93.) Of course no gardener would admit the preposterous notion that a Pomegranate would either graft or hybridise with an Orange.—*Gardeners' Chronicle.*

THE NATURE OF DEW.

The researches of Dr. Wells into the nature of dew, made a great many years ago, are still acknowledged as disclosing the true theory of the phenomenon, and yet there is ample room for further investigation. The popular idea is that dew falls, and anxious mothers still caution their children, especially if they are delicate in health, against exposing themselves to the falling dew. Dr. Wells proved that dew did not come either from the earth below nor from the sky above, but that it was condensed out of the air in contact with plants and other cold surfaces. And yet the popular idea not erroneous, for the vapor in the air may be condensed on floating motes and dust, giving rise to what may fairly enough be denominated falling dew, although it is really a gentle rain formed not far from the surface of the earth. Whether it should be called dew or invisible rain is a mere matter of taste, and a question of definition. There is really no reason why the popular phraseology should be changed, and even from a scientific point of view the term "falling dew" may be defended as preferable to "invisible rain." During a fog the beards and whiskers of men frequently collect quite a large quantity of dew, while in very cold regions the eyebrows may collect dew which is converted into hoar-frost. The fact is that dew is deposited whenever the grass, the air, or the hair falls in temperature below the dew-point. The analogy may be carried further, and it may properly be asked whether fog is anything else than floating dew. If the answer be in the affirmative, then the whiskers may be supposed to collect the dew already existing in the air, and the difference between falling dew and fog may merely be one of mass or quantity. Dr. Wells was no doubt quite right in saying that the dew which is visible on the surface of leaves, is condensed upon them directly from contact with moist air and yet it is quite possible that the quantity is increased by the incidence of falling dew—the phenomenon thus being the result of two or more influences. Prior to his time, there had been much discussion as to whether the dew rose from the earth below, or fell from the sky above. It had been ascertained that there was a heavier deposit of dew inside a bell-jar than there was outside, and it was argued that the dew inside must have ascended from the earth. The correct inference is that the vapour already pre-existent in the air is reinforced by an accession of vapor from the earth, the heat absorbed during the day serving to maintain evaporation after sunset, while the bell-glass merely served to prevent the dissipation of this vapor by the wind.

Some further light has been thrown by Mr. Aitken, of Edinburgh, on the dew question. He asked himself why dew was not deposited on gravel paths and dry ground, as well as on the vegetation in adjoining beds, and he has found the answer, which is—that dew is deposited on the gravel and dry earth, but it has to be looked for in the right place, namely, on the under-side of pebbles, while some of it is no doubt absorbed. There should, however, I imagine, be less dew on dry patches, because there is a more free circulation of air by which the vapor is carried off. The vegetation itself imprisons the moist air, and thus favors the deposition of dew.

Another form of dew, or of what is taken for dew, was discovered by Mr. Aitken. He found that some plants were more bedewed than others, that the surface of the leaf was not wet all over, and that the deposit on any part had no relation to its exposure to radiation or access to moist air. The position of the drops of apparent dew had a close relation to the structure of the leaf. On brocoli plants the drops were all placed at the points where the veins of the leaf came to the outer edge. On grass the moisture was in drops attached to the tips of some of the blades. Other considerations led him to the belief that these drops were not dew at all, but exudations from the plants. That plants exude such globules has been pointed out by other observers, but Mr. Aitken is the first to point out their relation to the appearance of dew. The explanation is exceedingly probable. The exudation is no doubt going on in all weathers, but it is only on dewy nights that the drops will hang to the plant. When the air is dry they are likely to be carried away as vapor. Experiments were made on leaves protected from all contact with the atmosphere, and on these the exudations made their appearance. These facts do not in any way invalidate the accepted theory of dew, but they serve to show that the phenomena are more complicated than has hitherto been supposed.

Mr. Aitken also made experiments on the radiation by night of several substances, and he found that they gave very different results from those obtained by experiments made in the day time. Black and white cloths were found to radiate equally well, a result which invalidates the received theory that absorption and radiation are equivalent. Franklin's experiment on the melting of snow under patches of black and white cloth in full sunshine will be here called to mind. Soil and grass radiate equally well by night. Lampblack and whitening are also alike. Snow in the shade on a bright day was 7 degrees colder than the air, while a black surface was only 4 degrees colder. This difference diminished as the sun got lower, and at night both radiated equally well. These facts are exceedingly instructive.—*Leader.*

ENEMIES OF THE SUGAR-CANE.

In India little or nothing has yet been done in the way of protecting its agriculturists from the losses caused by insects. There is a school of forestry at Dehra, and the instruction given there includes some account of the insects useful or hurtful to man and his industries, and we see references as to individual insects from time to time made to Mr. Wood-Mason. Some years ago Mr. Thompson, of the Forest Department, contributed a valuable pamphlet on the enemies of the forest trees; Mr. Haldane's "All about Grubs" mentions several beetles which injure the coffee shrubs; and Mr. Nietner in Ceylon, and Dr. Bidie of Madras, have added considerably to the existing information regarding them. But India has no reports or compendiums such as in England periodically issue from Miss Ormerod's pen, and the first attempt to furnish a general view of the Indian agriculturists' insect foes has been given in the "Cyclopædia of India," the third edition of which was mentioned in our issue of July 6. Yet the tillers of the soil of India are skilful, hard-working husbandmen and gardeners, but they are great sufferers from blights, and their patient toil should win for them all the care which the scientific skill at the command of Government can bestow. They are in many tribes and of different races, the farmers of recognised superiority being the Chasa and Khisan of Bengal, the Kunbi and Kurmil of the Western and Northern Provinces, the Tamil Vellalar, the Teling Reddi, Kapa, and Kama, and the Canarese Wahala, the finer garden work being carried on by the Tota-Kara, the Mali, the Kachhi, the Lodha, and others. We have been led to these remarks by the perusal of a pamphlet on, "The Animal Parasites of the Sugar-cane," by Hy-Ling Roth (Trübner & Co.). The cane is to be seen growing everywhere throughout British India, and, although used by the people more as a fruit than for sugar-making, it takes a prominent place among their garden plants. It receives from them great care for it is a costly plant to grow, occupying the grounds for many months, requiring a rich soil, with plenty of manure and abundance of water. It is liable to be attacked by several insects, and if, from boisterous winds, the tops become twisted, the growth is checked and the cane rots. The planters of the West Indies, South America, the Mauritius and Australia, have given much attention to the investigation of the diseases and injuries of the cane, and Mr. Roth has done good service to the planting industry and to science by summarising all that is known of its animal parasites. An examination of growing cane exhibits a variety of animal life which is simply marvellous; and the planter who thinks little of a single parasite

ignores two important facts: firstly, that parasite breed most rapidly; and, secondly, that myriads make up for want in individual side. Mr. Roth tells us that a species of Hoplosternus is the common chafer of Queensland. Its grub destroys the roots of the cane, causing the leaves to become brown and dry up; the growth of the cane is then arrested, and the first high wind knocks it over. In this manner whole fields of cane are killed. In the early stage the larvæ are occupied in gnawing the roots. In November and December the chafers, fully developed, appear above ground in swarms, inactive during the day but feeding eagerly at night. An ant, the Formica saccharivora, is supposed to get at the sweet juices of the plant and injure it. Another insect, the waxy sugar-cane louse, is known to the Mauritius and Bourbon planters as Le Pou a Poche Blanche. It is the icerya sacchari, and occurs also in Queensland, and Mr. Roth supposes that it is milked by a small black ant, Formica rufo-nigra, in the same manner as species of aphides are by other ants. He considers the Pou to be a cause of very great injury to the cane. The cane has its enemies in other countries. The sugar-cane beetle of the United States is the Ligyrus ruficeps, *Le C.* It is a stout black beetle, half an inch long, which bores into the stock of the sugar-cane under ground.

Sugar-cane ravages in Grenada are caused by the cane-spittle fly, Delphax saccharivora; in Natal by the cane smut, Ustilago sacchari, a disease, analogous to the smut of wheat and maize; in the Mauritius by the Proceras sacchariphagus, which Mr. Westwood has supposed may be indentical with the Diatræa sacchari; *Guilding*, and Phalæna sacchari, *Fabricius.* The Borer of the Queensland planters has been supposed to be the larva of this Diatræa sacchari. It enters the cane above ground and eats up the heart. It is supposed to be indentical with the Borer of the Mauritius, the Proceras sacchariphagus. The wire-worm, larvæ of the chick beetle, are found at the roots of the Queensland cane, but no damage from them has been detected.

Many suggestions have been made for the destruction of these and other insect pests. In this country Miss Ormerod is devoting herself, to the investigation of the field, and garden, and forest enemies of the vegetable kingdom, and has suggested several means for preventing or lessening the severity of their attacks. It has lately been said that many insect marauders are killed or scared away by a kerosine emulsion; a gallon of kerosine is mixed with three pints of water and a pint and a half of milk, and churned into a butterine consistence. This is diluted with twelve or sixteen times its weight of water, and has to be at once applied, because the component parts separate if allowed to stand. W. Bancroft writing in 1878, mentioned that he had with advantage sown the Dolichos lablal and Cajanus Indicus pulse among the sugar-cane fields, with the object of attracting the Ichneumon flies which destroy the cane louse. On lands which are cultivated on the rotation system all parasites have to seek fresh feeding-ground once a twelvemonth or oftener, and are thus kept away for a considerable period, or left to die in the absence of their special food. And the protection of insectivorous birds and bats has been recommended, with the hope of keeping down the pests by their means. The smut and rust, and yellow blast and black blast are planters' names for diseases of the cane which need scientific investigation. —*Overland Mail.*

The Indian Government Quinine factory sold, in ten years, something like 75,233 lb, of the drug. In other words, supposing that each patient took 20 grains—sufficient in most cases to greatly incommode all but the most hardened users—very nearly 22 millions of fever-smitten people had reason to bless an "oppressive and tyrannical bureaucracy."—*M. Mail.*

NOTES ON BAMBOOS.*

Bamboos may be propagated either by planting out sets from existing clumps, or by sowing seed. If sets are used they should be taken from vigorous two or three year old shoots with their rhizomes, and transferred with soil about the roots to the pit in which the bamboo is to grow. The stem should be cut back above a joint at about 5 feet, and the set planted about 8 or 10 inches deep in the early rains, and as quickly as possible after removal from the parent clump. The new shoots will then be thrown up from the eyes, and, all things being favourable, bamboos fit for sale will be produced on good soil in about six or seven years. The stem may be removed and the set laid flat under the soil, as is done with sugar-cane sets. This method has given good results, but the sets were regularly watered from a well.

If seed is used, it should be put down in worked earth, just below the surface, and should be lightly watered. It will throw up a shoot like grass, from the eyes of which new shoots will be thrown up during the first year. In the second year, other and larger shoots will be thrown up, and so on, each year's shoots being larger in girth and taller than those of the preceding year until the full size of the culm of the kind of bamboo is attained. With sufficient rainfall, and in a good but not too moist a soil, bamboos fit for sale may be cut in from about seven to ten years. On poor dry land, or on sandy soils, the period may extend to twelve years or more. The seed used should be not more than a year old, and should be sown very sparsely in the bed.

The first shoot that comes up from a seed never grows into a bamboo. As already explained, the eyes throw up shoots which develope into stems. Each stem comes up as large in girth as it ever will be. It first appears as a scaly cone covered with sheaths. It then rapidly attains its full height, when the leaf sheaths at its nodes either diminish in size or gradually fall off and give place to leaves; the stem branches on its upper half, and on completion of the branching is matured. It does not grow any taller or stouter, nor does it solidify or fill up inside year by year, but stands in the clump till it dies off and dies in from twelve to fifteen years. Each stem matures under ordinary circumstances in about twelve months. A clump of bamboos of, say, twelve years of age is thus a collection of stems from one to twelve years of age and of different sizes, the variety of size being caused not by the annual increase of the older stems, or of any individual stem, but by the fact that each annual crop of shoots produces stems of greater diameter and height than those of the preceding year until the limit of the normal size of the species in both height and girth is reached. That limit may be reached in very favourable circumstances in five years, a shoot of that year coming up, perhaps, two or more inches in diameter in the first heavy rains, and rising by October to 40 or 50 feet in height. The new shoot not being branched at first is able to make its way through its companions, and, as already said, it begins branching on attaining its full height. All that has been now written of the manner of growth applies equally to stems produced from sets or from seed. But a clump produced from seed has its normal period of life before it, whereas a clump from a set has before it only that portion of life period which had not been already spent by the parent clump from which the set was taken. The life of an individual stem is by no means the same as that of the clump to which it belongs. Individual stems die off in from ten to fifteen years, while the common life of the clump may extend over from twenty to forty or fifty years. Some species are shorter lived than others, and the duration of

* The above is taken from a very readable little pamphlet by Colonel van Someren, Conservator of Forests, Berar, and obtainable from Messrs. Thacker & Co., Bombay. It consists of papers on Indian Forestry originally published in the "Indian Agriculturist" for 1884, intended by the author to answer, in a popular manner, the question "What do you Forest officers do?"—Ed. *I. F.*

the longer lived species is not accurately known, but fifty years is probably the extreme. Individual stems thus dry up and die in succession without seeding, but the clump lives out its normal period, when it flowers, seeds, and dies; all stems then living, whatever their age or size, seeding and dying together.

As each stem matures separately, and, once matured, will never becomes any larger, it may be thought that when a clump has attained sufficient age to produce stems fit for sale, such clums might at once be cut out and utilized. But this would stop the increase of the clump, for it is only the young stems that are less than four years old that send up fresh shoots from their rhizomes. It thus follows that the younger stems should be left till at least their fifth year, while the older stems may be removed, for they are matured are no longer reproducing themselves and are saleable.

This peculiarity of the bamboo makes it a matter of some little difficulty to decide whether a block of bamboos is, or is not, being overworked. The condition of the separate clumps, or of a large proportion of them, must be studied, and measures must be adopted, and enforced, to prevent the reproducing stems being cut out. They are often among the finest in the clump, and often also the handiest to the axe of the cutter. They must be preserved, while if too many old stems are left, the young shoots will be hampered in their growth and become much twised in their lower portions. Owing again to this peculiarity the closing of blocks of bamboo forest against cutters for a term of years may indeed protect the newer culms, but will also lead to many of the older ones being wasted. Each case must be settled on its own merits, but where good supervision can be enforced the closing of blocks is not advisable.

In Bengal, in parts of the North-West Provinces, in the Deccan, in Mysore and Madras, and possibly elsewhere in India, it is an article of common belief among natives and acted up to in practice, that bamboos cut in the bright half* of the month are sure to be attacked by insects and to turn quickly to powder; while those felled in the dark half of the moon's course will last for a long time. It is also held that the new shoots are not sent up, even if rain falls, till the thunderstorms that precede the monsoon have set in; and, further, that the more the thunder, the larger will be the number of new shoots sent up that year.—*Indian Forester.*

THE VALUE OF SULPHATE OF AMMONIA AS A MANURE.

By Mr. F. J. Lloyd, F.C.S., Lecturer on Agriculture at King's College, &c, London.

Writing to the *Journal of Gas Lighting*, Mr. Lloyd, F.C.S., says:—Of late the *Journal* has contained some interesting matter in reference to sulphate of ammonia. Perhaps, therefore, a few words on this subject from an agricultural point of view might not only prove of interest to its readers, but, while dispelling from their minds the false views regarding the future of this product, enable them to rightly estimate the true relative merits of nitrate of soda and sulphate of ammonia as manures. Each of these substances has a manurial value; and both owe this value to the same fact, viz., that they contain nitrogen. In the one the nitrogen exists combined with hydrogen as ammonia; in the other, combined with oxygen as nitric acid. It is a well-known fact that 100 parts of commercial sulphate of ammonia, of 94 refraction, such as is now usually sold for manurial purposes, contains about 20 parts or more of nitrogen; while the detrimental impurities, the various cyanides, which used twelve or more years ago to be somewhat prevalent in sulphates of ammonia, are now seldom met with. On the other hand, commercial nitrate of soda, of 95 refraction, contains little less than 16 parts of nitrogen. Hence, unless it can be shown that the nitrogen in sulphate as ammonia is less valuable to the farmer than the nitrogen in nitrate of soda, it is evident that, so long as a ton of nitrate of soda can be bought for £10 (which is approximately its present price), sulphate of ammonia is worth £12-10s. a ton. Now, is the nitrogen of ammonia as valuable to the farmer as the nitrogen of nitrate? In order to answer this question, which lies at the root of the whole subject, it is necessary to briefly state some facts regarding the function of the roots of the plant, and the properties of the soil. The majority of plants take most, if not all their nitrogen from the soil as nitric acid. There can be no doubt, therefore, that nitrate of soda will act upon vegatation more rapidly than sulphate of ammonia. But it is equally certain that every properly cultivated soil possesses to a high degree the power of nitrification—that is, it converts all nitrogenous substances gradually into nitric acid. Ammonia is one of the substances most easily so converted. Hence it is certain that, when sulphate of ammonia is used as a manure, the soil will gradually convert the ammonia into nitric acid, and supply to the plant nitrogen really in the very same form as is supplied by nitrate of soda. So far it is evident, then, that nitrate of soda is only more beneficial than sulphate of ammonia, inasmuch as it acts upon vegetation more rapidly.

Next let us consider the action of the soil on these two substances respectively. The late Dr. Voelcker, among his valuable additions to agricultural chemistry, left none more valuable than his researches upon the action of soils on manures. By analysing the water flowing from the drains of large fields, where crops were cultivated under varying conditions and manures, he proved that nitrate of soda is washed rapidly through the soil by rain, so that a large quantity of the nitrogen so applied to the soil is never taken up by the roots of the plants; and during the time there is no crop growing the nitrate of soda is being merely washed away. Not so with sulphate of ammonia. Only once or twice in all his experiments, did he find ammonia being washed through the soil into the drains, and then only in minute quantities, and this was found to be the case even where the land had been manured with 4 or 5 cwt. of sulphate of ammonia—far larger quantities than are usually employed. What then became of the ammonia? It was found that all fertile soils had the power of retaining ammonia, which became only gradually converted into nitric acid; and then only, and not until then, was it washed out of the soil. Meanwhile any plant growing in the soil would be well able to take up the nitric acid as it was formed, so that less would be lost, than where the nitrogen had been applied as nitrate of soda. If then nitrate of soda is more active than sulphate of ammonia, still the latter is more lasting and less wasteful. It is evident that manure manufacturers are well aware of this fact, for one seldom finds nitrate of soda admixed in compound manures, except for special and forcing purposes, while sulphate of ammonia is largely and rightly used for mixing with phosphatic manures. If I have made my meaning clear, it will be evident that the producers of sulphate of ammonia have nothing to fear, from theoretical reason, as to the supposed inferiority of this manure, when compared with nitrate of soda.

As might be anticipated, practice in the field confirms these scientific conclusions. Thus the renowned experiments of Sir J. B. Lawes and Dr. Gilbert at Rothamsted, and the experiments by the late Dr. Voelcker at Woburn, for the Royal Agricultural Society, yielded the following results, where equal quantities of nitrogen were applied as sulphate of ammonia and nitrate of soda respectively:—

* An experiment to decide this, was carried out at Dehra in 1884, and the popular theory was fully confirmed, the 100 bamboos cut in the bright moon being riddled by insect borings, whilst the 100 cut in the dark half of the month are almost untouched. It is probable that, the insects which cause the borings only deposit eggs on bright nights.—Ed. *I. F.*

At Rothamsted the ammonia salts were applied in the autumn; but at Woburn in the spring. In both cases the nitrate was applied in the spring; and it is evident that there is an apparent superiority of nitrate of soda over sulphate of ammonia (and chlorides, for they were mixed) at Rothamsted. I have, however, brought forward these results because they illustrate very forcibly how much the value of a manure (and especially a manure like sulphate of ammonia) depends upon the time of its application. Undoubtedly the best time to apply sulphate of ammonia is in the spring—early spring—and in damp weather. And this is why the Woburn experiments yield more favourable results. Had the nitrate of soda at Rothamsted been applied in the autumn, it would have been largely washed out of the soil, and proved useless; and then the sulphate of ammonia would probably have yielded much larger crops than the nitrate. The fact that the sulphate remained in the land all through the winter, and produced a crop very nearly as good as the nitrate applied in spring, is a strong proof of its great value as a manure. In fact, the only legitimate conclusion which can be drawn from the preceding is that the nitrogen in sulphate of ammonia is every whit as valuable as the nitrogen in nitrate, provided the sulphate be properly used. But there is another advantage possessed by sulphate of ammonia, as opposed to a direct disadvantage under which nitrate of soda labours. It is this: nitrate of soda will often prove of more harm than good on stiff clay soils; while on such soils, sulphate of ammonia proves a most valuable manure. Indeed, there is no soil upon which sulphate of ammonia has proved to have any injurious effect; while there is evidence of farmers having found nitrate of soda injurious on their wet stiff clays.

It must not be supposed for a moment that in upholding the value of sulphate of ammonia, I wish to detract from the value of nitrate of soda. Each has its proper use; and each to give good results, requires care and judgement in its use. There are circumstances and conditions when, as shown, sulphate of ammonia is superior to nitrate of soda; but there are equally circumstances and conditions, when nitrate of soda is superior to sulphate of ammonia. This, however, is not the place to enter into the conditions. All that I wish to point out to gas companies and sulphate of ammonia manufacturers is this—that sulphate of ammonia is most valuable as a manure, and can be applied in the majority of cases with as great advantage as nitrate of soda. The unite value of nitrogen therefore in these two substances is (for the farmer identical; so that the price of sulphate can never be above that of nitrate of soda, except in so far as it contains 20 parts of nitrogen to 16 parts in nitrate of soda, and the market value of these two articles must regulate one another.

But the question of demand must be taken into account; into the supply of sulphate we need not inquire. What the manufacturers want is to create—or rather to increase—the demand. Those interested in nitrate of soda have already realised the importance of this; and hence, no doubt, the tempting bait of £500 which has been offered for the best essay on its advantages. That this essay will be in strict accordance with scientific and proved facts is certain from the names of those who have been selected as judges. Hence it will carry great weight and conviction; and the impetus which will be given, not only in England, but throughout the world, to the use of nitrate of soda as a manure, will be immense. Some twelve months at least must elapse before the prize essay can be published; and the producers of sulphate of ammonia will have none but themselves to blame if they refuse to utilise the interim in making more widely known the advantages of sulphate of ammonia as a manure—advantages which are as real, and as well proved, as any of those which can be brought forward in favour of nitrate of soda.—*North British Agriculturist.*

Cardamons in Queensland.—The Acclimatisation Society have just received, from India a small parcel of the seeds of those valuable plants *Elettaria cardamomum* and *E. robusta*. The cardamom, being of a purely tropical nature, is unfitted for cultivation in the southern portion of the colony; but in the far North many favourable localities an be found where the plant would luxuriate. The Society will therefore be pleased to supply with a small quantity of seed any of our Northern settlers who are desirous of giving this plant a trial; application should be made to the overseer, Bowen Park. It may be interesting to note that a plant of *E. robusta* was wintered at Bowen Park (in the bush-house) without any protection, the lowest temperature being 30°. This proves the plant to be much hardier than is generally supposed, although the higher the temperature the more success will attend its culture.—*Queenslander.*

The Subject of Tropical Fruits, and a probable future market for them, is one of great moment to Queensland settlers; therefore, we have watched with interest the doings of the sister colonies in their experimental shipments of fruit to Europe, and have from time to time informed our readers of the success or otherwise of these ventures. Considerable interest also has been felt in Britain at this sight of splendid fresh fruit "all the way from Australia." The other of the British colonies have not been behind and also in forwarding fruits, and notably from the West Indies have fine specimens of tropical fruits been sent. Being the nearest colony possessing a tropical climate, the West Indies will naturally supply the English market with pineapples, bananas, mangoes, &c.; still there is abundant room for Queensland competition, and the ease and success with which such a perishable fruit as the banana can now by the aid of cool store-rooms and swift steamers be landed in London argues well for a similar success from this colony, though the distance is somewhat greater. The taste for tropical fruits is one which increases the more they are eaten. Few people think much even of the banana the first time it is tasted, but soon the fruit becomes almost a necessity. The same with mangoes, &c. Once let the liking for these fruits get hold of the populous countries of the temperate portions of the world, and the demand for them will be insatiable.—*Queenslander.*

Peermaad.—A correspondent writes:—"The rise in the coffee market has cheered planters both in this district as elsewhere, but owing to the transformation of many coffee properties into tea and cinchona, there are not many proprietors who will benefit by the rise To those a golden future is in store, as the rise, from all accounts, promises to be a permanent one. Tea cultivation is increasing, and that too in the face of a fall on the market of 20 to 25 per cent, and a good deal of tea finds its way down to the Coast. Tea and cinchona have done much to save planters here from shipwreck, and were it not for the illiberal condition of the Travancore cardamom monopoly, that product would also have materially assisted them, as it grows well in the forests and belts attached to estates. Under the present rule, growers have to hand over their crops to Government agents, and when the cardamoms, are sold receive one third of the value for their expense and trouble. This rule is, however a dead letter, and the crop picked by planters nearly a year since has not been yet settled for, while the Government has realized on the sale as far back as April. Under these circumstances, it is not to be wondered at that planters scarcely care to work their holdings, and the cultivation of the spice must eventually be given up. The fault does not appear to be at the door of the manager of the department, who is a well meaning man and anxious to do his best for the growers, but the blame seems to rest with the upper administrators of the State."—*Madras Mail.*

THE TEA PLANTER'S MANUAL*.

25th October 1886.

"The Tea Planter's Manual" of Mr. T. C. Owen which has lately been issued from the Press is a useful little book, and comes to meet a much felt want. With tea as its topic, it has a wide horizon, and should have a wide circle of readers. Every manner of subject connected with our new product is more or less discussed, and the budding tea planter who is all alive for information and has an insatiable appetite for "wrinkles" as well as the man who poses as an authority and is above such things, may find in its pages something instructive to the one, and interesting to the other.

The book is unambitious; "more a compilation of the opinions of others, and the results they have arrived at than an original work" is part of the modest preface which introduces the reader to the "Manual."

Still Mr. Owen does not efface himself when in the presence of our most authoritative names, but objects to their finding when he sees due cause—"checks up" in the planter's vernacular—and in so doing he but evinces the every day characteristic of the class to which he belongs, who having acquired their knowledge in the school of experience are unwilling at the bidding of any to resign the heritage won therefrom.

In works of this kind there are several classes—compilations and compilations in fact—and those of my readers who are acquainted with an ambitious London book entitled "Tropical Agriculture" will, when comparing it with "The Tea Planters' Manual" appreciate the difference I speak of. The former is a thing of paste and scissors, bundled together any way, contradictory, confusing, and unsafe; whereas the "Tea Planters' Manual"—albeit largely the work of the paste pot and cuttings—has like the famous artist's paints, a mixture of brain therewith, and is all the more valuable for the addition. It is in fact a practical treatise from a practical man.

Yet it is not perfect and has some sins of omission, which might be remedied in another edition.

For example, in the estimate for opening 200 acres there is an item for roads and drains, and we can suppose a student of the "Manual" anxious to get some information as to the best kind of roads to cut. R15 an acre is allowed for roading and draining; but when he turns to the chapter on "Field cultivation," he finds nothing whatever to guide him regarding roads except a few general statements as to the desirability "to make all portions of the estate as readily accessible as possible." The information about the drains is complete enough: "good 18-inch drains at from 30 to 50 feet apart according to the character of the land, at a gradient of 1 in 15 ft." What I complain of is that similar definite information has not also been given regarding the roads. In a Manual there should be no taking for granted. A similar objection applies to the item under nurseries. It runs as follows:—"Nurseries and cost of 25 maunds seed which should have been laid down previously R2,000." Now how is this to be a guide to any one? How much for seed? How much for nurseries? Again I turn back to the chapter on "Seed and Nurseries," and although there is no reason to complain of the general information in this case, which indeed is very full, still the cost of making beds, planting, &c., is not given. All you have to guide you as to cost is the remark, "I do not think R2 per 1,000 is too high an allowance for the cost of raising good plants including cost of making a nursery." What a student of the "Manual" wants is *detailed* information which will be useful to him in his work as it progresses day by day, although the other is not without its value. To the experienced planter details are not so important, yet even he cannot carry about in his head the cost of everything, and I do not think that a Manual can be too explicit or too full. One man wants one thing and one another, and if both knew the whereabouts to enquire for everthing, they would go there.

The book has two coloured plans of factories drawn to a scale, which must have added very much to the cost of the "Manual," more I think, than they are worth: and although they help to wear your book out earlier than it otherwise should, still when you add to the plates the figures estimated to erect such a building—and remember what such estimates are worth, those who don't care for them as plans, can regard them as illustrations of what is expected from the Ceylon planter, and more especially from the favourite product, to the cultivation of which he is now so devotedly attached. May it prove a true prophecy.

There is very much in the "Manual" to which I should like to refer, but already I am near my limit, and must deny myself the pleasure. If I here objected to some things, it is not that I do not appreciate this new addition to the Ceylon Planting Manuals: but rather that I should see its present value enhanced. The book is stuffed full of information, and the wonder is not that there are some omissions, but that these omissions are so few. As an "Enquire Within" for everything about tea, I would commend it. PEPPERCORN.

*By T. C. Owen; published by A. M. & J. Ferguson, *Observer* Office, Colombo, 1886.

DR. H. J. FOX announces, in the *St. Louis Medical Journal*, that creosote is almost a certain cure for erysipelas, for he has treated some hundreds of cases with only one fatal result. The affected parts are kept constantly covered with cloths soaked in a solution of creosote in water—six to twenty drops of creosote to one ounce of water; or a poultice may be formed by stirring ground elm into the solution so as to make a paste.—*Madras Mail.*

ADVANTAGES OF CROWN GRAFTING.—By adopting crown grafting, almost all the advantages of budding upon single stocks are secured, and in this way part of the work can be done in the winter, and not all rushed into the hurry and bustle of summer. In crown grafting it is best to use good, first-class stocks shortening the tap root a little, leaving 9 to 10 inches of root, and use scions shorter than piece-root grafting, say about 3 inches, and make the splice or union just at the crown or collar of the seedling. Plant the graft about 1 inch below the joint, leaving 2 inches of it above ground. Should any of the scions fail, the seedling will throw up a sucker, which can be budded the same fall, and thus have nearly a perfect stand.—N. H. ALBUNGH.—*Journal of Forestry.*

LEMON.—The *Gardeners' Chronicle* says:—The lemon plant, or sweet-scented verbena of our gardens (*Aloysia citriodra*), holds a foremost place among Spanish herbs. Every leaf of it is treasured and dried for winter use, and it is regarded as the finest cordial and stomachic in the world. It is taken in two ways—either made into a decoction with hot water and sugar and drunk cold as a *refresco* and tonic, or, better still, with the morning and evening cup of tea. Put a sprig of lemon verbena, say five or six leaves, into the tea-cup, and pour the tea upon it; you will never suffer from flatulence, never be made nervous, never have cholera, diarrhœa, or loss of appetite. Besides, the flavour is simply delicious; no one who has drunk their Pekoe with it, will ever again drink it without a sprig of lemon verbena. It may not be generally known to our readers that some of our most successful tea mixers have acquired fame by using the leaves of this plant amongst their tea.—*Planter and Farmer*—["Is that so?" as they say in America.—ED.]

INSECTICIDES are always a subject of more than passing interest to cultivators, for they are brought directly face to face with these pests experimentally. A new and very promising one consists of camphor dissolved in methylated spirits to saturation, and mixed with soft soap to the consistence of cream. When diluted so as to be fit for use with a syringe, this has been found an efficacious substitute for fumigation in the case of mealy bug, scale, red spider, &c. &c., —*Planter and Farmer.*—[Too expensive on a large scale, we fear.—ED.]

FINE SALE OF CEYLON HYBRID CINCHONA BARK.—We have lately been favored with an inspection of an account sales of 6,124 lb. of bark from the Broughton estate, in Haputale, which netted, after paying all charges, £308 6s 5d, or about 1s a lb. nett. One lot of Hybrid renewed bark analyzed 3·72 per cent. sulphate of quinine, and realized 1s 3d. per lb., whilst another lot of renewed Hybrid analyzed as much as 5·73 sulphate of quinine, and fetched 1s 8d. per lb. These fine hybrid trees which are planted at an altitude of about 5,000 feet, are *robustas* of the most vigorous and robust type, and are naturally highly prized by the proprietor of the Broughton estate, to whom they must be a little gold mine.—Local "Times."

CEYLON TEA.—The *British Trade Journal* states :—The Ceylon Tea Agency, Thames Street Chambers, E. C., are offering to the public, in packet form, the "Colombo" brand of pure Ceylon tea. These lead packages, of various quantities, are carefully got up for the retail trade, each bearing the trade-mark of the company on a neat wrapper. The tea is selected from the best gardens, and possesses those qualities for which tea is growing in favour in this country. The leaf is free from mineral or other facing matter, clean, well-formed and free from dust, while its flavour and colour are excellent. It should need but little effort to induce the British consumer to patronise so good an article offered at so reasonable a price.

QUININE IN JAPAN.—Vice-Consul Russell Robertson writes from Yokohama :—The low prices ruling in Europe for quinine have tended greatly to increase the consumption here, and continental manufacturers, by reason of competition, have been bidding for the trade by coming into the market direct themselves to supply the demand. Leading French and German makers have their agents here, and consequently prices that have been ruling during the year have not offered any inducement for resident business importers. The English makers have not been so pushing, and their quinine is now almost unknown in this market.—*Chemist and Druggist.*

HOW SUNFLOWERS ARE USEFUL.—This plant is a vigorous grower and has been extolled as a preventive of malarial diseases. The seed affords excellent food for hens and also for horses. It is said that there is no kind of feed that will keep horses in health, give them a sleek appearance, and make them lively and spirited like the seed of the sunflower, feeding half a pint night and morning. It is particularly recommended for giving a horse power of endurance, being fed half a pint night and morning with other feed. The stalks and heads, after the seed is worked out, also make good material for fires, and are especially convenient in summer when a quick fire is desired and an enduring heat is not wanted. In their growth they make a showy appearance about dwellings and give an agreeable fragrance to the air. The latest direction in the line of utilization of the sunflower is the planting of a seed in a place at the proper distances, so that the stalks as they grow will serve as been poles. We have seen them started in that way this season, and as the stalks grow the leaves are removed, thus forming an excellent stalk for the beans, but what the effect will be upon them remains to be seen. The roots must tax the feeding capacity of the soil quite heavily.—*Germantown Telegraph.*

PLANTING IN WYNAAD.

(From *Annual Report of Wynaad P. A.*)

We have been ably represented on the Coffee Committee of the Colonial Exhibition by Mr. H. Pasteur. As you are all aware, he has for many years fought against the legalised adulteration of coffee, and though he has been unable to get Government to interfere in the matter, I hope that great good will result from his Committee's efforts to expose in a small pamphlet (thousands of which were distributed at the Exhibition), the frauds of the retail trade, and also from their sale of pure Indian coffees. We are indebted to Mr. Jowitt and his colleagues for an exhaustive report on the causes of colour or want of colour in coffee, which, if the result is not quite satisfactory, is from no fault of theirs, but from the difficulties inherent in the nature of the enquiry. However that it has been appreciated by the outside public is apparent from the numerous requests that I have had for copies. We are now carrying out experiments in barking C. Ledgeriana, which I hope will prove of general utility, and I only regret that Government has not seen its way to substantiate its avowed '*raison d' être*' as a cinchona planter by assisting us with free, or at any rate cost price, analyses. I must congratulate you on our improved prospects. During the struggle of the last years I know that I, and I daresay many others among you, have felt that another bad year might be my last in the district, and indeed if you only compare a list of our members of 1880 with one of today, you will see how many good friends have had to succumb. But at last we stand in the clear dawn of better times. That it is so as regards coffee, the following facts and figures which Mr. Pasteur has very kindly sent to me will I think, convince you. During 1885-86, for the first time for many years, the consumption of the world has overtaken the production, and stocks in all European ports have fallen nearly 70,000 tons. On the 1st Sept. last they stood at 146,000 tons, against 217,500 tons on the 1st Sept. 1885. This is the lowest limit that has been reached since 1881, and in that year prices ranged from 96s to 85s. The immediate future depends on this coming Brazilian crop, which is variously estimated from 380,000 to 300,000 tons. If the latter estimate prove the right one, as is generally expected, stocks must fall another 70,000 tons, and I need hardly point out to you that this could not happen without an extraordinary rise in prices. If coffee was to reach 110s or 120s per cwt. again, as in the days of 1875, with the present rate of exchange, we who have tried over the bad times should reap a golden harvest. The prospects of cinchona are also good. The two great scares of these latter days have ended in nought. The story of an artificial preparation of quinine, which was to reduce the price to 3d per oz., has ended in a ridiculous fiasco, and we have the satisfaction of knowing that even if they do succeed in preparing quinine synthetically it is sure to be an expensive process. As regards the 175,000 acres scare from Java, it is pronounced by people who ought to know as a gross exaggeration, I now beg to submit the accounts for the year, and lay my resignation in your hands."—*Madras Mail.*

CROTON-OIL PLANTS.—Wattagama, 26th Oct.—The caterpillar which proved so destructive to the croton seems to have disappeared and along with it the fear that the tea would suffer from the same cause, so that it is hardly to be wondered at that, the proposal to root out the croton trees and compensate the growers should have been lost sight of. I do not know whether croton growers would look with a more favourable eye on this proposal, than on their trees, now that they are again covered with leaf and showing signs of blossom. An authoritative and regular quotation of the price of croton seeds would be of advantage in making a decision.

WATTLE CULTIVATION.

We and our readers are indebted to "W. R. T." (see page 359) for the interesting information that there are wattle trees (*Acacia decurrens*) growing in Nuwara Eliya, 30 feet high at 25 to 26 months from the seed! We had previously heard from Mr. Nock, who showed us at Hakgalla, what he regarded as the true "golden wattle," that it was rare, if it existed at all, amongst the trees grown in Nuwara Eliya and on estates. But we did not understand Mr. Nock, to impeach the value as bark-yielding plants of the species which are now so common here. The truth is, that the number of acacias in Australia is very large and probably the majority of them yield yellow blossoms and are popularly known as "golden wattles." We shall never forget the glorious golden borders of the Mitchell river as we steamed up its channel to Bairnsdale *en route* to the Gipps Land Lakes, comparable, with their surrounding mountains, to the Loch Lomond district in Scotland. The varieties of acacias in the Melbourne Botanic Gardens, some of them exquisitely beautiful, is quite bewildering and many Australians are as much puzzled as we in Ceylon can be to distinguish the different varieties. This is shown by the extract from the *Australasian*, one of the foremost papers of Australia, to which our correspondent refers as appearing in the *Tropical Agriculturist* of 1881-82. We quote the note by the agricultural editor of that paper to a letter making enquiries as to species and varieties :—

[The real black wattle, or true tanning variety, is the acacia delbata. The silver wattle, which is considered inferior to the black, is the acacia mollissima, which can be easily distiguished by the silver appearance of the under part of the leaf, and the glaucous appearance of the bark; the flowers of the latter are a bright yellow, that of the former a dirty yellow. The silver wattle is in general found on the banks of creeks the black wattle on high dry ground. The black has rough bark, the silver being comparatively speaking smooth. The seed, so long as it is good, may be gathered from any tree.—Ed].

If that information is misleading, it was given not by us, but by one of the best authorities in the land of the wattle, and it is not fair to warn persons against "misleading statements in the *T. A.*" which are quotations, even if they were misleading, which we are not prepared to admit. For a note on page 251 of the volume referred to we are personally responsible. It runs thus :—

[All the wattles are acacias: the black wattle is *A. affius* or *mollissima*. It propagates only too readily from the roots, spreading all around, and being difficult to keep within bounds: a very deep trench must be cut for the purpose. It does not need topping, but grows very fast and shrubby, much more so than the gum. It is an excellent break-wind.—Ed.]

What is there misleading in this? Of course, there is "blackwood" as well as "black wattle," the former a tree the latter a large shrub. We did not speak of the value of the black wattle for bark but as a "break-wind," and what our correspondent says about the rapid growth of the trees in Nuwara Eliya shews how valuable the wattles are calculated to be as shelter belts and we should say for firewood for tea furnaces. But our personal experience induces us to warn planters not to plant wattles amongst tea. Some were inadvertently so planted out on Abbotsford and the result has been that in the cold, drizzly, windy weather which prevailed some weeks ago, the wattles shed their leaves, the tea bushes immediately around them following suit. The wattles have not, like the symplocos, killed the tea bushes but given them a shock. The wattles will, of course, be removed. They and gums and almost all other trees, ought to be cultivated in separate lots and not amongst tea,—Of course the £87 per ton of the *Indian Agriculturist* was a gross error for £8, which we ought to have corrected in taking the paragraph over. We scarcely think it would pay in Ceylon, to grow any of the wattles for the sake of the bark, but experiments in this direction might well be tried on the patanas around Hakgala and in Nuwara Eliya by Mr. Nock, from whom a paper on the whole subject would be valuable.

We take this opportunity of again quoting the reliable information given by Mr. Gamble in his Manual of the Timber Trees of India, regarding the species of Australian acacias hitherto cultivated in India. From the information thus given, it will be seen that *A. dealbata* is the silver wattle; *A. melanoxylon* is the Australian blackwood; while *A. decurrens*, so common in Ceylon is the black wattle. *A. pycnantha* is the broad leaf or golden wattle, which is *said* to be the most valuable for gum and tanners' bark. If this species has not been supplied by Australian seedsmen, it is matter for surprise. But any one specially interested in the subject and desirous of trying experiments, might apply direct to Mr. Brown, the head of the Forest Department in South Australia, or to Mr. Wm. Ferguson, Forestor of Victoria. Baron von Mueller, too, and Messrs. Guillefoyle and Moore of the Melbourne and Sydney Botanic Gardens, would readily give information and aid. Mr. Gamble writes :—

A. dealbata, Link,: Benth. Fl. Austr. ii. 415; Brandis 180. The Silver Wattle.

A tree spreading rapidly by numerous root-suckers The wood is moderately hard, light brown,, but warps considerably. Pores small, often in short linear groups. Medullary rays short, fine and moderately broad, well marked on a radial section,

Indigenous in New South Wales, Victoria and Tasmania. Introduced on the Nilgiris, and now naturalised since 1840.

The wood is extensively used in Australia for timber, and the bark for tanning. It is being tried in plantations on the hills of the Punjab, North-Western Provinces and Sikkim. Our specimen was cut from a tree 11 years old and 46 feet high, and was about 12 inches in diameter. Colonel Beddome, in his report on the Nilgiri plantations of April 1878, says that this Wattle grows very readily from the stool, but comes up in a dense mass of small twig-like stems so that it can only be depended on for very small firewood.

A. melanoxylon, R. Br.; Benth. Fl. Austr. ii. 415.; Brandis 180. Australian Blackwood. A large tree with hard and durable wood; heartwood dark brown and beautifully mottled, soft, shining, even-grained; pores mostly oval, moderate-sized and divided into compartments conspicuously marked on a vertical section. Medullary rays short and fine.

New South Wales, Victoria, Tasmania and South Australia. Introduced on the Nilgiris since 1840 and now completely naturalised. Also being grown in the hills of the Punjab, Kumaun and Sikkim.

With regard to its rate of growth, Colonel Beddome, in his report of April 1878 on the Nilgiri plantations, says that in the Bleakhouse plantation, Wellington, the average girth of the trees in the portion which is 21 to 22 years old, taken from the measurement of 30 trees as they came, was 35 inches at 6 feet from the ground (about 4 rings per inch of radius), the girth of some of the largest trees being 56, 55, 50, 46 and 44 inches. Our specimen was cut from a tree 20 years old and 90 feet high; it gave a plank 2 feet broad. The wood seems to be regarded on the Nilgiris as very inferior to that of *Eucalyptus Globulus*, either for timber or firewood; its growth is much slower and it is attacked by species of *Loranthus* which parasites in time kill the tree. It does not coppice well, unless cut very young.

Weight, according to Mr. Newbery (Timbers of Victoria, 1,877,) 41 to 48lb. per cubic foot; our specimen gives 36 lb.

It is used in Australia for cabinet work, coach-building, railway carriages and agricultural implements; on the Nilgiris chiefly for firewood. Its bark is used for tanning

Besides *A. melanoxylon* and *A. dealbata*, there are several other species of Wattle, some of which are cultivated in India. *A. decurrens*, Willd., the "Common" or "Black" Wattle, is a small or medium-sized tree; larger in moist localities. According to Mr. Newbery, the wood weighs 45 to 48 lb per cubic foot. It is being grown in several places in India. *A. pycnantha*, Bth., the "Golden" or "Broad-leaf" Wattle, is the most valuable species for tanner's bark and gum. Its wood weighs 51·5 lb per cubic foot. *A. homalophylla*, A. Cunn., is the Myallwood, a small tree with a hard, dark wood with the scent of violets.

Wattles grow in almost any soil, but their growth is best in loose, sandy places or where the surface has been broken for agricultural or other purposes. It is well, before sowing the seed, to soak it for a short time in warm water; this moistens the outer shell and induces more speedy germination. The seeds generally germinate in from 7 to 10 days, and are apt to damp off if too carelessly watered.

GOW'S TEA WITHERING MACHINE.

The experimental machine, which we cannot honestly call "a thing of beauty," for, externally it presents the appearance of a revolving horse box, perforated at intervals—was tried today in the presence of a large number of gentlemen interested: merchants, brokers and tea-tasters, planters, members of the local press, &c. The tea leaf used was only very partially withered by atmospheric air, was somewhat heated and contained a good deal of *banjy* or hard leaf. The quantity filled in was 200 lb., and the time occupied in withering was, as nearly as possible one hour. Good judges pronounced the leaf, when taken out, well withered and it must have gone pretty far in the process of fermentation, for it felt quite hot to the touch. Mr. Gow attracted attention to the bright appearance of the pekoe tips, although a good proportion of the banjy leaf was but partially affected by the withering process. The verdict of a tea-taster was, "The withering is well enough: let us see what the quality of the tea will be." We waited long enough to see the withered and heated tea put into one of Jackson's rollers, and to have our attention attracted by Mr. Gow to the readiness with which the roller acted on leaf withered in his machine. We were, therefore, surprised to hear him say that he wished to give the leaf an hour's rolling. Hearing this, we came away to write this paragraph (time, 20 minutes to 1, the experiment having commenced shortly after 11), but at Mr. Gow's request we promised to go "back again," which promise we hope to be able to fulfil.

Meantime we may say that the withering machine will require motive power to cause the huge drum to revolve, and to drive it into a stream of hot air which, with the moisture from the leaf, escapes through rows of perforations at intervals over the surface. There is nothing new in this application of hot air, so that the distinguishing principle of Mr. Gow's machine is avowedly borrowed from those original tea manufacturers, the Chinese. To imitate the celestial process of flapping the tea leaf between the hands, a series of wooden fans or flappers, working on hinges, is placed inside the drum, by which the leaves are struck in mid air (the hot air of the interior) as the drum revolves. In this flapping process the cells of the leaves are broken and fermentation is thus added to withering, both of which actions would be considered fatal to the tea in the ordinary process of withering, thinly spread on floors or shelves or webs, by means of atmospheric air, or by air, slightly warmed by the heat from sirroccos or other driers. As Mr. Gow claims as a distinct, indeed the distinguishing merit of his invention, the cell-breaking and partial fermentation so much dreaded by tea manufacturers who use the ordinary process of withering, we and others shall, of course, wait with great interest the final result of today's experiment and of the more perfect carrying-out of the process by the finished machines which are shortly expected in the island. The heat, we ought to have stated, was 140° when the leaf was put into the witherer; it rose spedily, after the door at the end was shut, to 160° and this was the height sustained until towards the end when Mr. Gow said he wished to see it up to 180°. Having heard so much of the cell breaking, we confess we were somewhat surprised to see how little in external appearance and to the feel, but for the great heat, the withered and partially fermented leaf differed from leaf withered by being spread at the rate of 1 lb. of green leaf to 6 feet of superficial space and operated on merely by atmospheric air of a shade temperature as is usually the case. When we are satisfied that leaf withered by Mr. Gow's process, makes good tea; then the question will arise how far the withering machines (and at what comparative cost) will supersede the enormous stores, with numerous floors and multitudinous Hessian web shelves, which are now deemed necessary for withering purposes. Of course longer machines can be built to take in more than 200 lb. at a fill and we suppose much less time than the hour occupied today, will suffice for the withering process. If the work is well done and speedily, then, of course, will arise the question of price. Our impression at present is that Gow's withering machines are not so much likely to supersede withering floors and webs (Mr. Gow prefers wire or small mesh fishing nets,) as to prove useful adjuncts to existing appliances in high and cold or very wet districts. In the Kelani Valley, too frequently, the heat of the atmosphere is so intense, that the tea leaf is withered prematurely. In wet and cold districts on the other hand, planters this past season especially were driven almost to despair by seeing their leaf still unwithered on the fourth and even the fifth day after plucking. It would seem that it is in the latter class of places that Gow's Witherer, if really a success and attainable at a moderate cost, is likely to be chiefly used.

3-15 p. m. We have now to add that the tea, which was not fermented in the usual fashion before being put into the roller, took a very good roll. It was then roasted under difficulties, by means of two trays and the sloping tube of an American Evaporator. All the tea showed a fine colour in leaf and cup, and that which was perfectly dried gave a good liquor. In answer to our remark that it was "very fair tea under the circumstances," a leading Colombo Tea Taster said, "It is very good tea under the circumstances." Samples are to be sent to the brokers and to the press, so that we shall be able in a succeeding issue to give the final verdict.

THE SALE OF CEYLON TEA IN LONDON.

The information sent to us by our London Correspondent by this mail detailing arrangements that have been made by well known Ceylon men for the sale of our island teas in the Metropolis and elsewhere throughout England will be decmed

satisfactory without doubt, as being a step in the direction we have always desired to see followed. But the particular case instanced is, after all, but a single step, and can scarcely be held to fulfill *all* the requirements of the position. The names of the gentlemen by whom this new venture is supported will certainly be a sufficient guarantee that, under their auspices, all will be done that can be done by a limited Association. But, while expressing this amount of satisfaction we cannot but feel that, if we are to obtain all the success that we desire towards the assurance that tea of a high quality shall always with certainty be obtainable by English consumers, it will have to be secured by means far more extended than are likely to be at the command of the Ceylon Tea growers Company, Limited.

It is to a Syndicate of the main body of those interested in tea-growing in the colony that we must look for the full realization of our desires. It must be by compact action that such will be obtained; by the sinking of rivalry and unworthy competition such as we fear we are not likely to be altogether free from when private interests are held paramount to the public good. Such a Syndicate has been much discussed in our columns. Our planters one and all should give it their support, and they must do so if they hope to see the chicanery of the retail grocer defeated, and to convey assurance to the Home consumer that what he purchases as pure Ceylon tea is what it is represented to be. We by no means undervalue the possible result to the enterprize now started. We have no doubt that the article it will submit for sale to the English public will be all that the best well wishers for the prosperity of this colony could desire. But they are bound in the very nature of things to have to submit to a competition by unscrupulous parties. Unless that competition can be effectually wiped out, such complaints as have of late been addressed to us by several correspondents are not likely to escape the need for repetition. It is only, as we have said, by quite a crushing influence being brought to bear, that the sale of inferior and impure teas which has brought our produce into comparative disrepute can be altogether stopped.

We think therefore that, valuable as this new agency is likely to prove, its establishment ought not to induce our planting community to slacken their efforts to effect such a desired combination as we have referred to. It will be seen from what our London correspondent writes that, as with previously formed agencies, it is the intention to practically limit its sale, so far as the primary effort of the Association goes, to those of the produce of particular estates. When that sale passes the limits of the producing powers of those particular estates, recourse will have to be made to purchase in the open market to make up the deficiency of supply. To ensure that purchases so made, shall be of corresponding quality to that of the produce of the estates concerned, it must manifestly be necessary to ensure that the agents employed are not alone perfectly honest but also entirely competent. Human nature being but what it is, we are driven to ask ourselves the question whether such ensurance can invariably be guaranteed? Even a single failure to obtain those qualities may altogether undo all or nearly all the good the Ceylon Tea Growers Company may on other occasions have effected.

Now, if the whole body, or the larger proportion, of Ceylon Tea Estates was represented by a Syndicate entirely representing their interests, it is scarcely within the bounds of probability that any demand would be in excess of the guaranteed supply by men who would have a direct personal interest in the quality of the supplies. In fact the interest which, in the case of the Ceylon Tea Growers Company, is centred in comparatively a few individuals, would be extended to a representative body so large and so influential that shortcomings such as we have of late had reason to complain of, could scarcely be dreaded. Under no circumstances hardly—in such a case—would resort have to be had to promiscuous purchases in the open market. Such a course, as we have pointed out, is always likely to prove the weak point in the armour of those who are acting as private individuals only. We wish the new concern every possible success, and appreciate the efforts and intentions of those who have devised it and are bringing it to a practical issue. But nevertheless do we feel that it is scarcely by such an agency, or by any multiplication of such agencies, that the peculiar needs of Ceylon Tea Estate proprietors can be met.

We have alone and specially noticed the Ceylon Tea Growers' Company, because it seems to some extent to be a rival to the proposed Syndicate, though on a much narrower basis; but this Company is by no means the only one affecting our teas of which the present mail has brought us information. We have besides the prospectus of "The Ceylon Pure Produce Company Limited" (£20,000 in 4,000 shares of £5 each) with such well-known names on the list of directors as Messrs. Dobree, R. W. Forbes, John Hamilton, J. H. Roberts (S. Rucker & Co.) and C. J. Scott. "This Company is formed"—says the prospectus —"for the purpose of supplying the Public with pure and genuine Ceylon tea, and to combine with it also the sale of pure coffee." Further we read:

"The intention is to open a Central Depôt or Warehouse in London, and, as opportunities offer, to establish Branch Depôts or Agencies in different parts of London and the Provincial towns, and to adopt all the necessary sources and means for publicity. It is intended to make the entire purchases in the London Market from all the importations as brought forward. In adopting this course continued uniformity of each description sold by the Company can thus be ensured, instead of depending always and solely on any particular estate, the quality from which may vary season by season. No other than Ceylon tea will be bought or sold by the Company. It would be premature to form any calculation as to the quantity of tea likely to pass through the Company's sources of disposal, but estimating the amount at only a quarter of a million of pounds weight, the profit would amply justify the expectation of a very good dividend. The sale of Coffee also should produce very satisfactory results."

Then our advertising columns have for some time shown that the "Direct Tea Supply Association of India and China (Limited)" claims the attention of Ceylon planters having 40 agencies for the delivery of tea direct to consumers. This mail too has brought us interesting information respecting the "tea" work of Mr. Pineo in America; of Mr. MacCombie Murray who is on his way thither—there is plenty of room for a dozen independent promoters in the United States—and of Messrs. Shand, Haldane & Co. in London. The last-named firm deal only in Ceylon teas and coffees and supplies asylums, hospitals and charitable institutions at actual cost price, and lay themselves out on all sides not so much for large gain as a large connection. Apart from all these agencies, and from Messrs. Buchanan Bois & Co. started locally, we learn that several other Ceylon Tea Companies are incubating in London, so that after all we begin to think there may be no room for the Syndicate in the old country; but certainly it could do much good in America and Australasia.

NATIVE CULTIVATION AND CATTLE MURRAIN—NEW PRODUCTS—SUITABILITY OF UVA FOR TEA.

(*From Mr. E. A. King's Report as Govt. Agent, for 1885.*)

Industries: Native.—The greater crop of the year (the maha) is reaped during the five months May, June July, August, and September; the lesser crop during the five months November, December, January, February, and March. The greatest activity in reaping is in June and July. The area of paddy land sown during 1885 is given by the headmen at 26,688 amunams, or 35,584 acres. There was certainly a larger area under crop than had been for many years, notwithstanding that there were complaints of want of seed paddy in Wellassa and Buttala in the early part of the year. Where there was plenty of water the crop may be estimated at twenty-five bushels an acre, but on the average it would be only safe to estimate at fifteen bushels the acre. The area of dry grain and Indian corn was 5,508 amunams, or 7,344 acres. The average crop was eight bushels. The sown area would have been larger had it not been that heavy rain in the end of 1884 had prevented the burning of many clearings. The chena harvest was accordingly rather shorter than might have been expected, and the cropped area was below the average. There is only one harvesting season for dry grain in the year, viz., during December, January, February, and March. It is gratifying to note that paddy cultivation is extending in Bintenna in the neighbourhood of the Horaborawewa, Kudawewa, and Hembarewa tanks. The native coffee crop for the year was extremely insignificant. Indeed, by far the greater number of the native gardens have died out completely. For the most part, what was once flourishing gardens is now a wilderness of dry sticks. It is no uncommon thing to see coffee gardens being felled for the cultivation of kurakkan. In the few cases where there has been utter neglect, little more can be said than that the trees have been just kept alive. The present state of things contrasts painfully with the luxuriance of native coffee in former days, when it put in circulation among the villagers annually in this district as much as R600,000. It was this that ensured the regular and cheerful payment of taxes, crowded the court with suitors, and filled the pockets of the arrack renters. There were occurrences of cattle disease in the first and third quarters of the year. Altogether 239 black cattle and 159 buffaloes are reported by the headmen to have died from disease. These figures do not include the mortality among transport bullocks, of which it was not possible to procure full information. Murrain and theft have been thinning the village cattle for some years back, but never were people accustomed to take so little pains to herd their cattle, preventing their associating with animals infected with disease, and guarding them against slaughter by cattle-stealers, as the Kandyan peasantry.

Industries: European.—Allowing for different products growing upon the same land, the following is a statement of estate cultivation in the district of Uva at the end of 1885, as compared with the previous year:—

	1885	1884
Coffee ...	31,755 ...	35,602
Tea ...	6,538 ...	522
Cinchona ...	10,629 ...	11,650
Cocoa ...	1,184 ...	482
Liberian coffee ...	132 ...	132
Rubber ..	122 ...	Not ascertained.
Cardamoms ...	488 ...	do.
Other products ...	186 ...	do.
	51,034	

Unlike other districts of the Island, coffee-picking in in a greater or lesser degree goes on all the year round in Uva, but the great harvesting seasons are in Spring and Autumn. The Spring crop is the chief of the year for high estates (say over 3,500 feet), the Autumn crop for the lower estates. Planters count the seasons from the middle of one year to the middle of the next. The Spring crop of 1885 was the best the estates had produced for many years, but the Autumn crop was poor. Though the Spring crop of 1886 is understood to be very short, it is gratifying to hear on all sides most encouraging prospects, based upon the blossom which has just set (April 15th, 1886). It is estimated that the later crop of 1886 will be a magnificent one. Encouraged by the promising appearance of the trees, many estates are giving special attention to manuring, when cultivation was beginning to be abandoned as unprofitable or absolutely wasteful. Coffee produce during the past season, 1884-85 (June to June), was much greater than the previous one, as the following figures will show:—

	Bushels.	Cwt.
Coffee crop of Uva for 1883-84 ...	386,589 =	128,860
Do. 1884-85 ...	542,387 =	180,795

A similar increase is shown in the produce of cinchona:—

	Cwt.
Cinchona crop of Uva for 1883-84 ...	7,545
Do. 1884-95 ...	10,880

Taking coffee and cinchona together, we have therefore the satisfactory result that the crop in 1884-85 was about half as much again as in the previous season. The ruling transport rates were 66 cents per bushel in 1885, as against 55½ cents per bushal in 1884. Cart hire rose 1885, owing partly to the larger crop to be carried, and partly to the presence of cattle murrain on the Ratnapura road. The result was the crops were very late in being despatched, causing great loss of colour to the coffee, which consequently fetched a low price in the London market. The coffee crop for the season 1885-86 is expected to be less than half what it was in the previous season; but it is believed that the quantity of cinchona to be sent into the market will be the largest Uva has ever produced. Leaf-disease in coffee is believed to be fast disappearing, and some planters are beginning to think that they made a mistake in clearing out coffee to make room for tea. In examining the figures at the head of this section, attention will be at once arrested by the large increase in the acreage of tea. Great and praiseworthy vigour has been thrown into this new branch of estate cultivation, notwithstanding the hardness of the times. Indeed, the manner in which the planter has roused himself from grieving over the shipwreck of his fortunes, and bravely entered upon new fields of industry, merits our greatest praise. It is now admitted on all sides that, in Uva, soil and climate are as well suited to the growth of tea as anywhere else in Ceylon, and that the only impediment in the way of our taking the position we ought to take in this industry lies in our isolation.

COFFEE PRUNING.

(REVIEW OF THE "WRINKLES AND HINTS ON COFFEE-PLANTING" WITH DIAGRAMS AND SPECIMENS OF FORMS BY GEORGE WILDES; MADRAS, ADDISION AND CO., MOUNT ROAD.

By an Old Ceylon Coffee Planter.)

It cannot be said, that in his article on pruning Mr. Wildes* adopts a false principle but the whole affair appears to me rather meagre and unsatisfactory The man who puts himself forward as teacher should be able to go to the roots of his subject, clearly explain and logically support his opinions. As the character given and mode of growth of the coffee tree varies with every variety of soil, climate, and exposure, within the range of its possible cultivation, the experience of any one individual planter is too narrow to embrace all the possible combinations and the danger, therefore, arises of elevating local circumstances into universal principles. However carefully the planter may study his own set of circumstances; however just the views he may arrive at and however correct the system that grows out of his experience, it is only a local system after all and may in many of its appliances and operations be totally inapplicable on the other side of his own mountain range, or even on the same side with a few hundred feet of difference in elevation, and this more affects the art of pruning than any other operation of cultivation.

In looking at an Arabian Coffee shrub two years old in its natural state any stranger to the habits of

the plant would conclude that through its whole life the plant would continue to develop its straight vertical stem with a fresh pair of primary branches over each pair of fresh leaves. This is not, however, what happens to the natural bush, the first crop is borne on the lower primaries and these may bear a small proportion of the next, but the second crop will be chiefly borne on the primaries developed while the first crop is coming to maturity. The same course will be followed by the third but as the tree is now nine or ten feet high and the stem has not gained a diameter in proportion to its height, it becomes unequal to the support of its vertical position under the increasing weight of its crop and droops into a curve; one or more suckers start from the point at which it leaves the perpendicular to assume its functions and be in their turn supplanted. Meantime the old wood, branch and stem, gradually rot and drop off, the plant assumes its regular regimen sending out fresh suckers every year to bear subsequent crops, none of which ever attains a height exceeding eight feet.

The bulk of the crops of the natural coffee bush being borne at the height of from five to seven feet from the surface and as wind tells disastrously on them during the first few years those facts originated the idea of the artificial bush in the minds of its cultivators. The advantages gained by this form were that the whole growth of the plant being kept within three feet of the surface the collection of the crop could be accomplished with less than one half the labour necessary to the natural tree, and the bushes being all stopped at the same height, the wind passes over them after the third year without doing any material injury. It is likewise generally held that the average crops of the artificial is greater than the natural tree bears, but this is one of those opinions that every one accepts but no one has brought to the test of actual experiment.

In imposing and maintaining the artificial form on the coffee shrub consists the science and the art of pruning. In treating of the science and the art of pruning coffee, or forming and maintaining an artificial bush I must choose my own set of circumstances, premising that only under the same conditions can my system be applied in all its details.

My elevation runs from 2000, to 3500 feet. I get 100 inches, more or less, of rain in the course of the year; more in the N.-E. than, in the S.-W. Monsoon. My soil is a dry crumbly one rich in decayed organism and becomes the loser from rain from sunshine and from treading on. The subsoil is a sandy and gravelly loam, in which quartz predominates and the presence of lime becomes evident on the application of acids. On this land I have planted my coffee 7×7 feet, I could not do justice to my trees with less room.

The first operation in the formation of an artificial tree is to take off the top of the stem, but if the tender stem be merely pinched off leaving the next pair of primaries to their free development they will in the course of two years most probably split the top of the stem down to the pair next below them. To avoid this the pair of branches next below the topping height should be pinched off at the same time. The suckers on all occasions originate at the highest buds left on the stem; thus the joint immediately above the highest pair of primaries left gains growth and strength to resist any pressure brought to bear subsequently. This first act of aggression, is the opening of a war with nature that admits of no truce. Two, three or four suckers immediately make their appearance and as after as they are stripped fresh ones succeed them. The sap beaten back by constant stripping at the top of the stem, seeks an outlet in the branches the upper primaries rapidly reach the same length as the lower one, and the latter begin to develop secondaries. The secondaries come out in pairs one on each side of the primary with which they form an angle of 45 degrees on the same horizontal plain. The first secondaries are seldom complicated with irregular growth but they are frequently too numerous in which case they must be thinned. Mr. Wildes assumes that this is always the case and proposes to remove one half of them either in alternate pairs or alternately from each side of the primary, but in the local circumstances I have chosen to treat, the quick growth of the primaries, assures a good length of joint and sufficient distance between the secondaries to prevent crowding and much less thinning that he recommends will generally suffice; its measure must of course be settled by the operator with the plant before him should thinning be judged necessary the first year that secondaries have to be dealt with or whether or not all growth within six inches of the stem should be stripped and next those so far out on the primary that their ultimate weight may sink its extremity below the horizontal line at which it should be maintained in the following year it will generally be strong enough to hold its proper position however weighted with crop. The bulk of the second crop of the artificial coffee-bush is borne on the first secondaries, and all that have borne crop on the greater part of their length should be removed as soon as possible after the last of the crop is gathered and the circular clear space round the stem should be enlarged to a diameter of eighteen inches.

The removal of the secondaries should be done in a clean cut with a sharp knife leaving no vestige of a stump on the side of the primary. As soon as the secondaries are disposed of there is a rush of young wood in succession from the buds round the cuts. As soon as this young growth is sufficiently advanced for selection that one shoot at each joint that makes the nearest combination of approach to an angle of 45 with its primary and a direction in the same plain must be left and all the others stripped, and should more irregular wood appear in the course of the season the operation should be repeated as often as necessary.

The operations of every subsequent year, are precisely the same as described above and may be conveyed in a few words such as

Strip all suckers as soon as possible after their appearance.

As the tree grows out enlarge the clear circle round the stem till it measures two feet in diameter.

Cut off after each crop every secondary that has borne on the greater part of its length.

Strip all superfluous and irregular wood as soon as possible after it appears.

If those directions be strictly carried out year by year, there will always be sufficient regular and symmetrically disposed secondaries, to bear the next crop; the pruning will be light and easily learned by the coolies and the bushes on the soil and in the climate I have mentioned will cover the whole space of seven feet and be equal to a yield of fifteen cwt. per acre in the fifth year from planting.

Inferior soils and situations will of course produce inferior trees and yield less crops; and in many places this system cannot be advantageously carried out in its integrity, but the principles are the same everywhere though practical modifications may be required to suit local conditions. The worst case that ever came under my notice was on a place with soil rather better than the average of its district the elevation run up to over 5,000 feet and a steep lay boldly faced the south-west. As heavy rain fell on something like three hundred and twenty days in the year the soil was always in a state of saturation. In this situation the form of growth was long slender primaries unable to carry the weight of their own foliage and they finally grew downwards like a weeping willow and on reaching the ground run along on the surface when cut back the growth did not go into secondaries along its whole length only threw out a pair at the end. The few secondaries that did grow bore crop on only a few joints and at the end of the crop had always a foot of new wood in front and when cut off the growth went into extending old wood rather than originating new. It was a case in which the conditions rendered the formation and maintenance of a symmetric artificial coffee-bush impossible and the wise course would have been

to leave it entirely to nature whether this was ultimately done: I know not as I have not seen or heard of it for twenty five years.

The cultivation of Liberian Coffee is not yet sufficiently advanced in Ceylon for the study of the mature plant but there are circumstances in its habits that at present appear to me insuperably negative in the matter of disposing of its bearing wood artificially in a limited space, but in eighteen months or two years if I live so long I will have a definite opinion to offer on this point. In the management of this plant there has been and will be great blunders before the true view is struck. I know that in the past I have contributed my fair share of the blunders but a philosopher learns even more from his failures than his successes.

PADDY (RICE) INSECTS IN CEYLON.

No. 1026. Office of the Director P. I. Colombo, 11th October 1886.

The Honorary Secretary, Agricultural Association.

SIR,—I have the honor to forward for your information the annexed extracts of reports received from the Head Teacher of the Walalla Anglo Vernacular Boys School, concerning a cure for paddy insects with which he has made successful experiments.—I am, Sir, Your Obedient Servant, H. W. GREEN, *Director.*

(*Extracts referred to.*)

Of letter of 16th Sept. 1886.

This is the remedy I used: well cleaned ashes and a little kerosine oil. This powder I sprinkled over the plants three or four times which made the insects to retire, the few that remained could do no harm to the ears. As to the efficacy of this powder in driving off the insects, there is not the least doubt; you may kindly recommend this powder with confidence to any body in the Western Province who is in need of it; but the powder most be carefully prepared with the proper quantity of kerosine oil, otherwise it will do more harm than good. It was advertised some time ago that a rope saturated in kerosine oil and drawn over the paddy plants will drive off the insects. I tried this method also, the result was that all the blades of paddy plants and ears that this oil touched withered, and the insects concealed themselves at the root of plants, came up after a few hours. No one is satisfied with the rope method. I have already given orders to my Goiyas to collect ashes to instruct them how to prepare my powder.

Of letter of 1st Oct. 1886. * * *

Take a pint of kerosine oil and mix well with one bushel of well cleaned ashes; press well this powder in a bag and keep in the sun mouth tied from three to four hours. When the powder is sufficiently dry, sprinkle it lightly over the paddy plants both morning and evening when there is dew; if the insects still remain repeat this every other day for sometime, for the second application however not more than half a pint of kerosine oil should be taken for every bushel of ashes. If the application of this powder is made immediately before the ears appear it is preferable. The dams or the ridges of the field also must be sprinkled over with the powder as insects too often take refuge in such places, grass should be cut short. The jungle near about the field especially Lantana or Ratahingura as it is called in the upcountry should be cleared. Even if a few insects remain after the above process they can do little or no harm to the ears. If a Goiya does not succeed in this plan to save his crop, he must be a very unfortunate man. Considering the immense loss that cultivators suffer yearly on account of insects, I suppose my powder will be of great use to them. I am &c., (Sigd.) D L. Wickremasingha.

THE ORANGE CROP IN VALENCIA.—As an illustration of the importance of the Orange crop in Spain it is stated that from the Port of Valencia alone over 3,000,000,000 Oranges have been shipped in the course of one seson. The fruits, which are considered the best of their kind in Europe, can now be delivered in England at 9*s.* the box, leaving a fair margin of profit to the producer.—*Gardeners' Chronicle.*

PRAISE OF CEYLON TEA FROM THE BEST-KNOWN MEDICAL JOURNAL.—We are indebted to Dr. Rockwood for the following extract:—"Analytical records.—Cassell's Ceylon tea. The tea plantations of Ceylon have been a great success, and have added in an important degree to the material resources of the island. The sample now before us is very satisfactory. There is no facing or other mineral matter. The leaves are small and clean, and give a strong decoction of delicate flavour. Such tea may well replace the product of China."—*The Lancet.*

MICA OR TALC: A NEW INDUSTRY.—It is rather a coincidence that just as we were taking up our pen to attract attention to the advertisement in another column in reference to a demand for this article a gentleman in the Fort should have sent us for inspection, two of the finest pieces of talc from Badulla we have ever seen in Ceylon: they measure more than a foot square about ¼ inch thick, beautifully smooth and form a capital mirror. Pieces of this description would meet with a ready sale we have no doubt. Anything above 8 inches is considered good and marketable; while three and six inches' pieces are considered small. We are aware that mica has been collected in Uva for some time. Perhaps the Messrs. Greig & Co.'s demand may give an impetus to the industry.

CINCHONA BARK IN MADRAS.—At an auction held on October 18th, Madras, by Messrs. Oakes & Co., of the Exchange Hall, the following prices were realised for Dodabetta Estate, Natural Crown Bark:—

Description of Bark.	No. of bales for each lot.		Amount realized.
Stripped ...	1	10	R6,400 at R64 per bale.
do ...	11	20	
do ...	21	30	
do ...	31	40	
do ...	41	50	
do ...	51	60	
do ...	61	70	
do ...	71	80	
do ...	81	90	
do ...	91	100	
Shaved ...	101	110	R3,000 at R40 per bale.
do ...	111	120	
do ...	121	130	
do ...	131	140	
do ...	141	150	
do ...	151	160	
do ...	161	170	
do ...	171	175	

Each lot contains 10 bales, with the exception of 171 to 175, which contain 5 bales.—*Madras Mail.*

WHAT IS BHANG?—I have always understood bhang to mean ganja leaves. But those who ought to know explain that bhang is a preparation of *burulla* leaves and opium; that the preparation is used for smoking in pipes, which is called madát, and that ganja leaves, leaves I think of the Indian hemp, have nothing in them in common with bhang. The Ordinance which prohibits the sale of opium and bhang except upon a license, does not prohibit the sale of ganja leaves. But I would wish to have some more information on the subject. As a matter of fact, ganja leaves are sold in many unlicensed boutiques. But they say the police levy a black mail on it.—*Cor.* [The inebriating preparation made from the leaves of the ganja or bhang, the *Cannabis Sativa*, is generally in a liquid form and is a fiercely intoxicating draught. Hemp leaves (washed in water) 3 dr., black pepper 45 grains, cloves, nutmegs and mace of each 11¼ grains. Triturate the ingredients with 8 oz. of water or milk, or with the juice of Water-melon seed or cucumber seed, and strain. The spices render it more inebriating. The dried Hemp plant which has flowered, and from which the resin has not been removed, is called "ganja." The larger leaves and capsules of the dried Hemp plant are usually termed "bhang."—(*Extract from "Balfour's Encyclopædia."*) The leaves or young leaf buds of the hemp plant, ganja, are smoked by themselves or added to tobacco.—From Dr. Vanderstraaten.]

Correspondence.

To the Editor of the "Ceylon Observer."

ELECTRICITY FOR TEA MACHINERY: A QUESTION FOR ENGINEERS.

Theberton, Ambagamuwa, 18th Oct. 1886.

Dear Sir,—I noticed in your paper of the 13th inst. an article on Branch railway feeders, and that electricity might be used to work them. I was just on the point of writing you on nearly the same subject, viz., cannot electricity be used to work our tea machinery? Steam-engines are expensive in *every way*, besides the difficulty to get them on out-of-the-way estates. Water in most places is only sufficient during the S.-W. monsoon. Dams (where possible) are very expensive to make "as a rule," and on our hillsides are difficult to keep water-tight. Through nearly every valley in the hills runs a river or a considerable stream of water, all the year round. Would it not be possible to work a water-wheel or turbine with the water from the river and generate electricity, in a dynamo there? Then bring it to the factory by wires to a second dynamo, which would work the rollers etc. There is generally enough water in most of our principal streams to work machinery, and if we could place our factory alongside of them, we should do very well, but as it is, this cannot often be done.

Do you not think it would be well worth finding out, what would be the cost to work our tea machinery by electricity? Would it be a saving on steam? The first cost, I fancy, would be nearly the only one, as there is no other that I know of; unless the armatures on the magnets oxydize in our damp climate, this could be provided against by covering the wires coiled round the magnets, the same way as deep sea telegraph wires are done. If this could be provided against, there would be only general upkeep of wear and tear of machinery.

To work steam-engines when the present supply of firewood is exhausted, will be a very expensive affair. Is it not worth while for those who have not yet decided on the motive power for their machinery to find out, if it is practicable to use electricity. Could you not give us some information on this subject?

I know farm machinery is both worked in England and on the Continent by dynamo machines. The question is: are they expensive play-things or practically useful? Of course, the question of first cost is the principal point. The wire rusting, etc., could be overcome, as, I believe, steel wires are used in some machines. If you think the subject worth ventilating and this letter of mine worth it, please give it a corner in the *Observer*. Your idea as regards railway feeders is a good one and worth considering.—Yours, very truly,

T. J. GRIGG.

[There are gentlemen in the island competent to give an opinion, and to make a practical experiment in connection with Mr. Grigg's question, and we trust one or other will do so and report the result.—Ed.]

WATTLE CULTIVATION.

21st October 1886.

Dear Sir,—I often read in your columns how profitable the cultivation of Wattles in Ceylon would be. In the *T. A.* of last month, page 248, you say (or rather the *Indian Agriculturist* says), "The bark now sells in London at £87 per ton"! Well, at 3 years we may confidently rely upon 2½ to 3 tons per acre, of bark of the *Acacia decurrens* the) variety referred to) and an additional ton per acre up to the 10th year! Who will henceforth think of the troublesome tea cultivation, with its so-called moderate profits? Who would take the trouble to dig for gold, or search for diamonds?

But I fear £8 per ton is nearer the mark, and that leaves so large a margin of profit, it is inexplicable to me, that its cultivation is not attempted in Ceylon

At Elephant Nook in Nuwara Eliya may be seen trees of *Acacia decurrens* now 25 to 26 months from seed, and just 2 years from nursery, standing considerably over 30 feet in height. These are not whippy and shew no ill-effects from the terrible winds to which they have been exposed for the past few months. There are strong branches from the ground to within a few feet of the top. A boy stood on a branch at 24 feet with the tape-line, his weight insufficient to bend the tree more than slightly.

The seed was brought by Mr. W. M. Mayes from Australia.

From the articles in *T. A.* 1884-85 extract from *Adelaide Observer*, pages 165-167, and report of Mr. T. E. Browne (Conservator of Forests) to Legislative Council, Adelaide, pages 916-918, I learn that there are two varieties of Wattles standing pre-eminent for the production of Wattle or Mimosa bark of commerce. *A. pycnantha* broad-leafed or golden Wattle gives the most valuable bark, but the tree itself is a much smaller one than *A. decurrens* or Black-Wattle.

	Average height.	Average girth.	Average yield tanning materials.	Average yield of bark.
A. pycnantha	25 ft.	8 in.	30 to 40 o/o	70 lb.
A. decurrens	40 ft.	24 ,,	29 to 34 o/o	500 ,,

These regularly planted 4" by 4" a crop is taken every third year. Selected trees I presume.

The wood and twigs all yield tanning materials, but the wood of *A. decurrens* is valuable for cooper's work (staves) and as firewood is very far superior to blue gum.

In your *T. A.*" for 1882-83, page 823, Mr. Jameson's Report, Botanical Gardens Neilgherry, is the following paragraph:—

"In three years an acre of *A. decurrens*, will give 2½ tons of bark selling in London at £8 to £11 per ton" (not £87).

The seed will germinate after being boiled for 7 minutes!

It is quite unnecessary to boil it. Soaked in warm water all night it germinates readily: within a week.

As may be inferred from its name, it spreads, but where there are weeding contractors the shoots may be broken off monthly. They grow readily, when transplanted shoots from the roots of those growing in Nuwara Eliya (before referred to) planted in the patenas some six weeks ago are growing well. I write this to elicit information. Mr. Nock says he doubts that there is a single plant of *A. pycnantha* in Nuwara Eliya; yet we so frequently read and hear talk of the Golden-Wattles in Nuwara Eliya. It is certain that the acacias termed "Black-Acacias" growing in Nuwara Eliya are not all "Blackwood" or *A. Melanoxylon*. Bark and leaves differ greatly.

Of course everybody knows, Black-Wattles and Black acacias (or Blackwood acacias) are totally different things. You will excuse my warning your readers not to depend on *T. A.* Vol. 1 (1881-82) for information *re* wattles and acacias.*

There are some misleading statements.

For instance, see pages 251 and 348 and there are more.—Yours faithfully, W. R. T.

* I refer almost solely to the wrong Botanical names given.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, October 7th, 1886.)

FISH-CURING IN CEYLON.

Dried salt-fish, known popularly as "Karawala," forms so large a portion of the food of the inhabitants of Ceylon, and especially of the immigrant Tamil coolies, and disease, including even leprosy, has so often been traced to the use of this article of food in a putrid or semi-putrid state, that all who have given attention to the question must have rejoiced when the Ceylon Government, following the example of the authorities in the Madras Presidency, determined on measures calculated to expand and improve the local industry. This they have done by commencing to open fish-curing yards, such as have been generally so successful in South India, and supplying salt for use in such yards at the moderate price of R1 per cwt., so low indeed as 80 cents at Hambantota. These yards are properly protected and supplied with guards by Government, so that the native fishermen who choose to avail themselves of the advantages offered, not only obtain good clean salt at a low price, but are saved the trouble and expense of watching the fish which, after cleaning they spread out to dry. In Ceylon as in India, one great cause of the inferiority of salt-fish sent into the markets for sale, (next to imperfect salting, often with salt mud merely) is the practice of drying the fish on the seashore sand. It is inevitable under this system that a very considerable proportion of sand should get into the substance of the fish or adhere to it, and so large is this proportion sometimes that the price even of putrid or inferior fish used for manurial purposes, has been regulated by the extent to which it has been freed from sand. In the Government curing yards the salted-fish is dried on wicker platforms. Where forest or scrub is plentiful, we would suggest that the experiment of smoking some of the fish, after the fashion of Scotch speldings or "Finnan haddocks" should be tried. We do not know if the Europeans who recently engaged in the fish-curing enterprise in Ceylon tried any experiments in the direction of smoking or "kippering." In any case, the dried fish they sent into the market was exceptionally clean and well cured, and, although we are not surprized to learn that in a pure y native industry like this, Europeans have not been successful competitors with the indigenous fishermen, we greatly regret the result. Our readers must understand that our Government in taking measures to encourage and extend the local fish-curing industry, must have contemplated a considerable sacrifice of revenue. The more dried fish is locally produced, the less will be the import duty collected on the, at present, very large quantity of salt-fish introduced from Southern India, destined largely, like our imports of rice, to feed the coolies who come to us from the same quarter. A duty on salt-fish, although the latter is a staple article of native food, has always been deemed necessary as to a certain extent a protection to the local revenue derived from salt, the quantity of salt in the imported fish as well as in that locally prepared being calculated in estimating the consumption of salt (from 12 lb. to 16 lb. per caput,) by the inhabitants of Ceylon. Besides loss of revenue in the direction indicated, Government sell salt for fish-curing purposes at less than half the monopoly price, and the yards, supplied by Government with superintendents and watchers, are not yet and probably will not for some time be self-supporting. But this Government, like that of Madras, is clearly acting not merely in the spirit of paternal benevolence, but in the line of positive duty in taking measures to improve and expand a local industry, whereby the seas around our shores shall be made to yield increased supplies in a wholesome shape of a species of food specially grateful to the natives, as giving body as well as piquancy to their curries, so largely composed of succulent vegetables in addition to the unfailing and absorbent staple, rice. The quantity of salt used in proportion to the fish cured, varies widely and any large excess above well-established averages, such as has occurred at some of the Ceylon curing yards, demands and will receive enquiry, so that the abuse of the privilege of obtaining cheap salt for a specific purpose may not be allowed. The following table shews the results, so far, of the fishing-curing experiment in Government yards, in the face of the inevitable suspicions of the natives that the whole scheme was merely a device to impose upon them additional taxation:—

The following abstract shows the results of the establishment of the yards in which work was carried on during the period from October 15th, 1885, to July 31st, 1886:—

Name of Yard	Period during which the yard was opened	No. of applications to use of yard	Weight of Fish brought to be cured		Weight of cured Fish taken out		Weight of Salt issued		Value of Salt sold			Expenditure incurred by Government		Quantity of Salt issued to each cwt. of Fish	
			cwt.	lb.	cwt.	lb.	cwt.	lb.	R	c		R	c	cwt.	lb.
Hambantota.	Oct. 15th 1885, to April 30th, 1886	1168	1217	3	845	38	282	0	225	60		543	29	25	95

Our readers will, of course understand that the discrepancy between fish received into the yards and fish taken out arises from the removal of offal and especially from the drying away of most of the moisture in the "Karawala." The figures shew only 2,501 cwt. of fish taken out for 2,886 taken in. The difference would be still greater, but for the

fact that quite a different style of curing to that generally in use was adopted at Gandara. Here 680 cwt. of fish taken in, had increased in weight to 814 cwt. by the time it was taken out. The mystery is thus explained in Mr. Ravenscroft's report, which was laid on the Council table on Wednesday and which we are reviewing:—

The system of preserving fish in vogue amongst the Gandara people is that known as "jadi," and as fish prepared by this method is wet when taken out of the yard, the excess of "fish out" over "fish in" is accounted for. When at Gandara on the 1st instant, with the Government Agent Southern Province and the Assistant Government Agent of Matara, we made inquiries as to the reason why karawala—*i. e.*, dried and salted fish—was not prepared, and were informed that the people found they could turn over their money more quickly by preparing "jadi," and sending it directly into Galle, where it commands a ready sale. I am, however, in hopes that some of the curers will undertake the preparation of karawala, which is more suitable than "jadi" for transport into the interior; but necessarily this must depend upon the market for "jadi" in Galle. Should the supply of the latter at any time exceed the immediate demand,—and there is a possibility of this,—the price will fall, and there will be an inducement to the curers to prepare karawala; but whether this comes about or not, I think there is reason for the continuance of the yard at Gandara. As I have already said, it has had a good effect in the direction of encouraging the fish-curing industry, and increasing the local production of a cheap and wholesome article of food for the people; and there is every reason to anticipate that it will tend to the further development of the industry.

The "jadi" fish is so cured as to retain its moisture which, of course absorbs a considerable quantity of salt, the weight being thus increased even above that originally noted when offal was included. The result is very different in regard to "Karawala," for it will be observed that in the case of Hambantota only 845 cwt. of dried fish resulted from 1,217 cwt. received as taken out of the sea. The mode of preparing the fish which, notwithstanding the addition to the cleaned material of a considerable quantity of salt, shows so large a decrease of weight, is thus described. We quote from the interesting report of Mr. Murray, Assistant Government Agent of Hambantota, in which much general information is embodied:—

The following few remarks about the fishing itself may not be out of place:—

The boats generally make an early start before daybreak, when the land wind carries them out of sight to the fishing grounds, where they remain the whole day. The return journey is made in the afternoon, when the wind changes, the boats arriving between five and six generally. The fish when landed is piled in heaps, and is either sold by auction to the highest bidder, or by private sale when a fair offer is made, the fishermen thus realising the full value of their fish at once.

At the commencement of the season, when the hauls were small, the prices ran up to R4 and R5 a cwt., but as the season advanced they went down to R2·75 and R2·50. The fish is at once cut open, and after being cleaned in the sea close by, conveyed in the pingoes and carts to the fish-yard, where it is weighed. The curers then set to work to apply the salt, being engaged at this during the whole night. The different process adopted in curing are:—

First, the ordinary one of salting and drying. The fish when cleaned are slit in parallel lines down the fleshy parts, into which pounded salt is well rubbed. They are then put into barrels and kept there for twelve hours, after which they undergo a second cleaning in salt-water, and are then exposed to dry in the hot sun for four or five days on raised stick platforms, so as to keep them free of sand. On the fifth day they are ready for removal.

Another process is that of placing the fish after it is rubbed with salt in jars or water-tight barrels, and sprinkling over each layer a good quantity of salt mixed with dried goraka fruit, the acid juice of which imparts a good flavour to the fish; when the jar is full it is covered over and left to stand for three weeks or a month.

A third way adopted, when large quantities of small fish, such as sardines, sprats, &c., are caught, is to steep them in brine, and then taken away.

The amount of salt required for curing varies according to the size and description of fish, as well as the process of curing adopted. For instance, in picking small fish in jars or tubs the proportion of salt to fish is one to two, that is, 1 cwt. of salt is required for 2 cwt. of fish. For dressing small fish the same quantity is required; for salting and drying large fish the proportion is one to three.

There are three descriptions of canoes employed in fishing, all of them with the usual outriggers. The first is a single-masted large canoe, called in Sinhalese *hedi* or *davalapanné oru*, capable of carrying 6 to 8 cwt. The second, the *vára oru*, constructed in such a way as to be able to sail out in stormy weather, and carrying a large oblong sail supported by two bamboo masts. This boat is chiefly employed in catching the rarer kinds of fish, such as seer, *paraw*, &c. The third kind is a small cockle-shell of a canoe, keeping close in shore when fishing, and only venturing out when the sea is smooth.

The large kinds of fish are caught with hook and line manufactured by the fishermen. There are a few draught nets, made of coir rope, and circular hand nets used in fishing from the shore. It would be well if they were abolished altogether, as the fishermen complain of their frightening away the small fry on which the large fish prey.

The different kinds of fish caught are given in return "A." *Kalamiya*, weighing on an average about 5 lb. is caught in largest quantities. Seer and *paraw* are the most prized on account of their excellent flavour, while the small sprats called *laggo* would make a good substitute for sardines.

A sample of the fish cured here under the salting and drying process in the yard of the European firm was forwarded to the Secretary of the Ceylon Committee for the Indian and Colonial Exhibition, and he writes of the excellent condition in which it arrived.

It is my opinion that this industry is capable of still greater development by the employment of more boats, and that a sufficient quantity of fish could be caught and cured to supply the whole of Ceylon.

I see no reason why tinning fish should not be carried on profitably. A seer fish costing about 15 cents would fill about three good-sized tins selling at R1·50 each. The tins would be manufactured by machinery on the spot for 25 cents each, and the labour, &c. would absorb another 25 cents, leaving a profit of R1 on each tin. No doubt this and other methods of curing will be tried by the English Company next season.

It does not follow that because there are a large number of boats in a populous fishing village fish-curing, is sure to succeed. It has been found that generally the number of boats is limited to the demand for fresh fish and that only enough is caught to meet the demand. I quote the case of Suriyagahawella, where there are over 200 boats, and a large number of fish caught and yet the quantity cured is very trifling. The season closes about the end of April, when the rough weather which indicates the burst of the south-west monsoon compels all fishermen to beach their canoes, and no attempt at fishing is made again till about September. So elated, however, have the men been with the encouragement given by the Government, that they have all promised to return as early as possible next season, and in larger numbers.

This District has probably never witnessed such a large fleet of canoes as came down this season, and residents assure me that never did such a large quantity of salt fish pass through the market and town for sale up-country.

I have endeavoured as far as possible, by the examination of the principal traders in the town, to ascertain the quantity of dried fish cured in Hambantota and Pattanagala the previous season before

the yards were opened, and give the result in the annexed statement marked C. The fresh fish of the previous season has been left out, as it was never weighed. The quantity cured this season is also given for the purposes of comparison. The trifling loss to Government is more than compensated by the large amount of nutritious food manufactured for the benefit of those who, living inland, have not the means of getting it except in a preserved condition. In a separate column will be found the number of boats engaged during the two seasons. Below will be found a statement showing to what District the dried fish has been sent. The quantity shipped to Colombo was by the European Company, while the native curers sent theirs principally to markets in Uva, where good prices were realized.

Abstract of Fish-curing Operations in the Hambantota Yard, from October 15th, 1885, to April 15th, 1886.

Number of applications		1,153
Description of Fish:	cwt.	lb.
Laggo	241	81
Lawayo	196	70
Paraw	39	38
Toru	41	50
Kalamiyo	275	11
Other kinds	412	8
Total ...	1,207	22
Fish removed	855	00
Salt issued	279	70
	R.	cts.
Rate per cwt.	0	80
Receipts	223	80

As far as I can ascertain, the cost of curing fish is R11·31 a cwt., and may be analysed thus :—

	R.	cts.
Cost of fresh fish, per cwt. ..	2	75
Cost of cooly labour in cleaning ..	0	75
Cost of 40 lb. salt ..	0	27
	3	77
Multiplied by	3	
R.	11	31

One cwt. of fish when dried is reduced to one-third its former weight, and the result must, therefore, be multiplied by 3, making R11·31 as the prime cost of one cwt. of dried fish. All native curers send their fish to the markets along the Badulla-road, such as Wellawapa, Koslanda, &c., where the prices range from R15 to R20 per cwt., and often as high as R30; after deducting R 1 per cwt. for cost of transport, the curer reaps a profit of from R3 to R4 per cwt.; where the fisherman is his own curer, the profits to him are double.

Colombo is not a good market at present, as it has to compete with foreign importations, which tend to keep down prices.

Fresh fish, as well as salt, is a favourite food with the Sinhalese, and where there is a full demand for unsalted fish, there is, of course, no motive to induce the fishermen to resort to curing. We are not therefore surprized to learn that one yard failed for reasons thus given by Mr. Murray :—

A third yard opened at Suriyagahawella on November 15th, has not turned out a success, for reasons which are easily explained. Though there were a larger number of boats there, and the quantity of fish caught exceeded that of Hambantota, yet so great was the demand for fresh fish by the dense population in the neighbourhood, and the prices were so high, that it was impossible for curing to be carried on profitably, and the little that was cured was the surplus remaining when large quantities of fish were caught. There is little hope, therefore, of anything being done there, unless curers specially engage boats on their own account.

There is ample scope for the extension of the fish-curing industry where fish is plentiful and population scanty, as the following extract from Mr. Ravenscroft's report shews :—

It was my desire to visit the Mullaittivu District in the early part of the year, and to have conferred, on the spot, with the Government Agent of the Northern Province on the subject of the establishment of fish-curing yards in that District, to which fishermen from the west coast of the Island resort in considerable numbers for the purpose of catching and preserving fish, of which the supply is abundant, during the south-west monsoon. In many respects this District offers special advantages for fish-curing. Fish are, as I have already said, abundant, and even under existing circumstances fishermen are attracted to the District from the other side of the Island. With a very sparse resident population there is a very limited demand for fresh fish; and if facilities could be given that would enable the fishermen to preserve a greatly increased quantity of fish, without the expenditure of a larger amount of capital than is now yearly invested in the business, it is not unreasonable to anticipate that the industry of fish-curing on this part of the coast would be greatly developed, to the advantage, not alone of the fishermen, but also of the people of the Island generally. Owing, however, to the many other calls on my time, I was prevented from carrying out my intention of visiting Mullaittivu, but I trust it may be within my power ere long to visit not only that District, but also the neighbourhood of Batticaloa, where the business of fish-curing is, I am informed, carried on to a considerable extent, both by local fishermen and also by men from the west coast of the Island, and where there are places—so it is reported by officers who have served in, and who are thoroughly acquainted with the District—at which fish-curing yards might be established with every prospect of success.

At Trincomalee, assisted by the Assistant Government Agent, Mr. Reid, I made careful inquiries, in order to ascertain whether it would be advisable to recommend the opening of a yard or yards in the neighbourhood of that place; but although I found and questioned fishermen from the west coast, temporarily located at Trincomalee, it did not appear to me that there was sufficient reason to suppose that if a yard were opened, it would meet with a reasonable amount of success.

In conclusion, I would say, although it is perhaps hardly necessary for me to do so, as it is self-evident that, however well suited a locality may appear to be for the successful working of a fish-curing yard, from the fact that the supply of fish is abundant, that fishermen are available, and that there is little or no resident population, the results must greatly depend on the interest taken in the undertaking by the local officers of Government. Without careful and well-organised supervision and attention to details, and the exercise of the strictest economy compatible with efficiency, by the Revenue Officers, the scheme although it may benefit the fishermen, and to some even to a considerable extent, the people of the country by placing within their reach a larger supply of preserved fish, cannot be expected to pay its way as, under favourable circumstances, judging from the experience gained in India, it may reasonably be expected to do if carefully supervised.

MR. GOW'S TEA WITHERER; THE RESULTING TEA SAMPLES.

To judge by the samples put before us, we think Mr. Gow may well be congratulated on the tea turned out by his new process—a process on which he has been experimenting, and gradually perfecting for some thirteen years. We have received five qualities :—Pekoe Souchong 30 per cent; Pekoe 31 per cent; Broken Pekoe 24 per cent; Orange Pekoe 12 per cent; Pekoe Dust 3 per cent; and the reports of four

of our Colombo tea experts on the same are as follows :—

Description:	Present London value.	Colombo, 30th Oct. Remarks.
Orange pek.	1s 10d to 2s	Blackish small mixed brok. pek. and fannings with gold tips, full dark rich liquor, good quality.
Broken pek.	1s 1d.	Blackish even wiry pek. leaf with ends, little broken, strong dark malty liquor; little pungent good quality.
Pekoe	1s 2d to 1s 4d	Blackish fairly made pek. souch. leaf few ends, dark malty liquor little pungent fair strength and quality.
Pek. Souch.	10½ to 11d	Blackish rather open choppy souch. leaf, dark pungent liquor, little thin.
Pek. dust	1s 2d to 1s 3d	Black, brownish, small. Small broken orange pek. and fannings, full of tips, strong dark pungent liquor.

pp. Somerville & Co., A. H. Thompson.
[E: 1s 6¼d F. £1 15]

Bro. pekoe blackish rather even little flaty bro. or. pek e 12 per et. full of golden tips a d strong 1s 8-10d 90c to R1·10
Bro. pekoe blackish rather even and twisted little bro. pekoe 24 per cent. fairly tippy, strong 1s 6d 88
Pekoe blackish rather bold uneven pekoe leaf 31 per cent few ends and good strength 1s 2d 71c
Pek. sou. greyish very uneven irregular leaf 30 per cent fair s g. 11d 4 c
Pekoe dust handsome tippy flat dust 3 per cent rather thin 1s (fr. app.) 55c

Forbes & Walker.
Exchange. Freight.
1s 6¼d £1 15s 0d

Character.	London value.	Colombo equivalent.
Or. pk. Black rather uneven little choppy leaf. Many orange tips strong thick liquor rather pungent little flavor good quality	1s 9d	1·04 cents.
Bro. pek. Blackish uneven little twisted semi-broken pekoe a few tips strong pungent liquor good quality ..	1s 6d	88 00
Pekoe Blackish rather uneven rather flaky leaf. Few tips; strong rather pungent liquor	1s 3d	71 to 77
Pek. Sou. Blackish uneven semi-bro. pekoe sou., good strength little pungent liquor ..	1s 0d	55 00
Pro. dust Small black flaky fannys full of orange tips. Fair strength	1s 3d	71 00

These teas are especially good considering they are made from leaf plucked from newly pruned bushes. The liquor being strong and of good quality, and the leaf of a fine black colour, free from all greyness.
Herbert Tarrant.

TEA IN AMERICA.

Writing from Philadelphia, Pa., under date 18th September, Mr. Pineo has a very satisfactory report of progress to make as follows :—

"The *Overland Observer* comes to me regularly. The paper is perused with the greatest interest and all matter pertaining to Tea has a special attraction, as I am, and have been, introducing your tea into the markets of the United States and Canada. I have established agencies in St. John, Chatham, Beauford, Toronto, Hamilton, Kingston and Montreal in the Dominion of Canada, and have secured the co-operation of one of the largest and best known jobbing houses of New York, hence I am in a position to place any quantity of tea on consignment in those towns. There are two great difficulties with which I have had to deal. First, to get the dealer to handle and the consumer to appreciate Ceylon tea, and second, to get a uniform quality in appearance of leaf and in liquor. There is too much red and irregular sized leaf. I am about starting an establishment here for the sale of Tea and Coffee in packets, and also for selling in original packages by wholesale.

"I have met Mr. Morris, Liberia Consul, and he agrees with me in thinking a good trade can be done here. We are only two hours by rail from New York." [Mr. Pineo's remarks will, we have no doubt, receive attention; and all in Ceylon will wish him success in his good work.—Ed.]

CEYLON *v.* INDIA AND CHINA AS A TEA-PRODUCING COUNTRY.

The following extract from the letter of an influential correspondent in the old country who takes the deepest interest in all that concerns the welfare of Ceylon, merits and has received our careful attention :—

"No one has studied the question of our exports more deeply than you, and I want you to reassure if you can many timid people connected with Ceylon from the Colonial Office to myself on the subject of tea. There is no apprehension as to the failing power of tea, but as to over-production in Ceylon, India and in China which will so reduce profits that the planter having no gain will cease to cultivate and there will be another and final depression of Ceylon. The fall in the price of tea has caused these reflections. The margin of profit is already becoming small, but what will it be five years hence, when our exports of tea shall have reached some 40 millions of pounds, and when the increase of Indian tea will be on the same advancing scale, to say nothing of the Chinese. Once open China by railways and I fear they will send in tea in such quantities and at such a price as to swamp our planters and the Indian also. You have seen what has been done by Indian railways opening up vast tracts from which formerly it was impossible to export the grain which was grown and which might be grown. Now Indian wheat is sent into the market for 29s a quarter, and has utterly swamped Russian and American wheat, to say nothing of our own—and they boast in the Punjab that they can supply the world with the best sample and at a rate of cheapness with which no

other country can compete. If we could get new markets all would be well, but when are they to be found? I am a good deal exercised in mind about all this, not only as interested in Ceylon, but as a tea-planter myself. Suppose you write a careful article on the subject in the *Observer* and send me a special copy, I know the subject will often be discussed hereafter in my presence, but pray do not let it be known that I have misgivings as to the future prosperity of Ceylon. I daresay you will dispel them."

Almost on the top of this, there comes a communication couched in much the same spirit from our friend "Old Colonist," who, fifteen years ago, pointed out to us the western slopes of Adam's Peak as specially fitted for the future tea gardens of Ceylon, just as poor Mitchell of Kelburne so far back as 1864, took us over Baker's Farm reserve forest with the view of starting a Company to cultivate tea in the neighbourhood of Nuwara Eliya, as he had seen it a year of two before grown at high elevations in Northern India. Here is "Old Colonist's" view of the situation :—

"Dikoya, 25th Oct.—I have seen Adam's Peak this morning for the first time in a dozen years, and a blithesome sight it is to an old Ceylon man. Now that I am satisfied it stands where it stood, I begin seriously to take my bearings, and the first thought that occurs to me is to marvel at your moderation in estimating the probabilities of tea, three years hence. I have not yet seen the Kelani and Kalutara Valleys, though from what I know of them I can readily credit them with a super-abundance of good leaf, but when I look at the vast expanse of these three sister valleys comprizing possibly over 40,000 acres of tea, most of which is under two years old, and I am told that shipments of 14 to 15 million lb. are confidently expected for the present year for the whole island, how can anyone be supposed to restrict their estimates for 1889-90 to 30,000,000 lb.? And when I look once more at the vast extent of suitable chena-land from Matale to Kandy and Kadugannawa to Nawalapitiya,—where I still hold that a dozen Mariawattes may be easily carved out,—and again peep at the other side of the Peak where what was the wrong side for coffee is right for tea—even from Bambarabatuwa down to Udugama, where J. C. R pluckily plays his last and winning card,—immense tracks of land will be found eminently suited for the fragrant leaf, to say nothing of Haputale, Badulla and Madulsima which will doubtless yet top the market with finest flavoured pekoe. With all this in view, I simply stand aghast at the bare possibilities of the leaf produce here, and wonder how on earth the consumption is to keep pace with this extraordinary quantity thrown on the top of the China and Indian supply. What *is* to be the upshot? Will the Chinaman cave in? Both Rama samy and Ranghamy are taking very kindly to this tea business and even John Chinaman cannot subsist on a 6d per day. If prices can only be maintained, there can be no possible fear of Ceylon. Meanwhile, capital begins to flow back—the clearest indication you have had of this for many years was the land sale of the 20th:—R48 per acre smacks of old times! Confidence once lost, however, is very hard to regain and much might yet be done to facilitate or encourage the return of capital by remodelling the Mortgage Laws. By all means let every man who can, with all this in view, keep his title-deeds clean, but as business cannot usually be conducted without borrowing and lending, now is the time to make the necessary reform."

We anticipated a good deal of criticism of the statement we ventured to offer at the meeting of the Agricultural Association to the effect that Ceylon tea could possibly, by-and-bye, be laid down in the London market, not costing more than 6d per lb. On reflection we thought this was going a little too far, and referred the question to a gentleman in our midst who has paid special attention to the detailed cost of our Ceylon teas. Here is his reply :—

"Colombo, Oct. 26th, 1886.

My dear Sir,—The reply to your question as to whether Ceylon tea can be laid down in London at 6d per pound, depends a good deal on rates of freight and exchange; the former fluctuates a little from week to week, and the latter from day to day as you know.

Calculating, however, freight at 40s per ton of 50 cubic feet, exchange at 1s 6d per rupee, and taking the cost of tea from estates in full bearing at 30 cents per pound laid down in Colombo, it would require 7d per lb to cover cost.

The home charges with 40s per ton freight, would come to about 1½d per lb. At present prices they are 2d per lb., but Insurance, Brokerage and Commission on 50 per cent under these prices would reduce these charges proportionately.

You have published over and over again in your daily issues, and also in your *Tropical Agriculturist*, statements from the highest tea planting authorities in the Island, proving that the produce of properly managed estates in full bearing can be laid down in Colombo within thirty cents per pound.

This being so, I am tolerably sure that no other country can drive us out of the field without, also succumbing; not even our chief competitor, China, as long as the internal and export duties levied in that country, which amount to the equivalent of 2½d per pound, are maintained.

Exclusive of these duties, the only advantage the China grower has over us, is that his green leaf costs him nothing to produce. Nevertheless, John Chinaman is no more disposed to carry his green leaf to market and give it away for nothing, than a Sinhalese will give away the coir, coffee and other products which also costs him nothing in the shape of wages to produce.

We are informed by the most recent authorities, that the usual price of green tea leaves in the interior bazaars of China is equivalent to 1d per pound. As they cannot manufacture their tea, however low wages may be in the manufacturing towns, (and they are not so low as is generally supposed) cheaper than we can, nor can they make their ornamented boxes cheaper than ours. It would not be difficult to *tottle* up a comparison between the cost of Ceylon and China teas.—Yours truly,

C. S."

Here, we might almost leave the matter, for "C. S." puts the case in a nutshell and if our esteemed home correspondent and "Old Colonist" want further information, is it not given in the pages of successive issues of the *Tropical Agriculturist* from 1880 onwards. For a fair and moderate summing-up on many of the practical points involved, enquirers cannot do better than study the "Ceylon Tea Planter's Manual." But something more will very probably be expected in support of the position which Ceylon tea planters begin now fearlessly to assume. That position involves a challenge both to India and China in respect of the comparative quality, cheapness of production, and probable demand for their teas, and the general feeling of most observers is that Ceylon has nothing to fear from the severest competition which may be offered. We none of us wish

to see the present average of prices reduced. But if there is a further reduction, the Ceylon planter will not be the first to stop. Our planters have already proved what they can do in respect of quality and further improvement in this direction may be steadily anticipated. All the patent tea machinery which has already found a birthplace in Ceylon is but a foretaste of much more to come. In regard to economy of working it is difficult to get those who are not personally acquainted with the advantages of Ceylon to give credit to what can be done here as compared with other tea-growing countries. Our climate, situation, facilities of transport and relative cheapness of labour will enable us to defy competition from any country where labour is paid for; and we certainly do not expect for a quarter of a century to come to witness that fiscal as well as transport revolution in China which would enable that great tea country to beat us in the race.—As to opening new markets for the consumption of tea, no one can say that Ceylon men are not doing more than their full share and we think there is much reason to anticipate that the taste for Ceylon and Indian teas will more and more supersede that for the inferior, and often adulterated China article.

CEYLON PINEAPPLES FOR HOME USE.

A correspondent lately returned from England writes as follows :—

"The best quality of pineapples in England during the month of May fetch half a guinea a piece, at least such was the price asked upon enquiry. Small ones, about as big as a coconut were sold at half a crown each. Ceylon pines are sold in the Colombo markets during April and May at prices varying from five to fifteen cents each ; of course, the difficulty is to get Ceylon fruit placed in the English market in sound condition. Has the exportation of pines from Ceylon ever been attempted ? Good sound fruit carefully wrapped in tissue paper and packed in pure dry cinnamon sand, coffee husks or other suitable vehicle and enclosed in boxes containing half dozen pines each, might prove a success. Each pine so packed could probably be put in the English market at 50 cents each, whilst the retail price would vary from two to eight shillings each, according to the condition and quality of the fruit."

At the old Industrial School, Mr. Thurston used to preserve pineapples and plantains for the home market, but beyond that we are not aware that any experiments have been made. It is a question how far Ceylon could compete with the West Indies, which are much nearer the European markets.

The Deleterious Action of Cockchafer Larvæ on Soil and Roots is thus described in an article in *Nature* :—

"A more extreme case is where the soil becomes damp and clogged with excessive moisture: not only does no oxygen reach the roots, but noxious gases accumulate in solution in the soil, and will hurry matters by poisoning cells which might otherwise live a longer life of usefulness. It is extremely probable that such gases find their way into higher parts of the plant in the air-bubbles known to exist and to undergo alterations of pressure in the vessels of the wood: this being so, they would slowly retard the action of other living cells, and so effect the upper parts of the plant even more rapidly than would otherwise be the case. Damp soil may thus do injury according to its depth and nature; but it need not necessarily be deep to be injurious if much oxygen-consuming substance is present. I have seen excellent soil converted into damp, stinking, deadly stuff from the action and accumulation of the larvæ of cockchafers: these "grubs" may, it is true, accelerate the devastation caused by the consumption of oxygen and the accumulation of poisonous waste matters in the soil by directly cutting off portions of the roots themselves, but the accumulation of oxygen-consuming substance, and the cutting off of supplies to the root-hairs evidently plays a chief part in the destruction."

The Amsterdam Quinine Works.—A general meeting of shareholders in this company was convened for September 15th, but no quorum being present the chairman adjourned the meeting for a month, when it is hoped sufficient interest will have been aroused to ensure the taking of a final decision concerning the future of the works. The board of directors propose to increase the capital of the concern to 3 9,000 florins (25,000*l.*), divided into three series of shares: the first and second of 50.000 florins each, in shares of 250 florins; and the third of 200,000 florins, divided in shares of 1,000 florins, 500 florins, and 100 florins each. It is further proposed to place the management of the works in the hands of a director, under supervision of a committee of five members, of whom two must be Dutch pharmacists of repute. If by October 15th a subscription of 150,000 florins in shares of the third series has not been secured, or no other means have been found to guarantee the possibility of continued existence, the company will in all probability be dissolved, but an appeal is made to patriotic feelings, and the continuation of the Amsterdam Quinine Works is described as matter of national importance. It is said that a committee of experts who have investigated the working of the entire concern have stated that the works are capable of being conducted at a profit, provided the active assistance of all Dutch pharmacists in pushing the preparations of the Amsterdam works in preference to those of any foreign firm be secured. —*Chemist and Druggist.*

China Grass or Ramie.—*The Textile Recorder* has been sent to us with the following paragraphs marked :—

"M. Marius Moyret insists upon his statement that it is only throwing money away to patent processes in Europe for decorticating ramie or China grass. It will not grow in Europe, and it is far too bulky to bring here in its native form. It must be treated near where it grows. He again states that the fibre can be separated from the woody part quite easily and cheaply. The cut plant must be dried gradually as far as possible in the sun, then put into a heated stove for a night. All that is required is now to beat the dried plant ; the wood falls off, and a bundle of fibre is left. If the drying is done too rapidly, the real fibre becomes, as it were, glued to the wood, and nothing can be done with it. A final process is required for separating the fibres from one another. This could be done in Europe. But the celebrated chemist and academician, M. Fremy, who in conjunction with Urbain has made a special study of ramie, spoke to the French Academy upon this substance on June 28th last, exhibiting some very fine samples of manufactured China grass obtained by a process which he has described. He remarked that it was to be hoped that French agriculturists would no longer hesitate to undertake the growth of ramie upon a large scale, for France would then possess a vegetable fibre resembling silk which skilful manufacturers would work up without loss of its silky lustre and produce goods such as China had done for a long period. Another instance would then be created of the services which science could render when it was associated with agriculture and industry. There is, it will be seen, a great difference of opinion upon the matter between the man of science and the man of practice."

The first process is new to us and seems worth trying, but so many sanguine expectations respecting rhea and aloes have been falsified that we are rather sceptical.

Correspondence.

To the Editor of the "Ceylon Observer."

WHITE CASTOR CAKE: AN ENQUIRY?

The Editor "Tropical Agriculturist."

The Siddra Bunnoo Estate, Koppa,
Mysore, 21st Oct. 1886.

Dear Sir,—I should feel much obliged if you would inform me the price of white castor cake per ton in Colombo, and also where the larger part of that shipped to Ceylon comes from? I have made enquiries in Mangalore and Bangalore and cannot get any. My object in writing is to ascertain whence the castor cake comes and to arrange to get some either in Mangalore (my nearest port) or Madras.—I am, dear sir, yours faithfully,

ROBERT BUCHANAN.

[This is a most extraordinary enquiry to make of us in Ceylon, seeing that all the castor cake now in Ceylon comes from India. It is sold here just now, crushed and delivered at Colombo Railway station, in boxes at R65 to R67 per ton, and comes chiefly from Calcutta.—Ed.]

THE CINCHONA ENTERPRIZE IN CEYLON!—AND IN INDIA AND JAVA: THE NEED OF FRESH SEED.

Gampola, 23rd Oct. 1886.

Dear Sir,—A great deal has appeared lately in your valuable paper on the subject of cinchona and it has surprized me that no one has noticed, while on this subject, the gradual though certain extinction of this important cultivation within the island. I shall preface my remarks with *the hazard*, that less than ten years will see the last of the present race of cinchona trees extinct.

In taking a retrospect of cinchona since say 1865, when only a few trees and isolated patches were scattered here and there over the country, all from one original stock and propagated by cuttings only, viz. from the Hakgalla Gardens, until the period between 1877 and 1882 when the cinchona plant threatened to become a troublesome weed, springing up everywhere over estates and being regularly weeded out along with other weeds until down to the present time, what do we see? and what have we learned?

All the earlier planted cinchona took five to seven years to come into seed, grew so far as I ever knew or saw, perfectly free from canker, attained to fine well-grown trees, and when cut down again grew to trees, retaining their original vigour.

When the *cinchona period* arrived and men counted their riches by the number of plants they had planted, (now the seedling period) taken wherever they were to be found, what a different appearance they presented: trees ran to seed from 1½ to three years old; along with this period came canker, sweeping out whole plantations, no doubt hastened somewhat by the abnormal seasons of 1879 and 1882, but I think most observing men will admit the great vital cause to be degeneration of species, till at the present time cinchona seedlings die off wholesale, before they have attained a foot high.

I maintain canker is but symptomatic. The disease is embryotic, *i. e.* the cinchona plant never has been, nor ever can be naturalized in the East and my remarks apply to India and the whole British Possessions where this valuable tree has been cultivated.

Now if we but take into consideration what part *Ceylon alone* has played in this mighty boon to humanity, in the matter of cheapening the cinchona alkaloids and bringing them within the reach of the poorest, is it not sad to contemplate if *extinction be admitted* how soon this gift may be swept away and quinine get beyond the reach of the poor.

I look on this as a *highly important Imperial question*, calling for the immediate attention of the powers that be ere it is too late; at any cost the British Government should keep up a small fresh annual supply of seed and plants from their native habitat and have them propagated and distributed, bringing them easily within the reach of all willing to undertake their cultivation.

What owner of land in Ceylon would not gladly plant up a portion of his estate in cinchona if he were satisfied there would be a healthy permanent growth as attended the early efforts?

I have no hesitation in saying like results would follow if seed or plants were again re-introduced, and planting confined to *original stock only*. I am very desirous to hear the opinions of those who have watched the progress of cinchona planting from its earliest start in the island to the present time, and what they think of its future.

Much might be written of *disappointed hopes*, but also much of the *great aid* it brought the struggling planter in his time of need, also what a lamentable fact it will be if we have to record its decay, when a little foresight might prevent such a calamity and give a fresh impetus to an industry so fraught with good.—Yours truly,

AGRICOLA.

[Our correspondent's idea is a good one, although we scarcely think he is correct in his vaticinations. If cinchona trees canker off in Ceylon and India, so they do in the Andean plantations, while in the forests of America, South and Central, the bark gatherers had to search for scattered groups of the fever trees. We believe we have in the eastern world as good a cinchona climate as exists in the western world, but in both hemispheres, the plant is particular as to soil and especially subsoil, dying off in damp, stiff clay. We should like to hear from other planters also what they have to say about the flourishing of cinchonas on soil opened up and drained by tea plants. Our own experience shows that in such cases they flourish wonderully.—Ed.]

COFFEE IN UVA.

Dear Sir,—I see the Uva men still try to live in a fool's paradise keeping up the hope that *their* coffee may resist the green bug. How true the proverb is that "Wise men profit by the experience of others, fools by their own." My coffee was among the healthiest and most vigorous in the Kandyan side, the soil, climate, cropping and growth were in many respects similar to those of Uva, while it was distant and separate from other estates. Green bug put in its first appearance only last year, but this year it is very bad on all over the coffee, stems, leaves and even fruit. Further it is not even confined to the coffee but it prevails on jungle bushes and even on forest trees. The merry men of Uva must, like their Kandyan brethren, just submit to the inevitable, and the sooner they face it the better. Green bug is far worse than leaf-disease, and neither good soil nor dry climate mend matters. Coffee must be replaced by tea, but for Uva to do this successfully, it *must* have a railway, no matter of what kind. The long weary years have proved the folly of Uva having allowed Rutherford's proposed temporary narrow gauge scheme to collapse—half a loaf would have been better than no bread.

DELENDA EST CARTHAGO.

BREAD AND FLOUR—INFORMATION FOR HOUSEKEEPERS.

Colombo, 2nd November 1886.

Dear Sir,—With reference to correspondence in your paper sometime ago regarding outturn of bread, we annex extract of a letter on the subject, received from an expert, Mr. E. Freeborn of the Western India Flour Mills, Bombay:—a gentleman whose experience in connection with flour and bread industry extends over the past twenty-five years.—We remain, dear sir, yours faithfully,

pp Framjee, Binkhajee & Co.
Pestonjee Dinshawjee Khan.

"Our percentage in bread made with our flour is 140 lb. bread for every 100 lb. flour; but in Colombo, where toddy is pure, and the dough is made softer so as to turn out light bread, the bakers ought to realize about 145 lb. Flour with plenty of strength and very dry will take more water than moist flour, or flour that has not much gluten in it. To distinguish good flour containing strength you need only mix an ounce in sufficient water to make a bolus or pill, and then to knead it well and draw it out into a string to see how long it will go without breaking. If it breaks short you may conclude it has little strength; but if the fibre extends and is elastic it is good strong flour and the percentage will be better. In colour, a pale white or chalk colour is not a healthy colour, good flour must possess a bright rosy hue or what millers call, a bloom on the flour."—pp. F. B. & Co., P. W. K.

A Wrinkle for Tea-planters (By a returned Colonist).—On your tea-chests, put only the nett weight, say "50, 90 or 100 lb. nett"—nothing more; and then state in invoice not simply the total, say "9 chests equalling 900 lb."; but rather put in 9 chests, *each* containing 100 lb = 900 lb. The word "each" is of much practical importance. Of course, a few ounces say ¼ lb. extra, should be put into each chest.

Recent Patents.—Tonic or Coca Bitters. (*Waters. No.* 6,899. May 22nd, 1886.) Any British or foreign wine is taken, and quinine, "cinchona," quinidine, or other bitter alkaloid dissolved in it until the proper degree of bitterness is acquired, and therefore it is mixed with coca leaves or an extract thereof, solution being, if necessary, aided by the addition of sulphuric, citric, or other acid, and the mixture afterwards clarified with isinglass or other finings. The claim is for the preparation termed coca bitters, and for a beverage containing an extract of coca leaf and a bitter alkaloid.—*Chemist and Druggist.*

The Successful Cultivation, since 1884, of the Ramie or China grass plant (*Boehmerianivea*) on the Champ-de-l'Air at Lausanne (altitude 520 m.) by Prof. Schnetzler, is an interesting fact in botany. This shrub, a native of China and Sumatra, has been grown in the south of the United States and of France for thirty years. Recently it has been introduced into Algeria. There is of course a striking difference in the conditions of temperature between Lausanne and the places in Asia where Ramie is grown. While the latitude of the latter is from 15° to 35°, that of Lausanne is 46° 31'. The mean temperature at Lausanne is 9° ·5 C. Last winter the plants underwent long periods of great cold; in one case, *e.g.*, the thermometer being below zero for 124 hours, with a minimum on the ground of—12° ·5 C:—*Nature.*

"London Purple" as an insecticide is thus noticed in the Melbourne *Leader*:—

Enquiries having been made respecting the codlin moth poison, we republish the following particulars from an American source:—Mr. T. G. Yeomans, speaks from experience in the *Country Gentleman* of London purple for orchard enemies as better than Paris green, because it is cheaper, mixes well with water, and does not need to be stirred to prevent precipitation. A pound to 100 gallons is a suitable proportion, the poison being first made like paste in a small dish and then added to the tank. He applies it with force pump, suction pipe, hose, &c.—costing, all complete, 10 dol.—one man driving the team and directing the nozzle, while another works the pump vigorously. Thus hundreds of trees may be sprayed in a day; he thinks the best time is about when the blossoms fall, or as soon thereafter as may be convenient, and the effect is very noticeable in improved quality of fruit, due to the destruction "not only of cankerworms and codlin moths," but of all other insects injurious to the apple.

Mica or Talc.—A correspondent writes:—I saw your para *re* Mica or Talc, and give you the following information received yesterday from a friend of mine in London. I send a large sample of the Talc he took home, and enclose herewith two small pieces, one is a bit off one of my samples, and the other is a piece of a marketable sample, and my friend alludes to them as being as different in color as a white man and a colored one:—"*Mica.* I spent money and time to succeed, but the one white quality is all I could get quotations for. I am in contact with the real buyers, and can sell quantities, but they must be large white clear sheets, any suspicion of amber or brown, I cannot get even an offer for. What I brought home is too brown and wavy, but I learned that a man of colour (a native no doubt) had been in the habit of shipping from Galle to Germany, mica of the right sort and quality, which fetched good prices, but suddenly supply ceased, and sometimes afterwards it was discovered he had died. Who it was I could not learn, but was told he shipped the mica from Point de Galle. It is used in Germany for making lamp shades, as per sketch, also for ovens, Magnetic Instruments, Screen paintings for fire places &c." I send this so that you may make any use you like, as some of those reading about Talc might go to a lot of expense and never get the *right color*, not being aware that the brown is worthless. [The specimens sent are certainly very clear and fine.—Ed.]

Java and Sumatra.—The Colonial report of 1885 has been issued. It shows that the population of Java and Madura was on Dec. 31st, 1884, 37,680 Europeans, 228,464 persons belonging to various Eastern nations, and 20,665,510 natives, together 20,931,654, against 20,630,102 in 1883, the population having thus increased during 1884 by 301,552 persons. In the district of Bagelen an epidemic prevailed during the first six months of 1884, which caused a decrease of the population of 20,239 souls; in all the twenty-one other districts there was an increase of 321,791 souls, viz. 371,824 natives, and 3,967 foreigners. About the condition of Java and Madura the following information is given. Owing to the small Government coffee-crop and the low prices realised for the plentiful rice crop, the natives have earned only a small amount of money, but the sanitary conditions generally gave satisfaction, almost all districts being free from epidemic diseases. Order remained undisturbed, except in certain cases of religious excitement, but which were soon suppressed. The relations with the various native Courts, and the neighbouring Colonial Powers, have continued to be of the most friendly nature. Agriculture was satisfactory, the outturn of the rice crops being plentiful. The coffee cultivation was less favourable, the plant having suffered much from the continued aridity and the prevailing disease of the leaves, which involved considerable damage and loss. The sugar cultivation has been satisfactory, but the tobacco crop unfavourable. Middle and Eastern Java suffered very much from inundations. Volcanic eruptions were only observed in April and October, the consequences of which were of little importance. The amount of the land-rent was 19 265,807 guilders, against 19,304,766 guilders in 1884.—*L. & C. Express.*

FARMING IN INDIA.

It is not always that we see ourselves as others see us. One of our much respected English exchanges (*North British Agriculturist*) has an article of Farming in India in a recent issue, a perusal of which will doubtless enlighten many of our readers, who are quite up in the agriculture of the country. Our contemporary says:—"The Indian farmer has scarcely any food, but what he has is of the simplest kind. There being no hard, gravelly soil, no stiff clay, no hard pan, and no sticky calcareous soil to work, is a great advantage to him. By a very crude implement, which can scarcely be called a plough, the land is torn up. This plough consists of a triangular piece of wood, about 18 inches in length, and 6 inches in diameter at the larger end, the other being pointed. On the flat side of this piece of wood a groove is made, into which a flat piece of iron, a foot in length, an inch wide, and half an inch thick, is inserted, and held in its place by a staple. The staple underneath does not interfere with the rooting. This iron bar, which is pointed, serves as a nose or point to the plough. The larger end of this triangular piece of wood is mortised into an upright stick, the latter about 3 feet in length, at the top of which is a wooden pin on the front side for a handle. About 18 inches from the ground a strip of board 3 inches wide, an inch and a half thick, and 8 feet long, is inserted into the upright stick, and serves as a beam and a tongue. The yoke is a straight stick, 6 feet long, 3 inches in diameter, with four wooden pins each 6 inches long, one on each side of the neck of the bullocks. A small hemp rope, or grass twine, goes under the bullocks' necks to keep the yoke in its place. The beam of the plough has a few notches under it near the end, and is fastened to the yoke by a small grass rope. The plough makes no furrow, but simply roots or tears up the soil, and the ploughman, with his little goad or whip in one hand, the other holding the wooden pin in the upright stalk, walks by the side of the plough. The cattle are of the Brahmin species, white, slender-bodied, long-legged, and very lean. About the only feed they get for months before the rain is 'bhoosa,' or wheat, straw, and chaff. Ploughing is hard work for both the little cattle and the man, and the best a man can do is to tear up three-quarters of an acre a day, and the work then is poorly done." "The land has to be ploughed in this way a number of times, especially for the more substantial crops. The cattle cost from £1 to £4 a pair, but the average price is about £1 12*s*. The average price of a plough is 1*s*. 8*d*. The only other implement used is a log or slab of wood 6 ft. or 8ft. long, drawn sideways across the field by one or two pair of cattle, to crush the clods and smooth the surface. After the land is pulverised, and finally this is well done too, the last ploughing takes place when a man or woman dribbles the seed from the hand into the furrow. The next operations are those of reaping and thrashing. The reaper consists of a blade of iron 6 inches in length, 1 inch in width, and curved like an old fashioned sickle with a notched edge and a short handle. Its cost is 2*d*. The harvester sits upon his heels, cuts a handful of straw which he lays down, and then waddles on without rising, and cuts another lot. He cuts about one-twelfth of an acre a day, for which he receives 2½*d*, out of which he has to board himself. After this primitive reaping machine comes a binder, who gathers up the grain and binds it into sheaves. It is then shocked, and a day or two after carted to the thrashing-floor. The thrashing machine consists of a floor—a bit of hard ground—a stake, a number of cattle, and a driver. The grain straw is piled around the stake in the floor, the cattle are connected by a rope tied to their horns, and one end of the rope fastened to the stake, and the driver keeps them going until the straw is trampled very fine, into what is called 'bhoosa.' This after the grain is separated from it, is fed to the cattle." We trust the English public will not need further enlightenment upon this subject.—*Indian Agriculturist*,

47

LETTER TO AN AGRICULTURAL STUDENT IN CEYLON.

No one denies that agriculture is essentially a practical thing; so is medicine; and will any one be fool enough to suggest that science be put away from the study of medicine? That would be senseless. The land is the subject of the cultivator's operations; how much do the cultivators of Ceylon know about it? Of course, they are convinced they know everything—

"ignaros viæ miseratus agrestes."

The object of agriculture is thus concisely put. To produce, in good condition, the greatest amount of produce in the shortest amount of time, at the least cost, and the smallest deterioration of the land. If this object is to be faithfully carried out, the cultivator must have a certain knowledge of such sciences as would help him. English agriculturists for a long time laughed at the idea of bringing Geology, Chemistry, Mechanics, Meteorology, Botany, and Natural History to the aid of agriculture. Land has been supplied by Nature with an enormous amount of natural food which can sustain it for an indefinitely long period; and for as long a period the cultivator may take no thought of how it fares, so long as it yields its return year by year without decrease. But time works changes, and old methods are not always the better. It must be understood by those who ridicule the idea of seeking the aid of the sciences I have mentioned above, that these sciences are not studied abstractedly, but only as applied to, and so far as they touch on, the main subject *i.e.* agriculture. Now I can assure that you in this sense, of being illustrative of Agriculture, and dealing with concrete things, they form a most interesting and charming study.

Geology, dealing of rocks and soils, tells you what soils you may expect in different quarters; and 'stratification,' 'dip,' and 'strike' all go to help you in draining, well-sinking, &c. Chemistry, of course, principally helps you in the matter of analysis of soil, water, manure, feeding stuffs, &c., and enables you to detect adulterations, and fix upon the relative value of important ingredients. Why supply manure generally and indiscriminately when you can find what element has been exhausted in the soil, or which plant-food the crop lacks. Thus expense is saved, and injury is averted; for certain elements that are superfluous may produce combinations or changes that would be better absent.

Mechanics helps you in the matter of implements. By an acquaintance with the branches of this science you learn the applications of steam, water, and wind; or, to put it in its most attractive form, you will be able to drive a working engine, set up a water wheel, repair a pump, and do a score of such useful things.

Meteorology comes to your aid in matters of weather, temperature, rainfall, moisture, forecasts, &c. Botany—you, of course, know how usefully this science comes in, in agriculture. It struck me lately how careful growers of cattle here are about the grasses of cattle feed on. In a fortnight or three weeks you can be perfectly familiar with all your grasses, know all their names and their nutritive value. How little do you attend to your grazing fields out there, caring nothing about grasses that keep your cattle back in condition, and otherwise exert most injurious influences. Why not have a pasture ploughed up and sown with a good selection of grass seeds, so that you may always have a good grazing ground on which the cattle will thrive?

Natural History *at least* will come to your aid in the matter of insect pests. Veterinary, you know, will be of inestimable value to you, and it is an interesting subject to study. I intend taking out Principal Williams' classes. You know he is said to be the greatest authority on the subject in Great Britain, and his writings are the standard works. The correspondent to the *Examiner* spoke about the variety of agricultural systems in different parts of the world. True, but the broad principles of agricultural science apply generally, and what knowledge you want is, I

suppose, of such operations as of ploughing, harrowing, rolling, drainage, irrigation, &c. I hear you are being instructed in ploughing. Well, you will know by this that even in such a simple agricultural operation you want to know something of the nature, constitution and texture of the soil and subsoil, and the advisability or danger of going deep or shallow; what width your furrow slice should be, &c. But now you must be laughing at the idea of my referring to ploughing at all when you know all about it by this.—"Examiner."

PLANTING IN FIJI.

The Rewa River.—The largest river in Fiji is the Rewa in the island of Viti Levu, the largest island of the group. It is formed by the confluence of the Wanibuka and Wainimala, and at 28 and 11 miles respectively from its mouth receives as tributaries, on its right bank the Waidina and Waimana. Including its tributaries, the river is navigable for about 72 miles, and it drains a surface area of about 1360 square miles, there is an approximate average annual rainfall of 130 in. The Rewa River has five entrances, all of which are, separated from one another by extensive delta. They are, however, protected from the fury of the ocean by a coral barrier reef. Nature has perfected the handiwork by leaving channels wide and deep enough to admit the largest ships through the barrier. After describing other smaller tributaries, Mr. Thomson remarked that the Rewa River system is a most important one, from both a commercial and an agricultural point of view. During heavy floods, which are of rare occurrence, the flat land on the margin of the river is enriched by the deposits from the waters, just as the Egyptian plains are through the overflowing of the Nile. The writer described the nature of the European land claims, and gave a table showing the area so claimed on the Rewa River. The different sugar estates were described at considerble length. The Fijians themselves cultivate cane upon small plantations, and sell it to the manufacturers, receiving the same price as the European grower. There are extensive areas of virgin soil available for the same purpose awaiting European capital and enterprise. The average annual rainfall on the Rewa is over 100 in., and the climate good. Prior to 1881 all the labourers imported into Fiji were Polynesians, but owing to the great competition in the Polynesian labour trade from other colonies, the Government established a system of coolie immigration from India, which has so far proved a great success, and now very few Polynesians are employed in the Rewa district. Each cooly or Polynesian can work from two to three acres of the cane field, and the number of labourers on each plantation is properly regulated. The cost of imported coloured labour, including introduction, &c., per head per annum was as follows:—Coolies, about £28; Polynesians, about £35; and Fijians, £27. Coolies cost £21 16s. 8d. introduction money; wages, 1s. per day for men, and 9d. per day for women. For the first six months the employer has to find the cooly in rations, deducting 5d. per day from his earings for the same. After that period he has to find himself. The term of service is five years. The percentage of sick and absent from work every day showed them to be an expensive class of labour. A new Fijian labour system has been adopted, to be assimilated with the cooly ordinance to allow the engagement of the Fijian by the day or task work, which would no doubt be a benefit to European agriculturalists. At present the European population on the Rewa River is about 2000, being mostly scattered throughout the district. The soil and climate were peculiarly adapted for the growth of all tropical and semi-tropical products. The cultivation of tobacco was much neglected, and was left almost entirely in the hands of the natives. The total value of the sugar exports during the last four years from the colony of Fiji was £708,569 2s. 11d. Sheep did not appear to thrive in Fiji, but horses and cattle did well, and the latter were often met with in large herds. All kinds of birds were there in profusion, and many natives could boast of well-stocked poultry yards. The natives of Fiji were a contented people, and much superior in physical and intellectual capacity to other Polynesians, the Maoris being their only superiors in the South Seas. Previous to the writer's visit there cannibalism existed, but the outrages committed against Europeans were, in his opinion, the result of great aggravation. However, the Fijians were now a useful race and were civilised. The youths were trained at various religious schools, and at the Government Native State Schools.—*Queenslander.*

A NEW INDUSTRY FOR QUEENSLAND: FIBRES.

Amongst the many interesting facts to be met with in the study of the vegetable kingdom not the least interesting are to be found in the history of some members of the nettle tribe. They are widely dispersed over the face of the globe, and like members of a human family exhibit immeasurably different characteristics, according to their habitat and associations. They have opposite or alternate leaves; their stamens are as many as their perianth segments and opposite to them. They have limpid juice. The flowers are unisexual or polygamous. Ovary, free one-celled, with one erect ovule. So much for the features by which we may know them, but in temperate regions they are only herbs, whereas in the tropics they attain the diginity of shrubs. According to Lindley there are twenty three genera and 300 species, but he adds that there are probably more known now.

So common is the Biritish nettle weed that it has given rise to the proverb concerning "Grasping the nettle."

The reason why the nettle does not sting when it is *grasped*, but does sting if it be touched lightly, is not generally known, except amongst botanical students; and almost all books on botany seem to be written with the express purpose of frightening people away by means of using the longest and hardest words that can be found. It is somewhat in the same way that the serpent uses the poison-gland at the base of his tooth that the nettles exude their poison, and one German botanist has fancifully described them as "the serpents of the vegetable kingdom." In the stinging-nettle there is a little bag situated at the bottom of a hollow hair; this bag contains an acrid fluid surrounded by a number of elastic cells. The point of the hair is sharp, and is protected by a tiny cap. When the nettle is touched lightly this cap is broken off, the point of the hair pierces the skin, and a drop of the stinging juice is forced into the blood. If the nettle be grasped firmly the tube is ruptured lower down, hence there is no sharp point to pierce the skin, and the juice is simply poured upon the exterior. Endlicher considers that the "causticity of nettle juice is owing to the presence of bicarbonate of ammonia," but the properties of the juices of virulently stinging nettles is a subject which still requires minute and careful investigation, for in the case of some exotic urticaceæ or nettles the wounds produced are so dangerous as to necessitate amputation.

According to Pouchet, "If we look at the minute quantity of venom with which one of their hairs inoculates us—not perhaps the 150,000th part of a grain—at the rapidity and intensity of the symptoms, it is clear that the poison of the nettle is the deadliest known." In fact, the true stories concerning the depravity of exotic nettles may in a mild way compare with the fabled wickedness of the Upas tree, though it cannot be said that "for three or four leagues around only dead bodies and skeletons of men are to be met with, whilst the birds which ventured into the surrounding air felt to the ground as if struck by lightning." What is true of the Upas tree is that eight drops of the juice injected into the veins of a horse killed it in a few minutes.

Leschenhault says that he has seen the sting of *Urtica crenulata* bring on the most horrible suffering for a whole week, whilst Shleiden declares that if a person is stung by the *Urtica urentissima* amputation is the only remedy, or rather the sole means of saving life.

The natives of Java call the latter the Devil's leaf and say that the effects of its sting last for a year or more when it does not cause rapid death; whilst *Urtica stimulans* in Java is another most dangerous species. Like the much talked of antidotes to snake poisoning, an antidote to the effects of the similarly venomous if less common violently stinging nettles has yet to be discovered. Having glanced at the malevolent and illbred members of the urticaceæ, let us turn to some of the useful and benign members of the family.

The foliage of *Boehmeria candita*, says Lindley, is used advantageously in Brazil in baths, as a relief for hæmorhoidal complaints, and in the same country an extract of *Pilea mascosa* is regarded as a remedy for dysuria. *Urtica dioica* is used as an astringent and diuretic. It is also used as a decoction, strongly salted, which will coagulate milk without giving it any unpleasant flavour. In Abyssinia an acrid species (*Urtica simensis*) is cooked and eaten by the natives as a vegetable. The tubers of *Urtica tuberosa* are esculent and nutritious, and are boiled, or roasted, or eaten raw by the natives.

The common nettles are used frequently in France; sometimes in England and in Scotland I have often seen women of the poorer labouring class carrying home great bundles of the tender and young portions of the nettles to put in their "broth."

The stalks of *Urtica cannabina* were manufactured at one time into hemp, but were not so successful as another species which will be mentioned hereafter.

Urtica tenacissima, called "caloose" in Sumatra, yields an extremely tough cordage. From the *Pooah*, or *Puya*, of Nepaul and Sekkim, which strongly resembles *Boehmeria nivea*, good cordage and strong sail cloth is manufactured in the East Indies. The shoots and tubers of the *Urtica tuberosa* are eaten by the Chinese. This plant is also prescribed by "Celestial" doctors for rheumatism, neuralgia, palsy, and lumbago. But of all the plants of the Urticaceæ family the most highly prized by the Chinese is what they call *Chü-ma*, which is generally known as "China grass" amongst traders, and the *Böhmeria nivea* of botanists, which is the same as the *Kunkhoora* or *Rhea* of India, and said to be similar to the *Caloose* of Sumatra. This *Böhmeria nivea* is most important to Chinese trade, and is extensively cultivated in Che-chang-fu, Kwang-sin-fu, Nam-sing-fu, and Wu-chang-fu. The fibres of the stalks are soaked in native soda, beaten and broken up with a rake-like tool, and heated in a dry boiler. The staple is manufactured into grass cloth and is mixed with silks in making several fabrics. Chinese physicians also hold the plant in esteem for medicinal purposes. The root is said to be cooling, pectoral, diuretic, and resolvent; and the leaves, vulnerary, alternative, and astringent.

But it is as a fibre-producing plant that *Böhmeria nivea* has the most importance. It is a perennial herbaceous plant with broad oval leaves, with white down on the under surface. It is asserted that it is possible to obtain three crops from it per *annum*.

It has lately been the topic of much consideration in the Indian Government, which considers that the manufacture of this *soievégétal* might become of great value in increasing the revenue in India if a practical scheme could be contrived for its accomplishment.

With a view to this end of the Indian Government some time ago offered a reward for an economical method of preparing the fibre of the "China grass." A few months ago Messrs. Fremy and Urbain, of Paris, invented a method for converting the fibres into filasse ready for spinning. Since then a Mons. Favier constructed a machine for gathering the fibres by decorticating the stems by means of steam. Belting for machinery has already been made of this fibre, and I saw a statement the other day to the affect that on this belting being tested it was found that it coud bear a strain of 8,326 lb. to the square inch; whereas leather could only sustain a pressure of 4,239 lb. to the square inch. A piece of water hose made of the same substance was subjected to the high pressure of 600 lb. to the square inch, and it was proved that it only "sweated as much as a good ordinary hose does under a pressure of 100 lb." It remains to be seen whether some enterprising Australian will start the cultivation and manufacture of this valuable plant in the tropical soil of Queensland, where it would probably flourish. So far as is known the Böhmeria is not indigenous to the mainland of Australia; but an allied species, the *Böhmeria calophle*, is endemic to Lord Howe's Island. There seems no reason why Queensland should be behind our Indian colonies in encouraging an Industry which has yet been an exclusive source of wealth to China.

Our friends the nettles may yet be the cause of giving employment to hundreds if not thousands of colonists, and of thus conferring blessings more than sufficient to compensate for the venom and malice of other members of their numerous family.—L. M. Alston.—*Queenslander*.

ROOTS. *

It is a fact which has become more and more evident to the practical cultivator that the results of his efforts manifest themselves on the whole in a sort of compromise between the plant and its environment; I mean that although he sees more or less distinctly what his plant should be—according to a certain standard—it is but rarely, if ever, that the plant cultivated perfectly fulfils in every respect what is demanded of it. Of late years this has of course forced itself more prominently before the observer, because the facts and phenomena constituting what is termed variation have been so much more definitely described, and the questions arising out of them so much more clearly formulated.

Two points can be asserted without fear of contradiction; first, the plant itself is a variable organism; and, secondly, its environment varies. Now within limits which are somewhat wide, when closely examined, the experience of man leads him to neglect the variations occurring around him, and so no one quarrels with the statement that two individual Geraniums belong to the same variety, or two Oak trees to the same species, although an accurate description of each of the two Geraniums or of the two Oaks might require very different wording.

The Water-supply.—It has also become more and more evident that although we cannot ascribe all variations to their causes—very often, indeed, we cannot even suggest causes for them—there are nevertheless numerous deviations from the normal, so to speak, exhibited by plants which can be distinctly referred to certain deviations from the normal on the part of their environment.

To illustrate this we may take the case of two plants of that very common weed, the Shepherd's Purse, growing at different ends of the same small plot of ground: the soil is sandy, and so much alike all over as to be regarded as the same everywhere, nevertheless the plant at one end is large, more than a foot high, and luxuriant, with many leaves and flowers, and eventually produces numerous seeds, whereas that at the other end is small, less than 4 inches high, and bears but a few stunted leaves and three or four poor flowers and fruits. The cause of the difference is found to be the different supply of water in the two cases; and if any one doubts that this may be so, let him try the experiment of growing two or more specimens of this weed in pots: the pots to be new, filled with soil which has been thoroughly mixed, and all the pots exposed to the same conditions—*i.e.*, practically the same—except that those of one series are watered sufficiently often, and those of the other only just sufficient to keep the plant actually living. The experiment is easy and conclusive with such a weed as the above. Now it is just such experiments as that above described—some of them equally simple, others less so—that the physiologist devotes much of his attention to, and

* A lecture by H. Marshall Ward, M.A., F.L.S., Fellow of Christ's College, Cambridge; Professor of Botany in the School of Forestry, Royal Indian College, Cooper's Hill.

in just such a manner has been gathered together a nucleus of information around which more knowledge can be grouped. I may make these points clearer by again quoting an illustration, and, not to confuse or mislead you by going too far afield, I will keep to the same line of investigation, partly because it is quite as simple and conclusive as any other of many that might be selected, and partly because it may be possible to set before you some facts which are interesting or even new to you.

Hairs.—It has been found that in some cases where two plants are growing in the same soil and under the same conditions as above, but where one plant receives less water than the other, that the dwarfed drier plant is more hairy than the larger and luxuriantly growing plant, which has been well watered. On looking more closely into this matter it turns out that the extra hairiness is (in some cases, at any rate) simply due to the fact that the hairs are closer together, because the little cells on the outer parts of the plant which grow out into hairs do not increase so much in length and superficial extent as those on the well-watered plant, and thus the hairs stand thicker together on the same superficial area of the organ—of a leaf, for instance. In other cases, however, the hairs are really increased in numbers and length—the plant is absolutely more hairy. It will be noticed that details concerning growth and turgidity, and of the influence of various minerals, and so on, are not under consideration here. I am not asserting that all cases of hairiness in plants are to be ascribed to this cause; but it does occur, as stated, and the point is a curious one in view of the fact that very many plants which grow in sandy dry soils are conspicuously hairy, whereas allied species growing in or near water, or even only in moister situations, are devoid of conspicuous hairs, or even quite smooth. The above peculiarity is not confined to leaves and stems, moreover, for experiments with roots have shown that the root-hairs, which are so important in collecting moisture, &c., from the soil, can be made to appear in enormous numbers when the root is kept in a soil which is very open and only slightly moist, whereas none or very few are developed on the same roots growing in water: this again is in accordance generally with the fact that the roots of land-plants growing in light soils develop innumerable root-hairs, whereas those of water-plants do not thus increase their surface and points of attachment. I cannot here go into all the interesting facts known about these hairs, but it will be sufficient if you bear in mind the main points just mentioned.

Deficiency of Water.—Let us now vary the experiments a little. It is obvious that we might suppose any number of differences in the amount of water given to the plants used in the experiments described above: but it would be found, as matter of fact, that however little be the quantity of water given to the soil in which the dwarfed plant is, compared with that put into the soil in which the luxuriant plant grows, the actual weight of water will nevertheless have to be considerable, taking the whole life of the plant into consideration—there will be more used than you probably know, moreover, because the soil itself will no doubt condense and absorb some from the atmosphere during the night. There is a minimum of water absolutely necessary, and if the plant does not obtain this it will die. Its death will be ushered in by drooping and withering of the leaves, stem, and roots, and this condition, in which the functions of the plant are interfered with beyond a certain point, passes into a condition of disease.

Excess of Water.—Now take another case. We might so arrange the experiment that we poured and continued to pour too much water into the soil. Here again it would be found that a condition of disease eventually sets in—*i.e.*, a condition in which the functions of the plant are again interfered with beyond a certain point. The symptoms and progress of the disease will be very different in the latter case, however, from those in the former. It may also be mentioned that in neither experiment is death inevitable if the disturbing cause is removed soon enough—*i.e.*, if sufficient water be added in the first case before the cells have ceased to be able to take it up, or if the previous conditions of the soil are restored soon enough in the case of the over-watered plant. Here we come to a matter which is less simple than may appear at first sight. You will note that the problem in the latter case is to restore the previous conditions of the roots and soil soon enough; I put it thus, because the conditions of the roots and soil may soon be very profoundly altered by the over-watering. To understand this, it is necessary to become a little more fully acquainted with the condition of affairs in what may be called the normal case, where the soil is light and open, and plenty of water, but not too much, is at the disposal of the roots. Such a soil will consist of innumerable fine particles, of different shapes, sizes, and composition. No doubt there will be grains of quartz, particles of broken up vegetable matter, and little rugged bits of stones containing various minerals; each of these tiny fragments will be covered with a thin layer of water, and you would probably be greatly surprised if I were to go into the proofs showing how extremely tenacious of its water-blanket each particle is. It may be enough for our present purpose if you accept the fact that it requires enormous force to deprive the particles of the last traces of their water-layers; they will give off some—or in some cases even a good deal—rather easily, and in fact when the layers become of a certain thickness no more water can attach itself to the particles, but it falls away, and the soil remains saturated, as we say.

Air in the Soil.—Now these particles of soil, each enveloped in its water-blanket, are not in close contact; there are spaces between them, and these interspaces influence the quantity of water which can be held back by the soil. Let us suppose such a soil perfectly dry; the particles above referred to being irregular in shape and size, and only roughly in contact at various points, the interspaces will be filled with air. If water be then added in some quantity, each of the particles becomes clothed with a layer of water, and some of the air is driven out, though bubbles of air will still exist in the larger interspaces.—*Gardeners' Chronicle.* (*To be continued.*)

CROPS ON DRY LANDS IN INDIA.

TO THE EDITOR OF THE "MADRAS TIMES."

Sir,—Having received no issue of your journal for the last two months, I happen to be very late, I am sorry, in replying to your remarks, under the head "Dry Lands" in your issue of the 24th ultimo, on a paper on the same subject read by me before the Agricultural Students' Association in March last. With reference to my statement that it will generally be possible to grow on dry land two crops of horsegram for green manure, in addition to the usual crop, you say that the absence or great deficiency of moisture in the subsoil and in the air of the interior of the Presidency is the reason why the ryot cannot adopt the plan proposed. Taking this for granted, the absence or deficiency of moisture in the interior of the country is, of course, no reason at all why the ryots in the more favoured Northern Circars and in the low Carnatic plain should not adopt the plan. Are the dry lands in neighbourhood of the Saidapet Farm, situated under the same or even better circumstances than that estate, cultivated with any more crops during the year than elsewhere? It cannot be denied that there are thousands of acres in the Northern Circars and in the low Carnatic plain, sadly wanting in organic matter, to which, at least, the plan of green manuring is certainly applicable. As regards the interior parts of the Presidency, one might see there, about the month of June, fair crops of gingelly and cumboo, which are, in fact, far less hardy than horsegram, while the adjacent lands, though similarly circumstanced, are quite bare. The reason why gingelly and cumboo are not then extensively grown is, not that the plants refuse to grow at all, but because the ryots are not certain that the supply of moisture will be enough for their *matura-*

tion, and I must admit that the season for cumboo and gingelly is indeed very precarious, though it would not generally be so, if only the production of stem and leaf were cared for. Were the moisture in the air and in the soil of the interior of the country really too little for the growth of horsegram about the month of June, the growth of the far more delicate crops of gingelly and cumboo, even on a single acre, would be absolutely impossible, which, however, is not the case. You have conceded that "it is not much moisture that horsegram requires, but some it must have," and that, even in the driest weather in the interior of the Presidency, hardy plants do endure and survive the drought. It must then be admitted that the fair growth of gingelly and cumboo at the time when I propose the plan of green manuring to be chiefly carried out, is conclusive evidence that horsegram, which is one of the hardiest of the cultivated crops, and which need not mature for purposes of green manuring, would grow far better. You say that in the low Carnatic plain and in the Northern Circars, the supply of moisture is so good that cultivation can be carried on during the greater part of the year, and the soils, though inferior, yield better outturns. Only the former part of this assertion holds good, and that only in comparison with the Ceded Districts, which are indeed exceptionally dry. In Coimbatore and Salem, which are but interior parts of the Presidency, a much larger percentage of the total extent of cultivated dry land bears a second crop, and the yield per acre is not less satisfactory than in Tanjore, South Arcot, Chingleput, Ganjam, Kistna, &c. The meteorological reports show that, from June forward until the outburst of the North-east monsoon, the relative humidity of the atmosphere in these districts is, in fact, more than that of Madras. In these districts, subterranean water is met with, in many places far off from streams and tanks, at no greater depth than on the Saidapet Farm, viz., about 20 feet. It is not unlikely that, even in the Ceded Districts, the character of the prevailing black soils, which will surely retain well the moisture of the few showers which occur from June forward, will make up for the deficiency of the atmospheric moisture. The recent trial borings with the augur at Anantapur prove that subterranean water may be tapped there in many places at even 14 feet below the surface. I beg to add in conclusion that, having seen horsegram cultivated with fair success even under most adverse circumstances on the Saidapet Farm, the plan of green manuring is extensively applicable to this Presidency. I am myself a native of Coimbatore, and my observations and information warrant me in concluding that there will be little difficulty in carrying out the practice of green-manuring there, during the season for gingelly and cumboo at least.

C. K. SUBBA RAO.

GREEN MANURE CROPS ON DRY LANDS.

A letter in our columns on the subject of Dry Lands by Mr. C. K. Subba Rau, Assistant Professor of Agriculture, Madras Agricultural College, ought to be read by those who feel an interest in agricultural matters. It is a rejoinder to an article in which we remarked on Mr. Subba Rau's lecture on the subject. The letter contains information which will be found useful in leading to a right conclusion in respect of crops of gram previous and subsequent to the principal or winter crop on dry lands—which additional crops Mr. Subba Rau proposed to raise for green manure. In relation to this question, dry lands may be classed as those along the coast and those in the interior; and the latter may be divided into lands very dry and under a very dry atmosphere; and lands less dry and under a comparatively humid atmosphere. As to the coast lands, they are very unequal in quality. Some, in the deltaic regions, are rich in the organic matter contained in silt; and they need no manure whatever. But these being wet lands, fall out of the scope of the present discussion. Of the dry coast lands, some we may consider deficient indeed in organic matter but so circumstanced as to grow, with comparative ease, crops that require but air and moisture for their nourishment. On such lands, destitute of, or deficient in organic matter, it would, doubtless, be advantageous to grow horse-gram or green-gram for manure, if the cultivator does not find it can be used to better purpose for fodder, or, if the crop matures, for food for both man and beast. However, for whatever purpose, a second crop of the kind indicated by Mr. Subba Rau would seem possible and advantageous on the poor dry lands of the Eastern Coast. But not all the dry lands in the plains along the coast may be deemed deficient in organic matter and require green manure; and on such as are not defective, or on which the expenditure of organic matter can be made good by cattle manure, it would be a pity to raise crops simply for green manure. If the lands have sufficient moisture to raise a second food-crop, that second food-crop ought to be raised; and if not, horse-gram might be raised for fodder rather than manure. Here at least, but probably in all cases where a green crop and that only can be raised, it will be found advantageous to let it serve as fodder, and to let the cattle convert it into stable manure.

As to the lands in the interior, our correspondent's letter shews that,—what with the natural richness of the soil, and the supply of stable manure at command,—there is no lack whatever of organic matter; the one thing wanted is moisture. Where this exists, the soil is capable of yielding summer crops superior to horse-gram and green-gram; so that these as green manure are quite unnecessary. And the growing of them would probably deprive the land of moisture which might be of use towards preparing it for the principal crop. As to the cotton soil in the Ceded Districts, Mr. Subba Rau himself has said that it is rich in organic matter; what need can there be then to raise a green crop for manure? He says the cotton soil is retentive of moisture. So it is; but there is none to spare, and what there is, is low down; and in years of late and deficient rainfall it requires four or five yoke of oxen to plough the ground with a large plough to break it up for sowing; and that sowing becomes of no avail, if the first rains are very late or scanty, or are not followed up soon by other showers. Even if a green crop could be raised before or after the winter crop, it would be a pity to exhaust the moisture by raising it for manure which is not wanted. Mr. Subba Rau makes use of an admission that in some of the very dry districts, as the Ceded Districts, some hardy plants do live through the hot weather. Yes, they do; but only if they are watered. Does Mr. Subba Rau propose to irrigate a hot weather crop of gram for green fodder in those districts, where, from deficiency of moisture, even the winter crop is on some lands but a poor crop of gram?

The conclusions at which we arrive are, that only on poor soil in the maritime districts would it be both possible and desirable to raise a crop of gram previous or subsequent to the winter crop, to serve as manure; though even here it might with more advantage be given to cattle, and their droppings used as manure. In the interior, in one or two districts, where there is moisture in the soil and air, there is no need of such a crop for manure; though it might be useful for fodder. And in the very dry districts it would not be possible or necessary to raise such a crop for either fodder or manure; and if it were possible, it would be undesirable to exhaust for this purpose the moisture in the ground; when it might be necessary for preparing the ground for the early winter crop. The first great want of the dry lands of the country is water; the second great want of the dry lands is water; and their third great want is water. Indeed, startling as the statement may appear, it is not much, besides what light, air and water can supply, that many plants need for their nourishment; and much of the agriculturist's labour consists in preparing the land, so that it can best absorb and retain water and air and transmit them to the plant. And even some of the manure that is used, helps but to lighten the soil—that is, to fit it for the work of communicating air and water to the rootlets of plants. And such

nourishment as plants require, besides what air and water can furnish, is to be found in a few ingredients, ammonia, lime, phosphorus, potash and the like, in different proportions. This has been shewn by a process of natural analysis; for it has been ascertained by experiment what ingredients plants take out of prepared soils, of which the constitution and composition were noted beforehand, and compared with the same after the growth of the plant.—*Madras Times.*

THE FRAGRANT PRODUCTS OF THE WEST INDIES.

The West Indies, like all warm countries, abound in fragrant products. Most flowers possess there a potency of aroma unknown in colder climes, and many fruits, plants, barks, leaves, gums, seeds and grasses exhale scents of their own, which combine into an harmonious whole. Those natural treasures, however, have, as yet, been but little utilized for commercial purposes, and this Exhibition affords an excellent opportunity for studying them, and seeking the way of turning them to account. This is the object of this brief sketch.

We shall confine our observations to Jamaica and the Bahamas; the former as being the largest and best cultivated British island, the latter as offering some difference with the Southern group.

The most fragrant flowers in Jamaica are the Rose, the Jasmine, the Orange (sweet and bitter), the Tuberose (*Polianthes Tuberosa*), the *Cassie* (*Acacia farnesiana*), the Frangipane (*Plumeria rubra*), the *Unona odoratissima* (called by the Tagals, in Manilla, *Ihlang-Ihlang*), the Mignonette tree, or Henna (*Lawsonia inermis*), the *Olea fragrans* (called by the Arabs *Zensfur*, and by the Chinese *Kwei-hwa*) the Volcameria, and the *Rondeletia odorata*. A strong but less delicate scent may be obtained from the leaves of the following trees:—The bitter Orange, Lemon, Cigar-Bush (*Critonia Dalea*), Mountain Cigar-Bush (*Hedyosmum mutans*), Wild Cherry, Bay, Pimento and Allspice.

Among other indigenous fragrant products may also be mentioned:—The beans of the Vanilla (*Vanilla planifolia*), Vanilloes (*Vanilla pompona*), and of the Tonquin (*Dipterix odorata*); Lemon Grass (*Andropogon citratus*), Kus-Kus Grass *Andropogon muricatus*), Cloves, Nutmegs, Cassia, Cinnamon and Musk-seed (*Hibiscus, abelmoschus*) some aromatic plants of the labiate order, such as Thyme and Rosemary, and various woods, the most remarkable amongst which is a species of rosewood, called *licoria odorata*, which yields an essential oil strongly resembling Bergamot in flavour.

The mode of extracting the fragrance from those various products so as to render it of commercial value differs according to its nature. Distillation is the most frequently adopted, but is only available for hardy substances such as leaves, barks, plants, &c. There are but few flowers that can be treated thus, and the usual processes employed to obtain, their aroma are either maceration or absorption, called by the French *enfleurage*. The former consists in infusing the flowers in hot grease or oil, which is strained off after repeating the operation daily for two or three weeks. This process, however, can only be applied to flowers like the rose, orange and cassie. More delicate flowers, such as Jasmine and Tuberose, are treated by the *enfleurage* system, which may be thus described:—A mixture of lard and beef suet, properly washed and clarified, is laid on a square glass tray and fresh flowers are scattered on it and renewed every morning until the grease has absorbed the perfume of the flowers. Those trays are piled up on each other to prevent evaporation. The same result may be obtained with oil, and in that case a thick cotton cloth, soaked in oil, is laid on a frame with a wire bottom and the flowers strewn on it. The best handkerchief perfumes are made by infusing this grease (called *pommade*), or the oil in rectified spirits.

Among the exhibits in the Jamaica Court is a most interesting one by Col. Talbot, who has the merit of having been the first to establish a flower farm on his estate, Worthy Park, St. Catherine. The products shown, prepared by Mr. John Gray, include Essential Oils of Bitter and Sweet Orange leaves, Lemon, Limes, Lemon-grass and Pimento and some Tuberose Pommade made by the *enfleurage* system above described. To the list of those exhibits is appended a note stating that many of the plants are very abundant and obtainable in large quantities, whilst others, like Jasmine and Tuberose have to be cultivated. The same is the case in the south of France, where there are large plantations of roses, jasmines, tuberoses, and other flowers; but aromatic plants, such as lavender, rosemary, and thyme grow wild in the neighbouring mountains.

The question of flower-farming is evidently exciting some attention in Jamaica, for the Director of the Botanical Department, also exhibits some Jasmine Pommade, made from the flowers of the *Jasminum grandiflorum*, besides Essential Oils of Pimento and Cigar-Bush leaves, Lemon-grass, Mountain Thyme (*Micromeria obovata*), and Juniper Cedar.

Mr. B. T. Scharschmidt (C. E. Mandeville) shows some essential oils drawn from the rind of the orange (*Citrus aurantium*), the lemon (*Citrus Medica*), and the Bigarade (*Citrus Bigaradia*), but they appear to be *distilled* and consequently inferior to those obtained in Calabria and Sicily by *expression*. The letter mode consists in placing the fruits between two cylinders armed with spikes and revolving in a different direction; the minute vesicles on the surface of the rind containing the essential oil thus become pierced, and the latter runs down a funnel at the bottom of the apparatus. The essence thus procured is quite pure, whilst that obtained by distillation carries with it the coarse flavor of the rind. The same exhibitor has some interesting specimens of Oil of Pimento leaves and berries, *Eupatorium Dalea*, Lemon-grass, and Kus-Kus (*or Vétivert*), some Jasmine and Tuberose Pommades, some Extracts of Jasmine, Muskwood, and Rose-wood, some orange-flower water and some rose apple water, distilled from the *Jambosa vulgaris*—a decided novelty.

The Honorable H. J. Kemble, of Kingston, shows some very fine *Oil of Ben* drawn from the seeds of the Horse-radish tree (*Moringa pterygosperma*). This oil was largely used by our ancestors in their perfumery compounds; it is mentioned in almost every page of the recipe-books of the sixteenth and seventeenth century. It has the valuable property of not turning rancid, and it is to be regretted that it is not more frequently employed. It would, no doubt, be found superior to grease in practising in Jamaica the *enfleurage* process—as above described, for it is difficult to keep grease fresh in a warm climate. As the seeds yield 30 per cent of that oil, it might, perhaps, be offered also to European perfumers at a sufficiently low price to induce them to return to its use.

In the Bahamas is to be found nearly the same flora as in Jamaica, and to judge of its richness and variety, one needs but to cast a look on that most interesting collection beautifully painted by Mrs. Blake.

In addition to the flowers already named may be mentioned the following, included in the above collection and possessing all an agreeable odour.—The *Dalbergia amerimnum*, the *Cassia Fistula*, the *Ipomœa Tuberosa* and *Quamoclit*, the *Bletia hyacinthina*, the *Glorisa superba* and the *Nerium oleander*.

The *Eucalyptus* has been lately introduced from Australia into the West Indies, and with its usual rapidity of growth it will no doubt soon spread and render important services to public health. The wonderful properties of the Oil of Eucalyptus, so strongly exhaled by its leaves, in checking fever and curing bronchial affections, are now universally recognized, and wherever that tree has been planted it has purified the air in a remarkable manner. Its latest achievement has been to drive *malaria* completely out of the Campagna of Rome, where it had been prevailing for centuries.*

*An oft-reapeated mistake.—Ed.

Mr. Wentworth Scott, an eminent analytical chemist, thus explains the atction of the Eucalyptus:—

"*Eucalyptoles*, a hydrocarbon of the *Thymole* type, appears to be what might be termed the 'active principle' of the Eucalyptus oil from a hygienic point of view. The oil of *E. globulus* seems to be the richest in this hydrocarbon, upon which its 'ozonizing' property depends; but the same body with numerous homologues in varying proportion is present in the oils secreted by all the plants of this genus, hence the remarkable 'healthful character' of the atmosphere in Australian forests.*

The antiseptic powers of *Eucalyptole* are, I find from crucial experiments, fully 3½ times greater than those of carbolic acid, while its use is certainly free from the danger that not unfrequently attends the latter."

The Eucalyptus leaves contain as much as six per cent of essential oil, which can be easily extracted by distillation, and which will always find a market in Europe, where the consumption is great. Not only is it largely used in medicine, but it makes a capital scent for ordinary toilet soap, and is still more valuable as a deodorizer. It forms the chief ingredient in Rimmel's Aromatic Ozonizer, a pine saw-dust impregnated with that oil, which, by simple evaporation, evolves the refreshing breezes of the forest, and acts as an agreeable disinfectant in dwelling houses or in places of public resort.

Being an orchid, the flowers of the Vanilla require the presence of an insect to fertilize them. This insect exists evidently in Honduras, as numbers of bunches of beans are found on the wild plants, but where it does not, its action may be replaced artificially by taking a little of the pollen which is deposited on the anther with a sharpened pencil or knife blade and letting it touch the viscous disk situated on the front of the white column which rises in the centre of the flower. This forms part of the instructions issued by the Botanical Department in Jamaica for the cultivation of Vanilla, and it would no doubt prove a remunerative one if carried out with proper care and attention, for it sells at a good price—being used both by confectioners and perfumers. The most esteemed sort in the market comes from Mexico and there is no reason why the West Indies—possessing a similar climate—should not produce an equal quality. That grown in Mauritius and Reunion is deemed inferior. There is also a good demand in Europe for bastard Vanilla, or Vanilloes (*Vanilla pompona*) and for Tonquin Beans (*Dipterix odorata*) already mentioned.

The only species of Orange Tree worth cultivating for its fragrant products is the Bitter Orange (*Citrus Bigaradia*), which is easily distinguished from the others by the peculiar form of its leaf, the petiole being heart-shaped. A very fine essential oil, called in Provence *Néroly*, is distilled from its flowers; another one, called *Petit-Grain*, from its leaves, and a third can be obtained from its rind by *expression*, as already explained. The edible Orange Tree (*Citrus Aurantium*), yields very inferior essences, and the Lemon (*Citrus Medica*), gives but one from its rind, which is not worth collecting when the fruit can be sold whole, as it could scarcely compete with that produced in Calabria and Sicily. If West India colonists will attend to this warning they will save themselves the disappointment experienced by the Florida orange planters, who have been of late years attempting to distil their orange leaves, and who, by employing indiscriminately those of all species and chiefly of the edible orange, have produced a very coarse essence of *Petit-Grain*, which has been offered all over Europe, but will only sell at a very low price.

In conclusion, the manufacture of fragrant products in the West Indies will, no doubt, prove ultimately a safe and lucrative speculation, but it requires a deal of study and attention. The first conditions of success are to create plantations of sufficient extent to obtain the necessary quantity of flowers, and the training of a skilled staff of operatives to work them. Distillation, when practicable, is the simplest process; maceration and *enfleurage* are open to the danger of the fatty basis turning rancid during the hot season of the tropics. Another method might be tried, and this is *percolation*, a system which Mr. Rimmel has brought to some perfection by means of an apparatus of his invention, which he calls *Myrogene*. Freshly-gathered flowers are placed in a sort of sieve, and some prepared alcohol drops through them from a great height and carries with it the most subtle part of their aroma. This alcoholic shower, after passing two or three times over fresh layers of flowers, becomes strongly impregnated with their perfume. Mr. Rimmel has been using this apparatus on a large scale for some time at his Nice manufactory for drawing the scent from flowers which can neither be distilled nor treated by the macerating process, and a specimen in operation was shown last year at the Inventions Exhibition.—*West Indian Court Guide Col.-Ind. Exhibition*, 1886.

* Dry atmosphere—leaves do not decay but are dessicated.—Ed.

NOTES ON GRASSE AND ITS CHIEF INDUSTRY: PERFUMES FROM FLOWERS.*

BY WM. SAUNDERS, F.L.S.

A few notes from this interesting old town, with some references to its chief industry, may possibly prove of interest to some of your readers. It is a land of flowers, where a large proportion of the perfumes of the world is made, and such an odd, out of the way corner of the country that but few visit it. Here odorous flowers are grown in immense quantities for the purpose of preparing the sweet scents in which civilized mankind and womankind delight, and it is from this district that perfumers everywhere obtain the chief ingredients from which by skilful combinations their celebrated perfumes are manufactured. On the main line from Paris to Rome, *via* Marseilles, about six hundred and sixty miles from Paris, lies the town of Cannes, on the Mediterranean shore, a noted health resort for invalids from Great Britain and other countries, the winter climate being remarkably mild and agreeable. Here a branch line of railway about twenty miles in length brings the traveller to Grasse. At Cannes the chain of mountains which for many miles on either sides runs along the seashore retreats to some distance inland, and the route to Grasse lies up through narrow valleys and broader slopes of hill and dale. For the first few miles the general aspect of the country is rather desolate; vegetation seems parched and stunted; even the pine trees are dwarfed, and the wayside weeds lack vigour. But soon vegetable growth becomes more luxuriant, fertile belts are reached, and fields of roses, jasmine, mignonette, violets and other flowers are seen on every hand, while groves of olive trees clothe the hillsides, along with plantations of the vine and of the fig tree. As Grasse is approached the valley widens to about four or five miles, the mountain slopes are grey with olive trees, and nearly the whole valley is utilized for flower-growing.

The town, with a population of about 12,000, lies high up the mountain at the end of the valley, where the roads and narrow streets are so steep that the occupant of the ground floor of the back part of a house may often look out of the third story at the front of it, and where the quaint old houses tower up to six, seven, and even eight stories high at the front. The route leads through fields and gardens of roses, jasmine, jonquils, tuberoses, etc., up steep winding streets and alleys, where long flights of steps afford short cuts from one point to another in the town, and where buildings hoary with age greet the eye of the visitor at every turn. Mountain torrents steam down the hillsides here and there, affording water power for the ancient looking olive mills and means of irrigation during the hot weather for the flower growers. These streams also fill the public troughs with pellucid water, where crowds of women may be seeing washing clothes from early morning until dark. It is said that this town was founded three hundred years before the Christian era; it is known to have been an important Roman station, and its excellent water privileges must have been a strong incentive to its early settlement. Nearly all the population excepting those engaged in mercantile busi-

* From the *Pharmaceutical Record*,

ness, and a few hundreds who are employed in the manufacture of olive oil are engaged either directly or indirectly in the flower industry. The shop-keepers display their wares in the tiniest little shops, in which they have scarcely room to turn about; the hotels are antique country inns; but the air at this season is balmy and delightful, and the views from the upper part of the town charming.

There are about sixty firms or individuals in Grasse engaged in manufacture of perfumes from flowers. Three or four of these are very large establishments, the others smaller. The harvest period here is a long one. It begins in February with the violet and the jonquil, which keep the perfume-makers busy until the end of March, when the mignonette comes in, which is followed in May and June by the orange flowers and roses, and in July by the jasmine, then with the rosemary and lavender, which are succeeded by the tuberose and cassia, which keep the trade busy until quite late in the autumn.

The rose bushes are grown in rows about three feet apart, with about eighteen inches of space between the plants. They are closely pruned in the spring, which induces a strong growth of young wood and an abundance of flowers. The jasmine and other flowers, where the individual plants occupy less space, are grown more closely together, the aim in each case being to have the ground as closely covered as is consistent with convenience of picking. The orange trees are about fifteen feet apart. It is the bitter orange which yields the most fragrant flowers; but the fruit of this variety is not eatable, so the trees are grown solely for the flowers they produce and for the oil obtained from the rind of the fruit.

In company with my genial travelling companion, Prof. J. P. Remington, I visited some of the principal establishments, where we were received with much kindness and courtesy; but to Mr. Warwick, of Warwick Fréres, we were indebted for special attention. We found that while most of the larger manufacturers have flower plantations of their own, the bulk of the crop is grown by the peasants and small landholders, who during the season bring them daily to the factories. We rose early in the morning and drove into the country, hoping to see some of the flowers gathered, but the flower-growers were up before us, and had their fragrant crops collected and packed in sacks ready to take to the manufacturer before we reached the ground. Nothing is known here of the movement in favour of short hours for the working man.

It has long been known that fatty substances absorb odours very readily and retain them with much persistence. The perfumers of ancient Greece and Rome understood this well, and made use of such substances to steep flowers in for the purpose of extracting their odours. At Grasse fatty substances are largely used for the same object, and the pomades made there consist of fats strongly impregnated with the odours of flowers, which odours may be extracted from the pomades by exhaustion with alcohol and used as spirituous perfumes.

Pomades are made by two very different methods, the one by maceration, the other by what it is known as the process of *enfleurage*. Pomades of rose, violet, mignonette, cassia and orange flower are all made by macerating the flowers in fat warmed to 6° C. The fat is allowed to remain in contact with the flowers for several hours and occasionally stirred, after which it is put under a powerful hydraulic press, by which means the fat is expressed with but a trifling amount of waste. The same fat is thus treated daily with fresh flowers for from twenty to thirty days, during which time it becomes strongly charged with the odour of the flower.

The jasmine and tuberose pomades are always made by the other process. A large number of frames or "chassis are prepared, each of which is fitted with one pane of glass about 18 × 24, set in a wooden frame, so that the wood may project on either side of the glass about $\frac{3}{4}$ inch and each side of the glass is coated with a layer of fat about $\frac{1}{4}$ inch thick. The woodwork of these frames is so constructed that when laid the one on the other they fit very closely, so as to avoid any waste of odour. The freshly gathered flowers are strewed over the fat in each frame in a thin layer and the frames then piled one on the other to a convenient height, the upper and lower frames in each pile being coated with fat only on that side next the flowers. The odour emitted by the flowers is rapidly absorbed by the layers of fat above and below them, and after twenty-four hours of exposure they are practically exhausted. Every morning the trays are examined, the old flowers thrown away and fresh ones put in their place, the surface of the fat both above and below being broken every few days by a toothed spatula, and mixed so as to present a fresh surface. This process is continued for about thirty days, by which time the fat has become saturated with the odour, when it is scraped off the surface of the glass packed in tin cans, the process being continued with fresh fat as long as the flower harvest lasts. Some of the larger factories have many thousands of these frames.

The buildings in which this work is carried on are built either of stone or brick, where the temperature is maintained as low as possible, so as to prevent the fat from becoming rancid. The fat is composed of a mixture of lard and mutton suet, melted together and carefully washed and treated until it is free from all trace of fatty odour. It is then slightly perfumed with orange flower, which is said to aid in preserving it from change. The fat is usually prepared during the winter months and stored in cool cellers until wanted for use.

Roses are picked in the bud every morning just as the buds are about to open. They are picked with the green calyx attached, and this appendage is removed in the factories by the women employed there before the roses are treated.

Mignonette is picked before the seed pods are formed. The flowers of the violet, jonquil and tuberose are picked with the calyx attached, but the jasmine flowers are pulled free from their calyx in picking.

The following are about the average prices paid for the flowers as they are received at the factories: –

Roses, 8 to 10 cents per kilogram; orange flowers, 17 cents per kilogram; violets, 70 to 80 cents per kilogram; jonquil, 60 cents per kilogram; mignonette, 40 cents per kilogram; jasmine, 50 cents per kilogram; tuberose, 50 cents per kilogram; cassia, 1 dollar per kilogram.

At these figures it is said the growers can make far more off their land by devoting it to flowers then they can from any other crop.

A large quantity of orange flowers are used for the preparation of oil of neroli and orange-flower water. To obtain these products the flowers are placed in large copper stills of water; steam is introduced and the water made to boil, when vapour arising is passed through coolers into suitable receivers. A small quantity of oil gradually accumulates on the surface of the water, which is removed from time to time. The water which collects in the receiver is the orange-flower. water of commerce. The largest part of the rose crop is similarly treated, and rose water with a small proportion of otto of rose the result.

Distilled perfumed waters when first made have a rank and rather unpleasant odour, which is softened and becomes quite fragrant after they have been kept a few months. While undergoing this mellowing process it is necessary that the jars in which these waters are contained should be uncorked. They are left either open or tied over with a piece of brown paper to exclude dust.

It is difficult to obtain reliable statistics of the quantities of flowers grown in this district, but the following may be taken as approximately correct. It is estimated that the sixty firms or individuals engaged in the manufacture of perfumes in Grasse consume annually about 3,000,000 pounds of roses, 4,000,000 pounds of orange flowers, 160,000 pounds of jasmine, 40,000 pounds of mignonette, 40,000 pounds of tuberose, 200,000 pounds of violet, and smaller quantities of jonquil and cassia. They also use large quantities of orange leaves for the preparation of oil of petit grain, and immense quantities of lavender, rosemary and thyme, from which the oils of these plants are distilled.

The aggregate value of the perfumes exported from Grasse is said to be about 3,000,000 dollars annually.—*Pharmaceutical Journal.*

ELECTRIC MOTORS FOR DRIVING TEA MACHINERY, AND THE ELECTRIC LIGHT.

It is necessary to correct the over-sanguine ideas of planting correspondents who, because the subject of Electric Motors has been ventilated in our columns, have begun to rush to the conclusion that the same can speedily be made available to them in supersession of steam engines or water-wheels. No such revolution can be anticipated for the present. We are merely in the early days of invention tending to the perfection of Electric Motors. Besides, where a given head of water is immediately obtainable for driving a wheel or turbine, so placed as to be convenient for the erection of a Tea Factory, no improvement can be made upon the practice in force, inasmuch as there is simplicity of detail and direct power available.

But, there are no doubt, many places in the island where such facilities do not exist and where water power is running to waste from its inaccessible position in reference to the erection of tea factories. By way of example, we may point to the Devon falls. A factory placed at the foot of the falls would be most inconvenient. Here we may well look by-and-bye, for the electrical transmission of energy stored by the aid of a turbine at the foot of the falls working a dynamo. Such power could be transmitted by cable to a second dynamo working the motor at any convenient part of the high land in the vicinity, and the former ought to be, we suppose, sufficient for tea machinery on a large scale. This case may illustrate the direct gain to be had by electrical transmission of energy which enables the turbine to be placed in the most favourable position as regards head and supply of water, and to erect distant factories on the most able favoursites.

As regards economy, the question of first cost and maintenance of working would probably be in favour of electricity against the steam engine with its outlay in fuel and complicated machinery; but here again, we have to wait for that practical experience in Ceylon which is being rapidly matured in the mother country, but which has not yet reached the Far East.

In reference to the cognate subject of Electric Lighting we have been favoured with the following remarks from a Ceylon resident now at home who has given special attention to the subject and who is deeply interested in the various practical applications of Electricity which the present day is witnessing. We quote as follows :—

"You asked me to let you know something regarding the progress of Electric Lighting in England and I therefore jot down a few particulars which may be interesting to you.

"In some respects Electric lighting has advanced during the last three years very materially, but in a pecuniary sense, the position of affairs is not satisfactory. Many of the Companies have been wound up and it is quite sufficient to mention the words electric light to cause the capitalist to close his purse. There are still advertisements in the papers of batteries of high electro-motive force and low resistance capable of doing wonders in the way of electric lighting, and there is now before the public a Library lamp, "the Regent" which is said to be a wonder. If so, the sooner the money is found to start it the better. No one will be better pleased than I shall be to hear of the success of any invention which will provide a good portable electric light suitable for reading purposes, but so far as I can ascertain, we are just as far off as ever we were from obtaining this desirable article and though such a thing is not altogether an impossibility, there is no lamp in the market which I would recommend any one to purchase for use in Ceylon.

"The incandescent light is only suited for enclosed areas, so much so that I am assured by the engineers in charge of the installation at the British Museum, that no number of incandescent lights would satisfactorily light up their vast Reading-Room which is now so admirably illuminated by five arch-lights. Judging from the flicker which is observed in most of the arch-lights which are seen in different places in London, it would appear very difficult to avoid this unpleasant movement, and I am informed that however much this quivering in the light may be controlled it will never be suppressed altogether. The Reading-Room of the British Museum, where the arc-lighting is almost perfect, is the best exhibition I know, of arc-lighting on a large scale, for not only is this quiver hardly perceptible, but the light undoubtedly consumes carbonic acid gas and in this and other ways has a decidedly advantageous effect in purifying the atmosphere.

"Given sufficient horse-power—the most important consideration—and if due regard be paid to cleanliness, Electric lighting may be worked with very little trouble. It is so vastly superior in many respects to gas and oils that it must in time supersede them. Mr. Preece, F.R.S., the other day, remarked at a meeting of the Telegraph Engineers, that no one who has experienced the advantage of having his house lighted by Electricity knows what it is to live until he exists under the influence of the Electric light; the introduction of which will, he says, do more good for society than all the sanitary institutions of the world. This is going a little far, but there is a great deal more truth in Mr. Preece's remarks than most people will be prepared to admit.

"In Ceylon and India we want a light which is not accompanied by heat. For small installations the engine and its management is the chief difficulty, and I am in hopes that something may be done to take advantage of the wind which blows so steadily at Colombo for the greater portion of the year. I am now endeavouring with the aid of Messrs. Siemens Brothers to put together a plant consisting of a windmill, a storage-battery and a dynamo. The windmill can be worked day or night in turning the dynamo which will charge the battery. There are difficulties in the way; but, if an effective and, at the same time, not too expensive storage-battery can be used, there is no reason why the scheme should not answer. As soon as we have given the arrangement a fair trial, I will communicate the results to you.

"In the meantime, I intend to see a great deal more of what is being done in the way of Electric lighting, in the hope that I may come across something which may be useful to us in Ceylon. Quite as serviceable as the Electric light will be a good Electro-motor when such a thing is invented, but I cannot go into this subject today."

"Rushing into Tea," we are told may be one bad result of the perusal of our yesterday" article. But where is land available we may ask ? No one surely would prevent planters who have estates capable of transformation from going ahead ; but apart from this, the Crown blocks the way effectively, by only offering some 5,000 acres per annum of new land for tea cultivation. How long planters may have to wait for the Adam's Peak or other reserve lands suited to the culture, no one knows.

OUR TEA INDUSTRY:

PROPOSED CEYLON-AUSTRALIAN TEA AND TROPICAL PRODUCE COMPANY.

Our shrewd and esteemed friend "Old Colonist" has not been idle during his present visit to the Colony in which the best part of his life was spent and in which he, in over a score of years' residence and hard work, gathered up an experience of the practice and conditions of tropical planting which has since placed him in the forefront of our planting critics and authorities.

Mr. Arthur Sinclair,—to whom we refer and who sails this evening (Nov. 4th) for Australia—is we understand, hopeful of forming still another Ceylon Tea and Tropical Produce Company, more directly linking us with the Australian Colonies. Our Australian cousins are the greatest tea drinkers in the world and though hitherto they have been content to use almost exclusively the China leaf there, as elsewhere, it is already apparent that Ceylon teas only require a fair trial and that few who give it, care afterwards to revert again to Chinese Congous. The object will be to get as many as possible of those directly interested in the wholesale tea markets to take shares in the purchase of suitable land for tea cultivation, and few amongst all our planters, old and young had better opportunities, in olden times, of knowing where to select such and, than fell to the lot of "Old Colonist." The only fault we ever heard attributed to him (Mr. Sinclair) as a planter and capitalist was that he was "too cautious." This ought to be a recommendation certainly to his supporters in the present case, but with caution, we have no ordinary shrewdness and experience of Ceylon combined—so that success ought to be assured.

After a careful inspection of the up-country tea districts, Mr. Sinclair we are glad to hear, is perfectly satisfied with the thorough soundness of the rising enterprise and we can only wish him every success in his efforts, to add another to the thriving Ceylon Tea and Produce Companies already in existence.

NUWARA ELIYA VEGETABLES.

Our chief towns are now likely to be well supplied with English vegetables, first Mr. Young advertised his good supply ready for the market and now Mr. A. Whyte comes before us, with a fuller list of what he can offer. The one difficulty with growers is to find ready *sale* when the vegetables are ready; and a number of standing weekly orders are what are needed to make this a paying experiment. The railway charges for packages of vegetables are now much lower than formerly; they run as follows:—

Cost of parcels of vegetables from Nanuoyato Colombo by passenger train:—From 1 to 5 lb., 50c.; 5 to 10 lb., 63c.; 10 to 20 lb., 93c.; 20 to 40 lb., R1·15; 1 cwt. vegetable R2·60.

The vegetables just sent to us by Mr. Whyte are certainly all that could be wished—fresh and crisp, succulent and tender and fully, but not over grown. We could not wish for finer specimens of English vegetables. In sending them Mr. Whyte writes:—"I send you a box of vegetables which you may look on as a sample lot of what we can do. The collection consists of 33 varieties—not such a poor list, considering I have not yet been a year at the work up here and have had to break up and clean rough grass land to operate on. The list includes:—1, sweet little E. York cabbage; 2, red pickling cabbage; 3, carrots; 4, turnips; 5, lettuces (cos and cabbage); 6, cauliflowers; 6½, spring onions; 7, Scotch kale; 8, beetroot; 9. salsafy or vegetable oyster; 10, artichoke; 11, vegetable marrow; 12, celery; 13, green peas; 14, long runner beans; 15, knol-khol; 16, endive; 17, leeks; 18, parsnip; 19, radish; 20, rhubarb; 21, brussel sprouts; 22, chou-chow; 23, tree tomato; 24, horse radish; 25, parsley; 26 to 33, thyme, sage, marjorum, sorrel and other herbs.—No. 9. salsafy, you may not be acquainted with. It is a regular 'bon-bouche,' is cooked first plain boiled, then pounded up and fried as oyster patties or spread on toast. No. 22, is the new perennial vegetable marrow and is cooked and served with white sauce just as vegetable marrow is. No. 23, the tree tomato, makes a delicious tart or jam. I was to send a dish of mushrooms and one of strawberries, but our beds of the former have been too closely picked and some of my friends, the insectivorous kinds are unfortunately also frugivorous and have pretty well picked the strawberries for me. However, you shall have them another time. When all our new things come into season, I shall have no less than 40 varieties of vegetables available and ought to be able to suit the most fastidious tastes. As these vegetable gardens (over three acres now in vegetables) are the first that have been opened and worked systematically to test the question of 'will it pay?' I think, we deserve encouragement and support, and rail-fare is now cheap for vegetables. By the way while on the subject of gardening, I may mention I have of late been very pleased to learn from several quarters that the cultivation of the splendid yams of the West Indies, which I introduced years ago, has at last been taken up by many of the intelligent Sinhalese of the low-country and others. The delightful little purple '*cush-cush*' yam is evidently the favorite, and is being planted up by some in quantity, so that, I suppose, ere long these really delicious and delicate roots, will soon be offered for sale in our Kandy and Colombo markets and form a most agreeable change, from the everlasting and in too many cases inferior bazaar potatoes.

A WARNING TO TEA PLANTERS.

(From *I. A. Rucker & Bencraft's Weekly Tea Circular*, Oct. 14th.)

Ceylon Teas.—"Bulked Unassorted."—We are glad to see how those who have followed our persistent recommendations to adopt this plan have profited by the same. A very striking instance of the advantage to the planter occurs in this week's sale. The produce of an estate has been apparently dealt with experimentally with a view to testing the correctness of our information. A portion of it has been subdivided in the usual manner into Broken Pekoe, 2 Pekoes, Pekoe fannings, Dust, and Pekoe Souchong, giving the already over-worked dealer six more samples to value than was necessary. A very high price was obtained for the few packages of Broken Pekoe, the remainder of the laboriously assorted parcel pulling down the average to *one shilling and one penny farthing per lb.*

The "Unassorted" portion, one sample only representing the bulk, fetched without trouble *one shilling and five pence farthing.* Loss by dividing into six breaks the remainder of the packet, 4d per lb., in this case nearly £300 sterling say Rupees 4235.

A reference to our Circulars of November 5th and November 26th, 1885 January 14th, March 4th, June 17th and 24th of this year, might have saved much money. [Whose tea was this?—Ed.]

DEATH OF MR. MOENS, THE DUTCH QUINOLOGIST.

Many in Ceylon as well as in Java—and indeed wherever an intelligent interest is taken in the scientific culture of cinchonas,—will hear with much regret of the death of Mr. Moens. We can well add our own testimony to that which follows as to the special attainments, ready courtesy and genial hospitable disposition of the deceased gentleman. We are glad to put on record, so full a notice of our friend as is given in the journals from which the following is taken :—

[*Translated for the "Ceylon Observer" from the Indische Mercuur of 9th October 1886.*]

Johan Card Bernelot Moens, our friend and fellow-laborer, unexpectedly succumbed to a short illness on the 2nd October. In him Netherland loses one of her most meritorious sons in scientific and colonial interests. And not only Netherland, but many friends and kindred spirits through the civilized world will lament his death as an irreparable loss. Since Netherland was restored from her deep humiliation to her position as an independent state, she has had but small weight in the scale of nations. Instead of being, as in olden times, the leader in Europe, she has generally occupied the back ground, and she would in effect have shrunk up into an insignificant and forgotten little land, had she possessed no colonies, and no men to strive in those Colonies with giant might. In the introduction of the cinchona tree into Asia from America, Netherland really set the example, and maintained her ancient renown. And this cultivation, of such vast benefit to all humanity, and which commence under the skilful guidance of the veteran leaders Korthals, Hasskarl and de Vrij who survive—has in a great measure to thank Moens for its success and development.

Born at Kratingen in 1837, he devoted himself from his sixteenth year to the study of Pharmacy and the teaching of the late Professor G. J. Mulder who trained so many learned chemists, directed the course of his life's labor. He went to Netherland's India in 1858 as Military Apothecary of the 3rd class, and in 1866 he had already attained the 1st class.

Heer K. W. van Gorkom who at the time directed the Government cinchona cultivation at Bandong did not long remain unacquainted with the extraordinary zeal and ability displayed by Moens in chemistry—and as early as 1866 Moens stood by him as a trusted friend with counsel and co-operation.

It was just then that the discovery of cinchona Ledgeriana had tended greatly to develop cinchona cultivation. Consequent on the large yields of alkaloids obtained from this sort it assumed the first place in general estimation, and of the earlier known sorts, only officinalis and succirubra were retained. Chemistry had now to come forward to shew how by cultivation the greatest development of alkaloids could be brought about.

And when in 1872 the Government appointed Moens to be Chemist to the National Cinchona Cultivation, the way was prepared for important improvements and for adding to the national name. "A new era," said van Gorkom, "was then opened that constantly brought striking facts to light, and gave more positive form and greater strength to the development of the cultivation." Three important processes were about this time brought into practice by the zeal and perseverance of Moens: the partial stripping of the bark and protecting with moss and other covering (first employed by McIvor at Madras), the collection of bark by scraping, and the propagation of cinchona trees by cuttings. Let a word of homage here be paid to the late Director of the National Botanical Garden, Scheffer, who co-operated with Moens and to Messieurs van Romunde (the present Director) and Venlemans, who have latterly continued his work. The destructive disease of the cinchona trees was discovered by the researches of Moens to be caused by an insect and thus the way was shewn for counteracting the evil as much as possible.

On the nomination of van Gorkom as chief inspector of cultivation in 1875. Moens was appointed to succeed him at the head of the cinchona cultivation—of which he was in sole charge for four years, till in 1879 Heer van Romunde was sent to his aid. In 1880 Moens was commissioned by the Government to undertake a voyage to Ceylon, Madras and Bengal for the purpose of examining the cinchona cultivation in those countries. This voyage, of which he published an account in December 1880, contributed not a little to establish the value of the new processes. In 1883 after a residence of 25 years in India he obtained two years' leave for the restoration of his health, and in 1885, at his own request he was honorably relieved from his office of Director of the cinchona cultivation. Soon after his return home he was charged by the Government with the analytical examination of the cinchona bark imported from Netherlands India. With great zeal and scientific conciencetiousness he acquited himself of this task up to the time of his death. His labors survive in the great work he wrote, entitled "Cinchona Cultivation in Asia," containing a full review of the cultivation from its introduction in 1851 up to 1882, illustrated by five photographic plates by Carl Lang. This work written in Dutch has obtained an international celebrity as well as his minor writings and numerous contributions to the *Indische Mercuur*, which were always republished in the English and German scientific and commercial periodicals. Notwithstanding that he was highly appreciated abroad, Moens remained always a warm patriot—he shewed this especially by the intense perseverance he displayed in protecting the Netherlands cinchona market from the overwhelming influence of London. By constant struggling for the Netherlands quinine manufacture and by conscientious valuation of the imported bark, he succeeded in preserving that market for Netherlands until now. During the most unfavourable crisis of the cinchona prices he frequently exclaimed "We can hold it no longer"—and only an expert can judge how painful such a regret must have been.

Moens was an honorary member of the Society for the Advancement of Medical Science in Netherlands India, and of the Netherlands Association of Industry ; corresponding member of the Royal Academy of Science, and member of many other learned Societies at home and abroad. He was made a Knight of the Netherlands Lion 1871. Married in India to Augusta Schenck. He leaves 5 children of whom the oldest is 19 years old, and the youngest barely one year of age. Moens was a quiet and retiring man, never coming uninvited to the front. He always sacrificed his personality to the great work for which he lived. But those who knew him intimately soon learned to appreciate his clear understanding and rich experience. There was something sombre in his appearance, but on his cherished subject he spoke with warmth and enthusiasm. He was far from being partial and

was quite at home on scientific, technical and social subjects.

For many years, I was in correspondence with Mr. Moens and became personally acquainted with him in 1883. To me in the Colonial Museum he was an invaluable oracle and counsellor. In him I lose more than I can now realize. And what is to become of our cinchona cultivation now that its great champion is stricken down? Shall that gigantic work at which so many of our best laborers have wrought now tend to its fall? Scarce ten days before his death, Moens paid me a visit, apparently recovered from a short but severe illness. We spoke of the Colonial Exhibition in London, which he would willingly have seen. He seemed worn out and sad, and in his voice there was a peaceful resignation. It was as though he misdoubted repose after a long and exciting labour. We parted and he promised to return soon . . . So pass all things away, but not the grateful remembrance of such a Netherlander as Bernelot Moens.—Haarlem, 5th Oct. 1886.

F. W. Van Eeden.

From the English *Chemist and Druggist* we quote as follows:—

Mr. Johan Carel Bernelot Moens, the celebrated Dutch quinologist, died at Haarlem on October 2nd after a short illness. Mr. Moens was born at Kralingen, near Rotterdam, in 1837, and studied pharmacy in Holland. At the age of twenty-one he left for Java having been appointed pharmacist of the third class in the Dutch-Indian army. Mr. Moens rapidly advanced to the position of military pharmacist of the first class, and showed special proficiency in chemical studies. Shortly before 1866 he made the acquaintance of Mr. K. W. Van Gorkom, then director of the Government cinchona plantations at Bandong, in Java, and soon found himself on terms of intimate friendship with that gentleman. About this time the discovery of *C. Ledgeriana* gave an extraordinary impetus to cinchona planting. The Ledgeriana bark, with its richness in alkaloids, gradually superseded most of the other cinchona varieties, the officinalis and the succirubra only being able to hold the field against it. It was found necessary to call in the aid of experienced chemists in order to perfect the cultivation of cinchona by showing how to obtain the largest possible percentage of alkaloids. Accordingly in 1872 Mr. Moens was appointed chemist to the Government cinchona plantations, and it was in this capacity that he created his reputation as a quinologist. The three principal discoveries in cinchona cultivation for which we are indebted to Mr. Moens are the propagation of cinchonas by grafting, the obtaining of bark by shaving, and stripping of part of the tree, covering the naked parts with moss, This latter process was first practised by Mr. Maciver at Madras. Mr. Moens's researches have shown that the disease to which cinchonas are subject is caused by an insect, and rendered it possible to successfully combat the disease. 1875 Mr. Moens was promoted to the directorship of the Government cinchona plantations, which post he filled unaided until 1879, when Mr. Van Romunde, the present director, was appointed as his assistant. In 1880 Mr. Moens visited Ceylon, Madras, and Bengal, in order to report to his Government upon the condition of cinchona culture in those countries, and in 1883, after a quarter of a century's residence in India, he obtained leave of absence for two years, his health having broken down He never returned to India, but was at his request relieved from his post under the Government and charged with the analysis of the Java barks imported into Holland. His work on "Cinchona Cultivation in Asia" contains a complete account of the introduction of the tree in the East Indies, and the progress of its cultivation. Mr. Moens's death is a severe loss to those interested in the Amsterdam cinchona market, for it was to a great extent owing to his talents and energy that that market has not long since succumbed to British competition.

PLANTING IN JAMAICA

(From an ex-Ceylon Haputale Planter.)

Jamaica, 12th Sept. 1886.

You may imagine with what pleasure I look forward to a regular perusal of your most valuable periodical. I have heard two or three persons here speak in the highest terms of your monthly gazette, the *Tropical Agriculturist*.

As you have expressed a desire to receive some news from this part of Jamaica, I will endeavour to give you from time to time a few notes of planting and general interest. Within the last four months the island has passed successively through an earthquake, a flood and a hurricane, all three visitations doing more or less damage to estates, houses, roads and railways. American intelligence would lead us to expect another hurricane in October, but I sincerely trust that we may be left in undisturbed security for many a long day.

Coffee.—Crops are over and the majority of estates have picked their estimates which although not large will leave a fair margin of profit to proprietors. This year prices in Liverpool are extremely good and but little inferior to those of last season. In the matter of value, I am glad to say that this estate's coffee came third in the last "account sales." The marks and prices are as follows:—Clifton Mount 136s, Radnor 131s, Chester Vale 127s, per cwt. At one time prospects for the coming year were good. But the Blue Mountain properties have suffered so often from wind and rain in the past twelve months, that the crops will be as small as those gathered in 1880 I am afraid. Last month when a good blossom was looked for we encountered the hurricane of which I have spoken elsewhere. During the last six years Jamaica has suffered from drought, but we are now supposed to be entering a wet cycle, and it is to be devoutly hoped that such is the case, for our planting of both cinchona and coffee has been more or less, a failure of late.

Cinchona.—The three or four plantations that hold land from the Government under certain "conditions" are gradually planting up the required acreage to qualify for a title, but otherwise no extension is being made in this direction. The present state of the market is anything but encouraging and indications are not wanting that the great mortality amongst trees of all sizes, is not alone peculiar to Ceylon.

Tea.—At the Government Cinchona Plantation some four acres, mostly Assam Hybrid, has recently been put in. They look healthy enough but appear to grow very slowly. I have not seen the Portland Gap clearing lately, but as the plants were exceptionally fine and the elevation more suitable, they should be showing up well by this time. No private individuals as yet have taken to the planting of tea in the island. Before closing my remarks on this industry, I cannot help giving praise to Mr. Hart of the Cinchona Plantation for the first class samples of hand-made leaf which he has produced. To one unaccustomed to drink anything but China tea its superiority is not always detected, or appreciated, but there is no doubt that this Jamaica sample, like Ceylon Tea is refreshing, strong and economical. Mr. Hart has manufactured several lots and I think I may say he goes on improving. But in the roll of the leaf there is yet room for great improvement. The above remarks I should not feel justified in making, had I not had some little experience in the "Lane," before coming out to Jamaica. In the early part of 1880 when I was established in a small way as a tea dealer, I submitted a splendid sample of Ceylon Tea to a broker. I tried to impress him with the special quality of this tea, but I am sorry to say he was not deeply enamored with it.

He admitted that the liquor was strong, but said that the leaf was badly made and the infusion rough to the tongue. How things are changed since then! He valued the sample at 1s 4d to 1s 6d and I know that the same tea was selling at 5s per 2lb packet.

Bananas.—Nearly the whole of the year the demand has been far above the supply of this fruit, The price for a long time remaining at £12 per 100

bunches. At this rate Bananas pay as well as anything cultivated in the island. Unfortunately, a vast amount of damage has been done to all the seaside properties by the wind in August.

CINNAMON CULTIVATION IN THE SOUTHERN PROVINCE.

(*From a Correspondent.*)

Of late years the cultivation of Cinnamon has greatly spread in the Southern Province, and it is interesting to note that Sinhalese capitalists are largely interested in the new plantations which have sprung up in Amblangoda, Wallahanduwe, Vowlagalla, Hapugalla, Matara, &c. The plantation spice from these estates is said to be of excellent quality, and the produce is readily taken up by the Galle merchants for export to Europe. The present market price all round is quoted at 36 cents per pound first cost. Our informant states that there are nearly 100 plantations and gardens now, whereas formerly there were scarcely half a dozen. To Mr. Simon Perera, the owner of the large estates in Galle, belongs the credit of having embarked so successfully in the cultivation and preparation of cinnamon in this province.

OUR CABINET WOODS.

We confess to a feeling of disappointment that the several reports appearing in the London *Times* and other home journals of the Conference lately held at the instance of Messrs. Ransome & Co. upon the Cabinet Woods exhibited at South Kensington this year, should make no reference to those of Ceylon. While the products of India, Australia, Borneo, &c., are the subject of remark, those of Ceylon are entirely left out of sight. This can scarcely have arisen from want of prominence given to the collection of Ceylon woods sent home. Indeed from various correspondents we have received the assurance that that collection is very complete and full; while we know that the magnificent calamander wood furniture sent to the Show by Mr. De Soysa has been made the subject on many occasions of highly eulogistic comment. It may be, however, that our exhibits in this particular have been somewhat deficient in the special form in which our many cabinet woods might have been shown to the best advantage. It is well-known that many of the most beautiful grained woods may be passed over as undeserving of notice if the proper treatment has not been applied to them to show off their graining. The colour of many of the timbers most in request for the making of furniture is due, it is well-known, to artificial treatment. The American walnut, now so extensively employed in England, and, perhaps, the most generally popular at the present time for Cabinet work, remained for many years a perfect drug in the London market, unused and even unenquired for. It was not until some expert either devised or learned from America the character of the dye or varnish required to develop the colour it is now made to assume that the trade commenced to use it. When once, however, this necessary process was attained to, the demand for the wood became almost excessive, beyond indeed what the export from the American forests could supply, and the result has been that it has risen enormously in price, nor is there we understand, any sign that its appreciation is decreasing.

Now a similiar result might have followed if many of our woods sent home to the Indian and Colonial Exhibition had had their qualities developed by some such treatment. It cannot be said that the wood of the *jak* in such common use among both natives and Europeans in this island is in its untreated condition very attractive looking. Indeed, its bright yellow colour when new may almost be said to be repulsive to the eye. As a rule, it is left to time, and to the effects of what is known as continued "elbow polish," to develop its really beautiful colouring. The beautifying effect can, however, be produced by artificial means. If the wood is washed over with a solution of lime,—which has the effect of at once deepening the colour,—and then treated with the common native wood varnish, an appearance of dark polished oak will result, and several intances are familiar where this treatment has been successfully adopted. Among our native woods, nadoon perhaps, comes the nearest in colour to the prized American Walnut in its virgin state. But its grain hardly possesses the variety and beauty to be found in some of the finer specimens of the transatlantic wood. Nevertheless we believe our local product might well rival the American, in the estimation of home wood-fanciers—to coin a term—if it were placed before them in an attractive form. The method which has become of late years so fashionable with English cabinet-makers of incising patterns in the dead unpolished wood, and relieving them in gold, seems to many judges, to be specially applicable to the nadoon, the natural colour of which would afford a striking contrast to the bright gold of such incised patterns. The roots of the suriya too possess a variety both in grain and colouring which probably only demands scientific treatment to be devoloped to suit the taste of home manufacturers.

Of Ceylon ebony and satinwood it is scarcely necessary that we should speak. They are too well-known, and too generally appreciated already, to call for special remark. Nor do they, indeed, come within the category of the woods which are the present subject of attention. They are widely grown in many other countries besides Ceylon, and although our island growths possess attributes which cause them to be largely in demand, the sources of general supply are, as we have said, too varied to cause us to feel disappointment that they should have been passed over without remark in the Conference to which we have alluded. But we think that that omission may have taught us a useful lesson. On future occasions which may occur, for exhibiting our island products in England,—such perhaps as may be one day afforded by the formation of a Museum for the proposed Imperial Institute,—we should endeavour to show furniture made after modern patterns from those of our woods which seem likely to be new and unknown to the trade at home. We feel that Ceylon has no reason to hide its head in this particular class of exhibit, and we feel that if our furniture-makers would bestir themselves, and if they were aided by some European advice as to the best means of developing the colour and grain of our native woods, very useful results might be attained. In our *Tropical Agriculturist*, we are republishing the full reports which have appeared on the Timber Exhibits, as the result of the Conference referred to, and although there is no direct mention of Ceylon woods, the information given is both instructive and locally interesting.

COFFEE PESTS—FUNGI.

Coffee planters are just now bewildered by an old disease in a new shape, which is likely, if not immediately checked, to cause much loss in crops, and some indeed look upon its destructive results as a graver calamity than bug, borer, &c. We allude to the disease known as leaf rot, of which there are several forms recognised—as black rot, mildew, &c., &c., caused undoubtedly by a superabundance of young wood (requiring handling off) and excessive moisture. These, however, are easily remedied by opening out the centres as soon as possible, and sickling the weeds which at this time of the year grow apace and shut out the light and air. But the disease is assuming quite another phase, and it is rather difficult to assign any reason for its appearance. We are inclined to the belief that it is a severe kind of *fungi* the spores of which enter the epidermis or bark, and cause disease in the first instance in the leaves which after, wards extends to the fruit-bearing portion of the tree as well as the fruit, all of which in course of time or near the close of the rainy season, drop off. The fungus acts by feeding on the juices of the plants, preventing the elaboration of the sap, obstructing the admission of air and the emission of transpired fluids. The limbs of the trees being thus overcharged with moisture, ultimately rot, while every source of nutriment is cut off from the half developed berries, which also rot and fall off.

There may, however, be another cause, which is necessary for the spread of *fungi*, occasioned by the roots, in which may be traced the want of correspondence between absorption and transpiration and a consequent stagnation and decomposition of the juices.

An estate which suffered considerably last season in this respect, was at once take in hand by the energetic Superintendent, by pruning back the trees to their primaries, removing all moss and lichens from their stems, renovating and manuring, which treatment within a month (September) directed the nutritive matters in the directions of the increase and development of subterraneous as well as aerial branches: the result is astonishing and shows that nothing but careful and high cultivation is necessary to bring the trees to a healthy state.

But in South Wynaad we learn that the disease is making great havoc, having assumed the form of an epidemic, and the planters scarcely know how to control it. We have adduced the above for their information, as we think it well worthy of imitation. Our opinion inclines us to the conviction that the sudden change their estates have undergone this year, from long and extreme drought and heat to sudden and excessive rainfall and moisture,—which we hear in Vythery alone has amounted to over 150 inches since May—has produced the phenomena. The drought must have brought the trees to such a low state of exhaustion, the spring showers having failed, or they might have gradually recovered with steady and moderate showers, and thus have regained strength and vigour for the monsoon. Thus when the rains did set in, they came on with a force and copiousness not known before; the trees being sickly were unable to benefit by it, and they became diseased in the manner described. The subject threatens to become one of very grave importance, so we trust planters will come forward with their views and opinions and see what can be done to put a stop to and evil which easily grows.—*Nilgiri Express.*—[This black rot has always been more prevalent in Southern India than in Ceylon, but it seems now to have appeared in a form of intense virulence. Alas poor coffee!—Ed.]

A Rival to Dr. Hewett.—The *Moniteur des Produits Chimiques* is informed that Professor Fischer, of Munich, after an extended research on the nature and properties of quinine, has discovered that a substance may be extracted from coal-tar which exercises on the human organism an action identical with that of quinine. The substance appears in the shape of a white crystalline powder. Administered in cases of fever it has the effect of rapidly lowering the temperature, and its efficacy in this respect is stated to be so remarkable as to permit the use of ice to be dispensed with; in the stomach the wonderful powder assimilates with even greater facility than does quinine.—*Chemist and Druggist.* [We wait for "more light."—Ed.]

Tea in Japan.—A dispute has arisen between Messrs. Mourilyan Heimann & Co. and the Mitsui Bussan Kaisha, as to the rejection of a quantity of tea which the former firm alleges is not up to sample. As the result of correspondence between the buyers of the tea in question and the Yokohama Tea Brokers' Association, a meeting of foreign tea buyers was held on Wednesday, at which it was resolved to appoint a committee to act with Japanese delegates in the arbitration of disputes between foreigners and Japanese. A committee of three was elected to bring the question before the Japanese brokers. A slight decrease has taken place in the volume of tea transactions, prices ruling firm all round. There must be heavy losses upon Japanese teas this year. Their selling price in New York was never before so low. It is strange that while the price of Chinese and Japanese teas shows a steady tendency to decline in Western markets, that of Indian and Ceylon teas goes slowly but surely upwards. This fact, taken in conjunction with the largely increased production of India and Ceylon, seems to indicate that Japan and China may one day or other be completely ousted from their monopoly of the fragrant staple. Perhaps we should limit the prediction to China, for Japan has the good fortune to possess the *entree* of the United States markets, where black tea is not popular.—*Japan Weekly Mail*, Oct. 2nd.

Artificial Quinine.—Messrs. Brookes and Green, of 25, Mincing Lane London, state in a recent Market Report:—"No sooner does the 'silly season' est in than the daily press astonishes its readers by announcements of 'remarkable discoveries' which are to 'revolutionise' either this or that particular industry. Last autumn a London journal published the startling intelligence that the present sugar industry—beet as well as cane—was to be annihilated by the wonderful returns of sugar which it claimed could be obtained from the *mahwa* or *mowra* tree of Hindostan. As was pointed out shortly afterwards, this was nothing but a Munchausen story, since the flowers in question contain only 1·04 of saccharine matter, and even that small quantity is fit for nothing but brewing and distilling purposes. We believe it was the same morning journal that reproduced the American hoax of the new species of cotton tree with pods weighing each from 2 to 3 lb., by which the cotton trade was to be 'revolutionised.' This year the same newspaper brings forward a 'remarkable discovery' of the artificial mode of making quinine, which will, we are seriously told, bring down the price of that drug to something like 3d per oz. We are also told that this important discovery 'was made by the accidental breaking of a medicine bottle.' But, as we are well aware that all great discoveries are usually the result of accident, this need not surprise any one. The really extraordinary part of the story is that good quinine 'can now be manufactured without limit by a very simple process from an article which can always be got in abundance in any part of the world.' In order to round off the story, it should have been stated that the artificially-made drug had been administered in cases of fever with the most satisfactory results; but to this extreme the inventor, doubtless with a discreet regard for his patients, appears not to have gone. We have the best authority for stating that the announcement that an eminent firm of manufacturing chemists has expressed itself favourably with regard to the alleged discovery is entirely false. It has yet to to be proved that anyone has really succeeded in producing so complex a body as quiniue synthetically; and it is extremely improbable that even if produced at all, it could be made at any very low price. Before such statements are accepted and published by any newspaper it would be strongly advisable to have certain evidence of their correctness."—*Madras Mail.*

A RUSSIAN PLAN to extract rusty screws is to heat a flat iron bar to a cherry red and press it in the head of the screw for a couple of minutes, after which the screw becomes loosened, and is easily extracted with a screw driver.—*Nilgiri Express.*

CINCHONA PLANTATIONS.—At the request of Mr. M. A Lawson, Government Botanist and Director of Cinchona Plantations, Government have sanctioned the abandonment of the Kalhatti Cinchona Gardens on the Nilgirris from the commencement of the next official year. The Collector has been instructed to dispose of the site in the manner most advantageous to Government.—*Madras Standard.*

PERFECT INSULATORS.—Some experiments lately brought before the Paris Academy by M. Luvini, combine with those of other observers (he considers) in warranting the conclusion that "gases and vapours, under any pressure, and at all temperatures, are perfect insulators, and cannot be electrified through friction, either with one another, or with solid or liquid substances."—*Nature.*

YOUNG BABOON.—Mr. H. H. Johnston informs us, (*The Kilima-Njaro Expedition*), that when in East Africa, he shot a baboon, young and tender, which he had cooked and ate. "I can only say that the succulence and quality of this creature's flesh were quite unexceptionable." He writes of having met elephants at the elevation of 13,000 feet, says they mount banks with the agility of goats, and is convinced that the elephant "can easily adapt himself to a mountain life."—*Nilgiri Express.*

COFFEE ROLLS.—Take twelve cups of flour, one of white sugar, one half of butter or lard, one of yeast, one grated nutmeg, and three eggs. Mix with three large cups of warm milk, and let it rise over night; if well risen in the morning, knead and set in a cool place until three o'clock in the afternoon, then shape into long rolls, and let them rise one hour and a half. Bake half an hour in a moderate oven. When done, glaze them with a little milk in which a little brown sugar has been dissolved and set them back in the oven for two minutes.—*Appledore Cook Book.*

NATAL TEA.—Our Tea Correspondent, the "Peripatetic Planter" was kind enough to send us two samples of Natal tea, which our Managing Agents, Messrs. Balmer Lawrie & Co., were good enough to have sampled and priced for us by a tea expert with the following result:—"*Natal Tea.* —The two samples of Natal tea, leafy broken Pekoe Souchong and rather open leaf Broken Pekoe, are not unlike Indian or Ceylon tea in appearance; in liquor they are softer, more like the China manufacture. I should describe the liquor as rather dark soft not strong; they want the strength and pungency of Assam teas, the outturn is dark, the quality generally not good: value in Calcutta today 6-3 annas broken Pekoe Souchong, 8 annas Broken Pekoe.—*Indian Planters Gazette.*

FLUID EXTRACT OF CINCHONA.—At the request of the Surgeon-General, her Majesty's Forces, Government have ordered a certain quantity of the new preparation of cinchona—the fluid extract by Mr. Hooper, the Government Quinologist—to be placed at his disposal, for trial in Upper Burmah, as there appears to be a large amount of inefficiency caused by fever in that country. To give publicity to the preparation, Government have approved of the suggestion of Dr. Bidie, to issue the drug gratuitously to certain charitable dispensaries, both for experimental trial in hospitals and for issue, free of charge, to outdoor sick in quantities not exceeding one ounce. This gratuitous issue is to be continued for one year, subject to a report at the end of that period. —*South India Observer.*

NORTH BORNEO, Oct. 7th.—His Excellency the Governor arrived from Sandakan, in the steam launch "Kimanis" on the evening of 31st August, on a visit to the West Coast Stations. The following day the Governor, accompanied by the Resident, rode to the Hakka Settlement. The gardens were looking fairly well but the men appeared to be planting up more land than they could look after properly. The Liberian coffee, tea, pepper, &c., were all growing luxuriantly. A visit was next paid to Limau Limawan, a small island lying five miles south of Kudat, and leased to the Imaum, Hadji Abdul Drahim, who first opened a settlement there towards the end of 1883. His village now contains a prosperous community of about three hundred souls. On September 3rd the Governor, the Resident, and Mr. Christian proceeded to the German Borneo Company's Estate at Limbuac, Banguey Island. His Excellency was much pleased with all he saw, and the party walked to Mitford covering the distance of a little over seven miles in a couple of hours. The road was found to be rather rough in some places. On the way to Kudat, in the launch the S. S. "Hong Ann" from Labuan was sighted off Muliangin, and Capt. Slaker kindly stopped her and delivered the mails, Owing to news received the Governor after a short stay in Kukad returned to Sandakan. Mr. Christian, a Ceylon planter, is opening an estate for Liberian coffee, cocoa, &c., three miles from Kudat on the road to the Hakka Settlement. The late Mr. T. Parry, examined this land at the request of the Resident, and thought there were five hundred acres of as good soil as that found on the Pangkalan River Banguey.—*British North Borneo Herald.*

NOXIOUS WEEDS.—On Tuesday evening the assembled wisdom of the colony collectively shirked the task of defining what is and what is not a noxious weed. Probably our legislators considered that the powers of Parliament are already sufficiently large without adding to them the function of making botanical classifications. But, impressed as they evidently were with the importance of constructing a correct definition, it was too bad of them to hand that duty over to the divisional boards. There is no saying what may be the consequences to posterity—who are our favourite clients nowadays—of arming these unscientific bodies with power to exterminate from the face of the land whatever they may choose to place under the category of weeds. Even if they should go no farther than sida retusa, prickly pears, and thistles, one may be pardoned for contemplating with somewhat of fear the extirpation of these fecund and hardy races. The secrets of Nature are nothing like half-explored yet, and who knows what potentialities of textile fabric may perish with sida retusa, what famine-defying ensilage with the prickly pear, what fortifying elixir with the thistle? What will posterity say if the virtues of these races, here exterminated, should be discovered in some other country, and the Government of the future be compelled to import them, like the American seed maize, and distribute them at so much a root? As the extirpation of these "noxious weeds," provisionally so-called, will cost a deal of money, it really becomes an important question whether it would not be as well to set aside a fair share of it as rewards for the successful interrogation of Nature as to what she had in her eye when she created them. Failing this—for the endowment of research is not likely to commend itself to the divisional board mind—by all means let us, in the interest of posterity, have sida retusa reserves, prickly pear reserves, thistle reserves; and, if even this simple suggestion should fail to find acceptance, we call upon all whose hearts yearn over their unbegotten descendants to put away privily a root or two of each of those doomed vegetables, where the divisional eye cannot see them, as centres of future propagation. There will be no difficulty about it. In fact, it ought to be quite an easy matter to elude the notice of such short-sighted legislation.—*Queenslander.*

Correspondence.

To the Editor of the "Ceylon Observer."

TRAVANCORE PLANTERS AND THE *T. A*

Central Travancore, Oct. 1886.

Sir,—I note in the *T. A.* for the current month a letter signed by the Chairman of the Travancore Planters' Association accusing you of "perversion of facts."* I have turned up the April number of the *T. A.*, pages 704 and 712 and find nothing there to warrant such language. The Chairman had not the authority of the Association (as he would lead the public to believe) to write to you, and he should have been more careful before assailing your good name and placing the members of the Association in a false position. I as a member of the Association, and I know many others never heard of this matter until I read the letter in the *T. A.* I only regret you let him off so easily in your foot-note, but I know it is from the fact that you have always taken a warm interest in everything that concerns planting in Travancore and I hope you will continue to do so, notwithstanding our Chairman's foolish production.—Yours, &c.

A MEMBER OF THE T. P. ASSOCIATION

ORANGES AND OTHER FRUITS FOR ENGLAND.

Dear Sir,—Can you or any of your correspondents inform me of the best mode of sending oranges home (in small quantities) and what other Ceylon fruits can be sent?—Yours truly, ENQUIRER.

[If care is taken that the oranges are neither over-ripe, nor in the smallest degree bruised, and the boxes in which the fruit is packed stowed in a cool part of the steamer, there is no reason why the fruit should not be transmitted in good condition. We do not see what advantage would be gained by wrapping the fruits in tissue paper, or adding any packing material, if the packing is so done that the oranges would not roll about. We fear pines and plantains would scarcely stand a voyage of nearly a month, but some of our readers may have suggestions—the result of actual experience—to offer.—Ed.]

COFFEE AND PEPPER EXPORTS FROM WEST COAST OF INDIA.

Tellicherry, 25th October 1886.

Dear Sir,—We have the pleasure to hand you our usual statement of exports of coffee and pepper from the West Coast for year ending 30th June 1886.

Coffee.—The export of this produce for the year exceeds that of any of the five preceeding years, the largest quantity being shipped from Mangalore. Estimates in Coorg and Mysore were realized and in many cases exceeded and the quality of the coffee generally maintained. From statistics compiled by the Commissioner of Coorg, we gather that 103,420 cwt. of plantation coffee alone were exported from that Province, 70,260 cwt. of which found its way to Mangalore and Tellicherry, the balance 33,160 cwt. going eastward for shipment in Madras.

A glance at our figures will show that comparatively small crops are obtained every alternate year, and the coming one will not be an exception to the rule, for we regret to say prospects as regards quantity are by no means good; but we anticipate this will be to a certain degree counterbalanced by the better prices that will be obtained, the market showing a decided upward tendency, which with exchange in favour of the planter we would fain hope is indicative of a return of prosperity to the coffee enterprize. A small crop too, invariably means better quality.

Pepper.—The export of this produce for the past year in quantity almost equals that of 1882-83, when as far as we are aware the largest quantity was shipped; and we have reason to believe that larger quantities still will be exported in the course of a year or two as a far larger acreage under pepper has still to come into bearing, and as prices are maintained, the cultivation is highly remunerative to natives in whose hands at present it rests.—We are, dear sir, yours faithfully,

ppro ALSTON LOW & Co.
Ralph Tatham.

[For the table appended see our Handbook and Directory.—Ed.]

* We showed that the Chairman referred to extracts from Indian papers with which we had nothing to do, and some of which positively praised Travancore.—Ed.

Planting in Honduras.—The following advertisement in the *Field* is of some interest to Ceylon colonists:—Colonial Opening.—A gentleman, resident for the last seven years in British Honduras, has during that time purchased 20,000 acres in that colony, the more fertile parts of which are suitable for growing bananas, coconuts, oranges, &c., for the American markets (with which there is regular communication by steamer), and the rest for cattle grazing. He has spent considerable sums in developing the property, and wishes to find a Partner or Partners, with about £,3000 capital (to be expended on the property), to take the active management in a year's time. The colony has been English for over a century; is twenty days' steam from England, and has a good climate. The estate is already working at a profit, and the coconut trees planted are gradually coming into full bearing

Notes from Agricultural Letter: Paris, Oct. 2.—Sulphuret of carbon has proved a valuable agent for the destruction of ants. First, batten down the hills, then make a hole, and pour in one ounce of the chemical. The vapours will soon penetrate into the interior and not an insect, but will be killed. The operator must be careful not to go too near the fumes himself. To render barrels, wooden troughs &c., inodorous and impermeable, paint them with a preparation of quick lime and alcohol. This will make fir-wood as hard as oak. The alcohol will dissolve the resin and the lime will replace it in the pores. Wash off any excess of the paint. Mr. Petermann, Director of Agronomic station of Gembloux, has been experimenting with bone dust since three years to test its nitrogenous value. He finds that a top-dressing of this manure, given to winter wheat in March,—the soil being sandy-clay and fair—will increase the yield of grain 13 per cent.

The Colonial and Indian Exhibition.—The Conferences under the direction of the Conference Committee of the Exhibition recommenced this week, a paper being read on Oct. 6th, on "The Pearl Fisheries of Ceylon," by G. Vane, C. M. G. On the 8th, a paper will be read on "Canada as a Flax-Growing and Linen-Manufacturing Region," by E. B. Biggar. Papers will also be read on dates to be hereafter announced, on "Stock-Raising in Canada," by Professor Smith; on "The Climate of Canada," by W. Hingston; on "The Canadian North-West," by Captain Clarke; on "The Coco-nut Palm of Ceylon: its Products and other Uses," by J. Capper; on "Ceylon Tea," by J. L. Shand; on 'St. Helena: its Past, Present, and Future," by Lieut.-Colonel Palmer; on "British North Borneo and its Resources," by W. B. Pryor; on "The Social Condition of Cape Colony," by Spencer Todd, C.M.G. It is also probable that a second conference will be held by the National Fish Culture Association. It has been arranged, moreover, to hold a meeting for the purpose of testing the qualities of the different colonial timbers exhibited at the Exhibition. The object of the meeting is to bring together the leading civil engineers, timber merchants, builders, and other users of wood, to meet experts from the various colonies. Samples of the woods will be converted by machinery into railway sleepers, joinery, casks, spokes for wheels, &c., so that practical men will have an opportunity of seeing what colonial woods can be most easily worked, and for what purpose they can be utilised in this country.—*London and China Express.*

VANILLA.

A lady-writer says:—But the most precious crop here (South Sea Islands) is vanilla, which is both pretty and lucrative, being worth about four dollars a pound. It is a luxuriant creeper, and grows so freely that a branch broken off and falling on the ground takes root of its own accord, and it climbs all over the tall coffee shrubs, the palms, avocado, pears, and orange trees, and everything that comes in its way, growing best on living wood, the tendrils thence deriving sustenance. It also flourishes best in unweeded grounds, the roots being thereby kept cool, so the steep wooded hill-side is densely matted with this fragrant spice, which scents the whole air; indeed, the atmosphere of the house is redolent of vanilla. It is like living in a spice box, as the pods are laid to dry in every available corner. They must be gathered unripe and dried in a moist warm place. Sometimes they are packed under layers of quilts to prevent them from bursting, and so lose their fragrant essence. All this sounds very pleasant, and only suggests light work. Yet in truth this cultivation involves most exhausting toil. The plant is an exotic; it lives in these isles by the will of the planter not by nature's law. In its native home exquisite humming birds hover over its blossoms therein darting their long bills in search of honey, and drawing them forth clogged with the golden pollen which they carry to the next flower, thus doing nature's work of fertilisation. Here the flowers have no such dainty wooers, and the vanilla bears no fruit unless fertilised by human hands. So M. and Madam Valles and their son divide the steep hill side into three sections, and each morning they patiently but wearily toil up and down, up and down again, again, and again in order to manipulate each blossom that has expanded during the night. "Faire le mariage des fleurs" as Madame Valle describes her daily task, is no sinecure; it must be done during the hottest hours of the day when any exertion is most exhausting. It needs a keen eye to detect each fresh blossom, and any neglected flower withers or drops. Each day the ripened pods must be gathered, and in dry weather the plants require frequent watering and indescribable toil.—*Planter and Farmer.*

NEW DEVELOPMENT OF THE WATTLE INDUSTRY.

Messrs. Borrow & Haycroft have established at Echunga, South Australia, a manufactory of tanage, which must be of great interest to all colonists, and from the methods employed is almost pharmaceutical. About 10,000 tons of wattle bark are sent annually from South Australia alone, and it is calculated that the waste in stripping is about four times this amount. The new factory converts the branches too small to pay for stripping into a strong fluid extract called *tanage*, which contains water 60 per cent, soluble tannin 38·2 per cent, according to an analysis by Mr. G. H. Hodgson of samples from the first 80 tons recently shipped to England. The wattle "trash" yields 12 to 16 per cent of tanage; two men can often cut and load 5 tons, and the waggons can bring in two loads a day, equal to 5 or 6 tons; and, at the price (1*l.* a ton) which the firm is paying for thinnings and tops and branches, so much is offering that the patentees are obliged to distribute their orders. The "trash" is tied up in large bundles and carted in to the factory. It is there weighed, close besides the machine which cuts it up into "chaff." This machine is very much like an ordinary steam-plane, the chisels revolving at a high speed, and cutting through 2½-inch saplings quite readily. The chips are shovelled into large wooden hoppers, into which steam is introduced from a large Cornish boiler. There are three steam-heated vats, and the liquor is transferred from one to the other, pumped into elevated tanks, and thence allowed to flow from a tap on to steam-heated evaporating pans about 30 or 40 feet in length. The evaporation is so rapid that in traversing the pans from one end to the other the liquid is converted into a thick, tenacious, treacly extract. At the end of the pans it flows into a cistern, and thence by a kind of treacle-gate into the casks, each of which will hold about 10 cwt. All that now remains to be done is paste on a label, put in a bung, weigh the cask, and send it off to market. In the process of evaporation a certain portion of the tannic acid is destroyed. The "plant" can be easily removed from place to place. It does not pay to cart the "trash" far, but a few square miles of wattle country will keep a factory going. The utilisation of thinnings allows the cultivation of the tree thickly on waste ground, and to begin cutting the third year. European tanners are quite accustomed to the use of such extracts, but it is said that it will be very hard to introduce it into colonial tanneries. The Chief Secretary (Hon. David Murray) and others were invited to make a visit of inspection on July 17, and seemed to have been highly gratified. While on this subject we may mention that Messrs. W. Mofflin & Co. have sent the *South Australian Register* a letter enclosing a cutting from a periodical called *Leather*, published in London, which seriously reflects on the credit of the Melbourne merchants, and it is likely to injure the bark trade. *Leather* states that a large proportion of the ground bark sold there as best Melbourne ground mimosa bark never grew on the continent of Australia, but in Tasmania, where the tree is plentiful, but the bark very inferior. Its value on the market at Melbourne is about 4*l.* per ton in the rind. "The superior quality of the bark grown in Melbourne and Adelaide has created a large and increasing demand for it on the London market. The shipments from Adelaide and Melbourne since January 14* have amounted to 3,874 tons. This is a large quantity, considerably more than the two districts can produce, so that it is certain that there has been a large admixture of inferior bark from the Tasmanian forests. Our correspondent informs us that the value of this second-rate bark in Melbourne is 4*l.* per ton; cost of grinding, 10*s.* do.; bagging, 10*s.*; freight, 1*l.* 10*s.* do. —6*l.* 10*s.* The best ground bark realises in London from 10*l.* to 12*l.* so that it will be seen it is a very lucrative business, and likely to continue so if the English buyers have no means of detecting the fraud."—*Chemist and Druggist.*

THE CULTIVATION OF CELERY AND STRAWBERRIES.

The close of the rains being the seed time for European vegetables, mallis are (or should be) very busy at the present season; and the following practical hints on the cultivation of celery one of the most highly prized of our home vegetables may prove opportune, especially as celery so often fails under the treatment of the native gardener. The seed imported should be sown in boxes of rich, light soil; it should be sown very thinly, and the best way to effect this is to mix a pinch of the seed with a little dry sand or earth, and then sprinkle it evenly over, the surface of the soil which should first be pressed down smoothly and somewhat firmly, by means of a flat board. After scattering the seed, cover it thinly with a little light soil and give a moderate watering. The boxes should be placed where they get plenty of light but no sun and the soil should be kept of uniform moisture. If the seed comes up very thick, thin out the weaker looking seedlings. When the seedlings show three leaves they must be planted out into a raised bed in the garden, to make which proceed as follows:—Select an open place on hard soil for the nursery and rise on it a bed four inches high of the richest thoroughly decayed stable litter or cow's manure a mixture of both is preferable. Press it down pretty firmly, and then transplant the seedlings on to it four inches apart. The plants should be shaded in the midday by means of a piece of matting suspended on sticks over the bed; the watering should be liberal both morning and evening.

* To what date is not stated.

It will now be found that the plants will grow very rapidly. Meanwhile the trenches should be prepared one foot deep and one foot wide. Place six inches of thoroughly decomposed manure at the bottom of the trench. When the seedlings have been a month or five weeks in the nursery bed, the largest of them should be removed carefully, taking special care not to disturb the roots, and planted in the trench, "two inches deeper in the soil than they were in the nursery bed," and nine inches apart. After transplanting give a good soaking of water (tank or river water is best where procurable). As the plants make growth, they should be earthed up by refilling the trenches by degrees with soil which was originally dug out. For an early crop, the trench should be out in the open; and for a later crop in a shady situation. If rivers are procurable, it is preferable to the garden soil for earthing the celery. It will be seen that the chief art of growing celery to perfection consists in rapid forcing by means of the richest manure.

Strawberries are well worth more attention than our native gardeners give them. At the beginning of the hot season this fruit very small and flavourless, finds its way to the Calcutta market in considerable quantities from the Patna district where it is grown by the native market gardeners; but none who have not tried the effects of cultivation can realise how vastly this favourite fruit can be improved. Firminger's plan, given in his "Manual of Gardening," is the one which should be followed; and for those who have not his work at hand to refer to the following brief abstract of his method is given:—Choose a piece of ground well exposed to the sun, and dig holes in it six inches deep, eight inches wide, and one foot apart. Fix the holes with a mixture of equal parts of old cow manure, leaf mould and garden soil; and in each put down a strawberry plant. Water at the time of planting and as often afterwards as the plant seem to require it. The plants should be put down early in October, and by February they will come into full blossom, and "when in blossom, the beds should be watered every day from a rose watering pot." Unless this is done, the fruit frequently does not set, and you get no crop. When the fruit is ripening, it should be protected from the ravages of birds by a net. The strawberry requires daily watering during its growth and bearing; and in the hot season the plants are sure to die unless regularly watered. The rains do not injure the plants. Care should be taken to plant out the young growth, *i.e.*, the new plants formed by runners from the old plants during the rains, as the old plants seldom bear fruit the second year. Strawberry plants are procurable from the North West Provinces, and doubtless, if good seed were procured from Home, superior varieties could be introduced. The seedlings would not, however, bear fruit the first year. The writer has by following the above method, grown strawberries as large a round as the top of a sherry glass, and of excellent flavour. —*Englishman.*

THE COLONIAL AND INDIAN EXHIBITION AT SOUTH KENSINGTON.

JAMAICA—*continued.*

Perfumery is represented by two or three exhibits, which do not, however, include such a variety as might have been expected from the number of plants in the island capable of yielding essential oils and perfumes. It is consequently interesting to learn from the official catalogue that Colonel Talbot, of Worthy Park Estate, is about to establish a flower farm, and to extract perfumes, this being the first attempt of the kind that has been made in the island. The essential oils exhibited by Mr. Schaarschmidt include those of lemon, sweet and bitter oranges, pimento berries and pimento leaf (oil of bay); also spirituous perfumes derived from *Bonplandia*, *Canella alba*, red muskwood and rosewood. Pomades made with tuberose and jasmine flowers are also shown by the same exhibitor. The essential oils prepared by Mr. J. J. Bowery, the Government analytical chemist, comprise, in addition to the above, the essential oils of *Eucalyptus globulus*, lemon grass, *Juniperus*, *Bermudiana*, *Critonea Dodea*, *Hedyosmum nutans* and *Micromeria obovata*. Ylang-ylang fruits are shown, but no specimen of the oil.

A specimen of aloes presenting the appearance of inferior Curacoa aloes, rather than of Barbadoes aloes, is shown by the Botanical Department. In this instance, and in many others throughout the Exhibition, it is evident that want of attention to appearance is one of the reasons that colonial products do not satisfy the requirements of commerce.

Large quills of cinchona bark are exhibited by the Botanical Department and Dr. Heaven, including *C. officinalis*, *C. Ledgeriana*, *C. succirubra*, a hybrid (*C. robusta?*), accompained by herbarium specimens of these trees and of *C. micrantha*, *Calisaya verde* and *Calisaya morada.*

The *C. succirubra* bark grown in Jamaica appears to have quite a different character to that cultivated in the East Indies, in not possessing the warty character of the latter, which is seen also in the South American *C. succirubra.* According to Mr. D. Morris, *C. Calisaya* was not rightly distinguished at the Government plantations in Jamacia until 1881, being included under *C. officinalis*, to which it bears some resemblance in the shape of the leaf.

Some very fine specimens of honey, both liquid and solid, are exhibited, the former by Mr. C. Gordon, and the latter by Mr. J. W. Aikman; both specimens are of good colour and fine flavour. This Court should not be left without noticing the beautiful ornamental articles exhibited by the Women's Self-Help Society, including baskets made of the luffa fruits, and of various seeds (*Leucæna glauca*, *Abrus precatorius*, *Adenanthera pavonina*, and *Coix lachryma*, etc.). The articles made of lace bark (*Lagetta lintearia*), and of the beautiful white tissue of the dagger plant (*Yucca aloifolia*), which is even more elegant than the celebrated rice paper of the Japanese, have been much admired, and would doubtless sell readily in this country. Probably the bright coloured seeds would also find a ready market in Roman Catholic countries for rosaries.

TRINIDAD.—The Botanical Gardens exhibit vegetable ivory nuts, mace, nutmegs, nux vomica seeds, and coca leaves. Nine varieties of tanning substances are shown by Mr. F. J. Hill. Of these the dividivi pods have been found to yield 65·08 per cent of tannin. A remarkable product, labelled "Cedar gum," is shown by the Rev. J. Morton in the form of long transparent tears. When dissolved in water it makes an enormous quantity of thick mucilage, deficient in adhesiveness, but forming an excellent size, like Japanese isinglass. It is probably obtained from the bastard cedar (*Guazuma tomentosa*), and seems worthy of further examination.

BARBADOES.—Several specimens of rock, recently discovered on Oxford Estate, St. Peter's Parish, and stated to contain nearly 70 per cent of phosphates, may be seen in this Court. A very interesting series of specimens, illustrating how these phosphates are formed in the coral rock, is shown by Mr. H. E. Thorne, of the Antilles Manure Works.

In the opinion of Mr. George Hughes,* the deposit of Aruba phosphate in the island of Barbadoes, which is estimated to contain not less than 500,000 tons, has been formed from a superincumbent layer of guano, the carbonate of lime of the coral reef having been changed into phosphate by the soluble phosphate washed out of the guano by the rain, etc. The guano has, however, now disappeared. The structure of the coral rock is seen to be perfectly retained, although the chemical change that has taken place is shown in the presence of phosphate of lime to the extent of 76 per cent. The Sombrero phosphate from Sombrero Island owes it origin to another cause, viz. the direct marine deposit of bone, and another deposit in the island of Barbuda to the excrement of bats in the bottom of caves. These deposits form a valuable

Quart. Journ. Geol. Soc., Feb., 1885, p. 8.

manure for the sugar estates. [Our readers will be reminded of poor Tytler's Sombreorum.—ED.]

MONTSERRAT.—The name of this island is perhaps best known in this country in connection with lime juice, although the principal produce, as in most of the West Indian Islands, is sugar. The Montserrat Company exhibits lime juice in various forms, such as cordial, bitters, sauce, etc., and also ecuelled oils of limes, bergamot and shaddock, as well as distilled oil of limes and distilled oil of basil (*Ocymum sp.*). The ecuelled oil of limes, judging from a specimen received some months since, is very superior to the distilled oil. Essential oils are also exhibited by Mr. J. S. Hollings, consisting, in addition to those mentioned above, of the ecuelled oil of orange (*Citrus Bigaradia*) and the distilled oils of *Canella alba*, cascarilla, lemon grass, bay (*Pimenta acris*) and wild basil; also the perfumed waters formed during their distillation

BRITISH HONDURAS.—The chief products of this colony are dyewood and timber, the amount of logwood annually exported reaching 17,000 tons. It is described as growing in immense thickets in marshy places, with a crooked trunk 16 to 21 feet high, and rarely thicker than a man's thigh in diameter. Two varieties of the tree appear to be recognized in this colony; one having broad leaves is considered the most valuable on account of its solidity, and of yielding a larger quantity of the dye, although the smaller-leaved variety is said to yield a better quality. Of fustic (*Maclura tinctoria*) about 100 tons are annually exported. The seeds of *Sesamum orientale* "used for flavouring cakes" are exhibited under the name of "wangla" seeds.

THE BAHAMAS.—To pharmacists these islands are best known as the geographical source of cascarilla and *Canella alba* barks and of sponges. The exports of sponge in 1885 were estimated at £60,000. Ambergris is also found on the shore and is exported to the value of £1,000 per annum. The most marked feature in this Court is the fine display of sponges, which will form the subject of a subsequent notice, and the many beautiful treasures of the great deep, including sea ferns, corals, sea feathers, sea stars, sea urchins and shells, etc.—*Pharmaceutical Journal*.

ROOTS,

(*Continued from p.* 372.)

A third case is conceivable—so much water might be supposed to find its way in, that no air remained in the interspaces between the particles of soil. Now it is true that such a state of affairs is not readily brought about in a normal soil; but I may indicate how the result is occasionally attained to a great extent. Suppose that a layer of clay or other impenetrable subsoil lies beneath the soil in question; then if water oozes into the soil in larger quantities than can be got rid of in the time, it is possible for nearly all the air to be displaced. Of course the object of good drainage is to prevent this; and it is often overlooked that drainage from below has the effect of drawing in air as well as of running off superfluous water—air is driven into the spaces as the water leaves them.

In speaking of the "bubbles of air" entangled in the interspaces between the particles of soil, each with its water-blanket, I have overlooked some details as to what the bubbles really are. As a matter of fact they will not remain of the same composition as ordinary air, and may soon differ considerably; besides the vapour of water, they may contain gases in quite different proportions from those in the air outside. In the type case, however, there will be some oxygen present in the bubbles.

ROOT-HAIRS.—It is not intended here to go very fully into a description of the roots of land-plants; enough if you are reminded how the smaller ramifications of a root are found to be more numerous and thinner as we approach the periphery of the mass of earth which they traverse. From the youngest rootlets are produced the root-hairs, in enormous quantities, new ones arising forwards—*i.e.*, near the tip of the rootlet—as the rootlet grows on, and thus, behind dying off after fulfilling their functions These functions are chiefly to apply themselves in the closest manner to the surfaces of the particles of soil, and in this way to place the water which they contain in direct continuity with the water which clings with such enormous force to the surfaces of the particles. Hence this water can pass from the soil to the plant and anything dissolved in the water can also pass into the root-hair, and thus up into the plant. I am not going to dwell on how the root-hairs themselves aid in dissolving mineral substances—corroding the surfaces of the particles of soil they cling to—nor shall I trouble you with the details of what substances will be dissolved in the water; for, of course, you will see that anything soluble will pass into solution and may be carried into the plant. The chief point to be insisted on just now is that this water in the soil will contain among other substances oxygen dissolved in it from the air-bubbles referred to above, and that this dissolved oxygen will pass into the root-hairs in solution together with the minerals and any other substances. This oxygen, moreover, is absolutely indispensable for the life of the root-hairs; it can be easily shown that if the supply of oxygen is stopped, or even diminished to any considerable extent, the roots begin to die, because the root-hairs cease to act. Let us look a little more closely into this point. Each root-hair is a tiny cell containing living protoplasm and certain other substances, all inclosed in a thin, elastic, porous membrane. Now it has been abundantly proved that if such a cell is deprived of oxygen, its protoplasm becomes dormant for a time, and slowly breaks up, as it were; subsequently it becomes decomposed into other and simpler materials. A sort of internal combustion and fermentation take place, and these processes result in the formation and liberation of bodies like carbondioxide, alcohol, acetic acid, and other acid matters—substances in the main not only incapable of supporting the life of the root-hairs, but actually destructive of it. Evidently, then, if we deprive all the root-hairs of oxygen, they will eventually die. Their death will entail that of the rootlets and roots to which they belong, and this for two obvious reasons:—first, it is the root-hairs, and the root-hairs alone which can absorb the necessary water and substances in solution from the soil to supply such a plant as we are concerned with; and, secondly, the noxious products resulting from their death accumulate in the soil and diffuse into the root, and so hasten similar decompositions in what were hitherto healthy cells. It must not be supposed that these disastrous consequences of the deprivation of oxygen always follow immediately. Not only are the roots of some trees, for instance, able to withstand ill-treatment longer than others, but, obviously, the kind and degree of ill-treatment may affect the problem of how long the plant shall survive. The number of rootlets and root-hairs, and the spread of the roots and other factors, will obviously affect the matter. Suppose the following case as an example. A young tree is growing and flourishing in an open, good soil, and, for some reason or other, more soil is heaped about the roots until the depth is increased considerably; the deeper situation has placed obstacles in the way of the roots obtaining oxygen so readily as before. Not only are the roots further from the atmosphere, but the water carried down has to percolate through more soil, and may part with much of its oxygen (or even all) on the way: of course the nature of the soil, the presence of organic matters, and other circumstances, decide this. It is not at all difficult to conceive of such a case where the supply of oxygen to the roots is thus diminished so far that the activity of the root-hairs as a whole is simply lowered, but not destroyed,—a stage or two further and they might become dormant, and their protoplasm undergo intra-molecular respiration for a time, and break up. It is clear that the diminished activity of the roots will affect the supply of water (and the substances dissolved in it) to the leaves; this will obviously react on the thickness of the annual rings, and this again on future supplies—since

the water passes up the alburnum, or young outer layers of woody tissue, moreover, a diminution of supplies from the leaves means less substance and power for replacing the root-hairs, and so on. In this way it may require some time to kill the tree, and all kinds of complications may arise meanwhile. This case is probably by no means uncommon. A more extreme case is where the soil becomes damp and clogged with excessive moisture; not only does no oxygen reach the roots, but noxious gases accumulate in solution in the soil, and will hurry matters by poisoning cells which might otherwise live a longer life of usefulness. It is extremely probable that such gases find their way into higher parts of the plant in the air-bubbles known to exist and to undergo alterations of pressure in the vessels of the wood: this being so, they would slowly retard the action of other living cells, and so affect the upper parts of the plant even more rapidly than would otherwise be the case. Damp soil may thus do injury according to its depth and nature; but it need not necessarily be deep to be injurious if much oxygen-consuming substance is present. I have seen excellent soil converted into damp, stinking, deadly stuff, from the action and accumulation of the larvæ of cockchafers: these "grubs" may, it is true, accelerate the devastation caused by the consumption of oxygen and the accumulation of poisonous waste matters in the soil by directly cutting off portions of the roots themselves, but the accumulation of oxygen-consuming substance, and the cutting off of supplies to the root-hairs evidently plays a chief part in the destruction.

There is another matter with regard to damp soils that cannot be left out of account. I have already told you that roots which are developed in water, or in very damp sandy soil—and which are perfectly healthy—have few or no root-hairs formed on their surfaces; whereas it may be readily shown that the roots of the same plant growing in a well aërated open soil, which is scarcely moist to all appearance, will be densely covered with a close set pile of hairs. Indeed it is by means of the millions of root-hairs on its rootlets that a Sunflower or a Bean, for instance, obtains the enormous quantities of water necessary for its needs from soil, which to our rough perception, seems to be dry. I cannot here go into all the proofs that such a soil is by no means so dry as it looks; but will simply remind you of what was said above as to the enormous force with which the minute particles of rock, &c., which form "soil" retain their hold on the thin films of water which constitute what have been termed their water-blankets. This is certain, that a healthy, well-rooted plan can take up water from a soil which is to all appearance air-dry; whereas a plant which has not yet had time to develope its root-hairs in sufficient numbers to take these firmly adherent water-films from numerous particles of soil would, droop and wither. Of course it must be borne in mind that we are speaking of land-plants such as we commonly meet with on ordinary dry land; in the case of plants which flourish in bogs or in water there are corresponding differences in the structures of their roots agreeing with the differences of environment. Even such plants need air at their roots, and an excellent illustration of this is afforded by some Willows. Our common Osier and Willows grow, as you are aware, in low-lying, damp, and even boggy places, often flooded; now it has been found that, if young Willows are planted too deep in the soil, they very soon send out new roots—adventitious roots they are often called—close to the surface of the soil, and these roots soon do all the work. There is no doubt that this power enables these Willows to live in places that would be fatal to them otherwise; and the same is true of some other plants.

Enough has now been said to show you how necessary it is that some care should be exercised in watering plants, or in exposing them to conditions different from those to which they are accustomed; and, it need scarcely be added, apparently mysterious diseases may sometimes be explained when it is shown that such precautions have been neglected. Any one can quote instances of plants which will grow in some soils and not in others, but no very satisfactory reason is afforded by simply saying that the one soil is suitable and the other not: however, all I have attempted to show you is that some soils are not suitable for some plants because the plants in question need more air at the roots than these particular soils can afford them under the circumstances.—H. Marshall Ward, M.A., F.L.S.—*Gardeners' Chronicle.*

(*To be continued.*)

QUINOLOGICAL WORK IN THE MADRAS CINCHONA PLANTATIONS.

BY DAVID HOOPER, F.C.S.,
Government Quinologist.

Last year I communicated to the Conference at Aberdeen the results of some experiments made in the cultivation of cinchona. A number of analyses were given of the different varieties of bark grown on the Government and other estates. It was shown how the alkaloids were distributed in old succirubra trees; and it was noticed how natural shade and the process of mossing promoted the increase of alkaloids in the bark. Some of these conclusions were perhaps not altogether unknown before, but I thought it desirable to confirm results which are liable to vary under different conditions of age. Another year's work shows some more extended investigations into the effect prdouced on alkaloids by the renewal of bark and by the manuring of trees, and tables are compiled from numerous analyses showing the rise of alkaloids in growth and their deterioration by age and other causes. I have again been permitted to quote extracts from my annual report, which has lately been forwarded to Government through Mr. Lawson, Director of the Cinchona Plantations.

Renewal by Shaving.—Shaving cinchona trees has been for some years a method of harvesting bark which in some districts works better than that of stripping and mossing. The cellular and richer portion of the bark is removed in this way, and the librous portion is left. The bark thus treated thickens again, and the shavings, taken from it are found to be richer still in alkaloids. The analyses of some succirubra shavings taken from trees grown in the Ouchterlony Valley will show to what an extent trees may be improved by this method. The renewals were taken after intervals of twelve months; the experiment therefore lasted over three years.

	Quinine.	Other Alkaloids.	Total.
Original bark ...	1·35	5·87	7·22
Once renewed ...	2·46	4·22	6·68
Twice renewed ...	3·60	3·99	7·59
Thrice renewed ...	3·87	3·71	7·58

The increase of quinine during the first and second year by renewing is most satisfactory; the increase is not so prominent in the third year, but the bark is good, and indicates that shaving for at least four years might be permitted. The trees upon which these experiments were made were six years old when the original bark was taken. If at this comparatively early age they are not injured by shaving, and renew their bark so well, it is not desirable to wait for the trees to become more matured.

When trees are allowed to grow until they are over twelve years of age, and then shaved, the renewal set in more slowly, and the resulting bark does not compare more favourably with the original bark than if the tree operated upon had been half the age. This may be instanced by quoting some more analyses. Last December some interesting samples were sent by the manager of the Glenrock Company, S.E. Wynaad, consisting of some natural and renewed shavings of succirubra taken from trees of six and twelve years of age. The following is the analysis of four of the samples:—

	Sulph. Quinine.	Total.
Red bark, 6 years, natural ...	1·34	5·00
„ „ renewed 2 years	2·54	6·95
„ 12 years, natural ...	2·43	7·41
„ „ renewed 2 years	2·71	7·01

Thus it is seen that by renewing a six year old tree, 90 per cent more of sulphate of quinine is obtained, and by working on a twelve year old tree only an increase of 12 per cent takes place during the same period of two years. With regard to the total alkaloids it should be also noticed that the shaving has made an increase of 39 per cent in the younger tree, while the older bark has somewhat deteriorated. One of the most important features in these results is that the renewed bark from the six year old tree is superior to the natural bark from trees of twice the age.

I have had very few opportunities of observing the effect of shaving on pure Ledger barks, containing little, if any, alkaloid, besides quinine; but it appears that hybrid Ledgers of the broad leaved variety, holding cinchonine, are capable of great improvement by the shaving process, as the following renewals of eleven months will show compared with the natural bark of six year old trees.

	Sulph. Quinine.	Total.
Ledger, narrow leaf, natural, 1885	4·09	5·97
„ „ renewed, 1886	6·62	8·49
Ledger, broad leaf, natural, 1885	2·90	6·61
„ „ renewed, 1886	5·19	8·51

The sulphate of quinine in the narrow-leaved Ledger had increased 62 per cent, and in the broad-leaved Ledger 79 per cent; the greater increase in the latter variety is due to the presence of other alkaloids which appear to develop quinine in the growth of the tree.

Shaving old trees has certainly not had a beneficial effect in some trials made on Government estates. Both officinalis and succirubra trees from sixteen to twenty-one years of age cannot well bear the removal of the bark in this way; the renewal takes place slowly, and is found to be impoverished instead of enriched. An officinalis on Dotabetta of twenty years' growth was shaved; the shavings gave 3·66 per cent sulphate of quinine. After six months some renewed shavings were taken and found to yield only 1·85 per cent; the bark was then commencing to decay, and the tree has since died.

Experiements in Manuring Cinchonas.—The effect of manuring cinchona trees in order to stimulate their growth and produce a greater yield of alkaloids has recently been tried at Naduvatam. The first experiment was made upon a succirubra of seven years' growth. Cattle manure, which had been previously kept for some time in closed pits, was applied some six months before the bark was taken for analysis. A sample of bark from a tree in the same plot, but which had not been manured, was collected at the same time for comparison. Two samples of magnifolia bark were taken from trees which had been manured in a similar manner to the succirubra; the first was seventeen years, the second twenty years old, and samples from unmanured trees were taken for comparative analysis at the same time. The results of the examinations are tabulated on the next page.

	Quinine.	Cinchonidine.	Cinchonine.	Amorphous Alkaloids.	Total.
Succirubra manured	2·29	3·78	1·94	·52	8·53
„ unmanured	1·51	4·13	2·03	·32	7·99
Mag'folia, manured	3·78	3·90	·28	·82	8·78
„ „ unm'red	3·13	4·39	·56	·39	8·47
„ 2 manured	2·59	3·49	1·21	·52	7·82
„ „ unm'red	2·62	2·67	·67	·56	6·52

It will be seen that the manuring has had the effect of increasing, in each instance, the amount of total alkaloids in the bark; and the quinine—the most important feature—has received a gain of 52½ per cent in the succirubra, and 20 per cent in the first magnifolia. In the older magnifolia bark the quinine remains about the same in quantity, and if no other influence is at work it might be inferred that older trees are not so sensitive to the action of manure as younger and more vigorous growing trees which have not reached maturity. The food of such plants as cinchonas, which yield alkaloids in large quantity, must of necessity contain some nitrogenous element, and as this must be taken from the ground it is only fitting that a manure of this kind, which contains some constituents that are similar in their nature to alkaloids, should be supplied periodically to the soil. Regarding the question from a commercial aspect, the higher value would cover the expense of the manure and the cost of its application to the land The succirubra bark mentioned in the first experiment, if the unit were 4*d.*, would realize in the market 8*d.*, per pound, whereas the bark of the manured tree would be worth more than 1*s.* per pound. I believe the effect of manuring would be more apparent in crown and Ledger barks, with large proportions of quinine in the total alkaloids; in such cases, the extra outlay on manurial agents, compared with the additional value of the bark, would be much more remunerative.

Increase of Alkaloids with the Age of trees.—A question of much importance in cinchona cultivation is the age to which trees should grow before the bark can be profitably taken. To settle such an inquiry a large number of analyses of barks taken from trees of all ages should be available. In the following tables I have made a selection of both Ledger and red barks, and have arranged them according to age. Some of the figures are averages of two or more analyses, and as the two lists represent some forty samples, I hope they will help to throw some light on the subject.

The first list comprises natural barks of the narrow leaved variety of *C. Ledgeriana*, and, with one exception, they all came from the Wynaad district.

The second list is made by taking from my laboratory journal all those red barks whose ages have been determined, whether they came from the Government Plantations at Naduvatam, or from private estates in Wynaad, Coorg or Travancore.

Ledger barks.	Quinine,	Cinchonidine,	Other Alkaloids.	Total.
20 months... ...	1·68	·66	2 77	5·11
2 years	2·18	·65	2·69	5·52
3 „	3·28	·55	2·90	6·82
3½ „	4·73	·93	1·81	7·46
4½ „	4·97	·79	1·78	7·54
5 „	4·57	1·02	1·46	7·05
5 „	5·09	1·06	·55	6·70
5½ „	7·54	·31	1·15	9·00
6 „	6·52	·76	·88	8 16
6½ „	5·97	1·18	1·00	8·15
8 „	7·59	1·16	1·45	10·20
20 „	5·58	1·24	·85	7·67

In the Ledger barks it will be noticed that there is a steady rise of quinine up to the age of between five and six years, after which there is no apparent increase.

In the second table of red barks the same fact is shown, that the bark has attained its maximum content of alkaloid when between five and six years of age. The quinine increases up to twelve years, but, as pointed out before, the renewed barks of the younger trees much exceed the slightly increased value of these older barks. The trees of sixteen and twenty years show a marked deterioration in alkaloids, although the bark is often in large thick fibrous pieces, similar to the drug that was originally exported from the South American forests.

Red barks.	Quinine.	Cinchonidine.	Cinchonine.	Amorphous Alkaloids.	Total.
2 years.	·55	·72	1·20	1 22	3·69
3 „	·85	1·75	1·67	·99	5·26
3½ „	1·08	1·65	1·15	·64	4·52

20 „	·78	1·13	1·37	·97	4·25

Effect of Mould on Bark.—It has been stated that bark loses much of its virtue when allowed to get mouldy, or when kept in a damp atmosphere. I was asked more than a year ago to analyse some mouldy bark to obtain its value, but not knowing the composition of the freshly dried bark the results would not have been very useful. I have therefore made an experiment which shows that little, if any, effect is produced by prolonged contact with mould. A sample of powdered bark of known composition was taken in December, 1884, and kept in an open dish on the floor of a dark damp room; a fungus (*Penicillium*) set in in a fortnight, and spread itself over the surface of the powder, and slightly increased its weight. The bark was constantly stirred so that fresh bark from beneath might be influenced by the fungus. It was mixed occasionally for ten months, and as the mycelium had by then penetrated to every particle of the powder it was analysed in October, 1885, with the following results:—

	Original bark.	Mouldy bark.
Quinine	2·82	2·80
Cinchonidine ...	1·22	1·25
Quinidine	·18	·11
Cinchonine	·90	·87
Amorphous	·31	·45
	5·43	5·48

It is thus manifest that the analyses being almost identical, moulded bark of ten months is not necessarily deteriorated.

Octacamund, India, July 16, 1886.

CINCHONA CULTIVATION IN SOUTH AMERICA.

BY DAVID HOWARD, F.I.C., F.C.S.,

Although Ceylon has of late occupied in the bark market the most prominent position of all the countries where cinchonas have been cultivated, it is to other quarters that we should look for reliable information on the scientific points involved.

Vast as has been the scale of the cultivation in Ceylon, the soil of the island is by no means of the most favourable for the growth of the cinchonas, and, unfortunately, far too little care has been taken to avoid the danger of hybridization, which takes place with marvellous facility whenever more than one species is found in a district, unless the greatest care is taken to isolate the seed-bearing trees. We thus find that Madras and Java give far better opportunities of studying the effect of cultivation on pure strains of the more valuable species, and it is interesting to add to what we have learned from the plantations in those countries, some light from those in the natural home of cinchonas in South America.

The jealousy which made it so difficult to obtain cinchona plants in the first instance still remains to a great extent in Bolivia, and although we have valuable information as to the progress of the plantations in Schuhkrafft's consular reports, no scientific information can be obtained from that quarter, except what is derived from the bark which already reaches us from them in considerable quantity. This we find to be of very fine quality, far superior to the average of even selected parcels of the uncultivated bark; a yield of 6 to 7 per cent of sulphate of quinine is quite as commonly obtained from them as one of 4 to 5 per cent was from the importations of twenty or thirty years ago, and it is evident that the influence on the calisaya of cultivation is just as favourable in its natural home as in Java. Among them are two new species, the flowers of which are as yet unknown, but the habit of growth of which clearly marks them out as distinct from the hitherto described species. As plants of both are under cultivation, it is hoped that before long we shall be able to add botanical descriptions of them.

The first it is proposed to call *Cinchona Thomsoniana*, after Mr. Thomson, who discovered it in the Central Cordilleras of the Columbian Andes, in the districts which yield the well-known *Cinchona lancifolia*, the soft bark of commerce. It has very large leaves, and grows with a rapidity equal to that of succirubra.

The young bark analysed, which was from trees only two years old, gave already 3·3 per cent of sulphate of quinine=2·5 of quinine alkaloid, traces only of cinchonidine and ·55 of cinchonine. The purity of the quinine and rapid growth make this a promising species for cultivation.

The other was discovered by Señor Pombo in the forests of Ecuador; the mature bark presents marked points of difference from the species at present known and yielded.

The sample of cultivated bark of the species two years old, gave quinine sulphate 5·70=of quinine 4·28, cinchonidine 0·43, no cinchonine or quinidine. This test is a very high one, and, if the growth is not too slow, it ought to prove a valuable species.

For comparison, I would add the analysis of the typical sample of the finest lancifolia bark, the calisaya Santa Fè, brought over by Mr. R. Cross, from Columbia, which yielded of sulphate of quinine 4·2=of quinine alkaloid 3·15, cinchonidine 1·90 and cinchonine ·30.

Of even more interest are samples of bark grown from plants derived from the Government plantations in Jamaica. The history of these barks shows the great influence of successful cultivation and favourable habitat upon the yield of all alike. The first samples received from Jamaica in 1872 gave the following results:—

	Quinine.	Sulphate.	Cichonidine.	Cinchonine.
C. Calisaya ...	1·65=	2·2	·7	·2
C. officinalis ...	1·35	1·8	·1	·1
C. succirubra ...	1·05	1·4	2·5	·8
C. succirubra ...	1·12	1·5	1·6	2·0

The improvement brought about by careful cultivation is shown in a marked degree by the following samples received from the same plantations in 1881:—

Elevation.	Sulphate Quinine.	Quinine.	Cinchonidine.	Cinchonine.	Quinidine.
— Calisaya	4·93	3·70	0·60	0·35	0·05
5500 ft. Officinalis	6·95	5·18	0·22	0·01	0·15
4800 ft. Officinalis (thirteen years old)	5·00	3·75	0·40	0·12	0·16
2400 ft. Succirubra	1·97	1·48	2·98	2·24	0·13
3400 ft. Succirubra (cold spring)	2·40	1·80	1·30	3·20	0·00

The descendants of these plants grown in Columbia give the following results:—

	Sulphate Quinine.	Quinine.	Cinchonidine.	Cinchonine.	Quinidine
C. Calisaya, 3 years old grown, at 8000 feet.	4·32=3·24		0·66	trace	0·00
C. Calisaya, 22 months old 7500 feet.	2·71	2·03	0·55	0·13	0·00
C. officinalis, 3½ years old. 8000 feet.	1·66	3·49	0·21	0·06	0·05
C. officinalis, renewed, 8 months under moss.	4·30	3·22	0·23	0·07	0·07
C. succirubra, 3 years old.	4·94	3·75	3·03	0·17	0·07
C. succirubra, renewed, 8 months without moss, grown at 7500.	7·00	5·25	1·90	0·67	0·00

All these samples are from very young trees and if we may judge from universal experience the more mature bark will give even finer results. The Jamaica calisaya is not of the finest type, the percentage of quinine is lower than in the best ledgeriana and the proportion of cinchonidine is much higher. I should have been inclined to suspect hybridization, but my late uncle, J. E. Howard, F.R.S., after a careful examination of the botanical specimens in 1881, reported of this bark: "It appears to me true to the

calisaya type; I should not think that it belongs either to the josephiana or ledgeriana form, but that the exact variety is perhaps not yet published. There is no appearance of hybridity." The succirubra is one of the finest specimens that I have tested. I have found very great variety in the tests of trees of this species growing alongside each other in Ceylon, the quinine varying even in the proportion of three to one and so it is possible that all the bark from the plantations will not be found of this admirable quality. Still we have here an additional proof that whether the result be due to favourable circumstances or to more or less permanent varieties, red bark can be grown of far richer quality than what we usually receive as such from the East Indian plantations.

Amid all the discouragements of excessive production and low prices that planters suffer from at the moment it cannot be too clearly borne in mind that the prospect of future profit in the cultivation of cinchona turns chiefly upon the cultivation of high testing bark. With favourable soil and climate the richer varieties grow at least as freely as the poorer and it is evident that, the cost of production being approximately the same, a bark of higher quality may yield a profit when an inferior quality may cause a serious loss. In Bolivia and Java these most important requisites are found, and the analyses I have given above show that the same favourable results may be obtained elsewhere. In the face of such competition it is evident that the profitable growing of inferior bark is impossible.—*Pharmaceutical Journal.*

TROPICAL GARDENING.

Hedges.—The best material for forming a hedge is the Barbadoes cherry, *Malpighia glabra.* Naturally it grows into a small tree, and as it yields abundance of fruit there is no difficulty in obtaining a supply of seeds from which to raise young plants. When the fruit is ripe it should be picked and thrown into a tub, to get the pulp removed and the seeds divided (these are from one to four in each fruit), by maceration and washing after which operation the seeds are ready for sowing. They are generally sown thickly in boxes, and require no attention beyond a little watering if the weather be dry. In sowing, the seeds should not be deeply buried, but should only be covered with a little more than their own thickness of soil. If the seeds are covered with much soil, they will probably not germinate at all, or if they do germinate many of the germs will perish before arriving at the surface. When the plants are a few inches high they are fit for transplanting. To form a stout hedge they should be planted in two rows, zigzag. After the plants have grown about a foot high, the hedge should be allowed to grow more than a few inches before being pruned again; by this means the bottom will be kept well furnished and strong. If left to grow two or three feet before being pruned, (and this is generally the case, as everyone is in a hurry to get the hedge up to a certain height,) the result will be a weak hedge and very few branches at the bottom where there should be plenty to form the foundation. When proper care is given to the pruning no other plant is so suitable for this purpose. At the present time it may be seen in many places in Demerara, showing how well it is suited for this work. This one kind of plant may be used for a hedge of any height, from an edging of six inches, to a screen of ten or twelve feet, and answers as well for one purpose as the other. Of course it cannot be kept as an edging all its life, as after a time with continual clipping when only a few inches high it becomes scrubby; it can then be taken up and replanted in a position where a medium sized hedge is required, and in due course can by the same method be utilised for a high hedge. Scarcely any other plant will bear transplanting better than this cherry, but it should be done in damp weather; with ordinary care plants of several feet high can be moved successfully.

Clerodendron aculeatun, commonly called wild coffee, or bitter fence, is a West Indian plant. It is very useful for forming a good strong hedge, and on account of the bitter taste in the young shoot and the short sharp thorns it bears at the base of the leaves, is not interfered with by goats; a strong recommendation for its use where it can be planted without setting up palings, or the protection needed by most plants against these animals. It is usually planted by cuttings, and so easy is its cultivation, that the shade and care generally afforded to cuttings is not needed. The branches may be cut up into pieces from six to nine inches long, and planted at once into the permanent position, by being pushed slantwise in the ground a few inches apart, leaving just the end of each cutting exposed, pressing the soil firmly as the planting proceeds. If the weather is damp, or case of drought if the cuttings are well watered, they will commence to grow at once and in a few days will have the appearance of an established hedge. Where failures occur fresh cuttings must be put in without loss of time, so that all may grow on together. When left to grow in its natural state, this *Clerodendron* is of a very straggling habit, so that to make a decent hedge it must be well and regularly clipped, and must be taken in hand as soon as a little growth is made, treating it in a similar manner to that advised for the *Malpighia*. It flowers freely and gives plenty of seed from which plants can be raised, but planting by cuttings is by far the quickest method of forming a hedge of this plant.

Croton variegatum, the commonest of the many Crotons now to be seen in gardens, and the only one which is used for the purpose, makes a very good hedge; but it must not be clipped, in pruning each branch must be cut separately with a knife. It is propagated by cuttings and scarcely any other plant is so easily grown. It is proof against goats, the sap being extremely bitter. The stain of the sap is indelible on linen.

Aralia Guilfoilei, is another variegated plant which can be used in the same manner of the *Croton*; it is propagated just as freely, and is as easily grown. It has compound leaves growing like small drooping branches, each leaf edged all round with white. It grows in an erect manner sending up long strait stems, which after being allowed to grow between one and two feet long, must be cut back to induce the plant to form a good bottom; for each stem cut several others will spring from below. Both this and the Croton are introductions to the West Indies.—*Indian Gardener.*

Sickly-looking plants may be taken out of their old pots, the roots washed, the weaker branches trimmed, and placed into as small pots as the roots can be placed into. Let such a plant remain there until by good growth it shows its healthy roots then it may have more earth in a little larger pot.—*Planter and Farmer.*

Liquorice Culture in Damascus.—A considerable amount of business, it seems, has recently been done in Damascus and Syria generally in the exportation of Liquorice root to the United States. About four years ago, one of the partners in an American firm in Philadelphia largely concerned in the commerce of this article, visited Damascus with the object of ascertaining the amount and quality of the Liquorice root grown in the country, and of making purchases. The result of his enquiries having proved satisfactory, he gave orders for somewhat large consignments to be shipped to the United States, and appointed an American gentleman in Beyrout, well acquainted with the language of the people and having a thorough knowledge of the country, to act as agent of the firm. The Liquorice root can be obtained in considerable quantities to the north of Damascus, and in the neighbourhood of Lattakia and Antioch, and a regular business is now being carried on in this article. The amount exported last year from Damascus and other parts of Syria was valued at £30,000.—*Gardeners' Chronicle.*

Increase of Fungus Diseases in the South.—President Berckmans in his recent address, notes that the three past seasons have been more rainy than usual, which he thinks may account for the remarkable prevalence of parasitic fungi among fruit trees.—*American Gardener's Monthly.*

Coconuts in Florida—G. T. Field, of Monmouth county, New Jersey, speaks in glowing terms of the prospects for success of coconut culture along the coast of Florida. All reports favor Mr. Field's enthusiasm. There can be no doubt, we think, that coconut culture is to be one of the profitable investments in this remarkable State. They bear in ten years, and yield from 100 to 200 nuts annually. *American Gardener's Monthly.* [They will do nothing of the kind.—Ed.]

Planting in Northern Australia.—Port Darwin, Oct. 10th.—The season's operations at the Shoal Bay Sugar Plantation have, owing to want of rain, saltness of soil, and of other causes, not been successful. The final result is about 5 tons each of sugar and molasses from about 40 acres. General sympathy is felt at Mr. Brandt's ill-luck. The general opinion is that the plantation is on an unsuitable locality. Different news has been received from the Beatrice Hills Plantation on the Adelaide River. Coffee and guttapercha are thriving splendidly. The plant exhibited here showed over 300 berries and buds.—*S. A. Register.*

Tea Planting in the South: Galle, 10th November.—The weather being very favorable, tea planting is being pushed on in the new clearings. At Gordon estate, near Baddegama, of which Mr. L. Christie is the experienced Superintendent, 50 acres have just been planted. Estate owners down South are waking to the necessity of having thoroughly experieneed tea-makers and the latest appliances for manufacture, in order to secure good quality. Citrus estate has now a European Superintendent. The tea in Monrovia estate, Ratgama, is said to be flushing vigorously and a further large acreage is being planted. Mr. R. Koch, who was lately in charge of this place has accepted an appointment on a coconut estate in Jaffna. I understand that the bug has made its appearance on a tea estate at Wallahanduwa, three miles from Galle. I hear that all the plants in a two acre field have been seriously injured by this pest, and that all the recognised remedies have proved ineffectual in removing it."

New Caledonia.—Coconut trees exist in the colony in different varieties, nearly all having been planted by the Kanakas. Most of the groves are on the eastern side, where the majority of the tribes are to be found. This precious tree produces yearly from 50 to 80 nuts. The kernels, dried in the sun, are readily sold under the name of *coprah*, at from 300 to 350 francs (£12 to £14) per ton. This is the chief means by which the natives obtain the goods and luxuries of civilization. A few important groves are, however, held by Europeans. The other principal fruit trees are orange, lemon, banana, canella apple, mango, guava, Shanghai peach. In spite of indigenous valuable timber, no important felling of trees exists in New Caledonia. The quantity cut is not even sufficient for the use of the colony since New Zeland and California imported timber amounts to the yearly value of 500,000 francs (£20,000).—*Journal of Forestry.*

The Lemon.—Few people know the value of lemon juice. A piece of lemon bound upon a corn will cure it in a few days; it should be renewed night and morning. A free use of lemon juice and sugar will always relieve a cough. Most people feel poorly in the spring, but if they would eat a lemon before breakfast everyday for a week, with or without sugar as they like, they would find it better than any medicine. Lemon juice, used according to this recipe will sometimes cure consumption. Put a dozen lemons into cold water and slowly bring to a boil; boil slowly until the lemons are soft, then squeeze until all the juice is exhausted; add sugar to your taste and drink. In this way use one dozen lemons a day. If they cause pain or loosen the bowels too much lessen the quantity and use only six a day until you are better, and then begin a dozen a day. After using five or six dozen the patient will begin to gain flesh and enjoy food. Hold on to the lemons and still use them freely for several weeks more. Another use for lemons is for refreshing drink in summer, or in sickness at any time. Prepare as above directed and add water and sugar. But in order to have this keep well, after boiling the lemons squeeze and strain carefully; then to every ½ pint of juice add 1 lb. of crushed sugar; boil and stir a few minutes more until the sugar is dissolved, skim carefully and bottle. You will get more juice from the lemons by boiling them, and the preparation keeps better.—*San Francisco Chronicle.*

The Artificial Manure Trade.—Of late a very large trade has sprung up in Germany in artificial manures, the chemical industry of this country having scored various successes over foreign products. In regard to Thomas phosphate, which is coming into extensive use, it is stated that when it is mixed with kainit in equal parts a manure admirably suited to barely ground is the result. A couple of years ago an agriculturist spread 1,600 kilog. (about 3,360 English lb.) of Thomas phosphate flour upon half a hectare of ground (5,980 square yards) in order to see if an excessive quantity acted injuriously and if the effect would last over several years. In the first year three excellent crops were obtained and this year a similar number, the quality of the hay being better than before.—*Kuhlow's German Trade Review and Exporter.*

How wood is made.—In many trees the annual layer is so regular, and seemed to be placed so nicely, that one not a botanist might be pardoned for believing that the sap was changed to woody matter in the leaves, and the new formed matter sent down, sliding over the old layer like the sections of a telescope; but though the food is prepared by the leaves in a great measure, the actual growth is made by the germination of some of the cells along the whole outside wall of last year's wood beneath the inner bark. The germination of the cells takes place about the middle of the June. He takes a healthy cherry tree and strips it of its bark to any length desired. At that season a viscid liquid will be found covering the woody surface in abundance. The stripped part is covered with a cloth to prevent evaporation, and in a few days numerous dots like needle points, will be seen about the sixteenth of an inch apart all over the surface. These are the young cells that have germinated from those of last year. They continue germinating, one from the other, until they meet, when they unite and form a complete surface. In the autumn a layer of wood will be found just as thick as in the part of the tree not disbarked, and a single layer of liber, with its outer coat of cellular matter—perfect bark—will have been formed over the whole. The entire formation of wood and bark can thus be seen by the ordinary observer, without the necessity of any nice microscopical work. Large apple trees have been seen that have had their bark peeled wholly off from their trunks, at the season named, make an entirely new layer of bark and wood, not only with no injury to the tree, but to its manifest enjoyment. By this experiment we learn that there is no difference primarily in any part of the annual covering. The same cell may become permanent tissue or generating tissue, and from the generative tissue may come before the season of growth closes every form of structure known to anatomists, from pure wood to the outermost cuticle of the bark. How these cells become differentiated may be passed over here. We know that cell-growth is not always uniform in its operations. The law that changes the outermost series of newly made cells into liber need not necessarily operate so exactly as to make them perfect to this end—a few may be thrown off into the liber as generative tissue—and granting this possibility we see how the woody granules in the apple bark are formed.—*Leader.*

FISH-CURING AND NATIVE INDUSTRY IN CEYLON.

Mr. C. J. A. Murray, A. G. A., Hambantota District.

FISH-CURING—FOOD SUPPLY—A NEW INDUSTRY.

Fish-curing.—Annexed is a copy of my report on the Fish-curing industry in this district:—

It was decided by Government, on the recommendation of the Auditor-General (Mr. Ravenscroft), to give some encouragement to the fish-curing industry in this country by the sale of salt at as low a rate as possible. Early in May the Auditor-General visited the District, and after inspecting some of the principal fishing stations along the coast, and making inquiries from the headmen about the quantity of fish caught and the number of canoes engaged in fishing, it was arranged to make a start at Hambantota. A yard was accordingly opened on the 15th October, in which the salt was retailed to curers at the reduced price of 80 cents per cwt., instead of at the Government price of R2·36, on the condition that the curing was to be carried on inside the enclosure. The dimensions of the yard were 200 feet by 100 feet wide. Three sheds were built for the carers to work in and store their fish, and also an office and a store for the salt, the whole being placed in charge of a Government Officer, with a salary of R30 a month, and two watchers at R12·50 each.

Unfavourable winds continued for a longer time than usual, preventing many of the larger boats from coming down from other stations along the coast; and this, combined with adverse currents, accounted for the small quantity of fish caught at first. About the end of January, however, things took a favourable turn: more boats began to arrive, and fishing commenced in earnest. The number of canoes of all kinds engaged in fishing amounted to twenty-seven. The annexed statement (marked A 1) gives the result of work in the yard up to the 15th of April, 1,207 cwt. of fresh fish were admitted, which turned out 835 cwt. of cured fish. A detailed statement of expenses, amounting to R514·93, connected with the yard during the same period is given in return B 1. 280 cwt. of salt realised R224, at 80 cents a cwt.; but as this sum only covers the cost of collection and transport, it cannot be counted as profit.

Encouraged by favourable reports from another fishing station, called Patanangalla, thirty-eight miles up the coast towards Batticaloa, I was induced to open another yard there on the 16th March, with the sanction of Government, and up to the present it has worked most satisfactorily: boats continued to arrive day after day until they numbered about nineteen. The amount of fresh fish admitted into the yard up to the 15th April was 360 cwt., turning out 120 cwt. of cured fish. The amount of salt sold at R1 per cwt. realised R65·20, and the cost of establishment, which is the same as at Hambantota, amounted with incidental charges to R132·50. Fishermen resort there for two months in the year, taking with them as much food as will last for that time. It is an isolated spot with no population, and nothing but jungle for miles around. A small bay affords some protection to the boats from the N.E. wind, and the sloping beach enables the canoes to be easily pulled up. Two small subsidiary stations were opened at Potana and Amadua to the right and left of Patanangalla, and were placed under the same officers. There were four boats at each place.

An English company started curing in this District on their own account in December, and sent down a manager to supervise all arrangements. It was thought advisable not to launch out into heavy expenditure at first, until some practical knowledge of the work was gained, and the quantity of fish that could be caught ascertained. The manager therefore confined himself simply to buying all fish at a paying rate, and salting and drying it according to the native method. The profits were not great, but the experience gained this year will no doubt be turned to good account next season, and produce some more tangible results.

The fishermen were the class who benefited most; for they sold their fish at once, and the competition among the curers raised the prices appreciably. Next come the native curers, who also derived a good profit, and this is proved by the large number (over 300) down in the register. They got their salt at a minimum price, the cost of watching was saved to them from the protection afforded by the yard, and the improved means used in salting and drying brought them a better price. They also took their cured fish to villages in the interior and to bazaars along the road to Badulla, getting a far higher price for it there than they would have obtained if it had been sent to Colombo. As far as I can ascertain, the cost of curing fish is R11·31 a cwt.

One cwt. of fish when dried is reduced to one-third its former weight, and the result must therefore be multiplied by three, making R11·33 as the prime cost of one cwt. of dried fish. All native curers send their fish to the markets along the Badulla road, such as Wellawaya, Koslanda, &c., where the prices range from R15 to R20 per cwt., and often as high as R30. After deducting one rupee per cwt. for cost of transport, the curer reaps a profit of from R3 to R4 a cwt. and where the fisherman is his own curer, the profits to him are double. Colombo is not a good maket at present, as it has to compete with foreign importations, which tend to keep down prices.

Food-Supply.—Annexed is a memorandum showing the yield of paddy and fine grain in this District, which, according to the last census, would give ten bushels per family. This is small compared with the supply of previous years, and is accounted for by the fact that a severe drought in Giruwa Pattu destroyed a good deal of paddy before it matured. The large yield of paddy at Tissa in Magam Pattu has produced a most marked change for the better in the condition of the villages lying near it; the inhabitants of which, intead of subsisting entirely on kurakkan and jungle produce, as formerly, have now a large proportion of rice for their food. Each village contributes a certain number of cultivators, who, after the harvest is over, bring back their labourers' share of the crop for themselves and their families. The paddy of this place even found its way to the Tangalla market, forty-seven miles off, in consequence of the supply there running short. The crop of jak-fruit in the gardens of Upper Giruwa Pattu was fair, and formed an important article of food among the poorer classes. Large quantities of the fruit are plucked when green, cut up and dried, and exchanged for paddy.

Miscellaneous. A new industry—that of making pith-hats—has been started in the jail. The plant which furnishes the pith grows in abundance in the tanks. It is cut into broad strips, and pasted over a mould of the required shape. The hats have been made, though not as neat as one could wish, have all been bought. I hope to induce the Malays in the town to take this industry up, as they show a peculiar aptitude for fancy work of this kind.

Sand Hills. A good deal of attention has been bestowed on the planting up of the sand hills during the year. There has been no further advance towards the town owing to the spike grass planted a year ago having taken root, and spreading so thickly as to prevent the sand from being blown along the surface. I speak only of the hill which threatened to overwhelm and bury the town; but for two miles down the road, towards Ambalantota, much has yet to be done in the way of planting spike grass. The parallel rows of live fences planted last year have been either killed by the intense heat or covered with sand. They have, however, undoubtedly been the means of checking the onward movement of the hills, and I have this year erected cadjan barriers to answer the same purpose until the grass spreads and renders them unnecessary. To give some idea of the rapidity with which everything is covered, I may state that the outermost barrier, fifteen feet high, was completely buried in a month. A sharp-pointed ridge of sand now marks its site. But I have to chronicle a more successful experiment in covering these hills with vegetation, and that is, the planting of palmirahs. This palm flourishes in similar soil in the Northern Province, and I saw no

reason why it should not thrive here. The dry climate is suited to its growth, and as the plant is tough and hardy it is able to withstand the strong wind that sweeps over the sand. The 500 nuts planted last year are all growing well, with healthy leaves, two feet and a half above ground. The success attending this attempt induced me to apply for 4,000 more, and these were planted in October and November last. They have all struck roof, and will no doubt appear above ground in another month or two. The successful growth of these palms is a subject for congratulation, as no one would have imagined in looking over the large expanse of sand that it was capable of producing anything. I have now applied to Government to assist me in procuring a fourth supply of 20,000 nuts. These will be planted out in thick belts, 100 yards wide by 200 long. The spike grass planted between the belts will be rooted out as more nuts are put in every year. The tops of palms will in time relieve the barren appearance of the place. Other experiments have been tried with the screwpine and warâ, both of which are growing well, specially the former, which will for a pretty fringe along the base of the hills.

JAVANESE FOR QUEENSLAND.

The following report from the British Consul at Batavia has been received by the Chief Secretary, under date 1st September:—

Sir,—I have the honour to acknowledge receipt of your despatch, No. 862,307, of the 9th July last, asking for information regarding the new class of Asiatic labour which is being introduced into your colony from Java, and in reply beg to inform you:

The natives who have been engaged here lately for employment on the sugar estates of Queensland belong almost entirely to the Bantam and Sunda districts of this island, and have the reputation of being hardy, strong, and well adapted for agricultural and other purposes; they are willing workmen at any trade, and are always ready to learn and set their hands to anything they are taught, although rather slow at picking up anything new. Their hours of work here are from 6 in the morning till 6 at night, with an interval in the middle of the day of about two to three hours. They cannot be said to be quick workers, but are very steady, and have wonderful powers of endurance. Their food is very plain, consisting chiefly of rice, fresh or dried meat or fish, and salt, With very few exceptions, hardly any of them have ever tasted alcohol, expressing a dislike for spirits of any kind.

They are accustomed to work in gangs under the direction of their native overseers, whom they look to as their masters, and whose word they attend to more than to that of a European; what they would consider as bullying from a European and resent as such, they would take without the slightest demur from their native headmen.

I am informed that the only provisions required by the Netherlands Indian Government to secure the welfare and return of the emigrants, after their terms of engagement has expired, is a bond, given by the firm here engaging them, certifying that they shall be well treated whilst in Queensland and guaranteeing their passage back to Java.

I am not at present in a position to venture an opinion regarding the probability of the natives remaining abroad after the expiration of their term of engagement, but I should think the difficulty experienced in obtaining women to accompany them would be a strong reason for their returning here when they can do so.

I have reason to believe that the Netherlands Indian Government is not in favour of this kind of emigration, and should it assume larger proportions, will probably prohibit it altogether, or place such obstacle in the way as to prevent it.

Enclosed I beg to hand you copy of a contract made between a firm here and some natives, who proceeded lately to your colony, which will doubtless be of interest to.—I am, sir, &c.,

N. M'Neill, H.B.M's Consul.

The contract referred to provides that the labourers shall "hold themselves in readiness to embark for Queensland, there to work for three years after arrival, certain of them as mandoors, the others as field labourers for and in accordance with the instructions of the other parties to the contract, on one or more of their sugar estates in Queensland." They are obliged to work ten hours a day, Sundays and other general holidays excepted. A salary of twenty-five guilders for every mandoor and seventeen guilders fifty cents to every field labourer will be paid per mensem from the date of their arrival in Queensland. Besides, they will be entitled to free board and lodging and free medical attendance. The food is to consist of rice, fresh or dried meat or fish, and salt. Their right to wages and food is immediately forfeited in case of their refusal to do the work assigned to them, only the case of sickness excepted, And an advance on his wages every appearer on the other part at the date of his going on board ship at——is paid an amount equal to three months' wages, to be paid back by monthly instalments to be retained on the said wages at the rate of four guilders for every mandoor and two guilders fiftycents for every field labourer. The passage from ——to Queensland, and at the expiration of the present covenant the passage home to——of the appearers on the other part is to be paid for by the appearer on the one part. The appearers on the other part, in so far as they have not appeared attended by their wives, may be accompanied by their wives. Only free passage out and home and free board will be allowed to these wives. On their performing any work wages are to be paid them, the amount of which is to be settled hereafter. Immediately after their arrival in Queensland the appearers on the other part are considered as having submitted to the ordinance enacted in 1861, regulating the connection between masters and workmen, the contents of which they declare to have well understood.—*Queenslander*

THE PURE PRODUCE COMPANY, LIMITED.

The Future of Ceylon Tea.

From "Stocks and Shares," October 16th, 1886.

"As an illustration of the position which Ceylon Tea is occupying in the London market, it may be interesting to note that only so far back as 1880, when attention was being practically drawn to this new industry of Tea cultivation in Ceylon, the production that year was about 115,000 lb, and this has gone on rapidly increasing to 7,000,000 of lb. in 1885-6; and the estimates for the next twelve months promise to reach 13,000,000 of lb., and so on till in 1889 90 the prospects indicate some 35,000,000.

"The imports of Chiua Tea into London during the past five years have uniformly averaged about 140,000,000 of lb, and from India there have been about 60 to 70,000,000, thus showing that while these two sources of supply exhibit no further development, that of Ceylon stands conspicuously forward as the channel whence we may derive the extra supplies to provide for the increased consumption going on in this country, and which at present averages 5 lb. per head.

"From all accounts, too, Ceylon Teas seem to possess qualities specially attractive, and if they could be placed before consumers at prices free from the heavy burden of excessive retail profits, which, from what we read and hear, amount to something like 8d. and 1s. per lb., they will no doubt enter largely into consumption, unmixed with Chinese and Indian.

"Profits like these of about £300,000 on 7,000,000 lb. of Tea, the value of which duty paid at, say 2s 6d. per lb. is £875,000, seems a large percentage. There can be no question, therefore, that any commercial enterprise having for its object the systematic development of the Ceylon trade cannot fail to prove highly remunerative. We commend this idea to Mincing Lane."

The above article, which appears in "Stocks and Shares," contains in its remarks so clearly the nature of the business which the "Ceylon Pure Produce Company" intend to carry out, that they take the

opportunity to reprint the paragraph in its entirity. The Company draw attention to the fact that they are making Ceylon Tea their speciality, as will be found in the accompanying Prospectus. The practical knowledge which will be brought to bear on the business they undertake, and their close connection with the Mincing Lane Markets, place the Company in a position to make their selections most advantageously from the entire importations brought into London; and by using all the extensive means at their command for publicity, the widest scope will be afforded to participate largely in distributing their Ceylon Tea at prices which will show an appreciable gain to the public, and in quantities to suit the most moderate orders.

Without indulging in any extravagant ideas, there seems no reason why the Company's sales should be limited to the moderately estimated amount of a quarter of a million lb annually, and if the profits be calculated, even at a considerable reduction, on the basis of those stated by "Stocks and Shares," they would still yield dividends which may be variously estimated from 20 to 30 per cent.

CEYLON TEAS.—"BULKED UNASSORTED."

In *I. A. Rucker & Bencraft's* Weekly Tea Circular October 21st, we read:—

Last week we referred to this subject, taking as an example of what we consider its importance the case of an estate, which shall be nameless, the produce of which we pointed out had apparently been experimented upon with a view to satisfying the planters as to whether or no our advice on this head was sound. We say our advice, as we have been hammering at it for a year, and have got some of our friends to adopt the method, while we are informed that in other quarters our recommendations are discountenanced, and the advantages we claim for the planter are denied by some who perhaps may not have had the time or inclination to go as thoroughly into the matter of blended Teas as we have in the last fifteen years. The proof in the pudding is in the eating, and we should have thought a clear loss of £300 on the assorted portion of the estate in question, even though only shown by our estimate, would have been enough to set people to work for themselves to see if there was "anything in it." For the satisfaction of those friends in Ceylon, who have acted upon our suggestions, we have determined to go a step further, and we now invite attention to the following facts which may confirm them in adhering to the decision to which we had led them, and which may benefit those who have not yet had a lengthened practical experience. It will be remembered that the "unassorted break"—which, we may explain to the uninitiated, was the portion of the yield, or picking, in which the Broken Pekoe, Two Pekoes, Pekoe fannings, and Pekoe Souchong were blended together and sold in one break—fetched one shilling and five pence farthing per pound. The remainder of the invoice sold in six separate breaks, averaged only one shilling and one penny farthing. We first heard it doubted whether the Teas were from the same garden. To this we can only say they are all marked with the estate name, and all comprised in one invoice. There is a slight discrepancy between the two lots which we shall allude to further on. The proportions in which the Teas came from the machine may be expressed thus:—Broken Pekoe 1·4; 1st Pekoe 5·8; Fannings 1·9; 2nd Pekoe 0·6; Dust 0·6; Pekoe Souchong 0·3. The dust, we take it, represents the entire quantity of dust from the whole invoice, whether assorted or unassorted, for we cannot find the proper proportion of dust in the 1s 5¼d parcel. We have taken the trouble to procure one of each of these particular six Teas, and have had them carefully blended in the same proportions as above, and with this result, our blend of the six Teas which when sold separately only averaged 1s 1½d, is worth a full *half-penny per lb. more* than the "unassorted" which realized 1s 5¼d. We account for this by the simple fact that the dust which of course sold by itself for a low figure—but has a grand pungent Pekoe flavoured liquor—assists to thicken and "fetch up" the bulk when added to it. Being, as we take it, removed from the entire parcel, the "unassorted," minus the dust, was in our opinion depreciated to the extent of ¼d per lb. Readers may recollect that in a less sprightly market on March 4th, 1885, we called attention to the sale of an entire invoice "unassorted" at 1s 6d per lb. "Certain buyers want fine broken Pekoes and give long prices for them, and we have to take that into consideration." To this we can only say, why should you take out the Pekoes, Fannings, and dust, to sell at a low figure in order that some one may buy the broken Pekoes at a long price and mix them again? "But then if everybody bulks his Teas 'unassorted,' we shall soon arrive at one dead level of price for Ceylons, and there will be no range from 7d to 3s 6d as formerly." John Chinaman has from the year 1840 adopted this plan, and a glance at a China Tea Broker's Circular will show there is no dead level for China Teas yet. Quotations for Congous still range from 5½d to 2s 6d in an average year, and this is for millions of pounds where Ceylons are still thousands. There is no doubt quality will tell in the price obtained for the "unassorted" Ceylons just as it does in the "unassorted" Chinas. Reflections will bring to mind several recent sales of unassorted parcels from different gardens selling same day and side by side at 11d and 1s 5d per lb. Besides we do not advocate treating the entire Tea crop of Ceylon in this way, it is quite open to the expert to decide how much of his broken Pekoe he will ship as it is, and how much return to the bulk, to assist in giving tip and appearance to the remainder of the parcel. It would be obviously absurd to lay down any hard and fast rule about it. Experience and judgment must guide the planter after all said and done, as to how he is to get the best return in money, and we trust we have indicated one direction in which he may look for a reward for thought and skill. There is no reason to be disheartened and discouraged if first efforts do not bring out a much higher result. The secret of the success of blending is that the finer Teas, owing to their greater strength and flavour, which over-master a much larger quantity of somewhat inferior Teas, and raise the quality of the bulk, but the exact limits to which to go without making the fine Tea resemble the proverbial needle in a bottle of hay, can only be arrived at by experiment and practice. It is perhaps worth while to point out once more that when there are ten millions of pounds of fine broken Pekoe the price is scarcely likely to be the same as now there is one million. In nine cases out of ten this fine broken Pekoe is blended—smothered we should perhaps call it—with vastly inferior Teas, for the drinkers of pure finest Ceylon broken Pekoes selling in the Rooms at 2s to 3s are few and far between. The description "unassorted" though perfectly well understood by the trade is somewhat misleading, and we are inclined to advocate boldly marking such Teas "Factory Blended." The planter may be sure of one thing, he is far more likely to send forward even quality by blending than by assorting. What planter would contract under penalty to ship from an estate a broken Pekoe of exactly the same quality six times running? yet by blending, contracts here can be taken for a year at a time with no fear of having goods declind as not up to muster.

The Ceylon Cinchona Syndicate proposal is discussed in the *Madras Mail*, in an article which will be found on our last page. Although a formal organisation is not likely to result now, yet the discussion will probably lead to a good many individual proprietors doing the work of a Syndicate, by holding their bark in quantities under warrant, rather than rushing it on the market. Advances can be got on such stocks within a safe margin.

THE CEYLON CINCHONA BARK RING SCHEME.

The low prices which have been realised for cinchona bark, owing to the enormous exports from Ceylon during the past two seasons, have led growers to cast about for some means of improving them, and a proposal, made by Mr. Sinclair, inthe Colombo papers, to form a bark "Ring," or Syndicate, has attracted a good deal of attention. Combinations of large holders of any article in general demand, who have agreed not to sell under a certain price, have occasionally resulted in large profits, and though the conditions existing in the present instance are very different, the idea must possess considerable fascination for the planter, with the unit of quinine down to 3d. The mode of procedure suggested is, that every producer in the "spicy island" should send his bark, after baling and analysis, to a store in Colombo, and agree only to ship in such quantity, and at such time, as the directors of the scheme should decide. Mr. Sinclair takes as his text the dictum of Messrs. Brooks and Green, wellknown London brokers, that "the price of cinchona depends entirely on the shipments from Ceylon,"—which may be accepted as a truth, though not an eternal one—and argues that, if growers could limit their supplies, the unit would rise from 3d to 6d A receipt specifying the variety and quantity of bark stored would be handed to the owner, and the Syndicate, by keeping itself well informed of the state of the market, could, it is thought, so regulate supplies, as to keep the price at paying level.

Mr. Sinclair himself mentions some of the difficulties to be encountered, but declares that none of them are insurmountable; for instance, that mortgagees would be unwilling to wait for their money; that most planters require the full value of their harvesting at once; "that the making a selection of bark for shipment would probably give rise to more discontent than any other difficulty;" and, lastly, that Java, India, or South America might step in and upset his plans. This last objection he cheerfully intends to combat by flooding the market on the first sign of aggressiveness on the part of any of these countries, and for our own part, we are disposed to think that "the selection of bark for shipment," on the occasion of one of these patriotic sacrifices being deemed necessary, would give rise to even greater discontent on the part of the devoted Syndics than the refusal of priority at other times. This could only be obviated by all growers agreeing to "pool" their bark; but such a suggestion is merely chimerical. The first and third difficulties might, perhaps, be overcome; as to the second, it is gravely suggested that the Banks would advance half the enhanced value (*i. e.*, the full present value) against the storekeeper's receipt. Perhaps Colombo Banks are fonder of dabbling in cinchona than Indian ones, but it would be a sanguine planter who, in this country, went to a Manager with such a 'heads I win, tails you lose" proposal; for, supposing the speculation failed, and prices did not rise, the Syndicate might simply hand over the key of the store to the Bank, and tell it to make the best it could of the business. Added to which—such are the peculiarities of the Ceylon law—if the store was found to be empty, it is more than doubtful if any remedy would exist. Another difficulty not noticed in the letter we are considering, is the fact that it is not so much the quantity of any articles that is actually up for auction in London, or Amsterdam, that fixes its price, as the quantity available, or soon expected to be available, in the export towns of the producing countries. The Brazilian planters used annually, when raising money for working expenses, to depress the coffee market with apocryphal tales of the magnificence of their blossom, and of the enormous crop they would be shipping in a few months. If rumours of this kind were believed, what might be expected to happen in the face of 10 million lb. or so, being actually stored in Colombo? Nor must the expenditure on rent, staff, and insurance be forgotten, all of which would have to be incurred for a very problematical advantage. The Syndicate is, apparently, to be worked without capital, excepting, we suppose, the monthly contributions of members for current expenses. The scheme is, however, one that essentially requires capital, and is not likely to succeed in the hands of men largely dependent for a livelihood on the article they are speculating with, and who are anxious to raise every anna they can to put into next season's tea extensions. For, after all, few Ceylon planters look upon their cinchona just now as anything but a means to that end. The price of bark is likely to rise in the near future, but it will be from the exhaustion of the supplies in Ceylon, and not from any artificial limitation thereof. Were it not for canker, it might be found more practicable to agree not to harvest more than a certain quantity of bark, whereby all storage expenses would be saved; but canker is ever present in the island, and the bark must be gathered from dying trees. The *Ceylon Observer* sensibly suggests that steps should be taken to ascertain what cinchona may be expected from India, and other countries; but such an enquiry would take time, and this the promoters of the Syndicate are anxious to save.

In conclusion, two facts may be borne in mind by any one desirous of meddling with a speculation of this kind, first, that though stocks of bark are not abnormally high, there does not seem to be any great competition amongst the buyers; all the bark is absorbed, but only on account of its low price. Enormously as the consumption of quinine has increased, there has been no exceptional demand—such as would be caused by a great war,—and it is very likely that a great deal of capital is looked up in quinine. Should, then, the supply of bark be limited, and the price be raised, manufacturers might be able to hold out, and refuse to buy for a longer time than would suit the Syndicate. The second point is that, when Ceylon planters boast of the possibility of driving all other bark than their own off the market, they forget that, in India certainly, and perhaps also in Java, bark can be harvested just as cheaply as in Ceylon. They have been talking so loudly of their "unrivalled labour supply"—which, by the way, seems to be rather short just now—that they have at last persuaded themselves that they work cheaper than any one else. As a matter of fact, a cooly on an estate in Cochin, Wynaad, Coorg, or the Nilgiris, often gets only half, and never more than two-thirds of the pay of his brother in Ceylon. It may be admitted that a 3d unit does not pay in either country, in the sense of giving a return on capital; but for one in the position of His Excellency's "enterprising citizen," with his cinchona ready to hand, it pays well enough for the mere harvesting and, as the Indian planters work more economically, it pays them better than the Ceylon one; so, as long as bark is saleable at all, no amount of Ceylon competition can drive out the Indian article. South American uncultivated bark can simply not be put on the market while prices remain at their present level; there is no question of capital involved there, but simply one of collection. It is usually said that a 6d unit admits this bark, and once the unit goes up to that figure it must be reckoned with. The Dimbula Planters Association has set to work to discover how much cinchona is actually left in Ceylon, and when the information has been published growers in Ceylon and elsewhere will know better what to expect.—*Madras Mail.*

COLIND EXHIBITION AND PLANTERS' ASSOCIATION.

Planters' Association of Ceylon, Kandy,
13th Nov. 1886.

To the Editors "Ceylon Observer."

Sirs,—I beg to enclose for publication copy of a letter from Mr. J. L. Shand on the subject of the Colonial and Indian Exhibition.—I am, sirs, yours faithfully, A. PHILIP, Secretary.

Ceylon Commission, Colonial and Indian Exhibition
South Kensington, S. W., 22nd October 1886.

Alex. Philip, Esq., Planters' Association of Ceylon, Kandy,

Dear Sir,—Your letters of the 14th and 24th have come to hand this week upon following days. The letter of the former date encloses addresses to which eight pamphlets have been sent and the latter a list of sixty-four. On receipt I have written to Messrs. P. O. Don & Co. but have not yet received their reply as to the 2,000 copies. I have not yet heard in reply to my formal application as to the registration of a trade mark, but as I was promised an answer within ten days, I am daily expecting it.

I have packed for you a box containing the Official publications connected with the Exhibition as per list enclosed. The box will also contain samples of the very best Trinidad cocoas which may be interesting for purposes of comparison, and a sample of Jamaica cardamoms. I conclude there is no use sending out samples of teas, though I shall be glad to do so at any time if it should be desired. We can draw no profitable comparison except from the finer Indian teas and I know many planters get regular supplies of these from home.

Referring to Mr. A. M. White's letter from which you send me extract, it is impossible to follow the course of markets by comparison drawn from specially prepared Exhibition samples, but the connection I have been able to form in the city among brokers in various products will enable me when I am released from my duties here to obtain information which may be of value, and such information will always be at the disposal of the Association. As regards improvement in cultivation or manufacture of our various products, we are so constantly taunted on this side with extolling our own wares, that it is gratifying to find there is still a school of disciples in Ceylon, but with the exception of cocoa about the mode of preparation of which there is much uncertainty, I am afraid I can offer no suggestions. When I asked Mr. Pasteur who is reporting upon the coffees in the Exhibition, if he could suggest any improvement in the preparation of coffee, his answer was that though much Ceylon coffee, now contained many defective beans, he believed it to be impossible to improve upon the system of curing in Colombo. I may mention that there is a strong and a growing feeling in favour of bringing coffee home in parchment and it is said that Java coffee sold in parchment in Amsterdam brings 6s per cwt. more than when cured in Java. Mr. Pasteur does not expect there would be anything like so much difference between Colombo and London cured coffee, but so many large dealers have spoken to me on the subject, that I have arranged to give it a trial. When I asked Dr. Paul if he could suggest any improvement in our systems of harvesting cinchona barks, he replied in the negative, but, he added, if you cease the shipment of twig and inferior barks your markets will improve. He is, as I mentioned before, strongly in favour of the cultivation of *C. robusta* in Ceylon. The same with tea, though Mr. Stanton tells us as we all well know that much Ceylon tea, leaves *much* to be desired in preparation. He will also tell you that the better marks from Ceylon leave *nothing* to be desired. Brokers have so long been pointing out the advantage of large breaks and of not sorting into too many grades that I need not enlarge upon it. I hope the few analyses Mr. Hughes is going to supply us with, may throw some light on the questions as to how much inferiority is due to faulty manufacture and how much to defective soil. It is hard, but I am convinced it often happens that Superintendents are blamed for bad prices when the fault lies really in the soil and this is a matter easy of proof. I hope the Association may see its way to a regular extended series of analyses. While on the subject of tea, I am sorry to hear that the result of Mr. Walker's enquiries as to the price at which crude petroleum can be put down in Colombo is by no means satisfactory, but as has just been pointed out to me by Mr. Hervey, the gentleman who first drew my attention to *Tarbutts Patent* we do not want crude petroleum, but the residue after the volatileilos have been extracted and he is sanguine that the result of further enquiries which have been set on foot will prove that the patent is practicable and will be economical in Ceylon.

I am sorry to be able to write in a different strain about the Japan tea chests to what I expressed formerly. My firm bought a shipment of Ceylon tea packed in half-chests of the momewood I think and several of them arrived with their sides stove in. The wood of which they are made is extremely brittle and shows that care must be exercised in purchasing these chests. I notice that some of the Indian chests have a small upright stick in each of the four corners of the chest from top to bottom which must tend materially to strengthen the chest. These Japan chests are so very neat and especially for sending to the country so much more attractive, that it will be a pity if the standard should be lowered.

The only Cardamoms in the Exhibition besides those from Ceylon, are a bottle from Jamaica a few from which I enclose as a curiosity: a sample of racemes (?) and fruit preserved in spirit from Grenada and two small boxes from India one from Merkara and one from Bangalore so there is but little opportunity of drawing comparisons, but ours are shown much better and look much better than any others. There is mention of cardamoms in the Straits Settlements' catalogue, but I have not yet been able to find them.

The Reports now being drawn up, on all those subjects will be interesting and though they are I believe in no way to draw attention to competitive merit, they will contain much valuable information. Mr. Stanton has, I am glad to say, had instructions to include Indian teas in his report. I will of course send you copies of these reports as soon as they are published. I have this moment had a letter from Mr. Pasteur asking me to go and see the samples of cocoa arranged in order of merit and I hope to do so. He showed me the other day a sample of cocoa which, guided by outward appearance only, would have been pronounced of great value, but which was almost worthless because it was mildewed inside.

Mr. White asks if I can not suggest any new products for Ceylon. I believe fibres on our wastelands and sericulture among natives will yet become large enterprises. Fibre machinery is rapidly being improved upon and if the proper machine for aloe manipulation can be found, it will yet be a large industry. If a chance of sending a few dried aloe leaves should arise, I think we might work out some practical good with them, but the market for the disposal of all the minor products which have been brought to my notice is so fickle and fanciful, that I hesitate to suggest, much less to recommend.

I enclose you rough copy of figures connected with the Tea Trade of the Colonies; there is nothing new in it, but it shews the extent of the various local markets.

There are few articles of food supply being pushed as Ceylon tea is; it is advertized everywhere, even on the programmes of theatres and new Companies are springing up all round us to push its sale. We have opened several foreign connections, which may I trust develope.

The fate and the future of the Exhibition is to be decided the day-after-tomorrow and you will probably know of it by telegram before you get this.

We had a Ceylon Dinner on Wednesday which the newspapers will probably have an account of. I need only mention that Sir Arthur Birch, Dr. Trimen and Mr. Saunders all referred to the excellence of the P. A. Arrangement and Show, and to how much this was attributable to Mr. Christie's personal exertion.

I lecture on Ceylon Tea here on Wednesday. I will send you by next mail an account of my receipts and disbursements. Meanwhile, to soothe the feelings of the anxious, I may remark that I hope to get a grant towards my incidental expenses from Sir A. Birch, which will leave the £50 you sent me untouched You will have heard of Mr. de Soyza's generosity.

Faithfully yours, Signed, J. L. SHAND.

CINCHONA BARK.

(From I. A. Rucker and Bencroft's Weekly Price Current.)

The last Bark sales went again in favour of sellers, and the unit may now be quoted at 3¼d to 3½d. Only 1,470 bales of Ceylon were offered, of which the bulk sold. 156 bales Java, direct import also all sold. Some of our readers may remember that in a recent circular we implied that at the September Dutch Bark sale, Barks were sold far and away cheaper than anything done in our London market, and we suggested that such a result must be additionally aggravating to the owners of the Java shipments, considering that the tone of our market was firm: the London sale shortly after the Dutch sale having given results slightly better than those of the London sale shortly before the Duch sale. We believe our facts to be correct, and the deductions drawn from them to be reasonable. Mr. Wischerhoff, a Rotterdam Drug broker, disagrees with us, and has written a rather lengthy pamphlet, which has reached us through the post, the receipt of which we take this opportunity of acknowledging with thanks. The basis of Mr. Wischerhoff's argument seems to be the following table, giving the results of the sale of 283 bales of Ledgeriana, on the 29th of September:—

Lots.	Sulphate of Quinine.	Price per ½ kilo. cents.			cents.
1 to 8	4.06	61	therefore per	unit	15.00
9 to 12	2.99	40	„	„	13.37
13 to 17	0.40	14	„	„	35.00
18 to 22	3.82	66	„	„	17.27
23 to 30	3.61	68	„	„	18.83
31 to 38	4.03	73	„	„	18.10
39 to 42	3.20	46	„	„	14.37
43 to 47	0.48	19	„	„	39.58
48 to 51	3.78	66	„	„	17.46
52 to 58	3.95	66	„	„	16.70

or on an average fully 20½ cents per unit. Of course, we may conclude that all these Barks were of a manufacturing quality, as, if Druggist's Barks were amongst them, Mr. Wischerhoff would not have felt justified in including them in his average. But the deductions drawn from such tests are of no commercial value. In Holland, either through erroneous testing, or through bad sampling, they appear to sell manufacturing Barks on one and the same day at 13 cents, and at 39 cents per unit. Mr. Wischerhoff, however, honourably acknowledges that the prices of Lots 13 to 17 and 43 to 47, are not comprehensible on the surface, and as, in a commercial argument, we prefer dealing with the comprehensible, not with the incomprehensible we have figured out the above table leaving out these two acknowledged doubtful lots, the result being that the unit value was 16¼ cents, not 20½ cents. All this, however, to our mind, goes for nothing. The question as to whether London or Amsterdam is the better Bark market, a question which some interests attempt to wrap up in obscurity, is really a remarkably simple one, and is solved by the large buyers whenever sales take place in Holland. Planters have and can again solve the question for themselves, but even they cannot know the rights of the whole question as easily and as completely as those who buy freely in both places. We should hardly have ventured to assert that the nett results of the last Dutch Bark sale were so very unsatisfactory, unless we had had high and unbiassed authority behind us. Growers and shippers of Bark in Java are no doubt fully aware that a Dutch Drug Broker would like to see Java shipments setting towards Holland, and that an English Bark Broker, on the contrary, would prefer to see his market getting the preference. As men of the world, therefore, we know that our opinion on this matter would carry but little weight, first, because we are biassed; second, because we ourselves have no means of getting properly drawn Dutch samples, if we had we could satisfy our own minds, by employing our own chemists, but Dutch firms would think the trial a doubtful one. Buyers, however, we think are to all intents and purposes unbiassed, indeed, if biassed at all, it would be towards the cheaper market. All Barks offered and sold during the year in London and Holland are analysed by the buyer who is the authority for our statement. The same chemists in the same laboratory work out the results for him, and as he is one of the largest, at the present date we believe the largest buyer of Bark in the world, we imagine his opinion will carry weight and practically decide this vexed question. He endorses every word we have said as to the superiority of this market. In addition to this we know that another large buyer interviewed him on this subject, in order to compare results, and that it was mutually agreed between them that far and away the cheapest Bark sold this year was at the last sale in Holland. Again, we have put the question to another large buyer, a gentleman whose firm's name is a household word in the Bark trade, and he assures us that there is no doubt about the matter, and that the causes are not far to seek. We believe we are correct when we state that the representatives of the two former gentlemen bought between them about three-fourths of the whole Dutch sale. We, therefore, with every apology to Mr. Wischerhoff, must perist in dogmatically asserting that his question is answered as far as results go, Java. Cinchona, Holland or London? London. Only a short time ago, as Java planters must by this time be fully aware, a consignment of 200 bales of Java Bark was most carefully bulked and divided, half going to Holland, half to London. The shippers made a bona fide attempt to solve the question of markets for themselves, the result being that their experiment cost them £120, the 100 bales sold in Holland, realizing £120 less money than the 100 bales sold in London. It is on the opinions of high class merchants, and on facts such as the latter, that we venture, to use Mr. Wischerhoff's own words, to offer our persevering, benevolent, and sympathizing counsels to those shippers who still doubt which is the better market. As we are short of time, we will only add that we disagree altogether with Mr. Wischerhoff's remarks about sampling: according to him, the more faulty the samples, the more they vary one with another, the more unrepresentative they are of the bulks, the better the competition and the more satisfactory the result. We, on our part, like to know that what a buyer thinks he has bought, he has really got, and such is the result of London sampling.

CINCHONA BARK ANALYSES.

We have been favoured with a copy of a Circular-report by Mr. T. R. Visey of the Analytical Laboratory, Ilford, which contains certain curious information worthy of the attention of our Ceylon planters. The correspondent who is good enough to send the circular, says, "the charges made against analysts generally are severe"; but unfortunately there is so much that smacks of self-advertising about some paragraphs that we can scarcely give so much weight as we otherwise should to all that is said. However, our readers can judge for themselves; here is the report:—

CINCHONA BARK.

Analytical Laboratory High Street, Ilford, Essex, October, 1886.—The Ceylon Crop for 1885-8, having just closed, and New Season commenced affords a fitting opportunity to glance at the general position Concerning the future it is a certain fact that the Crop of Java Bark will be heavier and probably include a larger quantity of fine quality. The export from East India will also show increase, but to what extent, depends materially upon the decision of the owners whether they will cut their Bark at preent rates; from a private source I hear there is an inclination on the part of some owners not to Harvest at present, but wait a little in hope of better

values. What will Ceylon Ship in the coming Season? This is the special question affecting everyone interested in Bark, whether Buyer or Seller. Although estimates ranging from 12 millions upwards have been mentioned, I do not think at this date it is possible to form any definite conclusion. The quantity that may be harvested (under any circumstances) to make room for Tea or other produce. Amount likely to be cut for financial reasons, and still more important the course of market, all these uncertainties render an estimate at present moment of little value. But unquestionably the principal point that will guide the bulk of the merchants, will be the price likely to be obtained, and it is to this I desire to direct especial attention. All interested in Bark are anxious to see the Ceylon export as moderate as possible and yet the same mistake made in previous years of quoting values too high is actually being made at the present moment, when the error can only be of disadvantage to owners. From the various analyses I have made, compared with the Manufacturers Tests, I state positively that the bulk of the Bark sold in Public Auction during the past month has been quitted at 2¼d. to 2¾d. per Unit, and for very low grades occasionally 2d per Unit. I heartily wish the rates were doubled, but there is no good in disguising facts, indeed at the present moment it is especially a mistaken policy to quote the Unit value above what is obtainable, and Manufacturers know that they have purchased on this (and very Fine Barks) at other Markets at the above prices.

The explanation of the principal cause of the Unit value being quoted too high is the most unpleasant duty I feel thrust upon me, but in the interest of owners I cannot avoid it, although the knowledge came to me during the first month I was established, I have deferred any reference to the fact, until my business was thoroughly successful, to avoid any reference.

For some considerable time past certain Analyses of Cinchona Bark have shown a failure to obtain the FULL and proper per centage of Quinine contained in the Bark Analyzed and as a necessitous result the price realized has worked out 3d to 3½d and in some cases even more per Unit. This failure to obtain a proper result or in other words an under estimate, is to me inexplicable with a thoroughly practical test; I have Analysed samples of Bark and seen the Parcel manufactured confirming my Tests and cannot give way to anybody in the question of accuracy and therefore feel confident in repeating that where Analyses during the past month have repeatedly shown a unit value of over 3d such results have not found the proper and full contents of the Bark, or in other words the Analyses were incorrect. But beyond the statement already made I would point out that German Quinine has been sold in large quantities recently at not over 2/- per oz. and manufacturers are now making fairly satisfactory profits :—

	£	s.	d.	
Now @ 3d per Unit = 100 Units = 1 lb.				
=100 Units @ 3d	1	5	0	per lb.
Manufacturers' charges, Buying Commissions, Clearing, Making, &c., say about	0	7	6	"
	1	12	6	
1 lb. = 16 oz. Quinine @ 2/- ..	1	12	0	

This I think is conclusive proof that buyers cannot affort to pay regularly even 3d per Unit at the present price of Quinine, as a matter of fact they have often purchased lately at nearer 2d per Unit as reckoned by the proper and full Analysis of the Bark.

Before closing my letter, there is one small matter I would refer to—Several Samples sent me the owners have desired an Analysis made giving all the Sulphates and Alkaloids (charge 17/6) and of course I am pleased to comply with the request, but as the Sulphate of Quinidine and Cinchona and Amorphous Alkaloids are not now of any particular value to Manufacturers and consequently the proportions do not affect the value of the Bark in the least, and it is no advantage to know the quantities contained therein, with the present low value of Cinchona Bark I would point out that an Analysis showing—

Sulphate of Quinine .. .. per cent
Sulphate of Cinchonidine .. do.

for which my charge is 12/6 is really all that Importers require, to determine the value of their Consignments.

The variation in prices of Ceylon Bark, I recently announced by Circular, continues; Parcels containing a heavy quantity of Cinchonidine, realizing less per Unit than pure Barks with little Cinchonidine.

I recently Analyzed some Ceylon shavings giving about 2 per cent of Quinine and about 3½ per cent of Cinchonidine, a most unsatisfactory Bark for manufacturers to have to work.—Yours truly,

T. R. Visey.

Ceylon Tea.—On the 27th instant, in the Conference-hall of the Colonial and Indian Exhibition, a lecture was delivered by Mr. J. L. Shand, representative of the Planters' Association of Ceylon, on the subject of "Ceylon Tea." In the course of his lecture Mr. Shand said that at the time when the prospects of coffee growing in Ceylon were brightest the whole industry was checked and finally blighted by the appearance of an ineradicable disease in the coffee leaf. Industrial attention in the country was then directed to the cultivation of various other products, but it soon became apparent that if the large area of hill property in European hands were to retain its value it must be by the agency of tea. The coffee plantations were gradually converted into tea plantations; and as the first specimens of Ceylon-grown tea sent to test the London market were very favourably received the industry developed rapidly. It was not, however, till 1880 that the Ceylon planters began to send tea to the English market in any quantity. In that year 115,000 lb. of tea were shipped to the United Kingdom, while the year 1885 this amount had increased to no less than 4,353,000 lb. There were now about 120,000 acres in Ceylon planted with tea, and it had been proved that the country was capable of producing a greater yield of leaf per acre than any other country in the world, and that its tea could command higher prices than any other tea in the market. In the very near future the tea export from Ceylon would amount to 40,000,000lb., and, indeed, the only danger which the industry had to apprehend was lest it should overflood the markets of the world, scientific authority having declared that the fatal disease which had attacked and ruined the Ceylon coffee plantations was incapable of injuring the tea plants. Did the British people thoroughly understand the difference between the pure, clean, machine-prepared leaf which was turned out from the Ceylon planter's factory, they would never touch the far from pure article prepared by the hands and feet of the natives in China or Japan. Ceylon offered advantages for tea growing which no other country could afford. The climate was favourable and thoroughly congenial to European life, there was an abundant supply of labour at hand, the facilities for transport over the country by road and rail were exceptionally great, and the soil was very favourable. The Ceylon planters had suffered considerably by the action of dishonest tradesmen in passing off cheap China teas as genuine Ceylon tea, which cost them nearly twice as much. The Ceylon tea was pre-eminent for purity, wholesomeness, and economy; and though nominally it could not be purchased so cheaply as some of the worthless China tea, yet it would be found to go much further than its low-priced competitor. In regard to openings in Ceylon for young men from England, he would advise that no young man should go out unless he had a certain prospect of employment or had enough capital to embark in tea industry and enough caution to control the capital. The field of employment was limited, only 146 European planters being at work, while vacancies were chiefly in the patronage of London firms. Moreover, there were no other directions in which a young man who had failed to find an opening in the tea industry could turn his energies.

CEYLON UPCOUNTRY PLANTING REPORT.

JACKSON'S AND LAW'S T ROLLERS COMBINED—TEA UNDER CINCHONA.

8th Nov. 1886.

I hear that if the table of Messrs. Law and Davidson's Simplex Roller is supplied to any of Jackson's rollers, it has the effect of getting about twice as much work out of the machine as it would otherwise accomplish. There is an arrangement of battens which brings about this result, assisted by the peculiar shape of the table. I fancy we will be hearing more of this combination by-and-bye, as there are several trials being made.

Tea grown under cinchona, is as we all know, not a happy combination: but it is being observed that although cinchona does not suit tea, the tea suits the cinchona giving it a more vigorous growth, and benefiting it all round. If this really be so, there is some comfort, and one will be able to regard the slow progress of the tea plant when shaded with cinchona with less fitfulness than before. The time will not be altogether lost.

The weather still keeps very suitable for planting and cacao—but we would all willingly take a little more sunshine just to brighten up things. But the dark skies are pretty persistent, and almost daily there is rain. There are very general complaints of the effects of this dull weather in retarding the flushing of tea, and the returns of quantity up to date are considerably below what were anticipated, and might have been got had there been more of our usual genial warmth.

The rise in the price of coffee is bringing round more than the ordinary number of Moormen who are all anxious to buy refuse. Evidently there is a little excitement among these keen traders, and they are not afraid to speculate. But their means of doing so are now very limited as compared to what obtained in the happy past, and one bad shot generally closes up the unfortunate for that season anyhow.

Still it is wonderful how they return to the charge, season after season, and are willing to try again so as to turn "the honest penny" if by any means possible. To deal with them, however, one wants to have a good temper for they will haggle for an hour over a few cents, and hang about for a day if half a rupee can be saved.

PEPPERCORN.

NEW INDIGO COUNTRIES:

TROPICAL CEYLON.

When youngsters, long before we even dreamt that our life should be spent in the East, we often pictured to ourselves paddling longrafts or rough canoes shaped from tree trunks through interminable forests, or inhabiting a cottage of wicker or hut made from the unbarked logs of some gigantic tree on every side surrounded by luxuriant vegetation, and jungles infested by wild beasts and poisonous reptiles. The reality of the picture is the plains of Hindustan, with their dry, arid landscape, where four months in the year we are roasted, four stewed, leaving four months to revivify the remains of vitality left by the two preceding operations. This reality was a sore blow to our youthful imaginations but years of labour and toil have tutored us to find some beauties even in the uncongenial clime of India. Nor do we admire the native, but long intercourse with him, his ways and his conditions of life make us sympathise, and in some cases have a sneaking fondness for the Hindoo. He is not a bad fellow if you have a touch of autocratic dignity added to the fellow feeling of man to man; but he is never grateful and never will be so. Let us take him as he is. He was made so and cannot help himself.

Ceylon realized the vague dreams of our youth. Here we found the vegetation of the tropics; on every side some new palm or gorgeous flowering shrub, while the elephantine polonga and the cobra proved by their presence that there were big beasts and reptiles to be found in the spicy Isle. The natives there, probably like all Orientals, were to the youngest child open and smiling. The young girl turned not away her head, as though we intended to eat her up, but though not understanding our particular language gave us a sunny smile and jabbered in her own tongue sonorous syllables of Sanscrit-like sound and merrily passed on to her work. The terraced ricefields peculiar to Ceylon attracted our attention when travelling by rail, and miles and miles of terraced ranges, from one to many yards wide, rose up and up till thousands of feet still saw these wonderful terraces rising one over the other to the mountain top. Rice is the staple crop of the Cingalese and the rice season varies, there are two sowings and reapings according to locality and elevation. The country in some places seemed suitable for the growth of indigo and in some parts of the island Mr. Falkner, a Bengal planter who visited it, found the indigo plant growing spontaneously and in considerable quantity.

The following notes are from one of the many useful books published in Ceylon by the *Observer* Office. The cultivation of indigo in the seven Korales begun by the Dutch in 1646 was unsuccessful, and Governor Barnes in 1826 lost money over this article. Mr. Henley, a Bengal planter tried indigo also in the Southern Provinces, but failed in his attempt to grow it properly. An attempt has more recently been made to grow it in the Northern Provinces. Bennett considered the Tangalla district the best adapted for the culture and manufacture of indigo, and he thinks it almost incredible that no export of the dye has taken place since the Dutch Rule in 1794, though the plant (Indigofera tinctoria) in both the varieties, sativa and agrestis grows in most prolific abundance. He adds that in 1817 an extensive Bengal planter, Mr. Falkner, who visited Ceylon, was delighted to see indigo growing wild and made a proposal to commence the industry, but it fell through.

A Swedish gentleman, a Mr. John Tranchell, next proposed the formation of an indigo factory to Sir Edward Barnes, but Mr. Tranchell's death in 1828 knocked the scheme on the head. From the above it seems that indigo has never been properly tried in Ceylon. The drawbacks are labour and getting land. Though the land in the low countries is very cheap, if the Government were anxious to help the introduction of a new industry, Crown land might be had on very favourable terms. There is no doubt that the climate of Ceylon would prove just the thing for indigo, and that indigo made in Ceylon would equal the finest marks of Bengal, Java, San Salvador or Guatemala. The difficulty of labour is every year becoming less, as large quantities of the Tamil coolie class, are really settling in the island, and the increase of steam implements to the indigo industry in all its branches, such a steam ploughs, steam diggers, tramways, pumping water—heating boilers—all by steam, only leave the pressing operations for hand labour and the necessary fine work such as hoeing, weeding and ploughing for manual labour.—*Indian Planters' Gazette.*

ARTIFICIAL QUININE.

The paragraph declaring that an English doctor had discovered a process for manufacturing artificial quinine is still on its travels round the globe. This week an East Indian merchant sent to our office to ascertain where he could buy some. Customers of his in Calcutta and Bombay had decided to try it. A cable message from us to our Australasian subsidiary journal anticipated any possible scare there on the subject, and we may also claim to have saved America to some extent from a reign of terror in the quinine market. The representative of the largest New York daily paper called on us immediately after the discovery had been announced, and intimated his intention of including the item in his daily mes-

sage. The correspondent had his own doubts as to the accuracy of the *Morning Post's* chemistry, and these doubts were confirmed after some conversation in this office, a conversation which left its impress on the message ultimately sent. Still, as we said, there are quarters where, naturally enough, the reports find credence. Within the past few days we notice that a well-known pharmacist of the Hague, Mr. J. Th. Mouton, who has interested himself in the Amsterdam Quinine Works, writes to the Dutch papers, begging them to point out that there is no truth in the discovery, or he says the efforts to raise fresh capital for the Amsterdam Quinine Works will fail, owing to the fear that the discovery is genuine.

Lastly, there have been gentlemen of the company promoting persuasion, who, neither believing nor disbelieving the assertions made; thought there might be enough faith on the earth to get a limited enterprise floated on the strength thereof. We have heard several times that preliminary steps had been taken, that some more samples were in course of analysis, that a prospectus was nearly ready, and so on; but hitherto no company has been actually registered.

The most definite report stated that everything was now ready, and that Messrs. Burroughs, Wellcome & Co., having satisfied themselves of the genuineness of the discovery, were taking it up, and that the manufacture was to be carried on at their factory at Wandsworth. To ascertain how much truth this statement contained we called on Mr. Burroughs, whose information was given somewhat as follows:—

"Mr. Cresswell Hewett was introduced to us by another medical man with samples of quinine, which it was professed he had made. We understood that he asked 20,000*l.* for his secret. This sum we told him we were willing to pay. He said he could make a ton a week. We told him a pound would be sufficient, but that we stipulated we should see him make it. Then he wanted 1,000*l.* a year salary. We told him he should have that too, and we offered to deposit 21,000*l.*, payable to his order as soon as he had satisfied us that his process was a genuine one. He went to see our factory and agreed that the arrangements were suitable, but he said he would have to go to the Continent to get some apparatus. We reminded him that he had declared he had made his samples in his own rooms, and declined to advance money for Continental apparatus. Ultimately he came on to our solicitors, and wanted to make other stipulations. We were willing to agree to most of his conditions, but we firmly declined to advance him any money for expenses or salary till he had shown us his process at work. He left us, I suppose to find some one more pliable."—*Chemist and Druggist*, Oct. 23rd.

AMERICAN OPINION ON THE QUININE MARKET.

A representative of the *American Drug Reporter* called last week upon Mr. L. Engelhorn, the manager of the New York branch of C. F. Bohringer & Sons, the quinine manufacturers of Mannheim, Germany, to ascertain if he found any new developments in the quinine market during his two months stay abroad which would give encouragement to operators here. After speaking about the exposure of the London chemist's tactics in the artificial quinine fraud, mention of which is made in our editorial columns, Mr. Engelhorn proceeded to discuss the subject in hand as follows:—

"The bark shipments were somewhat reduced during the past three months, and the trade thought that it was the beginning of a new era in prices, but the large shipments for the last auction rather dispelled this idea and made future calculations uncertain; they were too heavy to expect in the near future such a decrease in barks as to justify any considerable advance in the price of quinine. The principal argument for higher prices lies in the fact that a very large percentage of the receipts at London are root barks, thus showing a desire on the part of the planters to substitute more remunerative products, such as tea and coffee for the profitless cinchona barks, The time is certainly approaching when a shortage of barks will cause an important change in the quinine market, but that event is yet too distant for any reliable opinion to be expressed on the probabilities. Considering the present cost of making quinine, based upon ruling prices for bark, I must consider the present prices for quinine as cheap, and it is to be presumed that those who purchase now and can afford to carry their stocks will ultimately make some money on them. As to the profits of manufacturers, I would say that after striking an average for the year they will find themselves behind. The bark shipments have been a surprise to the manufacturers; they increase when least expected and the price of quinine is consequently forced down while that of bark is not, as the latter has never gone below 3d to 3½d per unit; since last October the shipments of bark have increased 25 per cent over the similar period of last year. Owing to the cheapness of quinine, the consumption of cinchonidia has decreased somewhat, but its production as a by-product of the Ceylon barks has increased largely, and is estimated at five times greater than the consumption, which caused prices to drop very low. For instance there was a sale of 20,000 ounces of cinchonidia in this city last Wednesday at 4c per ounce; one year ago we sold cinchonidia at 30c and today our price is 10c. About ten years ago that article was scarcely known as manufacturers of quinine did not know how to make cinchonidia, but now it is a by-product with all of them. Returning to the question of profit in making quinine it may interest to you learn that, as we are informed, some manufacturers are so thoroughly disgusted with the business that they would willingly receive proposals from some one to buy them out. The Amsterdam factory is closed for good after entailing heavy losses on account of small capacity, as it costs considerably more to operate a small work. But one more fact remains to be told and that is concerning the production of quinine, which has not increased to the proportion of increase in consumption which is gaining every year."—*Drug Reporter*, Sept. 15th.

ANOTHER OPINION ON THE QUININE MARKET.

Mr. J. Hasslacher, of the firm of Roessler & Hasslacher, agents for the Gold and Silver brand of quinine, is not inclined to entertain the opinion so generally expressed about cinchona bark and quinine prospects. As he has been spending some time abroad looking over the field, and arrived home last week, are presentative of the "Reporter" monopolized a portion of his time since then to inquire about the situation from his standpoint. He did not believe that quinine would ever reach the prices of former times; but it was more than probable that prices would continue to fluctuate on a low basis; competition is too close for manufacturers to realize any large margin on their product, and the price of barks is not likely to be much higher, for the reason that a plentiful supply may always be expected, except in case of war or some other unforseen circumstance. Mr. Hasslacher was asked:

"Are you not a believer in the reports about discouraged planters substituting tea and coffee for cinchona barks, on account of the low price of the latter?

"No, decidedly no; ever since the cultivation of barks commenced we have heard the same story repeated each year, and still they go on growing more barks than ever. The production of barks will keep on increasing, instead of decreasing, notwithstanding reports to the contrary, and the alleged fact that large shipments of roots are made to the London market. Planters have never been satisfied and never will, but there must be money in the business or they would not continue it. Whenever shipments of bark are light then we are informed as the cause that an important shortage exists and that other crops are taking its place; but the trade is surprised in the following few days or weeks by a deluge of barks, evidently held to await the result of the preconcerted arrangements to bull the market by unreliable rumors. No, the trade in quinine will not soon be benefited by any radical change in the bark situation, and I would advise speculators to let it alone—I mean those capitalists who buy and hold for a rise in the market, not the

legitimate traders in the article who contract ahead for supplies to meet regular wants, in anticipation of prices being against them in the future. Speculation, in the true sense of the term, is damaging to legitimate business and should be discouraged. The position of quinine today is not what it was several years ago, and manufacturers have to confront a change which is against their interests and to the benefit of the consumers. Instead of bark shipments being periodical and uncertain, made so by the crude method of gathering, the devastating wars, floods, &c., we can now rely on weekly shipments and a stock in London from which to draw upon, besides having no disturbance to trade or transportation.

"There is little money in the quinine business to manufacturers, but it can be produced cheaper abroad than here. We have enlarged our factory, as the increased consumption caused principally by the low market, makes it necessary to increase our capacity. During the fiscal year closed last June, our quinine factory created a sinking fund and declared a dividend of five per cent. This is a good showing for an off-year when prices never ruled so low. There is one important fact which has not yet appeared in print; in Germany the retail price of quinine is fixed by law, and consumers have been compelled to pay the same price established several years ago against their strong protest. Physicians state that the consumption of quinine in Germany would be much larger if the price was lower, and they are now agitating a change in the law to have the retail price fluctuate with the wholesale rate and allow the public to reap the benefit instead of the pharmacists, who realize a large margin of profit at present The feeling is so strong on this question that a change is looked for, and quinine manufacturers are of course helping the movement along. The so-called substitutes for quinine are not injuring the sale of the article abroad, as the substitutes are only used for reducing the temperature and not for destroying the germs of the fever, like quinine does."—*Drug Reporter*, Sept, 30th.

ARTIFICIAL QUININE.

It happened rather curiously last week that just as our editorial note, dealing with the somewhat unfortunate observations of the *Oil, Paint, and Drug Reporter*, was passing through the press, we should receive a communication upon one of the very subjects our contemporary appears to be so anxious about. Even yet, however, the *denouement* longed for by the *Reporter* has not—as its readers would probably say—eventuated. Mr. Cresswell Hewett's artificial quinine has, up to the present time, neither demonstrated its own veracity by being turned out by hundredweights per diem at a cost of 3d per ounce, nor has the entire scheme resolved itself into thin air, or something even thinner still, by exploding altogether as so many company concerns of the "limited" class did in the beginning, are doing at the present moment, and probably ever will do to the end of our national existence. Although we cannot oblige our transatlantic critic with the percussional sensation so ardently desired, we publish today an important narrative which he may probably regard as a small instalment of that *denouement* which our contemporary appears to consider as the only fit and proper solution of the whole mystery.

The salient points of this quinine story are capable of being summed up in a very few words, although, the last of such words—by a good many—has not yet been spoken. Let us state the chief facts of the case and see how we stand:—Observing an announcement in several papers nearly two months ago to the effect that a certain Mr. Cresswell Hewett had discovered a method of preparing quinine by synthesis, at a cost of less than 3d per ounce, Dr. Burton, of Bucklersbury, at once caused negotiations to be opened with the alleged discoverer, through the intermediary of a friend, in the first instance, as is usual in such cases. On his offers being accepted, Dr. Burton declared himself, and, according to the account furnished to our representative as given in another column, he has all along been desirous of pushing the matter forward to a satisfactory issue, and of fulfilling his part of the arrangement said to have been concluded as between vendor and purchaser. Representing not only himself, but several other gentlemen, including Mr. Bland, Messrs. Burroughs, Wellcome and Co., &c., it has been stated to us by Dr. Burton that, not only were the general, but also the financial, arrangements absolutely completed and the sum of £21,000 could have been handed to Mr. Hewett within seven days after he had really produced a couple of pounds of sulphate of quinine which should stand all reasonable tests, chemical and therapeutical.

That the latter proviso is fully as important as the former, cannot be doubted when we consider the large number of substances known to modern chemists whose composition is absolutely identical, but whose properties are widely different in one or more respects. Thus, for example, there appear to be a whole host of bodies with the common formula of $C_{10}H_{16}$ but perhaps in no two instances do even the physical characteristics of these substances agree. Their specific gravity, boiling-point, index of refraction, &c., are all unlike, to say nothing of the variations apparent in their odour, taste, and pharmacology. Sometimes these differences may be reconciled by a study of the particular way in which the elements they contain are grouped together; in other instances, the bodies split up precisely the same manner, and no light is afforded from this direction. Quite recently the readers of our "Science Notes" may have noticed that an Italian enquirer has ascertained that there are two distinct modifications of the vegetable principle known as Asparagine. Both kinds agree in most respects; in appearance, in composition, and in general properties they may be deemed absolutely indentical, but it is possible that they differ therapeutically to some extent, and it is certain that their optical properties are diametrically opposed. Hence we can only fall back upon an old and crude method of distinguishing them and say that a solution of *a*-Asparagine rotates a ray of polarized light one way, and *B*-Asparagine twists it just as much, but in precisely the opposite direction.

It may therefore be the same with quinine, and in our readiness to welcome the "Queen of Specifics," produced—if this can really be done—artificially, at a nominal cost, for the benefit of suffering humanity, there can be no more important clause in any agreement pertaining to what we consider as $C_{20}H_{24}N_2O_2$ than that which, as in the draft we publish today, provides that the substance must be *medically*, as well as chemically and physically, indistinguishable from "Howard's Quinine."

To return to our narrative; so confident does the inventor appear to have been of his success that he actually accompanied the intending purchasers of this secret to a factory at Wandsworth—the very same by the way, that was described and illustrated in these pages some time ago—where he selected the room and some part of the appliances needed for the production of the test sample. After this there was practically no progress made, or information obtained until the publication of our supplement of last week and the determination of Dr. Burton and his coadjutors to leave no stone unturned to discover the truth, and to bring the question to a climax of one sort or another, by applying for an injunction in defence of their alleged rights. Meanwhile a Mr. J. F. Bunting, described as a surveyor, of Ponders End, speaks with calm confidence of the prospects of the Atlas Quinine Company and of what his "principal" is going to do. In the interests of either or both parties to this curious *embroglio*, of the public, and of truth, we shall be happy to do anything in our power which may facilitate the investigation.

We shall next week publish a special analytical report upon an authentic sample of the "Hewett Quinine," and it is not improbable that our observations thereon may tend slightly to illuminate some points which today appear to be more or less obscure. —*British and Colonial Druggist.*

MR. HEWETT'S ALLEGED DISCOVERY.

HISTORY OF THE NEGOTIATIONS: LEGAL PROCEEDINGS THREATENED.

We published last week, as a supplement to this journal, the information, verified only while the issue for the 16th instant was actually being printed off, that Mr. Cresswell Hewett was out of London, but that his secretary, signing as for "Cresswell Hewett & Co." announced that orders for "artificial quinine," in quantities of 100 ounces and upwards, would be received and booked, although such orders could not be executed for a few weeks yet.

THE ATLAS QUININE COMPANY.

We were further given to understand that a company had been formed under the title of "The Atlas Quinine Company," for the due carrying out of Mr. Hewett's discovery upon a commercial scale; that offices had been taken for the said Company at Mary's Chambers, St. Mary Axe, E. C., and that the factory for the manufacture of artificial quinine would "probably be in Germany." As to price, little or no information was vouchsafed beyond the bare statement that the quinine would be sold at something under the market price ruling for the alkaloid derived from cinchona bark.

A great number of orders for the quinine, it is alleged, have been received from all parts of the world, as also applications for agencies, and offers of capital, one firm in particular being referred to as having tendered a considerable sum of money for the entire secret and the sole right of manufacture, but nothing could be gleaned from "Cresswell Hewett & Co." respecting the constitution of the embryo company in question, or the sources from whence its future output of quinine is to be drawn. We ascertained, as a matter of fact, that, up to a very few days ago, no patent for the preparation of quinine had been applied for at the English Patent Office, and no company, whose avowed objects resemble those of such an undertaking as has been sketched out in the foregoing paragraphs, has, as yet, been registered under the Companies' Acts.

Mr. Cresswell Hewett's chambers remain at the address given in our previous account, published Aug. 28th last,* viz., 50A, Lincoln's Inn Fields; but offices have been taken for the Atlas Quinine Company at 3A, St. Mary's Chambers, St. Mary Axe, E. C., although the name of the company had not been painted upon the doors at the date of our last visit and no clerk or other *employé* has been found in occupation of the offices when our representatives have called there. This narrative, meagre as it is, taken in conjunction with our previous accounts, gives practically the whole history of the matter so far as this can be obtained from what might be called the Lincoln's Inn brief.

A somewhat different complexion is, however, put upon the affair by the facts and statements we are about to record, "Cresswell Hewett & Co." and "The Atlas Quinine Company" having apparently, in the absence of their principal, written up "No thoroughfare."

INTERVIEW WITH DR. WILLIAM BURTON.

At this point we directed our enquiries into a different channel, and as a first result a member of our editorial staff called upon Dr. William Burton, of 20 Bucklersbury, E. C., and was fortunate enough to find that gentleman disengaged, and willing to afford us all the information in his power.

Dr. Burton received our representative with the utmost courtesy, and frankly explained his connection with this strange and eventful history from first to last, or rather from the date of our original announcement to the present, the "last" stage of the enquiry being by no means attained as yet. Omitting some points of minor detail, which, in view of certain proceedings to be elaborated a little later on, it may not be advisable to publish to-day, the sum and substance of what has taken place in relation to "artificial quinine" during the past few weeks is included in the following paragraphs:

£20,000 FOR THE SECRET.

On the first commencement of Mr. C. Hewett's alleged discovery, Dr. Burton, through the intermediary of a third party, put himself into communication with Mr. Hewett, with the view of making some business arrangements, or of buying the entire concern outright. After certain negotiations had been exchanged, the amended terms offered by Mr. Cresswell Hewett were accepted, and the name, &c., of the purchaser—Dr. Burton—revealed to Mr. Hewett. These terms, in brief, consisted of an agreement to pay the sum of £20,000 to the discoverer of "artificial quinine," and to retain his personal services and those of an assistant, in connection with the manufacture, for a period of not less than 12 months, at the salaries of £800 and £200 per annum respectively, in return for a full disclosure of the secret of the discovery to Dr. Burton, and those associated with him, the investiture of these parties with the sole and complete rights to manufacture and sell the article, and the actual production, in presence of the purchasers, of a sufficient quantity of the alkaloid for testing and trial, of a quality not inferior to "Howard's."

BURROUGHS, WELCOME & CO. AS PURCHASERS.

Mr. Hewett, however, Dr. Burton informed our representative, after himself proposing and agreeing to these terms was so constantly seeking to amend or enlarge them, that some of those who acted as Dr. Burton's colleagues in the matter, particularly Messrs. Burroughs, Welcome, & Co. and Mr. Bland, began to show some impatience at the new demands. These, however, were eventually agreed to all round at the instance of Dr. Burton, who considered that in a matter of such superlative importance, neither one or two thousand pounds, nor any individual peculiarities, should be deemed of great moment.

Mr. Hewett so frequently insisted upon the necessity of his visiting the Continent, in order to arrange for the starting and due carrying on of the new industry, and also of the inconvenience his withdrawal from his private connection for a year or more would entail, that, with the view of avoiding these objections and of facilitating the negotiations, Dr. Burton wrote a letter somewhat modifying the conditions previously laid down; the following is a verbatim copy or the communication in question.

LETTER FROM DR. W. BURTON TO MR. CRESSWELL HEWETT.

20, Bucklersbury, Sept. 9th, 1886.

Dear Sir,—In order to expedite this business, and, if possible, save you the trouble of a journey to the Continent, and the loss of your present connection, which would naturally follow the devotion of your entire time for the next 12 months to the manufacture of quinine synthetically, Messrs. Burroughs and Welcome join me in making the following proposal:—"That we undertake to make all necessary and satisfactory arrangements to pay you £21,000 promptly, on your demonstrating to us your ability to produce quinine at the price named by you, and your transferring to us the secret of its manufacture, and of the sole and exclusive rights to manufacture, under your process, and your undertaking to patent such process, at our expense, if we do desire. For this purpose the production of only a small quantity will be necessary to satisfy us, say 2 pounds. A laboratory shall be placed at your disposal, and we will leave the details of arrangements greatly in your hands. After you have manufactured the 2 pounds of quinine a sample of it is to be submitted to two analysts, one to be nominated by yourself and one by Messrs. Burroughs and Welcome. On receipt of reports from the selected analysts, certifying that the quinine manufactured by your process is veritable marketable quinine, possessing the medicinal properties of the present sulphate of quinine, the payment is to be made to you cash down. The advantage of your accepting the present offer is very clear: the £1,000 offered for your services for one year is added to the purchase price of £20,000 already agreed upon, and the actual cash will be placed in your hands within a very few days if you carry out your part of the bargain.—Yours faithfully,

(Signed) W. Burton.

Mr. Cresswell Hewett.

* "Artificial Quinine; Mr. Cresswell Hewett Interviewed," *B. & C. D.*, Vol. x, page 212.

These terms being, of course, more favourable for the vendor, were duly accepted, and a few days later the agreement, of which the full text is quoted hereafter was also acceded to :—

DRAFT OF AGREEMENT BETWEEN CRESSWELL HEWETT AND WILLIAM BURTON AND OTHERS.

40, Chancery Lane, W.C., 13th Sept., 1886.

RADFORD AND FRANKLIN.

Terms of proposed Agreement between Creswell and Hewett and Doctor William Burton.

Dr. Burton to deposit £21,000 with a banker to be approved by C. Hewett.

C. Hewett to manufacture within a week, in the presence of Dr. Burton and two persons to be named by him, a sufficient quantity of quinine, by a synthetical, or artificial process, at a cost of not more than 4d per ounce. The quinine so to be manufactured to be equal in quality to the ordinary quinine, and identical in its medical properties.

On the manufacture being completed to the satisfaction of Dr. Burton, C. Hewett shall be entitled to the said sum of £21,000, and also to shares in a company (with the capital of £250,000) intended to be formed, to the amount of £29,000, as the consideration for the disclosure to the said Dr. Burton of the secret process of so manufacturing quinine. Such £29,000 shares not to pay dividends until the ordinary share of the company shall pay dividends at the rate of 10 per cent per annum.

C. Hewett to communicate all information necessary to the manufacture of quinine by the process aforesaid, and to assist Dr. Burton in protecting the said invention by letters patent in the United Kingdom and all other countries. Such letters patent to be taken out in the names of the said Dr. Burton, or the said intended company, or other, the nominees of the said Dr. Burton.

VISIT TO THE FACTORY AT WANDSWORTH.

On the 4th ult. Dr. Burton, Messrs. Bland, Cresswell Hewett, J. F. Bunting, and S. M. Burroughs (Burroughs, Wellcome & Co.), visited the chemical works of the last-named firm at Bell Lane, Wandsworth, where Mr. Cresswell Hewett selected a room and certain machinery and appliances, to be supplemented by other apparatus of his own, and made various general agreements for the proposed demonstration of the actual process of quinine manufacture. Such process is stated to involve the admixture or manipulation of three ingredients only and the time occupied by the treatment of such ingredients, from the first handling of the raw material to the completion of the finished products, does not exceed 24 hours. Besides the "quinine," it is alleged that a "bye-product" is also formed.

After the incidents just mentioned, Dr. Burton informed our representative nothing particular occurred except that Mr. C. Hewett appeared to hang back a little, and could not be induced to fulfil or go on with his part of the compact, and neither Dr. Burton nor Messrs. Burroughs and Wellcome seem to have known much more about him except that he left England, presumably for the purpose of forwarding the business in view. It is thought by some that he has gone to Liége; another report has it that he is not a great way off Darmstadt at the present moment.

"BURTON AND OTHERS *v.* CRESSWELL HEWETT AND CO."

The announcement made in these columns on Saturday last, therefore, seems to have been the first intimation received of the existence of "The Atlas Quinine Company," and accordingly it fell with all the force of a wet blanket upon Messrs. Burton, Bland, Burroughs and Wellcome, &c. These gentlemen have nothing to do with, and have no cognizance of, "The Atlas Quinine Company," and they not unnaturally contend that its very existence is in direct contravention of their previous arrangements with Mr. Cresswell Hewett. It has, therefore, Dr. Burton informs us been determined, in the absence of any explanation from Mr. Hewett, to apply for an injunction restraining the "Atlas" Company and "Cresswell Hewett & Co." from selling, dealing in, or manufacturing the said artificial quinine, and should this come off shortly the whole matter will probably be well ventilated. "Having gone so far," said Dr. Burton to our representative, "we cannot stop where we are. Whatever it may cost now, I must sift this matter to the very bottom." Small samples of the "artificial quinine" and the "bye-product" are in Burton's possession; the former he retains for the present unopened, the last we are informed has been examined by Mr. Clayton, F.C.S., of Holborn Viaduct, who reports that he can make nothing of it.

It may be remembered that a sample of the "quinine," &c., was entrusted to us by Mr. Hewett. We have analytically examined this sample, and also the "bye-product," and we shall have some observations to make respecting them in our next issue.—*British and Colonial Druggist.*

INDIAN TEA COMPANIES' DIVIDENDS.

Statement showing the actual amount of dividends distributed by 24 of the principal Indian tea Companies, in respect of 1885 crop :—

	Capital paid up. £	Amount of dividend distributed. £	Rate per cent
Assam ...	187,160	37,432	20
Brahmapootra	114,500	18,320	16
Borokai ...	43,560	6,970	16
Jorehaut ...	100,000	15,000	15
Doom Dooma ...	116 100	15,383	13¼
Mookhamcherra ...	47,500	6,175	13
Jokai ...	56,037	5,604	10
Jhanzie ...	55,000	5,355	10
Tiphook ...	26,060	2,600	10
Panitola ...	58,810	5,881	10
Chargola ...	65,500	6,550	10
Lebong ...	82,070	7,386	9
Darjeeling ...	135,420	10,834	8
Dooars ...	106,000	*749	8
Hingajea ...	36,000	2,880	8
Borelli ..	78,170	4,690	6
Indian (of Cachar) ...	94,060	5,644	6
Dejoo ..	43,580	2,615	6
Scottish Assam ...	79,590	3,980	5
Moabund ...	35,007	1,750	5
Balijan ...	31,000	1,395	4½
Nassau ...	36,000	1,440	4

FIBRE CO.—In the case of Mr. C. E. Collyer, described as of Fenchurch-street, hemp, fibre, and China produce broker, trading under the firm of Collyer and Co., who filed his petition in August last, Mr. S. Woolf applied in the Bankruptcy Court for the approval of an arrangement come to by the creditors, whereby it was agreed that the property should vest in, and be administered by a trustee for the benefit of creditors in like manner as if the debtor had been adjudged bankrupt. The official receiver, for whom Mr. Aldridge appeared, reported that the debtor had traded after knowing himself to be insolvent, but the Court did not think that anything had been shown to disentitle the debtor to his discharge, except perhaps with a nominal suspension, and therefore would not withhold approval of the scheme. The application was accordingly granted.—*L. & C. Express.*

* Working part of year.

MANURES.

The character of the soil is, as is well known, an important element to be taken into account in the choice and application of manures. The general difference between strong and light soils may be taken to be that the former contains a larger store of the natural elements of fertility, though for the most part in an undeveloped state, while from an excess of clay the physicial property of retentiveness and its consequent drawbacks are too prominent; while light soils, on the other hand, are comparatively deficient in natural resources, and by season of a deficiency of clay possess the property of porosity in a too great degree, and hence afford a too ready passage for water, and other bodies necessary to vegetable growth.

Clay soils.—On stiff clay soils we have all the defects arising from the tenacious and plastic properties of this substance, and its consequent imperviousness to water, hence the first necessity towards the improvement of such soils must be drainage, in order to remove the excess of water, and without which the best manures will have but a meagre effect. All means of adding to the porosity of stiff clay soils are to be recommended—one of the best of which is burning in heaps with vegetable refuse, or small coal, in the mann r "ballast" is burnt, and which spread over the surface before digging, has an excellent effect in lightening the soil.

It is on these descriptions of soil that a thorough breaking up and stirring at favourable times is so beneficial, particularly before frost, which does more for strong clays than almost anything else. In fact, cultivation on these classes of soil must always be the primary resource for advancing their fertility—but supplemented of course by a judicious selection and application of manures.

Sandy Soils.—In sandy soils we find all the defects arising from an extreme porosity, or, in other words, an absence of retentiveness consequent on the paucity or absence of clay, which is the chief storehouse, so to speak, not only of the moisture of the soil, but also of plant-food, either artificially added or derived from natural sources, and from which the root-fibrils of plants draw their supplies as required.

The retentiveness of such soils may be enchanced by the addition of clayey composts, and by green manuring.

Green Manuring.—Is often an excellent source of plant-food in the lighter description of soil, and deserves to be more extensively adopted, as we thereby obtain a clear gain of nitrogen from natural sources, and at the same time gather up and preserve any nitrates present in the soil in a staple and efficient form; while the humus compounds arising from the decay of the vegetable matter affords absorbent for moisture, &c., in the same manner as clay. That vegetable matter in a readily decomposable state is a valuable form of manure is shown by the character of the Wheat crop following a Clover lea. Where the Clover has been successful, the Wheat plant, as well known to the agriculturist generally, corresponds, and *vice versâ*. Dead leaves and garden refuse of all crops not consumed as food should therefore be carefully returned to the land, as they are rich in manurial elements in the best possible state for future plant-life when prepared by decay in soil.

We may take it as a general rule not to burn any refuse that will rot in the soil, except in the case of foul turf infested with insects or seeding weeds, &c., since by so doing we lose the nitrogen and organic matter, besides rendering the ash constituents less available by mineralising them Sir J. B. Lawes and Professor Gilbert have subjected this theory to a most rigid investigation at Rothamsted.

The ashes of 14 tons of farmyard manure were applied to an experimental crop of Wheat, and gave no increase of produce whatever over an adjoining plot that was left entirely unmanured, and in succeeding years the ash constituents were found to be but very slowly available as plant food.

Besides all this, able chemists have demonstrated by growing plants in distilled water, that to produce a good crop there must be nitrogen in the soil or in the water. They have dissolved the ashes of plants in pure water, and then, by adding a few grains of nitrogen in the form of a nitrate, have produced a luxuriant vegetation; but without nitrogen only a very feeble growth could be obtained.

Weeds.—The field experiments at Rothamsted and also at Woburn conclusively prove that crops of every description grown upon ordinary cultivated land are greatly reduced by weeds. It is true that weeds, if again returned to the land, do not exhaust a soil, as, in their decay, the fertility which they have taken up becomes again available; but weeds take up nitric acid, which during their growth reverts to the form of organic nitrogen. When this occurs in regard to soluble plant food it is merely so much nitric acid employed in growing weeds instead of useful garden produce, and this nitric acid does not again become available as food of plants until the weeds have undergone decay in the soil and become nitrified.—J. J. W. —*Gardeners' Chronicle.*

AJI-AJI, THE PEPPER OF PEPPERS.

Our contemporary the *Saturday Review*, in its issue for September 18, had an article under the mysterious heading of "Aji-Aji," which the writer at once proceeded to explain was a "compound Quichuan word" for Pepper of Peppers, and further informed his readers that "both word and thing are largely distributed over South America," that "it is the finest of all Peppers. No other Pepper in either hemisphere competes with it, neither the Piper nigrum, nor the Capsicum baccatum, nor the C. fruticosum, the C. annuum, nor yet the Eugenia pimenta. All these are varied merely in pungency, some being sharp and fiery, others, caustic and stimulating, and some pricking and penetrating. But the refined and delicate Aji is persuasive and enticing, of not one flavour but many flavours; it never conceals, but, on the contrary, increases whatever of fragrance and sweetness of taste or smell it comes in contact with." The writer then proceeds to give a long list of its extraordinary virtues, and an enumeration of the articles of food it may be used to improve, from a new-laid egg to a Strawberry or a jug of mulled claret. It is said to prevent evil effects in a malarian atmosphere, and on this accouut we are told that "the War Department of the United States has secured a monopoly of all the Aji which is exported from South America," and further that "no Aji in these days finds its way to London, and that which we once enjoyed in the belief that it would never fail us has become nothing but a sigh and a regret. It remains to be seen," the writer continues, "whether the people who have acclimatised the Cinchona trees in the Neilgherries, in Ceylon, in Jamacia, and in Fiji will allow themselves to be deprived of their delicious and inspiriting Aji."

Perhaps the most interesting part of the *Saturday Review's* article is that which treats of the preparation of Aji, which is as follows:—"There are two kinds of Aji, but there is only one way of preparing it. The best is that which is made from the greatest variety of Peppers. The pods of these are taken when fresh, stripped of their seeds, and ground into a paste of the consistence of fresh spring butter. The paste is put into a small, well dried Gourd, prepared on purpose, of the size and shape of a well grown Orange. The Gourd, when thus charged, is then coated with a layer of well tempered clay, and placed in the sun to dry, or to ripen, as the simple people who prepare it say in their own tongue. By the time the clay is well baked the pulp or paste within has been dried into a fine yellow powder, and it is then fit for use. Many people, ignorant of this fine art of the Incas, have supposed quite naturally that these Aji-laden Gourds, with their exquisite flavour and refined taste, were some uncommon and little known natural fruits. The other method of preparing Aji is to grind the seeds with the pods, which simply adds great pungency to the Pepper, and is always used in the preparation of Maize or Indian Corn

which is boiled in its own husk with so much Aji' and surpass in flavour and pleasantness any vegetable curry of the East. The Gourds of Aji when thoroughly ripe are cleansed of their coating of clay, tied up in suitable leaves, well secured by the fibre of the Aloe, and which much resembles when ready for market reeves of large onions, a dozen Gourds making up one reeve of Aji. The cost of these in the good old times was 15*d.* for a dozen Gourds; what the price may be now is only known on the Exchange." From the references made in the preceding passage to the pods and seeds being ground to constitute the Pepper, it will be readily guessed that it is the produce of a species of Capsicum, notwithstanding that the writer of the article says it is "not the Capsicum baccatum, nor the C. fruticosum, nor the C. annum." In the Kew Museum are numerous varieties of the fruits of Capsicum annum, all bearing the name of Aji, and the museum also contains specimens of the small Gourds filled with Capsicum Pepper as described by our contemporary; so that the "Aji-Aji" of the *Saturday Review* is clearly the produce of Capsicum annum.—JOHN R. JACKSON, Curator, Museum, Royal Gardens, Kew.—*Gardeners' Chronicle.*

ROOTS.

(*Concluded from p.* 388.)

Many plants flourish in an open soil with plenty of sand in it, but will not grow in a stiff wet soil. This is not necessarily because the heavier soil does not contain the right food materials, but because its particles are so small, so closely packed, and so retentive of moisture, that the root-hairs do not obtain sufficient oxygen: moreover, the very damp state of the soil does not favour the development of the numerous root-hairs necessary, as we have seen. Nor is this all—though I cannot here enter at length into this point—root-hairs and roots cannot grow or act unless the temperature is favourable, and we have plenty of evidence to show that a close wet soil may be too cold for the roots at a time when an open drier soil (exposed to similar conditions as regards sunshine, &c.), would be of a temperature favourable to their growth. Many a pot-plant receives an overdose of water because it is drooping from the roots, being too cold to act properly. The opening up of stiffer soils by means of the spade or plough, or by the addition of other kinds of soil, such as sand, burnt lime, &c., or by means of drainage of various kinds, is thus to be regarded as a means of letting in air, and therefore oxygen, to the roots. "Sweetening the soil" is an expression one hears used by planters and others; this is often no doubt their way of expressing the fact that the air thus let in does so much to turn the noxious substances which have accumulated into other substances which the root-hairs of the plant can take up with profit. The exposure of certain soils to sharp winter frosts in part benefits the plants subsequently grown in it, because air can make its way into the cracks produced as the particles crumble: there are other advantages also due to the "weathering" of soils, of course, as also to the addition of lime, &c., but I am purposely abstaining from referring to points concerning the nutrition of plants as generally understood.

Let me shortly call your attention to a few other practical applications of the knowledge briefly summed up above. It is well known that a good deal of experience has been brought to bear on the question of what trees are the best to plant in or near large towns: there are very many facts to be considered. It is not sufficient to find a tree which will accommodate itself to the possibilities of the annual rainfall, or a diminished supply of sunlight throughout the year, and so on; nor is the problem solved when a tree is found that will put up with traces of acid gases in the atmosphere, and, as may follow, the accumulation of acids in the soil, and consequent alterations in its chemical composition. In many cases trees have been found to die as they grew older because the pavement or asphalt over their spreading root-system prevented proper aeration and a proper supply of aerated water to their root-hairs; imagine the effect of a few days' hot summer sunshine on roots just beneath the pavement of an exposed street! It is true the cover may prevent rapid evaporation, but it also shelters the soil from the well aerated raindrops; moreover, such sheltered roots will at certain seasons grow up to the surface of the soil and in contact with the lower surface of the pavement. Then there is the question of drainage. If the water which does find its way in slowly accumulates and becomes stagnant, the results are as disastrous or even more so; yet it is obviously a difficult matter so to arrange things that the accumulated surplus water of certain seasons shall pass away below, acting like a suction-pump and drawing in air after it, and still fulfil the other requirements hinted at above. I leave out the question of exhaustion of the soil—the dead leaves, &c., being carefully removed. Can we wonder that there are so few trees to choose from that will stand such treatment? The fact that there are some only accords with what has been already stated—that plants vary in their requirements and powers; and no one doubts that the variations have been influenced by variations in the environment.

We have now seen to a certain extent how variations of a particular kind may affect a plant. The plant responds to a certain extent—it is, as some people say, "plastic"—but if the limits are reached and slightly overstepped, the variations on the part of the plant become dangerous to its existence, and the plant becomes diseased and may die.

Not to dwell upon hypothetical matters, I will content myself with saying, in conclusion, suppose a variety of a given plant grows in damp places and has roots which form few or no root-hairs, and suppose an individual of that plant to become transferred to a more open soil; I have shown you reasons for regarding it as probable that the latter individual might produce more root-hairs and thus adapt itself to the altered conditions. If such a case happened, it is by no means improbable, but the contrary, that other circumstances co-operating or adverse would decide certain problems of importance to the existence of that particular individual.

But the main object of this lecture has been to show you how very complex the conditions may be which bring about a "diseased" condition of the roots. It is no uncommon event to see a tree flourish for years and then die slowly off from "something at the roots;" examination shows that the soil still contains the necessary foods, the water-supply is constant and good, the tree is exposed to no obvious adverse influences, and yet with steps so low that they are scarcely noticeable, the tree begins to die off before its time. In some cases this is probably because the root-hairs are not receiving their proper supply of atmospheric oxygen, and this may be due to very slight changes in this structure (not the chemical composition) of the soil: a very slight diminution in the activity of the root-hairs may cause a diminution in the supply of water to the leaves at seasons when they require much, and this means lessening their supply of food-materials. If the leaves are placed on short commons they cannot form wood, and so the next season's supply of nutritive solutions may be cut short; moreover, fewer root-hairs will be formed. No doubt differences will appear in different years or seasons; but if the tendency on the whole is in the above direction, the life of the tree is already limited—it may drag on for years as an object, which can scarcely be termed a tree, however, but its doom is sealed.

The difficulty of placing one's hand on an exactly illustrative case is due to the fact that other causes are usually at work after a short time. I have purposely avoided any reference to the changes brought about in the chemical nature of a soil by the addition or cutting off of air, &c.; and for the same reason—to keep your attention directed to the root-hairs as living cells exposed to the influence of a definite environment—I have left out of account some

questions of food supply. These matters do not invalidate anything said above, but they do profoundly affect the problems of the diseases of plants, and especially those diseases which start from the roots. H. Marshall Ward, M. A., F. L. S.—*Gardeners' Chronicle.*

TEA HAIR.

Tea-makers will agree with us that hair, of all substances in nature, is least likely and least desirable as a component of the fragrant leaf. But all Indian and Ceylon tea planters are familiar with a substance, somewhat resembling the pollen of flowers, which collects on the machinery in the process of manufacture and which we have heard generally described as "orange" or "golden pekoe dust." The general impression, we think, has been that the dust in question was specially derived from and was about the richest portion of the pekoe buds. Our attention has, however, been attracted to a paper in the "Year Book of Pharmacy for 1877," in which it is shewn that the main constituents of the substance, are hair-like processes which are separated from the leaves in the act of rolling. In taking over the extract we invite communications as to the proportion of this substance formed in extensive manufacture; whether it is generally collected for exportation and what its commercial value may be?

FURTHER RESEARCHES ON TEA HAIR.

By Thomas Greenish, F.C.S.

Under the name of Pekoe Flower, or Flower of Tea, this substance was brought before the Conference at Glasgow last year by Mr. Groves, and on that occasion I gave the result of its examination, mainly microscopical, which I had previously undertaken. At that time but little was known either by Mr. Groves or myself of its history, the position it occupied in commerce, or its ultimate destination. I followed up the subject with the view of supplying for this meeting that more complete information which was wanting on these several points, as the tea hair may probably crop up again as a natural curiosity for a lover of science, or to supply a sensational paragraph for a public analyst. The tea hair was said to have emanated from a house in the city, but the city is a large place in which to look for tea hair, and I found it so. For many months I worried with my inquiries tea brokers and tea merchants, but without result, until at last a friendly hint directed me to a tea broker's office, where I found a member of the firm who, in addition to a very discriminating palate as regards the strength and flavour of tea, had also acquired a vast deal of collateral information about teas imported from India and China.

It appears that tea hair finds its way into this country as an article of legitimate commerce, at tolerably regular intervals; its commercial name is "Pekoe Flower," and sometimes the "Bloom of the Pekoe Flower." It is a product of India teas, not of those of China. It is purchased somewhat as a curiosity, but there are those who buy it pretty regularly. Pekoe flower is never sold as tea simple or for mixing with tea. It is almost a necessity that it should be sold alone. If it be mixed with ordinary tea there is such a tendency to the separation of the tea hair and its agglomeration into lumps, that any attempt of this kind would probably result in the whole being returned as an adulterated tea.

In an essay on the cultivation and manufacture of Indian teas by Lieut.-Col. Money, and published in Calcutta, the whole process of the manufacture of the Indian teas is given, and it is not difficult to trace the condition in which this tea hair is found, to its origin. One part of the process consists in what is called "rolling" the leaves, when the juice is given out freely; and as to its results on the leaf, he says, "If the leaves which give Pekoe tips are separated from the other leaves and rolled *very little* and *very lightly* there will come out Pekoe tips of a whitish colour; if *not* separated from the other leaves, but manufactured with them, the sap from the other leaves, expressed in the rolling, stains these said leaves, which are covered with a fine silky down, and makes them look like the rest of the tea." This is evidently the part of the process in the manufacture of Indian teas which gives to the otherwise greyish-white hair its brown colour, and also that extractive matter which is found adhering to it.

Mr. Wigner, in his analysis of the tea hair, gives theine 1·5 per cent as compared with 3·5 per cent for Pekoe tea, and Mr. Groves remarks in reference to this, that "it is interesting to find theine present in the tea hair." I doubted the correctness of this conclusion. The hair of the leaf is an extension of the epidermal cells covered by the cuticle; there is an absence of chlorophyll, the cells being empty; this layer prevents too rapid evaporation from the parenchyma of the leaf, but plays no part in the plant's economy. I have no doubt but that the theine obtained by Mr. Wigner was derived from extractive and parenchymatous tissue adherent to the base of some of the hairs. To determine this point, I took 100 grs. of tea hair, exhausted it with cold water and evaporated the liquid to dryness. It yielded 15 grs. of extract; this closely agrees with the result obtained by Mr. Wigner. My object was now qualitative, to determine the presence of theine in the extract, and for this I adopted the micro-sublimation process. A little of the extract was dissolved in water, to which was added some calcined magnesia; the solution was boiled and evaporated to dryness; part of it was then placed in a cell on one glass slide covered by another, and at a temperature of about 120° C. I obtained successive crops of theine in acicular crystals. I then subjected the hair from which the extract had been obtained to the same process, but there was no indication in the hair freed from extractive of the presence of theine. It is evident that this experiment on the exhausted hair could not be considered conclusive as to the absence of theine in the normal hair of the tea leaf. I further picked carefully clean hairs from young Pekoe leaves, treated them in the same manner by gently boiling with a little calcined magnesia, and employed the same micro-sublimation process, but failed to get the slightest indication of the presence of theine in the hair itself when free from extractive matter and parenchymatous tissue. These experiments are to my mind conclusive that the theine was obtained from the extractive matter and parenchyma of the plant, and that there exists no theine in the normal hair of the tea leaf, and I believe that there is no known instance of a simple hair, such as that on the tea leaf, containing the active principle of the plant. A further careful examination of the tea hair, besides calcareous matter, shows the presence of minute particles of the elytra of beetles, the markings on which bear a close resemblance to the venation of a leaf, and which may easily be mistaken for fragments of some leaf other than tea. I may add that the tea hair has created considerable interest, and I have been applied to from the continent for museum samples, which until lately I was quite unable to supply.

Thanks having been voted to Mr. Greenish for his paper.

Mr. Groves said he could have saved Mr. Greenish a great deal of trouble if he had known that he was in search of the importers of the tea hair. It was no mystery—he had known all about it from the first. The general impression was that this tea hair was worked up into the compressed tea, as the only way of getting rid of it. As to the presence of theine, the presumption was in favour of Mr. Greenish's theory that it was not present.—*Year Book of Pharmacy and Transactions of the British Pharmaceutical Conference for 1877.*

Correspondence.

To the Editor of the "Ceylon Observer."

PADDY AND CATERPILLARS.

School of Agriculture, Colombo, 22nd Oct. 1886.

DEAR SIR,—I am sending you two kinds of caterpillars found in a crop of paddy growing in the Agricultural School compound: please ask your Entomological referee to what kind of moth or butterfly we are indebted to for this pest. The green-coloured caterpillar feeds upon the leaves of the paddy plant, but the other feeds in the culm, a little above the root and is by far the more destructive of the two. These insects cause serious damage to paddy crops, but if there is an abundant supply of irrigation water available, they need not give any cause for anxiety, for by flooding the field these depredators could be drowned and washed off the crop. In a season like this when no rain falls, the destruction of these caterpillars would be a serious difficulty.—Yours faithfully,

A. W. JAYEWARDENE.

[The specimens sent have turned into chrysales before they were fully recognized by our entomological referee; but they are probably only common visitors. Now-a-days every "poochie" seems to be pitched on as a new and formidable pest. If Mr. Jayewardene will send further specimens they will be fully identified.—ED.]

PINE-APPLE PLANTS FOR FIBRE AND FRUIT.

Kirimetia, 10th Nov. 1886.

DEAR SIR,—I enclose a sample of pine-apple fibre and will thank you for your opinion of it. It could be made much longer if required. In one acre of land there are ten thousand plants the first year, twenty thousand the second and thirty thousand the third year. Each plant has twenty leaves and each leaf gives thirty grains of fibre and with steam or water-power with proper machinery could be made in *any* quantity according to the force employed.

The plant will also give ten thousand pine-apples the first year, twenty thousand the second, and thirty thousand the third, which could be made into wine or brandy. Three full-sized pines will give a bottle of juice.—Yours truly,

J. HAWKE.

[The specimen of fibre looks very nice. There is no question as to the value of pine-apple fibre, but in this and in all other cases of the kind the question is will it pay to grow the plant largely and to use the requisite machinery. Pine-apples grown in the shade yield abundance of long leaves, but if regularly cropped, we suppose the application of manure would be necessary. Of all the fibre plants in Ceylon we have always regarded the pine-apple as the most likely to give good results. But an extensive experiment can alone settle the question of profitable returns. There is such a large and increasing demand for the fruit,—what with hotels and steamers,—that conversion into alcoholic drinks need not be contemplated. —ED.]

FRUIT FROM CEYLON FOR ENGLAND.

Catton, 12th November 1886.

DEAR SIR,—For the information of "Enquirer," in yours of 6th inst., I have sent oranges home on two occasions, through Mr. E. B. Creasy's Agency office, and they reached home in good order, and I must say were very promptly delivered, a great point with fruit of course. I may add that in my last package I sent home one of the largest sized fragile chatties used by natives for carrying and storing water in, just as a curiosity for my friends to see. I filled it with oranges, wrapping each fruit in paper, and put a straw envelope in centre for ventilation; the corners of the case I filled up with oranges in bottle-envelopes, the chatty also arrived in good order. S. B.

N. B.—The oranges were carefully gathered, and about a week or so before I expected them to get quite *yellow*.

"UNASSORTED" *Vs.* "ASSORTED" TEAS;—PER CONTRA—FOR THE BENEFIT OF MESSRS. RUCKER & BENCRAFT.

St. Leys, Dikoya, Nov. 15th 1886.

DEAR SIR,—Regarding Messrs. Rucker and Bencraft's Tea Circulars and their advice to us to ship "unassorted," I will give you my experience. In August last, I had two lots sold in Mincing Lane: one "assorted" 1,500 lb. and the other "unassorted," 1,000 lb. They were sent as a test, one against the other, and the teas were from the same bulk. The "assorted" was in five grades: Orange Pekoe, Broken Pekoe, Pekoe, Pekoe Souchong and Dust, and fetched an average of 1/5¼—the "unassorted" fetching 1/1. Messrs. Rucker's figures reversed. A leading Mincing Lane Broker expressed the opinion that, "it was a pity the latter had not been assorted, as there was a large proportion of fine tea in it."

"Who shall decide, when Doctors disagree"? *
Yours truly, JAS. W. HOLT.

CEYLON CULTIVATION AND MANUFACTURE OF TEA: CHANGE OF SYSTEM PROPOSED AS A REMEDY FOR OVER-PRODUCTION.

DEAR SIR,—The "Tea Planter's Manual" contains much information, which will be extremely useful to the young, and inexperienced planter, but there is almost a certainty that the progress of invention, and knowledge will at no distant date render valueless more than half of the contents of the volume you were good enough to present to me.†

The present ideas regarding manuring, plucking, withering, fermenting, and the necessity for large tea-houses, will; I think, undergo a change, and new systems will not only be forced upon us, but accelerated by the rapidity of our progress in cultivation.

In a few years hence, when Ceylon produces sixty millions of pounds, India eighty or more, Java thirty, on the top of two hundred millions from China, and fifty from Japan; we may find too much tea is produced, even for the increased consumption, which may naturally be calculated upon in every consuming country; and the inevitable result of producing a commodity, which at present can be successfully, and profitably grown over so large an area as tea will follow, namely, over-production and a decline in prices thereupon, to a killing point.

If this should happen, the important question will be: whether anything can be done to avert the consequences which a forced curtailment of production entails?

I think it is possible by changing the present system of cropping, not only to largely diminish production without reduction, or abandonment of cultivation, which, in the case of nearly every other

* Hear, hear!—It is evidently ridiculous to lay down any hard and fast rule.—ED.

† In which case a new and revised edition will be published, with all information brought up to date. But we don't think present systems will be so entirely and so rapidly superseded as our correspondent anticipates. —ED.

product, is the only way of attaining that object; but to render it possible to profitably continue cultivation undiminished, under almost the most adverse circumstances which are likely to occur. The compiler of the "Tea Planter's Manual," has in the last three paragraphs of his introduction, set forth the peculiar advantages Ceylon possesses for the profitable cultivation of tea, but I cannot recall that either he or any other authority, has ever pointed out, though the fact is well-known, that there is scarcely any product but tea, from which if he wishes it, the cultivator can harvest the finest and highest priced grades of quality, and leave the inferior and lowest priced on the plants, without detriment to them.*

When you reflect on what would follow if European tea-planters in India, Ceylon and Java, could at once, WHEN NECESSITY ARISES, curtail the production of their estates by fifty per cent, and still be able to keep up their full acreage cultivation, not only without loss, but at some profit, you will recognize the almost unique advantage a tea-planter enjoys over the producer of almost every other commodity.

That this can be done, I will endeavour to prove, although in the method I suggest, which can be gathered from what I have said above, I shall not be communicating anything new, for, I believe some of the planting cognoscenti adopt it now, not because they are forced to do so, but because they think it more profitable.

As long as the cultivation of tea is as remunerative as it is now, it is more than probable that the safest course to adopt in harvesting, is to continue the system now generally practised, that is, to take from the plants all the pekoes, and pekoe-souchongs they will yield, whether by doing so the planter obtains four, five, six or more hundreds of pounds per acre, but, if the time comes when over-production has to be killed, a different system must, I think, be carried out to avert abandonment, and that change is to pluck fine, and produce nothing but orange and broken pekoes.

We now know that by careful manipulation, planters can turn out on the present system of plucking, fifty per cent of orange and broken pekoes, which average at present in London, at least eighteen-pence per pound. If in the distant future prices decline fifty per cent below what they now are, orange and broken pekoes would be worth only ninepence. The question, therefore is, whether fine teas only, can be produced profitably, to sell in London at this average? My answer is, that planters whose estates now yield 400 lb. per acre at a cost of 30 cents per lb. in Colombo, could reduce their yield to 200 lb. per acre and lay it down in Colombo at a cost of about 36 cents per pound; this at present rates of freight and exchange is equivalent to 8d per lb. in London, leaving for interest or profit, a margin of a penny per pound.

In support of this statement, I offer the following calculation based on the figures given in the "Tea Planter's Manual," making such slight alterations as an entirely different set of circumstances would warrant. For instance, I have reduced the cost of management a little, because in times of great depression it is necessary to economize in every possible direction. I have omitted the cost of nurseries, as there is no need to provide for increased production, when reduction is the order of the day; and I have omitted the charge for machinery and buildings as not belonging to the cultivation expenditure on an estate in full bearing.

The working expenses of a 200 acres garden in full bearing would be:—

Superintendents and Tea-house Conductor	R3,500
Weeding R1 per acre: 200 acres at R12 ..	2,400
Pruning R6 per acre	1,200
Upkeep of roads and drains	500
Tools; contingencies, general transport and repairs	1,000
Total fixed charges on 200 acres ...	R8,600

which on 40,000 lb. of made tea, comes to per pound cents.. .. .. .. 21·50

The cost of plucking, manufacturing, packages, transport, are the same rateably, whether the yield is large or small, I, therefore, take the cost of these from the "Manual" .. 15·00

Total cost per pound in Colombo cents.. 36·50

It may be urged that the cost of plucking 200 lb. per acre will be greater than that of 400 lb., if this is so, then the 400 lb. may be plucked; the leaf passed through a green-leaf sifter, and the coarse leaf put into the manure-pit.

I need scarcely point out, that many charges fall more lightly on high priced tea than on low, and that the fixed charges on cultivation compare more unfavourably than they would do if worked out. There is no use of arguing, that as Ceylon planters can produce tea to sell without loss, even if prices decline fifty per cent below the present average of thirteen-pence-half-penny there is no necessity to reduce production; because as overproduction must be put an end to, prices will fall not fifty per cent, but sixty or seventy until that end is attained.

A falling-off of 50 per cent in supplies from India, Ceylon and Java, would not only enhance the prices of fine teas, but those of all descriptions; moreover the masses, would, whilst fine teas were selling at 9d per pound, be educated into appreciation of good tea, and would not easily be again induced to consume the low teas which form so large a portion of what is exported from China. The Chinese have hitherto exported very largely, descriptions not averaging as much as 8d per pound, a decline of fifty per cent would compel these accommodating people to consume their own rubbish. No doubt, they would adapt themselves to circumstances, and ship more of their fine teas, but it would take a considerable time to induce them to abandon old customs, we need not, therefore, dread an over-supply of fine qualities, when low sorts are not procurable. It is fortunate, that it would require no united action to carry my suggestion into effect, because if prices from over-production are brought down to a ruinous point every planter will be compelled to do something if he can, to avert ruin; each can "paddle his own canoe," without consulting his neighbour.

I may be asked, why I trouble myself to write a letter so long in advance, which, if not based on a fallacy, would do much to encourage that increase of cultivation, which those like myself who are already interested in it up to the hilt, would like to see stopped short. My answer is that so far as Ceylon is concerned, the mischief —if there is mischief in it—has been done already or is in the course of being done. There is every probability that the colony will, in the course of five or six years, export 60 millions of pounds or more without any encouragement, but the prospects of the immediate future—but there is no disguising the fact, that there is a strong undercurrent of opinion that the Ceylon tea planter in his eagerness to retrieve past losses, has already overshot the mark and has gone, and is going too far ahead

* Mr. Armstrong and other experts have characterized fine plucking as more trying to tea plants than medium gathering of leaf.—ED.

as he did in the case of cinchona, and in a small way with cardamoms.

It does not suit my book, nor I think the book of any one interested in tea planting to have doubts thrown on the permanency of an industry to which we are irretrievably committed: and I do not think I am cutting my own throat in doing what I can to disperse doubts, which many people make use of to suit their own views. I commenced this letter with the intention of criticizing the article in the Manual on Manuring, as it appeared to me that the compiler, Col. Money, and Mr. Carter, had fallen into the mistake of calculatiug the gross value of the whole of the increased yield from the application of costly manures as profit without deducting the cost of manufacture, chests and transport, in fact all rateable charges on the extra output, but as this letter has spun out to an inordinate length, I must postpone my remarks on the subject *sine die*, no doubt, to the great satisfaction of your readers. This letter will, however, only be read by the few who recognize the signature as that of the writer of one you published in August 1883, in which, for reasons given in it, the conversion of coffee estates into tea gardens was strongly advocated and this is a sequence to it.—Yours truly, C. S. as

---

The Artificial Quinine Scare.—A very complete and amusing exposure of the Cresswell-Hewett deception will be found on our back page taken from the "British and Colonial Druggist." It seems clear to us that Mr. C. Hewett bolted to the Continent to escape being put to the test by Dr. Burton and Messrs. Burroughs, Wellcome & Co., in doing what he promised, namely, to turn out 2 lb. of marketable medical quinine,—satisfactory to two competent referees—at a rate not to exceed 4d an ounce, besides a bye-product of some value! Cresswell-Hewett is evidently either a madman or a rogue.

Fruit to England.—In reference to "Enquirer" 's letter of 28th October, a correspondent reminds us that in *Tropical Agriculturist* 1885-86, page 445, we published a letter on the subject of sending oranges to England—a box of these to Norwich, sent through the London and Colombo Forwarding Agency, arriving in capital condition. We learn that another lot of oranges went forward by the same agency a short time ago, and we hope to hear the result very shortly. We are told the object of wrapping such fruit in tissue, or blotting paper is in the first place to prevent them from touching each other, as almost all fleshy fruits are apt to decay at the point of contact, though they may not actually be bruised; in the second place to absorb any moisture that may exude from the skin. All fruit confined in boxes sweats to a certain degree and it is important to get rid of the moisture, if possible.

Water Power and Tea Machinery.—With reference no doubt to our remark on the suitableness of electric motors for connecting machinery in factories placed at suitable centres with water-power at a distance, a correspondent sends us some interesting information respecting a Darjiling factory. He refers to the gardens of the Tukvar Tea Company and states that the power for driving ample machinery for a large tea factory is provided by a turbine situated at the level of the river nearly 1,500 feet below the level of the factory, the power is carried up the hill by wire-ropes running round pulleys about a chain apart. The factory is a large one and is one of the Show places in Darjiling. Mr. Curtis is a practical Engineer. The machinery works well, as several Ceylon residents who have seen the place can testify.

The Lungla Tea Company, Limited, is registered with a capital of £40,000 divided into 4,000 shares of £10 each, with power to increase. The object is to acquire and take over as from January 1st, 1886, from the present proprietors, the tea gardens, plantations, factories, land and property, situate in the district of Sylhet, in British India, known as the Lungla Tea Estate, and all the manufactured tea and all the tea-leaf and other produce thereof respectively, and all the houses, erections, buildings, machinery, implements, utensils, elephants, live and dead stock, and all other property of whatever kind thereunto belonging at the price of £36,000 to be paid to the said proprietors in 3,000 shares in this company, on which the sum of £10 shall be credited on each share as paid; and also to acquire such other tea gardens, plantations and property as shall be convenient for the purposes of the company, and to carry on the business of planting and cultivating the tea plant and the manufacture and sale of tea. The first subscribers are:—M. Fox, railway contractor, of Catherine Place, Bath; Major-General T. B. Harrison, Blackheath Park, S. E.; H. A. Harrison, Judge, B. C. S., Blackheath Park, S. E.; C. A. Goodrich, tea merchant, Dashwood House, E. C.; A. R. McIntosh, merchant, 47, Queensboro' Terrace, Bayswater; G. Seton, merchant, 34, Old Broad Street; J. Sanderson, solicitor, 46 Queen Victoria Street, E. C. The number of directors shall not exceed five, and shall not be less than two, and the qualification of each shall be the holding of £1,000 of the nominal share capital of the company. The following are to be the first directors, *viz*:—Michael Fox, Beanfill Harrison, Frederick Bailey, Edmund Theodore Roberts, and Charles Alfred Goodrich, Mr. Fox being chairman.—*Times of India, Cor.*—London, October 21st.

Cinchona Culture in Brazil.—The *Rio News* states:—During the Senate session of the 20th instant Senator Tannay took occasion to call attention to the question of cinchona cultivation, and asked the government for information regarding the Berreira cinchona plantation. He referred to the efforts employed by the British and Dutch governments to encourage this industry, and the advantages which the state might derive from its cultivation. Senator Dantas took up the same subject and stated that the cultivation of cinchona was begun in the country in 1868, and that the experiment had given good results. In entire accord with the preceding speaker, he thought that the Government ought to encourage its cultivation on a large scale. There can be no doubt whatever as to the good results of such an industry provided it is intelligently carried on and it is not handicapped by export taxes. So far as it can legitimately do so the government will certainly do wisely to encourage this and all other new industries, for the country needs a greater diversity of productions. But how is this to be done? And is it not a sad commentary on the state of affairs that no industry can be started without government aid and encouragement? Must we believe that the Brazilian people have come to that pass where no industry can be initiated and no enterprise carried on without such help? And what future is there for a country so helpless as this? Instead of trying to secure aid and encouragement for this or that special industry, however advantageous it may be, we are inclined to think that the first duty of the government is that of arousing the people to think and act for themselves. Industry should be made less dependent upon the public treasury, and more upon individual enterprise. Instead of confining their whole attention to coffee and sugar cultivation, why should not the planters exercise their own good judgment and undertake the production of other staples? The state may very properly obtain information for them, and may even carry on experimental farms, like this cinchona plantation at Barreira, but beyond this is the domain of private industry into which the state should not enter. The minister of agriculture should furnish all the required information in regard to this experiment, which should be published, but we do not see that anything further should be done. The people should be made to feel that the matter is wholly in their own hands.

PLANTING IN FIJI: COCONUTS, CINCHONA, COFFEE.

(*From the Handbook to Fiji*)

Under the heading "Agriculture" a considerable space is devoted to noting the prospects and possibilities connected with the chief products of the colony. Attention is directed to coconut cultivation, and after describing the method considered to be most suitable, probable results are thus referred to:—"Taking the produce in Fiji at 60 nuts per tree, per year, an acre would give, say, 4,200 nuts. This would make about two-thirds of a ton of copra, the average value of which is about £7 10s., from which deduct the expense of collecting and manufacture, which is about £2 10s., which leaves a profit of £5 per acre. It may be added that copra is shipped to Europe where it sells at from £16 to £20 per ton. And it must be remembered that in the above calculation no account is taken of the husks, or pericarp, which, by the use of the proper machinery, is manufactured into coir fibre and is of considerable value. As to the cost of land and the expense in labor, etc., entailed to bring a coconut plantation up to the bearing point, a rate cannot well be fixed as many causes may operate to vary the amount. Land may be purchased at a low or a high figure. Labor may be well and economically used, while on the other hand it may be wasted most enormously. Taking the above into considaration the cost per acre for bringing a cocoanut plantation into full bearing may vary from £20 to £40 per acre; it may be done for £20, but it might take £40. If therefore, a person has capital to purchase, say, 500 acres suitable coconut land in the proper locality, to clear, plant, and cultivate 500 acres of coconut trees up to full bearing point, he may calculate on an income of at least £3,000 per annum as the combined profits of copra, fibre, and cattle. As to the value elsewhere of full-bearing coconut plantations, a reference to the Ceylon newspapers will show that sales of such property there are never made under £100 per acre, and often much more.[a] * * * Probably no crop or product is to be found where so large a return is obtainable at so small a risk as that of coconuts. * * * The husks from 700 coconuts produce about one ton of fibre, which is of the value on the estates in Fiji of from £5 to £15 per ton, according to quality. Brush fibre or bristles is worth from £15 to £30 per ton in Fiji. The cost of labor to produce one ton of fibre, exclusive of cost and wear of machinery, may by putting down at from £5 to 10."

The exact value of the foregoing will at once be relised by the coconut growers of Fiji, while those who desire to be enlightened may easily attain to the most perfect assurance on the point through the same medium, experienced.

"Cinchona" is the next product noticed and after a truthful statement to the capacities of the group for this cultivation, the subject is quitted with the following observations:—"Here a planter who can afford to wait for the returns for seven years cannot do better than open out a cinchona plantation; whilst for one whose capital is too small to enable him to wait there are many products such as tobacco, corn, ginger, cardamoms, bananas, etc., which he could plant as well, and on the immediate returns of which he might live until the cinchona would be fit to cut. For the capitalist who requires good interest for his money and a healthy pleasant life there are few places like Fiji." Reference is here kindly permitted to the long roll of capitalists and planters who have realised this good interest, but whose names have unfortunately not been mentioned.

Relative to the next product noticed, "Coffee," the gentleman whose name appears upon the title page gives assurance that it can be received with perfect confidence. Possibly he may not have written the matter; but he has been a coffee cultivator himself; the scene of operation specially reffered to is one with which he is intimately acquainted, and these facts are a sufficient guarantee that he would not countenance an imperfect or insufficient statement of the case. With this premise it is only necessary to quote briefly:—"Perhaps no tropical industry offers more genuine attraction to a man possessed of ordinary business ability with a taste for agricultural pursuits than does coffee-planting. * * * The coffee industry is no longer in its infancy in Fiji. Questions with regard to soil, natural fertility, elevation, and shelter having now been proved by the experience of pioneer planters, may be regarded as settled, and any one now opening up a coffee plantation in Fiji need no longer run the risks attending experiment in these directions. * * * The coffee-leaf desease which some four years ago threatened to crush the coffee industry throughout the world may now be said to have all but disappeared from Fiji. Experience has shown that it may be best resisted by high cultivation, and for this purpose the incomparably rich soil of the group offers facilities that cannot elsewhere be met with. On the island of Taviuni, for instance, which on account of position and fertility seems to have been specially selected as a field for the coffee industry, the disease is rarely to be met with. Of this island Mr. F. B. Thurber in his 'Coffee from Plantation to Cup' remarks:—'In the island of Taviuni, in the Fiji Group, there are some half-dozen coffee estates ranging in area from fifty to three hundred acres. Coffee trees are just coming into bearing (1880). At the Sydney Exhibition the first gold medal was awarded to an exhibit of coffee from Fiji.'" This is all that is said as to the present prospect of the industry. It is of course left to the Executive Commissioner to dilate orally upon the astounding progress which has been made with these half-dozen estates since the date above quoted. He may also be expected to supplement it with glowing references to the Wainunu, Bua, Rewa, and Serua plantations, and to explain under what exceptionally favorable condition, apart from those of fertile soil and admirable climate, they have steadily attained to their present high state of remunerative development. Connected herewith his own personal experience will supply a most encouraging illustration, and it will further permit of the confidential intimation that as soon as the exhibition is over it is his fixed intention to rush back to Fiji, put in a large area of coffee and to retire in a few years upon the magnificent addition, he will thereby be able to make to the colossal fortune he has already amassed.—*Fiji Times*—[This is, of course, sarcastic, coffee culture in Fiji, so much vaunted by Mr. Mason in the Hand-Book having been, really a great failure.—Ed.]

[a] Surely there is some great mistake here! Has coconut property in Ceylon ever sold at £100 per acre?—Ed.

AGRI-HORTICULTURAL SOCIETY OF MADRAS.

The Dinde Tree.—Read the following letter from Mr. Morris, dated Kew, 6th July 1886:—"In the Report of your Committee for the year 1885, mention is made of the seed described as 'Dinde,' a valuable timber tree sent to the Society from Kew. Mr. Dyer desires me to say that since the despatch of the seed it has been determined as *Colorophora tinctoria* or the Fustic Dyewood of the West Indies. I notice that in your Report you do not speak very favourably of the 'Tree Tomato' in Sourthern India. It is quite possible that it may not be quite so good with you as it undoubtedly is in the West Indies, but on the other hand, it may be found, on larger knowledge and experience to possess qualities which may commend it to general approval. The fruit should be allowed to fully ripen on the tree. This is an essential point as regards flavour and size. For cooking purposes, all the seeds should be removed and the outer skin, then cut the fleshy part into quarters and stew or cook as you would apricot or peach, or make into jam or jelly. If found too acid, steep in boiling water for a few minutes before using, and the flavour will be much milder. The painters in Jamaica attribute to it very beneficial properties as regards liver disease; and indeed my attention was first drawn to it under th

name of 'vegetable mercury,' I cannot say anything about its medicinal properties for I have had no opportunity to test them; but I can certainly speak highly of it as a fruit prepared in the manner above described. '' Recorded with many thanks, and resolved that Mr. Morris be informed that from more recent Reports his introductions of the "Tree Tomato" to the Hills of the Southern India may be regarded as a decided success which is much appreciated.

Tree tomato.—Read the following letter from Charles Gray, Esq., dated Coonoor, 11th August 1886:—"I notice in the Annual Report for the past year that the 'Tree Tomato' is said to have proved a failure as regards the flavour of the fruit. All I can say is that on the Nilgiris every one that I have given a fruit to, has pronounced it most delicious; and if the longing looks cast on the fruits on the tree after one has been given as a trial, are to be taken into account, I quite believe it. Unfortunately my supply is limited, or I could have disposed of hundreds, and if you have any surplus seed, I should be glad of some, as I am continually asked for some. I write this, as I, for one, (and there are many others here too) am decidedly in favour of its propagation, it being a valuable addition to our limited list of really tasty fruits, as well as being most ornamental. I do not know how the plant grows in other districts, but in Coonoor it grows with a nice straight stem about 6 feet high, and then branches straight out, each branch being very even in length; the clusters of scarlet fruit, from 3-10 in number, which hang well below the foliage, give a perfect picture that makes the tree an ornament to any garden.

Coca.—Sir Walter Elliot (M. C. S. Retired).—Read the following letter from Sir Walter Elliot.

I have to thank you for the last Report (1886) of the Agri-Horticultural Society, which contains an interesting account of your endeavour to distribute seeds of the Erythroxylon coca. In the Report of the previous year it was stated that it was expected to form an anæsthetic agent which would be useful in India. I looked for a further notice of this discovery in the present Report, but the subject of cocaine is not mentioned. Colonel Beddome told me that some years ago he tried to use the dried leaves as the Peruvian miners do, who chew them with powdered chalk as a stimulant, but he did not perceive that it had such an effect. The trivial name recalls to me a substance with which I was familiar many years ago, when employed under the Bombay Presidency. It was sold in the bazaar under the name of Kokum, a soft or soapy substance procured from the Konkan, and applied to the skin when cracked and excoriat by the sun with good effect. It is prepared from the seed of Garcinia purpurea of Roxburg common in our forests, and is described by Colonel Beddome in his Icones p. 64. It has often occurred to me that it might be utilized more generally if prepared in a more refined form. I brought a piece home which I sent two years ago to my son when with his regiment, the Black Watch, on the Nile expedition. They were the most advanced party, and suffered severely when rowing all the day against the stream under intense solar influence. It did not reach him in time to give it a full trial, but if it had, I am convinced it would have been of essential benefit. It might be worth the while of the Society to consider this. The Report of 1884, for which I have also to return the best thanks, made special mention of the Fourcroya, and other fibre-producing plants. When in London, last year, I found my old friend, General Fred. C. Cotton, R. E., much occupied with an improved process for extracting fibres from the cellular substance which, by the present practice of applying water from above, is apt to cause entanglement of the finer fibres. The improved practice consisted in forcing the water from below, which by the experiment then making appeared to answer perfectly in bringing out the fibres undisturbed. Very likely you may have heard of this, but I think it was well to mention it in case you have not. Owing to my complete failure of sight, I am unable to take the same interest in these matters that I used to do, in addition to which my advanced age acts as a still further hindrance. I still, however, love my garden, and should be glad if you would send me a small packet of seeds of Nilgiri and other Indian plants, which I formerly had, but have lost, I may mention particularly the Meyenia and some of the handsomer Acanthaceæ and Scrophalaceæ. I sent a small packet of Ipomœa Quamocut seed to my daughter in 1859, which after her marriage was found in her room, where it had been overlooked for 20 years, I sowed them, however, in 1881, though without the least expectation that they would germinate. To my great surprise they did so, when, owing to the carelessness of a stupid gardner, they were lost during my absence, after they had attained a height of 10 or 12 inches; I should like to try this exepriment again if you can send me a few seeds, both old, if you have them, and new. I shall feel much obliged if you will make my grateful acknowledgments to the President and committee for their kindness in sending the Reports." Recorded. The seeds will be sent.—*Madras Mail.*

KAPOK, or tree cotton, is attracting some attention just now, not only abroad but in this country. We therefore reproduce in another column this week, a somewhat lengthy paper on the subject from one of our English exchanges. Our contemporary has got a little "mixed" about the various sub-orders which make up the natural order which chiefly contain silk cotton trees: for instance, the N. O. Trestromaceæ (the Tea and Cammellia order) is included among the allied orders of Bombaceæ. In other respects, the paper contains much interesting information, and will repay perusal.—*Indian Agriculturist.*

FIBRE.—Our esteemed correspondent, Dr. Bonavia, of Etawah, calls attention, to the *white* flowered variety of the *Calotropis Gigentea* ('Madár') as an excellent fibre-yielding plant. Owing to the branching habit of the ordinary 'Madàr' and its low, straggling growth, it loses much of its value as a fibre plant, as the staple is very short. With the white-flowered variety it is different. The plants are single-stemmed, erect in habit, and grow to over six feet in height. We have frequently come across this variety in the North-Western Provinces and the Punjab, especially in the Delhi district. Dr. Bonavia's suggestion is a good one, and the experiment is worth being carried out on a small scale at first, if necessary.—*Indian Agriculturist.*

BRICK TEA.—Mr. C. Maries, the Superintendent of the Durbhunga Rej gardens and parks, gives a Calcutta paper an account of the manner they make brick tea in China. It is interesting, *apropos* of the subject, to know that tea bricks are used as currency in Tibet, where the salaries of the Chinese officials are paid with them. Mr. Maries says:—"I have visited the factories in Hankow, China, where brick tea is made. I was there in 1878, and, after watching the process with great interest, I saw only dust tea used—generally of the dirtiest nature—the very siftings of siftings to all appearance. The dust was weighed out and put into thin cloth bags; the bag was then put over a cauldron or large boiler and steamed for a certain time. When thoroughly steamed (the time was, as near as I can remember, about five minutes), it was taken and put into a strong wooden mould and pressed under a beam press, coolies acting as weight for the press by running along the beam. All was done most quickly and easily: it was less like work than play. After the pressing the mould was taken into a drying room, where the tea was allowed to remain in the mould till the cake was hard. The cake was then turned out and dried like common clay bricks till perfectly free from moisture. I did not see any other material mixed with the tea; nor was it damped before steaming. If the dirty Chinese dust would make good tea for Russian consumption, I should think the clean dust and refuse of the Indian tea-factories, such as I have seen, would make a profitable article of export. This brick tea is sent overland from Hankow to Siberia."—*Indian Agriculturist.*

TREE ROOTS AND BUILDINGS.—At a recent meeting of the Society of Arts, in the course of a discussion on Indian Archæology, Mr. Sewell said he did not know anything which would advance the preservation of ancient monuments in India more than the discovery of some means of checking the growth of tree-roots on the temples. All sorts of things had been tried in Southern India, but they had discovered nothing effectual. They burnt the roots with red-hot crowbars, and some people had suggested putting sugar upon them, in order to attract ants and other insects, but he did not think that was very practicable. If any remedy were discovered and made known, it would be invaluable.—*Indian Gardener.*

REMEDY FOR EARACHE.—The *Therapeutical Gazette* recommends the following as an effectual means of administering chloroform in this complaint, and one which is absolutely devoid of danger. This is to fill the bowl of a common clay pipe with cotton wool upon which pour as much chloroform as it will retain without dripping. This done, insert the end of the stem carefully into the ear, and let some one blow gently the vapour of the chloroform against the tympanum. The person blowing through the pipe must of course be careful not to *inhale* the fumes of the chloroform. This is an exceedingly effectual relief for earache in children when there is no inflammatory disturbances. —*Burgoyne & Co.'s Price Current.*

CANARY ISLANDS COCHINEAL.—A recent consular report states that the value of cochineal exported from the Canary Islands during the past year was £127,023. It is still the most important staple of exportation, and the principal product of the islands. We hear, however, that an attempt is about to be made to cultivate the tea shrub on these islands. With regard to cochineal, in spite of the above results, there has been a general falling off, amounting to something like 10 per cent as compared to the produce of the year 1884, particularly on the Grand Canary, where the crop of cochineal is always more than half the whole yield of the islands. It is asserted that the trade is evidently declining. Nevertheless, the recent rise in price gives some hope that the cultivation of the opuntia for the rearing of the cochineal insect will not be entirely abandoned for many years to come. It is not a little surprising that the discovery of the coal-tar dyes should have injured the cochineal trade; and it would doubtless have ruined it ere this had it not been found that most of the coal-tar colours are poisons, which cannot be employed with safety in pharmacy or in confectionery. This fact alone ought to cause a revival of the "good old times" as regards cochineal.—*Burgoyne & Co.'s Price Current.*

THE BAMBOO.—The following is an extract from the "Exhibition" number of the Journal of Indian Art for May 1886, describing the plans of the Indian Courts at the Colonial and Indian Exhibition:—"In the centre of the Economic Court the great Bamboo Bridge, or as it may be called trophy, is a conspicuous object, and the collection of over 3,000 articles made from this most versatile material, can only be briefly introduced by a quotation from Colonel Yule's Anglo-Indian Glossary, page 41—'In fact it might almost be said that among the Indo-Chinese nations the staff of life is a bamboo. Scaffolding the ladders, landing jetties, fishing apparatus, irrigation wheels and scoops, oars, masts and yards, spears and arrows, hats and helmets, bow, bow-string and quiver, oil cans, water stoups and cooking pots, pipe-sticks, conduits, clothes-boxes, pan-boxes, dinner-trays, pickles, preserves and melodious musical instruments, torches, footballs, cordage, bellows, mats, paper; these are but a few of the articles that are made from the bamboo. To these may be added from a cursory inspection of a collection in one of the museums at Kew, combs, mugs, sun-blinds, cages, grotesque carvings, brushes, jans, shirts, sails, teapots, pipes and harps."—*Indian Gardener.*

THE SANITARY VALUE OF TREES.—Dr. Stephen Smith recently read a paper before the New York Academy of Sciences on the sanitary value of trees in the city It is a well-known fact that during the intense heat of summer there is more suffering and death from sunstroke and high temperatures in the Northern cities than in the South, a result which must certainly be attributed to the absence of suitable protection. From three to five thousand people die every summer in the metropolis from the effects of heat. In the arid, treeless streets and avenues the temperature often runs from 130° to 150° Fahr., when under the branches of a thrifty shade tree it would not exceed 70° or 80°. In the absence of sheltering trees, the stone and brick walls act on the principle of the regenerative furnace, and absorb the heat of the sun to yield it up again during the night. If trees were planted in the streets the pavement and surrounding walls would be much cooler, and at the same time the trees would absorb the deleterious gases thrown off from the lungs and from decomposing matter, yielding in return a supply of pure oxygen. The value of a systematic culture of trees in all of our large cities can hardly be estimated. From both a sanitary and artistic stand-point they are a very desirable addition to any city.—*Indian Gardener.*

COMICALITIES IN PLANTS.—There is a jack in the pulpit, the flower of the plant known as Indian turnip (*Arisæma triphyllum*). Who could ever look at one of these singular blossoms, says a writer in the *Western Review of Science*, without that same stirring the risible faculties which one experiences in perusing a parody or caricature, or witnessing a pantomime? The very sight of one is provocative of mirth. How many times in my school days did I challeng the teacher's frown by involuntary giggles of the whimsical look of the imprisoned Jack! Monk's hoo of the genus Aconitum, has quaint, comical flowers, suggestive of an old lady's head in a night cap. The well known fly-trap, *Dionæa muscipula*, strikes the mind with all the effect of a joke. The leaves of this plant are fringed with stiff bristles, and fold together when certain hairs on their upper surface are touched, thus seizing insects that light on them. Seeing the leaf stand temptingly open, a poor fly pops in for shelter or food. No sooner has it touched its feet than some sensitive fibres are affected, and the cilia of the top closes in upon the intruder, imprisoning him as effectually as if a boy had taken him and closed him in a box. The pitcher plant, or monkey cap of the east, although not particularly ludicrous, has a whimsical arrangement which borders closely upon the human economy. To the footstalk of each leaf of this plant, near the base, is attached a kind of bag, shaped like a pitcher, of the same consistence and colour as the leaf in the earlier state of its growth, but changing with age to a reddish purple. It is girt around with an oblique band or hoop, and covered with a lid neatly fitted, and moveable on a kind of hinge or strong fibre, which, passing over the handle, connects the vessel with the leaf. By the shrinking or contracting of this fibre, the lid is drawn open whenever the weather is showery or damp. When sufficient moisture has fallen and the pitcher saturated, the cover falls down so firmly that evaporation cannot ensue. The water is thus gradually absorbed through the handle in the footstalk of the leaf, giving sustenance and vigor to the plants. As soon as the pitchers are exhausted, the lids again open to admit whatever moisture may fall; and when the plant has produced its seed, and dry season fairly sets in, it withers, with all the covers of the pitchers standing open. The flower of the *bee orhcis* is like a piece of honeycomb, and the bees delight in it. Then there is the snapdragon, the corolla of which is cleft, and turned back so as to look like a rabbit's mouth, especially if pinched on the sides, when the animal appears as if nibbling. The flowers of the cock's comb, and the seed pod of the *mostynia probosscidia* bear curious resemblance to the objects which have suggested their names. Some kinds of the *Mendicago* have also curious seed-pods, some being like bee-hives, some like caterpillars and some like hedgehogs—the last being itself an essentially ludicrous object.—*Scientific American.*

VEGETABLE CULTURE IN NUWARA ELIYA:

INSECT PESTS—A NEW WRINKLE &C.

(*Written for the "Ceylon Observer."*)

Kitchen gardening at the Ceylon sanitarium is not "all beer and skittles." I have been up here for nearly a year opening up extensive gardens, for the rearing of choice European vegetables, and, though as is usually the case, I have had to pay for my experience, I have yet no wish to bottle up and hide under a bushel, any useful wrinkles, or little knowledge I may have gained.

You have long ago asked me, to jot down some instructions as to the growing of vegetables in the highlands of Ceylon. To begin with, I had not until lately acquired sufficient knowledge to authorize me to write on the subject with any degree of confidence. In the second place, constant outdoor work, superintending Nuwara Eliya coolies,—and *such coolies*—is not conducive to scribbling and desk work. I am not, I think, naturally a bad-tempered fellow, but if Job himself had had the ordeal to go through, I do believe the writings of that patient Saint of old, would have been handed down to his posterity in a very much more modified form. But I am wandering from my subject, and first let me give you a few lines on our insect pests.

1.—*Insect pests.*—The worst enemy to Horticulturists here, and indeed lower down to about 3,000 ft. elevation, is the "black grub," the most destructive of all loathsome creeping things, it has been my misfortune to make the acquaintance of. It is the larva of a small gray moth,* and reaches to the length of about 1½ inches. This black *imp* may be termed an *omnivegetarian*, feeding on no particular plant, but cutting down indiscriminately everything that comes in its way. Fancy what a blessing this little *cuss* would be if it would only confine its attacks to the herbage and weeds, which nature originally provided for it to feed on! Not a bit of it, his taste has got highly educated. He has a decided predilection for the succulent cauliflower, and is ravenously fond of a *good salad*, beetroot and lettuce plants not having a ghost of a chance with him. The omnipresence of *these* "varmints," seems to me to be a good example, of Darwin's theory of the survival of the fittest,or at least in this instance of the *most voracious*. The unkindest part of it is, that this knowing poochie, does not seem to feed on the plants it attacks, but simply cuts their throats, just at their junction with the ground. In a word, he is a regular little garotter. He leaves his victim prostrate and knowing his deeds are evil, proceeds onwards in the darkness of night, to repeat his wanton mischief. The *mothers* of these little imps must be bad ones, for they do not attach their eggs to any particular food plant, as most respectable and high caste moths and butterflies do, but deposit them in the *ground*—instinct dictating to them that their ill-begotten progeny from their naturally predatory habits—will have no difficulty in gaining a livelihood. Now what are the cures for this pest? To begin with we have a plant growing in Nuwara Eliya—a tall species of Lobilia, † which when cut up and put round the stems of the young plants, undoubtedly wards off the attack of this destructive grub. This acts, however, only so long as the acrid, milky juice of the plant is fresh and potent and this chopped up Lobilia requires to be repeated frequently, to be of much efficacy.

But now let me give you and your readers a wrinkle, which to a great extent, thwarts this villainous little vegetable garotter. My friend W. and I sometime ago put our heads together, and vowed vengeance against him. We made up ever so many horrible concoctions, the rehearsal of which would be far from pleasant:- many of them were most effective and such as no poochie ever born could *face*,—but too expensive and troublesome to pay. At last we got on the right tack, and the best and most effective cure we have yet discovered, is one, which I fear you will look on, as down right desecration and vandalism,—but the truth must be told. Our old *Ceylon Observers* are carefully cut up into squares of 3 by 3 and 4 by 4 inches. These little fragments of the "Old Rag," are carefully rolled round the necks of our cauliflowers, beet and cabbage plants &c., and form real *comforters*. We then finish off by giving these fragments of your valuable journal a dash of coal tar and when Mr. Poochie comes in contact with them, he sheers off in quest of a more palatable diet. The past numbers of other local papers are dissected in the same ruthless way, but I feel sure, the editors will excuse the apparent sacrilige, when they view the matter in a utilitarian and philanthropic point of view. The *London Times*, the *Spectator* &c., sent me occasionally by a very dear friend, share the same fate. It is indeed an interesting subject for reflection, that the mental food provided for man by so many able journalists, should scare away the black grub. Mr. Poochie has evidently no stomach for *tarred literature*.

The next destructive larvæ we suffer from here are those of several species of beetles—or what are generally known as white grub—repulsive looking things with big heads, but not very injurious to vegetables.

A much more serious pest is a little tiny black fly which appears only, thank goodness, at certain seasons. There are several species of these, some almost microscopical; two of them are evidently of the *Ichneumonidæ* family and to the minute larvæ of which, we fear, we have to trace much of the damage done to our very young seedlings. The wire-worm is also a severe scourge to say nothing of the cockchafers.

Sulphur when sprinkled over the seed beds just before the first or cotyledon leaves make their appearance, will be found useful in warding off the attacks of the small black flies: and of course, one of the best plans to keep down black grub, is to constantly collect them at the roots of the newly cut plants. This, however, is far too expensive and tedious a task in a large garden.

I have noted briefly our worst insect enemies, and in my next I will enumerate and return thanks individually to our best garden friends—the *insectiverous birds*.

A. W.

* *Agrotis segetum*—A clouded, dark grey moth 1¾ inch in expanse of wings, with whitish margin to upper wings, and abdomen whitish grey. A similar American species, is *A devastator*. the moth of the "cabbage cut worm." A specific name most appropriate to our DEVASTATOR.

† *Lobilia excelsa*.

BURMAH: PLANTING AND NEW PRODUCTS.

(*By an old Ceylon Planter.*)

ARRACACHA.

Arracacha is an esculent tuber known in the vernacular of the West Indies by this name; it requires no water, it flourishes equally well in dry or wet season, it gives a much larger yield than the ordinary potato; many people in Jamaica, even the blacks, prefer it to the yam and potato. No insect or blight—nothing seems to interfere with its growth, and it is believed that its general introduction into India would go far towards making many of our provinces nearly famine-proof! If such a result can be attained it is certainly worthwhile trying its introduction into this country. The Arracacha is a native of the elevated regions of equatorial America, Pasto and New Granada, where the root is largely cultivated for food. It has since a very recent date been introduced into Jamaica; it is called by botanists *Arracacha esculenta* and is classed in the natural order *Um-*

belliferæ.* In Spanish it is known as *Apio* (from the Latin *Apium*, celery), and is in appearance as a growing plant similar to celery, as a substitute for which the tender shoots can be used. It may be used with advantage when celery or parsley is used. It is also described as being somewhat like the hemlock, but its leaves are broader, its stem is dark-green, deeply striated but not spotted; it grows to about three feet high and its flowers are of a dingy, purple colour. The roots, which are the object of the cultivation, are large and divided into several tubers which in shape and size are like short carrots, but more oval or rounded and irregular in shape. As food, the tubers are very wholesome and nutritious, and when boiled are firm and have a flavour intermediate between a chestnut and a parsnip. A fæcula, analogous to arrowroot, is obtained from the root by rasping in water, as starch is from the potato. The yield in tubers is very large and as much as 16 tons can be had from land that will not bring more than 9 or 10 tons of potatoes. There are 36 heaped bushels to the ton; so, put this at the low rate of 50 cents per bushel, and so make your calculation. The mean temperature of the Arracacha country is said to range from 64 deg. to 82 deg.; the tuber is cultivated at an elevation from 4,000 to 6,000 feet above sea-level, the night temperature being from 55 deg. to 65 deg. in the shade. The climate is said to be free from the extremes of frosty cold weather and dry summer heat; it is one of continual moist. Would not this suit your beloved "Nuwara Eliya," Mr. Editor!

The Arracacha requires a deep, rich soil, or loose mould like the potato; and the ground if thoroughly cultivated so as to provide a deep friable clean bed, will give well-developed roots. A large number of sets is produced by one plant and the propagation is rapid. The *modus operandi* is as follows: the propagation of the Arracacha is effected by the separation from the plant at maturity of a number of small peduncles or heads (leaf-stalks) spreading from the central root, which also underground throws out the carrot-shaped horns which are the best of the edible part. The hard upper part of the central tuber to which these leaf stalks are attached serves for hogs or cattle, as do the leaves for the latter.

The planting is done in rows, with a distance of from three to four feet between each row, and as much between each in the rows. The sets are planted by simply making a hole in the prepared ground about six inches deep with a pointed stick and inserting the set slanting with the concave of its curve upwards, and then treading in the soil slightly leaving the short bit of the stem barely at the surface. The average length of the set with the small piece of root attached will not exceed three to five inches. The set being broken off, the root should be neatly trimmed to a clean smooth surface. Weeding and earthing-up constitute the subsequent culture as often as required. It is customary also when the plant grows large to gather together the leaves and twist their necks moderately—a process said to prevent running into head and favouring the development of the root. There does not seem to be any particular season for planting. In favourable situations the planting may take place whenever ground and seed are available, and probably the close of the well-defined dry season would be the safest period.

The plant requires from 10 to 12 months to reach maturity, but the tubers (or carrot-shaped roots) may be gathered two months earlier than this period if much wanted. In this event, of course, the produce in quantity is less, but it is said to be equally wholesome and agreeable to the taste.

As to diseases properly so called, the Arracacha has none. Occasionally, when exposed to much drought it becomes as it were frost-bitten, in which state it boils semi-transparent and remains hard after cooking, and is unfit for human food. If, however, plants so affected are allowed to remain till the return of the rains and to renew their foliage, the root will recover. Manure is never employed. I can, therefore, give no opinion based on experience as to its application.

But analogy would indicate that, as in the case of the other edible roots, the support and stimulus of manure could hardly fail to produce greatly-increased crops and improve quality of same.

Wild Silk in Burmah.

You will, I am sure, be glad to learn that the wild silks of British Burmah are attracting attention; and that those prepared and sent last year by the local Government to some English manufactories for experiment have been pronounced superior than Chinese and Indian *tussur* silks.

A further supply is now being prepared under the orders of the Chief, Sir Charles Bernard, and will be submitted for experiment to some of the leading Continental manufactories.

Tea in Burmah.

You seem to be all T., all tea; the *T. A.* is monthly all T. and the *Observer* is all tea (and tea machinery). Well, you have set me planting T. T. I have planted up 34 odd acres this year, and my tea-plants are really splendid from 2 to 3 feet high already, other products covering the ground some places rather too thick, in fact. As I have written you at greater length than I intended to do, I shall forbear until my next on planting, when I shall give you a line on planting and our troublesome war.

Indigo in Burmah.

Indigo manufactured in British Burmah has been sent to India for valuation during the present year. It is known that Indigo grew wild in the country, and that the Chins and other hill-tribes extracted a dye from the plant. No manufactured indigo had, however, been sent to India; and the first attempt has been made by a native of India named Kafir-nel-din, on the Wimpadnoo island of the Shwegyin district. The cultivation was tried on a small scale, but it was sufficient to prove that indigo could, in certain localities, be cultivated in the plains of Burmah. The indigo manufactured was valued at only £6 to £6 10s per maund. The defects pointed out in the report can be corrected by more careful manufacture.

* We quote from the "Treasury of Botany" as follows:—

Arracacha. A name applied by the natives of the northern parts of South America to several kinds of plants, possessing tubers or tuberous roots, but, botanically speaking, confined to a genus of Umbelliferous plants allied to the hemlock. Its principal distinguishing characteristics are—limb of the calyx entire; petals ovate or lance-shaped, purplish, with the point bent inwards; fruit turgid, compressed from side to side, wingless, surmounted by the thickened bases of the style; albumen curved. *A esculenta* is cultivated in the cooler mountainous districts of Northern South America, where the roots form the staple diet of the inhabitants. The plant is somewhat like the hemlock. (*Conium maculatum*), but its leaves are broader, its stem not spotted, and its flowers are of a dirgy purple colour; the roots are large and divided into several fleshy lobes of the size of a carrot which when boiled are firm and have a flavour intermediate between a chestnut and a parsnip. Trials have been made to cultivate the plant in this country but the climate has not been found suited for it. It might be tried in some of our colonies with advantage. M. T. M.

The name Arracacha is also given to one of the trubs-bearing species of Oxalis, *O. crenata*.—T. M.

FIREPROOF TREES.

TO THE EDITOR OF THE "PHARMACEUTICAL JOURNAL."

Sir,—The "Fireproof Tree," described by Mr. Dyer in the *Gardener's Chronicle*, and referred to in your issue of October 2, would seem to lend some credence to the wonderful tales of Methodius, Nieuhoff (quoted by Folkard) and others, of similar "vegetable salamanders" growing in various parts of the world. One of these, near the city of Buran, in Natolia, is described as rooted in fire, and yet flourishing in great luxuriance and beauty, whilst another, somewhere in Tartary, even when cut down and thrown into the fire, can neither be ignited nor consumed, for though it becomes glowing red in the flames, yet as soon as they are extinguished the wood is again cold, and precisely the same in appearance as before. You ask, naturally enough, "to what cause this immunity is due?" Is it possible these trees belong to the same order as the one described in Bishop Fleetwood's 'Curiosities of Nature and Art' under the name of *Mesoneidereos*, which grows in Java, has iron wire for pith, and produces a fruit impenetrable by iron? Or perhaps they are related to that equally wonderful plant which Sir John Maundeville saw in the city of Tiberias:—"In that cytee (says he) a man cast an brennyngne dart in wratthe after owre Lord, and the hed smote in to the eerthe, and wex grene, and it growed to a great tree; and yit it growethe, and the bark there of is like coles." However this may be we shall have in future to read these old travellers' tales somewhat less sceptically than heretofore.—C. O. BELL.

[The above from the *Pharmaceutical Journal* reminds of the property, of resistence to fire possessed by some of the Indian figures. After "a good burn" which destroyed most of the felled forest on a plantation being opened, we found some gigantic trunks of fig trees at an elevation of about 5,100 feet, not only intact but the bark retaining its natural colour. It was many years before the trees yielded to decay. —ED.]

COLONIAL AND INDIAN EXHIBITION.

COLONIAL PAINTINGS, PHOTOGRAPHS, AND DRAWINGS.—A most interesting and bulky volume might be produced on the photographs and paintings of Indian and Colonial scenery exhibited in the different courts of the Exhibition.

New Zealand.—The collections of New Zealand paintings will not readily be forgotten, especially those of the celebrated Pink and White Terraces, which have become famous, if not historical, on account of the recent eruption.

New South Wales.—The photographs also are of unusual excellence. The New South Wales collection of paintings will also be well remembered, many of them giving vivid impressions of characteristic vegetation, especially of forests scenes in which the various species of Eucalyptus play a prominent part. The splendid set of water-colour paintings of Australian plants by Mrs. Ellis Rowan will be especially valued for their general beauty and accuracy of drawing.

Trinidad shows some instructive photographs of the growth and preparation of Cocoa (Theobroma cacao), the staple product of the island; while on a screen between the Trinidad and the British Guiana courts is a series of excellent photographs, several of which illustrate the cultivation and preparation of sugar, including a general view of a sugar plantation, a field of young canes, banking and planting, weeding, passing canes through the mill, view of manager's quarters—a really fine house, behind which are the works, and in front and around some tall Palms and various tropical plants—apparently very comfortable quarters, which is fully confirmed by another photograph of interior of the manager's parlour, the appointments of which are even luxurious. This series is both interesting and instructive. One photograph which cannot fail to attract attention represents a portion of a trench 3 miles in length filled with the Victoria Regia Water Lily, the circular leaves of which are so thickly grown together as to form a covering from bank to bank. Three miles of this magnificent aquatic must be a splendid sight when in flower.

Straits Settlements.—In the Straits Settlements a collection of photographs of buildings and some of the principal economic plants are shown, amongst others a group of Sago Palms at Singapore, an avenue of Cocoanut Palms, also at Singapore; a Tea plantation, in which the plants strike us as being very wide apart, not only in the rows but from each other. That illustrating the preparation of Gambir (Uncaria Gambir) is of considerable interest. Outside the thatched huts, which are shown on either side, is spread the Gambir to dry on light Bamboo frames. Another photograph shows a very fine group of young Betel-nut Palms, the trunks of which are remarkably straight and slender. A Pepper plantation, with the crop in process of harvesting, is shown, as well as Liberian Coffee trees in full bearing.

Ceylon.—In the Ceylon court, besides others of special trees and characteristic vegetation, the series illustrating the preparation of Tea is extremely good, and will be found very useful.

Natal.—In Natal there are a large number of photographs of very varied subjects. Those bearing on subjects with which we are most interested are amongst a series exhibited by Mr. G. T. Ferneyhough, of Pietermaritzburg; one represents the smoking of Dakka, or Hemp (Cannabis sativa), or, as the Kaffir calls it, "Isangu." Dakka is described as being a "corruption of the Dutch work for the weed." The following description is given of the photograph:—"The plant grows wild all over Natal in waste places, and produces large crops of seed, but is useless for fibre—at least, so far as experiments have gone, and the natives alone make use of it. At a certain stage of its growth, *i.e.*, when the flowers are fully out, branches are cut off, and allowed to dry in the sun, and are then tightly packed in bundles, wrapped round with grass matting, when it is ready for use. The pipe of the Kaffir is a species of hookah, and is called 'Igadu.' It consists of a bullock's horn, in which about half-way up is tightly inserted a hollow stick in a slanting direction, which reaches nearly to the bottom of the horn. This stick is surmounted with a bowl or pipe-head, made of a softly cutting greenstone—"soap-stone," which is very heavy. The pipe being filled with 'Isangu,' or Hemp, the horn is filled with water, and the smoke is drawn up into the mouth; several puffs are taken, until a volume is secured, which is retained for a time and partly swallowed. This soon produces spasms, and results in a most violent fit of coughing, that would kill any ordinary white man. This is the luxury sought for, together with the stupefying and soothing influence of the narcotic contained in the plant. The fit of coughing having subsided, the saliva generated is then passed through a long hollow reed, and a series of bubbles results which are formed into circles, representing kraals, or into strings and other shapes, and according to number, size, and other indications are taken as signs of future wealth, number of wives, and other items interesting to the childlike mind of the Kaffir. This continues until they have had enough, and sleep or go away. The smoking of this wild Hemp is the most noxious and injurious habit that the native indulges in."

While writing of Natal it may be well to mention that the exhibits of Tea grown and prepared in the colony have attracted a considerable amount of attention, and that the Tea is now on sale in the Natal court. We have had an opportunity of tasting this Tea, and find that the quality is very good. The only fault is that it is a little too much roasted. This, of course, will be readily improved upon, and there seems no reason whatever against Natal becoming a regular Tea-growing country. Numerous samples of Tea from different estates are exhibited, and it is worthy of note that the China Tea from one estate—namely, that of Mr. Brickhill—was obtained from plants introduced from the Royal Gardens, Kew, twenty years ago.

Fruits, &c.—Amongst a fine collection of preserves from native fruits those exhibited by Messrs. Jameson & Co., of Durban, attract most attention, though from the fact of their being in sealed tins the public are unable to see what they are like, still less to judge of their value. Mention may, however, be made of three of these from characteristic tropical fruits, namely, the "Amatungulu" (Carissa [Arduina] grandiflora), which is of a dark reddish colour, not unlike Plum jam in appearance, but with a less decided flavour. The Papaw (Carica papaya), about the medicinal properties of which so much has been written of late; this produces a fine soft preserve of a yellowish-green colour, and a slightly acid taste. The Granadilla (Passiflora maliformis) has, perhaps, the most distinct and agreeable flavour of either, having a slight trace of Pine-apple; one objection, however, is the presence of the very numerous black seeds, which cannot readily be crunched between the teeth, nor can they readily be ejected, inasmuch as the pulp clings to them with great tenacity. It is interesting to see what can be done in the matter of preserve-making from tropical fruits; and though few, if any, can ever approach the best known English fruits, the foreign produce might be made to supplement that of our own country. Though it may not be practicable to import fresh fruits in any quantities into England from distant countries, there seems to be a field for tropical candied fruits, which might be brought in tins or jars, as well as for whole fruits preserved in syrup, and hermetically sealed in a similar way.

The Natal exhibits of vegetable food substances generally are very interesting, and great credit is due to Mr. Morton Creen for his readiness in making the exhibits known, and assisting by the help of samples to develope the resources of the colony.—John R. Jackson, Curator, Museums, Royal Gardens, Kew.—*Gardeners' Chronicle.*

HALDANE'S SUB-TROPICAL CULTIVATIONS.

This very instructive and well got-up work should be in the hands of all those planters, who desiring to profit by past experience in regard to coffee, are resolved to vary their cultivations as much as climatic conditions will allow. Mr. Haldane has entered very fully into the geographical and climatic distribution of the various classes of products with which he deals, in some chapters placing before his readers carefully prepared maps, on which are indicated the localities of certain growths. In many instances, such as that of vine culture, the reader is informed why certain latitudes are unsuited, and others suited to particular products, by attention to which planters and settlers may often avoid costly mistakes.

Of the Grape vine, Mr. Haldane says:—"Beyond the 50° parallel of latitude, the fruit is deficient in the saccharine matter required in alcoholic fermentation: the wine not possessing sufficient alcohol to preserve it is sour, and more like vinegar than wine. On the other hand, if the vine is grown in too warm a climate, too much grape-sugar is produced, and the grape gives a thick, sweet alcoholic fluid of indifferent quality. When the vine is cultivated in tropical countries, where there is no winter to check its growth, which is therefore uninterrupted, we find it producing in the same cluster flowers and both green and ripe fruit in consequence of which wine-making becomes impracticable." Whether this has been found to be the case in Ceylon I am not aware. The author alludes to the practice of the Jaffna vine cultivators of baring the roots of vines during the dry season in order to check vegetation, and arrest the flow of sap as is caused by a winter, but I find no notice of vine-growing in Colombo where grapes as good as those of Jaffna are occasionally produced, but the probability is that the climate on the west coast of your island is too humid for the vine, Mr. Haldane insisting on the necessity for a dry atmosphere.

The chapters on the *citrus* variety of fruits contain some interesting information, and seeing how readily the tree grows and bears in Ceylon it is surprizing that so little has been done for the production of a finer class of orange than is usually met with in your bazaars, where in fact the articles sold under that name are very frequently "sweet limes." The author tells us there are 45 varieties of the sweet orange, 31 of the sour variety, 12 of sweet lemons, 5 of bergamots, 47 of lemons, 9 of limes, 1 of citron, 17 of the cedrat, and 6 of the Shaddock or Pomplemouse (Pumeloe).

Mr. Haldane says he has eaten most perfect oranges in Ceylon grown at an elevation of 1,000 ft.; we have tasted some of the finest and most delicate flavored grown at almost sea level; at the same time we agree with the author that as a rule the Ceylon oranges met with in the native bazaars are sorry rubbish, of which the Sinhalese growers do not appear to be aware any more than they are of the difference between a good and a bad egg. It seems strange that, whilst in several of the warm colonies of Australia the cultivation of the orange for marketable purposes is carried on upon a large scale, little, if anything, has been done in your island towards extending the production of this really fine fruit. In New South Wales it is usual to estimate the value of a full grown orange tree at £1 per annum and fine trees in full bearing have given a return of £100 per acre. Large trees 18 years old have given from 150 to 200 dozen oranges yearly. The trees are subject to root-rot, the remedy for which is to bare the main roots for a short distance round the stem and expose them to the sun for a short time.

The lime is cultivated in the West Indies for the production of lime-juice, in which there is a large and paying trade to Europe, after the juice has been boiled down to a certain state of condensation. The tree grows readily from seed and taken from the nursery may be planted out fifteen feet apart; they begin to bear in four years and are in full bearing at eighteen years.

Mr. Haldane affords a good deal of information about tea and coffee cultivation as well as of rice, sweet-potato and arrow-root cultivation. The Olive cultivation is believed to have a good future in some of the Australian colonies, and would no doubt thrive in your hill districts. The best situation for this culture is on the slope of a hill facing the morning sun, beyond the influence of fog or mist, and well sheltered from high winds. The tree is very easily propagated and lives to a great age, some say 300 years. They commence bearing when 10 years of age and reach their prime at forty, giving a gallon of oil per tree: at the age of 30 years the tree will give a return of 2s. Space alone forbids our doing full justice to this very carefully compiled work, which is worth all the money charged for it.—J. C.—Local "Times."

THE COLONIAL AND INDIAN EXHIBITION AT SOUTH KENSINGTON: DRUGS.

Ceylon.—Drugs are largely represented in this Court. A collection of three hundred and sixty-two specimens of native remedies is exhibited by Dr. Trimen, the Director of the Royal Botanic Gardens at Peradeniya, and the special catalogue gives the vernacular and botanical names of these drugs, with their medicinal uses, making it one of the most perfect of its kind in the Exhibition. A case illustrating the cultivation and manufacture of cinnamon in all its stages, accompanied by series of photagraphs, and by specimens of the tools used in the process, forms a very interesting exhibit. This is from the property of Mr. David Smith, M.P. for Brighton. The exports of cinnamon appear not to have increased much during the last ten years, having been 1,262,250 bales of bark and 258,381 of chips in 1876, and 1,574,022 of bark and 628,914 of chips in 1885. The chips consist of the cuttings from imperfectly grown cinnamon branches; they are said to be largely used in perfumery and in the distillation of cinnamon oil, much of which is made in the island. The current value of cinnamon is given in the Official Catalogue as 1*s.* 3*d.* per pound for the first quality, 9*d.* to 11*d.* for the second sorts,

and 6*d.* or 8*d.* for the third; these prices allowing profit only on very well cultivated and carefully managed properties. There is also a good show of cardamoms, some of the samples being remakably fine. Two kinds of the plant are cultivated in Ceylon, viz., the ordinary Malabar kind, which throws out its racemes horizontally, and the Aleppy, commonly called the Mysore cardamom, which has upright racemes and is more robust and hardy than the Malabar kind, standing drought and a high altitude better. The Malabar cardamom is, however, usually cultivated, since it is more productive. The cardamoms known as Ceylon cardamoms are gathered by the Sinhalese from wild plants, and dried in a comparatively careless manner, while the cultivated cardamoms are treated with great care. The fruits are cut off with scissors by the coolies, then spread out in trays, slowly dried, and subsequently bleached, the chief object being to prevent the capsules splitting and to have them of a whitish colour and well filled and solid. If gathered in the immature state they are of a light colour, and have what is known in trade as "lean" appearance. A good deal of the spice is said to be consumed in India for cooking and chewing. Nutmegs are exhibited from the Kalutara and Kégalla districts. The tree is grown chiefly by natives, at altitudes ranging from 1000 to 1800 feet. The annual value of the exports amounts to only 26,000 rupees. Cloves are shown from the same districts. This spice is grown in similar localities to the last, and comes into bearing when seven years old, continuing to yield crops for fifty years or more. The yearly shipment of cloves amounts in value to 6,000 rupees. Pepper is shown by three exhibitors, but although commonly grown by the natives it is not exported; several varieties of the plant are in cultivation in the island. Of vanilla there are two exhibits. According to the Official Catalogue the flowers have to be fertilized by hand, the insects of Ceylon appearing not to be able to effect this process, unlike those of the native country of the plant (Mexico). The flowers usually appear during the hot dry north-east monsoon, *i.e.*, from January to April, and the pods begin to mature about the commencement of the following north-east monsoon, increasing in size and ripeness until January. As soon as they begin to show an orange tint, they are gathered and air-dried, cotton wool being fastened round them to prevent their splitting open. The plant thrives only in rich moist ground, under somewhat lofty shade, and fruits well in the neighbourhood of Kandy; with care it has borne fruit also near Colombo.

Cinchona bark forms a very prominent exhibit in this Court. A trophy formed of trees and large quills of bark serves to illustrate the varieties in cultivation and the several modes in which the bark is removed, as well as the usual size of the trees at different ages. From these specimens it is evident, however, that the name of Ledger bark is applied to more than one kind of bark rich in quinine. It was not until 1872 that the planting of cinchona was commenced in Ceylon in earnest, and it increased between 1873 and 1878, until about 4,000,000 plants had been distributed to planters, in addition to large plantings in private nurseries. Much of the seed obtained in 1886-7 from *C. succirubra* and *C. officinalis* produced trees of a hybrid character rich in alkaloid, these trees being known under the name of *C. robusta*. The methods of harvesting adopted in the island have been by uprooting, by coppicing, by stripping, and more recently by shaving. The last-named process has usually, but not invariably, been found to yield a larger percentage of alkaloids than the original bark. The extent to which it may be carried has not yet been ascertained. Many experienced planters recommend shaving the tree at five years, and again at six, and coppicing at seven, taking care that a good-sized sucker is allowed to start from the collar before cutting down the tree. The reason that the shaving process finds so much favour is that it enables the planter to obtain handsome and continuous returns without destroying the value of the tree. Although some of the finer varieties have at times yielded as much as 10·50 per cent of sulphate of quinine from trees three and a half years old at an altitude of 3,200 feet, at the present day there are few that give 4 per cent, the largest proportion yielding only 1·50 to 2·50 per cent. The shipments of late years have consisted largely of the strippings of the branches and twigs, containing not more than ½ per cent of quinine. The exports of cinchona bark from Ceylon have risen from 18,731 pounds in 1875 to 11,678,360 pounds in 1885. A specimen of sulphate of quinine is shown by Messrs. Symons and Cochrane, of Colombo.

The essential oils of cinnamon bark and leaf and citronelle and lemon grass oils are represented by several exhibits. According to the Official Catalogue the shipments of citronelle oil have increased from a few thousand ounces about a dozen years ago to 1,760,677 ounces in 1881 and 5,721,112 ounces in 1885, and there are now about 10,000 acres of land under cultivation; this over-production having caused the oil to fall to one-third its former value, and the price being now unremunerative, growers are now abandoning many of their grass fields.

The oil of lemon grass, or as it is commonly called oil of verbena, is manufactured entirely by the natives, but not more than 8,719 ounces were exported last year. Oil of cinnamon is distilled in the island from broken quills and the coarser portions of the bark, which are incapable of being worked in with the usual quills. The finest oil is valued at a rupee per ounce, but the inferior quality commands only one-fourth of that price. The shipments of the oil have risen from 41,719 ounces in 1881 to 117,023 ounces in 1885.

Of the resins exhibited the following seem worthy of notice, viz, that of *Doona cordifolia*, shown by Dr. W. C. Ondaatje, of *D. Zeylanica*, which is colourless and hard and makes a good varnish, and that of *Vateria acuminata*, which is a good clear white dammar-like resin. A fossil resin, dug up on the island, named "Bindummala,"* the origin of which is unknown, is also shown. Of dye stuffs that of the jak wood *(Artocarpus integrifolia)* is worthy of note. It is used by the natives for dyeing house mats and fibres for ornamental purposes and gives to cotton and silk the peculiar pale canary colour which is required for the robes of the Buddhist priests. Mililla wood (*Vitex altissima*) is used to give a still paler yellow, but neither of these dyes are exported. Sapan-wood, which in 1883 was exported to the extent of 11,404 cwts. has declined to 2,834 cwts. in 1885, owing to the low price now obtained for it.

The chief tanning materials used in the island are ranawara bark (*Cassia auriculata*), and the half-ripe fruit of the timberi (*Diospyros Embryopteris*). The latter is also used to coat the planks of boats to preserve them from the attacks of marine insects. The tannin of the plants of this genus appears to be of a peculiar character and to deserve further investigation. Very fine specimens of plumbago are exhibited in this Court from the western and north-western provinces. The trade in this article has increased from less than 1,000 cwts., forty-five years ago, to 279,057 cwts. in 1883, half of which goes to the United States, and of the remainder seven-sixteenths to the United Kingdom, and one-sixteenth to British India and Europe. The yearly value of the export varies from one and a half to two million rupees, the highest qualities ranging in value from 100 to 135 rupees per ton, and the lowest quality from 30 to 45 rupees per ton. The trade is entirely in the hands of the Sinhalese.

Of fixed oils coconut is the most important exhibit. The amount exported in 1885 was 274,998 cwts. The oils of the bright yellow, or "king" coconut, is said to be devoid of the strong aroma of the ordinary oil, and is highly esteemed by all classes of natives and many Europeans as hair oil. The value of gingelly oil exported is given at 7,500 rupees. The cultivation of croton seed has been

* The "Dammar" of the Ceylon export list.—ED.

taken up during the last few years by a few Europeans, and the samples exhibited look fresh and clean.

The oil of *Aleurites moluccana*, known in Ceylon as kekune oil, is said to be exported to Europe for soap making and for cloth dressing for which purpose it is reported to be superior to olive oil. Margosa or kohomba oil (*Melia Azedarachta*) is stated to be much used by native practitioners for suppurating scrofulous glands. The oil cake resulting from the preparation of coconut oil, and called "poonac" in Ceylon, is said to be used pretty generally by French military authorities for cavalary horses, since a small portion added to their ordinary food gives a glossy appearance to the coat of the animal, and at the same time promotes its general health*. Jaffna, or sea moss (*Gracilaria lichenoides*), which is commonly used in Ceylon as a nutritive food for persons of weak digestive powers, is only occasionally exported. Concerning the edible birds' nests exhibited, it is stated in the Official Catalogue that the bird which makes them (*Collocalia francica*) builds in large dark caverns in any locality, from the seaside to the highest hills. They contain much less glutinous matter than those of Java and Borneo (see *ante*, pp. 41-42). The nests are built close together against the face of overhanging rocks, and the bird is of a smoky colour, and darker on the head, wings and tail than elsewhere, whereas the Java and Bornean birds are said to be bluish. The nests are collected by Chinese, who pay Government a small annual sum for the exclusive privilege of collecting them in certain caves, chiefly of the Morowak Korale of the Southern Province. The yearly value of the export amounts to about 4,000 rupees.

In this Court, Dr. W. C. Ondaatje exhibits dried pulp of the nux vomica fruit, from which loganin was obtained by Professor Dunstan; also several medicinial barks, and the concrete milky juice of *Alstonia scholaris*†, which possesses some of the properties of india-rubber. Specimens of these products have been presented to the Museum of the Pharmaceutical Society by Dr. Ondatjee.—*Pharmaceutical Journal*.

GOVERNOR GRANT DUFF ON PLANTING IN MADRAS.

The last Budget of official papers brought us the Review Minute of the retiring Governor, from which we extract largely matters more or less directly concerning the Nilgiris, and local industries.

Cinchona, Horticulture, Botany, Economic Plants, &c.

It well may be that in some far off future the English may have the fate of the Portuguese, and that their most enduring monuments, in many parts of the Peninsula, may be the plants which they brought to India from other climes. Not the least important of these will be the various species of the genus *Cinchona*, although these have not, like the "promotion nut" (*Anacardium occidentale*) of their predecessors, shown any capacity in India for fighting, unaided by man, the battle of life. The story of the introduction of these precious trees by Mr. Clements Markham and others is well known. The Nilgiri plantations remained for many years under the charge of an intelligent gardener. After his death they were placed for a time under the Forest Department, but that arrangement was not one that could last; and in 1883, Mr. Lawson, formerly Professor of Botany, at Oxford, and in charge of the exquisite garden which stretches along the bank of the Cherwell close to the bridge which Macaulay has described in a famous passage, came out to take charge of our *Cinchona*, as well as of all the Government gardens on the Nilgiris. The time had arrived when a great number of important questions were ripe for examination by a trained botanist and a trained quinologist. Ere long accordingly we added to our establishment Mr. Hooper, who had worked under Dr. Koppeschaar at the Hague, and came out possessed of all the latest learning on this subject. Mr. Lawson soon saw that considerable changes in management were wanted on all the estates, and set himself to make them. First, with the assistance of Dr. Trimen of Ceylon, the plantations were carefully inspected, and some alarming doubts, which had been raised by Mr. Cross about the value of many of our trees, set finally at rest. Thereafter, a great number of trees which had done their work were cut down, and fine healthy shoots are now springing from them. Then, a considerable acreage in and near Naduvatam, which had gone or was going to ruin, was taken in hand, and is being replanted. Further, the Cuprea bark from New Granada, a species of *Rimijia*, a genus nearly allied to *Cinchona*, was sown, and will, it is hoped, give fair results, while the same is hoped of the *Cinchona Santa Fe* and *Carthagena*. The growth of the various species of Cinchona at different elevations, and the amount of their respective yield are also being carefully watched; while the diminution in the cost incurred in looking after our Cinchona estates, since Mr. Lawson took charge of them, is as remarkable as the increased efficiency which has characterised his management. One of the objects to which Mr. Hooper has turned his attention since his arrival has been the production of a preparation of Cinchona alkaloids, closely resembling that known as De Vrij's liquid extract. This he has succeeded in producing to the satisfaction of the Medical Department at an astonishingly low price,* and the problem now is to try to get it spread amongst the people. Time and patience will be required for this, though there are some very encouraging symptoms; but fever is in South India so terrible a scourge that ignorance and prejudice will eventually be sapped by interest. Mighty indeed, must be the political reform which would be worthy to be named with this in the promotion of true well-being. As I have elsewhere † pointed out, we want a class of practitioners intermediate between the really skilled persons turned out by our medical schools and the Vythians who have still such a hold upon the people. This want was much in the mind of the late highly-intelligent Maharaja of Travancore, and I have read an excellent private letter of his, upon the subject. We still hear at intervals the wish expressed that Government would divest itself of its Cinchona plantations in the supposed interest of private trade. To do this *prematurely* would be to take a very false step; but a very large part of the Government Cinchona plantations will, it is to be hoped, soon be devoted to preparing the cheap febrifuge to which I have just alluded. I need hardly say that the amount of the Cinchona even now put on the market by this Government, is as compared with what is produced by private growers in India, Ceylon and elsewhere altogether insignificant. Mr. Lawson also, soon after his arrival, began greatly to improve the Government Gardens at Ootacamund, and to give them a more markedly botanical character by carefully naming the very numerous and valuable collection of plants, which are scattered about over the large area of beautifully broken ground which they cover. He gave no less care to the gardens at Coonoor as well as at Burliar, and laid, by endless plant-hunting in every interval of leisure, the foundation of a very fine herbarium at Ootacamund.‡ At length the moment came for the

* This is quite new to us. Has coconut poonac ever been added to horse feed in Ceylon? The favourite food for cattle is gingelly poonac.—Ed.

†We have found it difficult to preserve these trees and *Cassia fistula*, in consequence of the value placed by the natives on the barks as medicine.—Ed.

* We expect to be able to sell a bottle containing eight doses of five grains each, for one anna, which represented I may mention for the English reader, three halfpence, *when the ruppee was at par*.

† Adress to the University of Madras, 1886.

‡ His own already very considerable collection has been supplemented by many of Wight's plants sent from Kew, and I was happy, before leaving the hills, to see them all comfortably lodged.

establishment of a botanical department, Sir Joseph Hooker and Mr. Thiselton Dyer lent their invaluable assistance, the Secretary of State agreed to our proposals, Mr. Lawson was satisfied to undertake new duties for a very slightly-increased remuneration, and the reproach was taken away from this Government that it did nothing systematic for the encouragement of either scientific or economic botany, for which Ceylon, Jamaica, and so many other less important British dependencies do so much. When the arrangements now in progress are entirely completed, Ootacamund, which is a particularly good climate for preserving dried plants, will contain the principal herbarium of the Presidency, but a typical collection will be left in Madras, and other collections will, doubtless, as civilisation extends, be formed in other important centres. In time, too, new botanical gardens will be created, with a view to making experiments to which the climatic conditions of the existing gardens do not lend themselves. The public spirit and intelligence of the rulers of some of the neighbouring states, such as Travancore (exceptionally well situated for botanical experiments) will, I doubt not, one day be enlisted in the same good cause. We have received from Kew not only a great deal of guidance during the last five years, but also many seeds, such as the following. I mention only plants of economic value, not those which are merely ornamental, or interesting to the botanist alone:—

Erythroxylon coca.	Cinchona Santa Fé.
Rhus vernicifera.	„ Carthagena.
„ succedanea.	Rimijia Purdieana.
Ceratonia siliqua.	Ipomœa chrysorhiza.
Quillaja saponaria.	Ullucus tuberosus.
Arracacia esculenta.	

I found *Erythroxylon coca* established in one or two places; but the immense medical value of the plant was quite unknown in 1881. It has been very gratifying to me to find that it can be so readily multiplied here, and that as Mr. Hooper and Dr. Drake-Brockman have proved, the alkaloid produced from the plant in Madras is as efficacious as that which is produced from it when grown in South America.

Arracacia esculenta and *Ullucus tuberosus* are both food-plants. The former is an important article of diet in the higher regions of Northern South America in spite of its near alliance to our familiar hemlock. The other is related to the *Bassella* or Indian Spinach, and comes from the Bolivian and Peruvian Andes. Both seem likely to succeed at Ootacamund.

Ipomœa crysohiza is a New Zealand form of the Polynesian sweet potato, which is well spoken of, and is certainly palatable.

Rhus vernicifera gives the valuable Japan lacquer; *Rhus succedanea*, the Japan wax; *Ceratonia siliqua* is the Caruba so important in Sicily; *Quillaja saponaria* is a Chillian tree, rich in a vegetable soap.

The others have been already alluded to. Another benefactor has been Mr. Thomas Hanbury, whose collections of living plants at La Mortola, not far from Mentone, are amongst the most remarkable in Europe. One cannot now walk through the gardens at Ootacamund without seeing many traces of his friendly co-operation. I have kept up a very close correspondence with Kew from the time I arrived in this Presidency, and have done what little I could to repay, by sending thither very large quantities of seeds,—the debt which every British dependency owes to that magnificent and supremely Imperial institution.* So slight was the connection between it and Madras before 1881, that I do not think any single person connected with the Royal Gardens, at all knew what was the ordinary vegetation, cultivated or indigenous, in the neighbourhood of that city. I have also had very careful lists made by that most devoted botanist, Mr. R. Hollingsworth, of the plants in the park of Government House Madras, and at Guindy, while to the collections at both places I have added,—thanks to the kindness of Dr. King of Calcutta, Mr. Gamble and others,—a large number of species. The Government has not had it in its power,—owing again to the pecuniary difficulties of the Imperial Treasury,—to do quite as much as it could have wished to help so valuable an institution as the Agri-Horticultural Society of Madras, excellently managed by Mr. Steavenson and others; but it contrived to enable the Society to lay the foundation of a botanical library, and I have no doubt subsequent and wealthier Governments will be able to do more. A great deal of miscellaneous, horticultural, agricultural, and vegetable economic information has been circulated in these recent years by the Government, and we have introduced the practice of sending every scrap of intelligence of that kind to Kew, where it is utilised for the general advantage of the whole of Oceania, and of many broad lands which do not belong to our Political System. Mr. Morris, now of Kew, but recently of Jamaica, lately informed me that the Pepper which was under the intelligent superintendence of Mr. Ross, C.S., transmitted a year or two ago, through Kew from Tellicherry, to that island, has succeeded perfectly. Considering the immemorial antiquity of the Malabar Pepper trade, it is strange that it remained for our generation to make this gift from the East to the West.

PLANTING.—Indian Governments have been sometimes blamed for not welcoming with enthusiasm the English capitalist. Madras is not open to that reproach. Every encouragement is given to the English capitalist to settle and to cultivate in those districts of the Presidency where the climate makes this possible. The planters on the Nilgiris and elsewhere have in the last five years met with special consideration; but the mischief is that the English *capitalist* won't come. There never was a truer maxim than that "the first duty of a landlord is to be rich." If he has not other means, it is idle to attempt to cultivate land in India or in any country I have heard to tell of, with a reasonable hope of success. No good-natured "concessions" on the part of Government can do anything more than stave off the inevitable. They are too often only a cruel kindness. I once said to a friend "How do the —s get on with their estate?" "Excellently," was the reply, "their father gives them the money to work it." "And what return does he get," I rejoined. "Oh, the return he gets is that one of them periodically returns to him." C'est magnifique mais ce n'est pas le commerce! What we above all things want in the Nilgiris and similarly-situated tracts is the English capitalist, who will buy his estate without needing to mortgage any part of it, and retaining enough money to live upon, and to work it to the very best advantage, without ever having recourse to the money-lender, while he gives as much of his personal attention to planting as he would give, if he meant to succeed in any other profession. Such men will be able to tide over bad years, and sooner or later may do fairly well, while those who count upon a succession of good years will certainly be disappointed, however much Government may do for them.—*Nilgiri Express.*

DEODORISING IODOFORM.—Coffee has been used for deodorising Idoform with very satisfactory results, and without interfering with its antiseptic effects Ground coffee is employed in proportions varying from thirty to fifty per cent. Fifty per cent is said to completely deodorise the Iodoform, and the coffee being itself an antiseptic no bad effect is produced. Iodoform so prepared should only be used for outward applications.—*Burgoyne & Co.'s Price Current.*

* Berlin, Cintra, Christiania, Upsala, Orotava in the Canaries, Cambridge in Massachusetts, the Island of Grenada and Mauritius are a few of the widely-scattered places to which our Madras seeds have found their way within the last five years. It often happens that, just from their very commonness, things do not get forwarded the great botonical centres in Europe from the tropical countries. I recently found that they wanted at Kew the *palmyra*; the Custard apple which appears so often on our breakfast tables; and last, but not least, the very handsome but ill-used tree which goes through life under the name of *Odina Wodier*, that is, if I translate it correctly, the worthless, worthless one.

TRIAL OF A COTTON-PICKING MACHINE.—A dispatch from Sumter, S. C., states:—The cotton-picking machine, invented by C. T. Mason of this place, was tested this week in the field in the presence of committees from the New York Cotton Exchange and the Charleston Exchanges and representatives of the State Agricultural Department. The machine picked cotton at the rate of 180 pounds per hour, without injuring the bolls or plants. The general opinion of those present is that the machine is correct in its principles, does fairly good work now, and can be made completely successful.—*Bradstreet's.*

A NEW VEGETABLE OIL FROM JAMAICA.—Samples of the solid fat of "antidote cacoon" from Jamaica were exhibited at the Colonial and Indian Exhibition at South Kensington. This is probably the first time that the solid oil of the last named seed has been exhibited in this country. In Trinidad it is used to prevent steel and iron from rusting. It is white, and of the consistence of coconut butter, without having any special odor. The seeds are excessively bitter, like colocynth, and appear to be a good purgative of considerable value in dropsy. The seeds contain, according to an unpublished analysis by Mr. E. C. C. Stanford about half their weight of fatty oil which if the seeds could be procured in sufficient quantity would probably find a use in commerce.—*Oil, Paint and Drug Reporter.*

KOLA NUT.—One of our English exchanges (*Planters' Gazette*) understands that Mr. Epps, the well-known cocoa manufacturer, has recently been devoting attention to the kola nut, and that he has succeeded in producing a paste containing all its valuable properties, and, at the same time, very palatable, especially when mixed with cocoa. It is found that kola nut is very beneficial to those who suffer from weak action of the heart, and there is an increasing demand for it, particularly in the United States. Such being the case, and as the kola nut grows and fruits to perfection in Southern India, this announcement ought to act as an incentive to planters in that part of the country, to take measures for the extensive cultivation of this plant, and open up a trade with European cocoa manufacturers.—*Indian Agriculturist.*

LANTANA AS A MEDICINE.—In a notice of drugs from the Cape in the *Pharmaceutical Journal* we find the following statement:—*Teucrium africanum*, the tribal remedy of the Kaffirs, seems to possess antiseptic properties. When a cow has died of milk fever the Kaffirs boil the flesh along with this plant, and believe they can eat it with impunity. It is used in ophthalmia, in glanders, and for snake bites, but in cases of very venomous snakes, *Lenotis Leonurus* is given with it. It appears to merit investigation as to its active principal. *Lantana salvifolia* appears to have similar properties, and is reputed to have the power of intoxicating birds. Dr. A. Smith found small doses of the infusion beneficial in incipient bronchial affections.—*Pharmaceutical Journal.*

EULYPTOL.—"Eulyptol" is the name given by Dr. Schmeltz to a mixture consisting of six parts of salicylic acid to one each of carbolic acid and oil of eucalyptus, which he considers preferable as an antiseptic to iodoform, corrosive sublimate or carbolic acid (*Journ. Pharm.*, Oct. 15, p. 361). Dr. Schmeltz considers that a chemical combination takes place between the ingredients, since carbolic acid cannot be detected in the mixture. It is described as having a strong aromatic odour and acrid burning taste, and as being nearly insoluble in water, but very soluble in absolute alcohol, ether, chloroform, and a mixture of equal parts of alcohol and glycerine. It is also soluble in ammonia and alkaline solutions. According to Dr. Schmeltz, it completely arrests the fermentation of all putrescible substances, a small quantity added to urine, under any condition, being sufficient to preserve it during a month.—*Pharmaceutical Journal.*

HYBRIDS.—In spite of an alleged instance of fraternisation, resulting in the production of a new hybrid, the experiment of turning cats loose in Australia to destroy the swarms of rabbits, is reported to have proved eminently successful. In one of the worst infested districts of Victoria 250 cats were bought at 1s. a head, enclosed for a time in a limited space by means of wire netting, fed on rabbits, and afterwards turned loose in batches, food having been still supplied in a rough building for any cats which might not at once support themselves by hunting. Not a single cat is known to have found its way to its original home, and as to the result of the experiment, the special reporter of the Melbourne *Farmers' Gazette* says:—"During a thorough inspection of the sand hummocks just a little before twilight, our party only succeeded in seeing three rabbits. The cats, on the other hand, were to be met with everywhere, and maugled rabbits, some slaughtered but recently, and others dead for weeks, were come across in all directions. The cats were evidently the complete masters of the situation." The writer goes on to express the opinion that there is no doubt whatever as to the success of the experiment, which is, moreover, as expensive as it is successful.—*Indian Agriculturist*—[But when the supply of rabbits runs short, we suspect the poultry yards of the settlers will be in danger.—ED.]

MUGA SILK.—Experiments, writes a Calcutta paper, were tried by the Agricultural Department in Assam last year to determine the practicability of growing *muga* silk for the English market. A small quantity of *muga* yarn was sent to Mr. Wardle, of Leek, in January last, which cost on an average R3-11 per lb., exclusive of carriage, but Mr. Wardle has not as yet reported on its value for the purpose of the English manufacture. Again, 6,000 *muga* cocoons were sent to a gentleman in Calcutta, who had invented an improved process of reeling this silk which would enable him, he fancied, to obtain a remunerative price for it in the English market. This, however, did not prove to be the case, for the yarn, when reeled and sent to England, was valued at a price insufficient to repay the cost of producing it in India. The largest experiment was made by the Bengal Silk Company, who were supplied by Government with three lakhs of *muga* cocoons at a cost of R600, or R2 per 1,000. These cocoons were reeled into 67 lb. of yarn, besides 58 lb. of marketable floss and waste. Unfortunately the yarn was damaged on its way to England, and proved unsaleable; so that the result of this experiment, by which it was hoped to test the possibilites of a trade in *muga*, was defeated. It is to be hoped that these failures will not prevent further experiments with the silk, which may yet prove an important addition to the industrial products of Assam. —*Times of India.*

AGRICULTURE IN MAURITIUS—For supplies of cattle and sheep Mauritius is entirely dependent on other countries, notably Madagascar, the Cape, and India; but fish abound in the surrounding seas. So much of the agricultural area of the island is taken up with sugar growing, that small room remains for other branches of farming, hence much of the grain consumed by the inhabitants, especially rice, is imported. The raising of cereals, such as maize, millet, gram dhal, and rice is attempted on a small scale, and yams, manioc, and sago have been produced in trifling quantities, but the total local supply of vegetable food stuffs is inconsiderable. Fruits, on the other hand, are cultivated to a large extent, and embrace apples, avocado pears, bananas, custardapples, figs, guavas, the *litchi* (*Nephelium litchi*), a delicious pulpy fruit from China, *mabolo* (*Diospyros discolor*) of exquisite flavour but objectionable odour, mangoes, pine-apples of the choicest kinds, shaddocks, and tamarinds. Mention must also be made of the papaw fruit, from which, in this island and Bourbon, a passable *compote* is made. Spices, raised in small quantities, comprise betel, cloves, ginger, nutmeg, pepper, pimento, turmeric, and vanilla, pods of the last-named being sometimes exported. The date palm has become well established; so also has the coconut, whose oil is now shipped in thousands of gallons annually. Sugar is the all-absorbing object of culture, engaging the whole population, and affording an export value of about £3,000,000 a year.—*Journal of the Society of Arts.*

INDUSTRIES IN MYSORE.

(*From our Bangalore Correspondent.*)

The tanning of skins for leather is an industry which is carried on pretty briskly at Bangalore. There are upwards of 30 large tanneries at work, all owned by natives and worked solely by them. Dressed skins from Bangalore have always maintained a good reputation; the export trade in these are good, large quantities being shipped *via* Madras to London, various places on the Continent, to America, besides being sent up to Northern India. The principal tanning material used is the bark of the *Cassia Auriculata*, which grows abundantly in some of the districts of the Mysore Province. The Government levies a license fee of about 8 annas per cent. and in the district of Toomkoor alone the fees so levied amounted in one year to R20,000. All the bark is brought into Bangalore, but much of it is passed on to parts in the Madras Presidency where tanneries exist.

The rains this year all throughout the Mysore Province have been seasonable and plentiful. The staple crops of the country have grown well and the yield will be a bumper one in many parts. Raggi, though the new crop is not in the market yet, is now being sold at 40 measures per rupee, and jola at 25. It is a curious thing, however, to note that the old gowdas and ryots do not like the bumper crops, alleging that a very good season is alway followed by a bad year.

The Mysore Government maintains a stud breeding farm at Kungal, about 30 miles from Bangalore, for the purpose of supplying remounts to the Silladar Cavalry, which latter is about 2,000 sabres strong. There are 11 stallions at the farm: 3 Australian and 8 Arabs; a thorough-bred English stallion is now on the way out. The total area of the stud farm is 257 acres, on which good crops of grass, oats and maje are raised. Australian and Cawnpore oat seeds are used and are found to do very well. Experiments with silos and ensilage making are carried on, and as far as the experiments have gone, the slow filling of silos seems to be the best method for preserving fodder. The stock mares are principally Australian, and stud bred, and it has been found that there is a smaller percentage of deaths among the foals of the former than of any other class.

JAVA BUDGET AND PLANTING.

AMSTERDAM, Oct. 27th.—The most important event of the past week has been the introduction of the Bill for Government assistance to the Sugar cultivators in Java. The Minister proposes to authorise the Governor-General to make an agreement with the sugar planters, working under Government contracts, by which delay of payment is granted of the excise duty due during 1887, providing that planters pay interest on the outstanding amount at the rate of six per cent per annum. Regarding free cultivation, the Governor-General may assist sugar manufacturers by granting advances on the crop of 1888 not exceeding the rate of one and a half guilder per 100 kilos at an interest of six per cent per annum, and under a guarantee that the Government advance shall have precedence of any other claim with which the undertaking might be charged, and in the event of suspension the total Government advance to be paid immediately. In introducing the Bill the Minister pointed out that the measure is only temporary, being proposed with the intent of assisting the sugar cultivators during the present difficult times, and as soon as an improvement sets in the advanced capital is to be refunded. For this reason a decrease of the fiscal burden is not included in the scheme, neither a reduction of the Government's railway tariff, which would only afford a trifling benefit. The Minister concludes by stating that the proposed measures will involve a temporary loss to the Government revenue, obtained from the sugar cultivation, which will be recovered when more favourable times set in. The maintenance of the sugar industry in Java being a matter of general interest, the Government urges an early consideration of the Bill. A revision of the regulation of the land rents in Netherlands India is in progress, and in connection therewith a revision of the export duty on sugar will be necesary.

The report on the Java Budget of the sections of the States General has been published. Some members expressed satisfaction at the fact that the Minister proposed to improve the financial position of the colonies. On the other hand, several members criticise the policy of the Government, which does not comply with the repeated complaints of those concerned in the Java trade, and maintain that the high railway tariff, the export duty on coffee and sugar, whereas a fresh tax on tobacco was put on, no decrease of the compulsory labour was introduced, and the endeavours made for an improvement of the military and naval forces would prove to be insufficient. This opinion was opposed by certain other members, who referred to the proposals of the Government for the construction of railways and the reorganization of the system of police in Eastern Sumatra, which will certainly be for the welfare of the population. Attention was directed to the unsatisfactory position of the Indian army and the reorganisation of the navy; the construction of a harbour for men-of-war was advised. The opinions regarding the concentration system in Acheen were divided. Many members disapproved of it, but others believed that it would lead to the pacification of Acheen. The renewal of the concession for steam navigation in Netherlands India was also a matter of consideration. Many members were against the existing monopoly, which is not to the interest of trade in the Archipelago, and advised to grant the concession to a Netherlands Company. A contract should be closed with one of the existing companies working the line between Holland and Java. Several members preferred the publication of the terms for the new contract and to invite tenders, a private agreement involving numerous difficulties. The idea of the Minister about the construction and working of the Government railroads was not joined, and some members advised to sell the same to private companies, while others opposed both the Government's regulation and the sale of the railroads.

In the month of May several commercial firms in this city forwarded a petition to the Minister for the Colonies to hold at least eight Government auctions of cinchona bark during the year instead of two, and to announce the dates of the auctions in the *States Gazette* and the *Java Gazette* in December of every year. Information has been received now that the Minister will comply with the request of the petitioners, and make a trial during the years 1887 and 1888, which will doubtless lead to a more favourable competition of this market with other foreign markets.—*L. & C. Express*, Oct. 29th,

THE POSITION OF CEYLON PLANTING PRODUCTS.

In criticism of certain correspondence which appeared in the local papers about two months ago, an esteemed correspondent now in England has sent us a communication which is evidently the outcome of the deliberations of not a few capitalists and proprietors interested in Ceylon. We accordingly give prominence to the views expressed :—

"We noticed more than one correspondent recently writing a few words of warning as to the danger of haste in the abandonment, or comparative abandonment, of one of your most important items of planting enterprize, Cinchona. One correspondent pointed out very forcibly how inadvisable it is to prematurely abandon this form of cultivation. According to him, many of your planters, owing to the low prices for the bark now obtainable in the European markets, are neglecting the further planting of the tree. The writer and others at home are at one with that gentleman in the view he expressed, feeling that there is every reason to hope that some day or other the demand for quinine, as its use becomes ex-

tended under the influence of present cheapness, will again bring about such a condition of the market for the raw bark as shall enable its cultivation to become once more profitable.

"That view has been strengthened by communications we have had with authorities at home. We have all seen how whole fields—whole estates we may say—which formerly grew little else but coffee have been transformed bodily into tea-gardens. It is perhaps due to a considerable extent to the consignments falling off in the Eastern exports of the berry, that prices are once again rising largely in Mincing Lane. It is not Ceylon alone, it should be remembered, which has had the prosperity of its coffee industry checked by that potent enemy leaf-disease. There is scarcely a coffee-growing country in the world which has not been more or less a sufferer from the same cause as has affected Ceylon. The adjacent continent, Java, Fiji and many other countries, have had to regret the presence of the disease and its results to their prosperity. But comparatively a few years have passed and we have before us the consequence of a reduced outturn in improved prices, prices which may well induce Ceylon planters, now that there are evidences that the effect of the fungus is weakening, to pause before they further denude their lands of the coffee bush, and revert to that wide acreage of a single product to which, we believe, we may in great measure attribute the birth of the disease on our estates. There is no reason to conclude that the perpetuation of such a system with regard to tea will be never free from its natural consequences than has proved to be the case with coffee, and although Dr. Trimen, when speaking at the Ceylon Dinner lately held in London, declared it to be impossible that the present form of leaf-disease which has proved to be so disastrous to coffee should attack tea, we have no assurance that some other form of pest may not be bred should we revert to our former mistake of devoting our lands wholly, or nearly wholly, to a single form of cultivation.

"Into this error we at home observe a disposition to fall; and we may, therefore, add our note of warning to that already given by yourselves and some of your local correspondents. We believe that some Ceylon planters already fully recognize that the impetuous clearing out of coffee is being carried too far. The Uva Estates Companies seem to be strongly alive to the danger of acting too precipitately in this direction, and they have determined to proceed henceforth with very great caution. Their directors are observant of the increasing rates for their coffee produce arising from the diminished supplies of its higher classes, and they now make a judicious selection of those fields wherever the symptoms of returning health to the coffee are most manifest, and retain them under the same conditions of careful and high cultivation as were formerly practised with respect to them. We counsel that such an example should, as far as may be possible, be generally followed, not with respect to coffee alone, but also as regards cinchona. It should be borne in mind with respect to the latter that the presence of cinchona trees on estates affords advantages altogether independent of the pecuniary value of their bark, and to sacrifice these by neglecting the further planting of the tree, would, it seem to us, be highly injudicious. Our experience of the markets for colonial produce has fully satisfied us that no single form of it has ever become so permanently reduced in price as to nullify all hope of future profitable cultivation. The markets follow of course the natural law attending supply and demand. Seasons of depression in prices, if this be long continued, cause decrease in production, and as the result, prices again rise to their normal level. Now this is what we see at the present time taking place with regard to coffee, and we believe the same result will as surely follow with respect to cinchona. The present favourable prices obtained for Ceylon tea will almost as certainly experience reaction due to its large production, present and prospective, and it may be, therefore, that the day will come—if the present course of wholesale denudation of coffee and cinchona be persisted in,—when your planters will strongly regret the total abandonment of those other forms of cultivation which have until lately appeared almost hopeless as to their yielding a satisfactory return. We should recollect the outcry in which all shared when misfortune overtook Ceylon as to the impolicy of treating all your eggs in one basket. Are you not tending once again in that mistaken direction? We fear that your are, and that the future will again force regret for doing so upon us. Reading the signs of the times, and warned by past experience, we would counsel less haste in the abandonment of coffee and cinchona cultivation than at present seems to find favour among the greater proportion of your Planting Community."

Amount of Quinine in Cinchona Trees.—The late Mr. Howard found that the amount of quinine varied largely in trees of the same species growing in the same locality. High-class barks should alone be cultivated.—*Gardeners' Chronicle.*

The Drying and Withering.—Referring to the work of the patent "Dessicator," a well-known planter writes that with reference to his withering he feels almost independent of the weather, now that he has got a "Brown's Dessicator" as his Drier. When the weather is unfavourable for withering, he simply conducts the hot air from the "Dessicator" to the withering room, and by that means he has the withering under his control with, as he thinks, a very satisfactory result. He adds:—"I find that in weather that would otherwise take two or three days to wither leaf, I can have the day's leaf ready, and well withered the following morning by keeping the fan going all night to raising the Dessicator heat, to say 230° to 250°."

Demand for Mica in Canada.—We have a letter from Toronto from an ex-Ceylon resident who says, he (along with a fellow-townsman, a former Kandy Banker) is interested in learning all about the mica procurable in the island. He encloses a specimen which is finer and clearer than the best we have yet seen in Ceylon. Of good quality our correspondent says a large quantity can be sold in America, but he has to learn that there have been several here collecting and buying before him for the London market, whence doubtless it is widely distributed. We shall be ready to give the address of our Toronto correspondent to any mica collector who may wish to try Canada with a parcel.

Inga Pulcherrima.—A small plant of this novel South American plant—a recently struck cutting—is now in flower at the Royal Exotic Nurseries, Chelsea. It is quite a tiny plant, but it has thrown one cluster of erect long crimson-coloured stamens. Mr. Court states that he has had the plant under his care at the above nurseries for the space of twenty-three years, but has never previously succeeded in flowering it, though he had seen fine specimens of it in Mexico, 6 to 8 feet in height, and covered with clusters of flowers. It is there cultivated as an ordinary greenhouse plant, placed out-of-doors during the summer, but housed during the winter. The cutting—now a blooming plant—was taken only in August last, and it was bloomed in the pot in which it was rooted.—*Gardeners' Chronicle.*

Correspondence.

To the Editor of the "Ceylon Observer."

ANTS ON CROTONS.

The Castle, Slave Island, 12th Nov. 1886.

Dear Sir,—May I so far trespass on your valuable time as to ask you how I can prevent ants attacking crotons. A kind of mould or blight appears and I notice whenever this is so, the ants are busy. I have lost several crotons from this cause and I would not have troubled, but that most of these shrubs are now attacked by this pest.—Yours faithfully,

BARLOW A. MOORE.

[We suspect that the crotons are infested with mealy bug, white scale, or some form of aphis. Ants are well-known destroyers of Aphis and this will account for their presence. A good remedy is to paint the stems thoroughly with the following mixture:—½ lb. of soft soap, ½ lb. of flour of sulphur, ¼ lb. of tobacco, and a wine-glass of spirit of turpentine. Mix the sulphur, turpentine and soap into a paste with warm water, boil the tobacco for an hour in a covered saucepan in some more water, strain it, mix it with the soapy mixture and then add enough water to make one gallon.—Ed.]

TEA PLUCKING: HEAVY AND FINE; AND COST OF CULTIVATION: A WORD OF WARNING.

Dear Sir,—Referring to "C. S."'s correspondence in your paper of 15th inst. *re* Tea Manufacture and change of system, I will, with your permission, make a few remarks. I think "C. S." is a little out when he says "that the cost of plucking tea per acre is rateably the same whether the yield is large or small." And further out when he remarks that "it might be urged that the cost of plucking 200 lb. per acre will be greater than that of 400 lb.; if this is so, the 400 lb. may be plucked and the leaf passed through a green leaf sifter and the coarse leaf put in the manure pit." No one ever said that the cost per acre for plucking 200 lb. would be greater than that of 400 lb. What is said and known to every practical man is that a small yield will cost more *per lb.* to pluck than a large yield *per lb.* The rates would be for plucking 400 lb. per acre 9 cents per lb.

200 ,, 16 ,,

So if my figures for plucking are correct and in practice, I fancy I am nearer to it than "C. S." His 200 lb. per acre (allowing all his other figures to be correct) will cost him in Colombo cents 43·50 per lb. "C. S's." system is not fine plucking at all. It only means the rejection of souchong leaf, either by leaving it on the bushes and only taking the bud and one leaf or plucking it all and, as he says, "pass the leaf through a green leaf sifter and put the coarse leaf in the manure pit." As I understand fine plucking, it is to take the bud and one leaf *before* a souchong leaf has time to form on the shoot.

Although I have not, like "C. S." sunk my bottom dollar in tea, I am deeply interested in it and I would be the last to run it down. Yet I cannot but think that inflated and inaccurate writing will have much of the over-production to answer for, and I think it is to be regretted, that some of the "authorities" have not based their estimates on a more moderate yield than 400 lb. per acre. Unless we are to assume that the capital invested in planting and in the erection of the palatial factories recommended in the "Manual," as sunk irretrievably, I think it but right that interest on this capital should be included in expenditure. If one of our "authorities" would frame an estimate on a more probable yield than 400 lb. per acre, say 250 lb., adding interest on capital, then show what it would cost f.o.b., it would be more to the purpose, though I fear it would be too late to do good, as the mischief is already done.—Yours faithfully.

PLANTER.

A NEW COFFEE TREE.

24th Nov. 1886.

Dear Mr. Editor,—I enclose an amusing cutting from *Public Opinion*:—

"A New Coffee-tree.—The *Giornale d' Agricoltura e Commercio* for August reports the discovery in West Africa of a new variety of coffee-plant, whose berry appears greatly to resemble that of Arabia in appearance and flavour. It grows, however, not on a shrub but on a tree nearly 7 ft. high, which develops rapidly and yields an abundant crop. Arrangements are already being made for introducing its cultivation in favourable localities."

The Italian paper seems to have discovered a very promising *mare's nest*, seeing that the claim of this coffee plant to be a new variety, is based on the *astonishing fact* that it grows on a tree *nearly 7 ft. high*; our own old variety would grow double that height if permitted. If you think it worth while, you might copy the "para" in the *Observer* for the edification of those who, like myself, once cultivated the noble shrub.

Ex K. C. B., now K. T.

ENEMY OF COCONUT PALM.

Pallai, 29th October 1886.

Dear Sir,—Will your entomological referee kindly afford me some information regarding the beetle I herewith send you. What name does it go by, and what is its appearance in the larva state? From interested motives I should also like to know what it generally feeds on! As far as my experience goes, it does not appear to be very common to this part of the country, and, until very recently, I was under the impression it was the black coconut-beetle, or *Kurumiriya* of the Sinhalese.

Is it at all destructive to coconuts, and if so, in what way?

I captured the present specimen on the ground, as he was taking a quiet evening stroll, having probably emerged from some hole or heap of rubbish near by. His appearance is certainly formidable, and I should say he was capable of doing a considerable amount of mischief with the pair of forceps or shears with which he is provided; but I trust they are not quite so powerful as to enable him to effect his escape from the parcel before it reaches you.—Yours faithfully,

"COCONUT PLANTER."

[Our referee has been trying to find out the name of the beetle, but has not been successful. It belongs to the family *Prionidæ*, genus *Prionus*, and the larva which is large, fleshy and white, feeds on the decaying wood of fallen trees. The beetle usually conceals itself in the daytime and roams about after dark. The one sent by our correspondent, is a male; the female has probably much smaller mandibles. The family comprises some of the largest known beetles.—If our correspondent could send some more specimens of the beetle, it would be well.—Ed.]

DOES TEA IMPROVE OR DETERIORATE BY KEEPING.

Dear Sir,—There is a question on the subject of tea, and one about which opinions vary so much that no definite conclusion can be arrived at by the uninitiated, and I know no one more able to ventilate

the subject than yourself, or the columns of whose newspaper are more freely placed at the service of the public. The question is this:—Does tea improve or deteriorate by keeping? Some tea planters say that it improves, and others say that it begins *at once* to deteriorate, unless put in bottles and hermetically sealed. I am a believer in the former theory, and will give my reasons, and shall be glad to hear any arguments in favour of the deterioration theory. In Australia, where tea is more universally drunk than in any other country, we no more doubted that age improved tea than we doubted the fact that port wine required maturing. In Britain *everyone* that I have made enquiries of, who has tried Ceylon tea, declares that it requires age, and I am, at the present time, using tea which has been standing in the open chest for over two years, and it is now very much better than at first. Many of my friends drink Ceylon tea only, and they invariably complain of the falling-off in quality, when they begin a new chest, but, as each new chest has the same fault, a fault which in a week or two disappears, I conclude that it is merely the want of age that is complained about. I am not asking you to convince me that my taste is wrong, and that the taste of my many friends here, who use Ceylon tea, is also deficient; that you will hardly be able to do; but I would be very pleased if you would give some practical reasons why some planters are so dogmatic on the deterioration theory, and others are just as inconvincible with regard to the opposite view of the case. What would those advocates for drinking new tea think of people always having an unopened chest in stock, and, as soon as it is opened, a new chest is purchased, to lie ripening in their store-room to be ready for use when the other chest is finished? I am not arguing in favour of old tea: I am only making a statement that I, and all the friends I have in Britain who drink Ceylon tea, are convinced that age improves the flavour and the strength of your staple. I will be much interested in your reply to this, and as I am asking you the question for the information of many others besides myself, I trust you will excuse my trespassing on your space to such an extent as I have done.—Yours truly,

Scotland, Oct. Ex-K.C.B.

The experience related is certainly contrary to the commonly-received opinion. The general idea is that tea is at its finest three months after preparation, and surely this is borne out by the rush every year for the new China teas—the race home, and the prize offered to the first steamer in, as also by the higher prices paid for these new teas. On one thing we are clear that like port-wine, "Ex-K.C.B.'s" tea must be kept hermetically closed, to improve by age; if the chest is left open, the tea loses bouquet, though if the surrounding atmosphere were rich in germs might gain a new flavour?—Ed.

Indian Teas.—There has been a good demand for Indian Tea, and prices remain steady, as the continuous heavy supplies have proved amply sufficient to meet the larger requirements. It has been frequently reported that the bulk of this season's imports would be much inferior in quality to those of recent years, but this has certainly not been confirmed by the late supplies. Of the finest sorts there has, it is true, been a diminished supply, but the medium and lower grades, for which the principal demand exists, are now not only more plentiful, but quite equal in quality and condition to the Teas of former seasons. There seems no good reason to suppose that the shipments yet to arrive will be inferior to those now being offered, and the latest advices infer that the total crop will be a large one. There is therefore every probability of a steady and increasing development in the consumption of all Indian Teas. The large Indian crop is further supplemented by the steadily-growing supplies of excellent Teas from Ceylon, which are not only freely used by the grocers for blending purposes, but are now being sold unmixed to the public for consumption. With an estimated import of 72,000,000 lb. of Indian and about 5,000,000* lb. of Ceylon Tea, the consumption of these kinds at current cheap rates bids fair to increase rapidly—*Produce Markets' Review*, Oct. 23rd.

The So-called "Bug" on Tea Near Galle.—Our informant of the other day on this matter, writes:—"I send you a sample of the tea leaves and the insects which were called bugs, but which appear to me a sort of fly, but ask your 'entomological referee' to look at them and report." We are pleased to receive the following report from the gentleman referred to:—"No. 5 (Aphis coffeæ or coffee louse) of Nietner's 'Enemies of the Coffee Tree,' with the larvæ of Syrphus splendens preying upon them; also a few wood-bearing caterpillars." This is a very different matter to blackbug, and ought to relieve the minds of our tea-growers in the South and elsewhere. Nietner says of the coffee louse:—

5. *Aphis coffeæ*. (Coffee Louse.)

Both sexes: naked, shiny pitch-black with whitish rostrum, antennæ and legs and greenish abdomen. The rostrum reaches to beyond the base of the second pair of legs. The antennæ are seven-jointed the first, second and sixth being short, the rest long, the two basal joints are black, the rest whitish, black towards apex. Legs with femora and tarsi nearly black, tibiæ nearly white, hind-legs with base of tibiæ slightly curved. Male four-winged, with black stigma in the upper ones. Female apterous. Abdomen in both sexes two-corniculate and with an anal tube. Size middling. Young individuals light coloured.

The insect just described is found in larger or smaller communities upon the young shoots and on the underside of the leaves of the coffee tree. Its presence in large numbers produces honey-dew and Syncladium, as in the case of the bug. The procreative powers of this family of insects (Aphidæ) is well-known, and unequalled in nature: from *one impregnatino* nine fruitful generations of females have been produced in three months: in another instauce eleven generations in seven months; in a third instance they continued to propagate for four years! (Westwoop.) The eggs being hatched in the body of the mother-iusect, the young come forth alive. Such productiveness, however, does not appear to exist among the *Aph. coffeæ*: at all events the communities are generally small, and their injuries of no consequence. But a species which feeds upon the orange and citron-tree is much more productive, From the anal tubercles a saccharine fluid is discharged of which ants are very fond, as in the iustance of the Coccidæ.

The *Aph. coffeæ* is subject to the attacks of various parasites—*Syrphus Nietneri*; Syrphus *splendens*. These are two large flies belonging to the family, the meauber of which from their resemblance to bees and wasps, might be called "bee-flies." They rather resemble each other, are of dingy colours, black abdomen variegated with whitish-yellow bands; the forme is pubescent, the latter smooth; they are both 3-8" long an 6-8" across the expanded wings. Their larvæ devour the Aphides: these are soft, unsightly, eyeless and footles worms, narrowed on one end ‡'; long when full-growd That of the *Syrphus Nietneri* is brown with a lighter dorn mark, the segments are drawn out into scale-like knobs which form a ridge along the centre of the back. That of the *Syrphus splendens* is green with a whitish dorsal mark. They make immense havoc amongst the Aphides, being so voracious that in twenty-four hours they increase double their volume. The pupa is pear-shaped, resting within the larva skin for eight days when the perfect insect comes forth. Another enemy is:—*Micromus Australis*. This is a pretty little insect allied to the tribe of the ant-lions. Feeding upon plant-lice the larvæ have been called, "Aphis lions," but from their shape they might more appropriately be styled "Aphis crocodiles." This larva is about 5-16" long, narrow, depressed, tapering towards both ends, lightly covered with white hair. It is of brownish colour; sides, dorsal line and under-sickle-shaped jaws, and long, slender palpi and feelers. The former are distinctly three-jointed, the last joint being very long, and the whole palpi as long as the mandibles. Between head and throat there is a distinct neck. The larva encloses itself in a light cocoon in which the pupa rests for two weeks, when the perfect insect makes its appearance. The latter is very delicate, brownish, with green eyes. The eggs of these insects are deposited upon leaves, each egg being furnished with a long, thin peduncle, thus resembling pins or certain fungi. There are several minute Hymenoptera parasitic upon the *Aphis coffeæ*, but I am unable to give their names.

* 15,000,000 surely meant.—Ed.

THE LARGEST GAS WELL YET is described in an American paper as being started in Western Virginia on Oct 8th:—Natural gas was struck at Fairmont, W. Va., today. When the gas was struck the force was so great that all the tools were blown from the well and stones thrown from 100 to 200 feet high, tearing up part of the derrick. It is said by experienced gas men to be the largest well in the country. The noise from the rush of the gas can be heard from six to ten miles.

TEA SEED in Assam is likely to be scarce this year to judge by the following extract from the letter of an Assam planter:—"I don't know what has made the seed so bad this year; it is a great disappointment to me, but can't be helped. Am making very good tea just now, and have received good valuations from Calcutta." Fortunately there is a considerable quantity of good seed available in Ceylon now and there should be less risk in using local seed.

RUBBER IN BRAZIL.—The following extract from a sketch of the physical geography of Brazil, lately published, gives a new idea of the importance of *rubber*:—"Amongst the immense stores of valuable vegetable productions of this great forest, the india rubber tree figures pre-eminently. It exists in such vast quantities, and the collection of the juice is so very lucrative, that it has attracted to even the most remote rivers thousands of adventurous Brazilians. Rubber is doing for the Amazons what gold did for Australia and California; although most other industries on the Amazons are neglected and paralyzed, rubber has enabled Para, Manaos, and other riverine cities to make unprecedented progress. It has covered thousands of miles of rivers with steamers, and spread a vast population over vast areas that would otherwise have remained dormant for many many years."

PESTS ON TEA.—We hear of an insect shewing up rather extensively on a field of tea in the low-country and our informant considered he had very bad news indeed in giving us the information. But taking the worst view of the case of such pests, it must be remembered that there is a vast difference between tea and coffee or almost any other field product. In the case of tea, very strong measures—such as burning or stripping off all the affected leaves—can be resorted to with little prejudice to crop prospects—with simply the effect of a pruning. For fighting pests—should pests really come, in any force, and no branch of agriculture is entirely free of such—tea affords greater advantages than almost any other tropical product. In the present case, probably treatment with lime will entirely dissipate the bug.

HOW TO COUNTERACT OVER-PRODUCTION OF TEA IN CEYLON.—We call attention to the letter of "C. S." (page 409) on this subject, to which we had appended the following note:—"By all means, let our correspondent persevere in his criticisms and suggestions, which others interested will carefully weigh, and give their reasons for adopting or rejecting the systems recommended. Of course, it is the net and not the gross returns from the application of manure on which calculations of profit should be founded and in the case of the system of fine plucking recommended, there can be no doubt of the saving in packages, local transport, freight &c., resulting from its adoption. The question then is as to the theory that fine plucking is more exhausting to the plant than ordinary medium harvesting of leaves as well as buds." On this "C. S.", having seen the above in "proof" wrote:—"No, the question is whether a lingering death from fine plucking, or a sudden one from abandonment is preferable: we are told that tea-drinking, and smoking are injurious; fortunately people on't mind being killed imperceptibly."

Fortunately, we have already in Ceylon, an example of the happy medium, between the process recommended by "C. S." and the ordinary practice in plucking. In the case of a wellknown plantation, which maintains a high average price for its teas, the process adopted has been described as a comparatively light or fine plucking; but not unduly fine, just such as keeps the bushes in good order; and then the throwing away of 25 per cent of the coarser leaves. This secures a very fine regular tea from what remains, and the fourth of what is gathered goes directly back to the soil. This process would suit "C. S." well in the time of "overproduction," when it arrives.

TEA IN AMERICA.—That the American people are in a fair way to learn all about "good tea" is very evident when we find such a paragraph as the following in a Chicago paper:—

CHEAP TEA-DRINKING.—The doctors are falling into agreement that the excessive use of tea is working great injury to its consumers. Tea is now set down as more deleterious than coffee, especially when taken hot. This being the case with good tea, it is painful to think that the article commonly sold and used is in quality far below that which our grandmothers were wont to gossip over. The Chinese have discovered that England and America want cheap tea, and they consequently ship over an article which a cooly in Canton would fling into the street. The use of this wretched stuff destroys the taste for really good tea. Yet there are people who drink the latter. Japan, India, and Ceylon have become formidable competitors with China in the tea trade; and there are brands of Japanese tea worth from $15 to $18 a pound. The Russians drink prime tea, and the best which is not reserved for home use is sent to them. A well-to-do Russian family rarely drinks tea worth less than $2.50 to $3 a pound; and this tea goes much further than the cheap trash, it being true economy to use it. The best grades of tea go far to supply the craving for wine and liquor, so that a man who consumed the finest Bohea or Peru from the I-baug district would soon get into bad odor with his wine merchant. The best Indian teas bring, at wholesale by auction, in England, 75 cents to $1 a pound. From this the quality of our cheap teas may be guessed.

TEA "BULKED UNASSORTED."—With reference to the above we do not altogether agree with Messrs. I. A. Rucker and Bencraft in their remarks; from reading carefully their circular it appears they advise all planters to forward their teas as "Unassorted" and to prove their ideas they quote the result of one Garden where, by the teas being sorted, the owner lost nearly £300 sterling. They state the sorted portion was divided into six different grades. This multiplying of grades both London Brokers and ourselves have often written against. We do strongly advise for small gardens just coming into bearing where the Tea is of MEDIUM QUALITY that it should be sold as "Unassorted" but FREE from dust; but for gardens that produce exceptionally fine quality teas we advise them to be sorted into five grades namely:—Orange Pekoe or Broken Orange Pekoe, Broken Pekoe, Pekoe, Pekoe Souchong, and Broken Pekoe Souchong, with an occasional Dust, where an estate by sorting as above, would be forwarding once a fortnight only 2 or 3 packages of each description, we would recommend them keeping it back until breaks over 8 packages have accumulated, even though it may be in some cases six weeks. Messrs I. A. Rucker and Bencraft state that the "proof of the pudding is in the eating"; this is all very true, but they are only able to state for example one instance out of the hundreds that are sold in London, so we consider the parallel does not hold good. In short where a garden only produces medium Teas such as Broken Pekoes selling at 1/1 to 1/2, per lb. Pekoe 11d 1/0 per lb., Pekoe Souchong 9½d to 10½d per lb., Broken Tea 8d per lb., we would advise the invoice being Bulked and sold as "Unassorted," but NOT for gardens producing good quality Teas.—*Wilson & Co.'s Fortnightly Tea Report.*

FIBRE MACHINERY.

On Saturday, the 17th inst., an *Argus* representative visited the shop of D. P. Burdon, near the city wharf, to look at the model of a fibre cleansing and washing machine, but, owing to crowded columns last week, we were unable to mention it. Some weeks ago we saw the first machine of the series—the one for extracting the fibre—which is now on a shelf in the patent office at Washington, and were impressed with its simplicity and wonderful working powers. The last model made, as we have stated, is the cleansing and washing machine, and there is yet one more to construct, when Mr. Burdon and his associates will have a set of fibre machinery which will be worth a fortune. No part of the globe furnishes so many valuable fibrous plants as Florida, and all that is needed is the proper machinery for its extraction, and the industry will be one of the greatest in the South. We have samples of fibre in our office, which were extracted from the Spanish Maguey plant by Mr. Burdon, which measures thirty-six inches in length as pliable as thread but as tough as wire. Can a better fibre for the manufacture of ropes, twine, etc., be conceived which is so easily produced and yet so valuable? The resources of Florida in this line have been only touched, properly speaking, and it seems that it remains only for Mr. Burdon to develop them. Should these machines prove successful and practicable (and in our opinion they cannot prove otherwise), a new industry will be inaugurated in Florida which will be even greater than that of orange growing, and which will accordingly command more interest and insure the investment here of more capital. That the manufactories will be located here is almost a foregone conclusion, for the raw material is at the door, and the shipping facilities as good as could be secured at any place. We wish Mr. Burden success, and know that he is able to attend to it.—*Sanford Argus.*

DESIGNATIONS OF DIFFERENT TEAS.

A correspondent writes:—"The terms "Pekoe" "Pekoe Souchong," and "Souchong" are here treated as referring to Indian, Ceylon, and similar teas, and have no connection with the same terms as used in describing China and such-like teas. Strictly speaking, these terms are used to denote tea manufactured from the leaves in different stages of development, though for ordinary trade designation, the actual appearance of the leaf is the standard for determining to which of these grades a tea belongs:—

"Pekoe" tea is manufactured from the first two or three young leaves at the end of the shoot, or "flush," as it is technically called. The just unfolding bud at the end, which in about another day would be a leaf (and often the just expanding young leaf next it), is covered with a white velvety down, which, if not stained dark by the juice expressed during the rolling process in manufacture, comes out light-coloured in the finished tea, and the tea that contains these whitey buds is called "tippy." This "tippy" form is the characteristic of Pekoe teas, as the lower qualities do not contain it. Pekoe is rolled with great care during the process of manufacture to curl the leaf well. "Orange Pekoe" is Pekoe containing an extra quantity of these Pekoe "tips" or "ends," and is more valuable than "Pekoe" inasmuch as these "tips" or "ends" are highly prized and add to the value of tea. "Flowery Pekoe" is manufactured from the aforesaid downy buds alone, and is prepared in a different way altogether from the other teas; very little of it is made, and it is quite a fancy tea.

"Souchong" is manufactured from older leaves than those from which Pekoe is got, and less careful manipulation is given to it. It rarely contains "tip," though a few tippy leaves may sometimes be found in it. It has a bold rough leaf.

"Pekoe Souchong" is made from the leaves, taken altogether, which manufactured separately, would produce Pekoe and Souchong. It contains usually some "tip" and also some large leaf, and in all its characteristics comes between the two former grades. This class of tea is manufactured more extensively than any other, as by picking all the leaves together a great saving in labour is effected—a most important point in tea cultivation. The larger and older leaves, when picked, make "Congou"—a very inferior class of tea; and that made from the still larger and coarser ones, if they are taken at all (which is not often done, as the tea obtained is hardly worth the extra expense), is called "bohea." This latter term is, however, now practically obsolete.

In ordinary trade nomenclature a tea is called "Pekoe" if it have a wiry, wellcurled leaf of greyish liquor, and a good general appearance; "Pekoe Souchong" is bolder and containing more ragged leaf; and "Souchong" if still larger and less tightly curled. Anything in the way of whole-leaf teas below these is now known as "Congou."

As these grades run imperceptibly one into the other, it is evidently impossible to lay down a hard-and-fast rule for distingushing the kinds, and the terms must be of necessity more or less relative, not absolute. They have, of course, distinctive kinds of liquor, but to refer to these would take up far too much of your space, on which I have, I fear, transgressed too much already; but I hope we shall hear something on this point, as for practical blending purposes it is far more important that that of leaf. Perhaps someone else may be found who will give us his experience on this question, as it is of great importance to those interested in tea."—*Planter and Farmer.*

TRIAL OF COLONIAL TIMBERS.

An important and eminently interesting demonstration of the industrial value of colonial timbers was held on Friday afternoon, Oct. 8, at the works of Messrs. A. Ransome & Co., Chelsea, in the presence of about 150 gentlemen, including the Agents-General of the various Colonies and a few of the leading civil engineers, builders, timber merchants, and others interested in the employment of timber in various branches of trade. Among those present were Sir Philip Cunliffe-Owen, Mr. Edward Woods (President of the Institute of Civil Engineers), Sir Charles Hutton Gregory, Sir John Coode, Sir Frederick Bramwell, Sir Charles D. Fox, Sir Charles Mills, Sir Graham Berry, Sir Arthur Blyth, Sir James Garrick, Sir W. J. Clarke, the Hon. J. Gordon Sprigg, the Hon. Adye Douglas, the Hon. Malcolm Fraser, Mr. Alfred Dent (Commissioner for British North Borneo), Mr. Charles Hawksley, Mr. A. H. Vesey, Mr. Henry C. Beeton, Mr. Ernest E. Blake, Mr. F. G. Baker, Hon. Alex. Hay, Colonel Beddome, Colonel Percy Smith, Mr. J. R. Jefferies, Colonel Lees, Mr. W. B. Lewis, Mr. C. K. Stuart, Mr. Charles Hawksley, Mr. J. C. Homersham, Mr. A. J. R. Trendell, Mr. H. Trendell, Professor Macoum, Mr. P. L. Simmonds, Mr. James Thomson, Mr. H. J. Scott, Major G. Malet, Mr. Sydney Cowper, Mr. George H. Hawtayne, C.M.G., Mr. J. L. Shand, Mr. F. R. Saunders, Mr. Oswald Brown, Mr. Alpin Thompson, Mr. N. P. Trevernen, Hon. R. H. Meade, C.B., Dr. Trimens, Mr. W. B. Pryer, Mr. F. Josselyn, and Messrs. A., J. S., and L. H. Ransome.

The object of the meeting was to test a number of important colonial timbers which, from want of a knowledge as to their qualities, have been hitherto commercially unknown in the English market, and with a view of practically exemplifying to what purposes they could be most advantageously applied, the various samples were converted by special machinery into such descriptions of work as the colonial experts present deemed them most suitable for. It is not too much to add that no more suitable or appropriate centre could be selected for such experiments than the Stanley Works, having regard to the world-wide eminence attained by Messrs. A Ransome & Co. as manufacturers of every description of wood-working machinery. And, before going further, we may here compliment the firm on their public-

spirited action in the matter—action which cannot fail to advance the interests of the Colonies and India, as regards one of the most valuable of their natural resources.

The following is a list of the woods that were dealt with, together with a description of the uses for which they have proved most suitable:—

New South Wales.—Blue Gum for ship and house building, wheelwrights' work, posts and rails, plough beams, railway sleepers, &c.; Ironbark for carriage building, spokes of wheels, piles, and railway sleepers; Mountain Ash for wheelwrights' and coopers' work, palings, and general building purposes; Forest Oak for veneers, cabinet work, &c.

Victoria.—Blackwood for all kinds of cabinet work, carriage building, gun stocks, &c.; is also used for making casks; White Box for railway sleepers. Blue Gum for beams, joists, railway sleepers, piers, and bridges; Red Gum for veneers, furniture, railway sleepers, &c.

South Australia.—Red Gum for railway sleepers, fence posts, telegraph poles, jetty and bridge piles, wheelwrights' work, &c.; Blue Gum for railway sleepers, posts, piles, planking, and general building purposes; Sugar Gum for railway sleepers, jetty planking, bridge piles, felloes of wheels, naves, posts, &c.

Western Australia.—Karri wood for joiners' work, railway sleepers, furniture, cabinet work, &c.; Jarrah for joiners' work, railway sleepers, furniture, cabinet work, and piles; Raspberry Jam wood for ornamental woodwork and furniture; York Gum for spokes of wheels, &c.; Tuart for wheelwrights' and railway waggon work; Wandoo for wheelwrights' and railway waggon work.

New Zealand.—Black Pine for house-building, furniture, and cabinet work; Red Pine for house-building and general purposes; Totara for veneers, furniture, and cabinet work; Kauri for building, furniture, and all general purposes; also for making slack barrels, and pattern-makers' work.

Canada.—Douglas Fir for pattern-makers' work, joinery, furniture, building, and all general purposes; Bitternut, or Swamp Hickory for spokes of wheels, joinery, &c.; White Fir for joiners' work and general purposes; Black, or Swamp Ash for building purposes, joiners' work, and cask-making; Iron Wood for handles of hammers, and agricultural implements; also spokes of wheels.

Cape of Good Hope.—Yellow Wood for furniture, pattern-makers' and joiners' work, and general building purposes; Umzumbit for bearings, walking-sticks, and tool-handles; Box Wood for engraving purposes; Kamassi for engraving and turnery; Sneeze Wood for piles, posts, and Telegraph-poles, cabinet and waggon work; Stink Wood for building purposes, furniture, waggon work, &c.

British North Borneo.—Bilian for beams, piles, planks, &c.; Russock for building and general purposes; Serayah for furniture, veneers, and cabinet making.

India.—Tun, or Indian Mahogany for tea-boxes, and all kinds of furniture panels, and carving; Black Wood, or Rose Wood for furniture, gun-carriages, cart-wheels, agricultural implements, and fancy articles; Sissoo for felloes and naves of wheels, and carved work of all descriptions; Long-leaved Pine for tea-boxes and general building purposes; Padouk Wood for furniture, joinery, and carriage-building; Chugalam for furniture; Sej Wood for house and ship-building, also for making carts and waggons.

As the samples of woods from West Indies, Ceylon Queensland, Straits Settlements, Western Africa, and Fiji, were found too small for practical experiments, they do not appear in the above list.

The experiments, which were conducted with more than forty different varieties of timber from India and the Colonies, comprised tree felling, cross-cutting, sawing, planing, moulding, morticing, tenoning, and boring; while the manufacture of such things as casks, doors, pick handles, carriage spokes, and railway sleepers was carried to its completion and the articles exhibited to the assembled guests. The woods experimented upon were of every variety, from the hardest iron-bark to the soft mild working Douglas fir, but the samples left the various machines with the same smooth finish, the only difference being that the harder qualities of wood were passed through the machines at a somewhat slower speed than the softer ones.

Among the more noticeable experiments were the felling of a rough log of hard Kauri (Western Australia) timber, 3 feet in diameter, which had been planted in an upright position in the yard, and which was sawn through close to the ground by Ransomes' patent tree-feller in four minutes, and the subsequent cross-cutting of a similar log in a still shorter time; the preparation of railway sleepers by a machine which in less than a minute planed the two rail seatings and bored the four spike holes; and the planing, grooving, tonguing, and beading at one operation of boards from each sample of timber submitted for experiment, the boards being passed through the machine at the rate of from 12 feet a minute for the harder woods to nearly 24 feet per minute for the softer woods. But perhaps the most interesting experiment of all was that of manufacturing light casks for spirits, &c., from such of the colonial woods as were suitable for that purpose. In this, the cooperage department, nine machines, worked alternately by one lad, were employed, of which four sufficed for the manufacture of the body of the cask, three for the preparation of the heads, and two for making the hoops. Although, in consequence of being made of different descriptions of wood, the casks presented a varied appearance, they were, in form and contents, all precisely alike, while in point of finish and solidity, they left nothing to be desired.

At the close of the experiments, and after some refreshments had been partaken of, a conference, at which Mr. Edward Woods presided, was held in the Pattern Room of the works for the purpose of eliciting information respecting the several varieties of timber experimented upon from the gentlemen representing the colonies in which they were obtained.

The proceedings were opened by Mr. Alan Ransome, who observed that those who had witnessed the experiments must have seen enough to convince them of the excellent quality and great serviceability of most colonial woods. The question, therefore, that now demanded solution was whether they could be imported into this country at a rate which would render them commercially useful. Summarising the conclusions arrived at from the experiments which his firm had that day and during the past fortnight been engaged in, he might state, in the first place, that among the 40 odd different species of timber dealt with, some stood out as pre-eminently suitable for the English market. There were iron bark and mountain ash from New South Wales, both suitable for wheelwrights' work, and the former, owing to its peculiar hardness, for piles and railway sleepers as well; black wood from Victoria, suitable for carriage building, cabinet work, and case making; Karri wood and Jarrah, from Western Australia, both useful for joiners' work, sleepers, furniture, and piles, of which he could say that there was no fault to be found; black pine, red pine, totara, and kauri, from New Zealand, which could be employed for furniture, cabinet work, house building, and general purposes, kauri being specially useful; Douglas fir and the swamp ash, from Canada, both suitable for building, joiners' work, &c., the latter being particularly sound, strong, tough, and cheap; yellow wood, stink wood, and sneeze wood, from the Cape of Good Hope, the two former species suitable for furniture, building, and joiners' work, and the latter, from its unusual durability, for piles, posts, telegraph poles, &c.; Billian and Sorayah, from British North Borneo, the former suitable for beams, piles, and every purpose where durability was necessary, and the latter for furniture veneers, &c.; and, lastly, Padouk wood from India, which was suitable for joinery, carriage building, and furniture, was exceedingly plentiful, and was grown near the coast. Many samples of wood sent had un-

fortunately been too small for experiment, but of those operated upon he could say that they had all been found suitable, so far as quality was concerned, for their various purposes.

The Hon. Malcolm Fraser, Western Australia, referring to the two principal woods supplied by the Colony he had the honour to represent—the Jarrah and the Karri—said that they were both highly appreciated at the Antipodes, the latter being the timber *par excellence* of Australia. A considerable quantity of these woods was now in London and could be obtained for about 7*l*. per load, equal to 50 cubic feet, and which was about half the price of teak. Moreover, railways had been constructed in the Colony with the view to the developing the supply of the timber.

Mr. P. L. Simmonds, while admitting the value of most of the New Zealand woods for useful and ornamental purposes—Brinsmead and others recognised their merits for furniture, &c.—expressed the fear that the Colony would not be able to complete with other sources of supply—first of the local demand, and next because of the long distance from the London market.

Professor Macoum (Canada) described in eloquent terms the valuable characteristics of the chief wood of the Dominion. The Douglas fir of Canada was fully equal to the white pine now employed, and when the supplies of the latter were exhausted the former would of necessity take its place. The Douglas fir grew in vast quantities, attained a great height, and tapered very gradually. In their black ash, too, the Canadians possessed a species of timber which would some day be very widely employed, for it had all the qualities of the now favourite white ash, and its supply was unlimited. The Douglas fir could be supplied in England at 5*l* a load, and the black ash at the same price as elm or white pine.

Mr. E. A. Cooper (Cape Colony) commended the peculiar qualities of the Umzumbit wood—its hardness and durability. The cape yellow wood could be supplied as cheaply as any, the price being about 6*l*. 10*s*. a load.

Mr. A. Dent (British North Borneo) stated that the Billian wood, which offered great attractions to the English merchant, grew in enormous quantities, was very easy of access, and exceedingly hard and durable. As to its cost, one firm was already prepared to supply it alongside ship at 3*l* 10*s*. per ton, to which about half as much again had to be added for freight, &c.

On the motion of Sir Philip Cunliffe-Owen, seconded by Sir. C. H. Gregory, votes of thanks were accorded to the chairman and to Messrs. Ransome & Co., and the proceedings closed.—*Colonies and India.*

THE RECENT COFFEE CROP IN COORG.

The figures for the last coffee crop in Coorg, as given in a memorandum prepared by the Commissioner, are:—Plantation coffee, 5,171 tons, Native coffee 829 tons, total crop 6,000 tons. The Plantation Coffee is no doubt very near the mark, as there are ready means of obtaining exact information; but there is reason to believe that a serious error has been made in the quantity of Native. The exports of all Native kinds from Tellicherry in the past season exceeded 5,000 tons, of which about 500 tons received from Mangalore must be deducted, leaving net exports 4,500. Of this not more than 1,500 tons could be the produce of North Wynaad, the only other district from which coffee is brought to Tellicherry. This leaves 3,000 tons for the receipts of Coorg Native coffee at Tillicherry. At Mangalore the receipts were probably not less than 1,000 world tons, but if taken at the very low estimates of 500 tons the total crop of Coorg Native will be 3,500 tons. Taking the Commissioner's figures for Plantation as above at 5,171 tons, and adding the corrected estimate for Native coffee 3,500 tons, and we get a total crop of 8,671 tons. This is the largest crop the district has ever been credited with, yet, taking the acreage under coffee, given in Mr. Girdlestone's minute to the Planters' Association of 18th March last, at, 73,199 acres, it only gives cwt. 2·35 per acre. Placing the acreage held by Europeans at 37,544, and cwt. 2·77 is found to be the average yield of Plantation. There can be little doubt that Mr. Girdlestone's figures include a large area of abandoned and semi-abandoned land, which it is unfair to include in calculating the acreage ratio. A careful revision of the area upon which the above Plantation crop was grown might prove the actual effective acreage not to be much over 25,000 acres, and of this, 5,000 may be put down as yielding very inferior crops. If this estimate be correct, not more than 20,000 acres would, therefore, be the area from which the great bulk of the present Plantation crop was drawn, and that, on the average the yield was about 5 cwt. per acre. Individual estates can shew an average of from 7 to 10 cwt. per acre, and some planters can point to fields which have given 12 and 13 cwt., but although the crop, taken as a whole, is a large one for the district, the acreage yield, even on a greatly reduced estimate of the total area, is not large, though very fair.

It is impossible to arrange the figures for Native coffee with any assurance of even approximate accuracy. Apart from estates of considerable extent held by the better class of Coorgs, there are innumerable patches of coffee distributed over every part of the province, the total acreage of which it would be all but very difficulty to arrive at. On every little holding, in the smallest compound attached to the meanest dwelling, under the shade of every small tope, there is coffee to be found, bearing fairly well. It is only at the ports of export that the total yield of this class of coffee can be ascertained with any decree of accuracy. Returns obtained at the toll bars for the entire crop of Plantation and Native would be useful if they could be relied upon, but they are notoriously defective, and too much trust has hitherto been placed in them. The importance of accurate statistics cannot be too strongly impressed on the authorities. It is probable that, from defective returns of crop, the coffee industry in Coorg has been underrated, and the interests of the planting community, and the affairs of the district, generally, have in consequence, not received the consideration to which they are entitled. There is reason to believe that if the official returns of previous crops were enquired into, similiar corrections to those now noticed would have to be made.

In Ceylon everything that can conduce to the interest of the planter has the Government's first attention. The planting districts are covered with a net-work of roads, the best of their kind anywhere, great care and much money being spent in keeping them in good order; 120 miles of Railway, if not more, have been made, running into the planting districts, and this at a cost that throws any proposal ever submitted for Coorg into the shade. A recent extension of 40 miles has been completed in Ceylon at a cost of £21,000 a mile. The island has passed through a period of severe depression which still weighs heavily upon it, but the Government does not abate its activity in providng further facilities for the planter of Coffee, Tea, Cinchona, Cocoa, &c., and in doing all it can to promote his interests. Further, railway extensions are recommended, and will probably be undertaken. With Coorg it is different. No more is spent on roads and communications than can by any possibility be avoided, and the internal communications are kept in notoriously bad order. Not much more can be said for the highways by which produce is conveyed to the coast, and to outside markets. Are, though, the Mysore Railway comes within forty miles of the province, and the finer coffee districts are within sixty miles of the coast, there is no thought of giving Coorg the benefit of Railway communication with those important points, although it could be done at a comparatively moderate cost, and with every prospect of profitable results. The Ceylon planters cheerfully consented to an export duty of one shilling per cwt. on coffee to provide a fund for their first Railway, and this they paid for many years, and they fully recognized the value they had received in return when the line was completed. Some-

thing of the same kind might be done in Coorg, and in fact, in connection with the coffee industry generally, for the purpose of providing Railway communication. The Province, however, suffers from being governed from Bengal. It is too remote to have the attention given to its affairs that it deserves, and so long as its contribution to the Imperial revenue is regularly forthcoming, it excites little or no interest. It is high time for this state of things to be put an end to. Coorg is, geographically, an integral part of Madras, and it should be ceded to Madras. The administration of Wynaad by the Madras Government is by no means all that can be reasonably desired; but, when Wynaad, Coorg and the Nilgiris present an united front, the local Government may be persuaded to do more than it has yet done to emulate the able broad-minded attitude of the Ceylon Government towards private enterprise.—*Madras Mail.*

A NEW METHOD OF GLAZING SASH.—It is well known that all glass (now both in portable sashes and in fixed greenhouses), is simply imbedded in putty, and kept in place by glazier's points, no putty being now used on top, as was formerly done. It has been found that when the glass lays on the sash-bar thus imbedded the putty soon rots or wears out, and water gets in and not only loosens the glass but rots the bar as well. A most simple plan to obviate this is to pour along the junction of the bar with the glass a thin line of white lead in oil, over which is shaken dry, white sand. This hardens and makes a cement that effectually checks all leakage. It is quickly done. I have seen glass, so cemented, that has stood for ten years, still in perfect order, and it looked as if it would stand for ten years more without further repair. This plan, which is but little known as yet, is of the greatest importance; had I known of it thirty years ago I would have saved many thousands of dollars in repairing, besides having the plants under this water-tight glazing in better condition.—PETER HENDERSON *in American Agriculturist.*

COMMERCIAL COPAL.—The copal from which varnish is made is found in a fossil state, chiefly on the east coast of Africa, and consists of the exudation of former forests long since submerged. It is never found far inland. Copal varies in quality according to the vicinity where it is obtained; sometimes two descriptions are unearthed in the same district, varying in quality, structure, and shape. The young copal of Sierra Leone is globular, or tear-like, brownish and slightly odorous; the "pebble" copal obtained there is more or less white, with thick opaque crust, and is odourless. That of Gaboon is in flat pieces, with a crust of branching striæ, and the fracture is conchoidal. The copal of Lango takes the form of broken sticks, of which there are two kinds, one white to yellow grain, the other reddish or brownish, and in irregular fragments. The latter, which is transparent, homogeneous, and fragrant, is the best. Of Angola copal one kind is globular, and of uniform quality throughout; another is in the form of sticks, mostly cracked, and found in common with air-bubbles and bark; it is yellow, red, or brownish. Slightly coloured copal has a dull appearance, and is not so uniform or transparent as the strong coloured. The copals of Manila, New Zealand, and South America are softer than other descriptions.—*Chemist & Druggist.*

BRICK-TEA does not excite much attention in this country, beyond the fact that there is a large trade between China and the countries bordering it in this article. Some attempts have been made to develope, a trade in Indian manufactured brick-tea between this country and Thibet but so far without any practical results. The composition of brick-tea has also been a subject of some speculation, and erroneous impressions would appear to be extant regarding it. But a Russian *savant*, Professor A. P. Borodin, of St. Petersburg, has been turning his attention to the subject, and has analysed several specimens of a kind for which there is a very large demand. The Russian name for these 'bricks' is *kirpitchnyi tchai*, and that of the Chinese makers is *Shun-Fan*. The name, however, throws no light upon the composition of the bricks, which are extensively used in Eastern Siberia, as well as in the East of European Russia. Up to the present, it has been supposed that brick-tea was prepared from a mixture of tea leaves and a decoction of starch or rice, with various foreign colouring substances. This seems to be quite erroneous. Professor Borodin, in the specimens analysed by him, found that it consisted of quite pure siftings of black tea compressed after softening by steam. It contained from 2·36 to 2·44 per cent of theine; from 7·91 to 7·96 per cent, of ashes; 22·5 per cent of soluble substances, and from 6·72 to 6·77 per cent of tea tannic acid. But it contained no essential oil, thus differing in that "particular from tablette-tea" (Russian *plitotchnyi tchai*] or ordinary compressed tea, which is prepared by subjecting *dry* siftings of black tea to the action of a powerful hydraulic press. The price of brick-tea is only 40 copecks (about 11*d.*) a pound. The foregoing particulars are of some interest, and suggest the propriety of Indian tea-growers developing an industry which opens a way to a trade with Thibet, Yarkand, Chinese and Afghan Turkistan, &c. Professor Borodin, moreover warmly recommends, the use of brick-tea generally.—*Indian Agriculturist.*

PROFESSOR WALLACE ON AGRICULTURE.—Mr. Robert Wallace, Professor of Agriculture and Rural Economy at the University of Edinburgh, delivered his introductory lecture to the agricultural class on Oct. 20th at the opening of the session. In introducing the subject Professor Wallace pointed out that even in this great manufacturing country the industry of agriculture was the largest and most important of all, locking up more capital and employing more labour than any other. He had already shown that the appreciation of gold, increasing for a number of years, had a tendency to lower the prices of all commodities, agricultural and other, and that those who were bound by leases must suffer each year. He thougt it entirely illusory to find in legislation alone a remedy for present or future evils. Proprietors should meet and consult together as to what would be the best course to follow in their own interests as well as those of the country. The system adopted in Scotland of leasing land for a longer or shorter term of years was, he thought doomed to vanish. All long lease contracts must come to an end. Proprietors would consult their own interests if they would at once, without waiting for the termination of leases, adopt a sliding scale for the fixing of rent, based on the average prices taken in the local markets. In fact this was an old custom and many rents in the Lothians had been fixed annually by the average yearly price of wheat. He stated as a noteworthy fact, drawn from his own personal experience, that the districts where systems of mixed farming were followed had suffered less than where one single crop or one single branch of agriculture had been depended upon to meet all costs. Mixed husbandry had many advantages. By dividing the risks among a number of crops or varieties of stock the principle of an insurance company was to a certain extent adopted. Further, the growth of a variety of crops conferred on land all the advantages of the improved systems of rotation. Variety of live stock was also a source of wealth as much as variety of cropping. Turning to the connexion between agriculture and the University, he said that the degree of Bachelor of Science in the department of Agriculture, which would be opened for competition in a few weeks, would give a grand stimulus to agricultural education. He advocated Lectureships or Chairs of Forestry and Agricultural Chemistry, and generally upheld the advantages of education in the art. In conclusion, he urged them to prepare themselves for any emergency that might arise in the future. Fortune helped those who helped themselves, and no one could succeed who did not rely on his own industry and perseverance. Success was impossible without application. He had no fear that Scotchmen would lag behind in the race.—*London Times.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, November 4th, 1886.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White, per cwt.	Slightly softish to good hard bright	£6 a £7 5s
Yellow	Do. drossy & dark ditto	£4 10s a £6
CINCHONA BARK—Crown per lb.	Renewed	1s a 3s

CEYLON AGRICULTURAL SCHOOL.

ANNUAL REPORT: NOV. 1886.

The Colombo School of Agriculture was opened in January 1884, and hitherto there has been no public prize day, the Director desiring that the school should be established on a firm basis before any public attention was drawn to it.

Now, however, that the training of the first batch of students has been completed, and very satisfactorily completed, the prohibition of publicity has been removed, and on behalf of the students I welcome your Excellency very heartily to this our first prize day, and we thank you, sir, for the great honor you have done us in coming here today.

A short history of the school may not be out of place. It was first proposed by the present Director in 1883, and it was very generally predicted that it would be a failure. It was said that Students who were cadets of the better families of Ceylon would be above working with their own hands at ploughing and other farm operations, while, if students of the lower class were admitted, no practical good would attend the opening of the school. Nevertheless, out of some 80 applicants for admission 28 students were selected and admitted in January 1884, only 3 of whom represented less than 100 acres of land, while many represented very large acreages.

The design of the school was to train these students for cultivating their lands and the lands of their friends by the light of more modern Agricultural knowledge, and, by the use of improved implements of tillage, care being taken in no way to do away with existing native customs but to bring out what was best in them, and to supplement them where necessary with more modern knowledge.

The few poorer students were to be trained for future use as school-masters.

There was at one time an intention to attach this school to Mr. De Soysa's Model Farm, but the Director considered Model Farms expensive and cumbersome, and arrangements were made instead to follow the German system, and to send the students out for their practical work to the lands of private land owners. And here I desire to publicly express our gratitude to Mr. Abeyratne for permitting us to work upon his property.

I am glad also to state that every one of the students now in the school has performed his full share of manual labour shrinking from nothiug, but working pluckily and heartily at the most wearisome details, thus improving their physique and health, and gaining practical knowledge of all operations, from tending buffaloes up to ploughing with their own hands.

The first year's work was theoretical only and was devoted to the ordinary subjects of a High school education, but substituting agriculture, chemistry and botany for Latin and Greek.

The second and third year's work has been both practical and theoretical with book work on the lines above mentioned.

Mr. Charles de Soysa has with his usual generosity given a prize for the best students in Agricultural Chemistry and analysis of soils, for which we thank him heartily.

With regard to the book-work of the school, it has been mainly in charge of Messrs. Charles de Silva and H. D. Lewis, whose services I desire to acknowledge, while the field work and actual Agricultural Teaching has been in charge of Mr. Jayawardene who was trained at Saidapet and who has turned his training to good account.

Our work on Mr. Abeyaratne's land has been heavily handicapped by two bad floods, but, nevertheless, we succeeded in obtaining a proportion of rather more than 12 bushels of paddy for every 9 bushels obtained by the native method, although the native land in competition with ours was the more heavily manured.

Experiments have also been made with various gardens, or dry-land products with a view to checking the wasteful cultivation of such soil-exhausting crops as anu, &c. in chenas. We have found for instance that dholl, which is seldom grown by the Sinhalese, will grow with little trouble in any soil, and it is a most agreeable and nutritious food. It is hoped that the students who leave us tomorrow will spread the knowledge of this valuable food amongst their own people in their own villages.

But I must not weary you, sir, with details. I will now only state that according to the proposal sanctioned by your Excellency, six of the students who are leaving us now will assume appointments next January as Village Agricultural Instructors at Mullaitivu, at Toppur, and at Kanankudah in the Tamil districts, and at Minuangodde, at Panapitiya, and at Bandarigama in the Sinhalese districts. Too much importance cannot be laid upon the success or failure of these young men. The natives of this country are very generally opposed to what they deem new-fangled ideas, and it will require much tact to guide them aright.

For instance they say that our ploughs are too heavy for their buffaloes; it will be for these village instructors to show them that they are not too heavy if the buffaloes are trained to their use. A horse requires breaking to harness, and a buffalo requires similarly training for these ploughs,

And above all it will be their duty to train up the boys of the villages to which they are sent, boys whose minds are not yet rooted into prejudice, to a knowledge which the grown up men may be too proud to acquire.

In this their arduous duty they will be cheered by your Excellency's presence here today, and I am confident that each one will do, if possible, more than his best, feeling that your eye, sir, is upon him, and that your best wishes attend his work.

H. E. GOVERNOR SIR A. GORDON said: You have been good enough, Mr. Green, to ask me to come here today to distribute the prizes to the boys of this school, and I have had great pleasure in accepting your invitation, though I should have had that same pleasure under any circumstances, because it is always an interesting thing to see boys assembled together, and yet more interesting to think, that those to whom the prizes are given, are about to go out into the world, and in their own persons experience the value of the lessons which they have learned: that is the case in any school and at any prize-giving; but the interest is today deeper and more peculiar, because it is not only the boys who are about to leave the Institution, but, it may be said in one sense, that it is the Institution itself which is now, for the first time, going out into the world. (Applause.) Hitherto its work has been confined to that of training; now it remains to be seen what the value of that training has been, and what its results will be on those who leave it and go out to apply elsewhere the principles which they have learned here. Those who so go forth from you today bear with them not only my good wishes, but the good wishes, I am sure, of all the company which is assembled here today. But, as is usually the case, it depends more upon yourselves than on any one else whether those wishes will be realized or not. We may wish you success, but the making or marring of that success is in your own hands. Some of you on leaving this place, go to try novel experiments and have received novel appointments. Now, it depends very much—I do not know that we should be very far wrong if we were to say it depends altogether—on the manner in which those first few students who are leaving this place discharge their individual duties whether this Institution becomes a failure, or whether it proves a benefit—and lasting benefit—to the country. But although those who go to take up these posts are the most conspicuous, and their failure or success will be most marked, do not think that I undervalue the importance of the action of those returning without such appointments to their own homes, and their own districts (Applause.) In some respects, their work is even more important than that of the paid teachers recognized by Government (Applause.), because the influence they exercise will not be the official influence, but simply the influence that their own good sense and their own tact may gain for them. Now, some of those who are educated here, when they go back to their own districts, and live among their own people, and are surrounded by their old associations and superstitions will no doubt forget a great deal they have been taught here and will take up again the old habits and associations which surround them: that is quite inevitable. It is not a thing that can be avoided in case any number of people are going back to their old associations. I mean that you will find that new methods of ploughing, new systems of agriculture are troublesome; that they are unpopular amongst those whom you live, and they will gradually be dropped out of sight and forgotten. That will be the case with some, and it will be a pity, although it is inevitable, but there are others with whom that will not be the case, and I am not sure that some of these others may not do more to prevent the success of our scheme here than those whom I have just mentioned—I mean those who go back

to their own district full of the importance of what they have learned and full of the importance which that learning has given to themselves, and who set themselves above all the people of the country as knowing something better than they, and are prepared to set them all to right and tell them that they are all wrong, and that unless they are listened to, nothing can be done properly, that nothing has been done rightly hitherto, and that they are prepared to shew they are right. Now you may depend upon it that that is not the way in which such influence will be gained: the lessons you wish to be taught will not be learned, and, perhaps, more harm to improved agriculture may result from want of tact and self-conceit than from indolent apathy or the taking again to old habits? But between those two extremes I hope, and I believe, there a will be others who will neither be elated by knowledge little more than their neighbours, nor yet so apathetic as to fall back into the prejudices and superstitions of those who surround them. From them I expect great results, and with tact, patience, care and good humour I have no doubt that you will do much to introduce improvements in agriculture into the rural districts of Ceylon; and in so introducing them you will increase the prosperity, the wealth and the happiness of the people to whom you belong (Applause.) I can conceive no happier destiny than that of those who are placed in a position which naturally confers on them some influence, who should exercise that influence with wisdom, moderation, and in such a manner as to enjoy the esteem and goodwill of those about them and lead them gradually into improvements of which they will see the result. As to those who are going with Government appointments, they too will require to exercise very great care as to the mode in which they perform their duties. Of course, so long as they teach merely in a Government school, they can make the Government school boys listen to them, but if they attempt to teach other people, as I said before, it will depend upon themselves whether they will get listeners or not. They may be like those crying out in desert places, or they may be real leaders of the people; that they may be of the latter is my earnest hope. I trust that in future years, when I, or my successor, who will more worthily fill my place comes amongst you to distribute prizes, that we shall meet here some of those who are leaving us to-day, and that you will then give some account of the experience which you have had since you left this place, and will be able to cheer all those who have taken part in this Institution and its management with the intelligence you give them of the manner in which your mission has been received by those among whom you have gone. Wishing you every success, not only as agriculturists but as individuals, I now beg to repeat the pleasure I have had in distributing the prizes. (Applause).

Mr. A. M. FERGUSON made some practical remarks with regard to the cultivation of dholl, and alluded to the grand physique of the men of Northern India, as a result of living on dholl porridge, dholl being largely cultivated in that part of India. He referred in eulogistic terms to the irrigation works initiated by H. E. the Governor, and went on to say that the fish in the globes around the room suggested to him that those in authority who had the power to initiate experiments should endeavour to wipe away from Ceylon the reproach of knowing very little about the cultivation of fish. In Java there were two harvests, one of fish, and another of grain, and the fish harvest was fully equal to the grain harvest. He mentioned this because fish was a very welcome addition to the table and there was no possible reason why they should not be largely cultivated in Ceylon, for it was really a part of the great science of agriculture.

BROKERS' REPORT ON CEYLON PRODUCTS:

COCOA, RUBBER, AND ALOE FIBRE.

(*Extract from letter from Mr. J. L. Shand to P. A. Ceylon.*)

In the box which I have packed ready for you and which I hope to send in a few days by Mr. W. Saunders. there is a parcel of several best Trinidad varieties of cocoa and also three samples drawn in London with valuation attached. Mr. Pink, who is a great cocoa authority and who is reporting upon the cocoas in the Exhibition, thinks Ceylon is making a mistake in copying the West India mode of preparation. He says the bright colored beans which Pallekelle used to send command a special market both at home and on the Continent. He considers we should continue washing and he values Wariapolla unwashed considerably lower than the same mark washed. He also thinks that the value of produce has not been increased by the introduction of new kinds of cocoa. External appearance goes for nought in the trade and the stoppage of fermentation at the proper time seems the secret of success. He considers Ceylon cocoas will never reach the height which some of the large full West Indian beans fetch, but I pointed out to him that this might be only a matter of age of trees. He says plainly that Ceylon is not sending as good a marketable colour as it did a few years ago and he recommends striving for the brighter colour.

I was in the City yesterday with one of the largest South American cinchona brokers who showed me by his books the days when the unit of sulphate of quinine was worth 2s. There has been a little activity in the market this week, but stocks must fall before prices rise much. The cultivated Bolivian bark which generally yield from 4 per cent to 6 per ct. of sulphur of quinine are what the trade look to most as the future source of supply. There is no belief in the very large quantity coming from Java and plenty of room for from 6,000,000 to 8,000,000 lb. of good Ceylon bark annually and considerable rise in prices should Ceylon exports fall to this figure, is the general verdict of the trade.

I enclose you two reports upon samples of the aloe fibre sent by Mr. Henry Brown and upon Wariapolla Ceylon rubber. The three samples of rubber were all taken from the same piece.—The coffee market continues firm and there is expectation of considerable further improvement in prices.

Patry and Pasteur present their compliments to J. L. Shand Esq. and beg leave to hand him a report on and valuations of the following samples of Ceylon Rubber:

1.—Fairly well cured and worth today 2s per lb.

2.—Badly cured and would be somewhat difficult of sale, worth say 1s 3d to 1s 6d according to position of market and buyers' requirements.

3.—Low, dirty and inelastic; badly cured and false packed value about 6d per lb.

38, Mincing Lane, 28th October 1886.

38, Mincing Lane, London E. C. 28th Oct. 1886

J. L. Shand Esq. Ceylon Court, Colonial Exhibition.

Dear Sir,—We have submitted your sample of aloe fibre to experts, who report upon it as follows:—The sample is of good quality and well prepared, and if the bulk prove equal to this, it should find a ready sale.

The present value is about £20 per ton. Great care must be taken to send it home perfectly clean *unentangled* and as long as possible.—We are, dear Sir, yours truly.

(Signed) PATRY & PASTEUR.

P. S.—We enclose our reports on rubber samples.

PLANTING IN CEYLON: SCOTTISH TRUST AND LOAN COMPANY OF CEYLON, LIMITED.

We are indebted to the local agents Messrs. Cumberbatch & Co. for a copy of the Report for the year ending August, 1886:—

Capital, ...	£250,000
First issue (fully subscribed)	£150,000
Of which paid up, ...	£45,000

The Directors beg to present their Ninth Report to the Shareholders, being for year to 31st August 1886. Since last Report the price of Coffee has materially improved, and Ceylon Tea is steadily maintaining the favourable promise of former years, but owing to the shortness of the Coffee crop, the heavy fall (50 per cent.) in the price of Cinchona, and to the fact that the Tea Plantations on the Estates in the Company's hands are not yet of sufficient age to give substantial returns, the Directors are of opinion that it would be in the best interests of the the Company to retain rather than to distribute the balance at the credit of Profit and Loss Account.

The Directors have to explain that owing to the want of full information, at the time of making up last year's Accounts, as to the apportionment of the produce of the different crops and years they were led to include in the Estate produce on hand and *in transitu*, at the end of 1884-85, a considerable quantity of Cinchona which really belonged to the crop of 1885-86. The prices at which the produce was valued in the last account were fully realized, but the error regarding quantity requires a re-adjustment of Accounts by taking the sum of £2,560 6s. 7d. out of the balance of Profit and Loss at 31st August 1885 and placing it to the credit of the Estates for the year to which the present Accounts refer. The balance therefore of £6,805, 8s 6d at credit of Profit and Loss at the end of last year must be reduced to £4,245, 1s 11d.

The Company's Estates being now thoroughly in hand, there has been no difficulty in determining what produce belongs to the year 1885-86, and care has been taken, as on the former occasion, to adopt a safe basis of valuation. Of the £4,651, 2s worth of produce stated as on hand or *in transitu*, £3,321, 2s has since the close of the Account been satisfactorily realised.

The net return from the Company's Estates for the year is £2,764, 13s 9d, as against £3,354, 19s 6d for last year (which is the corrected return after deducting £2,560, 6s 7d of crop over-credited as above explained). Had the price of Cinchona not fallen so considerably, the return for this year would have shown a considerable improvement over that of last.

The Company have now 863 acres of Tea under cultivation, and 177 acres more are prepared for planting. The Directors have ordered the erection of the Company's first Tea factory, which will serve for two of the estates, Annfield and Rahanwatte, from which some crop is expected during the current season.

The interest on mortgages in arrear last year has been paid up. Of the £1,723 19 9d. Interest in arrear at the close of the account, £820 14s 11d. has been either paid or provided for to the satisfaction of the Directors. Payment of £487 10s. of the balance, which is all due by one estate, has been deferred by arrangement until Tea production commences,—the Proprietors having undertaken to expend at least this amount in Tea extension,—and the remainder is being gradually paid off by consignments of produce to the Company's Agent in London.

Sums amounting to £10,148 18 6d. have been received during the year in extinction and reduction of Loans, and of the five remaining rupee loans the Directors have arranged for the conversion of three into sterling.

The Debentures which the Company agreed to renew at Whitsunday last were renewed at a reduced rate of interest, and the Directors have further reduced the rate for renewals at Martinmas. The Debenture Debt has been reduced during the year from £64,925 to £60,375, and will be further reduced at Martinmas from Cash on Deposit. It will then stand at little more than 50 per cent. of the uncalled Capital.

The Balance at the Credit of Profit and Loss Account is £3,522 5 2
and the Directors propose to carry to Reserve Fund. .. 1,000 0 0

Leaving .. £2,522 5 2

to be carried forward to next account.

Under the rotation fixed by the Directors Mr. Kidston retires from office at the Meeting; he is eligible for re-election in terms of Section 14 of the Articles of Association.

WIRE TRAMWAY TO CARRY ESTATE PRODUCE.

(*From our London Correspondent.*)

There has been shown to me very lately a drawing which fully illustrates a design for a wire-rope tramway to take down the produce from a Ceylon estate. For certain considerations, it is desirable that that estate should not be named. It is, however, one of many similarly situated as regards difficulty of transport. Its greatest elevation, and that on which the machinery of the estate is situated, is some 1,200 feet above the cart road, while the distance of the curing establishment in which machinery has to be worked is fully three miles from the river where water power to work it is obtainable. Very considerable previous experience has been had by the proprietors of the estate with similar tramways (I doubt that being a proper term) on other estates; but in all such cases the distance over which the wire-rope has to be actuated is very much less, the greatest distance hitherto absolutely worked with, being, I believe, one-and-a-quarter mile only. It was asserted to me that very close calculation, based on the experiences above referred to, shew that fourteen horse-power can be relied upon to give all the motive-power required for the greater length of line, to overcome all its friction, to perform its duty, and yet leave a sufficient residuum of force to work the machinery of the curing house. This amount of power, it is said, can be readily obtained from an overshot waterwheel to be worked by a stream running at the base of the hilly range on the summit of which the estate under reference is situated. The engineer who designed the rope-way shares in my own view that waterwheels are preferable to turbines in this and similar cases. Although the former are not so fully economic in their nett results as the latter, they are less liable to frictional wear in positions difficult to get at for repair as are turbines. It has, therefore, been decided to use the waterwheel. About 8 horse-power, it is determined, will suffice to carry the burdens and overcome the friction to be imposed upon the rope, leaving 6 horse-power available for driving the machinery of the factory. If this design is carried out, as I am assured it will be, and the limits of power assigned shall be found to be sufficient, it would, we think, give great impetus to the use of such means of conveyance on Ceylon estates. But it must be confessed that the spaces between the standards supporting the rope look somewhat alarming. One of these is fully a quarter of a mile, and we all know what a tremendous power would be necessary to stretch a wire rope over that span, quite independently of any load which may be imposed upon it. The catenarian curve, one would suppose, must prove so great that at some point or other between the supports the ground must be touched. We are told that such a supposition need not be entertained; but we shall undoubtedly feel more satisfied than we are when such an assurance has been justified in practice an ounce of which—we proverbially know—is of more value than a pound of theory. The names associated with this scheme incline us to attach weight to the probable efficiency of the design. Should it prove as reliable in practice as is claimed for it, there seems no reason why in the end a system of these rope-ways may not supersede any scheme of subsidiary tramways as feeders for your lines of railway in the hills. There would be a fine opening for some of your independent engineers—Mr. Grinlinton for example—to start a Company to establish lines of such carriers to tap the base of certain groups of hill estates. Subsidiary lines for each individual estate might well remain in the hands of their owners. If three miles prove capable of being worked by 8 horse-power, there seems little reason to fear, but that a line of ten miles could be worked between fixed points, and the transference of the boxes as they came down from individual estates to the principal ways could readily be arranged for. There can be no want of water-power at spots to be selected to drive a rope of ten miles, and supposing this rope to start from one of your railway stations, and take a course up a valley on the hillsides of which numerous estates are situated, such a line would prove to be of incalculable benefit to estate owners, and must pay well the enterprizing men who may start it. This suggestion is thrown out for what it may be worth; but it is due to a careful inspection of the design referred to, which is guaranteed to bear a practicable character. Of course, the value or otherwise of such a suggestion must be dependent upon such a guarantee being demonstrated by actual experience to possess worth. Presuming that to be established, however, it seems to those of us who have considered the question that there will be an opening of great public and private value for some of your public-spirited men to take up. It is probable, we hear, that the estate line named will be working before the first six months of 1887 have expired, and necessarily it will provoke intelligent observation. Upon the result of that observation should depend the decision whether the more extended application of the system might not wisely and with profit, be undertaken in Ceylon.

THE TEA PLANTER'S MANUAL.

Mr. Owen, who is already well-known to those engaged in tropical agriculture from his Cinchona Planters' Manual, has now written a similar treatise* on the present leading Ceylon industry, which is—though written principally with regard to the conditions existing in that island—likely to prove very useful to all tea planters. He has been well treated by his publishers, who have issued his book in a neatly printed and handy form, at a moderate price; the index and table of contents, too, appear full, so far as we have had occasion to use them. Amongst the attractions of this volume are two lithographed plans of factories which may be commended as the subject of a happy dream to the beginner in tea; they are said in the advertisement to be "worth the whole charge," and, to do our little fault-finding at once, we may pronounce them very elegant, but totally unsuited for a work of this kind. The first is to be built of iron, and the second of wood; supposing water power available, and therefore no steam power wanted, and the requisite timber procurable on the estate, the cost, including machinery, is, respectively, R32,000 and R22,000. "There are also," we are told, "numerous little details in the fitting up of a factory for which it is quite impossible to estimate accurately." Now Indian planters will willingly admit that Ceylon

estate buildings are generally a credit to their architects, and an example to be striven after, but the sums we have named are simply impossible to the ordinary cultivator, who, it must be remembered, will, in perhaps the generality of cases, have to also provide an engine. It would have been much more to the purpose if the author had given us half a dozen plans of less costly factories, and of existing buildings adapted to new needs. Some very fine tea houses—notably those on the Carolina and Mariawatte estates,—have indeed been erected, but it is improbable that imitators desirous of spending equally large amounts would omit to get professional advice, or copy a plan out of the book we are reviewing without attention to local circumstances. The vast bulk of Ceylon tea making is, however, done in more modest edifices.

Mr. Owen tells us that his "Manual" is more intended as a compilation of the opinions of others, and the results they have arrived at, than an original work. He has, however, done well in collecting this information from various scattered papers, and has brought it up to date. The Ceylon tea enterprise, which has recently made such remarkable strides, dates—commercially at least—from 1841; the Dutch are said to have previously attempted it, and failed. Messrs. Worms manufactured some tea about that date, with the assistance of a Chinaman, at a cost of about £5 per lb. but their estates, now owned by the Ceylon Company comprise a large area under tea. Coffee, however, paid, and, except in phenomenal cases, still pays better than tea, so until the terrible inroads of leaf disease and other pests made planter despair of pulling their trees round, little attention was paid to any other product. It will be in the recollection of readers of Mr. Owen's previous work, that the greatest difficulty was experienced in inducing Ceylon planters to believe that the cultivation of cinchona was worth attention as a commercial speculation. In 1867 only 10 acres were planted with tea; twelve years later this had increased to 6,500 acres; but there are now said to be 116,000 acres opened, including old coffee land replanted, and it is confidently predicted that this will be doubled in a few years. The total consumption of the world is said to have been 350 million lb. in 1885; two-thirds of this was taken by Great Britian, and it is worthy of note that the quantity of Indian and Ceylon tea in this proportion, has risen from 3 per cent. 20 years ago to 39 per cent. This loss has been borne by China, and it certainly looks—in the absence of any disposion on the part of the Chinese to mend their ways—as if the anticipated increase of Ceylon to 30 million lb. in 1888-9 would result in a further falling-off of the demand for the China varieties. The advantages possessed by Ceylon as a tea-producing country are naturally laid stress upon by Mr. Owen; in some respects it may be doubted whether a long enough trial has been given to establish these beyond dispute; however, the hill districts are certainly healthy, and the railway to Nanuoya (on the occasions when it is open for traffic) is a great convenience; the system of roads throughout the planting districts is on the whole above the Indian average. As to the low country, we are told that the principal new district, the Kelani Valley, "though very hot, is not specially unhealthy; residents have, of course, to take care of themselves, so that exposure to heat may not result in fever, but in general healthiness these districts compare most favourably with the plains of India." This is as it may be, but we have heard that residents in the Kelani Valley consider it imprudent to stay there more than three months without a change.

In selecting land for tea in Ceylon, the investor has two courses open to him: he may either purchase abandoned or semi-abandoned coffee land with a view to replanting it, or he can take up a block of forest in the low country; little forest remains in private hands at high elevations, where all Government lands is reserved. Tea has been found to thrive from a little above sea level to 6,000 feet, and taking one thing with another the profits seem about equal. At low elevations a type of plant closely approaching indigenous tea should be selected, and in the hills a hardy Assam hybrid. Under no circumstances does Mr. Owen recommend the China plant. The advice given respecting nurseries, manuring, manufacture, and the every-day working of a tea estate will we think, be found generally interesting and useful to planters in search of information on these matters. Clean weeding is of course insisted on; it is not usually adopted, for some reason, on tea estates in India, but it has been found the best system with coffee, and is undoubtedly the cheapest; the Assam plan is to grass-knife down the weeds, and then trench and bury in; it seems an unsatisfactory proceeding and likely to exhaust the soil, but it gives excellent results, and no amount of argument is likely to induce a change. Shade of all kinds is found injurious to tea, more especially that afforded by cinchona trees, which perhaps partly accounts for the extirpation of these trees which has been going on in the island. Some attention has recently been drawn to an alleged exception to this rule in the case of the "sau" or *albizzia stipulata*, but it does not exactly appear how it acts; there seems to be no doubt, however, that tea in its vicinity is in some way benefited; it is a quick grower, and is often planted with coffee. When it becomes necessary to renovate the soil, either cattle or artificial manure can be used; there can be no doubt that the former is infinitely the best, and if the amount said to be sufficient for a tree, both by the editor of the Tea Planter's "Vade Mecum" and the present author, namely 7 or 8 lb., is really so, it ought to be universally adopted. We believe, however, that on the most largely yielding estates considerably greater quantities are applied. Castor poonac seems to be the best artificial fertiliser, as far as experiments go at least, as a plot manured with 24 cwt. gave 961 lb. of tea to the acre. The art of manufacturing tea must be learnt practically; in his chapter on this subject Mr. Owen gives a good deal of instruction as to what to aim at and what to avoid, which is well worthy of attention. As regards packing and shipping, the leading rule is to send in as large breaks, and as few varieties as possible. A tea "account sale" is an even more distressingly complicated document than one of coffee, which is saying a good deal, but certain fixed charges mount up if there are several lots to be dealt with. Nearly all tea-house work is now done by machinery, and in chapter 9 will be found some account of the machines chiefly used in India and Ceylon, and an appendix contains instructions as to the care of boilers, taken from the *Indian Tea Gazette*. Chapter 10 gives estimates for opening an estate and bringing it into bearing. It is somewhat difficult in India to check this, and some of the charges more especially for the first year's weeding, usually heavier than afterwards, appear rather small. No doubt, however, every care has been taken to get correct information. A capital of R58,000 is apparently required for 200 acres; at the end of five years, supposing a yield of 350 lb. per acre all round to be obtained, and no manuring to have been necessary, R40,600 would be still outstanding. Of course with more gradual extension less money would have to be invested, as the old fields could be made to pay for the expenditure on new clearings, but probably 200 acres is as little as it is usually profitable to put up machinery for.—*Madras Mail.*

THE "lime-juice and glycerine" of commerce contains neither lime-juice nor glycerine, but consists of equal parts of olive-oil and lime-water, scented with essence of lemon.—*Indian Gardener.*

CHLOROFORM AND TOOTH EXTRACTION.—Chloroform applied after the extraction of a tooth has a twofold effect: it allays the pain, and arrests the bleeding. The best strength to use is two parts of chloroform in 100 of water.—*Burgoyne & Co.'s Price Current.*

ECZEMA, according to Dr. Wyss, succumbs to resorcin. To allay the itching, he used a vaseline ointment with 10 per cent of resorcin, and the effect was surprising and most gratifying. In every case he had tried it, it had been a success. When the eruption is oozing is the best time to apply this remedy.—*Burgoyne & Co.'s Price Current.*

LIBERIAN COFFEE IN NORTHERN AUSTRALIA.—Mr, Holtze returned from a trip to the Adelaide River last week, and he has kindly showed us a specimen of the Liberian coffee plant taken from the block of land experimented on by Fisher and Lyons. To us it appeared a perfectly healthy plant, entirely free from any traces of the ravages of insects, and Mr. Holtze describes it as a fair average specimen of some 10,000 plants growing on the plantation. He had taken from the plant no less than 320 berries, and as it is only about three years since the plantation was started, and during the major portion of that time it had been utterly uncared for, the bush gives an excellent idea of what might be done by careful cultivation. The whole of the plants are said to be in a fine healthy condition, with an average height of three feet, and many are already bearing luxuriantly. It is the intention of Mr. Holtze to send the plant to Adelaide as a practical proof of what the Territory can do in the way of growing coffee, and if such a result can be furnished by a plantation that is allowed to run wild, we think it is only a fair assumption that the industry would well repay a little care and attention.—*Northern Australian Paper*, Oct. 15th.

JAFFNA: AGRICULTURE AND PUBLIC INSTRUCTION.—This is the season for paddy cultivation in Jaffna. The rains for sowing were rather late this year, and then when the plant had germinated there was not sufficient rain to make it grow. And now the fields are being scorched by heat. This is unusual. The thermometer has risen from 82 to 88 degrees, and the paddy-plant is all over the peninsula, diseased, more or less. The disease is called in Tamil "Kurukkutti. When the fields are sufficiently flooded the diseased plants rot away hopelessly. The only way the farmer meets this disease is by pulling away the diseased plants along with the weeds by the roots, and replanting the vacant spaces. This year whole fields are diseased in this way, and the poor farmers are very busy with extensive replanting. There is another important disease from which the paddy-plant often suffers. We haven't any trace of it anywhere this year. It is called in Tamil "Sental." I have noticed this disease of the paddy-plant at length here, just to draw the attention to it, of the Government, or rather of Mr. Green, the Director of Public Instruction, and of his Agricultural School. Scientific farming is quite unknown in Jaffna, and it is high time now for the Government through its Agricultural School to lead the way for improvements and to enlighten the farming public in different ways. A good service has been lately done to Jaffna by one of its educated farmers by distributing freely the entire edition of his pamphlet on Agriculture. The work is dedicated to Mr. Green. Mr. Green is said to have already perfected his arrangements for agricultural teaching at least in Batticaloa, Trincomalee, and Mulaitivu. Cannot the funds at the disposal of the Director allow him to provide agricultural teachers to each of the following places, viz., Jaffna, Point Pedro, Chavcachcheri, Mannar and Vavuniya Vilankulam at least.—*Cor.*

TEA MACHINERY.—Yesterday afternoon (Nov. 27th) there was a trial at the Store and Works of the Colombo Commercial Company, of the new Cycloid Tea Roller patented by Mr. Hutson, Engineer to the Company. The roller is very simple in appearance and construction being an octagon box with an iron lid which fits inside above the charge of tea, pressing the same down as the rolling proceeds. Apart from this pressure the motion is entirely confined to the table below, on which grooves are scientifically cut to give the leaves the needful twist. The roller is very easily driven, and has already been at work on Hunasgiriya estate with very satisfactory results. It is also moderate in cost. The Colombo Commercial Company have altogether an exceedingly busy place in Slave Island—in great contrast with most coffee stores in Colombo. Mr. Hutson has metamorphosed a great part of the store besides adding new buildings. The steam engines now do other work besides driving coffee peelers, sifters, &c. There is extensive timbe sawing, and box-cutting and fitting machinery—the best in the island we suppose—for tea boxes, of which a large supply is turned out. Bone-crushing is an industry always associated with our Colombo mills; but it was news to us to learn that the bone dust was being shipped from this mill to Europe. Hydraulic machinery pressing cinchona into compact bales was working noiselessly and well; while another Department in its busy as well as noisy (hammering) action, gave evidence of the steady demand which has sprung up for Brown's patent "Dessicator" for tea-drying. This machine and its good work have already been described in our columns, and altogether we congratulate the patentees and the Company on the good useful work evidenced during a visit to their Stores. Of course, coffee is not dead yet in Uva, and a goodly share of the Principality's produce comes to the Slave Island Mills, so that altogether we have here as busy a scene as can perhaps of the kind, now be found in Colombo. Mr. Hutson is becoming well-known upcountry where his skill as engineer and machinist is widely appreciated.

JAVA; AMSTERDAM, Nov. 3rd.—Advices from Java continue to be very unsatisfactory. Sugar plantations and manufactories are being sold at ridiculously low prices, one manufactory at Probolingo being acquired by a mortgagee for the sum of fl. 4,000, what the second mortgagee sustained a loss of about fl. 400,000. Several other manufactories have changed hands at fl. 100 or thereabouts. These facts show conclusively how gloomy the present state of matters is, and how enormous the losses must be in this branch of industry, which formerly yielded large profits. It is not surprising that under these circumstances efforts should be made to secure more effective assistance from the Government than is afforded by the proposed scheme of the Minister. The Netherlands India Railroad Company has further reduced its tariff for conveying sugar by c. 25 per picul. According to statistics just published, it appears that the imports in Holland during last year decreased by 2 1-5 per cent compared with 1884, and the import by 3.25-100 per cent., whereas the general exports have increased by 77-100 per cent., and the transit business by 17.29-100 per cent.—*L. and C. Express.*

WILD-BIRDS PROTECTION.—The destruction and trapping of birds (says the *Singapore Free Press)* of all kinds and sorts is going on as actively as possible, notwithstanding the provisions of the Act in such case made and provided. This should be put a stop to, or the consequences will be serious to the fruit and coffee trees and tapioca and sugar plantations, which represent our agricultural poverty. If insects are allowed to get the upper hand, human as well as vegetable creation will suffer, and therefore, on purely selfish grounds, we hope the Government will urge the Police to carry out the law. Hundreds of birds are snared and shipped on board of steamers homeward bound, whilst the Frenchman in Malacca is said to be shipping his thousands of skins a month. It is no wonder that the traveller in the Malay Peninsula sees so few birds. Where there is nothing for them to eat, the feathered tribes do not care to congregate, and where there is they are shot and trapped. If the gunning tribe devoted their skill to snipe, or deer, wild pig, tigers, or elephants, they might be viewed as useful members of society, but when anything with a feather is indiscriminately sacrificed, massacre becomes a nuisance, and calls for the strong hand of the law to suppress it. There can be no objection to the flying-fox being added to the list of game, as it may help to keep the ardent sportsman from further evil, and a stray pariah dog might help to fill his bag, but birds, in general, should be protected from the devastating guns and blow-pipes of our Eurasian Winkles,

ABYSSINIAN ECONOMIC PLANTS.

Among the vegetable articles of diet of the Abyssinians, the first place is taken by *teff* (*Poa abyssinica*), a herbaceous plant, whose grains are as small as a pin's head; the meal from this forms the bread in general use. A much inferior black bread used by the poor is made from a kind of millet called *tocu so* (*Eleusine Tocusso*), frequenting the low grounds. In addition the roasted seed of the flax plant (*Linum usitatissimum*) is somtimes eaten, as it was by the ancient Romans and Greeks. Another admired vegetable is the flower stalk of the local plantain, called *ensete* (*Musa Ensete*), the fruit of which is dry and unfit for eating. The stem is cooked with milk and butter. It is cut off just above the rootlets, and about two feet high; if old, the green outer coat is peeled off till the white interior shows. It is as tender as a well cooked turnip, with a flavour like the best new bread somewhat underdone. It is an excellent dish, nourishing, wholesome, and digestible. From meal cakes a fermented drink called *bousa* is made.

The coffee grown in Abyssinia is principally sent to Djedda and Upper Egypt; though not of first rate quality, it possesses a special aroma, and is sold at the rate of 16 dollars per *cantaro* of 113 *rottoli* (say 37s per cwt.)

The women of Gurage make mats of the leaves of the *ensete*. The *ecca* of the Abyssinians, a species of asclepiad, produces a tough fibre, used in making cordage and tissues on the Red Sea littoral. The bark of *Calotropis gigantea* afford excellent fibre used for various purposes. The tender leaves newly pulled from the stipa of the *doum* palm are woven into all kinds of matting and basket ware. The powdered seed of a large tree called *berebera* (*Milettia ferruginea*) is thrown into the water to stupefy fish and facilitate their capture. The native dress consists of a large folding mantle and close-fitting drawers. The houses are rude conical structures covered with thatch.

Among the local products figuring in the exports are:—Calves' hides, salted and sun dried; beeswax, chiefly from Gedaref; ivory, tamarinds, ostrich feathers, gutta-percha, from Kassala; gum arabic, mother-of-pearl, leopard skins, about 1,000 annually to India; musk, contained in bulls' horns, to the number of 200 to 300 a year; honey, and tobacco, chiefly from Sanaaid.—*Journal of the Society of Arts.*

CINNAMON AND PADDY (RICE.)

Cinnamon peeling is now in full swing, and will be carried on, weather permitting, into the New Year. All planters are now paying special attention to the make of their Cinnamon, which, in spite of improved make, seems to be still receding in price. Quarterly sales, which conservative old-stagers authoritatively declared would arrest the downward course of prices, have been resumed only to find prices still going down. With the present prices Cinnamon yields but a narrow margin of profit, and if things do not look up, all excepting those who prepare quills of very fine quality will have to throw up the sponge, or cease manufacturing the coarse qualities of Cinnamon like Mr. De Soysa.

I read with great interest the correspondence relating to the alleged remedy for flies in paddy fields. Hulugala Ratemahatmeya too proclaimed his Kerosine oil remedy with the same confidence. It was tried and found wanting. Though I used Kerosine oil, both morning and evening everyday, and failed to stay the plague of flies, yet I was not so unfortunate in its use as Mr. Wickremesinghe, who asserts that the blade and ear that came in contact with the oil blackened and died. I have not much faith in the Kerosine-ashes cure, especially in the proportion of the materials and the intervals between application. Kerosine oil does not retain its disagreeable smell in situations exposed to wind and rain for so cosiderable a period as two days. I will be inclined to have faith in the efficacy of the Kerosine-ashes mixture, if applied twice a day during the week or ten days that the ears are hardening. The flies continue their ravages from the time the ears are forming till the husks of the paddy are too matured to allow of their being punctured—a period of about ten days. If remedies be applied towards the latter period, when the flies have ceased to be able to do damage, their disappearance is too readily attributed to the remedies used. Last season, after all remedies had failed and I had resorted to the old practice of catching them by passing a fan-like contrivance smeared with a prepared sticky substance over the ears, it occured to me that by substituting tar for the prepared sticky stuff, I might so taint the ears as to be avoided by flies. The results exceeded my expectations; but I was not quite certain that the disappearance of flies was due to the tar or to the maturing of the ears, or I might have posed before the public with my "perfect remedy." Through the courtesy of Messrs. Brown & Co. of Colombo, I was favoured with some carbolic powder for experimenting, but it unfortunately reached me after I had establisliied a scare with tar. I shall, however, during next season give both the carbolic and Kerosine powders a trial and report results. With reference to Mr. Jayawardene's letter to the *Observer* anent the attack of caterpillars on the fields under his charge, there is no cause for alarm in their attacks. I too, at one time had my field attacked by a green caterpillar on the leaves, and an orange coloured maggot at the heart of the plant. A free application of fresh ashes, or perhaps the "effusion of time," caused them to cease their ravages. I used the ashes of coconut husks, which are particularly rich in potash. I attributed the attack of worms to the stagnant water in the field, as the attack was during a period of drought when I was chary of letting out the water in the fields as I had not sufficient to replace it, and it stagnated.—Local "Examiner."

THE GROUND NUT TRADE OF PONDICHERRY.

The export of ground nuts from Pondicherry for the season of 1886, has nearly come to a close. A steamer is now loading in the roads, and the last for the current year is expected to arrive in a few days. The shipments up to date amount to 873,302 bags, and the two cargoes yet to be cleared will add about 50,000 more to the total, making in all 923,302 bags. At the beginning of the season we estimated the crop available for export from the districts served by the port of Pondicherry at upwards of a million of bags, and if to the above quantity is added the shipments of three cargoes from Cuddalore, say 85,000 bags, the total number of bags exported will be 1,008,302. A still further addition to this total should also be made for the export in ground nut oil, which, for the nine months ending September 30th, amounted to 15,589 casks, and for the whole year will probably reach 17,500 casks, representing in raw material, about 170,000 bags of nuts, Total export crop therefore may be taken, approximately, at 1,180,000 bags, as compared with 720,000 bags during the corresponding period of the previous year, and 850,000 bags in 1884; the increase being equal to 64 and 39 per cent respectively. Twelve years ago, ground nuts, as an article of foreign export, were comparatively unknown, the small crops produced being eagerly bought up for local consumption. The present trade seems to date from about the year 1875, when 211,470 bags were exported; but the season was quite exceptional; the crops being unusually heavy, and the home rates very high, and, in the following year, 1876, only 72,700 bags were shipped on foreign account. In the next two seasons, 1877 and 1878, succeeding the famine years 1876 and 1877, the traffic entirely ceased, the aggregate exports for the two years amounting to only 609 bags. But, by this time, the value of the nut had become known, not only in France but also in Italy, Germany, and Belgium, and during the two years which followed, large profits were made by all concerned in the trade, owing to the great demand in the continental markets. The following statement

gives the total shipments of ground nuts, and ground nut oil, and the approximate minimum and maximum price per local candy of 529 lb. (English) for each year from 1875 to 1886 inclusive:—

	Bags of Nuts.	Quotations Highest.	Lowest.	Casks of Oil.	Quotations. Highest.	Lowest.
1875	211,470	R. ...	R. ...	16,672	R. ...	R. ...
1876	72,700	...	...	7,278	...	...
1877	216	...	...	5,143	101	80
1878	393	...	...	6,057	96	68
1879	167,179	22½	19	6,060	68	52
1880	281,882	22¾	20½	7,273	76	55
1881	257,803	21	18¾	4,979	68	49½
1882	387,311	19	15	9,942	54	42½
1883	552,847	24½	15¼	8,777	63	42
1884	746,876	23½	19	10,492	64	56
1885	615,558	21	19¼	10,403	67	50½
1886	923,302	20½	14½	17,500	53½	40½

It will be seen by the above figures, that the prices of both nuts and oil have greatly fallen since the first report quotations were recorded. In 1879 the average rate was R20-12-0 per candy for nuts against R17-8-0 for 1886, the fall being equal to 18·57 per cent; and for oil, in 1877, R90-8-0 per candy as compared with R47 for the current year, or 89·48 per cent less. It is evident from these facts that the largely increased production has had the effect of lowering prices, and, judging from the increased cultivation year by year, it would seem that the producer has not suffered any material loss. Pondicherry has obtained the lion's share of the ground nut trade; for the total exports from the whole of British India during the three years ending 31st March 1886, amounted to only 1,533,314 bags, while the shipments from Pondicherry alone for the same period reached upwards of 2,250,000 of bags. It is shown also, by the accounts published of the trade of British India, that the export of nuts during the three official years declined from 534,716 bags in 1883-84 to 507,345 in 1884-85 and 491,753 in 1885-86; the fall being equal to 5·40 and 8·74 per cent, respectively, whereas, as we have already stated, the shipments from the French port for the same period increased by 39 and 64 per cent. The statement below shows the freight engagements (in sterling per ton of 20 cwt.) for Marseilles for the last eight years, *viz.*, from 1879 to 1886 inclusive:—

	Highest.	Lowest.	Avge.		Highest.	Lowest	Avge.
1879	£3-5-0	£1-12-6	£2-4-6	1883	£3-0-0	£2-10-0	£2-13-9
1880	3-7-6	2-15-0	3-2-9	1884	2-10-0	1-12-6	1-19 9
1881	3-5-0	2-17-6	3-0-3	1885	2-10-0	1-10-0	1-17-9
1882	3-2-6	2-17-6	3-0-6	1886	1-16-3	1-11-3	1-14-0

The French home prices have ruled very low throughout the season and notwithstanding the greatly reduced rates of freights, shippers have never ceased grumbling, even from the commencement of the year, when the nuts were quoted at R14-0-0 per candy. The trade is of vital importance to Pondicherry, forming, as it does, nearly three-fourths of the total exports of the port, and giving employment—apart from the cultivation—to several thousand people. The crop prospects for 1887 are excellent, far surpassing any previous season, and the area planted is largely in excess of last year's sowing.—*Madras Mail.*

ALL vegetables, when cut, may be kept fresh by putting the stalks into water. Servants generally insist on immersing them, which favours decomposition. Parsley, in particular, can seldom be guarded from a watery grave. Carrots, turnips, and the like, if placed in layers in a box of sand, will keep for many weeks.—*Indian Gardener.*

CINCHONA.—A local contemporary announces that the Government of Madras is apparently about to withdraw, partially, from competition in the growth of cinchona, and that at the request of the Director of Cinchona Plantations, the Collecter of the Nilgiris has been instructed to dispose of the Kalhati Gardens by the end of the year. This is a step in the right direction, and we hope before long all Government Cinchona plantations will be disposed of, retaining only such, if necessary, upon which it is intended to conduct special experiments.—*Indian Agriculturist.*

CEMENT.—A French authority gives the following recipe for transparent cement. The advantage claimed is the absence of the slightest yellow tinge, so that the addition of the cement is imperceptible, while it possesses an extreme degree of tenacity. Mix in a well-stoppered bottle 10 drachms of chloroform with 12½ drachms of non-vulcanized caoutchouc in small pieces. The solution is easily effected; when finished, add 2½ drachms of mastic, and let the whole macerate from eight to ten days, but without heat. A perfectly white and very adhesive cement is thus produced.—*Indian Agriculturist.*

ROOT HAIRS.—That the largest portion of the liquid used by the growing plant makes its entrance through the roots, from the soil, is a well-established fact; but those parts which are the most active in the absorption of this food material in solution, were for a long time not so clearly understood. By careful experiments and microscopic investigation it is found that the extreme tips of young roots are about the only portion which take little or no part in this work. A short distance back from the growing points, on nearly all growing roots, may be seen with the aid of a microscope a large number of minute slender bodies extending out in all directions from the surface of the root. These thread-like structures are not inaptly called root hairs, and consist of sac-like protuberances, as outgrowths from the epidermis or surface cells of the root. With the naked eye they are not easily seen, but their presence may be inferred from the manner in which they cling to the particles of the soil, when a young root is lifted carefully from the earth in which it was growing. This power which they have of fixing themselves to the grains of earth is very great; so that, when a plant is taken, violently from the soil, large portions of these delicate hairs are broken from the roots and retain their attachment to the soil. As the root grows along in the earth new hairs are produced, while those behind perish as the root becomes woody, and a dense, non-absorbing, protecting epidermis is formed; so that the active life of a single hair is of short duration. The office of these hairs must have already suggested itself to the reader. By means of these prolongations the greater part of the absorption takes place, though the newly-formed surface cells are also active.—B. U. HALSTEAD, in *Gardeners' Monthly.*

POROUS CARBON.—A report of a new system of sewage in operation at Southampton, published in last Saturday's *Times*, reveals the existence of a certain mineral powder found in Devonshire and known as porous carbon, which, according to the report, possesses remarkable properties. This substance is said to be rich in available iron, alumina, and carbon. By treatment the metals are rendered soluble, and then the mixture is a wonderful chemical precipitant. It is mixed with the sewage in the proportion of 2½ to 3 grains per gallon, whereupon it at once destroys all odour and precipitates and oxidises all solids and organic matter. The effluent water is rendered almost perfectly pure, while the precipitate "mixed with road scrapings" finds a ready sale to farmers, who fetch it away for manure, and pay 2*s.* 6*d.* per ton for it. If this be true, the sewage problem is solved, and for the solution we are indebted to Mr. W. B. G. Bennett, engineer, and Mr. Arthur Angell, chemist. The virtues of the porous carbon are not limited to its use as a precipitant. "In addition to its chemical properties," says the *Times*, "it possesses the mechanical property of adding to the lightness and porosity of the soil by reason of the presence of the particles of earthy carbon." There are several points of mystery about that sentence, but the chief one lies in the main statement. With only two or three grains of the carbon to the gallon of sludge there would only be about half an ounce to the ton of manure; unless this acts after the manner of a ferment, which would be very wonderful indeed, it is difficult to understand how much a minute proportion can have much mechanical influence on the millions of tons of earth which form the soil of a ten-acre field.—*Chemist and Druggist.*

DELI PLANTING TOBACCO.

(Translated for the "Straits Times.")

One mischievous drawback to planting life in Deli has always been the recurrence, year after year, of incendiarism in tobacco sheds on estates; several of the latter being continually marked out for the purpose by fire-raisers. These fellows always turn out to be Battaks exclusively, who take to this pastime not from any grudge against the planters thus singled out, but from causes which throw light upon certain peculiarities of Battak character. The available information shows that the Malay rulers who domineer over the Battaks treat them with indifference, harshness, and the utmost unfairness. The feeling of resentment at injustice done is so highly developed among these people that they turn to account every means that serves their turn to gratify it, no matter how strange the method may be to European ideas. Burning down tobacco sheds happens to be one favourite means to gain this end. They know, too, that incendiarism is a highly effective way to bring pressure to bear upon the planters, owing to the burning down of tobacco sheds at certain seasons, meaning nothing more or less than the destruction of the whole crop gathered in. They have now taken to destroying the standing crops as well, thereby making the tobacco growing business very risky indeed, all through the fault of the authorities in not taking stern measures to counteract the evil. The authorities burden the planting community there to the utmost limits with many and heavy taxes but afford them scant protection against evil-doers. The prospects in store for the planters are impoverishment by attacks of Achinese marauders, the burning down of their tobacco sheds and the destruction of their standing crops.

DYEING AND CALICO PRINTING IN INDIA.

BY J. BELMONT.

RED AND SHADES OF RED.—The Indian dyers, in using cochineal, employ alum very largely as a mordant, the result being a crimson. They employ a yellow dye, such as "harsinghar," together with cochineal, to get a good scarlet.

I have previously stated that cochineal finds a great competitor in coal tar reds. This is a great pity for the future of India, the country being so well adapted for cochineal production.

A shrub called *Grislea tomentosa*, belonging to the natural order *Lythraceæ*, yields a red dye. This shrub is not known outside India. It grows to a height of ten feet at least, and has long spreading branches. The bark is smooth, peeling off in thin scales; the wood is pale nut-brown, and is used for fuel. This shrub flowers between February and April, and the petals contain a red colouring which is of no little importance. It is found in many parts in India and is largely used in the Punjab for dyeing silk. It is valued at about two rupees per cwt.

Another shrub, *Lawsonia inertius*, yielding a red colouring mattter, is found in several parts of India. The Hindus call it *henna*. Dr. Balfour says that this shrub is the camphire of the Bible and is mentioned in the Song of Solomon. It has small leaves, and greenish yellow flowers of great fragrance. The Greeks, Arabs, and the Turk, Indian, and Persian Mahomedans, often present the flowers to their friends.

There is no doubt but that the camphire, or as it is also called in English, the cypress shrub, has been used for many centuries as a dye. It is fairly fast and is employed by the Mahomedan women as a dye for their nails and their hands and feet, the colour given being a reddish orange. By merely steeping the leaves in water, a light reddish-brown colour is obtained, which, applied to cloth mordanted with alum, is fairly permanent. Acids destroy the colour, but alkali and infusions of astringent vegetables deepen it. Camphire is largely used as a hair dye. Sometimes myrtle leaves are mixed with it, the resulting colour being a purplish black. It is sold in India at five rupees per maund (82 lb.)

One of the most valuable red dyes known to the Indian dyers is the Indian madder. There are several varieties of the plant, the roots of them all yielding a colouring matter. The plant is found in several parts of India. One species (*Morinda bracteata*) is a small tree with large shining leaves. It is known to the natives under various names, comprising *hurdi*, *huldi-Kunj* and *ronch* in Bengal, *mhan-bin* and *yaiyoe* in Burmah, and *Yahooganha* in the Sinhalese language. The bazaars of Bengal sell the wood, which gives a bright yellow colour. The native dyers use it very largely. Another species of Indian madder is the *morinda citrifolia*, called by the Hindus *al*. This tree has also smooth shining leaves and white flowers. It is found in several places outside India, including Queensland and several islands of the Pacific. In Madras it is very plentiful. The bark, especially that of the root, yields a red dye, which, fixed with alum, is fairly fast. Most of the red cotton turbans worn in Madras are dyed with this species of madder. Many uses are made of this dye. It is largely employed in dyeing handkerchiefs, cotton cloth, carpet thread, and in Calico printing. The root is usually sold cut in small pieces. This colouring matter is very cheap and plentiful. The best kinds can be purchased for 8*s*. to 10*s*. per maund (82 lb). The cultivation of this plant does not appear to pay in some parts of India, and its price has declined to a very large extent. At one time it was sold at the following rates:—The thinnest part of the root (bhara), twenty rupees the maund the middle part (jharan), ten rupees the maund, and the thickest or upper part (ghatiya), nine rupees the maund. The prices are now eight rupees, four rupees, and two rupees respectively. It is thought in India that European dyers would largely use this colouring matter if they were only better acquainted with its properties. Many of the Indian dyers use it along with more expensive dyes for producing reds. The plant after being dug up, is sorted into three qualities, and packed into bags. It is sold to the dyers in this state, and they extract the colouring matter when required.—*The Dyer and Calico Printer.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

COWS AND MILK—HOGS—MISTLETOE.

PARIS, Nov. 6.

M. Nicolas is a wealthy wine merchant in Paris, and has forty depôts distributed over the city for the retail sale of his wines. Later we shall see how he has utilized these. Like many commercial gentlemen he desired to occupy himself with farming: so he purchased an estate of 1,200 acres at Chaumes, thirty miles from Paris in the department of the Seine and Marue. The estate cost over half-a-million francs; it consists as a rule, of poor and cold clay land; about 270 acres were wooded, and 530 had to be re; claimed. The remainder were worn out from exhaustive cropping. Reclaiming, draining, road making and building suitable offices, were the first tasks undertaken. M. Nicolas having put his hand to the plough, never looked back. The soil requiring to be brought into a state of tilth and heart, a three course rotation was followed. This permitted the land to be cleaned, divided and fertilized. Manures had to be purchased, and these comprised the street-sweepings of Paris, farmyard manure, Peruvian guano, superphosphates, marling and limings. Lucerne is grown on a separate part of the estate; all the cereals are cultivated in lines. To rapidly ameliorate a soil without investing considerable capital in manure it was indispensable to maintain numerous live stock, but in what end keep the latter? What speculation would bring in tangible profit? It was in studying this phase of the question, that M. Nicolas decided to become a dairy farmer, and utilize his forty wine depôts in Paris, for the sale also of the milk. It may be remarked here, that the generality of public houses in Paris, now sell milk by the glass from capsuled

special bottles. M. Nicolas commenced with 12 cows; in 1878 he had 22; in 1883, 210, and at present, he has nearly 300. He confines himself to one race—the Normand. It is this breed which is peculiar to the rich pastures of Normandy, and that yield the famous Isigny and Gournay butters. The Normandy or "Cotentin" cow is a voluminous animal, and is invariably recognised by her brindled hide. The Cotentin was formerly a good beef-producing cow, but this has now become secondary to the milking quality —some cows yielding from 24 to 32 quarts daily—which is of course exceptional.

The cows are purchased always in calf in Normandy and kept for two years. Before being introduced into the general shed, they are placed during four or five weeks, in a little, special farm called the "quarantine." This precaution has completely prevented the introduction of the foot-and-mouth disease. Eight quarts of milk is the average daily yield of each cow. The morning milk is placed in wrought iron pans, plunged all the day in marble troughs, through which runs a stream of fresh water. The cows are a second time milked at noon. At five in the evening, the two milkings are mixed, submitted to a cooling process and poured into special glass bottles—with name of farm engraved thereon,—of ¾ of a quart to ½ quart each, hermetically closed and forwarded to the central depôt in Paris to be distributed to the branch depôts, and then to clients at their domicile at 14 to 16 sous the ¾ quart, following season. The general expenses amount to one-third of the selling price.

M. Nicolas delivers from 1,300 to 1,600 quarts of milk daily in Paris, and he aims to secure uniformity of composition in butter caseum and sugar. A leading chemist analyses samples of milk, and once a week the analysis is published in a leading city journal. The sheds and dairies are not only models of care and cleanliness, but the soil is also studied for the cultivation of the forage and the application of fertilizing agents. The scientific history of each field is kept and the special plant-food in which it is deficient, supplied. About 24 tons per acre of farmyard manure, specially azotised is the average applied. Vast quantities of cake are consumed. The action of each commercial manure on the various plants raised is recorded as well as the influence of the food on the general health of the stock, and in the production of milk. M. Nicolas keeps his farm expenditure with the same precision that he bestows on his wine transactions. The capital expended, represents about 480 fr. per acre, and the annual sales of the milk, amount to 350,000 fr.: that, which leaves a handsome margin for profit. M. Nicolas believed that with scientific aid united to ordinary commercial exactitude, it was possible to pursue practical farming economically and profitably, and he has succeeded.

Professor Holdefleiss of Breslau, makes cows contribute to their own dietary by employing skim milk in the rations to the extent of four to eight quarts daily even if the milk be acid. In distillery grains, cows absorb a much superior quantity of Gactic acid. The influence of this skim-milk diet tells most favorably on the richness and nutritiveness of the yield of milk. One-and-a-fourth quart of skim milk contains 46 grammes of albumen, 63 of carburets, and 3 of fatty matters. By judiciously combining the usual feeding stuffs the farmer in employing skim milk could economise in the matter of purchased food. M. Holdefleiss gives as a daily type ration, 8 to 11 lb. of hay; 40 lb. of sliced mangolds; 8 to 11 lb. of cut straw, chaff and issues; 5 quarts of skim milk and 2 lb. of oil cake. These proportions can be modified following circumstances.

The Comte de Bessenitz's experiments on fattening hogs, point to very practical conclusions. The animals were fed on crushed maize and cooked potatoes, made into a mess with boiling water and butter milk, but given cold. Others had crushed barley and rye, with cooked, mashed potatoes wetted with butter milk or scullery wash. The results proved that maize was more favorable to hog fattening than the same quantity of barley and rye; and further that it is more profitable to diminish the cereals and to augment the quantity of potatoes in the feeds.

Professor Wilckens of Vienna after a long series of interesting statistics, and Lootechnic comparisons, arrives at the following conclusions:—The age of a bull has no determining influence on the sex of the progeny. On the contrary, in the case of cows and generally young ones, their early calves are females, while with regard to older cows the contrary is observed; also rich feeding *tends* to produce female, and the poor dietary male calves.

It appears that the "Mistletoe bough," though pretty in song and story, is not at all popular in Normandy, where it is a veritable plague in the apple orchards, although it is profitably exported to England. A deputy is to introduce a Bill into Parliament, making the extirpation of mistletoe compulsory, as such also exists in the case of May bugs, &c. Birds and notably thrushes are very partial to the berries of the mistletoe and they are the agents which propagate the parasite. If the branch, on which the parasite commences to sprout, be not cleared effectually of the nuisance nothing can extirpate it later, save the amputation of the branch. A law-suit is pending to decide if a farmer who keeps poplars, on which to grow mistletoe for the London market, can be allowed to continue to keep up that nursery for contaminating orchards in his vicinity.

ANCIENT HINDOO PHARMACY.

From a paper in the *Archiv der Pharmacie* we extract the following interesting notes on medicine and pharmacy as practised by the ancient Hindoos. This race, it is well known, presented high intellectual attainments, which, together with the fact that Indian fauna and flora are peculiarly rich, is probably the reason why they have left in their writings distinct traces of intimate acquaintance with the science of medicine. In the Vedas, notably in Rig-Veda, Samu-Veda, and Atharva-Veda, we have many interesting facts regarding their modes of treatment, and these indicate, what we would expect, that much of the efficacy of the remedies employed was attributed to the religious and other ceremonies which accompanied the preparation and administration of physic. The holy Soma, (*Asclepias acida*), for example, had the credit of being the basis of the most efficacious remedies, and it was said to drop from the celestial fig-tree in the Himalayas. The physicians formed a distinct caste, called *Vaidya*, and were esteemed almost as highly as the Brahmins. Migasthems, ambassador of Silencus Nicator (300 B.C.), states, from personal observation, that the Vaidga method of treatment consisted as much in regulation of diet as in administering physic. It is not the case that they derived their knowledge from Grecian sources, for until 327 B.C. there was no direct communication between the two countries except isolated journeys by early philosophers (such as Scylax, about 515 B.C.). There is no mention of the Grecians in the Vedas; but it is possible that knowledge of Hindoo medicine may have come to the Grecians through the Persians. It is noteworthy, too, that translations from the Vedas exist in Tamul, Tibethan, Arabic, and Persian works; also through the Tibethan into Sanscrit, in which language medical literature holds high rank.

Pupils of the Vaidga were received at the age of 12, and their curriculum lasted for 5 or 6 years. Their admission, which took place in the winter season and at full moon, was attended with elaborate religious ceremonies. The instruction given consisted of lessons in minor surgery, such as bandaging and elementary anatomy, performed on dummies consisting of various fruits and wax-coated models; and the preparation and proper uses of medicinal agents, which we may put down as materia medica and pharmacy. Under practice of physic, such subjects as antidotes, mental diseases, diseases of women and children, and external treatment had a place; pathology and chemistry were also, to a limited extent, included in the required knowledge of the accomplished physician.

In surgery they were remarkably proficient and had as many as twenty different kinds of surgical knives. Cupping the actual cautery, and the clyster bag were familiar to them, as were also leeches, of which they had twelve varieties. The escharotics which they used appear to have been potash in different stages of carbonisation (*mite*, *mediocre*, and *acre*). These were prepared by burning various plants, such as *Butea frondosa*, *terminalia Bellerica*, &c., treating the ashes with urine or water and evaporating. Internal remedies were divided into the *mobile* and the *stable*. The former included all animals, and the latter plants, minerals, and earthy matters. These were further divided into 37 classes, according to the ailments for which they were used; the majority, over 600, were of vegetable origin, and asafœtida was the only imported remedy.

All plants were gathered, as they were administered, with definite religious ceremonies, and under certain rules and planetary influences. The list of crude drugs (roots, barks, &c.) used is too long for repetition here. It comprised most of the drugs which are described by Dr. Dymock in his able work on "Indian Materia Medica." There were also used gums, resins, and oils; prominent among them benzoin, bdellium, turpentine, ol. ricini, ol. lini, and other fixed oils. Expressed juices were rarely employed. The liquids obtained by fermentation and distillation are classified as *liquores spirituosi siceræ* (sicera was the sherbeth of the ancient Israelites) and *destillati*. The first were prepared from rice, barley, different varities of pepper, and Ceylon plumbago. The method employed was as follows:—2¾ parts of the liquid were powdered with 2 parts of jujube berries and two parts of myrabolans. The mixture was then placed, with 14 parts of water, 1 part of iron, and 24 parts of sugar, in a vessel previously coated internally with pepper, honey, and butter; closed, and the whole left for seven days in a barley-basket (*hordaceo corbi*). Sicera was prepared by boiling separately the juice of the *Dalberia sisu*, *Mimosa ferruginea*, *Fasineum auriculatum*, *Premna spinosa*, *Ruta graveolens*, and *Trichoranthes dioica;* diluting, mixing, and leaving them to ferment. Sicera were also obtained from *Ficus indica* or *Cassia fistula*. *Liquores destillati* are mentioned, but there is nothing said concerning the mode of preparation or the apparatus employed. From what we know otherwise of their acquirements, as well as of modern Hindoo methods, we may safely assume that the process of distillation and its applications were known.

The animal kingdom yielded several contributions to Indian pharmacy, notably the leech, the *Scincus officinalis*, a kind of lizard of which even now a species is used in Northern Egypt. Cantharides was also known to them. An insect called *fœtor* was used as a remedy against cepra; lizards and mice, against worms, cough, and catarrh. The milk of cows, goats, sheep, mares, elephants, and buffaloes, was held in high esteem; also cheese and butter, the latter being frequently used as an ointment. Butter made from human milk was used as *ambrosiæ similæ* in diseases of the eye. Animal fats, gall, and other animal secretions were administered internally and externally; and nails, skin, and hair were used as fumigants. Musk and similar substances were used as stimulants and for impotency. *Bezoar orientale* was also known to them.

Medicines derived from the mineral kingdom were comparatively numerous, and afford a proof of the acquaintance of the ancient Indians with alchemy. Amongst those employed were charcoal, sulphur, asphaltum (for diseases of the liver and of the urethra), gold and silver (for the prolongation of life), tin lead, copper, brass, antimony, spelter, and iron. Arsenic and mercury were known as the oxides and sulphides. *Ferri rubigo*, mixed with cinnamon and ginger, was given as tonic and antidote; *lapis magnus* as an antidote, and for gonorrhœa; yellow and red orpiment against leprosy; white arsenic with pepper and fragrant herbs for intermittent fever. Alum was used in the arts and in pharmacy, and salammoniac was also known. The following is the recipe for the preparation of ammonia, which was used as a local incentive in debility, fainting, and hysteria:—Dry carefully one part of salammoniac and two of chalk, mix, and sublime at high temperature. A very interesting description is given of the preparation of a kind of sublimate. Mercury was rubbed up with sulphur, and a layer of this "sulphuret" was placed over a layer of common salt in a vessel, half filled with bricks. Another vessel was inverted and securely fixed over the first, and the whole exposed to a strong fire for twelve hours. After cooling, the mercurial salt was found deposited in the upper part of the vessel. The ancient Hindoos were evidently acquainted with the preparation of acids, and they used vinegar, sulphuric acid, and nitric acid. The following is a specimen of the emetics which the Vaidgas employed:—Digest the ripe fruit of *Vangueria spinosa* in water, together with *Poa cynosuroides*, rub with cowdung, boil in rice or barley, then digest during eight days with *Terminiala Bellerica*, *Phaseolus mungo*, and rice. Next *Echites antidysenterica* and long pepper were added, and the whole dried in the sun. With the residue curdled milk, honey, and sesame were mixed, dried, and placed in suitable vessels. In the next stage a handful of the above mixture was digested for 24 hours in a hot decoction of *Saponanthus indica* and honey, then mixed with more honey or rock-salt, and administered by the physician, who looked northward, while the patient's face was directed towards the east. Hindoo pharmacy generally was somewhat after this fashion. Emetics of various kinds were employed in cases of poisoning. The Vaidga distinguished between animals poisons and those derived from the mineral and vegetable kingdoms. But the meaning of "poison" was somewhat wide, and we find *Calamus rotang* and *Piper nigrum* classed along with the juices of several species of Euphorbium; and amogst animal poisons we have "the evil eye," breath, claws of scorpions, and many nasty things, even a certain class of young females had the reputation of being highly poisonous!—*Chemist and Druggist*.

THE POTATO—SOILS SUITABLE AND THEIR PREPARATION.

(COMPILED FROM JAMES PINK'S WORK—"THE POTATO AND HOW TO GROW IT.")

The potato is one of the most convenient vegetable with regard to its culture, and will thrive on a greater diversity of soils than any plant in cultivation. There is no soil from the bog or peat earth, with its 70 to 75 per cent of organic matter and upon which no other plant can be made to produce a remunerative crop, to the clayey, with from only 3 to 5 per cent of organic matter, upon which the potato if properly cultivated may not be grown with more or less satisfactory results. The soil that is generally considered to be the best suited for the cultivation of the potato is a light sandy loam with a good natural drainage and with a gentle slope; but as all soils differ in their texture, and it is rare to find a soil just as we would have it, so we endeavour by tillage, by manuring, and by exposing the soil to the pulverising influence of the atmosphere, to improve its texture and thereby its fertility.

In preparing the land for the ensuing crop of potatoes it is especially desirable that the soil should be well pulverised, for tubers of first-class shape and quality are never taken from an unkindly soil, and if we wish to succeed at the exhibition table or to grow remunerative crops we must take advantage of every means of improving the texture and productive properties of the soil. To grow potatoes well the land should be prepared previously by deep culture of the soil. Of the several methods resorted to for this purpose double digging is the most preferable as it gives the advantage of improving the depth of the soil by placing the manure in the second spit and retaining the top spit, which is generally lighter and more friable, for the tubers to form in. Having selected the piece of ground upon which the potatoes are to be grown, the manure that is to be dug in

with the bottom spit should be spread over the ground. For this purpose the refuse of the garden is excellent; if farm-yard manure be applied it should be in a thoroughly decomposed state, for strong rank manures of animal origin should never be applied for the immediate crops of potatoes. Double-digging consists in taking out a trench 3ft. wide and one spit deep; the manure is then raked from the surface of the adjoining strip of the same width, and spread over the bottom of the trench. A shovelful of hot lime thrown in with the manure will greatly aid its decomposition and assist to eradicate vermin. The bottom spit should then be dug up to a depth of 12 in., well mixing the manure into the soil. The top soil of the second or adjoining strip of 3ft. should now be dug and thrown on to the just dug bottom of the first trench, and so on until the plot is finished.

This method of cultivation of the potato is specially suited to light sandy soils, which if the weather be hot and dry, part with their moisture too freely, so that the crop matures before the tubers have attained their full size. The manure that is placed in the bottom spit enters the rootlets downwards, for roots do not strike downwards into the earth by the force of specific gravity but by the power of nutritive attraction, and all plants possess the natural instinct of sending their roots in the direction that they can find nourishment most congenial to their wants. By placing the manure deep in the soil the plant has one uniform source of nourishment, and therefore receives no check from variations in the weather, during the growing season.

Notwithstanding the animal and vegetable manure placed in the bottom spit, should the land be poor and deficient in vegetable matter, a good dressing of well decomposed vegetable manure may be added. Poor soils never produce a good crop, neither are the potatoes of first-class quality, for vegetables, like the flesh of animals, are always deficient in flavour if they have been half starved. On stiff soils any substance that serves to render them less adhesive may be applied with benefit; such as old mortar, charcoal, burnt earth, ashes, lime, decayed leaves, &c. They should be applied as early as circumstances will admit and be well incorporated with the soil, which should be allowed to remain as rough as possible so that it may get the full benefit of frost, sun, and air.

Different kinds of plants take up in different proportions the various inorganic constituents of which they are composed. Thus we see the necessity for applying the special inorganic or mineral manures in proportion to the requirements of the plant. The inorganic constituents of the potato tuber, as contained in 1,000 lb. of its ashes are:—

	lb.
Potash	557
Soda	19
Lime	20
Magnesia	53
Oxide of iron	5
Phosphoric acid	126
Sulphuric acid	136
Silica	42
Chlorine	42
	1000

The above analysis shows the proportions that have been abstracted from the soil by the plant while growing. Potash, the principal alkali of land plants largely predominates; hence the special value of wood ashes as a manure for potatoes. Phosphoric acid is of animal origin, and is supplied to the soil in all bone manures; it is of special value when applied to cold wet soils, as it has a tendency to induce early ripening of the tubers. Caustic lime enters largely into the composition of the foliage of the potato, and independent of its food-giving properties. It is of great benefit to the land by improving its texture and dissolving vegetable fibre. Common salt should be used only with great care as a manure for potatoes; it may, however, sometimes be used with advantage on light dry soils, but it enters very slightly into the composition of the plant. Green crops ploughed under are a beneficial manure for potatoes on both stiff and sandy soils. They render the clays less adhesive, and add to their productiveness by allowing the rootlets freer access in search of food; while in sandy soils they attract and retain moisture. Artificial manures, when judiciously applied, are invaluable aids to the good culture of the potato, as well as of other crops. One ton of potatoes contains about 25 lb. of ash (which represents the inorganic or mineral food of the plant); supposing an acre to produce 10 tons of potatoes, there will be taken from the soil by the tubers alone 250 lb. of matter per acre in very nearly the following proportions:—

	lb.
Potash	141
Soda	5
Lime	5
Magnesia	13
Oxide of iron	1
Phosphoric acid	31
Sulphuric acid	34
Silica	10
Chlorine (salt)	10
	250

Some soils contain one or more of these constituents in abundance, so that it would be waste, and in some cases injurious, to add more of that substance; yet, being deficient of some others, it is impossible for the plant to arrive at perfection; so special artificial manures become a necessity for the success of every crop that depends on the presence, in an available form, of all the mineral constituents of which the plant is composed. Stimulating manures when applied to the potato in excess, are often injurious, for by inducing a strong rank growth of foliage the plant is rendered more susceptible to disease, and the quality of the tuber is never so good when stimulating manure has been applied to the growing plant.—*Queenslander.*

PACKING PEARS.—The French, who export more Pears than any other nation, cover the inside of the boxes with spongy paper or dry moss, which absorbs the moisture. Each Pear is then wrapped in soft paper, and placed in layers in the boxes, the largest and least mature in the bottom, filling all interstices with the dry moss. Thus, they will keep a month or more. They are so closely packed that though they cannot touch each other, all motion is prevented. If one decays the others are not harmed.—*Gardeners' Chronicle.*

THE PHILOSOPHY OF VINE PRUNING.—The production of grains of starch in the chlorophyll of the leaves when exposed to the sun is a well-established fact. This starch is subsequently dissolved, converted into sugar and other substance fit for the food of plants, and transmitted to the growing points or to the store-places, where it is again converted into starch. The production of starch in leaves is shown by immersing the leaves in boiling water, to which a little potash is added, and then plunging them for a quarter of an hour in hot alcohol. The leaves are by these means deprived of their green colour, and the starch in them is now easily rendered visible by the addition of tincture of iodine. By covering one-half of the leaf with some opaque substance, leaving the other half exposed to the sun, starch may be detected in the uncovered half, while none is to be found in that which has been shielded from the sun's rays. Signor Cuboni, who has made numerous experiments on the Vine, says that this production of starch increases gradually from the leaves at the base of a young shoot to the middle and as gradually diminishes from the middle towards the point, starch being absent from the very young leaves near the apex. These facts supply a reason for pruning, for the young leaves above the flower bunches, not producing starch, but on the contrary consuming it, in so far deprive the berries of their sugar.—*Gardeners' Chronicle.*

TOBACCO IN LOANDA.—Referring to the cultivation of Tobacco in Loanda, the British Consul reports that the plants are carelessly grown and gathered by the natives. When the leaves are sufficiently manured they are plucked from the stem, tied in bunches, and hung round the native huts to dry. No care is taken, no selection made, nor is any preparation resorted to beyond the bunching and drying.—*Gardeners' Chronicle.*

NOTHING will purify and keep a stable so clear from odours as the free use of dry earth, and every one keeping horses and cattle will find it pays to keep a heap of it on hand, to be used daily. A few shovelfuls of earth scattered over the floor after cleaning will render the air of the apartment pure and wholesome. The value of a season's manure pile may be largely increased by the free use of such absorbants. The strength of the gases and liquids absorbed is retained, and is the very essence of good manure.—*Queenslander.*

CINCHONA BARKS IN COLOMBIA.—In a recently issued report on the trade of Colombia, the Consul states with a view of illustrating the alarming depression of the export trade of Colombia, that the exportation of Quina bark, which was the staple article of Colombia, has greatly diminished in consequence of the competition of the Indian and Ceylonese growers, who produce an article which yields a far larger percentage of quinine than is obtained from the Colombian bark. In 1881 the value of the bark exported was about 5,000,000 dollars. It is estimated that since 1881 not half the quantity exported in that year has been shipped yearly.—*Gardeners' Chronicle.*

THE improved French method of preserving wood by the application of lime is found to work well (says the *Indian Forester*). The plan is to pile the planks in a tank, and to put over all a layer of quicklime, which is gradually slaked with water. Timber for mines requires about a week to be thoroughly impregnated, and other wood more or less time, according to its thickness. The material acquires remarkable consistence and hardness, it is stated, on beink subjected to this simple process, and the assertion is made that it will never rot. Beech wood prepared in this way for hammers and other tools for ironwork is found to acquire the hardness of oak, without parting with any of its well-known elasticity or toughness, and it also lasts longer.—*Queenslander.*

PEPPERMINT CULTURE IN JAPAN.—As an indication of the increased demand for Menthol in Europe the following extract from Consul Robertson's report on the trade of Kanagawa for the year 1885 will no doubt be read with interest:—"Peppermint oil has been an article that has attracted much attention in the past year because of its increasing importance as an article of export. The production has been steadily increasing for the past three years, and the latest crop has greatly exceeded those of previous year. This is principally due to the demand for crystals, a product of the liquid oil, and which are now largely used in pharmacy as a specific for neuralgia and other complaints. Japanese Peppermint oil is distilled from a species of Mint (Mentha arvensis) cultivated largely in the northern portion of the main island of Japan. Like the English Mint (Mentha piperita) there are several varieties of the Japanese plant, one only of which produces an article of good quality. The sudden and increased demand from abroad for the Peppermiut crystals has led to new plantations being formed, and these have, I am told, been for the most part laid out with inferior plants. The produce of these new plantations has been sold at very low prices, and the oil thus obtained is not likely to be of good quality. If this is sent to a foreign market, it will, perhaps, cause the Japan oil to be regarded with less favour, and thus damage the prospect of an otherwise promising export." Some blundering seems to have been made in printing this report which it would be well for the authorities carefully to look after in future. Though the report is issued under the authority of the Foreign Office, and is "printed under the superintendence of Her Majesty's Stationery Office," and is dated "Kanagawa, May 28, 1886," and further bears the word Japan on its title-page, the heading of every alternate page is "China, Kanagawa." Some one, therefore, whose duty it is to look after these things has apparently a hazy notion as to the country to which Kanagawa belongs.—*Gardeners' Chronicle.*

THE FOREST SPECIES OF JAPAN are thus noticed by a writer in the *Indian Forester*:—As far as I have been able to ascertain from personal observation and study of various books, the principal forest species of Japan appear to be as follows:—Metz (*Pinus Thumbergii* and *densiflora*), both of which species appear to be very common throughout the empire. Hinoki (*Chamæcyparis obtusa* and *pisifera*), both of which species form extensive forest in the Central and Northern islands. Suji (*Cryptomeria japonica*), found planted throughout the length and breadth of the country, and especially near villages and round all shrines and temples. Keaki (*Zelkowa Keaki*), kuri (*Castanea vulgaris*), much used for railway sleepers. 21 species of oaks, 25 kinds of bamboos, 30 species of cherries, many species being grown simply on account of their flowers. Numerous kinds of azalias, camellias, and laurels, besides various species of elms, maples, deutzia, hornbeam, viburnum, holly, olive, &c. As regards characteristic plants of Japan, they may probably be enumerated as follows:—Azalias, camellias *Cryptomeria japonica*, *Cydonia japonica*, chrysanthemums, Hibiscus, the Japan shrub peony, the famous water lily nasu (*Nelumbium speciosum*), asters, &c.The principal forest trees common to Europe, which are mainly confined to the northern islands, are elms, beech, larch, aspen, wild cherry, ash, yew; whilst amongst shrubs and other plants, the following are most common:—ivy, honey-suckle, lily of the valley, monkshood, marigold, wood sorrel poppy, chickweed, dock and dandelion. Palms are by no means common, and are confined principally to the southern portion of the empire.

TOMATOES AND VINES.—If science has its marvels which however well attested, often fail to convince, certainly ne-science has sometimes even greater marvels, which nevertheless are accepted as gospel by some folk. At one time, year after year, we received from a correspondent leaves of Violets affected with a fungus (Puccinia violæ). The leaves thus had a superficial resemblance to those of a Fern studded with spore-cases, and as the Violets grew beneath the shade of some Ferns was not that proof positive that a cross had been effected between the Fern and the Violet? It was no use appealing to structural and physiological reasons why such a cross could not be. Nothing could shake our correspondent's faith, and year after year, with an expression of surprise and pity at our incredulity, the specimens were sent. As we write a multiple Grape berry is before us such as often occurs at the end of the bunch, when two or three Grapes, from union in a very early stage of development, run together into a mass lobed like a Tomato. Now, as Tomatoes grew in the house, what more natural (?) than to infer that here we have a cross between a Tomato and a Vine? It would not be so unlikely as a cross between a Fern and a Violet, nevertheless we should be as incredulous in the one case as in the other.—*Gardeners' Chronicle.*

RAMIE FIBRE IN SPAIN.—Mr. Consul Wooldridge, reporting from Barcelona, refers to the opening in August last, near Gerona, of a manufactory, the first of its kind in Spain, for cutting and seperating the fibres of the Ramie, or Cunia-grass plant (Bœhmeria nivea). This establishment is described as the property of a French company, styling itself the "Compagnie Ramie, Française." This plant was introduced into the country as far back as 1870, and its cultivation proving a success, the above manufactory has been erected. There are three machines at present, of French manufacture, at work, which decorticate some 450 kilos of fibre per day, and the thread is said to be much cheaper, finer, and stronger than either hemp or jute, and produces a rich, glossy textile, and the refuse is used in the manufacture of paper.—*Gardeners' Chronicle.*

CINCHONA CULTIVATION IN JAVA.

A report by Mr. N. McNeill, Her Majesty's Consul at Batavia, which has just been published, affords a good deal of important information upon the Quinology of Java, and we extract the following as including the points likely to be of interest to our readers. The second table shows that the large and continuous fall in prices has been experienced quite as severely in Holland as elsewhere. The best method of cultivation does not seem to have yet been quite decided upon, as Mr. McNeill deals with it in the following manner:—The cinchona tree is found to flourish best at an altitude of from 4,000 to 7,000 feet above the sea-level. The seeds are planted in nurseries, well shaded from the sun, and transplanted when they are about six weeks old, and placed at distances, varying with the species, of from 4 to 9 feet apart, the ground between the plants being well drained by narrow channels. Grafting has lately been practised to a large extent with very satisfactory results, and seed planting has given place greatly to it. The names given to the different species of the genus cinchona, all of which are planted by the Government, are:—

(*a*) Ledgeriana. (*e*) Calisaya Anglica.
(*b*) Succirubra. (*f*) Hasskaliana.
(*c*) Calisaya Javanica. (*g*) Officinalis.
(*d*) Calisaya Schuhkrafft (*h*) Lancifolia.

Several different methods are employed by Government and managers of private estates for harvesting the bark, and it has yet to be decided which method gives the best result with least injury to the tree. Which course is adopted depends greatly upon the hardiness of the tree, this quality varying in different species. The bark obtained from the roots is generally found to contain the greatest percentage of quinine, that from the trunk coming next, whilst the percentage obtained from the bark of the branches is so small that it is not worth while collecting and exporting to Europe. The accompanying statistics show, as far as I can ascertain, the extent to which cinchona has been cultivated in the last few years on Government and private estates. The area of land planted in 1883 by Government with cinchona was about 1,800 acres.

CINCHONA STATISTICS.

Year.	Government Crop.	Private Crop.	Amount realized for Government Crops.	Plants in Nurseries.	Plants in Open Ground.

—*The Planters' Gazette.*

A WEST AFRICAN SUBSTITUTE FOR COFFEE is thus noticed by the *Pharmaceutical Journal*:—The root of Banta mare (*Cassia occidentalis*) is used as a preventive of fever, a decoction being taken every morning, and the leaves are applied in erysipelas and local inflammation. As much as fifty tons of the seed are said to have been exported from Senegal as a coffee substitute.—*Pharmaceutical Journal.*

COFFEE: PROSPECTS OF PRICES VERY BRIGHT. POOR CROPS IN BRAZIL: DISEASE PREVALENT.

[Here is a very important Circular, Coffee Planters will yet be happy—*Cor.*]

(I. A. Rucker & Bencraft's Price Current, Nov. 11th)

The statistical position continues as strong as ever. During the first nine months of the current year we have delivered in Europe 363,000 tons against 360,000 tons same period last year, and this notwithstanding the important advance established in value. During October we delivered 34,500 tons, 35,500 tons being the average delivery per month last year, and 42,500 tons the actual delivery in October last year. Stocks continue to decrease, and if our information be correct, this feature will be very marked in the summer. As regards Rio and Santos receipts on the 5th they totalled 2,535,000 bags against 2,500,000 bags same time last season. In the bulk of the circulars issued the present Rio crop is taken at 3,500,000 bags, Santos crop at 2,500,000, or together 6,000,000 bags, and many assert that all their calculations are based on this figure. The probability that these estimates are excessive must not be lost sight of. The reports that the prospects of the blossoming Rio crop are unfavourable are maintained; as regards the Santos crop, it is still too early to say anything. The Havre market maintains itself on a basis of 65 francs, and this notwithstanding the fact that unusual efforts have been made to get rates down. Current gossip asserts that many are out who would like to be in, and hence a great deal of the wire pulling.

The key to the problem, however, is not in Havre, but in the Brazils. The immediate future depends on the course of receipts in Rio and Santos, November being, perhaps, the most important month in the crop year. Our information continuing unchanged, if anything more favourable, we maintain our opinion that as time goes on the visible supplies of Coffee will get smaller and smaller, and that prices must rise in unison. Extract of a letter from Messrs. Andrew Muir & Co., dated Rio de Janerio, 20th October 1886:—"1886-87 Crop.—We are now feeling the weight of the crop, and all the more so at the present time because of the accumulation of Coffee up-country, caused by three months of constant rainy weather. We look for a very marked falling off in supplies, however, in a short time. Many districts are already bare of Coffee, having marketed their crops. The Serra Abaixo crop has been a complete failure this season. We expect then to have a very limited supply of Coffee to deal with during the first six months of 1887, and as the Americans will require all, or nearly all, of that supply, there should be a lively competition for it. We do not think the export for the current crop-year will exceed *three and a quarter million bags.* 1887-88 Crop.—We must inform you that the prospects for the next yield are so far anything but bright. During August and September it rained almost without interruption, and even during the present month we have had very little fine weather such as would favor the blossoming of the plants. Refreshing rains, followed by intervals of bright sunshine, is the kind of weather required to produce a 'bumper' crop, and this season the rainy part of the programme alone has been carried out. The result is that the trees do not seem to have had sufficient strength to put forth the usual preliminary flower during the month of August, where any appeared it was promptly washed away by the floods. We have been anxiously awaiting the appearance of the second flowering which invariably takes place in September and October, and forms the basis of the crop, but up to the present, over very extensive and important districts, no blossom whatever has been seen. News has just come to hand that in some parts a blossom is now commencing to be formed, but at so late a period it is extremely unlikely that such a flowering can produce a satisfactory result. The old trees are as a rule entirely bare, and the appearance presented by the new plants is very unsatisfactory. We have not had so poor a prospect for a crop

since 1861/1862. The state of cultivation now, of course, is very different from what it was in those years, and the vast area covered by the plantations almost preclude the possibility of an absolute scarcity in the production of the bean. On the other hand, we are assured that there is a disease at work among the Coffee trees, which has already caused considerable damage, and which must be carefully watched. An Imperial Commission has been appointed to inquire into this all important matter. The only chance for a moderate crop would be a luxuriant blossoming now, but even this would hardly be sufficient to save the situation, because before the cherries could be thoroughly formed, they would be assailed by the strong sun of November and December, we fear, with terrible effect.—S. Mansfeld & Co. London, 11th November 1886."

MANILA NEWS:—KAPOK, SUGAR, RAILWAYS.

(Translated from "Straits Times.")

The advantages of growing Kapok or silk cotton has so far attracted attention in the Philippines that, according to the *Comercio*, the authorities there have decided upon taking measures to further its cultivation. It is their intention to secure seeds or young plant of that useful produce articles. The object in view will be to experiment with its cultivation in those islands to find out the possibility of acclimatising it. Should the trial planting succeed, the Philippines will be the gainer by the consequent increase in the tale of export articles sure as it is to thrive in the country, and yield handsome profits indeed to enterprising cultivators.

The local committee for ensuring a suitable display of Philippine products at the coming Madrid Exhibition have so slackened their energies, that the Central Committee in Spain have been obliged to stir them up to increased activity by means of circular letters.

The handicapping of Philippine sugars and produce generally by heavy import duties in Spain to the great detriment of trade between the two countries, has been at last remedied. The Home Government has decided upon lowering these duties considerably, and admitting into Spain sugar from the Philippines duty free when borne in Spanish vessels.

After four fruitless calls for tenders to construct a railway from Manila to Dagupan, an important seaport, an English firm sent in the only tender opened at the last call. Should the firm secure the concession it is by no means sure whether the venture will pay. The expected passenger traffic will it is said, not pay expenses. The goods traffic has no prospect of expending sufficiently to yield a high income.

HUNASGERIYA TEA COMPANY, LIMITED.

At the annual general meeting of this company, held in London on the 26th ultimo, the Directors presented the following report:—The total value of produce secured during season 1885-86, amounted to £1,558 9s 5d. This sum has been deducted from the cost of planting, upkeep, &c., and the balance of £2,189 6s 10d has been carried to Property Account, so that the Estate now stands in the Company's books at £21,509 13s 3d.

As stated in last report, the planting of a large acreage of Tea was accomplished at the beginning of the season now under review, and besides the expenditure on this and the upkeep of the former clearings, the Ceylon expenditure includes outlay on machinery, tea houses, &c., and also the cost of seed, nurseries, and general preparation for the planting of further 75 acres; this latter clearing has now been planted up, making the total area under Tea 585 acres as under:—

AREA UNDER TEA.

Planted July—October,	1882	...	25 acres
Do do	1884	..	188 „
Do do	1885	...	297 „
Do do	1886	...	75 „
Total under Tea at this date		...	585 acres.

The weight of Tea manufactured on the Estate for the season amounted to 12,527 lb.

The yield per acre is considered very favourable as the leaf was secured almost entirely from the 25 acre clearing, only a small plucking being taken from the 188 acres towards the end of the season.

It will be seen that the average price of the Tea sold in London was 1s 0½d per lb. Although the Tea market was ruling very low during last season, a higher average price would have been secured had the quantity coming forward from the Estate been larger.

The small area yielding leaf, and the consequent minute daily pluckings during the early part of the season, made it necessary to retain the manufactured Tea on the estate longer than is usual, so that parcels large enough for shipment might be sent off, and this, to some extent, caused a loss of flavour. Even then the breaks of Tea were not of sufficient size to command the full competition of the trade, and from these causes the Tea realised a lower price than would otherwise have been obtained.

Now that the plucking is being carried on over a much larger area, these disadvantages are disappearing, and good saleable breaks will now come forward with regularity. The market for fine Ceylon Teas has also improved. The returns given by the other minor products were in accordance with the expectations. As stated above small pluckings of leaf were being secured about the end of last season from the 188 acres planted in 1884, and as the yield is rapidly increasing, it is thought that between 40,000 and 50,000 lb. of Tea will be secured during the current season, viz.: 1886-87, and this, with the returns from the other products, should very nearly meet the year's expenditure. Looking at the age of the Tea, and the small area yielding leaf, such a result would be deemed most favourable, and the prospects for the following season, 1887-88, are very encouraging as that will be the first season during which any applicable area will be old enough to yield a considerable crop of leaf. A reference to the planted area, as given above will at once show that there will then be 510 acres of Tea giving larger or smaller supplies of leaf. With these facts before them the Directors cannot but feel that it would be greatly to the advantage of the Company if from 100 to 200 acres of Tea could be planted up each season, until a total of 1,000 acres is reached; but with the capital at present subscribed the Board do not feel justified in sanctioning any further extension. They would, therefore, strongly impress on Shareholders the desirability of at once subscribing Shares to the extent of £4,172, thus bringing the capital up to £25,000, so that the further planting of Tea may not be delayed. A clearing of 25 acres of Cardamoms has been planted up during the season, making a total of 33 acres under this product.—*Planters' Gazette.*

TEA HAIR.—We have received from Mr. Gow a small tin of this curious product of our tea with the bright colour which indicates tannin and golden tip. Under the glass the fine hairy particles of the mass are readily discernible. The sample can be seen at our office.

THE LUMINOSITY OF LEAVES.—Dr. Gorlam has discovered that the light reflected from green leaves consists chiefly of red and green rays, and by ascertaining the proportions of these colours reflected from leaves, and taking a revolving ring with the like proportions of colour on it, he has been able to mix these colours as it were in the eye and reproduce the tint of the leaves. He found during the enquiry, however, that the simple colours did not exactly reproduce the colour of the leaf required, but that a certain admixture of black was necessary to this end. Black, it may be remarked, is well known to exist in the cellular structure of leaves in the form of carbon. It is deposited there, as is believed, from the absorption of carbonic acid gas from the atmosphere by the *stomata* or mouths on the underside of the leaf.—*Indian Gardener.*

A CORRESPONDENT from Uva writes:—"I send you by parcel post three fruits that I think are unmistakebly *lemons* (Malta or any kind you like to call them.) I found a tree laden with these fruits in a village garden near here, and the villagers treating them as *wild limes*, using them only while bathing and washing their hair with them. They can give me no account how this lemon tree got into the village. Can it be possible that a native lime seed sported into a *lemon* tree? not unlikely I should think." The fruits sent are undoubtedly citrons of a very good kind.

BONDED TEA WAREHOUSE ACCOMMODATIONS.—The Wholesale Tea Dealers' Association have memorialized the Lords of the Treasury in regard to insufficient accommodation for the proper storing of tea. They say, also, "We are informed on the best authority that the complaints from country grocers as to spoilt tea owing to careless warehousing are more numerous this year than ever. The tea comes in the months above mentioned in immense quantities, and warehouse keepers, whose hands are full to overflowing with work, allow the chests to remain for months uncovered without even the lids being put on, and thus teas, especially the finer sorts, are greatly damaged."—*Indian Tea Gazette.*

COCAINE (CRUDE).—A case, containing 3,765 grammes just arrived from Lima, was offered in sale. The analysis was given as follows:—

Crystallisable cocaine	91·4
Ash	5·0
Moisture, &c.	3·6
	100·0

The whole was bought in at 10d per gramme. We understand that one of the principal English makers offered 4½d per gramme, but this bid was declined. We have described this cocaine, which is extracted from the leaves in Peru, and of which frequent shipments are received at Hamburg, in a recent issue. COCA LEAVES remains quite neglected, 47 bales offered in sale this day found no purchasers.—*Chemist and Druggist.*

KAINIT AS A FERTILIZER.—The following deserves your consideration at this period of the year, (say Messrs. Samuel Downes & Co., Liverpool, writing on September 30th). Intending users will please to observe that it should not be applied to stiff but light sandy soils and mossy lands which are deficient in potash:—The late Dr. Voelcker wrote:—"By far the best mode of applying kainit to light or to heavy land is to sow broadcast in *autumn* or early *in winter*, both for wheat and potatoes. For winter wheat on heavy land the kainit may be mixed with dissolved guano in the proportion of 2 cwt. of kainit and 3 cwt. of dissolved guano (8 per cent quality dissolved guano), and sown broadcast, either before sowing or soon after the seed has been sown. For potatoes it is best to sow broadcast 3 to 5 cwt. of kainit per acre early in winter, and to plant the potatoes with 4 to 6 cwt. of 6 per cent quality dissolved guano diluted with ashes or burnt soil, or any similar bulky material, which has the effect of spreading the dissolved guano more freely upon the land, and preventing the concentrated manure coming into direct contact with the seed potatoes. Kainit should always be sown in autumn or early in winter. For rather heavy land 2 to 3 cwt. are sufficient; for light soils 3 to 5 cwt. per acre may be applied with advantage.—*Agricultural Gazette.* —[Has any one tried kainit with dissolved guano, or with white castor-cake as an application to tea?—Since writing this, we have learned that Messrs. Freudenberg & Co. have been appointed Ceylon Agents; and the proprietor having got samples from them, some experiments with kainit for tea are to be made on Abbotsford, and the results carefully noted for publication.—ED.]

CEYLON PLANT IN REQUEST.—Says a correspondent of a home medical journal:—"I hear tha the leaves of a Ceylon plant, the *Michelia nilagerica*, have been found by a foreign medical authority to possess great antipyretic properties, a decoction of the drug acting in this respect better than one of cinchona bark. A peculiarly bitter principle is also said to have been extracted from these leaves."—From the "Treasury of Botany" we take over all under the heading of Michelia, as follows:—

Michelia. A Florentine botanist of the early part of the eighteenth century is commemorated by this genus of *Magnoliacæ*, which consists of lofty trees, natives of India and the islands of the Eastern Archipelago, and is nearly allied to *Magnolia*, but distinguished by the axillary flowers, the looser arrangement of the carpels, and the more numerous ovules.

M. Champaca, the Chumpaka of the Hindoos, is cultivated commonly in India for the powerful fragrance of its flowers, which, indeed, according to Sir W. Jones, is so strong that bees seldom if ever alight on them. The tree is sacred to Vishnu, and is therefore an object of superstitious regard on the part of the Hindoos, who adorn their dark hair with the rich orange-coloured flowers. The root, like all parts of the tree, has bitter properties, and is used medicinally. There appears to be some difficulty in defining the species; or probably that just mentioned, having been ong cultivated, has originated numerous varieties which are mistaken for species; thus *M. Rheedu* is referred to *M. Champaca* by Hooker and Thomson. The timber of *M. Rheedu* is employed in Bombay for cabinet work, and has been tried in ship-building, while various parts of the tree are used medicinally as stimulants, &c. *M. Doltsopa*, anotl er variety of the Champaca, is mentioned as furnishing a fragrant wood used in house-building in Nepal. Lindley mention the bark of *M. montana* as having proprieties like those of cascarilla, but milder, and that of *M. gracilis* as having the odour of camphor. *M. Champaca* is cultivated as a hothouse plant in this country, where, however, it does not appear to be as great a favourite as its Indian reputation would lead us to infer. [M. T. M.]

A FEW NOTES ON THE SOIL OF CEYLON.—As to the soils of Ceylon, that of Colombo consists of either sea sand or of laterite, locally called *cabook* or a mixture of the two. It is a pretty well established fact that the sea in former ages covered the present site of Colombo and the Cinnamon Gardens, hence the sea sand deposited there. Further inland we have the large expanse of paddy-fields—cultivated by the natives who have been for ages experts in terracing and irrigating their lands—may be said to be a deposit principally of gneiss—still further on the slopes of the hills of the Central Provinces, the soil, where wonderful crops of coffee were in former days made, is anything but rich, being of a loose, friable, gravelly nature, very apt to get washed into the paddy terraces of the Cingalese Gova below, a circumstance which "Apaswammy" thoroughly appreciates. In fact the wonderful returns of various tropical products from the soils of Ceylon is more due to the climate than to the richness of the soil. When we arrived at Nuwara Eliya we exclaimed what grand black soil. To our astonishment we were told by a friend that this black deposit on the plateau of Nuwara Eliya is utterly worthless, inert stuff, being simply peat in a high state of decomposition, and which would burn as peat cut from the bogs of Scotland. On the slopes of the hills of Nuwara Eliya the soil is of a better character and grows good tea and chinchona the latter however suffering somewhat from the hoar frosts in January, February and March. Notwithstanding the poverty of the soil of Nuwara Eliya wonderfully good English vegetables are raised by an enterprizing Scotch-man, Mr. White, who has a large garden within the grounds of the Grand Hotel, Nuwara Eliya, and from which he supplies people in that station, planters in the district and hotels and steamers at Colombo. W. M. R. —*The Indian Planters Gazette.*

REPORT OF THE DIRECTOR OF GOVERNMENT CINCHONA PLANTATIONS, NILGIRIS, FOR 1885-86.

1. SEASON AND RAINFALL—(*See Statement No.* 1, *a*) *Dodabetta.*—The season for the past year was very favourable for carrying on all works connected with the upkeep of this estate. The total amount of rain registered during the year was 53·25 inches, spread over 154 days. This was about 8 inches less than what fell during the previous year, but it was spread over 154 days instead of 123 days, showing an increase during the past year of 31 wet or cloudy days over last year. Very little rain fell during the early part of the year; indeed the spring showers failed almost entirely, and it was not till the breaking of the monsoon, which began early (3rd of June), that the earth got at all wetted. The monsoon broke very gently, and continued with hardly any intermission for nearly six weeks, after which the weather continued very favourable till the end of the year. The wind was never furious, and with the exception of one storm in November, the rainfall was never excessive. On the 17th and 18th of this month, 4·30 inches of rain fell, but nothing more than a little wash on the steeper and more exposed parts of the plantation was experienced.

(*b*) *Naduvatam.*—The quantity of rain which was registered on this estate during the past year was 90·40 inches, spread over 132 days; this being very nearly the same amount of rain and the same number of wet days which occured during the previous year. The season was good for all kinds of work, and the new plantings on the old plots which had been made during the last three years, are looking very well.

(*c*) *Pykara.*—This estate now comprises the two which were formerly known under the names of *Hooker* and *Wood.*

(1) *Hooker.*—The rainfall for the year on this plantation was 90·77 inches, spread over 134 days. Last year the amount of rain was 104·27 inches, spread over 136 days. With the exception of a storm in November, when 10·1 inches of rain fell in two days, the weather during the season was all that could be desired. On the occasion of this storm some damage was done, by reason of the great wash which took place on some of the slopes which were exposed to its full blast. Considerable damage was also done at the same time to several of the roads and paths on this estate, owing to drains and culverts becoming choked. The damage done, however, was not more than might have been expected from so violent a burst of wind and rain. The general appearance of the plantation is good and the younger plantings are much improved.

(2) *Wood.*—On this estate 74·18 inches fell during the year, and were spread over 129 days, the amount which was registered during the year before being 86·06 inches, which was spread over 139 days. Some damage was done to a portion of the coppice of 1884, which lies just below the water-course that runs from the Pykara river to the coffee estates in the plains, owing to the bursting of the bank of the water-course during one of the heavy storms which occurred during the autumn. The water-course has now been repaired and there is no further apprehension of the accident occurring again.

III. PERMANENT PLANTATIONS—(*a*) *Dodabetta.*—The condition of the estate is much the same as when I reported upon it last year. The coppice and interplantings are doing very well. All these were manured and will, I have no doubt, show the result of this liberality by an increase in the vigor of their growth. Statement No. 8 gives calculations of the number and the different sorts of plants growing at present upon this and the other estates.

(*b*) *Naduvatam.*—The general condition of this estate has materially improved during the last year. All the young plantations were highly cultivated and many of them freely manured, the result of which and the favorableness of the season is a fine vigorous growth of all the young plants. A considerable amount of the land, which in former years had been pitted for planting, but which had either never been planted at all or where the plants had died out, I planted up during the past year, chiefly with *Cinchona magnifolia.* Most of the remaining pitted land lies on slopes which are too steep for convenient cultivation or on poor soil or on places too much exposed, and all this land I propose to abandon.

The shelter belts which I have put up round many parts of the estate are doing well.

Santa Fé.—In my last year's report I mentioned that I had very nearly lost my only remaining specimen of cinchona *Santa Fé,* but that it had been saved by the skill of Mr. Jamieson; and I am happy in being able this year to report that not only is the old plant living, but that Mr. Jamieson has been able to raise between 20 and 30 new plants from it, most of which are now well rooted and will be ready for putting out in the plantations during the present season. Four hundred and twenty plants of *C. Carthagena* raised in the Government Gardens, Ootacamund, from cuttings were planted out on the Naduvatam and Pykara estates, the lower elevation of which seems to suit them better than that of Dodabetta. As I mentioned in my last year's report those at Dodabetta are not doing satisfactorily.

The *Remijias* which I mentioned in my last report were planted out during the autum on this estate; they have as yet made little or no progress, but they look perfectly healthy and will, I have no doubt, begin to grow during the warm season after the rain. On the same plot of ground adjoining the land on which the *Remijias* have been planted, I have put out specimens of several species of cinchona, and this year I shall put out all the remainining species which we possess. These are not intended for commercial purposes, but by their being placed side by side and allowed to grow in a free and natural manner, it is hoped that they will enable those, who are interested in the subject to examine the characters of the different kinds with greater readiness than can be done when they are scattered, not only over different parts of the same estate, but even over the different estates themselves as occurs at present.

(*c*) *Pykara*—(1) *Hooker.*—This plantation has greatly improved during the past year. The young plantings have been highly cultivated, the whole of the ground which they occupy has been deeply pitted and the greater part of it manured. The remaining portion of the estate requiring renovation is but small, when compared with that which has already been carried out during the last two years, and I shall, I hope, be able to complete it during the present season. The sambur are still troublesome on some parts of this plantation, but as barbed wire has been ordered from England and its arrival is now being daily expected, I hope that I shall be able before long to put up such a fence as will effectually keep out these intruders.

(*c*) *Pykara*—(2) *Wood.*—This Plantation is hardly in a more satisfactory condition than it was when I reported upon it last year. Some of the succirubra coppice has done well and some of the planting close to the lines and the head overseer's dwelling, where the sambur dare not come, are also doing well, but in all the other parts of the plantation which lie at a distance from human habitations the young plants are destroyed as much as ever and no hope of any improvement can be expected until a substantial fence has been erected. Some underwood consisting chiefly of strobalanthis which was encroaching upon the plantations, I ordered to be cut during the winter as that tended to harbour the sambur, and I regret to say that towards the end of the dry season this brushwood caught fire during a high wind and that the fire spread through a portion of the shola which surrounds the Pykara falls and has seriously injured, if not killed, many very fine trees. In a former report I recommended to Government that they should give up the cultivation of the Wood plantation altogether, but Government at that time

thought my experience was of too short a duration to admit of their rashly adopting the suggestion, and I was desired to do my best to put it into repair; but my experience of the past three years makes me doubt if it will ever be very profitable to Government to retain it. The soil in many parts is poor and stony, other parts again are exposed to devastating blasts, and it is in bad weather difficult of access. At the best it will cost a large sum of money to repair the plantation, and it will be many years before it yields any reasonable returns to the money invested. If the greater part of the Wood plantation was abandoned and the few acres of land round the head overseer's bungalow and the drying sheds only were kept, the Pykara head overseer would be able to pay more attention to the Hooker plantation, which is now becoming a very valuable property. This would save nearly the whole of the expense of the upkeep of the Wood plantation or about R8,000 per annum.

IV. UPKEEP.—The maintenance of the buildings, roads, drains, bridges, &c., with one exception has been well attended to on the Dodabetta, Naduvatam and Hooker estates. The exception is the Mucroochy bridge which spans the river crossing the road which leads from Naduvatum to Hooker.

V. MANURE—(*a*) *Dodabetta.*—I have been able during the past year to obtain abundance of manure for this estate from purchases made in the town of Ootacamund, and on this account I have transferred the greater number of the Dodabetta cattle to Naduvatam.

Cattle.—Many of the draught cattle belonging to the Dodabetta estate are very old and several of them died during the past year. These I propose replenishing by young ones which may be obtained at a resonable price during the fairs which are held yearly at Murally at Mysore: The great want on estates and indeed in all farms of this country is the want of a sufficiency of manure. Almost every estate has cattle upon it, which may be regarded purely as manure-making machines, but these machines are worked at very great waste, because owing to the cost of storing up fodder they are obliged to be sent out during the day on the hill sides to graze where all the manure which they make during the day is lost; but if a sufficiency of fodder could be stored in stacks or silos, these cattle might be altogether stall fed, with the result that there would be an immense increase of manure coming into their owner. At the same time, they would become much fatter and therefore saleable for the purposes of the butcher. During the past year very considerable economy has been effected by using more largely than had hitherto been done the Government carts and bullocks for the transportation of bark to Mettupálayam and for the carriage of supplies to the estates.

(*b*) *Naduvatam.*—Owing to the transfer of the Dodabetta cattle and the purchase of the few additional animals, this estate has been much better off for manure during the past year than it had ever been before.

(*c*) *Pykara.*—Both the plantations of Hooker and Wood continue to be well supplied.

VI. HAYSTACK.—During last autumn, I made a large haystack of grass obtained from the hills on the Government estate at Naduvatam at a cost of R109; the grass was cut by sickles and was well dried before being stacked. The hay turned out very fair and sufficed to keep in good condition all the cattle on the estate during the five dry months of January, February, March, April and May. I made another smaller stock on the Dodabetta estate consisting entirely of *Briza maxima* commonly known as *Jacobs' tears*. This grass completely covered may of the plots and often grew to the height of nearly two feet. The hay was not very well got on account of the weather being wet at the time it was harvested. Nevertheless it proved very nutritious and horses and cattle took to it readily. Dr. Shaw, Inspecting Veterinary Surgeon, Madras Army, to whom I sent some of these hays for experimentation, has been good enough to send me the following very interesting report on their quality, and the suggestions which he makes with regard to the other kinds of grasses, which may be used as hay, will be attended to during the present year:—

Adverting to my letter, No. 45-86, Ootacamund, 10th April 1886, I have the honor to report on the two samples of hay forwarded with your letter, No. 38, of 10th April.

2. The Naduvatam sample (name unknown) did not prove a success. It was in the first place coarse and wiry in its nature, and I should say over-dried, being crisp and crumbly when rubbed, and fracturing into small particles. It had little or no aroma and was here and there mouldy as if it had been exposed to dry on damp ground. The horses I tried this sample with, did not evince any keenness to eat it, and two out of five absolutely refused it for some days, after which it was only sparingly partaken of.

3. No. 2 sample (*Briza maxima*) or Jacob's tears was better saved, had an aroma of hay and, I think, if it had been cut a little earlier, or when more succulent, it would have afforded a better sample. Four horses partook of this sample, and kept in fine working condition on it. The fifth (a horse I had in training) being at the time on an allowance of oat hay, occasionally nibbled at it only.

4. As regards the feeding properties of the two samples, I do not think sample No. 1 is good enough to persevere with as a horse fodder; at the same time, I think it far preferable to the bad grass which is brought in during the dry months and which forms the bulk of stable supplies up here from November to May.

5. The question of stable fodder as an industry on these hills is one, I think, capable of great extension and would prove a remunerative investmeut to the agricultural classes if they could be encouraged to grow them. The cultivation of oats by General Morgan and Mr. J. Sullivan has proved that three crops can be produced from one tillage. The first and second crops can be cut as green fodder and the third allowed to go to ear and made into hay. I am using such now with the greatest success. The soil and climate of Ootacamund are particularly favorable for the cultivation of oats; the stalks of which attain a great size; and I have seen it growing with the ear just budding though seven feet high. I have no experience with the "Bromus" or South American oat grass but General Morgan tells me it has taken favorably to the soil and has proved a valuable fodder.

VII. SILOS.—In my last year's report I stated that I had made silos on the Dodabetta and Wood estates for the preservation of fodder during the wet weather. The silo on the Wood estate was never utilized, as a heavy storm flooded it before it could be properly roofed; but on the Dodabetta estate I made six silos, all of which have been successful, and I will describe their structure and the mode of filling them.

No. 1 was a brick-built pit lined with cement the internal measurement of which was as follows:—Fifteen feet long by ten feet broad by twelve feet deep; the walls from top to bottom had a slope given to them inwards of six inches. This pit was roofed with zinc so that no rain could by any possibility get into it. The cost of building the pit was R206. I began filling this pit on the 14th of October and finished on the 19th idem. The plants used for filling the silo were very numerous; indeed, almost everything was put in which it was known the cattle would eat in a green state such as *maize, cholum, ragi, lucerne, Spanish needle, Polygonum nepolense, Jacobs' tears*, grass from the lawns of Government gardens, hill grass, swamp grass, &c., &c. All these with the exception of lawn grass, which had been cut by mowing machines, were passed through chaff-cutters and cut into pieces not bigger than an inch in length. As this was cut, the mixture was thrown into the silo and when a stratum of about two feet in thickness had been put in, it was trodden well down. This was repeated until the silo was completely filled when mats were placed on the top, then planks of blue gum and then two feet and-a-half of moderately dry earth. In the course of a week the earth sank exactly one foot, after which there was no further subsidence. During the subsidence the earth cracked around the edges of the pit and it was necessary to dig up the earth about these cracks with a fork and then tread it down again, to prevent the access of air to the fodder below. It was opened on the of April in the presence of His Excellency the Commander-in-Chief, Brigadier-General Elles, C.B., Adjutant-General, Dr. Shaw and others who had experience in the making of silos. The fodder on

being uncovered had lost its bright green color, owing to the partial decomposition of its chlorophyl, but with this exception it differed little in texture and appearance to what it had presented when first put in. On weighing a portion of it each cubic foot was found to contain a little over forty-seven pounds. The smell was exceedingly offensive, especially the upper layer of about half an inch in thickness. His Excellency the Commander-in-Chief, Brigadier-General Elles and Dr. Shaw pronounced it to be good, and on its being given to some of the bullocks it was at once greedily eaten by them, and since that time they have been fed upon nothing else, and they are said by Mr. T. Narrainasawmi Nayudu, the Assistant Superintendent, and Mr. McDonald, the Sub-overseer, to be generally in better condition than they have ever known them to be before at this time of the year and this in spite of their having done, at least, double the usual amount of work. Besides this silo which was both costly in its construction and in its filling, I made five others of a much cheaper description and which turned out ensilage, every bit as good as that from the big pit. These consisted of pits six feet cube dug in the earth in a place where there was no fear or springs or stagnant water. The fodder was put into them as it came from the field, that is without being cut up, and after it had been well trodden down mats were placed on the surface, and on the top of these two or three feet of earth, which was heaped up and slope like a grave, and over these mats, thatch or plates of galvanized iron were placed to shoot off the rain. The ensilage in these pits shrank more or less, according to the particular plants which composed it. In one instance the earth sank as much as three-and-a-half feet, and it was necessary, during the first few days, to fill up the cracks which were made in the soil by this shrinking. In one of these pits I stored up *Jacob's tears* separately, in a second *Spanish needle*, in a third *Polygonum nepolense*, and in the two others a mixture of plants. The fodder, which was turned out from all of them, proved, on experiment, to be everything that could be desired, although during the time that they were being filled, it was raining hard and the stuff saturated with moisture. I shall in the future make no more costly silos, but use these earth-pits, only making them of larger dimensions, and covering them with a roof of thatch. The estates, hills and sholas of the Nilgiris and the Wynaad must possess an enormous amount of nutritious fodders which grow readily in the wet season, but which cannot be preserved for future use except by means of silos, and I look forward to the time when knife-weeding upon a cinchona or coffee estate will be regarded no longer as a disagreeable necessity.

VIII. NURSERIES.—The demand for seed is still decreasing and that for plants and seedling also. Most of the applications which I received during the year were from the planters in Ceylon.

IX. CROP.—The total amount of dry bark produced by the estates during the past year was 113,366 lb. In addition to this, there remained on the 31st March 1885, 125,663 lb., making a total of 239,029 of all sorts. Of this quantity, 113,940 lb. were disposed of during the year, so that the balance in stock at the end of March last was 125,089 lb.

XIII. COPPICING.—Several questions having been addressed to me during the year relating to coppicing, I have carefully attended to this matter, and, so far as my experience goes, I believe (1) that it is immaterial at what time of the year the trees are cut down; (2) that they should be cut quite close to the ground for then the shoots have a better chance of making roots for themselves, and so becoming independent trees, than if they are allowed to spring from a point at a distance from the ground; shoots springing immediately from the ground are much less liable to be blown down by the winds; (3) the number of shoots which should be allowed permanently to remain will depend entirely on local circumstances. If the shoots are far apart, then two or even three may be allowed to grow, but if the shoots are close then one will, as a rule, be sufficient. No fixed rule, however, as to the number which should be left can be given; but if it is borne in mind that wood and bark are the result of the activities of the leaves, it will be readily understood that those trees which have the most leaves exposed to the light will produce the thickest stems and the largest amount of bark. The planter should therefore see that his coppice is not so thick as to prevent each individual shoot having its fair share of light.

XIV. GRAFTING.—The nearly allied species of cinchona seem to lend themselves, rather readily, to being grafted; but the labour entailed in grafting is so great that I do not believe it will ever pay to do this on a large scale.

XV. QUINOLOGIST'S DEPARTMENT.—Mr. Hooper in accordance with the instructions issued in G.O., No. 550, of 12th May 1885, Revenue, went down to Madras to start the manufacture of 1,000 lb. of *De Vrij's Cinchona Liquida*. Of this amount, however, 500 lb. only were made and for some reason or other the manufacture of the febrifuge did not turn out quite satisfactory. So I asked Government that Mr. Hooper might be allowed to make the remaining 500 lb. in Ootacamund. Government accorded their sanction to my proposal, and Mr. Hooper has just completed his task. The febrifuge which he has turned out seems to be in every respect excellent, and will, I hope, prove a cheaper and at the same time as efficacious a drug as any that has as yet been made. Should the febrifuge prove acceptable to the poorer classes of natives, not only will all the bark which can be raised on the Government estates be required to meet the demand, but a very great deal more.

XVI. OTHER MATTERS connected with the chemical aspect of quinology, I leave Mr. Hooper to speak for himself, whose very interesting report I enclose.

XVII. URGENT NEED FOR A CHEAP FEBRIFUGE.—I am indebted to Surgeon-General G. Bidie for the following statistics. The population of the Madras Presidency was 29,000,000 at the last census. The total number of deaths during the last year from all causes was 615,449 as detailed below:—

Deaths from undescribed causes ...	260,960
Fever	218,786
Cholera...	58,109
Small-pox	34,726
Bowel complaint	31,209
Injury	11,659
Total	615,449

From these figures it will be seen that nearly one-third of the total number of deaths are due to malarious fever. A proportion which must be regarded as too high when it is considered that we have a specific medicine for this fatal disease.

XVIII. PROSPECTS OF THE CINCHONA MARKET.—So long as the cinchona alkaloids are produced chiefly for the European and North American consumption (non-fever stricken countries) the supply will always be in excess of the demand and the present low prices will continue to exist; but if a market can be found for the alkaloids in the malarious tracts of the tropics, this state of things would be reversed and the price of bark would go up.

Dr. Bidie tells me that he believes every one in the Presidency would be benefited by taking quinine in more or less quantities during certain seasons of the year, and he does not think that forty grains per head would be a high figure at which to place the yearly requirements of the country. If this be correct then close upon 2,000,000 pounds of bark averaging 6½ per cent. of total alkaloids will be required for consumption in this Presidency alone.

ENCLOSURES.

Letter from D. Hooper, Esq., F.C.S., Government Quinologist, Ootacamund, to M. A. Lawson, Esq., Government Botanist and Director of Cinchona Plantations, Nilgiris, dated Ootacamund, 6th July 1886:—

I have the honor to present the following report on the analytical work conducted in the Government Laboratory for the year ending March 31st, 1886.

2. The report includes a valuation of the cinchona bark sold by auction in Madras during the year, and

complete analyses of all the different species of bark which were sent to the Colonial and Indian Exhibition in London. Some experiments in renewing bark and manuring trees are recorded; and tables are given showing the increase of alkaloids by growth, and the deterioration of alkaloids by age and other causes. The liquid cinchona which was partly made last year has been completed. Most of the analytical work has been done for Government, but several barks have been received from private parties, and I have to thank some of these gentlemen for information respecting samples they sent, as this enabled me to summarise results which are of general usefulness to planters.

3. There have been six sales of Government bark in Madras during the year, viz. September, October, November, December, 1885, January and February 1886. Samples of the various kinds have been valued, which has given a reserve price to the auctioneers, but the competition being so brisk at each sale, these prices were exceeded.

I append a statement showing the qualities of barks disposed of, their value in sulphate quinine, and the value of the unit in pence.

Description of Bark.	Sulphate quinine. Per cent.	Value of unit. d.
September 1885.		
Dodabetta Natural Crown ...	4·18	4·06
Naduvatam Root „ ...	4·46	4·90
October 1885.		
Dodabetta Renewed Crown ...	4·06	5·85
„ Mossed „ ...	4·70	5·48
Naduvatam „ „ ...	4·05	5·37
„ Root „ ...	4·46	5·38
November 1885.		
Dodabetta Natural Crown	4·18	6·70
„ Branch „	1·17	7·90
„ Root „	4·33	6·93
Naduvatam Natural „	3·52	7·10
„ Renewed „	4·22	7·52
„ Branch „	2·16	7·06
December 1885.		
Dodabetta Natural Crown	3·10	6·69
„ Mossed „	4·73	5·55
„ Renewed „	6·56	5·49
January 1886.		
Naduvatam Natural Red	1·56	4·97
February 1886.		
Naduvatam Renewed Red	2·54	4·62
„ Root „	1·38	5·25

4. These barks are, on the average, of the same value as those sold last year, but with regard to the value of the unit it will be observed that the market has experienced a great fluctuation during the year. In September the unit being 4·48*d*, October 5·52*d*, November 7·20*d*, December 5·91*d*, January and February 4·94*d*.

5. *Renewal by shaving.*—Shaving cinchona trees has been for some years a method of harvesting bark which in some districts works better than that of stripping and mossing. The cellular and richer portion of the bark is removed in this way and the fibrous portion is left. The bark thus treated thickens again, and the shavings taken from it are found to be richer still in alkaloids. The analyses of some succirubra shavings taken from trees grown in the Ouchterlony Valley will show to what an extent trees may be improved by this method. The renewals had been taken after intervals of twelve months; the experiment, therefore, has lasted over three years.

	Quinine	Other Alkaloids.	Total.
Original Bark	1·35	5·87	7·22
Once renewed	2·46	4·22	6·68
Twice renewed	3·60	3·99	7·59
Thrice renewed	3·87	3·71	7·58

6. The increase in quinine during the first and second year by renewing is most satisfactory; the increase is not so prominent in the third year, but the bark is good, and indicates that shaving for at least four years might be permitted. The trees upon which these experiments were made were six years old, when the original bark was taken. If at this comparatively early age they are not injured by shaving, and renew their bark so well, it is not desirable to wait for the trees to become more matured.

7. When trees are allowed to grow until they are over 12 years of age and then shaved, the renewal sets in more slowly, and the resulting bark does not compare more favorably with the original bark than if the trees operated upon had been half that age. This may be instanced by quoting some more analyses. Last December some interesting samples were sent by the Manager of the Glenrock Company, South-East Wynaad, consisting of some natural and renewed shavings of succirubra taken from trees of 6 and 12 years of age.

The following is the analysis of four of the samples:—

	Sulphate quinine.	Total.
Red bark, 6 years natural... ...	1·34	5·00
„ „ renewed, 2 years... ...	2·54	6·95
„ „ 12 years, natural... ...	2·43	7·41
„ „ renewed, 2 years... ...	2·71	7·01

8. Thus it is seen that by renewing a 6-year-old tree 90 per cent more of sulphate quinine is obtained, and by working on a 12-year-old tree, only an increase of 12 per cent takes place during the same period of two years. With regard to the total alkaloids, it should also be noticed that the shaving has made an increase of 39 per cent in the younger tree, while the older bark has somewhat deteriorated. One of the most important features in these results is that the renewed bark from the 6-year-old tree is superior to the natural bark from trees of twice that age.

9. I have had very few opportunities of observing the effect of shaving on pure Ledger barks, containing little, if any, alkaloid besides quinine, but it appears that hybrid Ledgers of the broad-leaved variety holding cinchonine, are capable of great improvement by the shaving process as the following renewals of 11 months will show compared with the natural bark of 6-year-old trees:—

	Sulphate quinioe.	Total.
Ledger bark, narrow leaf, natural 1885	4·09	5·97
„ „ „ renewed, 1886	6·62	8·49
„ „ broad leaf, natural 1885	2·90	6·61
„ „ „ renewed, 1886	5·19	8·51

10. The sulphate of quinine in the narrow-leaved Ledger had increased 62 per cent and in the broad-leaved Ledger 79 per cent the greater increase in the latter variety is due to the presence of other alkaloids which appear to develop quinine in the growth of the tree.

11. Shaving old trees has certainly not had a beneficial effect from some trials made on Government estates. Both red and crown trees from 16 to 21 years of age cannot well bear the removal of the bark in this way and the renewal takes place slowly and is impoverished instead of being enriched. A crown bark was taken from Dodabetta aged 20 and shaved. The shavings gave 3·66 sulphate of quinine; after six months some renewed shavings were taken and found to yield only 1·85 per cent sulphate of quinine, the bark then was commencing to decay and the tree has since died.

12. *Experiment in manuring Cinchonas.*—The effect of manuring cinchona trees in order to stimulate their growth and produce a greater yield of alkaloid has been tried recently at Naduvatam. The first experiment was made upon a succirubra of 7 years growth. Cattle manure which had been previously kept for some time in closed pits was applied some six months before the bark was taken for analysis. A sample of bark from a tree in the same plot, but which had not been manured, was collected at the same time for comparison. Two samples of magnifolia bark were taken from trees which had been manured in a similar manner to the succirubra; the first was 17 years, the second 20 years old, and samples from unmanured trees were taken for comparative analysis at the same time.

13. The results of the examination are tabulated below:—

	Quinine.	Cinchonidine.	Cinchonine.	Amorphous alkaloids.	Total.
Succirubra manured	2·29	3·78	1·94	·52	8·53
„ unmanured	1·51	4·13	2·03	·32	7·99
Magnifolia 1 manured	3·78	3·90	·28	·82	8·78
„ „ unmanured	3·13	4·39	·56	·39	8·47
„ 2 manured	2·59	3·49	1·21	·53	7·82
„ „ unmanured	2·62	2·67	·67	·56	6·52

14. It will be seen that the manuring has had the effect of increasing, in each instance, the amount of total alkaloids in the bark; and the quinine, the most important feature, has received a gain of 52 per cent. in the succirubra, and 20 per cent. in the first magnifolia. In the older magnifolia bark the quinine remains about the same in quantity, and if no other influences were at work, it might be inferred that older trees are not so sensitive to the action of manure as younger and vigorous-growing trees which have not reached maturity. The food of such plants as cinchonas which yield alkaloid in large quantity must of necessity contain some nitrogenous element, and as this must be taken from the ground it is only fitting that a manure of this kind which contains some constituents which are similar in their nature to alkaloids should be supplied periodically to soils. Regarding the question from a commercial aspect the higher value of the bark would cover the expense of the manure and the cost of its application to the land. The succirubra bark mentioned in the first experiment, if the market price of the unit of quinine were 4d, would realize eight pence per pound, whereas the bark of the manured tree would be more than one shilling per pound. I believe the effect of manuring would be more apparent in Crown and Ledger barks with large proportions of quinine in the total alkaloids; in such cases, the extra outlay on manurial agents, compared with the additional value of the bark, would be much more remunerative.

15. *Increase of Alkaloids with the age of trees.*—A question of much importance in cinchona cultivation is the age to which trees should grow before the bark can be profitably taken. To settle such an inquiry, a large number of analyses of barks taken from trees of all ages should be available, and in the following tables I have made a selection of both Ledger and red barks and have arranged them according to age. Some of the figures are average of two or more analyses, and as the two lists represent some forty samples, I hope it will help to throw some light on the subject.

16. The first list comprises natural barks of the narrow-leaved variety of *C. Ledgeriana*, and with one exception, they all come from the Wynaad district.

17. The second list is by taking from my laboratory journal all those red barks whose ages have been determined, whether they come from the Government Plantations at Naduvatam or from private estates in Wynaad, Coorg or Travancore.

5½ „	1·32	2·15	3·11	·63	7·21
6½ „	1·31	3·22	2·18	·71	7·42
7 „	1·70	2·69	2·28	·93	7·60
7½ „	1·78	3·18	1·97	·53	7·46
12 „	1·81	2·62	2·08	·90	7·41
16 „	1·08	·94	1·04	1·57	4·63
20 „	·78	1·13	1·37	·97	4·25

18. In the Ledger barks it will be noticed that there is a steady rise of quinine up to the age of between

five and six years, after which there is no apparent increase.

19. In the second table of red barks, the same fact is shown that the bark has attained its maximum content of alkaloids when between 5 and 6 years of age. The quinine increases up to 12 years, but, as pointed out before, the renewed bark of the younger trees would much exceed the slightly increased value of these older barks. The trees of 16 and 20 years show a marked deterioration in alkaloids, although the bark is often in large thick fibrous pieces similar to the drug that was originally exported from the South American forests.

20. *Effect of Mould on Bark.*—It has been stated that bark loses much of its virtue when allowed to get mouldy or when kept in a damp atmosphere. I was asked more than a year ago to analyse some mouldy bark to obtain its value but not knowing the composition of the fresh bark the result would not have been very useful. I have, therefore, made an experiment which shows that little if any effect is produced by prolonged contact with mould. A sample of powdered bark of known composition was taken in December 1884 and kept in an open dish on the floor of a dark damp room, a fungus (Penicillium) set in in a fortnight, and spread itself over the surface of the powder, and slightly increased its weight. The bark was constantly stirred so that fresh bark from beneath might be influenced by the fungus. It was mixed occasionally for 10 months and as the mycelium had by then penetrated to every particle of the powder it was analysed in October 1885, with the following results:—

	Original bark.	Mouldy bark.
Quinine	2·82	2·80
Cinchonidine	1·22	1·25
Quinidine	·18	·11
Cinchonine	·90	·87
Amorphous	·31	·45
Total...	5·43	5·48

21. It is thus manifest that the analyses, being almost identical, moulded barks of 10 months are not necessarily deteriorated.

22. *Liquid Extract of Cinchona.*—At the suggestion of Dr. Cornish last year, I prepared a sample of liquid cinchona which was reported upon most favorably by several medical officers in the Presidency and called forth an order from Government for the preparation of 1,000 lb. (G.O., No. 550, 12th May 1885). In August last, 1,000 lb. of bark were supplied to the Medical Stores in Madras, and resulted in the manufacture of 595 lb. of liquid extract (*vide* demi-official letter from Principal Medical Storekeeper, dated 10th September 1885.) As a loss must have taken place in this outturn I received orders to produce another batch immediately under my supervison in Ootacamund (G.O., No. 55, 25th January 1886). 500 lb. of bark was powdered by the Medical Store Department, the maceration with the necessary chemicals and percolation was conducted in my laboratory, and the evaporation was made in ordinary chatties in an adjoining out-house: 340 lb. of liquid cinchona of the prescribed strength, 40 grains to the ounce, were thus made in two months at a cost of R211 as detailed below:—

	Rs.	A.	P.
Grinding 500 lb. of bark	4	0	0
Glycerine	52	0	0
Acid	9	0	0
Fuel	24	0	0
Labor	20	0	0
Chatties	3	8	0
500 lb. of branch succirubra bark estimated at 3 annas per lb. (taken the current value of the unit of quinine)	94	0	0
Rent	5	0	0
Total ..	211	8	0

Allowing for the high cost of buying the chemicals in Madras instead of from London direct, and taking into account the special expenses of this experiment, I consider that if made on a large scale and continuously, it should not cost more than R7 or R7-8-0 for an amount of liquid extract containing 1 lb. of solid ferbrifuge.

CHICKMAGALUR COFFEE PROSPECTS.—The rains have been timely and mother earth very prolific. The berries on coffee plants set well and have developed nicely, in some quarters of the district where the temperature rises very high during the day, the berries are ripening and picking will soon commence, and the cry for labour is beginning to rise. There are planters who, owing to one reason and another, are always able to command sufficient labour, but there are other unfortunates who can never get sufficient, in consequence of which, fine estates are overgrown with weeds, and useless suckers have to be allowed to drain the plants of their very life-sap, and thus the quantity of berries is injuriously affected. Those who look for labour only within the district generally meet with disappointment; others import their labour from South Canara and more distant parts.—D. P.—*Madras Weekly Mail.*

HOW TO BULK TEA.—A gentleman, some years in the China Tea trade, gives the following method as being the simplest and least expensive: Four square and wooden posts grooved on two of the adjoining sides, and several planks of say, 18 inches in breadth are all that are required. These should be made into a pit or large box, the posts forming the corners and the planks the sides. The pit should be built raised some 4 feet from the ground, the bottom being made of having a sliding trap-door in the centre, so made that the outlet can be enlarged or reduced according to the size of the leaf to be bulked; when the pit is being filled with tea the trap-door remains closed. The tea to be bulked should be spread out in layers as thin possible, one quality on top of another, until all the tea required to be bulked is inside the pit. Now open the trap-door, and the tea will run out from the top, taking a little from each layer in its downward course, the result being a *perfect bulk.* The bottom of the box should be made slightly on a slope from the sides to the centre near the aperture, so that the tea may get away equally. By means of a zinc tube the current of tea leaf can be carried direct from the pit into the package standing on a lever scale. A sand-glass will illustrate the above on a small scale. Tea is bulked in China on the same principle as the above, but there, one side of the pit is drawn away and packages filled from the tea that collects at the foot of the pile.—"Ceylon Advertiser."

† Containing Tricalcic phosphate 3·50.

MR. G. H. D. ELPHINSTONE ON RUSSIA AS A MARKET FOR CEYLON TEA.

Russia being, next to Britain, the largest consumer of tea of any nation in the world, our readers will peruse with interest the graphic letter in which Mr. Elphinstone records his experiences in the modern and ancient capitals of "the White Czar's" vast dominions. What he says about his sufferings from intense cold will cause our readers to appreciate the desire of the Muscovites to

"—— see before they die
The groves and temples of the south."

The cemeteries and mosques of Constantinople being, however, substituted in Tennyson's lines. The instinct which drives the northern hordes southwards is next to irrepressible, and we suspect that do what England, Europe and the world may, the banner of "Holy Russia" will yet float over the mosque of Sophia, in its new character of a cathedrial of the Greek "Orthdox Church." The Russians may then, like the Turks take to coffee, but meantime we have to regard them as incessantly engaged in brewing tea in their samovars to keep out the bitter cold, which Mr. Ephinstone, though a Scotchman, found too much for him. But the tea the inhabitants of St. Petersburg drink, is of a peculiarly delicate quality and has artificially imparted to it a special flavour. Then there is a "ring,' such as we had to do battle with in Melbourne, and such as exists also in the United States, who are determined, if possible to, keep out a new thing calculated to interfere with their vested interests. But the crusade against monopoly commenced by an energetic Ceylon planter will be carried on by others, and long before the Russians are sitting in "the Sublime Porte," they will be delighting in the consumption of large quantities of Ceylon tea, unadulterated and of unsophiscated flavour. The battle against vested interests, custom, habit and taste, may be severe and long protracted, but Ceylon tea which has conquered the markets of Britain, will yet triumph in Russia and in the United States. Mr. Elphinstone tells us in a private letter that he will send out to Mr. Rutherford the samples of tea he brought from Russia, and he promises to let us have the opinions of London brokers on those samples. We cannot doubt that the movement thus initiated by our good friend "Logie" will be followed up by the Planters' Association of Ceylon and by individual planters. If so much tea is drunk in Russia, burdened as the article is with a duty equal to 1s 6d per lb., we may look forward to an enormous increase when a less onerous tariff is adopted by the Russian Government. Not much in this direction, at an early date, however, is to be hoped for from a Government which discredits its own depreciated paper money by refusing to accept its promissory notes and insisting on gold and silver payments. Still reform *must* come, even in Russia. Even as matters stand, her tea market is worthy the careful attention of our planters and merchants.

MR. ELPHINSTONE ON RUSSIA AS A MARKET FOR TEA.

To the Editor,

London, 18th Nov. 1886.

DEAR SIR,—I have for long believed that one of the best markets for our Ceylon Tea could be found in Russia and I accordingly made up my mind to visit St. Petersburg and ascertain for myself what chance there would be for the sale of Ceylon Tea, either by wholesale or retail agency. Through the kindness of a friend of mine, one of the largest merchants and shipowners in the Leith and Petersburg trade, I was enabled to do my journey at a nominal cost and I am satisfied that my fortnight in Russia gave me more *bona fide* information as to the requirements of the trade than any amount of letter-writing would have done. Thinking a short account of my trip may be of interest to some of your readers, I send you a few notes of what I saw and ascertained while in Russia.

I intended leaving Leith by the S. S "Petersburg" but was unable to leave London the day the steamer started and fortunate it was for me as after leaving Leith she had to lay two whole days in Aberleddy Bay, and after that had a fearful passage across the North Sea, arriving fully four days to five days late at Cronstadt—I went *via* Flushing, Hanover and Berlin to St. Petersburg by train. At Cook's office I got a second-class ticket for £9 10 10 which took me right through, and after a most comfortable journey, extending from 8-30 Wednesday evening till 6-15 Saturday evening, I arrived in St. Petersburg. The journey from London to Petersburg is full of interest to anyone who has never travelled that way before, for besides the charm of novelty, there is so much to be seen of real interest.

The well-cultivated canal-divided Holland has much sameness, but is of great interest. Then in Germany one passes through varied scenery, and none of more interest than the Black Country where the coal and iron industries are carried out. This is entirely between Hann and Hanover; Berlin is reached 24 hours after leaving London, another 24 hours brings one to the Russian frontier, and another 24 hours St. Petersburg.

Once into Russia the temperature was sensibly a great coat colder and at St. Petersburg with ordinary English winter clothing the cold goes right through one.

On my arrival I was fortunate enough to secure a most comfortable hotel, the Hotel de France. On the following morning, Sunday, I started with a guide to find the S. S. "Petersburg," as she had then ample time to have arrived, but I had a wild-goose chase, for, after 4 hours' cruising up and down the river among the shipping, I ascertained that she would not come further up than Cronstadt. I can tell you I had a good taste of Russian cold, 15 degrees of frost in St. Petersburg in an open boat with no furcoat is no joke, and I was right glad after cruising about for some time to see "Dundee" on the stern of a steamer. I promptly called on the Captain and experienced not only his kind hospitality in the way of a good hot Scotch dinner, but he also gave me a lift down to Cronstadt, as he informed me none of the Leith vessels came up further. Cronstadt is 23 miles down the river, the Naval Arsenal and the harbour where, until the completion of the canal, all steamers were unloaded and loaded, the river not having deep enough water for heavy draught before the completion of the canal. Cronstadt is the key of St. Petersburg, and in addition to the real island there are several artificial islands on which fortifications are built. From what the older English inhabitants say, Cronstadt ought to have been taken in the Crimean war, but by some mismanagement it was not. I did not find the "Petersburg" and was informed she would not arrive till Monday, so I returned by one of the river boats. Next day I returned to Cronstadt and found the "Petersburg" had arrived. I was thus able to get my box of samples. It would take longer than you would care to read, to narrate all the trouble I had to clear my box of samples. The difficulty lay in my hav-

ing booked the box as passengers' luggage, and not having accompanied the box myself. However, I did at last get the box passed and I do not grudge the time spent, as I ascertained fully all the intricacies of the working of the Custom house. The duty on tea amounts to about 1s 6d (English money) per lb. Russian. A Russian pound is 10 per cent less in weight than an English pound. The duty *must* be paid IN GOLD. The authorities will not accept their own notes, not even if you offered lemon may be added, and all the teas have a more or less artificial aroma, which must have been added by either dried Gardinia flowers or dried Lime leaves. As I said, I cannot speak with certainty, but I believe our inferior tea would suit Russia well, and the flavour now in their teas could, I believe, be easily added in Ceylon if requisite for their disposal. I enclose memo. of samples brought from Petersburg with prices attached. Next mail I will give you London values. It is extraordinary, the quantity of tea which is drunk in Russia and the tea shops in Petersburg and Moscow are as numerous and well distributed as the Public Houses in London. I visited Moscow, but having only one day there I could not find time for seeing the Cremlin and other objects of interest. However, I found out all I wanted about tea. Already some Indian or Ceylon tea has been sold in Moscow, imported by a young Englishman and with a mixture of China has sold well. I mention Indian or Ceylon as he was not certain which it was. He bought it in London from a firm I know. The translation of the Russian advertisement with reference to the tea is as follows:—

Newly Received
Tea from India
The crop 1886
Commenced to be sold at
ROUBLES 2 per lb.
2·20 Koopecks *
3· sold in 1 lb., ½ lb. and ¼ lb. packages.

Indian Tea under the name of Kakwyan (a place in India) is distinguished by its aromatic and soft taste and surpases the Chinese.

Customers outside the town may buy through the post office. All orders executed by

P. Bycloff & Co.,
Moorsuskeen,
Moscow.

Of course, there will be for some time a prejudice against Ceylon and Indian Tea, but that will soon be overcome as in England. A good deal of tea comes from China overland to Moscow and with that means of transport we can certainly compete.

List of prices of teas I brought as samples :—

Petersburg Teas.		Moscow Teas.	
No.	Roubles.	No.	Roubles.
1	8	1	2·68
2	5	2	2·20 (o)
3	4	3	2·

8	2·		
9	1·84		
10	1·60 xx		
11	1·20 Brick Tea, not much used.		

12 Spurious tea made from a shrub growing in Russia used for mixing, 10 k. per lb. Not allowed by Government.

x xx These teas in principal use in Petersburg.

(o) (oo) These teas in principal use in Moscow.

I returned by sea from St. Petersburg ; stormy accross the Baltic, but fine in the North Sea.—Yours faithfully, G. D. ELPHINSTONE.

* A koopeck at present exchange is about 1s 4d ; it is really 100 of a rouble.

TEA PLANTING MANUAL.—In closing a review of *Owen's Manual*, the *Straits Times* says :—"These bright prospects speak volumes for the energy of the Ceylon tea planters who, taking every advantage of the favourable conditions enumerated above, have lifted the Colony out of the slough of depression, into which it had fallen on the collapse of the coffee enterprise. The Manual itself bears every mark of painstaking care. It is full of information on every subject connected with tea planting. Intending tea planters in this quarter will never regret the money spent in procuring copies for their behoof. To them it will prove indispensable indeed."

TEA IN WESTERN DOLOSBAGE is flourishing apace: we have just heard so good a judge as Mr. Gow speak in high terms of the Ardross and Glenalla estates as including some of the most vigorous tea he has seen in the country. On the latter property there is a field of 38 acres planted with seed at stake in 1881 and consequently about five years old, which has given this year so far, close on 1,000 lb.—certainly over 900 lb.—per acre and the tea has had no manure nor does it appear to suffer. Mr Drummond's Gangwarily is also doing well and he has got a splendid crop of cocoa this season; while it is needless to say that Mr. Blackett's far-extending tea fields are cropping. Some experiments in Dolosbage made by Mr. Gow in tea-making—improved fermentation —have resulted very favourably, to judge by the prices got in Mincing Lane for sample invoices.

THE USE OF COFFEE appears to be rapidly declining in England. The reduction of the duty to three-half-pence a pound has had no effect on consumption, and in the year ending 31st March 1886, some 314,000 lb. were consumed less then in the previous year. "The decline is attributed," "says the *Spectator*, "to the comparative difficulty which the poor find in making coffee; but it is quite as likely that the true causes are the declining use of alchohol, and the cheapness of tea and sugar. The bulk of the people prefer tea to coffee. If tea were ever to become really cheap—say, sixpence a pound—nothing else would be drunk ; and it would be drunk all day, cold as well as hot. The taste for it is becoming universal, and distinctly increases with the admixture of the Indian teas, which are rougher, and develop the special 'teacy' flavour."—*Madras Mail.*

ORNAMENTAL TREES AT HAKGALLA.—The following list of ornamental plants supplied by Mr. Nock from Hakgalla to a recent purchaser (R30 cost of all) for planting on a piece of ground at Nuwara Eliya, is of interest as showing what can be procured at the Gardens for a very moderate charge:—

		Height
Conifers or Fir tribe.	100 Frenela rhomboidea—Australian Pine	50-90ft.
	25 Pinus longifolia—Chir Pine ...	60-100ft.
	18 „ sinensis—Chinese Pine	30-40ft.
	6 „ massoniara from China)	30-40 (?)
	18 Cupressus macrocarpa—Citron Pine	150ft.
	18 „ tournefuti looks as though it would be large)	
	12 „ torulosa—Bhootan Cypress	180ft.
	6 „ Lawsoniana—Port Oxford Cypress	100ft.
	6 Thuja Orientalis—Chinese Arborvitæ	18-20ft.
	6 „ Nepalensis	12-20ft. (?)
	12 „ aurea-semper-aurea ...	3-6ft.
	6 „ conpacti	(?)
	6 Tristanea conferta—Queensland Box	50ft.
	6 Fraxinus Americana—Am: White Ash	60-80ft.
	2 Quailaja Saponaria—soap-bark Tree	60ft.
	12 Tecoma velutina—Velvety trumpet flower	12-20ft.
	6 Psidium montanum—(Hard-wooded Jamaica tree)	30-60ft.
	12 Leptospermum scoparium—Broom Tea Tree	12-20ft.
	6 Callistemon rugulosum (Bottle-brush)	10-20ft.
	18 Salix Babylonica—Weeping Willow	40ft.

Correspondence.

To the Editor of the "Ceylon Observer."

COFFEE AND GREEN BUG.

DEAR SIR,—If this bug is more to be feared than leaf-disease, or any other previously known coffee-pest, the different Planters' Associations would do well to collect all the information available with regard to its increase, decrease or stationary character, and publish the same periodically. Coffee is now, or soon will be, so valuable that it is worth even this attention yet. If it is retiring all along the line, I should not be surprized to see a little coffee planting started again in favorite localities

PROPRIETOR.

COCONUT FIBRE DUST.

Colombo, 2nd December 1886.

DEAR SIRS,—Will any of your numerous correspondents give their experiences with that curious substance which we call coconut fibre dust, which comes away from the dry husks of the coconut in the proces of extracting the fibre.

The absorbing properties of this substance are well-known and it is for this reason that I presume it is so extensively employed in gardening.

It would, however, appear that it is applicable to other, and probably more useful purposes, for a young French Chemist, Mr. P. Germain, has brought it to notice in connection with Primary and Secondary Batteries. M. André Reynier, the Electrician to the Société Générale des Téléphones has investigated its uses in connection with electricity.

From a report which has been written by M. Reynier for *L'Electricien*, we gather that "sporique," as its finer variety is termed, is prepared from the husks of the coconut; it has the colour and aspect of coco powder.

The extraordinary properties of this substance arise from its extreme lightness, its specific gravity being represented by the abnormally low figure of 0·08. Under the simple pressure of the hand its volume can easily be reduced to one-third, and even then its density is only about one-fourth that of good sponge. Its absorbing power surpasses that of all other known materials. A given volume of "sporique" can easily be made to take up a volume of liquid equal to itself, without any perceptible increase in the total volume; or, in other words, the volume occupied by "sporique" in the combination is *negligible*.

A good sponge will absorb seven times its own weight of water: "sporique" absorbs 12·5 times its weight of water. The substance has hitherto been found to be insoluble both in acids and in alkalis and in solutions of salts. It is, therefore, evident that it will thus readily lend itself for use in primary or secondary batteries. M. Reynier states that the resistance of the battery is not perceptibly increased by its presence, and it is suggested that by saturating two slabs of the substance it may be employed in two fluid batteries, thus doing away with the porous cell. Not only are liquids thus kept separated and preserved from accidental spilling, but it is also found that the loss from evaporation proceeds much more slowly. It would appear that the substance is certainly worth a trial for the purpose indicated, and I hope the day is not far distant when the heaps of refuse coconut fibre dust now looked upon as worthless may possess a commercial value sufficient to make the export remunerative. Whatever the results, I trust this brief notice of a substance so well-known to us may stimulate enquiry.—Yours faithfully,

ED. B. HURLEY.

TIMBER FOR GUNSTOCKS.

Haldummulla, Dec. 2nd 1886.

DEAR SIR,—I enclose a cutting from the last *Field* on the subject of wood for gunstocks. Perhaps, your botanical correspondent may know whether the tree in question (Orcodaphne bullata) grows in this country. I have myself seen in the Kegalle district trees which emit a sufficiently villainous odour to merit the epithet applied to Orcodaphne; and whilst living in Badulla, I had a gate made of a heavy white wood which always smelt very unpleasantly after a shower of rain. If the Orcodaphne is found in Ceylon it might pay to export the timber for the purpose indicated by the *Field* correspondent.—I am, yours faithfully,

EDWARD F. HOPKINS.

STINKWOOD (ORCODAPHNE BULLATA) FOR GUNSTOCKS.

Sir,—The subject of this excellent wood being used for gunstocks made in this country has recently been mooted in the leading daily paper. As it is of consequence to sportsmen in India, South Africa and its interior, or other parts of the world where climatic influence or rough wear may have to bear on the gunstock, to know the most serviceable, I ask your permission to give in *The Field* a few particulars respecting the Orcodaphne bullata, a wood that cannot be too highly recommended. The orcodaphne is of two shades of colour, a lighter (sometimes almost approaching Hungarian ash), and the darker, ordinarily selected for gunstocks. This has been compared to mahogany, but perhaps it more resembles something between rosewood and American walnut. It is decidedly a handsome wood, and in grain is firm, close and tough; it is not given to warp when seasoned, nor snap across the grip like walnut; in fact, it possesses every merit almost desirable, except being heavier than walnut. In its seasoned state it has not the slightest disagreeable odour. Botanically the tree has been thus described in Hooker's "Botan. Mag." t. 393 l.:—

Orcodaphne bullata, Nees ab E. (stinkhout, stinkwood), much branched, branches divaricating, smooth; leaves, alternate, leathery, elliptical, veiny, netted, glabrous, attenuated into a chanelled stalk, and having at the axils of the lower costals veins, on the underside, deep hollows, ciliated at their edges, and showing on the upper surface corresponding blister-like protuberances; flowers, small, racemose; racemes, lateral or exillary; perianth, 6 parted; lobes, obtuse, deciduous; corolla, none; stamens, 9; grands of the outer stamens large, capitate; style, tapeling; stigma, peltate; berry surrounded at base by the enlarged, thickened, cup-shaped tube of the perianth.

Though this wood was the African oak of Barrow, Dr. Pappe has stated, in his "Silva Capensis" (Cape Town, 1854), the real African oak of commerce is "Oldfieldia africana." I would strongly recommend the leading English gunmakers to have a supply in stock of Orcodaphne bullata, and to suggest its adoption by any customer about to proceed to a hot climate, or requiring a gun or rifle stock for rough work; but it must be observed that the wood has become scarcer, it appears, and is therefore probably dearer than it used to be some years ago.

In a memorandum on the Crown forests of the Cape Colony, published in the *Times*, September 25th 1885, it was stated: "The two kinds of timber most sought for in these forests are "stinkwood" (Orcodaphne bullata) at the Knysna, and "sneezwood" (Pleroxylon utile) in the eastern districts, and these two kinds have been fast disappearing." It is also stated in that memorandum that the Orcodaphne bullata, when cut, possesses the singular property of throwing out from the stump shoots, which again throw out roots descending (*sic*) the old stump.

FREDERIC R. SURTEES.

Boxley Abbey, Sandling, near Maidstone, Oct. 26th.
—*Field*.

[The Ceylon "stink-tree" is thus described in *Ceylon Timber Trees* :—

"Celtis dysodoxylon," Thwaites En. p. 267. *Goorenda*, S. Moon's Cat. p. p. 26 and 32, Nos. 418 and 531 pt. 2. *Urene*, S. ex Ainslie 2 p. 317 *Poodacarapan Puttay* (its bark,) *Tamil*. *Pau de merda*, and *Pau sujo*, Port. A middle-sized tree in the Central Province up to 5,000 feet. This is a notorious tree from the fact that I believe its freshly cut wood has the most abominable and disgusting odour of all plants in the vegetable kingdom. Hermann wrote about it upwards of 200 years ago, but mixed it up with the *Wel-boorenda*, S. ("Clerodendron inerme,") and misled Linnæus and Burmann by so doing. His explanation of the Sinhalese name, and other remarks I give in his own words, as no doubt applying to this tree :—"Ghu stercus humanum notat. *Rhœnda* fœtorem stercoris. Est et alia species arborescens. Alias *Rhœnda* notat proprie lignum sublato cortice cæterisque." Mus. zeyl. p. 23. Thunberg when in Colombo in 1777, gave the following account of it :—

"The stink-tree was called by the Dutch *Stinkhout*, and by the Sinhalese *Urenne*, on account of its disgusting odour, which resides especially in the thick stem and the larger branches. The smell of it so perfectly resembles that of human ordure, that one cannot perceive the smallest difference between them. When the tree is rasped, and the raspings are sprinkled with water, the stench is quite intolerable. It is nevertheless taken internally by the Sinhales, as an efficacious remedy. When scraped fine and mixed with lemon-juice, it is taken internally, as a purifier of the blood in the itch, and other cutaneous eruptions, the body being at the same time anointed with it externally. I was at great pains to procure some blossoms of this tree, in order to ascertain its genus, but was constantly disappointed. Of the Sinhalese, whom I sent out for that purpose far up the country into the woods, I could only obtain some branches without any blossom; from which, however, I could perceive, that the tree was neither the *Anaygris fœtida* nor the *Sterculia fœtida*. I had likewise set some live, but small, plants of this tree in boxes, and carried them with me alive quite to the English channel, where they were totally destroyed, together with several other scarce trees and plants, by cold and storms. Of the wood, I carried with me some pieces to my native country, which, however afterwards lost their scent to that degree, that now not the smallest trace of it can be perceived."—Travels 4 p. p. 234—5. "What this tree absolutely is, becomes a subject for future research. Ain 2 p 318. For Thwaites, therefore, remained the privilege of naming this tree Botanically.]

TEA HAIR.—No. I.

SIR,—This is nothing more than the "fluff" from the pubescent tips of the tea buds, the hairs from the fine pekoe or orange pekoe. It is a provision of Nature for the protection of the young leaf when in embryo. All plants are provided with a protection to the young or embryo leaf or fruit bud. With coffee a resin or gum, coats the blossom and many think when the blossom buds or "spike," as we call it, is burnt it is simply the resin or gum exuded from the plant: a wise provision of nature to protect it from the hot sun. The first fall of rain or genial shower at once dissolves the gum, the burnt blossom bud opens and the snowy white of a beautiful plant in full bloom replaces the burnt spike. All plants have some protection and in many cases the leaves, as with several varieties of cardamoms, retain their pubescence, but the tea shrub throws it off as the leaves develope. This fluff has been shipped from Ceylon as "bloom," it is practically worthless and has never found a market; let the curious try it in the cup. One thing is certain, however, this pubescent fluff is so fine that it will permeate the whole of a tea factory and lodge on every beam and corner and it is not only easily ignited by a match or light carelessly thrown down, but like "punk" or German tinder, once lighted it will smoulder for days and when least expected will break out in a red glowing mass, never flame, but quite sufficient to burn down the factory. The smell of the burning fluff, however, is so pungent that it is readily detected. A few drops of coconut or kerosene oil dropped on the tea hair will or may create spontaneous combustion, like cotton waste it might be in a few hours; therefore, keep your tea factories and especially your machinery and sifters, where there is both oil and fluff, thoroughly clean and free from red dust and the risk of fire will be greatly reduced.

If you have to pluck "banje" you will have proportionately more hair, fluff, pubescence, red dust or bloom, because the "banje" tip the effect of a cold wind or other cause is so tightly wrapped up in its warm pubescent covering, that it is nearly all fluff and only genial showers and a rush of warm sap will set free the imprisoned bud.

J. IRVINE.

P. S.—I may add the tea hair is both interesting and very beautiful under the microscope.

No. II.

December 3rd 1886.

DEAR SIR,—Your article on above subject in paper of 30th is very interesting.

I sometime ago tasted tea hair but did not repeat the experiment. Liquor was very thin in appearance and had no strength, whilst flavour was awful and *nose* of cutturn almost did for me—it was just exactly like something I never heard or thought of before. I tasted it with a view to ascertaining whether or not it could in any way add to strength or flavour of tea, and I came to the conclusion that it did neither. In my opinion it spoils the appearance of finer teas and I have in consequence, ever since trying above experiment, carefully extracted it from my teas and —thrown it away. But if there be a market for it at home, the sooner our Colombo brokers take it up the better. Just fancy having a "tea hair sale"! Of course it's hard rolling that brings out the hair and I have seen so much of it that the sifting cooly was glad to put his head out at window to get a mouthful of fresh air. And I may say in conclusion that if "tea hair" manipulation is to be successfully gone about, Barber's Rollers will yet cut a way for themselves like—Yours truly,

OLD HA(IR)RY.

COCONUT DUST.

Colombo, 8th Dec. 1886.

DEAR SIR,—Referring to your remarks on Mr. Hurley's letter on the question of utilizing coconut fibre dust for scientific purposes, I may mention that about three years ago I made some experiments to ascertain its fertilizing value. I got some from Horrekelly and put it into forty cement barrels. I mixed the coir with liquid manure in varying quantities and allowed the barrels to stand for a year until the coir decomposed. After the expiration of that time I planted vegetables in the barrels, they grew pretty well, but not altogether satisfactorily. I therefore turned out the contents of one of them, and found it full of large white grub. I then turned out all the others and I should say there was a hundred in each barrel. The crows had a jolly feast of them.

This facility for breeding grubs appears to me to be a great objection to the use of coir in bulk as a fertiliser, when it is formed into one. It can, however, no doubt, be used very advantageously

by horticulturists in those cases where the use of decayed leaves or wood is beneficial especially with ferns.

At the present moment I have ten large pots filled with coir, mixed with liquid manure, in which brinjals are planted; they are growing fairly well, but nothing like as well as those in pots with sandy soil and the same quantity of manure. The objection to the use of coir as a top dressing for coconuts, is, that it retains the moisture, and thus draws up all the young roots to the surface and finding no sustenance in it, they die off especially in dry weather. Simply put on the surface, it appears to be very injurious, indeed, in a dry climate like Horrekelley, all surface manuring, which draws up the roots, instead of allowing them to seek the moisture lower down, must in the *long run* be injurious.

If the coir is put into holes, the remote benefit from it, when it becomes humus, does not compensate for the immediate expense of burying it.

What the late Mr. D. Wilson contended for was, I believe, that the coir dust without being mixed with manure, was not of any immediate value as a fertilizer, and that the Horrekelley sand was a better and cheaper medium for applying manures than coir, with fewer drawbacks.

No one who knew Mr. Wilson's inventive genius, and mania for experimenting almost equal to my own, can doubt, that every method of utilizing the vast mounds of coir at Horrekelley was employed, and when such a man came to the conclusion that the Horrekelley fibre dust could not be beneficially used, it is a good excuse for his successors, not doing more than experiment with it; whichI believe they have done.—Yours truly, C. S.

TEA-MAKING AND TEA PRICES: LARGE AND SMALL BREAKS; USEFUL HINTS.

Nahalma, 13th Dec.

DEAR SIR,—I have read in your paper of 8th, Messrs. Forbes and Walker's letter anent tea prices; also your footnote, in which you remark "how easy it is especially when dealing with small quantities, to show exceptional rates. Averages for large quantities are doubtless the true test." Seeing that so many, even when dealing with small quantities, fail to show exceptional rates, it would be a great boon were you to point out the very easy way you allude to. Nahalma tea goes forward in small quantities, because it is found convenient to dispatch it weekly, by coolies going for their rice; but as every sale so far, has proved that buyers appreciate this tea, I cannot see how the "small quantities' has anything to do with it. If it has, the Brokers would only be doing their duty if they advised all local sellers to send in their teas weekly.

But granting that larger quantities are a better test of value, I send you my average for the month of November. Messrs. Lee, Hedges & Co. sold for me in that month 4,242 lb for R3,437·77, or an average of over 81 cts. per lb. If Kaluganga, Glentaaffe and G. V. (in dia:) have done better, I congratulate the owners.

I note Messrs. Forbes & Walker say, "moreover Kaluganga, and G. V. breaks contain everything made, we do not think the others do." That the Colombo world may be furnished with proof of the great penetration and astuteness of these gentlemen of the hammer, I admit that my last break did not contain everything made. Messrs. Wilson & Co., sold 30 lb at 90 cts. and I sold 20 lb. damaged dust at 30 cts! But including those large outside sales, Nahalma average for Nov. is 81 cts. Of course, I agree with what Mr. Forbes has assured many of my friends, that the tea sold much in excess of its value,

I hope you will give this opinion of our leading Colombo broker publicity in your *Overland*, as I see by your issue of 10th that London buyers are also labouring under a delusion with regard to this tea. Nahalma average, you give in the London sales as highest, except that of Riverside; and in the grades sold from Riverside, Nahalma prices are considerably higher than those of that estate! —Yours &c. WM. MACKENZIE.

[We learn that all Mr. Mackenzie's tea is sold in Colombo, that is all made at Nahalma since they began to manufacture their leaf, with the exception of a small quantity of tippings taken after pruning which is sold to a native. In Nov. Mr. Mackenzie made at the rate of 550 lb. per acre from 80 acres two years and four months old. Quantity and quality are due to good work in opening those 80 acres, good jât and good soil. The credit for choice of land, seed and work are due to Messrs. Forsythe and Bett; but Mr. Mackenzie is responsible for the manufacture and he may well be congratulated.—ED.]

TEAS FOR THE AMERICAN MARKET.

SIR,—I have just received the accompanying samples of Oolong from Foochow that planters may see the class of tea required for the American market.

Planters wishing to examine these teas for practical purposes can do so at my office.

Kindly return samples at your convenience.

At foot I give report.—Yours faithfully,

FRANCIS F. STREET.

Colombo 14th Dec. 1886,

The following is the report alluded to above:—

Box No.	Grade	Character of leaf	Liquor	About value per lb.
43	Fully fair cargo	Blackish, rather stalky and yellow	Fair brisk	20 dollar-cents
170	Fully good to Superior	Good blackish	On fine	28 ,,
62	Fully fine	Fragrant blackish little stalky	Fine flavor	36 ,,
89	Finest to choice	Fine fragrance blackish even wiry little stalky	Choice	50 ,,

These teas are grown in Saryune country.

The export of Oolong to America to 12th of last month was 15,630,000 lb. against 17,250,000 lb. same date last year, the former being more than three times the export of Congou—the consumption of which is comparatively small—the figures from all China this season only reaching some 5 million lb. to same date, against 3½ previous season. To the above has to be added the export of green teas from China and Japan, some 34 million lb. to 12th November.—Yours faithfully,

FRANCIS F. STREET.

RICINUS COMMUNIS CULTIVATION IN THE UNITED STATES.—According to the *Oil, Paint, and Drug Reporter*, there is a belief among American commerical men that there are millions in cultivating the *Ricinus communis* and extending the castor oil industry. Two new companies for this purpose have been started in the south, and there are many inquiries for particulars regarding the culture of the castor plant. It is claimed in the South that the farmer can cultivate the castor seed on his poorest land and make more money than with cotton on the richest bottom lands, and at the same time command cash for every load. In Texas, twenty-five farmers were furnished with seed this season and guaranteed the full St. Louis price for the seeds, which to-day is $1·70 per bushel. Some years ago castor oil was so abundant in the South, that it was principally used for illuminating purposes, but other more profitable crops gradually displaced it, and the revival of interest in the article may be a repetition of history, as larger production means lower prices,

THE DRY ROT FUNGUS.

MERULIUS LACHRYMANS.—The dry rot fungus is one of the most widespread and destructive of all fungi. It is espe ially common and well known on the squared timber of ill-ventilated buildings, and from dressed wood it will quickly spread to walls, whether built of stone, brick, or concrete; it will often grow through the mortar of a thick wall, and perfect itself on the bricks both outside and inside. We have seen it growing on damp concrete between the girders of iron fire-proof floors, and seen it spread from wood on to plate-glass, and perfect itself on the latter substance whilst drawing its nourishment from the wood. In wine cellars it will spread from the wood work and walls to the bins and even to the corks of wine bottles. The mycelium of the fungus will luxuriate between the cork and the neck of the bottle; a slight attack of this sort is said to make the wine "corky."

The dry rot fungus prefers the squared unpolished wood of coniferous trees as a substratum on which to luxuriate, but we have seen it on polished Mahogany, and it will spread from other woods to Teak and destroy Teak-built ships. It is not uncommon on the fallen timber of Pine woods, but, like some other plants, it has long been peculiarly associated with man and his dwellings. It destroys churches, houses, ships, bridges, railway sleepers, telegraph poles, and many other objects. It must not be assumed, however, that the true dry rot fungus is the sole, depredator. There are twelve British species of Merulius, inclusive of M. lachrymans, and several of these appear at times in our houses. We have seen M. coriun almost as destructive as M. lachrymans. In addition to the dry rot fungi, it is by no means uncommon to find buildings destroyed by different species of Polyporus, Lentinus, and other fungi.

Merulius was so named by Fries on account of the shallow pores or wrinkles of the spore-producing surface, and lachrymans on account of the drops of moisture, like tears, which stud the fruiting surface of the fungus when growing in full vigour.

The upper part of the accompanying illustration (fig. 125, p. 629) shows a small plant of a dry-rot fungus; the circumference is white or livid in colour, and thick and fleshy. The whole plant is fleshy and almost meaty when cut. The odour is very strong and Mushroom-like. The livid rim consists of transparent interwoven fungus tubes and cells as illustrated, enlarged 400 diameters at C; tubes of this nature and size also form the entire base of the fungus. The fungus cells or tubes break down the substance of the wood upon which they grow and transport the juices of the wood to the fungus for nourishment. The central part of the surface of the Merulius is rich reddish-brown in colour and indented with coarse shallow pores or wrinkles, as illustrated in the upper figure. A reddish livid juice is exuded from all parts of this fungus; this juice stains every object with which it comes in contact. A section of the wrinkled surface is shown natural size at A. Every part of the reddish wrinkled surface produces spores, the same portion distills drops of moisture, chiefly derived from the wood upon which the fungus grows. By breaking down the substance of the wood and extracting its juices, the timber is ultimately left in a state little better than dry sawdust or powder, hence the popular name of "dry rot," a curious name for a naturally wet or "weeping" fungus. If a very small fragment is cut from the wrinkled surface of an example of Merulius lachrymans, and a very thin transparent slice is then removed from the exposed surface and examined with a microscope it will be seen, if enlarged 400 diameters, as at B. The coarse transparent tubes of the base of the fungus become much narrower as they gradually grow up towards the brown wrinkled surface, and in the latter position they support tall colourless cells or bladders as shown; each tall bladder throws out four minute horns or spore-supporters at its apex, and on each horn an ovel spore of rich brown colour is borne, as illustrated. When the ripe spores fall from their supports on to damp wood in close confined air, they germinate and throw out fine mycelial tubes, the tubes penetrate the sweating wood and soon produce a perfect dry rot fungus by drawing from the wood the material necessary for the life and well-being of the fungus. The fungus continues to grow till the supporting timber is completely exhausted and reduced to tinder or dust; the fungus itself now perishes, but not before it has produced myriads of spores which have probably been carried away by currents of air to destroy other damp wood, or wood in damp places. The dry rot fungus will under favourable conditions attain a very large size, its dimensions appear, in fact, to be only limited by the size of the object or material on which it grows; we have seen huge thick growths, like large pancakes, a yard or more in diameter. As the growth of the fungus is as rapid as it is exhaustive, it follows that when dry not once gets a footing in an ill-ventilated building the work of destruction is rapid and complete. Floors rot, roofs fall, galleries collapse, and window sashes turn to powder and drop out. As the air of the infested building is full of dry rot spores it is useless to replace old wood with new, for new wood merely supplies fresh food for the fungus. Sometimes improved ventilation is beneficial but it is impossible to really cure dry rot, and almost if not quite impossible to stop its progress when once well started, as the fungus is always ready to invade various other materials in addition to wood. To keep well clear of dry rot its attacks should be prevented.

Petroleum will quickly destroy the dry-rot fungus, and prevent its reappearance, but it is so extremely dangerous to thoroughly soak a building or ship with petroleum, that the remedy is as bad or worse than the disease. Burnett's mode of preserving timber is by the application of chloride of zinc; this, without injuring the wood, has a tendency to protect it from destruction. Kyan's method (hence the term kyanising) consists of the use corrosive sublimatic, but this material can only be applied effectually on dry (as opposed to wet or damp) timber. Margary's method (hence the term margarising) consits in the application of the sulphate or other salts of copper. Bethell's method, which is the best, consists of "creosoting" the wood, by the application of coal tar or oil of tar. This substance does not get driven out of timber by moisture, whereas all the salts of metals fail in this direction. Coal tar, a material which looks like treacle, is derived from coal in the process of gas-making. When coal tar is distilled, light oils, heavy oils, and pitch (the residuum) are produced: the oils heavier than water are the "creosote" of Bethell. The most effective heavy creosote for timber preservation is derived from the best Newcastle coals, a less valuable material is distilled from Midland coals. A good deal of our knowlege of wood preservation, as possessed at the present day, seems to have been known in part at least to the ancient Egyptians, who filled the pores of their wooden statues, columns, &c.,—to say nothing of the grand-mummies (!),—with oils and bitumen.

Mr. Boulton states that Fir timber is capable of taking up from 60 to 150 gallons of water to the load of 50 cubic feet, he also states that he has extracted 50 gallons of water from a load of railway sleepers. In the process of creosoting the timber is first made quite dry and the extracted water is then replaced under heavy pressure, by oil of tar. More than one patent has been taken out for "creosoting," and the efficacy or otherwise of creosoted timber depends on the quality and constituents of the oil of tar and the method of forcing it into the pores of the timber.

The proper antiseptic treatment of wood is a subject of the highest importance when studied in reference to the preservation of telegraph posts, railway sleepers, piles for harbours, ships' timbers, and to cases where wood must of necessity be exposed to the action of water, damp earth, or moist air, but in buildings which are designed to be constantly kept dry no creosoting is necessary. In horticultural

buildings, however, where the contained air is always moist, the dry rot fungus, or one or other of its allies, often makes sad havoc. Tiles, iron, &c., are now so much used in greenhouses that wood often only occupies a minor place in their construction.

Without some antiseptic treatment it is impossible to prevent the decay of wood when as in ships it is placed in water or as in posts, and piles, buried in the ground, but there is no reason why our public and private buildings should be so constantly destroyed by the dry rot fungus. Without damp stagnant air and wood saturated with moisture, Merulius lacrymans cannot exist; keep these evils away, and no dry-rot will be seen.

It is very necessary that foundations should be well built with cement on concrete or rock, that all the basements should be thoroughly well ventilated, so that currents of air may be able to pass through windows or other openings. The timber used for building purposes should be perfectly sound and dry. All good builders are aware of the best methods for preventing damp rising from basements, or passing up or through walls; and it is only by the culpable neglect of well-known commonsense precautions that so many public and private buildings are destroyed by the dry-rot fungus.

We are being constantly asked for a "cure" of dry-rot, and we often find ourselves without patience to write a reply. It is as impossible to "cure" rotten timber as to "cure" a rotten animal; when advanced in decay both are too far gone for cure. commonsense must be used in the prevention of the attacks of the dry-rot fungus.

Dr. J. Gwyn Jeffreys says (*British Conchology* vol. i., p. 130, under "Limax") that slugs in cellars will eat the dry-rot fungus. WORTHINGTON G. SMITH, Dunstable.—*Gardeners' Chronicle.*

CULTIVATION OF TEA IN FORMOSA AND CHEHKIANG.

Tea cultivation in North Formosa is chiefly confined to the hills, and though a good supply is grown within three miles of Tamsui, the main centre of the production is in the hills some twenty miles to the south. The soil there is generally a kind of reddish yellow sticky clay, in wet weather resembling cream, and extremely slippery; this is on the lower and middle slopes, that of the upper is inferior, and these slopes are often so steep that it is difficult to understand how it is possible to till them. The Commissioner of Customs at Tamsui says that everywhere one is struck by the amount of new ground which is being broken up in order to set more tea. The first thing is to clear away the long grass and brushwood, cutting down the trees, digging up the roots, burning them, and planting indigo. When this plant has run for some little time it is replaced by tea, and in the matter of planting, the plan adopted in Formosa differs very considerably from that followed in many of the other tea districts. There a large quantity is produced by means of slips or cuttings, as well as by seeds, and no manure is used, while in the Ningpo and Tientai districts seeds alone are employed. In the latter district several holes are made, and five or six seeds are dropped into each and covered up, and liquid manure or wood ash is then applied. During the following three years the ground is carefully weeded and manured; at the end of this period the young plants are separated from the older ones. If carefully tended and pruned of the old wood, a bush will last many years. The first picking takes place generally in February, and the second in May. The soil is light and friable, being composed of a mixture of sand and vegetable mould. In the Ningpo district the most luxuriant tea is that of the alluvial plain, and is grown between rows of mulberries. At Tientai, in the province of Chehkiang, Commissioner Hancock states that the finest tea is grown, the soil being light and sandy, corresponding in a great measure to that of the Bohea mountains. The following is the method of cultivation practised:—Pieces of bamboo about six inches long are placed in holes made in the ground, and about fifteen seeds put into each tube, the tubes are then filled up with earth; this operation being performed in the month of September. In the following June some of the seeds having germinated, appear as small plants at the top of the bamboo which is then removed. The growth is at the rate of about four inches a year, and the first picking takes place four years after planting. There is only one picking each year, in April, but lower down on the mountains the first takes place when the plants are three years old, and there are as many as three in the year. The plants are not considered to have attained maturity until they are ten years old; they are never changed, but from time to time the decayed wood is cut away. In the Formosa tea plantations little attention appears to be paid to drainage on the steepest slopes; the furrows, instead of being run in a slant, are generally carried horizontally, in consequence of which a more direct barrier is placed against the descent of water during heavy rains, so that in some places where the soil is stiff, the water remains, while in others the soil is swept away. The distance at which the plants are set apart differs very considerably, according to district—in some places they are placed at intervals of thirty inches, which, allowing for the spread of each bush and the necessary ploughing between the rows, is as close as practicable. In Formosa the advantages of soil and climate are so great that there are often no less than seven pickings in the course of the year, the three first being the best, while in the Ningpo district there are never more than three.—*Journal of the Society of Arts.*

NOXIOUS INSECTS.

Every person of observant habits who has had opportunities of watching fruit trees during spring and summer must have noticed that the benefits which they afford are not at all confined to the service of man, but extend also to the provision of homes and nutriment for a great variety of insects, which as a rule, are hatched from ova deposited in the flower buds when these are scarcely formed, and devour the fruit before it comes to maturity. Every schoolboy who has gone in quest of black-berries or nuts, is aware that the former are scarcely ever free from maggots, and that the proportion of nuts spoiled in like manner is very appreciable; but an adequate conception of the importance of fruit-destroying insects, of the numbers in which they exist, and of the extent, measured by a pecuniary standard, of the damage which they inflict, is quite a recent addition to the sum of human knowledge. At the same time, it has been made apparent that fruit-growing is an industry which may become extremely helpful to the depressed agricultural interest; and many landowners, among whom Lord Sudeley holds a prominent place, are endeavouring, alike by precept and example, to direct the attention of their tenants to the profits which may be thus obtained. The number and vitality of living organisms will always be in proportion to the abundance of their food supplies; and hence it can be no matter for surprise if fruit-growing, as it is rendered a more and more important branch of agriculture, should be more and more liable to the attacks of creature whom we, in our cynical indifference to their comfort and welfare, are wont to describe as "pests;" while they, it may be hoped or imagined, return good for evil to the extent of recognizing the fruit-grower as a benefactor. However this may be, it is at least certain that ravages, which may be only annoying and disappointing when they are confined to a pleasure-garden, or to one which, although worked for profit, is little more than an ornamental appendage to the serious business of a farm, may become almost ruinous when the garden itself constitutes the farm, and when the crops which the insects destroy are those on which the hopes of the cultivator are based. In view of these considerations, the Agricultural Department of the Privy Council, has acted

wisely in devoting special attention to the insects which are injurious to crops, whether of hops, corn, or fruit; and we have before us today the third of a series of reports upon the subject, prepared for the Privy Council by Mr. Whitehead, and dealing specially with the enemies of fruit. We also publish a letter from the same eminent authority, in which he warns farmers of the injury likely to be produced by the attacks of the "Hessian fly" upon wheat. It is very evident that the enemies to agriculture which are thus described, although individually insignificant, are really very formidable from their numbers, their voracity, and their power of reproducing their kind as an affliction for future seasons; and that no care or pains should be spared in the endeavour to compass their destruction. In the attainment of this end, the science of entomology is calculated to render most important help; since a knowledge of the aspects, the habits, and the metamorphoses of the peccant insects is plainly essential to the conduct of a campaign against them.

In a general way, it may be stated that the life history of an insect destructive to fruit is, that the adult female deposits an ovum in the young flower bud, at such a time that the larva may emerge when the germ of the fruit is in course of formation, and fit to furnish a nutritive and succulent meal. The larva pursues its depredations with great caution and judgment, not killing the goose which lays for it the golden eggs, but carefully abstaining from any attack upon the actual germ, the vital portion of the immature fruit, as long as there is anything else to be consumed. When the germ itself is devoured, famine may be said to impend over the larva, but by that time it has attained a considerable growth and an enlarged capacity for independent action, and it seeks new worlds to conquer. When, as in the nut tree, the once tender fruit husk has become hard, and encloses the maggot in a shell, the maggot is provided with jaws of corresponding strength and sharpness, insomuch that it can gnaw a hole through the covering and thus make its escape. It is almost annoying to read that, in the majority of cases, the creature has become so fat as to experience some difficulty in squeezing its body through the aperture which is gauged by the diameter of its head; but this difficulty seems usually to be overcome. In fruits which have the eatable portions unprotected and external, as in the raspberry, strawberry, and blackberry, the satiated maggot has only to drop off when its larder shows signs of exhaustion; and in almost every case it seems to reach the ground, sometimes having but a short distance to fall, sometimes lowering itself cautiously by the aid of a silken thread. On reaching the ground, it seldom travels far, but usually buries itself at the foot of the plant on which it has been fed, and awaits the transformations which will convert it into a winged insect, when it will rise again, prepared either to deposit the ova which will produce a fresh generation upon the same hapless tree to which it was itself indebted for food and shelter, or to go further afield in search of another victim. In some cases the larvæ do not reach the ground at all, but take refuge in chinks of the bark, and there undergo their changes; and in some their attacks are not directed to the fruit, but roots are gnawed and injured by larvæ which have sprung from ova originally deposited in the ground, and have always been subterranean in their habits. In every case, however, it seems to be the ground, and especially the ground close to the stem of the affected plant, which affords the chief harbour for these insidious and formidable enemies.

In order to minimize the evils produced by these creatures, it is in the first place necessary that fruit-growers, and farmers generally, should learn what it is that insects do, and should no longer attribute to unknown cause the mischief which they so constantly produce. Not only the Privy Council, but also the Royal Agricultural Society, has taken much pains to spread abroad the required information; and the writings of Miss Ormerod, for the latter body, cannot be passed over without appreciative notice. Thanks to her and to Mr. Whitehead, as well as to the labours of American and other entomologists, there is now but little excuse for any faliure to recognize the attacks of insects; and considerable progress has been made in the direction of measures of prevention. All authorities agree in attributing to certain small birds, especially to titmice, an excellent appetite for the destroyers, and a remarkable faculty for discovering them; and it is also said that they are a prey to various other enemies, even to parasites, who live upon their small bodies, and inflict upon them, it may almost be hoped, something of the annoyance which they cause to others. Agriculturists, however, have but a restricted confidence in small birds of any kind, and would generally be more disposed to apply them to culinary uses than to preserve them in their fields or gardens; and, in support of this almost instinctive feeling, it must be admitted that even a titmouse, when searching for a delicate morsel within the folds of a half-expanded blossom, would be likely to handle it with an amount of roughness which might well prove detrimental to its future prospects. On the whole, the best hope of dealing successfully with the "pests" seems to be derived from the *habitat* of the larvæ in the earth, where they are more or less accessible to mechanical and chemical treatment. To this end it is recommended that they should, as much as possible, be deprived of intervening or neighbouring harbour—that is to say, that all grass and herbage around the roots of trees or plants should be kept closely cut, or, what is still better, eaten down by sheep, and that no straw or farm litter should be placed upon the ground even in strawberry beds—to the abandonment of the custom, which prevails in many places, of putting down straw to preserve the berries from being soiled by contact with the earth. On the same principle, cover for the larvæ is to be destroyed as far as possible by scraping or almost grooming the trunks and larger branches of trees so as to remove cracked and rugged bark; and, when these precautions have been adopted, the ground at the foot of the trees should be loosened and turned up by forks and the soil saturated with various unsavoury mixtures, ranging from soap suds to petroleum. Compounds destructive to insect life or comfort may also be applied to the upper parts of large trees by various mechanical means; due care being taken, in the use of hellebore or other active poisons, as well as in the use of petroleum or other strongly flavoured liquids or mixtures, that they are not applied in such a manner as to adhere to the fruit and to render it either hurtful or nauseous. By such means as these, used with due care and circumspection, there seems to be no doubt but that much good may be effected, of course not from the point of view of the insects; and it is further probable that great importance should be attached to the employment of all possible precautions in small gardens, where all sorts of measures hostile to insects can be conducted more efficiently than is possible on a larger scale, and from whence it may fairly be surmised, fresh generations of destroyers may not unfrequetly take their flight in order to extend their destructiveness to localities far beyond the narrow limits of their original birthplace.—London *Times*.

MANURING.

All attempts to improve the nature of a soil should have for their object *the bringing it to a state of loam*, by the addition of those substances which are deficient. A loamy soil requires less dung to keep it in heart than either clay or sand; for which it is favourable to the process by which organic matter buried deep in the soil is converted into *insoluble humus*; it also permits that part of it which is nearer the surface, to attract *oxygen* from the air, and thus it is converted into a *soluble extract*, which is to the roots of plants what the *milk of animals* is to their young, or ready-made food easily converted into vegetable juices.

The mineral elements of soils become parts of plants, *Life modifies chemical laws, and converts inorganic matter into organic.*

The fertility of a soil is dependent on other things besides its chemical composition. We must consider the office it performs is twofold, namely, (1) to retain the plant firmly in the position most favourable to its growth, and (2) to supply a certain amount of food. Hence *mechanical texture* becomes a matter of great importance; it must be *firm* enough to afford the proper degree of *support*, and at the same time *loose* enough to allow the delicate fibres of the rootlets to extend themselves and also access of air to take place, without which the plant cannot live. It must be of such a texture as to retain, for a cosiderable period, the water which falls on it and at the same time *porous* enough to suffer the excess to *drain away:* otherwise the roots of the plants will rot. It is for these reasons that the nature of the solid substratum at some depth beneath the soil must be borne in mind. These and other things, such, for example, as the condition of the surface with respect to its *absorbent* power for heat, all tend greatly to complicate the subject, and render decisions concerning the comparative value of different lands, founded on merely chemical evidence, exceedingly prone to error.

The great essential principle to be sought for in manures is this great law of nature, that *substances strengthen vegetation mainly by their contents of nitrogen.*

In *dung* and in *liquid manures*, the *nitrogenous* matter is partly combined with *hydrogen*, and has thus become *ammonia.* Farm-yard dung contains *all* the principles withdrawn from the soil by the growth of plants: the decomposed *straw* furnishes *silica* in a minute state of division, still having with it a little *potash* and various *saline* substances. The *solid animal extrements* contain abundance of earthy *phosphates*, while the *urine* gives up by its putrefaction at once *carbonate of ammonia* and *more phosphate*, besides smaller portions of other principles. The only thing at all *defective* is *potash*, and that frequently exists plentifully in the soil, and is gradually liberated by disintegration.

Solid animal manures should not be allowed to putrefy in heaps *above ground*, because a great portion of the manuring matter, in that case, assumes the *state* of *gas* and is *wasted.* In the heap, previous to fermentation, the nitrogen, the essential element of ammonia, and of supreme value to the planter, is variously combined with carbon, oxygen and hydrogen; but when it leaves its former arrangement in obedience to the action of decaying bodies, it uniformly adapts one and only one, new one. *Every nitrogenous compound exposed to air and moisture liberates its nitrogen to unite with free hydrogen and form ammonia.* This is a *principle of fermentation* which admits of no exception. The true economy of farm-yard manure may be thus indicated; *nothing must be allowed to run away in the form of a fluid, or to fly away in the disguise of a smell.* Therefore, we must store the dung daily in proper pits under shelter.

The cow-sheds, of whatever material the walls and roof may consist, as long as ventilation is ensured, must be floored with *pucca* terrace flooring, paving stones, tiles, bricks, concrete, and Portland cement, or planks, and must have a gentle slope towards a gutter running down the centre. In this manner not a particle of dung or drop of urine and *washings* can run to waste. At a convenient distance, though as close as possible, let the manure pits may be made. The best plan is to have the manure shed parallel to the cow-shed, on the slope of a hill immediately above or below it. The pits, arranged side by side, should if possible be floored and lined with masonry, if not possible with hard moss, being previously well puddled. They should be made as water-tight as possible. The cowherds should daily collect the dung and litter, and spread it evenly in a pit, also spreading a few inches of *dry* earth, of which a heap should be collected and stored in an adjoining shed in dry weather, over the mass, then tread it well down. The gutter running down the middle of the cow-shed, should either be connected with the manure shed or end in a spout, under which tubs, or large earthen bowls should be placed. The urine and washings, thus collected, should be poured over the dung and litter previous to the dry earth being stamped in. If no litter is used, any grass will do, though paddy straw is the best. When one pit gets filled up with these daily layers of dung, litter, and earth, cover all up with another good layer of earth and turves, and commence filling up the next pit. These pits should be *emptied* in the *same order* they are *filled*, and only *wooden* rakes and implements should be used.

Every description of sweepings, stable litter, elephant's dung and litter, and all the ashes from the factory and cooly lines should be carefully collected and immured in the manure pits along with the dung from the cow-sheds. Dead bodies of animals, and excrements objectionable to the caste prejudices of the coolies, can well be disposed of by being burned anywhere about the plantation among the bushes with a good sprinkling of *lime* if possible.

Ashes.—The really enormous amount of this valuable manure daily prepared in the factory, engine-house, cook-room and, last but not least, cooly lines, and generally wasted or frittered away, is lamentable on most plantations. Every particle of ash should be carefully collected, stored along with the charcoal dust and sweepings of the charcoal godowns in a convenient, *water-tight* shed, for manurial application during the cold season. All the wood of the tea prunings should be gathered and burnt in bare patches all about the plantation, and applied to the neighbouring bushes. This is really *returning the actual elements* of which the tea bush is composed.

Lime is abundant and cheap in some tea districts as Sylhet, Cachar, and the Darjeeling Terai, and is a most valuable manure. Soils and sub-soils, far below the reach of ordinary cultivation, always contain a very sensible quantity of *ammonia.* The action of lime, in the presence of water, is to set free from the soil as nearly as possible one-half of the ammonia. The application of lime on cold, spongy marshy soil is most profitable. The chemical action of lime, and the effect which it produces as a manure, appear to be of two kinds. On the one hand it acts upon vegetable mould, accelerating its decomposition and rendering it soluble and then fits it to enter the roots of plants. Lime deprives some mould of its *acidity*, and renders it fertilizing. But, on the other hand, there is every probability that, by means of its *carbonic acid*, lime produces some other effect, and furnishes the plants with some nutritive matter. The roots of certain plants, specially tap-rooted ones like the tea plant, appear to have the faculty of depriving lime of its carbonic acid, which it immediately *re-absorbs* in equal proportion *from the atmosphere*,—boring through limestone in its hunger for lime.—*Indian Tea Gazette.*

DAVIDSON'S No. 1 AND T "SIROCCOS."

To the Editor of THE HOME AND COLONIAL MAIL.

SIR.—In the issue of *The Indian Planters' Gazette* of 19th Oct. ult., there appears a letter signed "Cor," in which my No. 1 "Siroccos" are highly praised; but in referring to the T shaped "Siroccos," "Cor" says that, "although they (the T "Siroccos") do more work, they do not do as good work as the No. 1;" and he goes on to say that he thinks the causes for this are, that in the T "Sirocco" the top row of trays being exposed to the air, their temperature in consequence of this remains comparatively low, and, therefore, the damp leaf coming freshly into the machine does not receive a sufficiently sharp heat to promptly check fermentation.

Although I do not quite agree with "Cor" as to the particular causes he assigns for the effects described, probably those of your readers who have an interest in the subject, and who may have seen his letter, will be further interested to know that the objections to the T "Sirocco" therein cited are now altogether disposed of in my present make of the apparatus.

The top of the drying chamber is now closed in with perforated plates, and a portion of the fresh hot air from the stove is, in the large size of the

apparatus, now delivered *direct* to the upper tier of trays, without having to pass at all through the lower trays, so that all the top trays receive a very sharp heat indeed, and a prompt and effective check to fermentation is given the moment the fresh tray of leaf goes into the drier. In this respect the new T "Sirocco" has a considerable advantage over the original No. 1, for in them the whole of the air has to pass through three trays before reaching the wet roll on the last tray put in.

The perforated cover is so adjusted that it regulates effectively the passage of the hot air up through the trays, and an exceedingly equal distribution of the heat from end to end of the drying chamber is the result. It required a series of carefully worked experiments extending over several months to get at the proper adjustment of this cover and its perforations, for no cover at all gives better results than one wrongly placed or with an incorrect arrangement and area of perforations.

When I at last got the cover correctly adjusted it proved highly beneficial to the apparatus, not only by increasing the evaporative power, but by enabling the stove to keep up the requisite temperature for the drying with about half the fuel that is necessary when no cover is used, and as the stove is constantly being worked at a greatly reduced temperature, the castings in it suffer so little from the effects of the fire, that they will wear three or four times longer than formerly.

The perforated covers can, with great advantage, be applied to existing No. 3 and T "Siroccos," as well as to No. 1's, altered to T shape; but for particulars of these, and the other very considerable improvements made in the apparatus this season, I must refer your readers to my new advertisements and circulars, as this letter is only intended as a reply to the particular objections raised by "Cor" to the T "Sirocco" of last and previous seasons' make.—Yours faithfully, S. C. DAVIDSON, "Sirocco" Works, Belfast, Nov. 15th, 1886.

[In reference to the above letter, we would call our readers' attention to Mr. Davidson's new advertisement in this issue. A very perfect little working model of the new type is now on view at the offices of the Planters' Stores Agency Company, Limited, 1, Great Winchester Street, E. C., and will, doutless, create quite a sensation among those interested, as the recent improvements, when added, are said to double the outturn of the "Siroccos" now in use.]

BRICK TEA.

Elsewhere will be found an extract from the *Englishman* of 24th November on the brick tea of Szechuen, largely used in Thibet. The writer of the article has nothing new to say regarding the brick tea: in fact, he simply quotes Mr. E. Colborne Baber's description of its manufacture, and does not quote Mr. Baber's equally valuable account of how the Thibetans prepare their tea, nor the very important statement that Chinese brick tea prepared for use by Thibetans is an infusion difficult to characterise. Baber describes it as "like English tea with rich milk, but without any sugar or *tea*," and "yet," he adds, "nobody would mistake it for milk and water; for the tea principle affects the flavour, while itself becoming modified into some un-tea-like astringent. It is evident that astringency is the property desired, seeing that the many thousand Thibetans who cannot afford tea use oak bark." The only point of interest in the article is the statement that Thibetan coolies laden with tea from Szechuen are disposing of their loads in the Darjeeling Bazaar "at higher prices than the best Indian tea can command.' The writer states that "it seems almost incredible that our planters should allow such a state of things to continue under their very noses," and, again, the article goes on, "Meanwhile our planters, who are now allowing the prunings of their gardens to be taken away and used as fuel, might make a few experiments, in brick tea manufacture, with the immediate object of displacing the Chinese article that is now consumed in the midst of their own gardens; and with the further view of being in a position, when the time arrives (safe reservation) to supply the vast market north of the Himalayas with Indian tea suited to the palate of the Thibetans." We do not say that Darjeeling and Assam planters should not, when time and means afford opportunity, experiment in brick tea; but the writer, in common with others who at intervals urge the Indian planter to plunge into this hypothetical brick tea trade which is conveniently and clearly described as a "vast market north of the Himalayas," does not seem to realize that the manufacture, of brick tea by the Indian planter practically implies a new process of manufacture, new apparatus, new appliances, new methods, in short everything new; and that the knowledge on which this new brick tea industry is to be built up is of the vaguest and most meagre kind. It seems to us that the immediate business of the Indian tea planter is to avail himself of the experience he has already gained in growing and manufacturing tea for the European and Colonial markets, to beat the inferior qualities of the China article out of the field. In America and the Colonies, and even in Great Britain, there is considerable room for the displacement of China tea by Indian; and the Indian article is slowly gaining acceptance everywhere. When Indian tea has attained its true position in the markets of the world, it will be time enough for tea planters to reconstruct their methods of culture and manufacture, import new machines and appliances of sorts and bend their energies to the task of ousting China brick tea from that delightfully well, defined tract of Asia spoken of so familiarly by the writer in the *Englishman* as "the vast market north of the Himalayas."—*Indian Planters' Gazette.*

TEA OF ASSAM.—The *Bengal Hurkaru* says that the Assam Tea Company propose to send to England samples of the indigenous and cultivated Tea of Assam, in a raw state. The leaves to be packed as taken from the trees, after being dried, and the subsequent preparations of the tea for use, to be left entirely to parties at home where, it is thought there would be no difficulty in preparing it for consumptiou. The party from whom our contemporary has derived his information, seems confident that the experiment will prove successful if acted upon: and among the advantages which would follow its realization the foremost are,—India would in short time be able to supply the demand of Great Britain for Tea—the leaf in its raw state might be compressed into less bulk than at present, and by the exclussion to a much greater extent of the atmospheric air, reach England with a higher and purer flavour. And further, it is probable that the Tea introduced into England in its raw form for manufacture would be exempted from the duty imposed upon manufactured Tea. We trust that the trial may be made, and that the success, the attempt deserves, may result.

THE USE OF SUGAR IN CEMENT.—On this subject Dr. Wray writes to a contemporary as follows:—"The combination of sugar with *chuna*, or lime, in mortar has been used in India from time immemorable. This mortar is so tenacious that when, in Calcutta, the remains of the Old Fort (in which was the site of the infamous Black Hole) had to be removed, some thirty years ago to make room for the new Post Office, the mortar proved to be as hard as the bricks which it bound together, so that it was impossible to separate them. The best *chuna* is made of calcined sea-shells. Another remarkable cement used in India for wood, called *soojee*, is made from dough of fine flour, kneaded in water until gluten only remains. To this gluten is added a small quantity of *Chuna* these combine and when mixed together form a cement (of the nature of bird-lime) as tenacious for wood as the other for brick-work. This *soojee* is used in India by the makers of musical instruments, and resist damp. The objection to its use for European viols is that they could not be taken to pieces but there must be many other uses to which it might be applied instead of glue, which will not stand damp."—*Planters' Gazette.*

THE PLANTERS', ASSOCIATION AND "COLIND" EXHIBITION.

Ceylon Commission, Colonial and Indian Exhibition,
South Kensington, S.W., 19th Nov. 1886.

The Secretary, Planters' Association of Ceylon, Kandy, Ceylon.

On 9th November I was asked to attend a meeting of those interested in the coffee adulteration and admixture question, and I was appointed one of a provisional Committee the other members being Messrs. Clifford and Pasteur, and Dr. Watt (India) to draw up a scheme for the formation of an Association. Ceylon and the Planters' Association have always been in the van in the discussion of this question and though it is unfortunately now but of secondary importance, I felt that I could not ignore it. My hope is that as soon as coffee has been placed on an equal footing with tea a joint Association for the trade protection of both articles may be be formed. To those interested in the question, the P. A. report for year ending 17th February 1883, conveys much information and further analyses and the reports of the local Government Board and the Board of Customs have greatly strengthened our case. The Mysore P. A. have placed £100 at the disposal of their London representative towards the expenses required, and I think a Bill will be introduced during next session of Parliament. Should the parent Association or any of the branches see its way to contribute moral or pecuniary support, the representation of the case and the chance of success will be strengthened thereby.

I attended by invitation an interesting meeting of the Pharmaceutical Society on 17th instant, where a paper was read upon the drugs in the Exhibition by Mr. Holmes. There were several references to Ceylon drugs but I was too late to hear what the speaker had to say about cinchona. In remarks which I was called upon to make, I pointed out how much the growers suffered by the maintenance of high price of quinine by retail dealers and how much consumption must be checked in consequence.

The Bark market has risen a little lately, but there are large stocks, and a broker told me a few days ago he had sold 2,000 bales of S. American at 9d per lb. for which 5s per lb. had been refused two years ago. Coffee is very firm and rising steadily, and a continuation of good prices may be looked for. "Ceylon teas remain firm and are much wanted," is Messrs. Gow, Wilson and Stanton's report of 10th. My firm yesterday purchased Nahalma, Hardenhuish, and Avisawella teas: all good teas, and at prices which must be pleasant to the seller. When I write to you next I expect to be able to tell you that I have wound up the Exhibition work.—Faithfully yours.

(Signed) J. L. SHAND.

P. S.—I enclose an explanatory letter from Messrs. Davidson & Co. on the subject of "The Tea Plucker," and I heard yesterday from the Patent Office that my application had been refused. Messrs. H. S. King & Co. have converted the good will they gained at the Exhibition into a Company for the sale of Indian and Ceylon teas and coffees, and have opened new premises in Gracechurch Street. Other new Companies are springing up all round.—(Initialed) J. L. S.

Sirocco Works, Belfast, 8th Nov. 1886.

J. L. Shand Esq., c/o the Ceylon Commission, Colonial Exhibition, South Kensington, London, S. W.

Dear Sir,—Your favour of 3rd instant was not received here before we left off business on Saturday, 6th instant. We wrote you on that day to know if a letter addressed to the Ceylon Court would find you as we wished to communicate with you in reference to the subject of the "Leaf-gatherer" trade mark. We are very sorry that our having adopted this mark has in any way conflicted with the interests of your Syndicate but we do not see that it is possible to abandon the "Leaf atherer" as our mark (having used it now in our extensive tea business for a year and a half) while it is quite possible for your Syndicate to adopt another one for theirs. We received the Photo from a friend who arrived home from India in January 1885. It was simply one of a large collection of similar subject purchased and brought home by the gentleman in question. At this time our retail tea business was just developing into pretty considerable dimensions; and as we considered a trademark, which would be illustrative of some process in the manufacture of tea desirable on our packets, we applied in April 1885 to the Patent Office to have registered as our trademark a representation of a girl plucking leaf from a tea bush, and the sketch which we handed in with our application was, in fact, copied from the photo above referred to. There was no name, or description on the photograph as to where, when or by whom it had been taken, and it had no intimation whatever on it as to copyright or other reservations, so that we considered ourselves at perfect liberty to illustrate the subject as our registered design, by copying this photograph. Had we had the slightest idea that it was private property, or yours in particular, we would have communicated with you before copying it for our illustration. Our application, however, was in the first instance refused by the Examiner at the Patent Office, owing to a Mr. John Stalkart of Darjeeling having previously registered as *his* trademark a "representation of tea plucking," and as ours was a similar subject; the Examiner informed us it could not be allowed unless Mr. Stalkart's consent was obtained to our registration of this trade mark, and provided Mr. Stalkart was not actually using his. We thereupon communicated with Mr. Stalkart, and as he was not using his mark, he kindly gave his consent to our adopting the design submitted to the Examiner. We may here mention that Mr. Stalkart's design was as unlike our sketch as it well could be (to be classed under the same heading), but a difference in the delineation of the picture was, the Examiner said, of no importance in the matter. Having obtained and produced Mr. Stalkart's consent our design was duly passed and registered in August 1885, and we have been using it ever since on our tea packets."

We saw a picture in the *Graphic* some months back entitled, we think, "Leaf gathering at Strathellie Tea Estate, Ceylon" and at once saw the similarity between it and our registered mark, but, until then we had no idea as to what particular place the picture emanated from. We are sorry that in this matter we should now find ourselves in collision with the claims of any of our planting friends, but trust the explanation above given will be considered by you and the Ceylon Tea Planters' Association as satisfactory.

Our Mr Davidson hopes to be in London by end of next week and would be pleased to meet you if you would kindly let us know at what address he would find you there.—We are, dear sir, yours faithfully,

(Signed) DAVIDSON & Co.

COFFEE ADULTERATION:—DRAFT REPORT OF PROVISIONAL COMMITTEE.—The Provisional Committee appointed at a meeting of Coffee Producers, Merchants and others, held at South Kensington, on Tuesday, November 9th 1886, beg to submit the following recommendations:—

1. That an Association be formed to be called "The Coffee Association."

2. That the Association be formed for no purpose of trade whatsoever, and that none of its members be allowed to use its name, directly or indirectly, for any such purpose, but that it have for its sole end the protection of the coffee producer and consumer.

3. That with a view to these objects the aim of the Association be to prevent the sale of adulterated coffee or coffee admixtures, promote the consumption of pure coffee, and compel vendors to sell separately any chicory or other ingredients which may be required by consumers.

4. That having regard to the declining consumption of coffee in the United Kingdom, and the consequent loss of revenue a result attributed by the Board of Customs "in a great degree to notorious adulteration," such an Association may properly claim the support of producers, merchants and dealers; while the shameful frauds which are committed upon consumers of coffee, especially among the poorer classes, make the objects of this Association of public interest and advantage.

5. That according to the annual reports of the Local Government Board and the Board of Customs, the existing law has been found wholly ineffectual to protect either the consumer or the revenue, and, therefore, stands in urgent need of amendment.

6. That, besides endeavouring to amend the law in the directions indicated, the efforts of the Association be directed, through the various temperance organizations, or otherwise, to stimulate the public taste for infusions from pure coffee, and encourage attempts to supply cheap and easy methods of coffee making.

7. That representatives of India and the Colonies now in this country be requested to communicate with Planters and their various Associations, and invite co-operation and subscriptions.

8. That donations and subscriptions be also invited from all other persons interested in the proposed Association. An annual subscription of 1 guinea for each member, and of 2 guineas for each firm, or a donation of £5 5s to constitute membership.

THE NEW DIMBULA COMPANY, LIMITED.

DIRECTORS' REPORT AND ACCOUNTS, SEASON 1885-86.

Directors.—Herbert Brooks, Esq., Chairman, W. S, Bennett, Esq., W. J. Carver, Esq., J. B. Morphew. Esq. Manager in Ceylon—Mr. F. R. Sabonadiere. Agents in Colombo—Messrs. J. M. Robertson & Co. Chief Estate Superintendent—Mr. J. E. A. Dick-Luder. Solicitors—Messrs. R. S. Taylor, Son & Humbert. Auditor—Mr. G. Sneath (Messrs. Price, Waterhouse & Co.) Bankers—The New Oriental Bank Corporation, Limited. Secretary—Mr. J. Swan.

The directors have pleasure in presenting their First Annual Report for the season ending 30th June, 1886. This comprises the period from the formation of the Company on the 15th March, 1885, to the above date. Referring to their circular of the 11th January last, they have to mention that no additional shares have been issued, and that the list has been closed.

The prime cost of the estate has been £20,938 4s. If to this is added the £64,120 of Bonus Shares, issued in terms of the prospectus, the nominal cost of the property will then be £85,058 4s. The "working account" for the season shows a balance at credit, transferred to "profit and loss account," of £1,610 1s 8d. To the former has been debited all expenditure in Ceylon on upkeep and crop, and charges in London; also all expenses incurred in the formation of the Company. It will be noticed that two-thirds of the value of the Cinchona Bark have been deducted from the proceeds and transferred to a "Tea Extension Fund," the Directors, after mature consideration, being of opinion that the whole of the said proceeds could not justly be considered as belonging to income, inasmuch as the capital value of the Cinchona plantations has been depreciated by somewhat extensive felling. This balance of £1,610 1s 8d. will suffice to provide for the full dividend of 8 per cent. per annum on the A Shares, leaving a small balance to be carried forward to next account. The Directors will propose a resolution to this effect. An interim Dividend at the above rate for the period ending 31st December last has already been paid. The "Tea Extension Fund" has been created for the purpose, mainly, of planting a considerable portion of the estate with tea in place of Coffee. The expenditure already incurred in this direction, amounting to £3,545 2s 1d., has been debited to this account. The property now consists of 700 acres of coffee in bearing; 1,204 acres of Tea, of which 50 acres are already in bearing; 255 acres of Cinchona; and 966 acres of forest, &c.—Total 3,125 acres. The Directors are of opinion that the considerable measure of success which has attended the first year's operations of the Company is, to a large extent, due to the careful manner in which their interests have been watched over by their Manager, their Agents, and the Chief Estate Superintendent, and to the zeal and ability displayed by their Secretary. The Director who retires by rotation is Mr. W. S. BENNETT, who, being eligible, offers himself for re-election. By order of the Board, J. SWAN, Secretary.

52, Gracechurch Street, London E. C. Nov. 5th 1886.

TEA-BUYING BROKERAGE IN CALCUTTA.

The following letter was addressed to the Calcutta *Englishman* in September last, and attention is drawn to it by a Calcutta correspondent, who thinks it necessary to point out to Indian Tea importers anxious to reduce the cost of their Teas, that the payment of the Calcutta buying brokerage is quite optional with themselves. It is to be supposed that in these days of abolishing middlemen's charges, this payment will be swept away if, as implied, no service is rendered for it:—

To the Editor of the "Englishman."

SIR,—A committee is sitting with the laudable purpose of placing Tea brokerage on a satisfactory footing. The committee has assumed a very responsible task, and will doubtless be glad to be helped to a wise conclusion. Under the present system the seller entrusts his Tea confidentially to a broker for sale at the highest obtainable price, and the buyer entrusts his order confidentially to the same broker to be implemented at the lowest possible price. Clearly, if the committee be men of commonsense and if they really mean to do honest work, this feature will at once be disposed of. In support of the above indicated system certain curious arguments have been evolved. To justify the payment of brokerage by the buyer (who in nine cases out of ten does not want a buying broker at all, and is seriously hampered in his purchases by having to employ him), the following considerations are put forward :—

It is said that the buying broker guarantees the seller against loss by failure of the buyer, so that the seller takes the risk of the selling broker, the selling brokers guarantees the buying broker, and the buying broker takes the risk of the buyer; an ingenious chain constructed to afford some kind of *raison d'etre* for the buying broker.

It is said that the buying broker is to guarantee the buyer against false packing,—another instance of the anxious search for some ground on which to justify the buying broker's existence. Can any one divine on what principle these two responsibilities are to be taken from the selling broker, on whom (if not on the seller himself) they naturally rest?

Another benefit to be derived from the buying broker is accommodation for a day of two for the packing, which is done in the selling brokers' godowns. A note of admiration is the only comment that is here required.

It is alleged that the buying broker refuses orders from London for the benefit of the Calcutta buyers. If this means restricted competition, it calls for instant remedy. The trade wants the freest competition without fear or favour. If it is not a broker's business to act as agent of a London house, to decline so to act is no favour to the Calcutta buyers.

The fact is plain that the only duties which can reasonably performed by a buying broker are to place his valuations and his knowledge, his services in the sale-room and possibly during delivery, at the disposal of the buyer who pays him. The aggregate imagination of the trade cannot add to these duties without dressing the buying broker in plumes kindly lent by the selling broker for the purpose of giving him an imposing presence.

When the Port Commissioners' Tea warehouses are completed, all the Tea that passes through Calcutta will be accommodated there. The trade will then want a selling broker (or, brokers), whose duty will be to taste garden musters, to value for sale, to give advice, to act as auctioneers, and to collect proceeds. There need be no *del credere*, because an impecunious buyer would have no difficulty in getting for a mere Bank commission the assistance of a good firm to father his purchases between the signing of a delivery order and the bill of lading, If there be a buyer so untrustworthy that even this cannot be done the sooner the trade is rid of him the better.

Let buying brokers be paid by those who ask their services. We want open auctions, with full publicity and the widest competition, and we wish the present brokers to be relieved of the painful and embarrassing double functions under which they now groan. When the trade is put upon an intelligible and self-working basis, I expect to see the gardens avail more freely than hitherto of the nearest market for their roduce. A PROPRIETOR.

—*Produce Review.*

CEYLON UPCOUNTRY PLANTING REPORT.

CACAO CROP AND PREPARATION—NEW VARIETIES—TEA AND TRADE MARKS—HOW TO GAIN REPUTATION FOR WISDOM WITH COOLIES.

6th December 1886.

The Cacao crop which is at present being gathered still keeps up its fair promise of being a full one.

The new system of drying the beans unwashed is, judging from Mr. Shand's letter and the reports of some of the London brokers, not finding that favour at home which some of us would like.

Still the sale of 50 cwt. unwashed and unassorted, which is reported to have got 78s would lead one to conclude that the condemnation of the system may have been somewhat hasty, and that the expression of opinion against the new mode, might have been modified with a fuller knowledge. Even if the price were not so good for unwashed as for washed, it has to be remembered that the former has a considerable advantage in weight—as much as 20 per cent some say, although that does seem an outside figure—and then the risk of damage to the bean is lessened, as also that of moulding. For while the outside skin of the nib remains uninjured, the chance of its getting mouldy inside is reduced to almost nothing. The exterior may mould, but a rub on a mat or sack will remedy that, whereas if the mould gets into the inside of the bean, it is hard then to know what to do.

While on this subject I may say that I saw a pod taken from one of the new variety of cacao trees growing in the Peradeniya Gardens which contained as many as 40 nibs, and these too, large and plump. To have a decent acreage planted with trees of that variety and doing well, would give a handsome return and as far as I could learn it was quite as hardy a variety as any of the others. So many of the stronger type of cacao certainly do not turn out the kind of nib which fetches the big price in the London market, the beans being flat instead of round, that when there is one to be found which comes up to required conditions it is well to know of it. The cacao being harvested just now seems to me, from what I have seen, to be fuller, rounder, and bigger than what usually obtains, the result doubtless of the fine season we have been having.

In these days when an effort is being made to reach the consumers of Tea direct, the subject of Trade Marks is not an unimportant one. A neat packet which takes the eye has much to do with success, and an attractive trade mark is not without its effect.

A friend suggested to me the other day "The Bishop's Brand"—a bishop in full canonicals,—holding that Ceylon and her bishop were well-known at home, and this more especially in religious circles where tea drinking represented at times devotional feeling. I think the suggestion is a valuable one, and might make the fortune of a pushing Company, skilled in the arranging of tea fights. As a motto for "The Bishop's Brand" what could be better than the off-quoted hymn of Heber's, those two lines, at least, but slightly modified, which too often represent the knowledge of the civilized world in regard to the island and ourselves :—

"Where every *product* pleases
And only man is vile."

To have a bishop in full war paint, in a trade mark of pure Ceylon Teas, coming before the British public as a type of Heber's "man" would certainly remove all doubt as to our belief in the doctrine of general depravity; and our strong, fine-flavoured teas as the latest specimen of our newest "product," would in time gain such favour as to call for a revision of the hymn books, and all new editions would eliminate

"Where every *prospect* pleases.

for the new reading of "The Bishop's Brand"

The story is told of a Planter who just returned from a trip home, incidentally letting out to his tea-maker the extent of his knowledge of manufacturing tea. During his absence, his property had come into bearing and the tea-house was in full swing when he arrived on the estate from his home trip. He had made up his mind to go in for the kind of reputation which can be won by silence: feel his way, and speak only when he felt he knew what he was talking about. Accordingly in his walk through the tea-house there was a "cock in his beaver," a repose in his manner, and a solemnity of silence which might have imposed on the most skilful, and have sat becomingly on the highest authority. There was, however, a tray on the fire, and when with a fine gravity he proceeded to stir gently the tea therein, smell it, and look wise, alas! alas! for his reputation, even the humblest cooly in the firing squad, knew that "someone had blundered."

Since then I hear he has recovered the good opinion of his subordinates. He stuck up a thermometer in the factory, hung up a slate with a pencil below it, had a look at the degree of heat registered from time to time, jotted them down on the slate, put on the look of wisdom, and kept silence. This little game I fancy he will keep up until he feels satisfied he knows what is what, and then he will speak to the purpose. It is strange how the cooly is so easily imposed upon in this way! I had a kangani, the most suspicious Tamil I ever had to do with, but he told me one day of a wonderful native doctor whom he had consulted, and who had promised to cure him. "Has he done you any good," I asked him later on, "that you should think so much of him?" "Well no, but he's a good physician, for he sat for a whole day turning over the leaves of his books to find what ailed me and how I could be cured." He never cured him, but yet the kangani never lost faith in the man.

PEPPERCORN.

TEA ROLLERS AND DRYERS.

In the following article, which appears in their advertising organ, Messrs. Davies & Co. combine public information and indications of altered business arrangements after a pleasant manner:—

The well-deserved and pronounced success of the Roller of the day, "Barber's," bids fair to far exceed the expectations of its enterprising inventor. The unavoidable delay in its introduction in the Indian market, caused by Mr. Barber's absence in England, is much to be regretted, but the reputation it has established will speedily result in its universal adoption in that country. That we are justified in forming this opinion must be admitted when we state that last month, November, we wired to the manufacturers in England confirming an order received for India for no less than Sixty Barber's Rollers. This, we think we may venture to assert, is the largest order for Tea machinery ever secured.

Intending purchasers in Ceylon will do well to order in sufficient time, to prevent disappointment, as the execution of the above commission will necessarily occupy the attention of manufacturers for a considerable time. As the fortunate Agents of this desirable machine, we cannot feel very much regret at losing the Agency for Lyles's Roller. Last month, in accordance with instructions from the proprietors of Lyles's Patent, the Calcutta Planters' Stores and Agency Coy., we formally transferred the Ceylon Agency to Messrs. Mackwood & Co. From the fact of our utter inability to dispose of any of the Lyles' rollers during the two years we have acted as Sub-Agents in Ceylon, we must candidly admit the justice of the proprietors' action in effecting a change, but whether such change will prove of advantage to them or their new Agents is very questionable. This machine necessitates the employment of bags, against which system (so far as our experience teaches) there has been, and still is, the very strongest objection. The change, therefore, is required in the machine itself. To ensure business by agents or principals it is necessary to produce a durable machine, simple in construction, giving the best description of work in the shortest time, and easy of manipulation, at a fair and reasonable price.

In anticipation of our becoming Agents for Barber's New Dryer, and at the request of Messrs. Davidson & Co., we have likewise transferred the Sirocco renewed parts to Messrs. Mackwood & Co. In this Agency Messrs. Mackwood & Co. have more reason for congratulation than in the case of Lyles's rollers, for with the increasing number of Siroccos brought into use, and the great susceptibility to wear and tear of parts in the Sirocco, the constant demand for the renewal of such parts must prove a source of great profit alike to manufacturer and Agent. As a Tea Dryer, however, there is no doubt Davidson's Sirocco at present stands first on the list, and knowing this we are fully alive to the task Mr. Barber has before him in perfecting a Dryer to beat the Irish Machine. Under the circumstances, it would be somewhat premature for us to enter upon the merits of Barber's Dryer, but one leading feature which has been kept constantly in view by the inventor is that the annoyance, trouble and expense to which Planters are now frequently put in providing new parts to the Dryer should be as much as possible, if not altogether, avoided. Messrs. Ruston, Proctor & Co., of Lincoln, have had the Machine in hand for some time past, and before this is published we expect the first one will be on Blackstone Estate for trial.

WEST INDIA PRODUCE.—A series of interesting articles on the West Indian products at the Colonial and Indian Exhibition, which has lately appeared in the *Sugar cane* magazine, concludes with remarking that, on the whole, these attractive and nicely decorated courts give one a very satisfactory idea of the products and capabilities of our West Indian colonies. The survey is, however, not altogether satisfactory at the present moment. These islands are certainly not developed at all as they might and ought to be. Much capital has, no doubt, been spent upon them, and the results have not been always satisfactory to the investors. Assuredly this is not because the West Indian islands are incapable of producing ample high returns. The bulk of the land is at the present time purely waste, and probably the main difficulty is the actual impossibility of procuring sufficient labour. The islands, we are told, in spite of the large commerce in drugs, fruits, &c., are certainly now suffering, most of them, from their exclusive devotion to sugar culture. But if the labour difficulty could be met, and a judicious variety of products could be introduced, there seems little doubt that the return would be nearly as profitable as of old, if not still more so. The papers to which we have just alluded conclude with the following:—"Since most of them [the islands] are Crown colonies, surely it behoves the Home Government to stir in the matter, and see whether it cannot help these once favourite colonies to help themselves."

THE QUININE MARKET.—A London Correspondent who has been consulting a large dealer in quinine and an authority who carefully watches the market, sends us the following result of enquiry:—"The general opinion in the trade is that this article has touched the bottom. Its downward course was determined by the following reasons:—1. Larger exports of bark from Ceylon. 2. The frantic efforts of the fraudulent Milan Factory who made millons of ounces annually which they deposited with Bankers to draw against, when the crash came. This quinine was forced on the market, lot after lot, as fast as possible, prices falling with every sale. 3. This affected the trade of regular makers who bought less bark, the smaller demand again brought bark (and quinine) down. It will probably experience a steady rise for:—1. Low prices have stimulated consumption. 2. Makers are again at legitimate work and the Milan Factory has gone. 3. Smaller (probably) import of bark. The bark market is all ready

better; and quinine has risen 4d per ounce, and makers are selling carefully." A home journal which refers to the correspondence and discussions in the *Observer* says :—

"If the statement made by a leading firm of London brokers that 'the price of cinchona bark depends entirely on the shipments from Ceylon' be well founded, it certainly seems desirable that the Ceylon planters should take suitable steps for regulating their supply more in accordance with the natural demand."

THE QUINOLOGICAL LABORATORY established at Harlem (Holland in 1884 by the late Mr. J. C. B. Moens will be continued by Messrs. N. van def Sleen and W. J. E. Hekmeyer, under the style or Moens, van der Sleen and Hekmeyer.—*Chemist & Druggist.*

QUININE MANUFACTURE.—An advertisement from from Madras in our columns today ought to have a special interest to gentlemen meditating experiments in the local manufacture of quinine. If the owners of cinchona clearings were able to form a Syndicate for the purpose of establishing such a manufactory or even one to secure the less refined alkaloids, they would probably do more to increase the value of their bark than by any other meeans.

TEA IN DARJEELING.—I hardly think I can remember so many changes in the management of gardens as have taken place this year. The season has been simply disastrous for many estates especially in the Terai, and Messrs. Lloyd and Co.'s failure will, of course, not mend matters for the concerns which were being financed by them. Some gardens have done well, but I think if an average could be struck it would be found that the season just passed was the worst on record for many years. Most hill gardens have done very fairly well owing to being able to maintain the "hill flavour." Given a bad season, and the universal remedy—change of management—is adopted. Foolishly I think in most instances, because a man who knows all the ins and outs of a garden as well as all the coolies, so long as he has a fairly good head on his shoulders and does his work will arrive at much better results than a stranger. The gardens which do best in this district are those which have been under the same management year after year. Local expenditure is being heavily cut down, another mistake I think. It is in Calcutta that the pruning knife should be applied, and that not by any means sparingly. But there is little chance of that step being taken as the "ring" always takes very good care to command the majority of votes at every shareholders' meeting. The "practical gardener," with a Bible in one hand and a spade in the other, seems to be the coming man. He can live and grow fat on a salary that a gentleman would starve on, and will put up with "midshipman's allowance"—more kicks than half-pence. Pruning is well in hand on nearly all the gardens now. By the way, talking of pruning a friend of mine, who is an old and very successful manager, told me that he was going to try what to me is a new departure on a small scale. It is to prune early, and, as he hopes, to get a small flush a week or two after. This of course meant pruning before the sap had ceased to circulate. It will be interesting to hear what results he has obtained.—*Indian Planters' Gazette*, Dec 7th.

COCA LEAF AND SIR R. CHRISTISON.—This well-known Professor of Materia Medica in his 78th year in one of his many mountain climbs experimented in the way of chewing the Peruvian cuca or coca leaves. He took long walks, and finally ascended Ben Voirlich, where he experimented with the leaves. In his journal, he writes thus of what took place on Ben Voirlich :—

"I reached the top very tired. Determination alone carried me the last six hundred feet. As soon as I arrived, I began to chew cuca leaves, and consumed ninety grains during the half-hour spent on the summit and the first half-hour of the descent When I started for the descent, the sense of fatigue was entirely gone. I went strait down without a stop in one hour and a quarter to the road, not much tired—able to walk comfortably a mile and a half to meet the carriage. Although my limbs felt rather heavy to move, I seemed not to care for this." In a more formal report on the subject, he says :—

"The chewing of cuca removes extreme fatigue and prevents it. Hunger and thirst are suspended; but eventually appetite and digestion are unaffected..... ..... It has no effect upon the mental faculties, so far as my own trials and other observations go, except liberating them from the dulness and drowsiness which follow great bodily fatigue."

Surely--says the London *Spectator*—this Peruvian leaf ought to be better known than it is. What is doing with it in Ceylon by planters? At Peradeniya Gardens the other day, Mr. Ferdinandus gave us leaves to try "in the heat of the day," the chewing of which was not unpleasant, though the taste somewhat resembled that of grass. The Garden authorities ought to experiment with their collectors, getting them to use the coca leaves on their long jungle journeys, and to report the results.

TEA WEIGHTS.—A trial of some interest to the tea trade has recently been decided in the Court of Queen's Bench in favor of the plaintiff, who sued the defendants, their Calcutta Agents, for the value of difference in weight of 96 chests Indian tea bought by them for the order of the said plaintiff. The difference was 587 lb on an invoice of 9,225 lb. being the garden weight, and which their agents had accepted as correct and paid for as such. The cases were in good order and the difference could not have been stolen, lost or caused by driage. The defendants pleaded the custom of paying for the garden weights and not actual weight, and some evidence was called on this point, which was, however, not very conclusive. The Judge, in summing up, concurred in thinking that the action was one of some importance, because on the one hand there was a sort of imputation that fraudulent conduct had been pursued somewhere, and on the other hand a custom had been set up which, if it existed, was a somewhat dangerous one—that where principals ordered an agent to send them a certain quantity of tea, he should have the power by custom to send them a much smaller quantity, charging at the same time for the larger quantity—a custom which required a great deal of watching, inasmuch as customs often arose in a trade which were very much to the detriment of the public and the customer. In this case there were two issues—one being for the plaintiffs to establish, and the other for the defendants. It was for the jury to say, first, whether it had been made out to their satisfaction that the plaintiffs had given instructions to the defendants to buy so many chests of tea for them, that they paid for the chests on the basis that the chests would contain a certain weight of tea, and that when the chests came home they were found to be so much short of the invoice weight. The defendants suggested that the short weight might have been caused by pilfering, but the jury would not presume frauds and rascalities unless there was strong ground for supposing that such malpractices were the true explanation of the deficiency of weight.' The jury had been made aware by pleadings of the nature of the custom which the defendants had set up as an answer to the claim. Such a custom must be certain —so certain that if nothing was said, the custom would be assumed to be imported with the contract. It was entirely for the jury to say whether there was so universal a custom that, if an agent sent home chests of tea which were materially and substantially short in weight the principal was not entitled to receive in respect of the deficiency. Could they say that a custom was implied into the bargain, that garden weights should be accepted? If that was not made out to their satisfaction the defence of the custom failed; and then the only remaining question would be whether the plaintiffs had made out, in the absence of specific evidence as to the breaking of the chest in transit, that the invoice weight was in excess of the actual weight, and that they had paid for the excess.—London *Cor.* Local "Times."

ON THE IMPORTANCE OF LIMING.

The value of lime for agricultural purposes has been known from a very remote period. According to Pliny, the Gauls applied lime with great success to their corn lands, while the Romans found an occasional dressing very beneficial to vines and olives. In our own country the practice of liming—that is to say, the use of kiln-burned limestone—is confined to certain localities. Thus, in Scotland, in the northern and western counties of England and in South Wales, it is much esteemed by practical farmers; while in the southern and eastern counties, where the soil is naturally more calcareous and associated with the upper and lower chalk formations, and where the climate is drier and the rainfall less, it is not customary to apply caustic lime, though great benefit results from the use of chalk marl once in nineteen or twenty years. It is to be feared that, with the disappearance of the summer fallow, the practice of liming has been neglected, and too much reliance has been placed upon artificial fertilisers. This, if true, is greatly to be regretted, inasmuch as, in order to get the full benefit from any manure, it is absolutely necessary that the land should contain a sufficient supply of available lime. We should remember that not only is lime a necessary constituent of the mineral portion of all plants and crops, but it promotes the more rapid decomposition of those organic matters which are present in the soil, or which may be added as manure—converting them, in fact, into nitrates and carbonates. Further, lime exercises an important solvent action on the insoluble silicates which are dormant in the soil, but which may be decomposed by caustic lime, and made to liberate their potash and soda. Again, lime neutralises, all vegetable acids, and is therefore especially necessary in the reclamation of peaty land; while on stiff clays it improves the physical character as well as the chemical composition, and thus promotes a more healthy and vigorous growth in the future crops. Lastly, its judicious use is considered a specific on those soils which produce turnips affected by the disease known as "fingers-and-toes;" and where acid manures have been used year by year, a good dressing of lime cannot fail to be specially useful, and to insure the complete utilisation of the soluble phosphate contained in superphosphates and dissolved bones.

It is, therefore, evident that lime is a most important element in all fertile soils, and has been truly likened to a key with which the stores of plant food may be unlocked and made available. Indeed, excessive liming is most exhausting, and has given rise to the old saying that lime is good for the father, but not for the son. Liming should be followed, however, by manuring, and then the full benefit will be obtained.

In the analyses of drainage waters from the Rothamsted experimental plots, made some years ago by the late Dr. Voelcker, it was clearly shown that practically the whole of the nitrogen compounds which were lost in the drainage water passed off in the form of nitrates in combination with lime. Thus, from the unmanured plot there were 6·87 grains of lime and 1·05 grains of nitric acid per gallon; while from the plot manured with farmyard dung the drainage water contained 10·32 grains of lime and 4·34 grains of nitric acid per gallon. From the plot where 600 lb. of sulphate of ammonia was applied per acre, the water contained as much as 13·81 grains of lime and 4·55 grains of nitric acid. Lime, therefore, furnishes the most effective carrier or fixer of the nitric acid as fast as it is formed in the soil; and we have every reason to believe that the composition of drainage water presents us with the best idea how and in what form plants take up their nourishment—at least, so far as their food is in a soluble form. It also appears from these interesting analyses that sulphate of ammonia becomes decomposed during its passage through the soil, sulphuric acid uniting with lime and passing off in the drainage, while the ammonia is retained in the soil, a portion only being lost in the form of nitrate of lime.

Having said so much respecting the value of lime, let us briefly consider the chief characteristics of the best qualities. Usually the most suitable limestone for agricultural purposes is that which yields, after burning, the purest and finest powder on slaking, also the whitest and lightest lime; for the less weight per bushel, the better the quality.

It is important that lime should slake readily and break up into a fine powder, which can be easily and uniformly scattered on the surface of the land, which, if arable, should be subsequently harrowed. Lime should never be ploughed in, for it has a natural tendency, as it becomes dissolved, to work downwards, and beyond the reach of ordinary farm crops. Mountain limestone yields excellent lime; as a rule, 1 ton should give on careful burning in the kiln, about 11 cwt of caustic or quick lime. Great care has to be taken not to overheat the kiln, for when highly burned the lime will not slake readily. The goodness or richness of different qualities of lime may be noted by observing the quantity of water which each sample will take up or absorb during the process of slaking—the more the better, as the superior kinds swell out and increase in bulk from three to four times their original size.

Quick lime is soluble in 770 parts of water, and has a hot alkaline taste, as opposed to the mild taste of powdered chalk, which is only soluble to the extent of about two grains per gallon, or 1 part in 3,500 parts of water.

It frequently happens that limestones from the same district vary considerably, both in their physical properties and chemical composition, so that sometimes the less pure stone yields the better lime, as it slakes quicker and without water being specially added; moreover, it contains appreciable quantities of phosphate of lime. In such cases, where any doubt exists in the farmer's mind, it is desirable to have the aid of chemical analysis before making a selection, especially where carting some distance has to be considered.

In addition to the mountain or carbouiferous limestone, which occurs so extensively in South Wales, Somersetshire, Devonshire, and other counties, there are very fair lias limestones—as, for instance, that found at Aberthaw in Glamorganshire, which has a great local reputation, chiefly, however, for building purposes, as it sets and does not swell much on slaking, so that it is better adapted for cement-making than for agricultural purposes.

In Pembrokeshire we find the Sulirian limestone, also the Caradoc, which, although containing 80 per cent of carbonate of lime, is regarded by geologists as a sandstone, on account of its gritty formation. Lastly, the oolitic limestones of Gloucestershire, and the chalks of Kent and Sussex, form another class which yields a great variety of caustic lime; but we have only space to observe that in most cases, the softer the original rock, the poorer and weaker is the lime.

Now a few words regarding the kind of soils that are improved by liming. It may be truly said that there are few soils which are not benefited by the occasional application of lime in some of its numerous forms.

On peaty land and heavy clays there can be no doubt that slaked lime, applied at the rate of 4 or 5 tons per acre, will prove an economical dressing every seven or eight years.

On light sandy or gravel soils, as well as those formed from the decomposition of granitic rock, which are naturally poor in humus and organic remains, much smaller applications are advisable; thus not more than one ton, or about fifty bushels per acre, are perhaps quite sufficient. Indeed, on such soils it is generally safer to apply lime in the form of ground chalk, chalk marl, shell sand, or in some cheap form of phosphate and carbonate combined, such as the recently introduced basic slag, which in certain localities can be obtained in a finely ground state on moderate terms. Those who are familiar with Cornwall are aware that immense quantities of shell sand are sent inland annually, for application to the arable land. This sea sand varies in its richness in carbonate of lime, according to the amount

of finely ground shells present; thus at Padstow it contains as much as 80 per cent, while further up the Channel, at Bude, the proportion of carbonate becomes reduced to 50 per cent, and at Hartland Point there is only 30 per cent, the remainder consisting of siliceous sand, associated with some oxide of iron.

Practical experience has taught the native farmers which locality yields the sand richest in carbonate of lime, and therefore the most economical for their land, and it is interesting now to know the reason for such selection. Further, this local practice of dressing light soils with finely-ground shells is a strong argument in favour of the value of insoluble phosphate when applied judiciously, in the form of ground bone ash or Cambridge coprolite, on land naturally deficient in lime and fairly rich in vegetable matter. Of course, these insoluble phosphates take longer to become available than is the case with soluble phosphate, which becomes at once precipiated when mixed with the soil, and consequently is in a much finer condition than any ground raw phosphate. Hence, for turnips superphosphate or dissolved bones will be preferred, because they afford an immediate supply of that food which the young plant requires in the period of growth, so as to get quickly beyond the reach of the ravages of the fly. On land poor in lime we should either use a mixture of soluble and insoluble phosphates, or we should apply a dressing of chalk, say 4 or 5 tons per acre, and see that it is well spread over the surface before marking out the turnip ridges and applying superphospoate, as, for instance, was done in one of the experiments with swedes in Warren Field at Woburn, where the application of 5 tons of chalk alone per acre caused an increase of 2 tons of swedes over that obtained on the unmanured plot.

On pasture, lime is best applied in the form of composts made from ditch cleanings, heaped together for some months and put on during frosty weather; also road scrapings, if derived from limestone, make an excellent dressing for grass land, for some of the best and sweetest herbage is grown on old pasture which has been well chalked or is naturally already rich in carbonate of lime. Lime destroys the coarser grasses, and favours the growth of the finer-flavoured and more nutritious herbage.

In addition to turnips and swedes, the following are crops specially requiring a liberal supply of lime:—Clover, peas, beans, vetches, and sainfoin. On land that has been properly limed, clover sickness is said to be less known than where this old practice has been neglected.

During the last twenty years the writer has had numerous instances brought to his notice where judicious liming has been attended with the most satisfactory results, both on arable and pasture land. But lime should be applied with caution and in moderate doses, and, moreover, be followed with manure of some kind, for crops require other constituents besides lime. In these times of depression in agriculture it is well to recall the attention of farmers to some of the old practices of their predecessors, and to remember that such were introduced into the category of local customs as the result of many years' practical experience.

There is, of course, judicious liming and injudicious liming, and there are certain districts where the practice is carried to excess, while in other it seems to be almost entirely neglected.

Further, it has been pointed out in this paper, there are a great number of light sandy and gravelly soils which will not stand the application of lime in its fresh caustic state, but which would be greatly benefited by a dressing in its original form of carbonate of lime, such as we find in chalk, shell sand, or ground coral.

In conclusion, there is one form in which lime can always be applied with safety and without any fear that the results will be unsatisfactory, namely, as a compost with vegetable refuse and soil. If the ditches along many of our country roads were more frequently cleaned out and used in this form, a most valuable dressing would be afforded for the neighbouring fields, be they in pasture, corn, or roots, while the roads would be drier, and less liable to get flooded during wet weather. JOHN HUGHES, F.C.S.,

Consulting Chemist to the Ceylon Planters' Association, 79, Mark-lane, London E.C.—*Field.*

THE QUEENSLAND SUGAR INDUSTRY.

Brisbane, October 24th.

The sugar-cane growers and sugar manufacturers of Queensland seem destined to meet with unexpected troubles. Only a few years back they were nearly swamped by reason of the "rust" disease; then after a brief period of prosperity a series of dry years obtained, and the crops were very short, so much so that it got to be commonly asserted that the lands were exhausted; on the top of this came the scarcity of labour and political harassings, accompanied by a fall of 100 per cent in the price of sugar. Last year was a glorious season, and far more sugar was manufactured than ever before, the total quantity being 66,000 tons, but this year there comes the singular trouble that a still more glorious season than was that of 1885 has prevailed, and so there is far more sugar in the fields than can ever be gathered. Usually the tropical growth of vegetation in Queensland commences in December (about Christmas), and ceases in May, and the rest of the year the characteristics of the climate are decidedly nontropical, for the winter, spring, and early summer are almost rainless, and dessicating westerly winds prevail. This is the time the sugar manufacturer chooses for his operations, for then the cane ceases in a great measure to grow, the juice attains a high density, and carting to the mill of the thousands of tons of cane is easily accomplished through the ground being hard. Now, this past winter and spring have been abnormally wet and mild. Rain every week, and heavy continuous rain every fortnight, would about characterise the weather report. The temperature has been mild, too, the drying winds having been absent. Consequently the cane has never ceased growing, and there is the grandest crop ever known on the fields, even on the old cultivated lands, until lately supposed to have been worked out. The planters have made several starts at crushing, and as often have had to discontinue through the lowering of the density of the juices, the difficulties of keeping the mill supplied, and getting the megass (crushed cane) dry enough to use for fuel. The manufacturing season is now well advanced, and the probability is that the weather will continue showery, for the thunderstorm season has set in; that it will close early is also likely, for the summer rains will begin about Christmas. It is thus absolutely impossible that these fine crops can be gathered this year. This is more or less the state of things at all the centres of the industry, from the extreme north to south of Brisbane, for even on these southern rivers the winter passed without the slighest touch of frost; the cane kept green and growing, so that crops of the south are almost as luxuriant as are those in the north. From Mackay northwards, the rains have been excessive. At Cairns and the Johnstone about 140 inches have fallen since Christmas last. At Mackay they had 8 inches during September, which is usually the best crushing month of the year. It is now night and day, continuous work, at all the principal mills. Nevetheless, it is certain that the gross returns will be considerally less from that district than were those of last season. The selectors who grow cane for sale to the mills of course will feel this absence of returns severely, for the mills will take but a limited quantity of outside cane so long as their own is left uncut. The quality of the sugar produced is quite equal to that of last year, and which obtain such general praise in all markets.

There is one district which this singularly wet season has suited exactly, and that is the Burdekin delta lands. This locality has the least rainfall of any of the sugar centres, and although an immense expenditure of capital was incurred in establishing

the industry, the returns so far have been disappointing, solely in consequence of the non-growth of the cane through want of moisture. Consequently the large Airdmillan mill (which, by-the-by, I believe mainly represented Victorian capital), after an expenditure of over £100,000, was closed, and arrangements made for the cane to be crushed at an adjoining estate. The result of the frequent rains is that the cane crop on Airdmillan is splendid, and it is doubtful if the two large mills, Seaforth and Pioneer, will be able to take it off. Cane which had been left to run out has astonished every one by its growth, and second ratoons have yielded 30 cwt. sugar per acre, thus proving the suitability of the delta soil if only it can be watered. The droughts of preceding years led to extensive irrigation works being adopted, and at the two plantations above-named they have pumps which throw 300,000 gal. an hour, there being an inexhaustible supply of good water at a depth of seldom more than 12ft. Irrigated land has been found to yield four tons of sugar per acre.

The reports from the Wide Bay and Burnett districts are exceedingly favourable, and the return this season promises to be what the local paper terms "phenomenal." The output from millaquin, on the Burnett, is calculated by Messrs. Cran and Company to reach 10,000 tons, and the same firm consider that their manufartory at Yengarie, on the Mary River, will turn out 5 000 tons.

bane and Southern districts. Here there have always

The only places in which there will be a notable decrease of yield through the closure of mills and the relinquishment of cane culture will be the Brisbeena number of small mills, and every year makes it more apparent that such cannot compete with the larger establishments and there more perfect machinery and organisation.

Of late there has been no difficulty about the labour question. The supply of Kanakas has been ample, and a great part of those now on the plantations and that arrive from time to time are those who have previously served a term of years, and who elect to reengage for plantation life in preference to ramaining on their own island.

Mackay, Oct. 25th.

The first half of the crushing season 1886 has been a continuous trial to the patience of sugar growers in tropical Queensland. The spring months, the driest of the twelve, according to records extending over 20 years, have this year been the most rainy, the fall during September having exceeded that of any month of the wet season. As a consequence, instead of half the crops being in at this stage, barely, one-third are yet milled, and in place of the rich juice usually supplied by canes cut in October a density of 9 deg. Beaume only has ruled until within the last fortnight The quality of the liquor manipulated, accordingly, involves an abnormal consumption of fuel, and as such is gall and bitterness to the careful-minded proprietor; the quantity, however, measured per ton of cane is above average, and, in this respect, has seldom been excelled. If the curious reversal of seasons continues, and the late spring is followed by an equally late summer, with January dry, the harvesting will probably be completed, and the total estimated output of 20,000 tons successfully attained. Under less favourable cicumstances many estates will be compelled to leave fields to stand over until 1887. In order to avoid this undesirable result the most strenous efforts are being made to recover lost ground, and labour of all kinds is in brisk demand. Brisbane has been opportunely relieved of some of its unemployed by the maligned planter, who, no doubt, rejoices in this heaping political coals of fire on the heads of the Queen-street Government. It is a case of the north to the rescue, and seldom has better labour been offered mill owners than the young fellows who have lately been landed here at Government expense under agreements for three months at a wage of 10s. to 12s. per week with rations.

The Javanese, on the other hand, introduced as a substitute for the failing Kanaka supply, are constantly in the Police Court on various charges, and have disappointed expectations. In physical activity they are deficient as compared with the cheery Polynesian, but they endeavour in mental quickness to atone for this shortcoming, being prolific in every variety of deceit in order to escape work. These remarks are particulary applicable to the town hands from Batavia or Singapore. Those agricultural labourers from the interior of Java, who have recently being indented with their families, are a quieter class, from whom better results are anticipated. The Kanaka, however, remains *facile princeps* in all the essentials of a reliable nature.—*Australasian.*

COFFEE PROSPECTS IN KADUR.—Nov. The Koppa side of the District has begun coffee picking, just the first round of a little ripe here and there. The general picking will most likely begin in about 15 days more. The season is later than last year by nearly a month, in Koppa, and will be almost two months later in the Chickmuglur and Mudgiri Talooks, due wholly to the lateness of the blossom showers which fell at the close of April, instead of the usual middle of March falls. The crops too will turn out a much smaller average. I have not heard yet of any of one estate with a full bearing crop. I have heard, though the boast of two or more estates with a "splendid crop" but the estates belong to persons whose words are always taken with a very liberal pinch of salt. You may rely on this! The crops are not equal to the usual average; some have half, and others three-quarters, and this is as close as it is possible to make to an average.—B.S.—*Madras Weekly Mail.*

COFFEE-DRINKING AND ITS EFFECTS.—New York has a doctor of unusual brightness, who has busied himself lately writing pithy and scholarly monograms on some of the baptised and endorsed evils of society. His latest manifesto is on "How Coffee Affects People;" and the aim of the paper is to show that coffee is one of the most powerful drugs in the list of medicines. The proof of its power as a drug is shown by the fact that it is used to a greater extent than any other as an antidote for poisons, both animal and vegetable. He urges that he does not desire to reach the ear of the public in general, but of those who have pains in the region of the heart, oppressed breathing, and an irregular pulse; those who are exceedingly nervous and unable to sleep at night; those who have a full feeling, dizziness, and pains of a neuralgic character in the head; who have nausea and sourness of the stomach without; having transgressed the laws of life; who have pains in the liver, a yellow skin, with eyes of the same sortd and lastly, who have hemorrhoids. If the doctor supposes he has left out one or two of all creation from this list he may be right, but he certainly is moving a wide swath, and may honestly say he is after the ear of the public. To these he offers one suggestion. Omit coffee for a time, throw physic to the dogs, and find out if the trouble after all is not in the drug used as a beverage. In moderate doses coffee raises the blood pressure and accelerates the heart. Now, says the doctor, heart disease is in the main an easily prevented disease, and it is very frequently due to the excessive use of coffee. He enumerates several instances where he had been called to prescribe and had found his patients given up to die, but there was really nothing the matter but the breakfast drug. He wisely suggests that in this day of sudden deaths we are called upon to review our methods of eating and living in order to get at the cause or causes. "The heart and brain require rest as well as other organs of the the body." If the vessels in the brain are kept distended we have as a warning dizziness and pain, and, if the warnings are unheeded, appoplexy. So with the heart. So short are its intervals of rest when beating at 72 to 84 that we can hardly conceive it. Add to this the stimulus that sends it up to 90 and we must produce disease. He concludes that for our regular meals and at evening parties we should substitute the simpler cocoa or bouillon and escape danger.—*St. Louis Globe-Democrat.*

CINCHONA CULTURE IN JAVA AND SOUTHERN INDIA.

We have received the annual Report in Dutch of M. von Romunde, Director of the Government Cinchona plantations in Java, which we have had specially translated, and also the Report of Mr. Lawson, Director of Government Cinchona Plantaticns, Nilgiris, for 1885-6. We give them in detail in the pages of the *Tropical Agriculturist*, see pages 479 *et seq*. There is very much of interest to the practical cinchona cultivator and especially to the Ceylon cinchona owner at this time when anxiety is felt as to future bark supply and condition of the bark market. In Java there was no special extension of planting operations in 1885, but preparations were being made for a good deal of work in the current year and in 1887. More particularly was attention being given to the planting of a hybrid between Ledgeriana and Succirubra, and to the increase of the grafted Ledgers on Succirubra stems. These latter are said to be flourishing so far, and as grafts are only taken from trees tested up to 10 per cent of quinine, in fact "from the richest known mother trees," it is evident that the Ceylon proprietor has some cause for anxiety in this direction. As regards private enterprise some idea may be formed—though by no means a correct one—from the results of the sales of seed which in that year amounted to 13,471 florins (rupees we may say) and besides, there were sold 2,730 florins' worth of grafts. We are struck by the very careful and improved system of cultivation employed by M. von Romunde, in clean weeding, thorough draining and digging all over his fields. He speaks, too, of thorough digging before replanting a field with ledgers on which coppicing and uprooting had taken place. Close planting is very strongly recommended. *Helopeltis* continued to give annoyance occasionally. Shaving old officinalis trees had been very successfully practised; but in other cases the process of shaving only half the circumference at a time had done harm and a series of experiments in shaving now going on are described. Close planted Ledgeriana trees are said not to stand shaving at all. The total Government harvest of bark in 1885 was about 500,000 lb. As regards the extension of cinchona planting by private owners, the Director says there has been a decided check, but he affords no estimate of the total area planted. There is much more and detailed information, especially as to analyses, and official experiments made at the instance of private planters, anxious to save freight &c. by sending alkaloid extracts in the rough to Europe; but the report on this *quinium* experiment from Holland is not given. It would appear as if 22 lb. of bark (10 kilogrammes) were reduced to 2 1-5th lb. (1 kilo.) the latter (quinium) having 60 per cent alkaloid against 6 per cent in the bark. It seems a pity that M. von Romunde's Report was not available sooner, for it contains a great deal of valuable information. The common idea in Ceylon is that shaving causes the bark to increase in thickness, and that the renewed bark is much richer in alkaloids than the original bark. This, among other things, is apparently proved not to be the case in Java.

Turning now to the Nilgiris Report, we need only notice here that in connection with coppicing, Mr. Lawson considers after careful experiment, it to be quite immaterial at what time of year cinchona trees are cut down. Mr. Lawson gives most encouraging information as regards the great need for an extension of consumption, showing on Dr. Bidie's figures, that Government will not do its duty until 2 million lb. of bark averaging 6½ per cent of total alkaloids are provided for the people in the Madras Presidency alone! At this rate all the present season's crops in Ceylon and India should be kept for the use of the people in these countries. Mr. Hooper (the quinologist) gives valuable information as to shaving and manuring of cinchona trees, the extraction and preparation of cheap alkaloids, &c. Of Mr. Hooper's further good work we have a specimen in a separate Report which has reached us from Madras giving the result of his investigations into the inorganic constituents of cinchona bark. We give this (see page 476) as well as all that is of practical use in the Botanical Director's Report in our pages.

THE CLOUD LIFTED FROM QUININE.

The better feeling in the quinine market, which has been noted in our regular reports for the past few weeks, is not based on any speculative ideas, but seems to be the result of natural circumstances, with a solid foundation to work upon. The violent fluctuations and remarkably low prices which have marked the course of this alkaloid for a long period rather discouraged investors and consumers, and it became recognized as a dangerous speculative article. There were many persons who considered quinine cheap at half a dollar per ounce, but when it touched that figure they were not so ready to invest; consequently there is less stock in the hands of manufacturers and speculators than at any previous period, as less bark was worked into quinine.

The large shipments of Ceylon bark, from 1883 to 1886, rather mystified operators in quinine, and they lost confidence in the market because of the impression that increased area was under cultivation, and that this bearish element would continue to influence values. The Reporter has previously pointed out the fact that root bark had made its appearance in the London market which was evidence of the destruction of cinchona plantations, the trees being uprooted instead of stripping the bark, owing to the industry proving unprofitable. This has undoubtedly accounted for the large receipts, as whole roots came to the market instead of strips as heretofore. It is stated that the acreage under cultivation in Ceylon is two-thirds less than during 1883, which is a strong argument alone in favour of a reaction.

But what of the Java and South American fields. The latest information from Java was published in these columns last week, and showed a decline in the industry, according to a British consul, but previous reports gave more encouraging prospects; still, that country is not yet recognized as an important factor in the situation. South American barks received a back set from previous experience which it will be difficult to recover from, but in the event of a scarcity of Ceylon barks, followed by extreme prices, South American barks will have to be drawn upon, but the comparatively low percentage of quinine they contain prevents them from being an equal substitute. Manufacturers are speaking more hopefully of the future, and are firmly inclined to the belief that the extreme low prices will never be reached again. The rumor of a combination among foreign manufacturers has no foundation in fact; such a thing is among the improbabilities, as their experience with the syndicate disgusted some of them, and brought about a determination to oppose all pools.—*American Oil, Paint and Drug Reporter.*

JARRAH AND WHITE ANTS; TANNIN IN PINE; STARCH IN PLANTS. NOTES ON POPULAR SCIENCE.

By DR. J E. TAYLOR, F.L.S., F.G.S., EDITOR OF "SCIENCE GOSSIP," &c.

I understand that Mr. Bosisto, with characteristic energy and scientific acumen, has been engaged in investigating the reasons why the Jarrah wood (Eucalyptus marginata of Western Australia) is enabled to defy both the attacks of white ants on the land and those of ship-worms, &c., in the sea; and, further, that he has discovered the chemical principle, and is able to extract it. This is a most valuable discovery, inasmuch as it will now doubtless be possible to make a solution of the substance and impregnate other woods with it, after the manner of creosoting timber. Here is another new industry for Australia. By and by, in a century or so, your descendants will perhaps be sorry you have been in such a hurry to ring-bark and destroy your characteristic gum-tree forests. How hopeless we are to withstand the attacks of white ants is well indicated by the reply of Professor Riley, the well-known American entomologist, who when asked for a remedy against these insects, could only advise his querist to "burn all the wood work above and underground" in his green-house.

A discovery has just been made which may indirectly affect you in Australia, where the wattle is grown for the sake of the usefulness of its bark in tanning. For some time past attempts have been made in Sweden to extract tannin from a native species of pine. This species is nearly related to the American hemlock (Pinus canadensis). Hitherto these attempts have all turned out failures. During the present year a Swedish chemist (Dr. Laudin) visited America for the purpose of experimenting on the hemlock, and he appears to have succeeded, for, on his return to Sweden, he obtained tannin from the Swedish pines by a chemical process. The tannin is said to be equal to the American, but the leather produced by it is yellower in colour. The Swedes are in hopes that this new discovery will have the effect of causing a great tanning industry to spring up in their country. The character of tannin in plants is now better understood than formerly. It is no longer regarded as a purely waste or excrementitious material, but under some circumstances may be converted into good material.

It has been discovered that the leaves of plants are able to form and store up starch, not only from glucose and cane-sugar, but also from mannite, and even glycerine. Potato-shoots growing in dark rooms are also able to form starch out of glycerine, as well as out of glucose and saccharose.— *Australasian.*

GAMPOLA-KADUGANNAWA, 20th Dec.—A good deal of rain fell yesterday and last night. This morning showery, and it looks as if it was going to continue, so I have put a few coolies to supply my tea field with others following them with fern and other shade to place over the young plants. What destructive little creatures rats are, they have been amusing themselves running over my clearing, and nipping the small tea plants in half. If it was not for the dense lantana, what a glorious district this would be for pig-hunting.

THE CULTIVATION OF TEA IN ALBANY, S. AFRICA.—Lower Albany, which may be said to be a suburb of Grahamstown, is anxious to make the most of its resources, and has taken to the cultivation of tea. This is an industry sure to pay, because it gives little trouble, and tea is in constant demand in the Colony, at good rates. Moreover, the tea plant is well adapted to the climate, and is nothing dismayed at a stretch of drought, or an occasional frost. As Mr. Cannell, of Port Alfred, has seedling plants for sale, at a small cost, it may be expected that many people will take up this industry.— *The Colonies and India.*

TEA PACKING.—A buyer writes (sending us a newspaper extract):—"You would be doing the trade a service if you drew planters' attention to the enclosed hints on the packing of tea. It would be very desirable if standard weights were adopted for each description of package, 40 and 45 lb. half-chests are the most expensive weights to work in the London warehouse, besides the heavy percentage of loss in weights by draft and trade customs in mode of weighing the gross and tare." The extract is as follows:—

Packing.—It would seem from the various net weights of Ceylon packages received on this market that the reduction of freight and warehouse charges and loss in weight to the lowest possible point *per lb.* is not sufficiently studied. I find on going closely into the subject that the most economical weight for *leaf* tea to pack in a half-chest is 55 lb. of Broken tea and Dust 60 lb. might I think be packed—care being taken that the tare of the latter does not exceed 19 lb.

For chests, of a handy size, 95 lb. net or even 100 lb. in Japan would is the most economical weight. Chests, when practicable, should always be used when a sampling break can be made up so packed, as besides effecting a saving of about 20 per cent. on the item of Warehouse charges alone, freight and loss in weight are both less. Boxes should not be used except for very choicest teas as besides Warehouse charges and freight per lb. being about double that of chests, the loss in weight is invariably very excessive 7 per cent not being at all uncommon. Boxes, unless those imported from Japan, should neve contain more than 15 lb. of tea, care being taken to ser that the Gross is not over 28 lb. As the market for tease in boxes is somewhat of a fancy nature it is very doubtful if the extra price generally paid is equilized by the extra working expenses and loss in weight incurred. Care should be taken to get the tares of all packages slightly *under* the lb. with Gross weight a good ½ of a lb. *over* the pound, so as to guard against Colombo sampling reducing the gross weights to under the lb. entailing a loss frequently of a lb. on every package, not difficult of attainment if a full ½ of of a lb. extra tea is given in with each package. In hooping packages on the estate for local sale the lid should be left *un*hooped to admit of ready sampling without breaking or cutting the hooping.

OODEYPORE.—Mr. T. H. Storey, the Superintendent of the Gardens of the Maharana of Oodeypore, forwards us a copy of his annual report. Oodeypore is the only station in Rajpootana, and one of the very few places in the native states where the garden establishment is directed by a professional gardener. Mr. Storey, we believe, was trained in the Edinburgh Botanic Garden. The following extract will suffice to show the different conditions under which gardeners in India have to work from what obtain here:—

"FLYING FOXES.—There has been a colony of flying foxes, which had taken up their quarters here for the past fifty years, and were quite a nuisance. They seemed to keep up all day a horrible screaming noise. They were hanging on to large Ficus, Mango, and other trees. There were also many swarms of bees, and the foxes had a very poor time of it. The bees appeared to hate them, and used to chase them all round the place. The trees were quite leafless, and to all appearance half dead. On His Highness coming one morning this way, I took the opportunity of speaking to him about them. He told me, if possible, to have them hunted away, an undertaking which, I am happy to say, was successful. I collected all my men and boys, gave them old tin pots, tom-toms, &c., and made them get up on the trees to the very top. When they began beating their tins, the whole of the foxes got on the wing, and kept them for a few hours, when a few of them took the lead, and the whole flock went off three or four miles away. I expected them back in the morning, and I was not much disappointed, for they were returning to their old place from their night's feed; they must have been disgusted at seeing the men still perched in their quarters. The men went up the trees at 3 o'clock in the morning, and did not allow them to alight so off they went, and have not returned. The trees they were on are now covered with leaves and looking well."—*Gardeners Chronicle.*

Correspondence.

To the Editor of the "Ceylon Observer."

THE VALUE OF LIME TO PLANTERS.

Analytical Laboratory, London E. C. Nov. 19th 1886.

DEAR SIR,—I believe you see the *Field* every mail and if so, you will notice an article on Lime, on Nov. 13th. which may be of interest to the readers of the *T. A.* You remember I recommended the more extended use of lime, while in Ceylon and have frequently referred to the subject in letters from here. I have had so many practical proofs of the great benefit from the judicious use of lime in some of its numerous forms, that I find the testing of soils as to the *presence* or *absence* of a fair supply of lime one of the most important points to be ascertained before considering the kind of manure likely to be most suitable for such soil.—Yours in haste, JOHN HUGHES.

[The paper in question by Mr. Hughes in the *Field*, will be found on page 470.—ED.]

COIR FIBRE REFUSE.

10th Dec. 1886.

DEAR SIR,—The manurial value of fibre refuse is, I see, again being discussed in your columns. With all due deference to the veteran "C. S." and his greater "inventive genius and mania for experimenting" than Mr. David Wilson's, I submit that Mr. Wilson's allowing heaps or mounds of this valuable refuse to accumulate on Horrekelle, is not "a good excuse for his successors not doing more than experiment with it." Mr. Wilson cannot be allowed to have been anything more than an amateur engineer. He was by no means an agriculturist. Very many people imagine that because they own properties and take an intelligent interest in their cultivation, they are, therefore, competent practical agriculturists. To say that because "such a man came to the conclusion that "Horrekelle fibre dust could not be beneficially used," therefore, his conclusions are to be accepted as final, is absurd in the extreme. If fibre dust is of no manurial value, which I by no means admit, yet it possesses a high agricultural value owing to its absorbing properties and owing to its being so retentive of moisture. As a "vehicle" for all artificial manures these properties ought to make it invaluable. It is wellknown that roots *absorb* manure, and to do this moisture must be present, or the manure will remain inert, therefore, a substance that can absorb "12·5 its weight of water" and in which "evaporation proceeds much more slowly" than in open vessels, must be of immense value for application with manure, especially in a dry climate and in a sandy soil through which moisture passes as through a sieve. If a cattle establishment, a *sine qua non* on a properly cultivated coconut estate exists on Horrekelle, what better bedding can be found to absorb all the liquid deposits of cattle?

No one suggested as "C. S." imagines, fibre dust to be used as a top-dressing by itself for coconut plantations. Mixed with artificial manure it can with advantage be deeply ploughed into the "Horrekelle sand." It will, in decomposing, improve the texture of the soil and prevent its too rapid drying. I must join issue with "C. S." when he says that put into holes the benefit is remote and is reaped only when it becomes humus. I maintain that if put round trees after the sand has been scooped out, the benefit is immediate. Coconut trees revel in moisture which when absent cause the leaves to turn yellow and droop. The benefit which so much moisture, as say 15 baskets full of fibre dust represent is not to be despised, especially in a period of drought. With a Decauville Portable Railway the "vast mounds" of valuable substance could in a short space of time be placed in the right place.

If "C. S." has ever seen a heap of coconut husks burnt, he will have observed that in the resulting ashes there are cakes of potash salts. By asserting that fibre dust is of "no value as a fertilizer," does he assert that potash is present only in the fibre and not in the dust? The purity and strength of these salts is so great, that in the villages the husk-ash takes the place of soap with the Dhoby. —Truly yours, A. W. B.

P.S.—"C. S." not growing brinjals successfully in fibre dust proves nothing.

A NEW PLANTING COMPANY.—The Mammoth and Alpha Skull Estate Syndicate, Limited, was registered on the 3rd inst., with a capital of £20,000, in £1 shares, to take over lands, estates and properties in India, and in particular the Mammoth and Alpha Skull Estate, situate in the South-East Wynaad in the Nilgiri District of the Madras Presidency,—*Planters' Gazette.*

"GALLELLA TEA ESTATES COMPANY LIMITED. —Is the latest addition to local planting Companies and we are glad to find that under the auspices of Mr. C. H. Wilkinson,—a well-known planter with about a dozen years' experience—this Company brings in entirely fresh capital into the Colony. The Gallella property of well-nigh 500 acres with 200 acres in tea from 4 years old downwards, about 100 acres good coffee and some cinchona, has been purchased from Messrs. Cross and Ballardie for a cash sum in sterling on behalf of a few capitalists, who are associated with Mr. Wilkinson, belonging to the English Midland counties. Gallella teas have already made their mark in Mincing Lane, averaging up to 1s 5½d. Mr. Wilkinson settles down as local manager, and the directors of the Company hope to find a direct market for their teas in the country commanded by Leicester, Derby and Nottingham. We wish the Gallella Estates Company all success.

NATIVE AGRICULTURE AND PLOUGHS IN INDIA.— —Says the *Pioneer*:—

"The writer whom the *Times*, has employed to describe the Indo-Colonial Exhibition tells us that all attempts to introduce improved agricultural implements in India have failed; that as the hard soil below three inches is completely sterile, deep ploughing would prove a dead loss to the farmer for probably five years; and that the experiment farms and agricultural institutions of India have had no effect on Indian agriculture. These statements are altogether too sweeping. If the writer had taken the trouble to look at the list of implements and machines "used with marked success in India during the years 1882-83 to 1885-86" he would have found 16 different ploughs of an improved make in use, one American, several European, and some merely improvements on the old country ploughs. Still less accurate is to say that experimental farms have been a failure. To take only one of many examples, the Cawnpore Experimental Farm manufactures and sells two sorts of improved ploughs, and imports another for distribution among the cultivators. During the years 1883-84 and 1884-85 some 400 of these ploughs were sold. It is no doubt true that very much yet remains to be done to meet the wants and overcome the prejudices of the native agriculturist but a good start has been made by these experimental farms. Without professing a knowledge of agricultural chemistry, we must beg leave to doubt the five years' loss entailed by deep ploughing. Taking the average of all the experiments at the Cawnpore Farm in 1884-85, deep ploughing gave an increase over the ordinary shallow country ploughing of 53·5 per cent. when the land was ploughed 9 inches deep, and 43·5 per cent. when ploughed 5 inches deep, although the shallow ploughings were twice as frequent as the deep,'

INORGANIC CONSTITUENTS OF CINCHONA BARK.

Dr. Hooper, the Madras Government Quinologist, has reported as follows:—I have recently been engaged in examining the inorganic constituents of cinchona bark, and, considering the results would be of use to all engaged in cultivating cinchona, I forward you the results of my analyses. The dried bark always contains from 2 to 4 per cent of ash, the young bark yielding more than old and renewed specimens. I have analysed samples of bark from *Cinchona officinalis* growing in the Dodabetta plantation, and also from *Cinchona succirubra* growing at the lower elevation at Naduvatam; and it will be seen that there is a great similarity in the composition of the ash derived from both these species:—

	C. officinalis.	C. succirubra.
Silica	5·75	5·60
Soluble Silica ...	1·42	4·40
Alumina	2·70	4·24
Iron oxide	2·85	3·21
Lime	32·70	32·80
Magnesia	2·07	2·52
Potash	16·35	12·49
Soda	3·40	2·28
Carbonic acid ...	27·22	27·77
Sulphuric acid ...	1·16	1·08
Phosphoric acid ...	3·93	3·19
Chlorine	·45	·42
	100·00	100·00

The chief constituent of the ash is the lime, which forms nearly one-third of the whole. It probably exists in the bark in the form of kinate or oxalate of lime, and when incinerated becomes carbonate of lime. The next element of importance is the potash, which amounts to one-sixth and one-eight part of the whole ash respectively. The examination shows that both lime and potash must be present in soils where cinchona plants are grown.

THE CEYLON TEA PLANTER'S MANUAL.

Mr. T. C. Owen has issued a very useful little hand-book, under the above title, which cannot fail to be of much interest to Ceylon Tea planters. There is a good deal of valuable data regarding Buildings, and cost of working on Ceylon Tea Estates. The author says that as a tea-producing country Ceylon possesses many advantages over others. The hills are eminently suited for Tea, the localities are healthy, and the transport facilities are very great. Labour is abundant, though not very cheap; rainfall is well distributed and amply sufficient, so that the check of growth which causes the Tea to winter in India, does not occur so markedly in the Island. Although the harvesting of ripe seed is found to be very difficult and expensive matter in Ceylon, great progress has been made in this direction, and Ceylon is now by no means so dependent on India as she once was for her seed supply. The seasons differ so widely in Ceylon from ours that, necessarily, the systems of cultivation differ widely from ours, but the Indian planter may nevertheless be interested in comparing the two; and this the Book before us will enable him to do. The figures given as to yield and cost of manufacture are particularly interesting. It is stated that 400 lb. per acre on the hills, and 600 lb. per acre in the lowcountry, are easily obtainable, but these figures have been in several cases considerably exceeded—in one instance enormously so,—the Mariawatte estate having yielded 1,200 lb. per acre.

One great advantage which Ceylon Tea estates enjoy is comparative freedom from blight. The worst enemy in the Island for cocoa is the Mosquito Blight, but it has not yet seriously attacked Tea. It is far otherwise with us, unfortunately. Whether, as Tea cultivation in Ceylon extends, the present comparative immunity from Blight will continue, is a question. Lately, it is said, a *Caddis worm*, or insect closely resembling one, has proved destructive to the bark of the tea-bushes, but this insect can easily be picked off and destroyed. Reference is made to the jungle-tree *Symplocas obtusa*, whose decaying roots kill all the tea-plants within their range, but as its evil effects on Tea are so well known, it is not difficult to avoid it, by extermination. Any who may think of trying their fortunes in Tea, in Ceylon, should obtain the Work under review.—*Indian Tea Gazette.*

CHEMICAL IMPROVEMENT OF TEA SOILS.

We proceed now to consider the *chemical* requirements of what should be a good tea soil, and by what means imperfect soils may be brought near the standard of perfection.

It is well known that the soil is the source from which the plant draws through the medium of the root the mineral or inorganic portion of its plant-food, the organic portion being derived through the leaves from the atmospheric air.

In order to determine now what mineral plant-food, a would-be good tea soil must contain, and in what proportion, we must base our remarks upon the tea plant itself, and upon the inorganic substances we find in it as revealed by an analysis of its ashes.

Mr. Schrottky gives the composition of the ashes of young leaves of the *Assam hybrid* tea plant as follows:—

	In 100 parts.
Chloride of Sodium	2·247
Soda	8·941
Potash	36·514
Magnesia	10·089
Lime	8·517
Oxide of Iron and Manganese ...	3·966
Phosphoric Acid ...	16·214
Sulphric Acid ...	13·017
Silica	0·439
	99·944

And states that old leaves and stems will contain more lime and silica than here represented.

Now a soil, to be a *first class tea soil*, should contain all these constituents in proportions which closely approach the above percentage; that is to say, the rootlets of the tea plant should find distributed in the soil, for every 36 parts of potash 10 parts of magnesia, 8 parts of lime, 16 parts of phosphoric acid, etc., etc. If we find, therefore, that any soil contains these substances approximately in the above proportions, not leaving out of sight that potash can take the place of soda, and lime that of magnesia, then indeed it would be impossible to further improve its *chemical* constitution. But it must be remembered that the mineral plant-food in the soil exists in two different states, which stand in very different relations to the requirements of the plants we refer to,—mineral plant-food in *physical* and in *chemical* combination. In the former state it is immediately available for the purposes of the plant, while in the latter it can only become so after the prolonged action of climate and atmospheric influences upon it. At present we have only to do with the former.

Let us assume now, that we find in a soil all the different constituents of available mineral plant-food to be present in proximate proportions to those required by the plant, with the exception of phosphoric acid, of which, say, only 6 parts are available for every 36 parts of potash, etc.; than every pound of phosphoric acid added would render a correponding quantity of the remainder of mineral plant-food, heretofore useless to the plant, available to it, and consequently stimulate the formation of new tissues; *i.e.*, increase the outturn. We can distribute through the soil 10 parts of phosphoric acid in addition to the 6 parts already present, and we will thus make up the 16 parts necessary to correspond with the remainder of available inorganic plant-food. Every pound of phosphoric acid added in excess of this quantity is perfectly useless, as there is not the corresponding quantity of potash, lime, &c., present

and if we wanted to further increase the capabilities of the soil we would have to add the whole of the mineral plant-food in the proportion indicated in Mr. Schrottky's analysis. What has been said of phosphoric acid holds, of course, good for any of the other substances: they have all certain functions assigned to them; they are all jointly and separately indispensible to the plant; and there is not one more important than any other, as far as the requirements of the plant are concerned. If we should find that there is plenty of available phosphoric acid and lime, &c., but that for every 16 parts of phosphoric acid there are only 15 parts of potash present, we must add 21 parts of it in order to bring the proportion of available plant-food up to the standard required by the plant and *thus enable the soil to produce its maximum* with a minimum outlay

In fact it is that ingredient of available mineral plant-food which, if present in smaller proportion than required by the standard when compared with the rest, regulates the outturn of a tea garden; every additional pound of this substance added will start, so to speak, into life the slumbering power of the soil; every pound added will have a marked effect upon the outturn, until the quantity added shall make up the proportion in which it is wanted by the plant. It is, not always necessary to add the exact mineral wanted, if, for instance, we find a deficiency of available potash and phosphoric acid in a soil in which there is an abundance of these two substances in chemical combination as insoluble. Phosphate of lime and silicate of potash, and addition of common salt and burnt lime, will have the effect as the addition of potash and phosphoric acid. For common salt will dissolve the phosphoric of lime, and enable it to enter into physical combination with the soil, while the caustic lime will decompose the silicate of potash and set the alkali free to enter into such combinations as are available to the plant. It is, therefore, a most important point for the tea planter to ascertain whether the availabe mineral plant-food present in his soil comes up to the standard required by the plant; or if not, what constituent is present in relatively minimum quantities. The determination of this point cannot be over-estimated in its importance: it may save the planter hundreds and thousands of rupees, and it is the only way by which he may know thoroughly the nature of the capital he is working with. The knowledge of what available plant-food there is in the soil, and in what proportion, should be the basis of all agricultural operations: it should decide what manure is to be applied, and in what manner. It falls, of course, within the province of the agricultural chemist to supply the planter with the facts dilated upon, and it is our opinion that any expense thus incurred will be amply repaid by a judicious use of the knowledge acquired. The first use of this knowledge should be to supply to the soil the minimum constituent of available plant-food, or if chemical analysis should reveal that abundance of this minimum exists in chemical combination, to add to the soil such substances as will free it from its locked-up state, and render it available for the purposes of the plant. When the plant-food in the soil has by either of these means been brought up to the standard, all further manuring must have reference to what is withdrawn fom the soil, and we cannot too much recommend the planter to bear in mind the Chinese axiom of agriculture that "*without continuous manuring there can be no continuous harvest.*"—*Indian Tea Gazette.*

THE COLONIAL AND INDIAN EXHIBITION.

West Indies.

Vegetable products, as might be expected, formed the bulk of the exhibits in this attractive Court, which had an air of comfort and finish not excelled in any other part of the building. Entering the Court from the northern end, the first bay on the left hand was devoted to

Trinidad, an island celebrated both for the quantity and quality of the cocoa grown upon it which indeed is the staple article of produce. The value of cocoa exported from Trinidad in 1885 is stated in the official Hand-book to have amounted to 421,974*l.*, and in some "Notes on Trinidad Industries," by Mr. John McCarthy, F.C.S., the Assistant Commissioner for Trinidad, recently published, it is stated that the quantity of cocoa imported into England in 1885 amounted to 10,530 tons, against 10,120 tons in 1884 and 9986 in 1881. Numerous specimens of cocoa seeds are exhibited, as well as prepared cocoa and chocolate. Mr. McCarthy describes the cultivation of the cocoanut (*Cocos nucifera*) as a very profitable industry, though the tree does not bear much before it is eight years old. Experiments, he tells us, "are now being tried in Trinidad to make it act as a shade tree to the cocoa (*Theobroma*)" instead of planting the quick-growing "Bois immortelle." The idea of this planting is to realise from the same land a double crop, namely, that from the *Theobroma* and that from the *Cocos*. It is estimated that seventy trees planted upon an acre of land would, when in full bearing, yield 5000 nuts per annum, which would net, on an average, from 3*l.* to 4*l.* per thousand in Trinidad. The annual import of nuts into London is said to be about 12,000,000, besides which, New York imports enormous quantities, and they are also used to a very large extent for the expression of oil in Trinidad itself. Coffee has also a prominent place in the products of Trinidad, and the plant is stated to thrive well, although it has not yet produced even sufficient coffee for home consumption. More attention has, however, been directed of late to coffee culture in the island, so that it is largely increasing. The cultivation of tobacco is also an industry that promises to become of some importance, and the tobacco is described as being second only to the finest Havana. There is a good exhibit of cigars, which are said to have met with general favour, so that a demand has arisen for them.

Bahamas.—In the Official Hand-book, Sir Augustus Adderley gives a very readable sketch of the history of these islands, and briefly refers to the natural products, foremost amongst which are corals and sponges. He describes the "sponging and wrecking vessels" as fine models and fast sailers, built by the islanders of native hard wood known as "horseflesh," and planked with yellow pine obtained from North Carolina. Conch shells are exported in large quantities to the value of about 1200*l.* per annum, and the pale pink pearls which are found in them to the extent of 3000*l.* per annum. The sponge exports were estimated at 60,000*l.* for 1885. Mention is made of the abundance of plants valued as medicines, many of which might be further developed by systematic trial of their effects in this country. Perhaps the two best known medicinal plants are the Canella Bark (*Canella alba*, Murr.) and the Sweet Bark or Cascarilla (*Croton Eleuteria*, J. J. Benn.). The first has a bitter, acrid, and pungent taste, and a cinnamon-like smell. With us it is used as an aromatic stimulant, and as a condiment in the West Indies. The sweet bark is a bitter aromatic tonic, formerly used as a substitute for Peruvian bark, but now chiefly as an ingredient in pastilles and for mixing with tobacco for the sake of its pleasant musky odour. The cultivation of perfume-yielding plants is recommended as a probable commercial success, demand for perfumes at the present time being so great that it has even been proposed to cultivate in Australia on a large scale such plants as are now grown at Grasse, Nice and Cannes.

Jamaica.—The contents of this Court were both numerous and varied. Rum and sugar were fully illustrated by a large number of samples. Coffee was also well represented; of this article the Official Catalogue states that two distinct classes are produced in the island, the total annual export being about 84,000 cwt. per annum, of which about 10,000 cwt. is Blue Mountain coffee, a fine quality, consigned almost entirely to the Liverpool market. Pimentoe or allspice is a product exculsively of Jamaica, where

it is grown in plantations or gardens known as "pimento walks." The commercial article consists of the dried berries, which were exported from Jamaica to the value of 53,867*l.* in 1885. It is very largely used as a spice as well as in medicine, on account of its aromatic and stimulant properties. The fruits contain a quantity of oil, which is obtained by distillation, and is used in perfumery and for similar purposes to which clove-oil is put. Pimento-sticks are amongst the strongest and best for walking-sticks and umbrella-handles, on account of their strength, rigidity, and non-liability to crack. The pimento-tree is of low growth, and is known to botanists as *Pimenta officinalis*.

In this Court were shown some remarkably fine samples of Annatto seeds (*Bixa Orellana*), noted for their plumpness, as well as for their bright colour, the waxy coating of the seeds being highly valued as a red colouring-matter. A large and interesting collection of fruits preserved in a salt-solution were here shown; amongst others the following will attract attention:—Star-apple (*Chrysophyllum Cainito*), Cocoa-plum (*Chrysobalanus Icaco*), Blimbing (*Averrhoa Bilimbi*), Akee (*Cupania edulis*, better known, perhaps, as *Blighia sapida*). Many of these are the produce of introduced plants, and the fruits are for the most part fine examples. Amongst a number of specimens of essential oils from well-known plants, most of which are apparently of excellent quality, are some that are but very little known, such, for instance, as those from the Bermuda Cedar (*Juniperus bermudiana*), the Mountain Cigar Bush (*Hedyosmum nutans*), Mountain Thyme (*Micromeria obovata*), Cigar Bush (*Critonea dalea*), and the Sand Box-tree (*Hura crepitans*).

Barbados.—The exhibits from this island consisted largely of similar produce to the islands already referred to. As illustrating the extent of land occupied by sugar cultivation, it is stated in the introductory notice of Barbados in the Official Handbook, by the Hon. C. C. Knollys, that "out of a total acreage of 106,470 acres, an area of 100,000 acres is devoted to canes." Tobacco is recommended for extended cultivation, and root-crops such as arrowroot and cassava give heavy returns.

British Honduras.—We take this dependency in this order, as it occupied a position in the Exhibition next that of Barbados. The importance of timber in the produce of British Honduras is seen by a simple glance at the exhibits, and to the future development of these timber resources lies in a very great measure the future prosperity of the colony. In the introductory notes to these exhibits the following paragraph occurs:—"To its timber and dye-woods the colony of British Honduras owes its existence, and whatever measure of progress and advancement it may have attained. To the discovery, first of logwood, and subsequently of mahogany, its original settlement must be ascribed."

Notwithstanding the importance of the forest produce, very few of the timbers are yet known either to commerce or to science, but many of them are of exceptional hardness and beauty. Mahogany is, of course, the most important wood in the colony, and, next to it, the cedar (*Cedrela adorata*), which is not only exported to a very large extent, but is also used in the colony for light indoor work—cigar-boxes, trunks, packing-cases, and for dug-out canoes, several of which were exhibited. Amongst a collection of lianes, or climbing-plants, is a specimen of the chew-stick (*Gouania domingensis*), with the singular information, besides that of its use as a tooth-brush and tooth-powder, that "it is used in place of yeast to start fermentation in making ginger and spruce-beer, &c." Probably the most striking object in this Court is a large and beautifully figured slab of mahogany; the dark wavy cross-markings are extremely beautiful and very remarkable in this wood; the plank is moreover, without a flaw.

Dominica.—The space occupied by this island, as well as by the remaining colonies, was small; the exhibits on the whole, however, were interesting, and some were worth noting, such, for instance, as the husks or shells of the Liberian coffee, which are said to be worth from 1 to 2 cents per pound in the United States, the fruits of *Acacia Farnesiana*, stated to be used in tanning, and bark of Guava, the *Psidium Guayava*, which is rich in tannin, and is used as an astringent. Raw lime-juice is exported from Dominica in increasing quantities, but the greater part of the juice is boiled down until ten or twelve gallons are reduced to one, and is shipped in this concentrated form to England and the United States for the manufacture of citric acid.

Montserrat.—Sugar and lime-juice are the principal staples of this island, and these were the most prominent exhibits.

St. Kitts and the Virgin Islands.—From these islands the exhibits were but small, and without special interest.

Antigua.—The chief product of this colony is sugar, the average crop of which for the last twenty years is stated to have been about 12,000 hogsheads. Yams, potatoes, and Guinea corn are also grown in large quantities for native consumption. The exhibits were for the most part such as were shown in other West Indian Courts.

Grenada.—Cocoa is the most important article grown here, and some very fine fruits of good colour were shown, as well as nutmeg (*Myristica fragrans*) custard apples, or bullock's heart (*Anona reticulata*), papaws (*Carica Papaya*) Kola nuts (*Cola acuminata*). These latter were remarkably fine specimens. A good deal of attention, we are glad to see, has recently been paid to its cultivation. The tree exists in all parts of the island, and was introduced in years past by the African slaves, who used to regard it as a specific against intoxication.

Tobago.—The productive resources of this small island are varied, and were well exemplified in the collection of fruits, seeds, fibres, &c. The collection of preserved native fruits in syrup, and jellies prepared from them, was a special feature in this Court, a sample of preserved or candied papaw (*Carica Papaya*) being especially good.

St. Lucia.—Sugar, rum, and molasses are the chief products; cocoa and log wood are also produced in quantities, though the latter is stated to be at the present time a drug in the market. Tobacco, it is stated, has been tried in one district with most satisfactory results, so that it is purposed to extend its cultivation. Neither the individual exhibits in this Court, nor in the remaining one of St. Vincent, call for any special remark. We cannot conclude our notice of the West Indian exhibits without a reference to the series of over 100 water-colour drawings, by Mrs. Blake, illustrative of the flora of the West Indian Islands.—JOHN R. JACKSON, Museum, Royal Gardens, Kew.—*Nature*.

OPENINGS FOR CAPITAL IN CEYLON: THE O. B. C. ESTATES.—The long advertisement in local papers of estates offered for sale in connection with the O. B. C. liquidation must have attracted general attention. At first sight, we thought the new Estates Company was parting with some portion of the list of properties transferred to them by the Liquidator. But this is not the case. The Oriental Estates Company or whatever the title is to be, bought altogether 20 estates from the Liquidator, comprising about 11,000 acres, and the Directors have no intention of selling any of them. But it appears the Bank Liquidator has still the properties advertised on hand, and it must be acknowledged that some of these are exceptionally desirable with reference to more than one branch of cultivation in Ceylon. We would instance Mahabiriatenne, Attabagie, Mooroottie and Ancoombra. The first-named, we are told, is likely to give a profit this year of R20,000. There is therefore much encouragement for capitalists looking after these properties, carefully availing themselves of the advice of practical men of established local reputation in reference to the values to be placed on them.

CINCHONA IN JAVA:
REPORT ON GOVERNMENT GARDENS FOR 1885.

Translated from the "Medical Times" of Netherlands India, 26th Volume.)

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE IN THE PREANGER-REGENCIES FOR THE YEAR 1885, BY R. VAN ROMUNDE, DIRECTOR OF THE GOVERNMENT CINCHONA ENTERPRIZE.

1.—Weather.—The year 1885 was remarkable for the sudden change from a very rainy to an equally dry east monsoon. The rains continued to about the middle of the month of May, when a very severe east monsoon set in, during which hardly any rainy days are recorded and which lasted to the beginning of November. The month of November and the early part of December were very wet, whilst the rain considerably diminished during the second half of December. At Nagrak, in the Tangkoebanprahoe range of mountains, there was a rainfall in the middle of August, which in a few hours amounted to fully 100 milimeters accompanied by a fall of hail which caused some damage to the plantations. Night frosts were recorded during in the months of June, July and September, but they caused little or no injury to the plantations; the flat and hollow parts of the land were most affected, these had suffered during the previous year and are not intended to be replanted.

Storms were felt during the months of March and December, and wrought some mischief to the plantations, especially at the establishment Nagrak.

2. Extension.—The number of plants put out into the open ground amounted at the end of the year to 1,567,000. Though a lower figure has to be given for this year's planting than that for the previous year, yet this is solely to be attributed to a more careful enumeration of the existing plants, and not to a real decrease. The number in the nurseries is estimated at 1,390,000 of which 1,165,000 are Ledgerianas and 225,000 succirubras of which a great part will be planted out in the field during the 1st quarter of 1886. Among the Ledgerianas are comprised + (plusminus) 35,000 grafts, which in the 1st and 4th quarter of 1886 will serve to extend the plantations at Tirtasari which consist exclusively of grafts and suckers. Every export has been made to extend the cultivation of Ledgeriana and Succirubra seedlings. The long continued drought was, however, unfavorable to the development of the germinating beds and nurseries and disappointed our hopes of having an enormous number of seedlings ready for supplying and planting out during the last quarter of 1885. It will only be in the first quarter of 1886 that the whole of the ground, which has been dug over will be again planted with Ledgerianas and Succirubra. The comparatively small number of plants raised from seed, which have been transferred to the open ground is to be accounted for by the fact, that only the very strongest and best developed plants were used for that purpose. In large and hardy plants it is easy to recognize the best sorts, so that all undesirable hybrids can be rejected, the upkeep of young plantations which have been formed of hardy plants requires careful and attentive supervision and much less supplying is necessary. But the great advantage of the use of well-developed plants for putting out, lies in the shortening of the period, during which the young plants require very careful upkeep, by which an important reduction of cost is obtained.

For the replanting of certain gardens where the ground has been dug over across between C. succirubra and plants raised from hybrids derived from Ledgeriana seed has been exclusively used. Especially in the establishment at Tjibitoeng the plantation of these hybrids was very considerably extended and from this a very important harvest may shortly be expected. The cultivation of the grafts of Ledgeriana or Succirubra has been during the past year pursued with greater vigour than ever. At Tjinjiraean two germinating houses have been prepared, which are completely successful, whilst about ten small buildings of light materials have been constructed for the grafts which have already taken root. Besides the 35.000 grafts which will be ready to put out in the open ground by the end of 1885, the nurseries contain about an equal number of growing graft plants which will be ready for planting out in the latter part of 1886. The graft nurseries are formed exclusively of the richest known mother trees, of which mention is made in the report for last year. Nos. 25, 34, 38, 75, 94 and 120, the bark of which contains more than 10 per cent of quinine. The plantations of grafts from these trees, was not however extended beyond what was neccessary for the due completion of the gardens. The grafting of the sorts richest in quinine obtained from the mother trees Nos. 23 and 38, the bark of which yielded at least 11 per cent at the age of 6 to 7 years was pushed forward with greater force. From these grafts already planted and still to be planted great hopes are entertained as regards the seed harvest. The cultivation of the Ledgeriana seed plants is now coming more to the front, since some analyses of grafts from known mother trees appear to shew the (beneficial) effects which the succrubra stem exercises on the constitution of the bark of the Ledgeriana grafts.

The extension of the cultivation of the hybrids of C. Ledgeriana and C. Succirubra spoken of in the report for last year, for want of the necessary graft nurseries, has not been so great as was hoped for and expected and the plantations thereof have only been slightly increased. The original Ledgerianas produced in the course of 1885 not only abundance of seed for the Government enterprize, but sufficient for important public sales of succirubra and Ledgeriana seed at stated times. There has always been a great demand for seed produced by the graft and sucker plantations at Tirtasari, which command good prices.

Consequent on the large quantity of seed from original trees, which from time to time was exposed for sale, the demand for the typical Ledgeriana descendants became so small that the collection and sale of the seed was discontinued.

In the month of December 1,000 grafts were sold by public auction.

The proceeds of the sale of seed during 1885 amounted to	*f*	131,471	25
That of grafts	„	2,730	00
Total guilders		16,201	25

On the sale of each lot of seed a portion of it was set to germinate on the government's establishment, for the purpose of having the means of forming a judgment in respect to any subsequent complaint that might be made, as to the germinating power of the seed sold.

All these trials gave favorable results, and no well-founded complaints regarding the seed thus sold were heard of. The demand for succirubra seed made by Foresters was fully met, but the culture of cinchona as a means of forming forests does not seem to answer to former expectations. The demand for Ledgeriana and succirubra seed by botanists or by the representatives of scientific institutions under foreign governments has been insignificant during the past year. At the end of December 1885 the two and three year old grafts in the plantations Tirtasari began to blossom freely, this is especially the case with the grafts from the mother tree No. 25 of which a great portion of the Tirtasari plantation consists.

These trees so rich in quinine promise to yield a large quantity of valuable seed in 1886, but the abundant blossoming and seeding must undoubtedly have an unfavourable influence on the development of the plants.

On a great many of the grafts the blossom is so thick that the fear of their being killed the effects of of it is by no means groundless. Therefore every effort is being made by manuring and by plentiful turning up of the soil, to force the trees to form leaves and to bring about a hardy growth. The evil of overblossoming would certainly have been much greater, had not the ground been well worked during

the long dry monsoon, so as to maintain the uninterrupted growth of the plants as far as possible. With the exception of the graft plantations of No 23 which is naturally prone to excessive blossoming, the blossom thrown out by the typical Ledgerianas even by the mother trees is considerably less than might have been expected after such an unusually dry monsoon, which fact must indisputably be attributed to the repeated and deep upturning of the ground.

The harvest of Ledgeriana and Succirubra seed in 1886 will not only be amply sufficient for the requirements of the government establishments, but also for holding numerous large public sales.

3.—Opening and upkeep.—The opening of new ground has been limited to a few ba-oes of forest land at Tirtasari, intended for the putting out of graft plants.

On the old establishments both the plantations which have already been dug over and those about to be prepared offer most satisfactory opportunities for replantiag the ground with C. Ledgeriana and C. Succirubra to which sorts the government cinchona enterprize is to be limited for the future with the exception of a few experimental gardens of other kinds of cinchona. On the upkeep of the plantations, still greater care is now bestowed than used to be exercised in former years. The young fields are kept constantly clear of weeds, whilst besides this they are forced into strong growth by a deep overturning of the whole surface. All over the old fields the system of deep drains is applied, which has also produced the most favorable results, and has exercised a good effect on the already gathered harvest, which will be more perceptible in the next harvest. In spite of the severe and long continued east monsoon the plantations all over continued to develope well—whilst soon after the setting in of the November rains, a most remarkably strong growth was to be observed both in the old and young fields. By careful upkeep of the recently planted fields the side branches of the young plants were able at once to develop their strength with disturbance and by close planting 4×4 Rhineland feet, the surface of the ground soon becomes shaded and the growth of weeds is checked. Close planting is adhered to as much as possible not only for furthering the rapid formation of humus out of the fallen leaves and thereby improving the soil chemically as well as physically, but also to attain the maximum produce at the lowest possible upkeep. The beneficial influence of close planting for the developement of cinchona is particularly remarkable in the replanted fields, where at first the growth of the plants was slow, and where their development became rapid as soon as the surface became shaded by the branches and masses of leaves. Combined with close planting, the greatest possible care is taken in these fields with the harvesting, so that by means of lopping and thinning out, everything is done to aid the further developement of the plants. The planting out in the open fields was continued during the prolonged west monsoon which lasted to the middle of May until the rains ceased. Before the planting out in March, April and May, large and deep holes were dug for the plants to provide against the desiccation of the soil during the severe drought of the east monsoon. Not only did this precaution prove justified in every respect, but the execution of the work answered perfectly for the attainment of the object.

The planting out of some fields with graft plants had hardly been two days completed when a drought set in, and notwithstanding its severity the plants grew well and the supplies for these fields were of little or no signification. The measuring of the Ledgerianas planted in 1879 was commenced. The mean height of eight-year old plants at Tjibeureune reaches now 4·53 metres and the circumference of the stem is 0·29 metres. The maximum height is 5·63 and the maximum measurement round the stem is 0·38½ metre. At Tirtasari the measurement of six-year old grafts and suckers gives a mean height respectively of 3·79 metres and 3·03 metres, and the mean circumference round the stem is 0·35½ and 0·28 metre, whilst the maxima of height and circumference of stem are respectively 4·85 and 4 metres and 0·35½ and ·33½. The fact deserves mention that the plantations to be measured, especially the seed plantations at Tjibeureune and the graft plantations at Tirtasari yielded a not unimportant harvest of branch bark. The Helopeltis Antoni continued to shew itself during the year now reported on—throughout all the establishments, except that of Kawa Tjiwidei, but thanks to the strict search after the insect and not less to the lopping and burning of all the attacked portions of the plants, the injury done was of little or no signification. At Nagrak in the commencement some damage was caused to the plantations by caterpillars and locusts against which the catching and destruction of the insects appeared to be the only remedy. At Riveng-goenoeng the Western plantations and specially the nurseries had again to suffer severely from the larva of a certain beetle, known by the name ku-uk (oeret).

The continual attacks to which the nurseries there have been subject from this kind of larva, and which have caused so much disappointment with reference to these plantations have necessitated the removal of the Ledgeriana nurseries to the neighborhood of the establishment at Kawah Tjiwidei. The damage done by blight and the larva of a beetle (uter-oeter) was during the past year of little or no importance. The topping Ledgerianas and officinalis plantations of which mention was made in last year's report has not been continued, since the results of shaving the bark for obtaining a rich produce in the shavings does not appear to have come up to what was expected.

4. *Harvest of Cinchona.*—The harvest of 1885, amounted to 216,359 kilograms of bark, the whole of which is intended for sale in Netherland. No demand for bark has been made by the Military Medical department. The harvest was gathered by digging out the roots of backward and diseased C. Josephiana on about four gardens, by digging out the roots of a plantation of C. Calisaya, by thinning out and lopping thickly planted Ledgeriana and Succirubra plantations and by the removal of hybrids from young Ledger fields, whilst a considerable quantity of produce was obtained from Ledgerianas which in consequence of the extensive scraping practised in 1884, had assumed an unhealthy appearance, and threatened to die out.

The produce consisted of

Sort of Cinchona,	Number of Cases.	Net contents in ½ Kilograms.	Number of bales.	Net contents in ½ Kilograms.
C. Succirubra... ...	170	21,094	325	40,703

Total... ...	1,008	117,038	2,026	315,680

The last experiment in the application of he shaving method on old officinalis trees at Kawah-Tjiwidei, but the results of the trial since it was carried out on a large scale in 1884 have appeared so unfavourable, that this system of harvesting has been given up for good.

All the shaved trees retained their fresh and healthy appearance, those trees which had only yeilded a single harvest by the shaving of the bark off one-half of the circumference shewed one year after the operation that the undisturbed portion of the bark was much better developed than that on the shaved portion.

Some careful experiments are still being made to ascertain plainly with the help of figures the difference in the growth of the bark—both when the

shaved portion has been covered, as well as without that precaution.

The bad results, of the use of the shaving method in 1884, by which at the end of a few months only one-half of the circumference of the tree was subjected to the operation at a time, became apparent at the beginning of the 2nd quarter of 1885—when at Tjibitoeng and Rioeng-goenoeng, and in a less degree at Tjibeureum, a very considerable number of trees, first estimated at (plus or minus) 5,000, though later on the number had to be doubled, shewed such signs of decay, that it was thought advisable to root out the injured trees.

The partial shaving of the whole circumference was almost exclusively confined to Ledgerianas of inferior quality, and therefore the damage done by the subsequent untimely harvesting of the trees, was of less importance.

But in the closely planted fields at Rioeng Goenoeng, from which only a single harvest of Ledgeriana shavings were obtained, the shaving system was still more unfavourable in its results. Although no dying trees were met with, yet the trees continued to droop for a long time, and during the long-continued rains the exposed portions of the bark began in some few instances to rot.

Should it appear that the trees in closely planted fields cannot stand the operation without danger, then the great advantage which such close planting affords by yielding the maximum produce, at the minimum cost of upkeep, and by the formation of a large quantity of humus and its accompanying amelioration of the surface soil, will cause the system of shaving to be entirely abandoned. If the application of the MacIvor system by which regular strips of bark was taken from the trees, has not in the long-run answered expectations, the results of shaving off the bark have been so detrimental that its continuance is not to be depended on. So that there is nothing left for us to adopt but a systematic thinning out of the plantations, with a carefully limited lopping of the trees, and finally the complete uprooting of the plant.

The shaving system can only be of service, in case a sudden rise in the Cinchona market, should render it desirable to obtain a large amount of produce, and to preserve the plantations, or when the urgent necessity for funds, forces the owner to sacrifice the future to the present. The produce of the harvest of 1884 was disposed of by two public sales, on the 4th March and 22nd September 1885 held at Amsterdam. The prices at the former sale were very inferior to those realized subsequently in the 22nd September. The gross amount obtained by both sales was *f*372,571·86.

The following prices were obtained for the half kilograms:—

	1st Sale	2nd Sale
C. Succirubra	18 to 123 cts.	25 to 301 cts.
C. Calisaya Javanica ...	22 to 72 „	30 to 196 „
C. do Schuhkraft	13 to 86 „	19 to 257 „
C. do Angilica ...	24 to 50 „	55 to 170 „
C. do Hasskarliana	23 to 31 „	
C. Ledgerina	19 to 172 „	87 to 295 „
C. Officinalis	80 to 129 „	112 to 194 „
C. Lancifolia		42 „
C. Papudiana		27 to 121 „
C. Caloptera		46 to 163 „

The average price obtained at both sales was *f*0·944 per half kilogram.

The existing drying stoves at Nagrak and at Tjinjiroean continued in damp weather to render good service but in prolonged rains they were found insufficient for a large extent of produce.

The necessity for drying arrangements, made itself felt more and more on other establishments.

Before proceeding to construct drying arrangements all over, the Director of the Government Cinchona enterprize has been authorized to inspect some private undertakings in the Preanger Regencies, for the purpose of ascertaining the advantageous system for drying cinchona bark.

His visit to some tea estates in Salkarboeme and Soemedang led him to form the conclusion that Davidson's T Sirocco was in all respects the most deserving of approval.

5. *Establishment—Funds.*—By the Government minute of 30th December 1885, No. 20, the establishment was increased by two pupil-overseers each on a salary of *f*50 a month, and an arborist at *f*150 a month, and a premium of one cent for every graft or sucker of C. Ledgeriana suitable for planting out prepared by him, or under his directions up to a maximum to be fixed by the Director of the Government Cinchona Enterprize.

G. Tockamp Lammers was appointed arborist, he having acted in that capacity for nearly four years.

The acting overseer of the 3rd Class A. Von Estaroff was relieved with honor from his acting duties, and his place was temporarily filled by W. Burck. The fixed native establishments at the end of December consisted of one carpenter, one storekeeper, a messenger, 20 overseers and 235 field laborers. The wives and children of the field laborers earn low wages, and are employed, as far as possible, in the nurseries, the upkeep of the young plantations, the harvest and in the destruction of injurious insects.

During nearly the whole year labor was abundant, so much so, that in consultation with some Managers in the districts of Bandoeng and Tjitjalangka wages were reduced by 20 per cent.

This reduction was only made in the wages of temporary laborers and newly engaged fixed-laborers and did not cause the smallest complaint notwithstanding this reduction of wages, and the numerous demands for labor in the private neighboring estates, employment could not always be given to laborers who tendered their services. For payment of the native establishment, constructing and restoring nursery sheds, purchase and repair of tools and other expenses the estimates of 1885 provided the sum of *f*46,000.

It was at once evident that this amount was inadequate to cover the expenses of an abundant harvest, and the introduction of high cultivation, so that an additional sum *f*34,000 was placed at the disposal of the Director of this cultivation.

The outlay for the service of the enterprize amounted to:—

Salaries of the Director, Assistant Director and other Europeans on the Establishment... ...	*f*29·675
Correspondence...	260
Travelling expenses	3,203·50
Salaries and wages for the native establishment, construction and restoration of nurserysheds, purchase and repair of tools and instruments and other expenses ...	80,173·80
Total...	*f*113,412·39

being *f*35,402·39 more than was contemplated in the estimate for 1885.

According to the report for 1884 the total expenditure including the transport of the produce to Batavia during the year was	*f*107,801·54
The total cost of transport of the produce to Netherland together with that for its sale &c. come to	40,583·55
Total...	*f*148,385·09

The gross proceeds of the sales at Amsterdam in 1885 was *f*372,571·86 so that the harvest of 1884 yielded a net profit of *f*224,187·77, exclusive of a farther sum of *f*17,102, realized by the sale of cinchona grafts and seed.

The whole of the outlay including that of transport to Batavia, brings the cost of the half kilogram of bark to the following sales.

The produce of 1884	*f*0·2693
„ „ „ 1885	*f*0·2621

showing a saving in 1885 of *f*0·0072 per half kilogram of bark—which was effected notwithstanding the increased expenditure connected with the purchase and transport of three times the number of cases than in the previous year.

The transport to Europe, sale &c. of the produce of 1884 come to *f*0·1028 per half kilogram so that

the net profit per half kilogram of bark came to. $f0{\cdot}944 - (f0{\cdot}2693 + f0{\cdot}1028)$ *i.e.* $f0{\cdot}5719$

By Government minute dated 21st October 1885 No. 2, the management of the Government cinchona undertaking was placed under the supervision of the Resident of the Preanger Regencies, whilst the inspection of the cinchona plantations and the nurseries is to be performed by the Head Inspector of the coffee cultivation.

6. *Extension of Cinchona.*—The demand for waste land on lease for the purpose of cinchona cultivation continues to diminish, and little or nothing is heard of new undertakings.*

It is true that on existing estates the cultivation continues to be extended but confidence in cinchona culture has felt such a shock by the steady falling of prices that capital worth naming, is not to be had for new undertakings of the kind.

It remains for the future to decide whether this want of confidence is well grounded or not; the figures given in sections 4 and 5 of this report, it satisfactorily appears, however, that the prices now paid for cinchona bark, afford no ground for the increasing want of confidence in this cultivation.

From these figures it appears at the same time, that no regular correspondence exists as yet between the cost of production and the prices which cinchona bark commands in the European market, and with absolute certainty a steady fall in cinchona prices may before told a circumstance well worthy of consideration with reference to new undertakings.

7. *Knowledge of the kind of Cinchona Cultivation in Java.*—The results obtained from plants raised from seed received from Heer Schuhkraft in 1880, have not come up to what was expected, as was mentioned in last year's report. Now that the plants blossom more generally they display a relationship to very diverging kinds. If some varieties approach the type of C. Josephiana others again come near the C. Ledgeriana.

Among those classed as fine and finest Calisaya raised from Mapivi plants there are with them striking varietics, of which the best seem as if they ought to be classed with C. Ledgeriana, Var. Chinidinifera, and C. Ledgeriana var Cinchonidinefera. The plants raised from seed received in 1883, through the intervention of the Minister of Colonies under the name of C. Verde (C. Calisaya oblongifolia) approach still nearer to the type of C. Ledgeriana. The kind planted at different elevations from 4,000 to 6,000 feet, C. Triande (C. Petoyansis) continues to thrive all over. A single plant has begun to put forth buds.

8. *Chemical Researches.*—As in former years the analyses of the harvest of 1884, were carried out in Europe by Heer Moens. The results obtained appear in appendix B and B. The analyses in the interest of the cultivation continue in the charge of the Assistant Director of the Government cinchona enterprize. Those analyses of which the results are given in appendix C. were made in the first place for the purpose of obtaining rich varieties raised from seed of the richest mother trees, to the end that these might be multiplied artificially for the creation of seed plantations.

It was not alone among the plants derived from the rich mother trees No. 23 and 33 that such plants were sought, but also from a very typical Ledger plantation raised from the seed of the mother tree No. 34 a remarkably fine specimen was obtained for chemical examination. It is remarkable as a phenomenon that the bark of all these varieties, some of which are distinguished for containing a very large proportion of quinine, show in a greater or less degree the presence of cinchonidine, an alkaloid of which traces are found in the bark of the mother tree. Plants thus derived were, therefore, not considered fit for the formation of graft plantations for the production of seed. A very important series of analyses of succirubra-hybrids raised from Ledger seed gave surprizing results, in so far, that hybrids greatly resembling the Ledgeriana in habitus, flowers and form of leaf, were all similarly distinguished by a very large proportion of alkaloids. For the attainment of more certainty respecting the influence of the Succirubra stem on the constitution of the bark of the Ledgeriana graft ingrafted on it, the produce obtained by shaving and by partial peeling of the bark, has been submitted to chemical research. A large percentage of cinchonidine was found both in the shavings as well as in the bark removed in long strips. Whilst two analyses of the bark of the two mother trees gave the following results:—

MOTHER TREE No. 75.

	Quinine.	Chinchonidine.	Chinidine.	Cinchonine.	Amorph Alcaloids.	Total.
	℔ cent	℔ cent	℔ cent	℔ cent	℔ cent	℔ cent
in 1876	10·59	—	—	0·31	0·43	11·33
in 1881	9·79	—	0·05	0·53	0·56	0·951

MOTHER TREE No. 89.

in 1876	10·79	—	—	0·23	0·51	11·53
in 1881	11·20	1·17	—	0·57	0·45	13·39

The analyses of stripe bark taken off 5 years old graft plants of these mother trees show 3·30 per cent and 1·40 per cent of cinchonidine. From these results the influence of the succirubra stem on the bark of the Ledgeriana grafted on it appears incontestable. Moreover the bark of a graft from the known mother tree No. 23 was analysed; it contained 1·11 per cent cinchonidine, whilst the bark from the mother tree by two analyses was shown to yield:—

	Quinine.	Chinchonidine.	Chinidine.	Cinchonine.	Amorph Alcaloids.	Total.
	℔ cent	℔ cent	℔ cent	℔ cent	℔ cent	℔ cent
in 1874	9 97	—	—	traces	1·90	11·87
in 1881	11·01	—	—	0·59	0·13	11·73

Analysis No. 33 deserves particular attention. It shows, that five years after the introduction of the Mac-Ivor-system, and three years after the covering of the barked stem was left off, the bark not only showed no indication of a return to its original constitution as Succirubra bark, but even the quantity of quinine in the renewed bark was effected to a greater extent than is harvested during the limited lifetime of three years.

At the request of private cinchona planters H. E. the Governor-General of Netherlands India has caused experiments to be made in the chemical Laboratory at Bandoeng for obtaining a coarse extract of the cinchona alcaloids solely for the purpose of saving the cost of packing and transporting a useless mass of woody fibre.

For this experiment 10 kilograms of bark was selected containing fully 6 per cent of alkaloids; of this by means of boiling with lime and spirts of wine, *quinium* (a resiuy substance) was produced, which by analysis was found to contain about 60 per cent of alkaloids, whilst the ascertained loss in preparation appeared to be little or nothing.

To answer the question as to whether this *quinium* affords a suitable material for the preparation of quinine and other sulphates, it was requested that it should be sent to Netherland which has accordingly been done.

Bandoeng, 23rd March 1886.

A NEW TEA DRIER.—A gentleman with large Assam experience as a practical planter has arrived in Ceylon with a new patent tea drier which he anticipates, will secure the favour of our planters both on account of its good work and economy in price in proportion to efficiency.

EUCALYPTI IN ARRAN.—I have been much interested in the correspondence on the Eucalyptus as grown in the island of Arran. I may state for your information that several plants of the Eucalyptus are growing at Auchmanes, Portincross, West Kilbride, which is thirteen miles east of Lamlash, and ten miles east of Corrie, in Arran. A seedling of 1881 was planted outside in 1883, and is now 22 feet in height. Several seedlings of 1885 were planted outside this summer, and are now 12 feet in height, having grown this season 6 feet 6 inches. The plants are grown on light soil sheltered from east and north-east winds, at about 60 yards above high-water mark.—J. MACLEAN, The Gardens, Auchmanes, near Kilbride.—*Gardeners' Chronicle.*

NEW PRODUCTS IN WEST INDIES.—Considerable interest continues to be taken in the suggestions in respect of new industries contained in a letter sent to the West Indies by Mr. Morris. Certainly, the subjects of which he treats are of such deep importance to the people of those islands that they have only to be mentioned in order to engage their serious attention. One idea mentioned by Mr. Morris is that tea will grow in Trinidad at elevations above cacao, and that this is obviously worthy of careful consideration. The cultivation of the ground nut has much to recommend it, while a great deal might be made out of fibres. The Agricultural Society of Trinidad at the instance of Mr. Lange, has been considering whether China grass can be grown at a profit in that Colony. The decision taken by the society to have pamphlets on "China Grass," translated and printed for general information cannot be too highly praised. It seems, however, that the society has fallen into discredit in the past, since a contemporary ventures to suggest that the vacancy in the presidentship of the society offers an opportunity, which may not again occur soon, to infuse new life into it, by a respectful request to His Excellency the Governor, to be in future not only a tron but its president. No doubt, such a step, successful, would rally round the society, the tive support of the best man in the Colony.—*olonies and India.*

TEA IN CHINA.

I have within the last few days, at a friend's house, come across a curious Chinese book of colored plates illustrative of the growth and manufacture of tea in the Celestial Empire. The book was sent to my friend by a relative in Canton in 1844 and consists of 24 paintings on rice-paper, bound in colored silk, the whole folio volume weighing only some 9 oz. The first plate represents the holing of the ground, and the next the seed being dibbled in; while in the third the young plants are shown above ground and a man is raking the soil between the rows. In the next picture, the plants are somewhat larger and are being watered by a man with a small wooden pail at the end of a bamboo. The next picture represents a woman *sitting on a stool* before three tea bushes, from which she is picking the flush. (I believe this is the universal custom, but what would Ceylon tea-planters think of their coolies indulging in such luxury!) Next we see a lanky cooly taking the green-leaf from a basket, and sifting or winnowing it into two heaps; and in the next picture another man appears to be picking out coarse leaf, &c. The next scene is a strange one: it represents a cooly with a heavy pestle in his hands *pounding* the green leaf in a large stone mortar, preparatory to the rolling by hand in a flat bamboo basket, which is shown on the next page. The man employed in rolling seems to have discovered something in the leaf which ought not to be there, and is holding it near his eyes and gazing at it with an expression of disgust: what the object is, it is impossible to say. In the next picture a woman seated at a table appears to be engaged in picking out stalks, &c., from the rolled tea, and in the following one the tea is shown in the form of round flat cakes on a basket, where they have been left to ferment. On the next page we see the balls broken up and a lad with a bamboo whisk stirring the leaf about and adding some liquid to it from a little tub; and then we see the leaf in baskets, being placed on a bench to ferment for a further period. The next picture is the most remarkable of all, it represents a man with a shaven head and a long robe, the fold of which he is holding out, gazing up at a *monkey* who is seated on the rocks above and is grasping with one hand a tea bush which the man below is requesting him to throw down! Here is a valuable hint for Ceylon tea planters as a settlement of the labor difficulty! In the next picture we are shown a man seated at a block on which he is holding with his left hand a tea branch while with a cleaver in his right he is stripping the leaves off. This is a strange way of gathering leaf certainly. In the next page we see the tea grower sack on back and balances in hand on his way to sell his leaf to the trader. Then we see the green leaf being packed in stone jars covered with bamboo wicker, and so transported by boat to the factory, the operations in which we are now introduced to. The first is the firing in a furnace, and then comes the tasting, the taster being a regular 'masher.' The next picture is not one for a lover of China tea to gaze at; it shows a nearly naked cooly trampling down the made tea into large chests. The next picture shows the chests being filled up by a cooly with a long stick in his hands; and then the boxes, nailed up and papered, are having the familiar hieroglyphics painted on them; the last picture representating a cooly carrying one such box on his shoulder.—D. W. *F. in Observer.*

NEW PRODUCTS IN OLD DISTRICTS.

We were not mistaken in seeing many a chena field and many a big patch, now forlorn and neglected, which we remembered to have seen in full cultivation. But on the other hand we had most cheering and quite wonderful expanses of *the* new product—tea—as green, healthy and vigorous as ever its predecessor looked. To a stranger "without reminiscences" there would be in fact little or no evidence in these Northern districts of the time of depression; for estate after estate has now its tea fields covering areas rapidly approaching to those formerly covered by coffee, and it is difficult to say whether "the new Queen" flourishes better on the old "King's" fields, or on previously unopened land. The young tea clearings on the Hatale property seem as promising as the most critical of old-school Visiting Agents could desire and farther on we had a look at fields planted on patana and chena land from tea seed at stake, than which no growth could be better at two and three years old. In the middle of the Knuckles we came on a new estate, planted with tea, cleared from patana, with a lay of land and a promise in much of the soil which may well justify the proprietors in anticipating a second Mariawatte. But of all the cheering sights we saw, commend us to the picture of old Maousakelle and its two year tea on patana soil. Anything better than this we have nowhere heard of in Ceylon, not even in the best of the chena clearings on the side of old Hantane mountain range where again tea is working a very wonderful change. Indeed green flourishing fields predominate throughout the Hantane, Hewaheta and Nilambe districts as much as in the northern group of Kelebokke, Knuckles and Rangala. We are therefore quite prepared now to welcome the original planters of forty years ago, should any of them, dead to the island for a generation, "revisit the glimpses of the moon," to spy out the nakedness of their old clearings. They would simply return, as we have done, saying the half had not been told them and that unless they had seen for themselves no one could have made them believe that tea could flourish so vigorously, not to say luxuriantly on old coffee, patana, and chena land. "Will it last?" may be the cry; but we have no doubt Ceylon Planters will answer that question after a very practical fashion as time rolls on. Meantime "tea" is not the only "new product" that astonished us during our brief passing visit. But of "cacao" in Panwila and Dumbara, we must have a separate notice.

CEYLON UPCOUNTRY PLANTING REPORT.

COFFEE AND GREEN BUG—WHAT IS PROVIDENCE ABOUT? TEA PROPERTIES AND BUYING AND SELLING—CLEARINGS ALONG THE MATALE LINE.

20th December 1886.

Now that *coffee* is going to be trumps those in these districts who have any of it left regard the presence of the bug—black or green as you may choose to call it—with increasing interest. Unlike leaf disease, which resembles the poor in being always with us: bug comes and goes. A bad attack of the former, nay, even a series of attacks, might be got over, but a thorough inroad of bug is as near to sudden death as anything I know of. A slight attack, described by the innocent as, "here and there in patches, but nothing to speak of you know," is like the shadow of impending doom to those who have

experienced with what virulence it can sweep round an estate, and have seen the wreckage it leaves in its wake. Bug has put the philosophy of many a man to the test, and has formulated questions which were hard to solve. One who was suffering mentally and financially from a bad attack of bug, said in reference to it, and in serious earnest: "I really don't know what Providence can be thinking about?" Poor fellow, he had a hard nut to crack, but his attitude of mind was reverent enough, albeit his form of speech was not devout. The other who saw in leaf-disease Providence as having a controversy with the planters, and who looked upon the invasion of bug as the last act in which those who had survived the first visitation, were to be ruined under the second, *had* made an attempt to answer the query as to what Providence was thinking about. But was it a good shot? I heard the other day of a lecturer in Melbourne impressing on his audience that every insect pest has its use, dwelling especially on the mosquito, the cloth moth, and the garden snail. At the close of the lecture, a gentleman got up and asked for something more definite as to the snail. His garden, and indeed almost all the gardens in Melbourne, were over-run with them; his boys caught hundreds of them every night, and it was with the greatest difficulty young plants could be protected. The lecturer was a little nonplussed, but said the snail was fulfilling the aim of its existence, namely eating! If it had been a planter's estate which was being handed over to the destroyer instead of the garden of an energetic colonist, there would have been some one about "to point a moral" and the snail would never have fulfilled the aim of its existence until it had showed a decided partiality for the belongings of reprobate planters.

But this is a long way from the bug on our coffee. To return to it, it is a pleasure to notice that the pest is dying out, evidently in the same way that it did about the same time last year. The appearance is as if a white fungus were growing on the insect. Will it keep away? Is it worth while in these parts to prune, manure or cultivate, even if coffee is to go very much higher in price? If we only knew what Providence was thinking about, it would not be difficult to make up our minds as to what to do with what remains of our coffee.

At present, I fancy, there are more sellers of tea estates than buyers; but it is a happy token to hear of a tea property near Watagama for which £3,000 was refused. It is not a big place, and only a year-and a-half old.

There is the other side, however, of wanting to sell and not being able, like what occurred the other day, a man in search of an investment, for the offer of the property at a rattling big figure. Sterling money of course, and after reading the unsolicited letter which contained the terms of the proposal he said: "Well, Ceylon is far from being worked out yet, when people can have the cheek to ask such a price. There must be something in tea."

I understand that land suitable for tea lying near the Matale line is being looked after, and that next season should see more clearings there.—PEPPERCORN.

TEA, SUGAR, CINCHONA, AND COOLIES IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

According to the Samarang *Locomotief*, tea plantations in Java, bid fair, this year, to turn out an enormous yield. On one estate in particular, called Sinagar Chirohama, the tea produced is said to materially excel the British India kind in quality. This heavy outturn is generally ascribed to the dry East monsoon in 1885, followed by a lack of destructive insects. In spite of the promising future in store for this branch of planting enterprise there, capitalists in Java shrink from investment therein. For instance, two tea growing companies started in that island last year, have to work with capital mostly drawn from Britain, so it is said. What with the depression of trade and fall in prices, it is no wonder that they mistrust the paying nature of plantation undertakings under present circumstances. Moreover, it is evident that the enormous increase of the tea yield to be expected within the next few years, might readily result in overproduction within, say, four or five years. Even were years of adversity sure to come, there is every sign of prosperity for tea cultivation in Java, provided growers be not borne down by fiscal burdens sure to ruin them in times of crisis.

Of late, natives have been engaged in great numbers in Java for labour purposes in British North Borneo, Queensland, and German New Guinea. The local authorities before authorising their emigration, had ascertained that these recruits were fully aware of the terms of their engagement, and had agreed to them. The authorities also prevailed upon the companies concerned to give security for returning these labourers free of charge to Java, should they wish to come back at the expiration of their contracts. The Netherlands India Government has not yet decided what other line of action to take with regard to the recruiting of natives for foreign countries, or whether special provision be made to protect more effectively the interests of coolies.

In the opinion of experts there is at present no prospect of any rise in the price of sugar which continues to be low indeed in Java. The only remedy worth a thought is that of striving to make the article pay even at the discouraging quotations ruling, by calling in the aid of science and carrying out improvements wherever feasible to increase the outturn on less expenditure.

Steam ploughs have turned out not to meet requirements in Java. Trials have proved conclusively their unremunerativeness. In supervision alone, each plough costs about 150 guilders. Another drawback is that the plough had no steady work. Sometimes it stood still for months. It seems that among the many steam appliances which have replaced manual labour in agriculture the steam plough is one of those which answers the worst.

Uncertain as are the prospects of Java Cinchona planters from over-production of bark in Ceylon, they hope to make head against competition, by relying on the advantage, Java bark has over the Ceylon kind in containing less cinchonidine. Sometimes Indian and Ceylon barks show even 50 per cent higher percentage of cinchonidine than of quinine. The consequence is that their value has become depreciated. For instance, out of 2,518 bales of Ceylon bark put up for sale by auction at London, on the 28th June last, 1,330 proved unsaleable. The 169 bales of Java offered all found buyers readily. Under these circumstances, it is no wonder that the 21 millions of cinchona trees planted in Ceylon when coffee growing proved unremunerative, are being rooted up to make room for tea.

INDIAN HEMP: "BHANG."

An excellent paper was read by Dr. Watt, the Commissioner of the Indian Economic Court, on Indian Hemp which we take the liberty to reproduce.

"He said that it was a common experience in this country that the extracts obtained from the drug were of different strengths. This was due to the use of different kinds of the drug. The drug which was produced in Eastern Bengal was the best, and there were two kinds of it—the flat and the round ganjah, as stated by Mr. Holmes. These differed considerably in strength; moreover, the round was taxed by the Government a fourth more than the flat. The duty on the round was from 35*l.* to 40*l.* per maund, exclusive of the licence to sell it either by wholesale or retail. In connection with this taxation there was a curious anomaly existing in India to which he wished briefly to refer, viz. that the yearly returns in Bengal showed a consumption amounting to 6,000 maunds with a tax of 20,000*l.*, whereas in Bombay the consumption was

9,000 maunds with a taxation of 10,000*l.* only. The law which imposed the tax was passed about ten years ago, and he was surprised that the difference referred to had been lost sight of. These quantities did not represent the total produce of Indian hemp. Two thousand maunds were yearly exported from Bombay to Liverpool and London, duty free, the result being that it could be bought in London at one-twentieth the price at which it was sold in Bombay. (Laughter.) The wonder was what became of it, and he feared that it was reshipped for consumption in India after escaping the customs. Dr. Watt next gave an interesting account of the cultivation of the drug in India. He said that the wild variety—known as Bhang—differs from the cultivated ganjah. It is much weaker, and is used for the preparation of an intoxicating liquor and sweetmeats. The liquor is called *Hasheesh*, this word being the source of our word assassin, a corruption of the native word "Hasheeshcen" applied to the intoxicated and homicidal persons who drink the liquor. The sweetmeats are made by digesting the bhang in ghee, a kind of butter—the mixture being afterwards made into a suitable mass. Ganjah is entirely smoked, never eaten. The drug, Dr. Watt explained, is placed in a pipe, ignited in a certain way, and two or three whiffs are all that is necessary to make a man delightfully drunk. (Laughter.) Bhang is smoked in a different way. It is placed on a fire in the middle of a room in which a number of persons sit, and as the fumes fill the apartment all in the room get drunk together. (Laughter). After explaining that these details were not taken from personal experience but from observation, Dr. Watt proceeded to describe the collection of *Churras*, the resinous exudation from the stems of the plant. For the purpose a number of men are employed. They are stripped of the little clothing which they wear, their bodies well oiled, and they are made to run through the hemp fields in all directions. As they press their way through the stems, their bodies become covered with the resin. They are then conveyed to head-quarters and scraped. Another substance, termed *Mummia*, is a much more nasty preparation. This is referred to in the last edition of Johnston's 'Chemistry of Common Life.' The preparation is made in Nepaul. A certain plant is administered to miserable wretches, and it produces upon them a loathsome eruption. It is this eruption which is scraped off their bodies and used like ghee along with bhang. Incidentally Dr. Watt, remarked that he did not consider that much was to be learnt by associating with the native doctors. They knew all about the many hundreds of drugs which were in India, and there were not more than 40 or 50 of them of any real use. Moreover, the natives kept the drugs in their shops until they were perfectly rotten and worm-eaten, and as they were dependent upon them for many of them, that fat accounted for numerous specimens in the Indian Court being in a bad condition. Again referring to ganjah, he said that it was essential for its production that the fields of it should be quite free from male flowers otherwise a single male flower present in a field would by fertilisation, convert it into bhang. In cultivated fields of the hemp the male flowers were separated by native doctors, who are most proficient in their work. When the plant consists only of a short stem, 1½ feet high these doctors after striking a bargain, go through the fields, and, singling out every male plant cut it down and leave not a single one standing. Dr. Watt had endeavoured to get at the bottom of this wonderful skill, but even with the help of a microscope he had failed to find any satisfactory point of distinction between the male and female plants at this point of growth. He described how the heads are prepared for market. A hollow space is made in the earth, and the freshly-pulled heads are placed in it; the workpeople then roll it about with a shuffling motion of their bare feet the amount of pressure which the heads are subjected to determining the form of the product and strength."—*Wiiri Express.*

COFFEE ADULTERATION.

Not before it was time, an influential meeting has been held of those interested in the growth of Indian and Colonial Coffees, to concert measures for putting a stop to the prevalent adulteration, which is slowly but surely destroying the Coffee trade of this country. Though people are often unaware of the precise reason, all articles of food and drink are consumed for some useful part that they perform in the human frame. They may be nutritious or stimulative, or they may prevent waste of tissue, and it is for the two latter purposes, so physiologists say, that substances like Tea or Coffee are used. These effects depend upon the alkaloids—Theine in the case of Tea and Caffeine in Coffee—which those drinks contain. But if these essential properties are overwhelmed with a mass of burnt woody fibre, such as Chicory consists of, the object of Coffee-drinking is at an end. Nevertheless, in the case of Coffee, if advertisements on tins and otherwise are to be believed, the very thing that destroys its efficacy, is vaunted to be an improvement. This would matter little if the public were not misled by such statements, as they undoubtedly are. English people, as a rule, through the long course of medicinal Chicory they have undergone, are totally ignorant of what true Coffee is like, and a degraded public taste has been created which actually calls for a certain amount of the bitterness and thickness which Chicory gives to Coffee. But this is no reason for the public being kept in ignorance of the proportion of Chicory they are buying, and the present law, by which a simple declaration of admixture, covers the addition, even of 80 per cent of Chicory, simply leads to the grossest abuse. No substance ought to be sold as Coffee unless it contains at the very least 50 or 60 per cent of the substance by the name of which it is called; and in this, as in all other admixtures, the amount of foreign matters added should be clearly declared to the purchaser by a distinct printed label. The present Government stamp on mixtures of Chicory and Coffee, with other things, simply puts the official seal of approval on what is sometimes a fraud. A number of samples of "Coffee" have recently been analysed in London, and proportions of 60, 70, and in one case 92 per cent of Chicory and the like substances, have been found in them. Certainly no such compounds should be allowed to be sold as Coffee at all. If the word "French" be a recommendation to these mixtures, it would equally recommend the word "Chicory," and the proportion of Coffee could then be declared. There is a sort of precedent for dealing with Coffee in the recent Spirit laws, which do not allow Spirits of less than 25 degrees of alcoholic strength to be sold without a legible declaration on the bottle of the exact amount of added water. But this precedent does not go far enough in the case of Coffee. The addition of water in large quantities is absolutely necessary in the case of pure alcohol, which is simply a poison if undiluted. The addition of Chicory to coffee is in no way essential or desirable, and the purer a Coffee is, the better is its effect upon the human frame. It would seem fair, therefore, to go a step further than with Spirits, and to say that the proportion of *all* Chicory, whether much or little, added to coffee, should be legibly declared. The planters in their proposals as reported in *The Times* of Wednesday last, went further than this, and were inclined to ask that no admixture whatever should be permitted, and that people who want Chicory should be compelled to buy it separately, and mix it themselves. This, however, has been already tried in this country, and has been given up, as it was found to be unworkable. Since the first meeting of the Planters, it is understood that a compromise may be entertained, by which a certain proportion of Chicory should be allowed to be admixed, without declaration. To admit this, however, would be practically to defeat the object of the movement, and if such a weak compromise be accepted, the agitation would be better left alone. Those who like Chicory in their Coffee, and tens of thousands do so, would have no objection, but the contrary, to the declaration of the proportion added, while those who

do not want Chicory, ought not to be supplied with it without their knowledge, and under the protection of the law.

In dealing with this and similar matters, the public press is too apt to put down abuses to the retail Grocers, and with great injustice. In the present case, the excessive admixture with Chicory, which is doing so much harm, is not due to the Grocers at all, but to the packers, who introduced a substance with a taking title at a time when Coffee was very high in price. The Grocers had no knowledge or means of knowing the constituents of the mixture and the demand for it has since been endorsed by a special Government stamp, in cases where constituents besides Coffee and Chicory are used. The further step of obtaining a similar profit from the use of Chicory for themselves, instead of for the packers, is not one to be wondered at, but the Grocers if asked for Coffee free from Chicory will always supply it, whether whole or ground. It is, indeed, quite a mistake to suppose that the retail Grocers, as a body, would object to a stringent law dealing with Coffee adulteration, for they see as plainly as anyone else, that, at the pitch which things have reached, the destruction of the Coffee trade is a question of time.

Nor can those who vaunt the superiority of their compounds to Coffee, as the latter is given us by nature, object to their merits being no longer hidden, under the vague general declaration of of admixture with "improving" ingredients. On the contrary, the philanthropic packers who improve upon nature, should be thankful for any law, which compels them to emerge from their modest reticence, and to say how much per cent the "Coffee" in question is kindly "improved." If, on the other hand, they do object to such added fame, the public might doubt the truth of the alleged improvement, and insist, on its own account, on the proportion of admixture being declared. So far as the true home Coffee trade are concerned, that is, the Importers, Brokers, and wholesale and retail Dealers, who sell Coffee and not Chicory, they have for many years past desired a stringment change in the law, which may, perhaps, be carried now that our Indian and Colonial Planters have taken the matter up, especially as the question has a material bearing on the revenue of the country.—*Produce Markets' Review.*

CEYLON PRODUCE IN 1886.

The different articles exported from Ceylon to the various markets of the world have been fairly remunerative to producers during the past year and we make the following notes regarding the movements of them, and prospects for the coming year.

COFFEE.—The high prices now prevailing in Europe consequent upon the short supply from Brazil have caused a similar advance here and planters who still have coffee left, ought to be congratulated on the prices obtainable. It is not likely that more coffee will be planted but, what there is, is being cultivated with more than ordinary care, and, as the ravages of leaf-disease, grub and bug, are now more modified, a fair average export may be looked for.

TEA cultivation has been rapidly extended during the past year and in 1887 we shall probably see more than double the quantity exported that was produced in 1886. Towards the close of the year quality improved very much, and there was good competition at home for all fine teas possessing point and good liquor. As the China Tea season will not commence till May and as the Indian Export Season is about over, supplies will not be brought into the London market in such volume as they have been for some time. It may therefore be fairly expected that prices for desirable qualities will be maintained during the next few months. A number of Indian Tea Companies' averages have been very low this year, and this must be regarded as a somewhat unfavourable feature for Ceylon Planters, inasmuch as it may result in the collapse of many companies, and the acquirement of their concerns by others at ruinously low prices, and fresh competition.

COCONUT OIL.—The year 1885 having been a comparatively dry one, the yield of coconuts in 1886 has in consequence been limited and the production of copra and oil has been on a moderate scale. In the early part of the year the price in Europe fell to an unprecedentedly low level owing chiefly to larger supplies of tallow, palm oil and palm-nut kernels; it has now however somewhat recovered, although it is still much below the average of former years. There has been a good Indian demand throughout the year for oil and copra, but this has fallen off owing to the larger supplies of copra to Indian ports from Zanzibar and the Straits. The manufacture of white oil is a new departure to be noted. It resembles Cochin oil and fetches about R20 more than ordinary Ceylon. As the rainfall in 1886 has been more abundant than usual, the crops of coconuts in 1887 ought to be good after the hot months of the year have been passed.

CINCHONA.—The large export of last year has weighed heavily on the London market, but during the last few months there has been a distinct curtailment in the quantities sent forward, and if this continues a recovery in the price of bark will be brought about. It is to be feared however that when the price improves shipments will be again rushed home and the improvement will be again lost. The quantity still in the country is large; although not increasing, but in the course of another year a great deal must come out to make room for tea, and after that there will probably be a marked falling-off in the production of cinchona in Ceylon.

CINNAMON.—This article still suffers from overproduction, and there is more in the markets of the world than can be freely disposed of even at the low range of prices now ruling. The reverting to quarterly sales has helped the market in some degree, but what is required is curtailment of export of the low common qualities and chips which drag down the value of good cinnamon. Arbitration as to the quality and allowances have been very frequent latterly in the markets of Europe, indicating a want of sufficient care in the making of cinnamon and the sorting of it.

PLUMBAGO.—The demand for London has fallen off during the past year to a remarkable extent, but this has in some measure been made up by the export to Continental ports. The enquiry for America has been good as there has been a considerable revival in the steel trade there. Prices have been fairly remunerative to native producers, but their endeavours are, as usual, hampered by insufficient means of communication in the absence of roads, which the Government do but little to provide.

COIR YARN.—The home markets are borne down by enormous stocks, and losses in the article have been during the past year tolerably widespread; nothing but the curtailment of production will restore the nominal value. A good trade was done with the Australian ports for a time in coir stuffs, but it was overdone, and latterly seems to have been almost snuffed out.

KAPOK.—In this article for a time there was a good business with Australia, but, whether owing to a substitute having been found or some other cause the trade has fallen away and this branch of native industry has suddenly ceased to yield a profitable return.

HIDES, HORNS, HOOFS, &c.—A more extensive busi-

ness could be done in these if the hides were better cured, and if they were more free from brand marks, and if more care was observed in the keeping of the different descriptions of horns separate, instead of *mixing elk and deer together indiscriminately.*

When we come to review the course of the PLANTING interests, both in the hills and so far as it affects the welfare of Colombo, the retrospect of the past year exhibits a very varied study. The rapid and uninterruptedly steady extension of the enterprise in tea contrasts in a very striking manner with the almost equally steady and rapid decadence in coffee and everything connected with it. It is doubtless true that some—and in perfect good faith we may say many—of the estates in Uva are this year giving handsome returns, aided by the rapid and important rise in value of the produce which has recently been established in the European markets. It is also by no means an unimportant fact that we may still find amongst the sale lists of coffee in London, the names and distinguishing markets of many estates in the other districts which we have been led to suppose had long ago been compelled to abandon the cultivation of the berry altogether. The fact, however, is none the less established that the acreage to be recorded as "under coffee cultivation" has during the past year been very materially reduced—in the majority of cases the bushes have been rooted up and the ground thoroughly cleared—whilst over a very considerable area the tea plants have been planted in the already established fields of coffee. Uva still holds its own as the last stronghold of coffee culture, but it is deplorable to note how even here the devastating attacks of the most recently developed pest have spread with marvellous rapidity during the last twelve months. It had required a period of three years, more or less, for the green bug to work its desolating way all through the northern districts, and from thence southward through Kotmale and Hewaheta, spreading to the newer districts around the Peak and Nuwara Eliya; but it has required but a brief 12-months to make its appearance upon almost every estate in Udapussellawa and the newly-created province of Uva. Unless deterred by some climatic influence which may induce the destruction of the insect itself, or by the existence in the plant itself of some recuperative energy with which we are at present unacquainted, it does not need much foresight to predict the ultimate fate of this the last remaining stronghold of coffee cultivation in the island. It must not be forgotten however that coffee in Uva has withstood to a very great extent the influence of leaf-disease which has proved so fatal to remunerative cultivation in the other portions of the island, and there consequently remains to planters no little hope that after all it may not be compelled to succumb to the attacks of the much dreaded green bug. Tea cultivation, as we have already remarked, has been rapidly extended in every direction, land which has previously been under cultivation as well as newly felled clearings have been planted up, and the produce of earlier extensions has already begun to shew a very marked increase in the figure exports—the figures for 1886 being about 7,800,000 lb. as against 4,374,000 in 1885. The buildings and establishments on old coffee estates are rapidly undergoing reconstruction to suit the new manufacture, and life and activity have once more been restored to many an estate which of late years had gradually fallen into decay and abandonment. Following out the course of investigation and review, we find, to our regret, that the era of revivification—whilst affecting in so marked a degree the planting interests as a whole—does not in too many instances follow the fortunes of the individual. There are unfortunately very many whom the future presents but little more than a continuation of the toil and trouble with which in earlier life—and for a long series of years—they had attained a comfortable position during the more lucrative years of coffee planting. Of the many to whom the fragrant leaf will prove the means of attaining wealth and position, there will be but few who survive to tell the tale of the rise and fall of the once important coffee interest in Ceylon; and fewer still who will be able to attain a fair share of the good things attendant on the more modern product of the day. It would be superfluous for us to dwell at any great length upon the influence which this total revolution in the planting industry of the island exerts upon the mercantile houses of Colombo. The profits previously accruing from the manipulation of the berry on the seaborde were lucrative to a high degree in themselves as well as from many sources attendant upon its shipment. The profits arising from a Tea Agency are comparatively insignificant, and to a great measure arise from the supply of material and machinery, whilst the details require but little less attention and outlay than was the case with the old staple. The consequences of this alteration in the course of business are becoming year by year more evident and the Agency houses in our city would seem to be compelled in time to give way to a very considerable extent to tea brokers and tea buyers. There is no necessity for us to dwell at greater length upon the revolution that is so rapidly being effected in the commerce and cultivation of the island; but we must not omit to note its effect as more especially concerns the native populations more or less dependent upon them. A very large proportion of the villagers in the Kandyan provinces have for many years past been directly interested in the cultivation of the berry—being themselves cultivators and proprietors of the coffee plant; many others were in a variety of ways dependent upon or, at any rate, interested in its cultivation upon the large estates of Europeans. To both these classes of natives, the decadence—we may almost say extinction of the coffee plant—has proved disastrous in the extreme. The facility with which the increased value of their produce had enabled them to hypothecate their crops and to incur a variety of monetary liabilities as a natural consequence, tended to intensify the difficulty of the situation when the produce was no longer forthcoming. Poverty and distress have consequently during the past twelve-months run riot throughout the hill country, aggravated unfortunately by a very extensive failure of the paddy crops, consequent on the ravages of a minute fly, which has devastated the fields over large areas of cultivation in the Central Province, as well as in the low country. At the present moment there is being exhibited the very serious and harrowing spectacle of the original inheritors of the soil being steadily dispossessed of the lands which have been handed down to them from time immemorial, the lands meanwhile falling into the hands of strangers, and the few more wealthy amongst the native proprietors. It is difficult to conceive a more distressing, nay, we may say dangerous position, than that which is being established in the Kandyan Provinces, a whole population of landowners and their families being absolutely and literally dispossessed of their native soil and habitations and forced to seek subsistence as best they may from other sources. Nor are the consequences of the failure of coffee, as regards a very large proportion of the native population in and around Colombo, much less

serious than to those in the hill country. The numerous and extensive stores for the preparation and shipment of coffee in the port of Colombo afforded a means of subsistence to many thousands of women and children who were thereby enabled to earn a very substantial portion of the daily expenditure of their households; indeed in many instances they were entirely dependent upon such earnings. The mills and machinery to a large extent have been stopped altogether, and others afford employment to a but a small proportion of those who in former years had resort to them for work. Few indeed are those who can offer anything like permanent employment, and it is needless for us to point out that no other means of subsistence now exist for thousands of women and children who are consequently a burden rather than otherwise to their households. It needs but little consideration to show how serious a matter this is to the native population of Colombo,—one that affects some 15,000 to 20,000 of its inhabitants, and to these the industry which is being substituted for coffee offers no help whatever now or in the future.

THE KOLA NUT.

Messrs. Christy & Co. now publish an analysis of Kola nut (by the Consulting Aanalyst of the Royal Commissioners for Victoria, Fiji, Mauritius, &c.), the report of which reached them too late to be included in "New Commercial Plant," &c., No. 9.

—*British and Colonial Druggist.*

* Inverted by boiling with a 2·25 per cent solution of nitric acid for 10 minutes.

† Containing nitrogen = 1·387.

‡ Not definitely separable; chiefly resembling some oxidized resinoid matter, and the red-brown colour very like that of the roasted cacao-bean.

§ Apparently one or more of the numerous modifications of tannic acid common in the vegetable kingdom.

A SUBSTITUTE FOR QUININE.

TO THE EDITOR OF THE "BRITISH AND COLONIAL DRUGGIST."

A VALUABLE DISCOVERY,—SIR,—It may interest some of your readers to know that Professor Fisher, of Munich, has, after a series of experiments, obtained from tar a special "carbure," in the form of a white crystalline powder, possessing all the therapeutic properties of quinine. An application for a patent for this discovery has already been made in Germany. Yours truly, R. M. J. TEIL.—Wolborough, Newton Abbot, November 11th. [There are now of course several artificial bases, *e.g.*—kairine, thalline, antipyrine, antifebrine, &c.,—whose antipyretic properties cause them to be recommended in place of quinine. We do not profess to know precisely what may be intended by "carbure."]

COFFEE AND ITS CURERS.

We are indebted to Mr. H. C. Johnston, of the Ouchterlony Works, Beypore, for the following very interesting letters :—

A great deal of comment, and no little antagonistic feeling, has of late arisen between planters and coast agents on the subject of coffee curing. Doubts have been expressed, and an idea spread abroad that curers do not do justice to their part of the business, and it has been asserted that what little they do, is charged for at extortionate rates. As I have not hitherto cured for the public, I hope what I am about to say on the subject will at least be considered disinterested. The figures may, I think, be relied on. I feel certain that if planters were more acquainted with the details of the coffee trade, their complaints would be less frequent.

One of the chief causes of irritation is the loss in the curer's yard by drying. On this point, as on others, I speak from the results of my own experience. Eighteen bushels per thousand is a fair allowance for dryage over a large quantity; I have known parcels lose sixty, and others that gain in the bushel measurement; small lots of 50 or 100 bushels which do not get the turning over, in gathering and spreading that 2,000 to 2,000 bushels do, almost invariably gain. It seems to have escaped planters that when parchment coffee has, by exposure to a coast sun, arrived at dry point, any further exposure renders the parchment so brittle that it pulverises when raking up, measuring, and bagging. It is absurd to think that the curer, whose work is compressed into a limited space of time, can turn on and off the labour tap at will, any more than can the planter, whose crop comes on with a rush. So a higher percentage of loss by dryage is recorded in the curer's books. A good curer can tell almost to an hour when a particular lot will be dry, but it does not always follow that labour is available at the exact time. In the season of 1884-1885 the estate that gave me the largest percentage of dryage gave the best outturn. In the previous season this estate showed the smallest percentage of dryage. In Ceylon yards there are two degrees of dryness known as "bone" dry and "horn" dry; the latter is when you can indent the bean with your teeth, instead of cracking it like a nut. Coffee will peel in the "horn" dry condition, but no respectable curer would do so, and it is only practised by cheap men. There is a curious fact in drying coffee which does not seem to be generally [illegible] planters. Parchment will lose 2 lb. to 2½ lb. the first day, and 1 to 1½ lb. the second, that is for coffee arriving at 38 to 40lb. per bushel.

Another source of complaint is the difference between the estate measurement and coast measurement. I don't think there is much to growl about. The difference over nearly half a million bushels comes out at ·025, which speaks well for Mysore cartmen. The question of shade drying, and the colour of

coffee, has of late occupied the attention of some planters. Shade drying on the estate is a resurrected fad, that ended in a fiasco years ago. Unfortunately, no advance has been made by recent experiments on the conclusions arrived at sixteen or eighteen years ago by the then generation of Wynaad and Coorg planters. One planter writes me, it takes twenty-five days to dry to 35 lb. per bushel; another that he hopes to get out of it with only £13 per ton loss. One thing is certain that the curers can do no more than fix the colour already in the bean when received into their yards. It stands to reason that if the desired colour does not exist in the berry, no curer can put it there. It is equally certain that the planter can do a great deal to conserve what colour there is in his coffee by careful pulp-house work. But after all, the true solution of the question lies in the two words *high cultivation*. Mocha coffee cannot be said to have any colour at all, yet it fetches high prices. The best colour I ever got, came from a lot received at 47½ to 49½ lb. per bushel. It took six days to dry to 29½lb.: dryage 2·26 per cent, outturn 91·5 bushels per ton. Outturns are discussed by planters with great interest. They are looked upon as a test of the curer's efficiency, or to call a spade a spade, how much is not stolen from his yard! It seems almost unnecessary to attempt any defence. You have a body of men managing large concerns along the coast, controlling large sums of money, some of whom have been planters themselves, accused by implication of not being able to defend property entrusted to their care. Most planters would show fight at such an imputation; still, the idea prevails that regular and systematic robbery is permitted in the curing yards. It is ridiculous on the face of it. The best outturn I ever heard of was 79 odd decimals from Mr. Finlayson's Dunkeld Estate in Coorg. I know of more than one case where 80 bushels to the ton was approached. These are, I think, exceptional. If a planter gets 95 all round without any large percentage of clean, and no undue proportion of dry cherry he will take no harm. As a matter of fact I beat this last season by over 4½ bushels.

It has lately been asked in the Wynaad Planters' Association what curers grant as to the maximum waste of weight allowed on coffee shipped home? Just nothing at all. These are the facts:—

Single bags net weight shipped ...		...	168 lb.
" " of bag ...		...	2½ "
		Gross ...	170½ "
Trade tare on bags ...	3 lb.		
Draft on do. ...	2 "		5 "
			165½ "
Nett loss to Planter ...	...	...	2½ "
		Nett Coffee ...	168 "
Double bags the same; they weigh		...	4½ "
And the London Trade exact ...		...	5 "

Draft the same.

Cases take a 3 lb. draft, and anything over 3 cwt. a 5 lb. draft. Bags of any weight under 112 lb. carry a 1 lb. draft, however small they may be. In addition to the above, 3 lb. extra draft has to be allowed on all bags sea damaged. A Broker writes:—'The question of draft allowed on bags has been frequently raised, but dealers have persistently refused to buy without customary allowances. Some time back bags shipped from Jamaica were made heavier. The trade objected to this, and insisted upon a 3 lb. draft on all bags weighing 1 cwt. 3 qr. and upwards.' So our fellow planters on the other side of the world gained nothing by this move. I have proved that coffee thoroughly dry will take up moisture equal to 50 lb. per ton if exposed. The question of draft is a serious one, and Coast Agents have, from time to time, attempted its reduction. The planter, of course, is at liberty to impose on the London Trade any conditions he thinks proper when selling his crop. I have, however, a slight suspicion that in the long run he will come off second best.

Prices are all governed to some extent by certain trade customs and allowances, with which it is impolitic to attempt to interfere. The Yercaud Planters' Association asked some time ago how it was that while they only netted £50 a ton, coffee was selling retail in London at 1s. a lb. or £112 per ton. The following approximate memo will explain a good deal of it. Out of the balance has to come the London wholesale buyers' profit, often the provincial wholesale dealers' profit, the cost of distribution, including a provision against bad debts; insurance and house-rent; and an old curer reminds me of an ancient custom of the retail trade to make tea and coffee pay for the loss on retailing sugar:—

Value nett per ton to Planter...	£50	0	0	Planter pays.
Draft 14 bags at 2 lb.=28 lb. at £56	0	14	0	
Discount 1 per cent ... p. ton...	0	11	2	
Marine Insurance	1	10	0	
Freight 45s p. ton of 18 cwts. ...	2	10	0

Duty at 1½*d.* p. lb.	14	0	0	
3 mos. credit to grocer at 5 p. cent	0	17	11	
Cartage from dock to roasting estabt. not including cartage to grocer's shop	0	15	0	
Charges for roasting 3*s.* per cwt...	3	0	0	
Loss in weight roasting avge. 18 p. ct.	13	14	2	
	92	1	0	

NOTE.—20 per cent is the actual loss calculated for low class coffee in roasting.

On the subject of curing charges I am somewhat reluctant to speak, lest my motives be misunderstood: I will, however, give the conclusions I have arrived at, and my opinions must be taken for what they are worth. I am fully convinced that no curer can put the proper amount of honest work into the curing, or employ efficient supervision over the various processes for 35*s.* per ton, and leave a fair living margin of profit for himself. In these days of leaf disease the expenses of garbling have been enormously increased. I have not had much experience of Sheveroy Hills coffee, but what I have seen, contained almost everything that a good sample of Parchment coffee should not, and I have heard curers complain dreadfully of its quality. What does the cheap curer's offer amount too, skinned?

Curer loquitur:—"I offer to cure your coffee at a reduced rate thereby effecting for you a visible saving of R10 per ton. It is not my business to tell you that I cannot afford at that rate the necessary labour, or supervision. It is not my business to tell you that the coffee will be left spread out on the barbacues all night, subject to the detrimental dews, which I know fall all over India during December, January and February. It is not my business to tell you that I shall peel in the horn-dry condition, skimp the garbling, and not be particular about measuring the coffee from the barbacues, or weighing it from the peelers; that I shall pack in the cheapest bags I can get, and, if possible stick you in the matter of freight; any more than it is my business to tell you that, while I am morally certain you will lose 2*s.* 6*d.* per cwt. I am of opinion that it is more than probable you will obtain 5*s.* per cwt. less than if your coffee had been properly and honestly cured. This is a point, however, you cannot very well bring home to me. I defy any curer, no matter where he comes from, to present to the London trade in its best condition for sale a foxy mixed crop, with leaf disease written on the face of it, for R35, or even R45, and make a profit."

To quote the words of "Wyvern" on his cook :—"I doubt the policy of quarrelling with your best friend." If a curer of his own free will offer a substantial reduction, planters may depend that the offer means slovenly work, and a loss to themselves by way of prices realised. The recent failure on the Coast proves that coffee curing is not all "beer," although there may be a good deal of "skittles" about it sometimes; and even at R45, coffee-curing does not always pay.

In connection with curing, *freight* is a subject much discussed, and some little misunderstanding appears to prevail. The enterprising agents of the British India Company offer to contract for 35*s.* per ton, against 42*s.* 6*d.* to 45*s.* of the coffee steamers, and some planters cotract to ship apparently oblivious to the fact that the British India rate is for 12 cwt. (Bombay scale) or 52*s.* 6*d.* for 18 cwt. (Coast scale). So the planter pays at least 10*s.* per shipping ton more to the British India Co., than he would do to the coffee steamers. Last season the difference was 12*s.* 6*d.* per ton in favor of the coffee steamer. The shipper by the British India has, besides, the above the benefit of transhipment in Bombay, and sometimes the additional luxury of having his coffee delivered in London in broken-up parcels, the cargo being sent off from Bombay as it suits the P. and O. Company to take it. There is an alternative line of steamers, which is being patronised by most of the large shippers on the coast to whom the tone assumed by the British India for so many years has become monotonous. I can speak to the fact that the Asiatic Company and their agents are most desirous of meeting the wishes of planters, and no effort is spared in protecting shippers' interests. An old custom still survives with a few planters of shipping in cases. I cannot account for the reason of it. There is most certainly no enhanced price realised now-a-days, in comparison with bags. On the contrary, the same coffee shipped in bags will net about 4d. per cwt. more than in cases, and there is besides a saving in freight, and R5 per ton in curing charges. In conclusion, I may state, without the slightest hesitation, that it would pay planters hand over fist to spend more money on the preparation of their coffee on the coast.—*Madras Mail.*

"BELOW THE HORIZON:"

COFFEE AND CACAO 100 YEARS AGO IN THE WEST INDIES.

It is, perhaps, a little late in the day to write about coffee and coffee estimates; but yet there is some interest in it even for many of us who, through force of untoward circumstances, are now out of touch of the fragrant berry. We can all appreciate anyhow the present upward course of the market even if we have but tea to sell; for if coffee is going to be scarce, and in time become a beverage only for the wealthy, then, we will have more consumers for our tea, and thus indirectly benefit it by the enhanced value of coffee.

I have lately been dipping into an old history of the West Indies in two volumes by Bryan Edwards, published in 1794, an elaborate book with maps and plates and bound in a way which tells of honest work; for although now nearly a hundred years since it left the hands of the binder, it seems strong enough still to outlive another century. In the chapter on the products of the islands there are two at least, which are of interest to the *Observer*'s readers:—Coffee and Cacao. Regarding the former the writer gives a very clear and full account of the then style of cultivation and curing with an estimate for opening an estate of 300 acres, worked by slave labour.

There is not much for the coffee planter of today to learn from the old methods and it is more for the curiosity of the thing than for ought else that I seek to bring the system of these old planters under the notice of your constituents. They planted 8 ft. by 8 ft., which few Ceylon places could stand; but wide as this was it was found to be too close at times, and the planter of those days "thought it advisable to cut down every second row, within ten or twelve inches of the ground, and by well moulding (? manuring) the stump they will furnish a succession of hearty, young trees while the rows which are left will bear much better for the room which is given them." The trees were topped at a height of five or six feet, so as to have from thirty-six to forty-two bearing branches. The average crop was about six cwt. an acre, but individual trees had borne at the rate of forty cwt! The coffee was not picked until the berry was "black red," and a negro with a bag hung round his neck, provided with an iron hoop in the mouth to keep it open, could, if he were industrious, bring in three bushels a day.

They had two ways of curing, drying in the cherry, and pulping and then drying. By the former method, if the weather was favourable, coffee could be cured in three weeks, the bean "weighing four per cent heavier than if cured without the pulp."

It was also considered a better quality of bean. As to the pulper in use, it seems to have been a simple crusher:—"The pulping mill consists of a horizontal fluted roller about eighteen inches long and eight inches in diameter. The roller is turned by a crank or handle, and acts against a moveable breast-board, which being fitted close to the grooves of the roller prevents the berries from passing through." There was no means for separating the parchment coffee from the skin, it had to be taken out by wire sieves. A negro could pulp a bushel a minute. The coffee was not fermented, but put out to dry at once.

About the time the book under notice was published, the duty on coffee which had been 1s 6d a pound had been reduced to 6½d, and the efforts of the planters were being put forth to meet the increased demand at home which had arisen in consequence. In the island of St. Domingo, which was a formidable rival to Jamaica, the slaves had rebelled and destroyed over a thousand of the coffee estates: the result was a greatly diminished export and a rise of prices in the European markets from 70s to 90s per cwt. There were, therefore, good times before the Jamaica planters and they saw their way to take advantage of them, provided "labourers shall continue to be procured from Africa at moderate prices." They hoped in time to do away with the necessity of importing slaves, through the natural increase of those already in the island, as they would be much healthier on hill estates than they had been in the low country. By this means they would gradually abolish the slave trade and this "without giving reason of complaint to any body of men." This was the state of things when the following estimate was framed to encourage capital to embark in the culture of coffee:—

"Estimate of the expense and return of a coffee plantation in the mountains of Jamaica, fourteen miles from the sea, calculated in the currency of that island being forty per cent worse than sterling:—

	£
First cost of 300 acres mountain land of which one-half is preserved for provision and pasturage at £3 per acre..	900
Ditto of 100 negroes at £70 per head ..	7,000
,, of 20 mules at £28 ,, ..	560
Buildings, utensils, mills and negro tools..	2,000
Expense of maintaining the negroes the first year before provisions can be raised (exclusive of other annual expenses charged below) £5 each	500
	10,960

Compound interest for three years before any return can be expected at 6 per cent ..		2,093
Annual expenses..		13,053
White overseer and maintenance ..	£200	
One other white servant ..	70	
Medical attendance on the negroes	25	
Negro-supplies, clothing, tools, salt fish, &c.	200	
Colonial taxes ..	100	
	£595	
Three years' expenditure ..	1,785	
Compound interest ...	221	
		2,006
Total expense..		15,059

Returns the fourth year at £4 per cwt, being the average price of coffee for five years previous to 1792:—

From 150 acres of young coffee may be expected the fourth year 45,000 lb..		£1,800
Deduct annual charges for the fourth year ..	£595	
Sacks and saddles ..	40	
	635	
Clear profit (being equal to £7 14s per cent on the capital.)... ...		1,165
Returns the fifth and subsequent years 150 acres yielding 750 lb. per acre, 112,500 lb. at £4		4,500
Deduct annual charges as before ..	£595	
Sacks and saddles ..	80	
Repairs of mills, &c..	100	
		775
Clear profit (being equal to 24 3-5th per cent on capital)		£3,725

PEPPERCORN.

SUGAR appears to be the one absorbing topic throughout the West Indies. As in Jamaica, British Guiana, and Trinidad, so in Barbados, it is discussed and looked at all round, in the hope that something may be done to improve its marketable value. A writer in the *Barbados Herald* thinks the West Indies might help themselves by the abandonment of obsolete modes of manufacture, the erection of modern improved machinery, and their emancipation from many inveterate prejudices which, he alleges, impede, their progress. With the abolition of the bounties, or such readjustment of duties as will enable them to compete on even terms with other manufacturers the principal grievance would be removed, and if then sugar cannot be produced at a profit he suggests that it should be abandoned as a forlorn hope.—*Colonies and India.*

COFFEE: THE LANKA COMPANY AND COFFEE CULTIVATION.—Our London Correspondent was misinformed—though he named some one who ought to know, as his authority—in saying that the Lanka Company were rapidly clearing out all their coffee in order to replace it by tea. Such is by no means the fact. The Company's Manager has, of course, allowed certain fields never very favourable for the old stapie, to be cleared and planted with tea; but the main portion of the Company's coffee in Haputale, Udapussellawa and Dikoya was never more carefully conserved and cultivated than at present and well it may be, seeing that crops of from 4 to 6 cwt. per acre are likely to be gathered over a considerable area. Altogether the Lanka Company is fortunate enough to own from 1,000 to 1,200 acres of good coffee; 1,500 acres of tea chiefly young, but with enough in bearing to give perhaps 50,000 to 70,000 lb. this coming season; besides 400 acres cacao in Mtaale, doing well, and cinchona, cardamoms, &c. The Company has not yet done much for its shareholders in the way of dividends; but certainly it has been making money when the Directors have been enabled to plant so much tea without calling in any additional capital. The dividends, after the tea comes into full bearing, ought to be satisfactory to the shareholders.

CULTIVATION IN MADRAS.—The total area under cultivation in the Madras Presidency during the past official year was 22,900,594 acres. No less than 24 per cent was under paddy, 17 per cent under cholum, ten per cent under cambu, seven per cent under ragi, six per cent under cotton, three per cent under castor oil seeds, 2 per cent under general seeds, and one per cent under indigo. The quantity under sugarcane was only 0·2 of the total area. In nearly all the districts the produce over half the area was either middling or poor, and only eight per cent, of the total area yielded a full crop. It would be interesting to know whether the areas here given are even approximately correct.—*Pioneer.*

MR. ELPHINSTONE ON RUSSIAN TEAS, &c.—Mr. G. H. D. Elphinstone is good enough to write to us with the Report and Valuation on the Tea Samples referred to in his last. He says:—"As promised in my previous letter, I herewith send you copy of the London Report and Valuation on the Russian Tea Samples I brought with me. I have sent Mr. Rutherford the samples, I think you will be satisfied on looking over the comparative values that Russia is undoubtedly next to England the best tea market. I know myself from experience in both the American and Australian markets that neither market was as good as Russia, and I trust by a gradual process we may be able to introduce the Ceylon tea into Russia, and so keep up the price for our teas when the yield of the island has increased so as to exceed the English demand."

LIST OF RUSSIAN TEA SAMPLES: LONDON REPORT AND VALUATION ON SAME.

Petersburg Samples.

No.	Roubles.	s. d.		s.	d.	
1	8	@ 1 11	equal	15	4	Reddish leaf not in London Oolong liquor value 8d.
2	5	,,	do	9	7	Flowery pekoe value 1s, not in London.
3	4	,,	do	7	8	Moning with flowery Tip-leaf, not in London Liquor value 9d.

11 Brick Tea Roubles 1·20. No value in London.

12 Petersburg spurios Tea worthless, used for mixing and adulteration.

Moscow Samples.

No.	Roubles.		s.	d.	
1	2·68	equal to	5	1½	Ninchow Pekoe, 1s 1d to 1s 2.
2	2·20	do	4	2	Pungent Ninchow Pekoe Flavor 1s 6d.
3	2·00	do	3	10	Ninchow 1s 1d.
4	2·00	do	3	10	do 10½d.
5	1·80	do	3	5¾	do 10d.
6	1·40	do	2	8½	Moning Spantum 6½d

Remarks.—You will note that on the whole Moscow sells a better tea than St. Petersburg.

Duty amounts in English money to 1s 6d per lb.

Freight, landing charges, &c. in English money to St. Petersburg .. .. 3d per lb.

Do do to Moscow .. 4d do

10th Dec. 1886. G. H. D. E

Correspondence.

To the Editor of the "Ceylon Observer."

COCONUTS AND THE COCO-DE-MER.

Mahé, Seychelles, 22nd Nov. 1886.

DEAR SIR,—The letter of your correspondent "Latch" dated 25th August 1886, has come under my notice through the medium of your invaluable work the *Tropical Agriculturist*. *En passant*, I may mention that I hear that periodical highly commended by all to whom I have had an opportunity of introducing it, but more than one has said "it savours rather too much of tea." Knowing Ceylon as I do, and the revolution that has taken place in its principal culture, I am not surprized that much of the space in the *Tropical Agriculturist* is devoted to the Tea industry.*

With regard to the coco-de-mer, I think I may safely say that the Island of Praslin is its home. There are a few isolated specimens on Mahé 20 miles from Praslin but these have been introduced. The celebrated coco-de-mer groves, where the tree flourishes in all its unique grandeur are on the aforementioned island, and it is from these groves that the nuts are sent into the market at Mahé. The average price is about R1 per nut. The majority are purchased for export to Mauritius. The few that circulate in the country are used as measures for shellfish and native vegetables or as "balers" for pirogues (native canoes) and a few are polished and sold to visitors as curios. The inside of the nut is a whitish pulp about the consistency of butter, it is edible though not much appreciated. About three years ago I took a few full nuts to England and although essays have been made to propagate them in some of the principal Botanical Gardens there, I do not think they have been attended with success. Nuts that have commenced to germinate have been forwarded to the Botanical Gardens at Pamplemousses (Mauritius), with these the Director has been successful. I will try and procure some for you and forward them in a wardian. One peculiar feature of the coco-de-mer is, that the plant may appear above ground twenty or thirty feet from where the nut has been sawn. The late General Gordon when here made some very interesting sketches of the habits of the tree, as also did Miss North. Those of the latter are to be seen in that lady's gallery at Kew. I enclose you a photograph showing the coco-de-mer nut and germ. I am sorry, I am not well up in coconut lore, so cannot say if those that grow here are the same kind as in Ceylon. From what I remember, there is a great similarity in both the appearance of nut and tree. There is undoubtedly a small variety here, the most noticeable being "the Nicobar," which is almost a sphere and of a pale red hue. I am not inclined to think that "the larger the nut the greater its value" for I find that many of my smallest nuts yield most oil.

I am not, however, a professed coconut planter. Most properties here represent *multum in parvo*: on the one from which I am writing there are cacao, cloves, nutmegs, pepper, vanilla, pine-apples (about 50,000) sugar cane, manioc, sweet potatoes and tropical fruits in numbers; here and there a tree or plant, a wilderness of disorder and as great a variety of soil as there are forms in a kaleidoscope, but everything grows or would grow if properly cared for. So great is the fertility of the soil and so propitious the climate, that it has been said "you have only to plant your walking stick and it will grow." Vanilla is now all the rage and Seychelles has become the largest vanilla-producing country in the world.

Hitherto but little known, Mahé is about to become a large coaling station; it is to be the *tête-de-ligne* of the Messagaries Maritimes in these waters. The Orient Line contemplate coaling here instead of at Diogo Garcia and in all probability it will shortly be made a Naval station. We are woefully deficient in hotel accommodation —wish you would send us a d'Silva—and there is ar capital opening for an English mercantile house I am glad to read that there appears to be a prosperous future for Ceylon, though many old and valued friends have, since I left, gone to "that bourne" from which no traveller returns. I too have travelled far, seeking "crust or crumb" since dark clouds o'ershadowed the pleasures, and at one time the prosperity of a Ceylon coffee planter's life. Yet there is ever a lingering desire to return to the country where I spent nearly twenty not unhappy years. May they who had the courage to stay be rewarded.—Yours, very faithfully E. H. EDWARDS.

* A reference to the index of any of our *T. A.* volumes will shew that there are very many papers on all tropical products: in fact we omit nothing bearing on tropical industry.—ED.

COCONUT FIBRE REFUSE.

23rd Dec. 1886.

DEAR SIR,—If further proof be wanting for my assertion that fibre refuse possesses an agricultural value even if it does not possess a manurial value to the tree that produces it, I have only to mention the high agricultural value of sand for a certain description of soils. Though sand is composed almost entirely of siliaca, constituent that plays a minor part in the vegetable economy, yet when applied to stiff, heavy clays it increase its porosity and therefore fertility. Because sand is intrinsically valueless, will we be justified in saying that because when analysed it gives very disappointing results, therefore it possesses no value in agriculture? What "C. S." who is but Mr. Symons' champion says, will possess some weight if the soil of Horekelle is a stiff clay very retentive of moisture, though even there decaying vegetable matter mixed with it will increase its porosity; but "C. S." tells us the soil is sandy. The defects of such soils are its "extreme porosity or absence of retentivene," the cure for which is said to be the addition of "clayey composts, or green manuring." Neither of these is practicable, generally, on a propertyof over 1,000 acres, however well they may suit a few acres. But as the "humus compound arising from the decay of vegetable matter affords an absorbent for moisture in the same manner as clay" I most unhesitatingly assert that the Horekelle Company can put their "vast mounds" of fibre refuse, allowed to accumulate from the time of the late David Wilson, to no better use than to be sown broadcast in the estate and well ploughed in. Mr. Symons very (il)liberally offered this valuable refuse to anyone who would cart it away. Why? Because Mr. Wilson subjected it to analytical tests and found it worthless. This may or may not be the case but it only proves how little claim that gentleman had to be reckoned as a competent agriculturist and how pernicious a thing it is for gentlemen with no agricultural training to "direct" the working of a purely Agricultural Company. In attempting to do this they have blindly followed the lead of one who was (agriculturally) blind himself and we know what is the usual consequence of accepting lead of the blind.—Truly yours, the A. W. B.

TEA IN KALUTARA 1885-1886. THE KALUTARA PLANTERS' ASSOCIATION FIRST ANNUAL REPORT.

Your Committee in presenting this its first Annual Report, is happy to record that the past year has been one of progress and good promise for planting interests. Since the day the first lots of forest land were sold in the district, many changes have come about. Liberian coffee, cacao, citronella, rubber and cardamoms have all been extensively planted, but the past year has seen nearly all these products superseded by tea. The year 1886 may be said to commence the history of Kalutara as a tea district, pure and simple, and your Committee is glad to note that results both as to yield and price obtained are very satisfactory. In proof of this, the following figures may be adduced;—Tea on Culloden estate, now seven years old has yielded 740 lb. made tea per acre during the past financial year; while tea of about the same age on Gikiyanakanda (manured with citronella grass refuse, has yielded in the past 2 years 900 and 1,100 lb. per acre. As regards young tea, results are equally satisfactory, yield on Ambatenna estate, from tea 2 years and 3 months old, being for the month of November last, at the rate of 600 lb. made tea per acre for taking these facts with the average prices realized, your Committee congratulate you on the good prospects for the future,

COFFEE CORRUPTION.

Mr. Frederick Clifford's letter to the London *Times* brings into prominence the gross injustice permitted in England in connection with the sale of coffee, an article of produce which, here, and in Ceylon, has had to struggle with numerous and often overwhelming natural difficulties bringing sorrow and ruin on many a hapless Planter who has embarked capital and spent years of hard and laborious toil in its growth. The trials connected with its growth are unfortunately inseparable from the enterprize, and with these he must lay his account; but it is hard, indeed, that the laws of his parent country should be such that the most worthless compound can be passed off for the valuable product upon which he has toiled so hard, thereby baulking him of the full profit and advantage from the same which are his due. It is a mistake to suppose that the principles of free trade justify this sort of thing. It is no part of the free trader's doctrine that the merchant or dealer should be allowed to sell goods of the true nature of which the buyer is virtually ignorant; or that the buyer, while believing he is receiving an article of a certain kind, gets something quite different. Under whatever Act the dealer claims to be justified, it is wrong. The law presumes the buyer to know what he is buying; but as a matter of fact, in the case of coffee, he does not, for are we to believe that the average Englishman is such a fool as to give *one shilling and eight pence* a pound for a thing he could buy in a different form for *one shilling* or less? If so, then we may well concur with Carlyle in his opinion of the British population that there are "thirty millions—mostly fools." It has been proved that many of the samples of the article sold as coffee contained no less than from 40 to 90 per cent. of other ingredients of little comparative value; therefore, notwithstanding the precautions provided by the Act for the prevention of fraud, the fact remains that the public are duped into buying daily such mixtures as these, in the belief that they are getting pure, or all but pure coffee; and what is more, they pay pure coffee prices for them.

In the cases which Mr. Clifford brings to the notice of the public through the columns of the *Times*, that of three grocers brought before the Stratford Magistrates and let off, although the article offered for sale as coffee contained 45 to 65 per cent. of foreign ingredients surely makes the inefficiency of the English law glaringly apparent. Packages may bear the mark showing that the contents are a mixture; but the buyer, if he knows anything of it at all, knows nothing of the extent of the mixture. It is quite obvious he is duped, and so some more effectual means are necessary to check the shameless imposition. It is clear that some alteration in the law must be effected, such as will prevent the general buyer being made the dupe of every town and village grocer in the country, and give those who toil on our plantations a fair chance of earning their full and legitimate share of profit. If there be some who prefer a moderate mixture of chicory with their coffee, either let the chicory be sold separately; or, if a mixture be permitted, let the law take care that means are adopted for making the mixture and the precise proportions known without doubt to the buyer. Every consideration must be given to the multitude of ignorant people there are amongst the lower and uneducated classes in England; and the law should guard with great care against their ignorance being taken advantage of.

The Planters of India have no more than one occasion moved the Home Government to deal with the matter; but with no effect. The Indian Coffee Planters' Committee at the Colonial and Indian Exhibition is a good organization for working up the question, but it would be well if the various Planters' Associations on this side urged the Viceroy and the Indian Government to bring the weight of their influence to bear upon the Home authorities. They should also get the Indian Members of Parliament, of whom there are a good many now in the House, to take up the subject. England is the chief customer for Indian-grown coffees, foreign sorts being mostly used on the Continent; so the question affects our Planters in a special degree. The proposal referred to by Colonel J. A. Campbell, in an interesting paper read at a meeting held under the auspicies of the above Committee, namely that they should start shops for the sale of their own produce, is probably a good one. A Co-operative Society, with branches, would, perhaps, be better. Why should they not also make arrangements with existing Co-operative Societies, such as the Army and the Civil Service, &c., for the sale of their coffee? They could rely on these institutions selling their produce unadulterated. Whatever means are employed either to educate the public to appreciate good coffee, to point out how they are being imposed upon by the ordinary dealer, or to direct Government attention to the inefficiency of the Adulteration Act, the general body of Planters and those interested in the trade should not rest till the present abuses are removed, and till knavery is no longer permitted to interfere with their produce reaching the consumer in a pure and unadulterated state.—*Daily Post.*

COCONUT OIL.

An article so long in the market, so widely known, and so extensively used for scores and even hundreds of years, as Oil can hardly respond to what is known as "pushing" in dealing with new products and new brands. A larger consumption, save with reference to the increase of population, and new uses are hardly to be expected; but there is one point which demands and should have early attention—the price of Ceylon Oil. A smaller supply is generally followed by higher prices; but the causes which have led to the diminished exportation of Coconut Oil forbid the hope of this desirable sequence. It is not, however on the low prices ruling in comparison with former local prices that inquiry is needed—during the Crimean War the price of Ceylon Oil was double the present quotation and the normal price was between £40 and £50—but on the difference in price between Cochin and Ceylon Oils. How is it that almost in this article alone the Island is unable to secure the pre-eminence it has won in almost all its products—Coffee, Tea, Cocoa, Cinnamon, Plumbago, &c.? What is more remarkable is that the difference in prices is growing wider to our disadvantage. Thus, whereas in 1884 and 1885 Cochin Oil realized only £3 per ton more than Ceylon, at the present time the difference is £11 sterling, the prices being £37 10s. and £26 10s. respectively. One of the reasons we have heard named for the higher price paid for Cochin is that it is richer in stearine—that is the fatty or the more solid principle in Oils, which is of special value in the manufacture of candles, soap and lubricants. It would be well to ascertain by analysis that this poverty in stearine is a fact, and then to trace the causes to which it may be due. Two of the most obvious causes would seem to be defects in cultivation and defects in manufacture. If it be the former, the defects may probably be removed by supplying the soil with the constituents in which it may be deficient. If the latter, we rather think it must be due to the quality of the raw material operated on than to defects in the manufacture itself. The machinery in use in the Island is believed to be the most finished and effective that can be devised, and certainly leaves very little oleaginous substance in the poonac residuum; but the Copperah which is crushed is too often smoke-dried, and as often the kernel of immature nuts. The same ignorance and necessity which prompt the villager to pluck unripe fruits and send them to the market—including Areca-nuts, though our paternal Government knows naught of it—induce them to pluck immature nuts and hasten them into the market by exposure to a fire on lathed shelves. The conversion of immature and fresh-plucked nuts into Copperah, and the exposure of the kernel to fire may have more to do with the poverty in stearine of Ceylon Oil than anything else.

What would seem to be needed are analyses of Cochin and Ceylon Oils; and if a material difference is established, it would be well to secure analyses of the Copperah produced in the two countries, and also of the soils in which Coconuts are grown. Are the higher prices paid for Kalpitiya and Marawila Copperah due merely to the stuff being better dried —sun-dried not smoke-dried—or to the nuts being maturer, resulting in a thicker kernel more rich in Oil, or to the soil yielding nuts richer in Oil? A comparative analysis of local soils too would be useful; but a visit to Cochin Mills and plantations by a competent observer would seem to be absolutely necessary. It is worthy of note, as indicating that the difference in price cannot be wholly due to quality, that Ceylon Oil for India fetches higher prices than for London. Can it be that our Oil is used for mixing, or that it finds its way into Cochin packages? The subject is one that should be fully investigated.

A Merchant who may be considered an authority on this subject writes:—"The Ceylon white Oil is a new departure, and not fully introduced yet in Europe, prejudice being against it, as well as the fact that the progress made in manufacture is not sufficient to produce an *even* sample. No doubt, in course of time, experience will teach us to overcome that difficulty, and then our white Oil will have a better chance of approaching Cochin in price. Cochin Oil is mostly used for the manufacture of *white* soap. Our white Oil has still a yellowish tinge, and is therefore not *quite* suitable for white soap; and soap-manufacturers say that if they have to colour the soap, the ordinary Ceylon Oil is quite good enough for the purpose. The difference in price between Ceylon and Cochin Oil is so great (£11) only in London, not on the Continent, and Cochin Oil can be bought cost freight in any Continental market considerably below £37-10. There are additional reasons, quite apart from quality, why Cochin is kept so high in London. I have also reason to believe that, the moist climate of Ceylon affects the chemical composition of Oil, and that white Cochin (not Monsoon-Oil) contains more stearine, than Ceylon." It will be seen from the foregoing, that our information is correct about Cochin Oil, being richer in stearine, but is the cause suggested for Ceylon having less stearine the true and only one? The quality alone too, as surmised by us, does not account for the difference in price. As a matter of fact, Ceylon parcels of good quality have sold beyond the price quoted, while Cochin could always be had under its published price. Is not the difficulty in securing samples of Oil of even whiteness due to Copperah being smoke-dried?—Local "Examiner."

THE WILD DATE IN SOUTHERN INDIA.

Read Letter from J. S. Gamble, Esq., Conservator of Forests, Northern Circle, to the Secretary to the Board of Revenue, dated Madras, 29th September 1886.

In continuation of paragraph 2 of Mr. Peet's letter, dated 16th February 1886, No. 2,156, I have the honor to submit, for the information of the Board of Revenue, the following extracts from the reports received from Collectors in this circle regarding the growth, distribution and habitat of the wild date (*Phœnix sylvestris*) as I find that some interesting information has been collected. The Collector of *Ganjam* reports that the wild date is abundant in Chicacole, less so in Berhampore, and comparatively rare in Goomsur. He says further that it is often found along roadsides, but more frequently along streams where the bed is sandy. It also affects "kunkar" soils. The tree is tapped for toddy and the fruit is eaten and can occasionally be purchased in the bazaar. The Collecter of *Vizagapatam* reports that it is common in the coast taluks of the district, and especially so in Sarvasiddhi. Everywhere it is tapped for toddy, and the fruit is regularly eaten and is taken to the bazaars to exchange for grain. The imformation from *Godavari* is very slight; from *Kistna*, the Collector reports that the tree is found throughout the district and best on sandy soil. He says the fruit is not regularly used, but the poorer people sometimes eat both the fresh, ripe fruits and cooked unripe ones. When used for toddy the pot is coated with chunam inside if sugar is being made, if not it ferments The "cabbage," *i.e.*, the tender young leaves inside the crown of the tree, is sometimes eaten. The Collector of *Nellore* write as follows:—"The date is common all over the Nellore district, growing chiefly on the banks of streams and nalas and in depressions where water stands after heavy rain. The soils which seem to suit it best are sandy loams and sand. It is a common weed in all the mango topes, quite spoiling them for camping purposes. It also comes up under the shade of all other trees, except tamarind, where they grow on fairly good soil. The *fruit* is not used for food, but it is sometimes collected and sold to children for an equal measure of grain. But it is not a regular article of food, being generally allowed to fall unpicked. The tree has no value except for toddy and for the good fibre obtained from its leaf stalks." In the Ceded districts the wild date mostly occurs in swampy places where the soil contains either salt-earth or "kunkar." A characteristic locality may be seen close to the old Guntakal station on the Madras Railway. The Collector of *Cuddapah* reports that it is found in all taulks to some extent usually in groups of 200 to 500 trees. He adds that the yield of toddy is better in damp localities; but that from trees in dry places is more intoxicating. The fruits are eaten and the seed is sometimes chewed like arecanut.

The Collector of *Kurnool* also states that it is found all over the district and especially in Nandikotkur taluk. The Conservator has seen it in abundance in salt-earth swampy places in Ramallakot. The Collector also remarks that it is eaten, but has very little pulp. From *Bellary* the Collector sends some interesting remarks which are reproduced as follows:—He says that there are about 19,000 acres covered with it in the district, but chiefly in Adoni taulk:—

"The plant appears to be distributed throughout the district and is found growing principally in the vicinity of vankas (hill streams) in sandy soil impregnated with salts. The plant also grows on regada (black cotton) soil, but not so well as on the sandy soil called 'mussabu.' The fruit is eaten, but not as a regular article of diet. In the Bellary taulk the plant covers an area of 583 acres and is found growing best near vankas on light sandy soil. In the Alur taluk the extent covered by the plant is 12 acres, a part of which is situated in the limits of the village of Hollalagundi and a part in the village of Nagarur. In this taluk the soil is nearly all regada on which account I suspect the area on which the date is found growing is so small. In the Hospet taluk, in the villages of Chilakanhatti and Antapur, the growth of the plant is pretty thick, elsewhere in the few other villages where it exists it is found scattered. In this taluk also the plant is found growing near venkas in mussabu soil; extent 37½ acres."

"*Rayadrug.*—In this taluk near the villages of Kottapalli and Thalakerra the growth is pretty thick, but elsewhere scattered. The soil is mussabu, and the area over which the plant is found growing is 928 acres. In the Harpanahalli taluk the plant is found growing thickly in Yeddahalli, Tellagi, Ragimosalarada and Adavihalli villages and in a few others scattered. The extent on which the plan is found growing is 100 acres. In the Hadagall taluk the extent over which the plant is found growing is 38 acres. In this taluk also it is found growing best in mussabu soil alongside vankas. In Kudligi the plant covers an area of 1,295 acres and is found growing in sandy saline soil near vankas. In the Adoni taluk the plant appears to have spread a good deal, as the area on which it is found growing is 16,000 acres or five times as much as the total area of the remaining seven taluks. The soil on which it is found growing is a light reddish sand impregnated with salts near vankas. From the foregoing remarks it will be observed that the habitat

of the plant is near vankas where the soil is always humid and that naturally it prefers a light sandy soil impregnated with saline matter. The fruit is not used, because the use of the tree as a producer of toddy is general, and it is valued for this purpose alone. The sites favourable for the growth of the date are indicated all over the country by the mounds where salt modas once were situated. These mounds and the land immediately adjoining them are in almost all cases waste and at Government disposal, for their use for the manufacture of salt or saltpetre has been abandoned; the presence of an old moda site implies existence of salt in the soil and a supply of water handy, and the plantation of these old sites with date would result in a distribution of groves all over the country whose value to Government might be very great as their use under restrictions, if permitted, would greatly increase the value of the toddy farms."

The Collector of *Anantapur* also remarks that it is universally found, especially along streams, in a saline or calcareous soil. In Madakasira it is sometimes met with on black-cotton soil. The seed is regularly neate and is procured by barter for paddy. The tree does not occur in the *Nilgiri* district. The smaller wild dates are found in all districts and of several species. In the forests of the Circars the *Phœnix acaulis* is common and the fruit is also edible and sweet, though it has but very little pulp. On the higher hills, as at Mahendragiri, it 'grows into a small tree 10 to 15 feet high, but this may be the species *Onseleyana*. On the Cuddapah and other hills of the Ceded districts the *Phœnix farinifera* is found of very similar qualities, while the species which covers such large extents of country on the northern slopes of the Nilgiris and affords a pleasant fruit is probably *Phœnix pedunculata*. But all these species are difficult to distinguish and may prove to be mere varieties (as is the Arabian date *Phœnix dactylifera*) of *Phœnix sylvestris*.

TEA BLENDING.

The art of tea blending is one which cannot be too thoroughly or too methodically studied by every tea dealer who wishes to make a position for himself in his trade.

The man who has really mastered it can defy all competition; by careful tasting he can buy as well as the large houses, and by making the characteristics of the water of his locality his special study, he can please his customers far better than any outsider can possibly do, however extensive his operations may be, and at the same time secure a good profit for himself.

The main principles of this art are easily laid down; their practical application must be a matter for the personal consideration of each blender, guided by the peculiar circumstances of each case.

It is of the utmost importance to select teas that will mix well; for instance, to put a fine flavory tea to a coarse rasping tea will deteriorate both, while to add it to a full rich liquoring tea will improve both.

Desirable Indian teas may be used very freely to give strength, point and flavor, but sour or acrid Indians, or low Javas, should never under any circumstances be used.

Avoid unsound teas most rigorously; a tea with the least trace of mustiness or the least mousey flavor will spoil any blend.

Scented teas are often used most unwisely; for ordinary purposes 1 lb. in 12, or even 1 lb. in 16 is quite sufficient to give the blend a distinctive flavor. Fine Oolong or Foo Chow Pekoe are the most desirable kinds.

Of course this applies to ordinary trade; in the Caper districts people will sometimes drink a mixture and one part Caper, one part pungent broken Assam and one part Moning, and appear to like it.

When the mixture is made up, it should be allowed to stand in air-tight canisters at least a week before it is sold; the flavor of the component parts thus assimilates. Remember—if your tea is allowed to stand near any strong smelling articles, it will absorb their flavor; the finest teas are often spoilt by contact with soap, cheese, or other items of a grocer's shop.

We would, in conclusion, repeat—be sure your blends have some distinctive flavor; let them always be the same style and always kept up to a standard quality, so that people will learn to rely on them and come for them again and again; it is thus big businesses are built up.

The following specimen blends are of the simplest possible character, and are merely intended as a basis or guide for those commencing the work of scientific tea blending; as the complexity of the blends increase, the possible variations become so numerous that it is obviously impracticable even to indicate them within reasonable limits, but to a practical man keeping pace with the times," fresh developments and new combinations growing out of these foundations will constantly suggest themselves.

The following is a specimen:

SPECIMEN BLEND NO. 1.

Low-priced broken leaf. Principal ingredients:—
Kaisow siftings.
Assam or Ceylon fannings.

Notes.—Moning siftings are preferable to Kalsows, but are scarcer, and in consequence often cannot be obtained at a low enough figure.

Where dust is not inadmissible an Assam Pekoe dust should be added; it is a marvellous improvement to the liquor.

For flavouring use Scented Orange Pekoe fannings; or, when prices will allow, Namuna broken Pekoe.

A fraction of a penny in buying low broken teas will often make all the difference between a good and a common tea; it is false economy to inflict nasty rubbish on your customers to save a farthing.

SPECIMEN BLEND NO. 2.

Low to medium priced tea. Principal ingredients:
Saryune.
Oonfaa.
Broken Assam.

Notes.—Above will make a strong thick tea, will come out well in all waters; as, even in soft-water districts, buyers of low-priced teas look more for strength than quality.

Scented Capper or scented Orange Pekoe can be used where desired.—*Tea and Tea Blending.*

THE COCOS NUCIFERA OR COCONUT.—By W. Lascelles-Scott, M. S. A. The following from recent analyses of my own, shows the average percentage composition of a Ceylon coconut:—

Exterior fibre (coir)	32·65	per cent.
Shell	17·30	,,
Flesh or edible portion ...	26·40	,,
"Milk"	23·65	,,
	100·00	,,

Of the "flesh," or edible portion of the nut, the constituents are as under:—

Nitrogenous (albuminous) matter	6·48	per cent.
Fatty matter...	67·11	,,
Sugar and gum	5·89	,,
Mineral matter	3·65	,,
Cellulose and colour matter ...	9·76	,,
Water and loss	7·11	,,
	100·00	,,

Lastly, the analysis of the interior fluid or, "milk" gives these results:—

Nitrogenous matter	·712	,,
Gum and trace of fatty matter	·305	,,
Sugar...	4·150	,,
Mineral matter	·261	,,
Water	94·582	,,
	100·000	

British and Colonial Druggist.

COCONUTS IN CEYLON: LOWCOUNTRY PLANTING REPORT.

COCONUTS AND COPRA—"THE VALLEY"—BURNING WEATHER.

HAPITIGAM KORALE, 3rd Jan. 1887.—1886 has been a good year for the staple product of this district; there has been no long droughts—and ample of both rain and sunshine, the two climatic wants of the tree. A numerically average crop has thus been well filled, and has resulted in more than an average weight of copra. Besides improving the quality of the current crop, the fine season has put a crop on for 1887, much above the numerical average. The proprietors have thus secured one good crop, and have a fair expectation of a better coming.

A visitor to the valley has lately informed you that all the estates are in excellent order. It is true that within the past few years there has been progress, but progress is magical in different cases, and all the estates cannot justly be classed as excellent.

A fortnight of burning sun and dry searching wind has had a sad effect on all vegetation; the grass is already withered down to the roots, and garden stuffs are nowhere. Every thing is drooping, brown and yellow leaves are falling in showers, with every gust, as well as immature fruit of kinds; and the last planted coconuts are beginning to die. Fortunately the drought has not yet affected the older trees, but their time is coming if this weather continues much longer.

CEYLON TEAS —"BULKED UNASSORTED.

We are heartily glad to see that our Circular of 21st Oct. has at any rate attracted the attention of Messrs. Wilson & Co., of Colombo, who favour us with some comments upon it. With their permission we may state broadly that though they do not altogether agree with us, they go so far as to admit that Bulking unassorted is in some cases beneficial. We shall show by and bye they do not know when. We must be allowed to remind their readers that we most distinctly guarded against a hasty conclusion being come to that "all planters are advised to forward their Teas unassorted." On the contrary, we stated emphatically, "it would be absurd to lay down any hard and fast rule about it." Our critics overlook this, and rather commit themselves to a rule they immediately proceed to lay down. We think it a little misleading to state that we were "only able to point to one instance out of the hundreds that are sold in London." It is quite true that the particular case quoted by us, was the only instance we were aware of in which the entire produce of an estate had been divided and treated, as to one portion, by subdivision into six breaks, and as to other by Bulking unassorted, and sold side by side the same day; but we have repeatedly referred to the prices obtained for unassorted parcels. We learn from an interesting letter of Mr. Jas. W. Holt, of St. Leys, published in the *Overland Ceylon Observer*, of November 18th, that in his experience the figures were reversed, and the assorted got 1s 5½d, against the unassorted 1s 1d. Mr. Holt, with the best intentions, publishes his letter for our "benefit." We should doubtless profit more by it if he had kindly taken the trouble to state the exact proportions in which fine and common Teas entered into his unassorted division. As it is, though his statement is a fact, it benefits no one; we learn nothing from it; not even from the Editor's foot-note:—"Hear, hear! It is evidently ridiculous to lay down any hard and fast rule." Our own words to a tick. We notice a difference between the quantities when divided in Mr. Holt's invoice. 1,500 lb., he says, were assorted into five grades, and 1,000 lb. were blended. The 1,500 lb. fetched 1s 5½d, and the unassorted 1s 1d. We fear Mr. Holt's experience of blending Teas is of little use to him if he cannot do better than that. If he were to try to write a Doctor's prescription containing six ingredients he might achieve even more startling results not of course so easily expressed in pence. And here, in justice to ourselves, we may repeat what we said at the time we were writing fully on this interesting subject. "Besides we do not advocate treating the entire crop of Ceylon in this way. It is quite open to the expert to decide how much of this Broken Pekoe he will ship as it is, and how much return to the bulk to assist in giving tip and appearance to the remainder of the parcel. *It would be obviously absurd to lay down any hard and fast rule about it.* Experience and judgment must guide the planter, after all said and done, as to how he is to get the best return in money, and we trust we have indicated one direction in which he may look for a reward for thought and skill. There is no reason to be disheartened and discouraged if first efforts do not bring out a much higher result. The secret of the success of blending is that the finer Teas, owing to their greater strength and flavour over-master a much larger quantity of somewhat inferior Teas, and raise the quantity of the bulk, but the exact limits to which to go without making the fine Tea resemble the proverbial needle in a bottle of hay, can only be arrrived at by experiment and practice." The thanks of all his readers are due to the editor of the "Overland Times" of Ceylon for his able and exhaustive leading article on the subject. He at any rate discerns our desire to further the interest of the Ceylon planter. Supposing we were absolutely wrong in our views, is it not much better that the matter should be thoroughly ventilated and all the arguments *pro* and *con* discussed freely so that the best course for all parties may be arrived at? But we are no theorists on the matter of Tea blending. Ours is practical experience extending over many years, and leading us to certain conclusions, but it was a long time before we could dictate a blend of seven or eight Teas, as we do to dealers every day, to get the best result with least money. The "Overland Times" says we appear to hold very strong views on the subject. We do, and we are glad to say we have succeeded in impressing them upon some others. Messrs. Wilson & Co., in theirs of 23rd November, sum up "in short, Gardens producing medium Teas such as Broken Pekoes selling at 1s 1d to 1s 2d per lb. Pekoe Souchong 9½d to 10½d, Broken Tea 8d should bulk unassorted, and Gardens producing fine Teas should not." To what advantage? What is the average of 1s 1d, 1s. 9½d, and 8d? Where does the improvement of the bulk come in? Do Messrs. Wilson & Co., or does any one suppose that by mixing Teas from 8d to 1s 1d, they will get an average of., 1s 2½?—*Rucker & Bencraft*, London, Dec. 17.

THE LANKA PLANTATIONS CO., LIMITED: COFFEE, CACOA, CINCHONA, TEA.

DIRECTORS.—R. P. Harding, Esq., *Chairman*, Geo. Allen, Esq., James Thomas White, Esq., Sir Herbert Bruce Sandford, Horace George Hayes, Esq. Resident-Manager:—Mr. Edward Gonne Harding. Agents in Colombo:—Messrs. J. M. Robertson & Co. Secretary:—Mr. William Bois.

Authorised capital, £200,000 in 15,000 ordinary shares of £10 each and 5,000 reference shares of £10 each.

REPORT

To be presented at the Sixth Ordinary General Meeting of the Lanka Plantations Company, Limited, to be held at the offices of the Company, on the 30th December, 1886, at 12 o'clock at noon.

1. The Directors submit their Report for the twelve months ending 30th June last, together with the Balance Sheet and Accounts of the Company made up to that date

2. The weather has again seriously affected the coffee crop in all parts of Ceylon, the outturn for the year in that Island being about one-fourth of what it was a few years since. The The Company has suffered with the rest. The cause is to be found in deficiency of sun heat, superabundance of rain, leaf disease and new insect pests. Extraordinary climatic effects have occurred in most parts of the world, and until they cease and normal weather returns giving well ripened wood and good ripening seasons, Coffee crops will continue to be short, and although short crops result in better prices, such prices do not compensate for short crops.

3. The quantity of Coffee (estimated at 2,516 cwt. shipped home was 2,416 cwt. against a crop of 5,499 cwt. last year, and the amount realised from Coffee gives a total of £7,762 13s. The price of the Company's Coffee during the past year has been better than in 1884-85, having averaged 66s 8d per cwt. against 60s per cwt. last year.

4. The Cinchona Bark harvested has been about 165,580 lb. (of which 30,402 lb. were sold in Ceylon: the greater part has been realised and the whole is expected to produce £4,922 14s 5d.

5. In consequence of injury to the shade trees and the consequent prevalence of insect pests the Cocoa which was estimated at 500 cwt. has only produced 165 cwt., realising £528 15s 6d, but additional shade trees have been planted and the general appearance of the Cocoa has greatly improved, and there is every prospect of a good crop for the current year.

6. The plantations of Cardamoms have not produced the estimated quantity, only 893 lb. having been received which realised £50 3s. The prospect, however, is more promising for the present year.

7. The first plantings of Tea of Fordyce Estate have fully answered expectations; the estimate for the year was 15,000 lb., but the shipments received amount to 34,519 lb. realising £1,770 5s 6d and showing a net average of 1s 0¼d per lb.

8. The Tea Factory at Gonagalla having been found unequal to the proper manipulation of the largely increased pickings of Tea leaf, a Jackson's Excelsior Tea Roller has been purchased and shipped for Ceylon. This will anable the Manager to prepare and send forward the greatly increased quantity of Tea which the Estates are expected to produce. The estimate for the current year is 120,000 lb. As the Tea trees on the Company's 450 acres of Tea at Fordyce and Gonagalla come into full bearing, they will supply sufficient leaf for the Gonagalla Factory and consequently our Colombo Agents concur with the General Manager in recommending the erection of a Tea Factory at Fruit Hill Estate, which is close to the Railway and conveniently placed for the purchase of leaf in the event of the 237 acres of Tea there, not furnishing enough to keep it fully employed. The estimated cost of this factory is about £1,250 and there is ample water power at Fruit Hill for working the factory.

9. Your Directors have pleasure in stating that of the proposed issue of 2,000 six per cent £10 Preference Shares (part of the authorised Capital of 5,000 Preference Shares) of which 1,100 had been allotted at the date of their last Report 230 shares in addition have been since applied for and allotted, leaving 670 shares still available for applicants.

10. The dividends on the Preference Shares issued prior to the 30th June last, have been duly paid out of the profits shown by the Accounts.

11. No addition has been made to the Company's estates during the year under review, and the present state of cultivation is sufficiently shown in the Tabular Statement contained in paragraph 19 of the Report for the year 1884-5.

12. Your Directors regret very much that they are not in a position to pay any dividend on the Ordinary Shares. Since of the formation the Company its management has been a constant source of anxiety and responsibility, but although the Directors have been well nigh beaten by bad seasons, low prices, leaf disease and other causes over which they have had no control, they still consider that, with better seasons, the Company will before very long be in a better position than it has been for some time past. The Directors have now four products to rely on, coffee, tea, cinchona and cardamoms and they rely on each of them, coffee and tea as their support, Chinchona and Cardamoms as helps. Ceylon Coffee will shortly be if it is not now a luxury, and many parcels have been lately sold at over 100 shillings a cwt., whilst Ceylon Tea is making a most remarkable progress in the estimation of the Tea drinking public. Although costing more, Ceylon Tea goes much further than most other Teas, and in the opinion of these most competent to judge there will always be a maket for it so long as it is carefully prepared. On these points the following Extract from the *Ceylon Observer* of the 9th November last may be interesting:—

"We think our home friends may rest assured that Ceylon can compete with any other country in supplying superior Teas at moderate prices, and as the English taste gets educated to the fine Indian and Ceylon Teas, clearly the bulk of inferior 'China' kinds will not pay to export. A certain proportion of fine China Teas will always find a good market in England, but we certainly expect to see inferior Teas superseded. Ceylon Agents are everywhere pushing our Teas in new markets. As regards planting and crops, the work of supplying and even planting out Tea has been carried on vigorously upcountry. Big crops of Coffee are being gathered in Haputale and some other parts of Uva. There is great activity still about Cinchona bark, but later on a slackening here, simultaneous with a large increase in the export of Tea, is anticipated."

If the cultivation of Cinchona does slacken it will be good for the Company, as great attention is being given by the General Manager to the proper cultivation of this product. The Directors acknowledge with pleasure the zeal of their General Manager and of their Colombo Agents. Mr. Henry Bois, the senior member of their Agents' Firm has lately visited the Company's Estates, and has written a very interesting Repors thereon. The Report was not intended for publication, but as it will put the Shareholders in full possession of our Agents' views, the Directors have determined to publish it as an Appendix to this Report. The Shareholders may rely on the Directors continuing to exercise the utmost care in the management of the property. The very large share they hold in the capital of the Company, to say nothing of that held by their personal friends, is a sufficient guarantee that they will do all they can for its benefit. The two Directors who on this occasion retire are Mr. George Allen and Mr. James Thomas White, and they both being eligible offer themselves for re-election,

Mr. John Smith (a shareholder) the Auditor, also retires and offers himself for re-election

By order, WILLIAM BOIS, Secretary

No. 8, Old Jewry, E.C., 16th Dec. 1886.

APPENDIX.

REPORT ON ESTATES BY MR. HENRY BOIS.

Colombo, Ceylon, 7th Oct. 1886.

The Secretary, Lanka Plantations Company, Limited, London.

Dear Sir,—Between the 7th and 18th ultimo, I visited nearly all the Company's Estates, that is to say, Fruit Hill, Gonagalla group, Rillamalle, Rappahannock, Ampittiakande, Arnhall and Thotugalla. Mr. Harding, who accompanied me, has sent you Reports upon some of the Properties.

Speaking generally I found all the Estates in a good state of cultivation, quite as good as we could expect for the money spent upon them. I doubt if any further material economies can be effected or if any changes could be profitably made anywhere in the superintendence or management of the Properties. The Tea is growing well nearly everywhere and the Coffee did not appear to me to have gone back since my last visit. Gonagalla has a very fair crop upon it and the Autumn crops in Haputale are also fairly good. Spring crops will, however, certainly be short. The season has been most unfavourable, constant rain when sun was wanted. At the date of my visit the weather was fine but rain has since fallen I believe, and in any case it is now too late to expect anything more than very small Spring crops from the Haputale and Uva Properties.

As regards Fruit Hill the tea is growing satisfactorily but not so vigorously as on some places that I have seen. The estate is, however, so conveniently situated that it can be worked cheaply and the leaf can be sold to great advantage, owing to the proximity of the estate to the railway station, should it be found impracticable to manufacture it all at Gonagalla as at present. *I do not think it will be advisable to put up a factory on this property*, at all events not for some time. I see no reason to doubt the estimate of 20,000 lb. of tea and 300 bushels coffee for 1886-7. A few acres of coffee manured with refuse from the bazaars has put on a very large crop. I do not suppose,

however, that this would be repeated a second season or that it can be taken as an indication of what coffee would do if heavily manured.

GONAGALLA (Group)—Owing to constant rain the ground had a soddened appearance and the coffee looked as if it wanted some sunshine. Assuming that the bearing acreage of coffee is correctly estimated I do not think the estimated crop more than is on the trees. *The tea is coming on satisfactorily and further provision will have to be made formanufacture*, the present Rolling Machinery being inadequate. I believe Mr. Harding wrote to you about sending out an Excelsior Roller, Mr. Murray Robertson has just purchased one for us direct from the manufacturers and you will no doubt be able to do the same, thereby saving the extra sums charged by Mr. Jackson's Colombo Agents.

From Gonagalla I proceeded to RILLAMALLE and I wish I could write more favourably than I can of this Property. It is, in my opinion, the most unpromising of the Company's Estates. The Coffee which was so fine when it was young is now yellow and unhealthy, the wood wiry, and the general appearance indicating but little prospect of crop. Mr. Harding and Mr. Owen both insist that this is the result of long continued wet weather and that with normal seasons the trees will recover and crop well. This may be so to some extent but it is also true that leaf disease, green and black bug, and, Mr. Owen says, also grub are at work upon the Coffee, and it is probably the combination of all these adverse circumstances that is answerable for the unsatisfactory appearance of the Property. So far there had been little or no blossom and it is certain that the crop will be very small, how small cannot be determined just at the moment, for Mr. Owen was still hoping that fine weather would force out a blossom. There being sufficient Tea Plants in the nursery for the purpose the 70 acres planted with Tea are to be increased *to 100 this year. I should stop at that for the present* to see how it does. On the neighbouring Estate the Tea planted some years ago shows a very fair growth and Rillamalle will probably do the same. There is, however, *much against Tea cultivation at this spot.* The transport is very difficult, everything having to be carried 10 miles, part of the way over a very rough mountain road to Padiapelella on the high road to Kandy. It (Padiapelella) is possible that something may be done by Government to provide the district with a proper outlet, in which case Tea cultivation will be less handicapped, but there is no immediate prospect of any such work being undertaken.

I should like to see Rillamalle again some months hence—in the meantime I do not see that anything else can be done than what is proposed by Mr. Harding—the trees certainly want pruning. This means expenditure; but the coffee has hardly a chance to do much with a lot of very bad wood upon the trees.

RAPPAHANNOCK is another unsatisfactory property. It has, in common with nearly all Uva estates, missed its blossom for spring, and crop will certainly be very short. There is a large quantity of healthy cinchona on the estate, and a corresponding large harvest of bark can be secured; but unfortunately prices are so low that large shipments of bark do not mean very much money. I think that about 150 acres in the centre of the estate should be kept and cultivated as coffee, manure being applied whenever a set blossom promises a fair crop. All the cinchona should be cut out or uprooted in these fields, for it is a fact beyond all question that *cinchona and coffee will not grow together after the former is some years old.* The coffee almost invariably deteriorates, and ceases to be productive. I agree with Mr. Harding that the 57 acres at the bottom of the estate should be put into tea.

The fine coffee on AMPITTIAKANDE looks, I think, as well as ever it did, and it has the best crop on it that I saw anywhere. The acreage of the fine coffee however, is smaller than it used to be, and there is not sufficient area to admit of the place giving very large crops. I was agreeably surprised to see how well the tea was growing on this estate, and I see no reason why it should not be a success. Transport difficulties are no doubt against it, but they are not really serious as is the case with Rillamalle. I think when tea is manufactured in any quantity the factory for both Ampittiakande and Arnhall should be at the latter place.

ARNHALL has a very fair autumn crop upon it. The coffee did not strike me as having gone back since I last saw it, and there is no doubt the rain has been favourable to these low-lying places. The quality of the coffee should be much better than it is when picked in a dry season.

THOTULAGALLA *is about the finest sheet of coffee in the company's possession*, and with fine weather I believe it would have given a very satisfactory crop this season. 4,000 bus. (parcht) are supposed to be on the trees; how much more will be yielded cannot yet be quite estimated. For the expenditure incurred, I think the condition of this estate creditable to Mr. W. Harding. Pruning is, perhaps a little behindhand but it is not possible to do the work very quickly on such large trees with the limited labour force kept upon the property. Mr. W. Harding's health seems to call for a change to England for a time. I think during his absence the necessary work of the estate might be carried on by Mr. Bouton, he drawing his own pay and half Mr. Harding's. The latter getting leave on half pay.

The *green* bug to which Mr. E. G. Harding refers is, in my opinion, not the old variety of cocus that we have known in former years. Its attacks appear to be of a more persistent character, and there is no doubt that in many instances serious results have followed upon its attacks. I saw it more or less everywhere on my travels, and I am not disposed to minimise its importance. I am in hopes that fine vigorous coffee will not be permanently affected by it, but, on the other hand I am bound to say that I have seen really fine trees almost killed by it. Thatching the trees with Mana grass and applying lime perhaps do a little good, but in olden days we found that there was no real cure for it until nature caused its disappearance.

The railway to Haputale is still an unsettled question. It is hoped that the Governor's strong recommendation of the work will induce the Colonial Office authorities to agree to the commencement of the extension. Personally, I have no faith in a 2-feet gauge line to Uva.—I am, dear sirs, yours faithfully, HENRY BOIS.

PLANTING IN NETHERLANDS INDIA AND JAVA.

(*Translated for the Straits Times.*)

The *Java Bode* asserts that in consequence of the Supreme Government refusing to do anything permanent and thoroughgoing, to relieve the planting interests in Java from the disproportionate burden of taxation weighing it down, the eyes of many enterprising individuals there are directed towards British North Borneo where sounder economic priciples are put in practice. So far as fertility goes, British North Borneo is not one whit superior to many of the latter, such as Celebes and Sumatra, and is in nowise better off as to population, so that only fiscal conditions count in its favour. These differ so widely from those predominant in Netherlands India, as not to admit of comparison. Already a Netherlander, Mr. Geloes d'Elsloo has applied for 30,000 acres of land within the territory of the British North Borneo Company At Batavia a syndicate has been started for the purpose of turning that acreage to account on adequate capital, which was being raised by last advices. No wonder that British North Borneo is coming into favour among the planting community in Java, considering the drift and scope of the Government relief measures for their behoof in these hard times. After beating long about the bush, the Second Chamber of the States General has finally decided to abolish provisionally only the tax on the free cultivation of sugar, and to grant a delay of five years for half payments to the Government by sugar growers working under contract with the latter, and to abolish the export duty for five years. However welcome this instalment of justice has proved to the planters, they regret that the Supreme Government cannot break away from half measures, and make up its mind to do away altogether with a form of taxation quite unsuitable to changed circumstances, and free, once for all, European planting industry there from crippling burdens.

COFFEE REDIVIVUS IN CEYLON.

It is very satisfactory to hear anyone with long planting experience say a good word for the coffee tree on Ceylon plantations nowadays. But we have had such a good word spoken by a gentleman with practical experience in several districts. He instances Koslanda estate, Haputale, run down some two years ago and now very flourishing with a big crop. Although our informant's interest in coffee is now limited, he does not believe that "green bug" cannot be successfully driven away. It has disappeared from several places where once it was bad. Yoxford, Dimbula, is giving 5,000 bushels of crop, and it was thought to be far gone; another mid-Dimbula property, is giving 3,000 bushels; still another 4,000 bushels; and farther west, where a Superintendent was ordered to take out the coffee, and refused "the Colombo orders," because he expected a thousand bushels, he is gathering 1,200;—all found money! One of the best known planters in the country—with Uva, Deltotta and now Dimbula experience—calling on us today, expressed confidence in being able to do something with coffee yet in Ceylon. We suspect all over the country now, that every coffee bush with a green leaf will have the utmost care taken of it, and all manner of help given to the tree in fighting against bug or any other enemy. We trust, therefore, that, where still to the fore, our old friend, coffee,—especially in the Uva and Udapussellawa divisions—may have a long career yet of crop-bearing to the benefit of the planters, the labourers and the Colony at-large.

In this connection we may attract attention to the information on our back page in reference to the Lanka Company's plantations, and we may add that no greater treat met our eyes during a recent visit to some of the north Kandy districts than the sight of some 300 acres of vigorous young (three years old) coffee in blossom on Pallekella, Doombara. Long may it flourish and bear the bean which is likely to become more precious, than ever before in its history for the past forty or fifty years.

CINCHONA IN JAVA AND CEYLON.—We had an interesting visit today from Mr. Dinger of Batavia, the very intelligent proprietor of extensive cultivation in Java and a gentleman thoroughly interested in social and political as well as planting progress. He has presented us with a copy of the pamphlet written by Mr. Mundt ("Ceylon and Java") mainly made up from our "Handbook and Directory" (but without acknowledgment!) in which Ceylon is held up as a model to the Dutch Government in respect of its planting enterprise. Mr. Dinger has one cinchona plantation in East Java of about 350 acres with trees 6 by 6 feet or 2,000 to the acre from 7 years old downwards. He has experimented in harvesting by all plans, shaving, coppicing, uprooting, having no difficulty in getting fresh trees to grow over old ground. Mr. Dinger is evidently of opinion that a large—very large deduction—should be made from Mr. Mundt's calculation as to the area planted with cinchona altogether in Java, although he agrees that the export thence is bound largely to increase. We have told him that present appearances point to Ceylon sending as much bark as last season. Mr. Dinger being interested in laws and legislation, is to send us a complete copy of the Java-Dutch Code, more especially with reference to the admirable Law of Mortgages prevailing in Java. We shall have the same looked into, on receipt.

PETROLEUM AS A FUEL is thus noticed in the Home Letter of the *Indian Engineer*:—The other day, a number of gentlemen visited the works of Messrs. Priestman Brothers, Holderness Foundry, Hull, to attend the trial of a patent engine, the motive power of which is obtained from the use of common petroleum. These engines are made under Messrs. Eteve and Hume's patents, and are extremely simple in their internal arrangements. The petroleum is stored in a small tank containing one to two days' supply, as the case may be. A small pressure of air is put into this tank, and the petroleum is forced out of it into a vessel in a vaporized condition, in which it is then drawn into the cylinder by the outstroke of the piston, and having been compressed on the instroke the charge is ignited by means of a small electric spark. This immediately explodes the contents in the cylinder, and the piston is driven forward. The engine, in which the highly refined petroleum is used, is very similar to that in which the common petroleum is employed, the only difference being that in the latter engine the oil is taken into the cylinder in a heated condition. The cost of the oil is estimated at a half-penny to three farthings per indicated horse power per hour. Four horizontal engines were at work, two with benzoline and two with common petroleum. One of about three and-a-half indicated horse-power, supplied with benzoline, was driving easily four blasts at which chain-makers were at work, besides a a punching and a shearing machine. A vertical engine of about four-horse power was driving a namcar and doing work with ease. The tests were considered most satisfactory.

COCA LEAVES show no improvement whatever. Four bales, mostly sea-damaged, *huanoco* leaves sold at 8d. to 8½d. per lb. From Hamburg the article is reported decidedly firmer, the stock at that port having within the last fornight been diminished by 15,000 kilos. partly for German and partly for American consumption.—*Chemist and Druggist.*

CINCHONA BARK.—A correspondent writes:—Some fifteen years ago experiments were made to grow cinchona at Singapore, but the young plants would not flourish, and the attempt was abandoned. In some of the protected States, for instance Perak, cinchona is grown, but whether it will become a profitable product is doubtful. Some of the planters who have ground from the Sultan of Johore have also planted cinchona. Of these places, Perak, which is a protected State in the Malay Peninsula, is as yet the only one which can have trees fit for barking. The Hon. Sir Hugh Low has done much in promoting cinchona cultivation in Perak.—*Chemist and Druggist.*

BOTANICAL EXPLORATIONS IN COSTA RICA.—The district of Chirigui in Costa Rica, whence the bulk of the so-called Jamaica sarsaparilla comes, was lately explored by an English botanist, who gives an interesting account of his journey in *The Gardeners' Chronicle*. Among other things he mentions finding an anonaceous plant, probably a Hylepia exhaling a perfume very like that of *Cananga odorata* (ylang-ylang), and a tree known as the "samba gum tree," which yields on incision a creamy-looking yellowish sap, which after a time becomes hard and resinous and then resembles the tenacious hog gum of Jamaica, the produce of *Symphonia globulifera*. He also met with a thin-coated coconut one-third larger than the ordinary kind, and which he thinks deserving of cultivation. The natives ornament their cheeks with paint made among other things from an oleoresin resembling elemi, yielded by a tree called "pontapée." This paint is prepared by burning the oleoresin and collecting the lamp-black, a purpose for which it is doubtless well adapted.—*Chemist and Druggist.*

THE LINNEAN SOCIETY, DEC. 2ND.—CEYLON PLANTS.—As a chapter in the history of East Indian botany, Dr. Henry Trimen gave a paper at the Linnean Society meeting, on the above date, "Hermann's Ceylon Herbarium and Linnæus' *Flora Zeylanica*." The collection of dried plants and the drawings of living ones made in Ceylon by Paul Hermann in the later half of the seventeenth century possess a special interest as being the first important instalment of material towards a knowledge of the botany of the East Indies; but Hermann himself, who died in 1695 published very little of this material. Some of his MSS. were subsequently printed by W. Sherard including a catalogue of the herbarium as then existing, under the title of *Museum Zeylanicum* (1717). This herbarium was lost sight of till 1744 when it was recognised by Linnæus in a collection sent to him from Copenhagen. After two years work at it, Linnæus produced in 1747 his *Flora Zeylanica*, in which all the plants that he could determine are arranged under his genera. At that date Linnæus had not initiated his binomial system of nomenclature, but in his subsequent systematic works he quoted the members of the *Flora Zeylanica* and thus Hermann's specimens became the types of a number of Linnæus' species, for the most part additional to those in his own herbarium now in the possession of the Linnean Society. Hermann's herbarium is now in the botanical department of the British Museum, having been purchased by Sir Joseph Banks from Prof. Treschow, of Copenhagen the specimens are in very fine preservation, but some were originally scanty or imperfect. The paper consists of the results of a critical examination of the whole of the collection, and a catalogue is given of all the *Flora Zeylanica* species as named by Linnæus, along with the determinations of Hermann's species of each as now identified. Not a few difficulties, ambiguities, and misapprehensions of Linnæus' species have been thus recovered and cleared up, and the most important of these are discussed in a series of short, critical notes which form the conclusion of the paper.—*Gardeners' Chronicle.*

THEINE AND CAFFEINE NOT IDENTICAL.

Recent experiments by Dr. Thomas J. Mays, *Therapeutic Gazette*, and summarized in the *Druggists Circular*, demonstrated that the theine of tea, and the caffeine of coffee, were not identical, at least, so far as their physiological action is concerned. Discovering that the theine and caffeine of commerce are made " indiscriminately from tea, coffee, kolanut or paraguay tea," he took special pains to secure alkaloids beyond suspicion and from two different makers of high repute. The results of the use on frogs of theine and caffeine from sources indicated by their names are summed up as follows:—They agree in (1) affecting the anterior extremities; (2) in diminishing respiration; (3) in producing hyperæsthesia during the latter stage of the poisoning process. They differ in the following particulars:—(1), Theine principally influences sensation, while caffeine does not; (2), Theine produces spontaneous spasms and convulsions, while caffeine does not; (3), Theine imparts the nasal reflex early in the poisoning process, while caffeine does not, if at all, until the very last stage; (4), The lethal dose of theine is larger than that of caffeine. Enough evidence has now been adduced to show that theine and caffeine, while they have properties in common, also differ so widely in others that their separate manufacture becomes imperative in order that they may be more fully investigated both physiologically and clinically; and it further teaches that a knowledge of the chemical constitution of a substance is a very feeble and misleading guide to its physiological action —*American Grocer*.

COFFEE PREPARATION: DRYING AND CUR IN INDIA AND CEYLON.

(To the Editor of the "*Tropical Agriculturist*.")

MYSORE, Dec. 22nd, 1886.†

DEAR SIR,—Last year there was considerable attention paid by planters to the alleged deterioration of coffee sample. All sorts of theories were promulgated and a good deal of light was shed on the question. My own idea from experience in Ceylon and India is, that if the Ceylon method of rapid drying and despatch were adopted and closer attention paid by the Coast curers, the trouble would cease. Open sheds close to the barbacue, and a liberal supply of coir-matting will asist greatly to improve the sample. From what I have been able to learn, the Indian men dry their coffee very slowly. The coffee is kept in the sun for 10 or 15 days when by spreading more thinly and using coir-matting five days are ample. I have already this season proved this. When I first came here, I was puzzled at the universal system of raised platforms. I was told that you must do so here as coffee would not dry otherwise. I have proved that it dries on coir-mattiug in less than half the time required for the raised platforms. Men also speak of the cold wind interfering with proper fermentation, as an excuse for badly washed coffee. Old planters have told me that it is so cold at night, that the coffee mucilage will not come off in the orthodox time (36 hours). I have proved that that is all fudge. The coffee washes beautifully when the coolies are made to tramp it thoroughly. All sorts of theories are put forward. They say that too ripe coffee makes it foxy; under-ripe coffee makes the colour pale, &c., &c. Evenly picked coffee quickly dried on coir-matting after being well washed and promptly despatched, ought to turn out a good sample if the curers do their duty.

I cannot help thinking that many practices in vogue in Ceylon have been adopted in India without duly considering whether these plans are absolutely necessary under different conditions. My idea is that *pulping*, and *washing* coffee was found useful in rainy weather upcountry in Ceylon because of the absence of sufficient sunshine. In doubtful weather, *parchment* is more easily dealt with than cherry. But in the normal dry season here, why should not planters dry their cherry on coir mats? Then again mills were erected and worked in Colombo because upcountry (1) there was not flat ground available for large barbecues, (2) there was not a sufficiency of cheap labour, (3) there was no certainty of sunny weather,* and (4) Colombo was the seat of estate financial arrangement and control through the agency firms. But here, curing works could surely be worked if they are worked in Bangalore. Planters (especially proprietors) would like to see what is going on at the mills; but on the Coast everything is done in deep mystery. With cloudless weather, flat country and cheap labour, there is no reason why curing works should not be started nearer the planting districts especially, as we expect a railway soon. If we could dry our cherry on mats and send our coffee to the mills near by, to be peeled and despatched, I feel sure much expense would be saved, and curers would not be left in undisturbed quietness and profit-making. The west coast surely is more humid than towards the east. I myself cannot see the gain in sending the coffee so far out of our sight. Were the curing works brought nearer to us, then a local market would arise and brokers would be attracted; and these again would attract capitalists to invest in coffee property. Dried green coffee or strippings are universally *pounded* on the estate as pounding is so cheap. But how injurious is this pounding! A large percentage is broken by this crude and cruel method.

There is an idea here that, if you spread the parchment thinly the parchment cover will break. Fudge again. Surely it is injurious to allow the coffee to blister in the sun in very thick layers, for say, 14 days; whereas by a quicker method you have your heaps sweet and cool (if properly turned and in open ventilated sheds) with only five days' exposure to sun.

Heaping coffee in the sun or in close rooms without windows is very apt to taint the coffee.

If we could be sure that these curers gave their strict attention to the care of the coffee entrusted to their charge (for which they exact heavy costs) then things would be more satisfactory. But how much of this work is left to subordinates? There is no sample sent down by post as in Ceylon; and men use new bags *turned inside out* to keep the bag clean for home despatch and send the coffee off with the *sewing outside*. Then each bag is carefully *sealed!* What is the good of locking the door of a room with the window left open? Surely it would pay to keep a stock of bags for country use, and send the coffee home in bran new bags. Still better would it be if casks (as in Ceylon) charred in the inside were always used.

A Ceylon planter when visiting his neighbour during crop looked at the *sample of parchment* and commented thereon. Here youngsters of a few years' experience discant learnedly on the proper weight to dry down to. They rub up a handful of parchment and examine the colour with a knowing look when really a planter who has proper appliances should not look inside at all, but be satisfied with colour of his parchment. Some day I must visit the curing works at the Coast, and I will send you the result of "a chiel's" notes.

ABERDONENSIS.

THE COFFEE INDUSTRY,

We have all heard the old saying about giving a dog a bad name, and the consequences that would be likely to ensue. The name may be given without any reason, and the application is very general. For instance, several industries in India have had a bad name given to them, and people are told to keep clear of them. The industries may be sound, and such as would pay, and pay well, in any other country; but here we are told they are unprofitable. The fault in most cases lies in the way they are

* The principal reason: drying and packing complete were tried in Dumbara and Hantane, but even there was not considered an economical success.—ED.

taken in hand, and not in the undertakings themselves The latter may be everything that may be desired; the former may be all wrong. We have been told, over and over again, that gold mining in India will not pay; that there is gold, but that the cost of working will more than eat up the money obtained from the sale of the precious metal, and that only millionaires who can afford to lose money should engage in the industry. Those who express this view of the case think only of the reckless manner that companies went to work some years ago. Fine houses were built for the Superintendents, costly machinery was brought out, and everything was conducted on a most extravagant scale. The result might have been seen from the beginning—the ruin of many of the shareholders, and the collapse of the whole undertaking. If gold could be dug up in the same way as potatoes, it might be made to cost more than it could be sold for. But, when economically worked, there is no reason why the gold industry should not pay. The shareholders have learnt a lesson from previous failures, and they are doing now what they ought to have done before—working the mines in a sensible manner. Gold has not yet had a fair trial in this country, and it cannot be declared a failure till it has. In the next place, we have the coffee industry, and we are often told that it has gone to the dogs, wherever the abode of those animals may be. We are, however, of a different opinion, and believe that the industry, if properly taken in hand, will pay and pay well. The price of the berry is going up. and, in a short time, it may touch a hundred rupees. We will not undertake to say that the large fortunes; that were made in former years can be made now but we hold—and with reason—that a fair amount can be obtained from the cultivation of the coffee-plant. If we ask the reason why so many have failed who went into the industry, we shall be told that leaf-disease, the borer, low prices, &c., have been the cause of the mischief, and we are willing to make all allowance for them. But we must not stop here. There are other causes, and we will give them. In the first place, men often engage in the industry who cannot tell a coffee tree from a rose bush, they and their friends are of opinion that no special knowledge is required; that a man has only to take up a piece of land, plant the trees, and enjoy the proceeds of the undertaking. Sir M. E. Grant Duff in his "Review Minute" gives an instance of the way young men "go into" coffee, and we have heard of many cases like it. It is hardly the correct thing to lay the blame on coffee when the fault lies in altogether another direction. Then, again, men commence coffee-planting without capital, or with very little, and the interest on the capital eats up the whole profit. Sooner or latter such men come to grief, and the blame is laid on the industry—very erroneously, it must be said. Capital is required in this industry as well as in others; it is also required that it should be judiciously employed, and if these two necessary conditions are neglected, it is unreasonable to expect that coffee-planting should pay. No other industry would pay under the circumstances, and yet people wonder that planters—or rather so-called planters—fail. But we have not yet come to the end of the list of the evils that are adverse to coffee. Some of the planters are absentees. As soon as they have raised a good crop they take a trip to England, and there spend the money that they ought to have laid out on their estates. They have to leave their estates in the charge of others, and when they return they find them much in the same state as Solomon described the garden of the sluggard—the weeds higher than the trees, and the whole having a most dilapidated, out-at-elbow appearance. It is well known by all engaged in coffee that an estate requires the most attention the year after a good crop has been raised, and the neglect of this has been the ruin of many a planter. Then, again, the owners of estates—or some of them—too often leaves them in charge of overseers, while they enjoy themselves at the nearest large station. We have heard it said that the Ootacamund Club ahs had more to do with getting coffee in the Nilgiris a bad name than the leaf-disease; and though there is exaggeration in this, it is not without truth. The estates are left during the absence of the owners in the charge of those who, too often, neglect them. When the master is away enjoying himself, the servant see, no reason why he should not follow suit, and this he does to the detriment of the property. Till these mistakes have been remedied, it is wrong to talk so much about the failure of coffee. The old planters lived in a very different style from their successors, and they succeeded and did not complain. Their houses were not the palatial edifices that are to be found here, and there in the planting districts, neither did they think it their duty to be always running home. They lived in the plainest style; dressed in the homeliest manner, and the consequence was—they made money. If the planters of the present day were to follow their example their rupees would be more and their complaints less.—*Madras Standard.*

ALOE FIBRE ROPE.—We have been shown a sample of rope made by hand from the fibre of the ordinary aloe. The rope appears to be very strong and close, much more close than rope made from the fibre of the New Zealand flax. If rope of equal quality to that shown us can be turned out in any quantity, there should be another enterprise open to those who wish to see colonial produce utilised.—*Natal Witness.*

RINGING FRUIT TREES.—The effect of ringing fruit trees is a question of the flow and return of the sap. If the branch is ringed below the fruit spur, the result will be that the fruit will attain extraordinary size, and that the ripening will be accelerated. Some of the peach growers at Montreuil, near Paris, have practised ringing for some years; but they do not publish their secrets.—T. FRANCIS RIVERS (Sawbridgworth).—*Field.*

COCONUT OIL.—Veyangoda, 7th January, 1887.—My idea always was that the chief cause of the disparity in price between Ceylon and Cochin Oil was in the colour. I remember reading years ago in the pages of the *Observer*, that some one interested in Oil did enquire personally as to the low price his Oil fetched, and was told that it was owing to its colour. All that could be done in the Colombo Mills with the wretchedly discoloured Copperah they press, is to clarify it. The colour of the Oil they cannot change. The remedy is in the hands of the Mill-owners. If they make a stand against purchasing discoloured Copperah, or pay, as a discouragement to careless manufacture, low prices for it, it will be to the interest of the Natives to bestow more care in drying their Coconuts. The Mill-owners might also press clean and dirty Copperah separately and classify their oil. If better prices were obtainable for clear Copperah, Estate proprietors and lessees of large Estates will devise means to dry their Coconuts, even in wet weather, without contact with fire and smoke. As it is, they sell their crops to regular dealers, who, even in the best weather, resort to fires under lathed platforms to dry the nuts, owing to a belief they have that smoke and fire-dried Copperah is heavier than that dried in the sun, and because the more tardy and expensive process of sun-drying does not give them appreciably better prices. If such a delicate article as Tea is dried by heated air from a furnace, it will not require much inventive skill in Coconut planters, to devise a sheet iron room with a furnace underneath to dry their nuts; but, as I said before, there is no inducement for it. It pays better to sell our nuts on the spot. There is a great deal in your surmise that the Oil from immature nuts may account for paucity of stearine. It is notorious that small landholders do not wait till their nuts are mature to pick them. One reason is that if they do, thieves will be before them. I wonder whether, if Sir Arthur Gordon receives as many petitions from owners of Coconut land as he said he received from owners of Arecanut plantations, to protect their produce, he will next year insert Coconuts amongst the other products, in the clause, to possess which is an offence!—Local "Examiner."

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, December 16th, 1886.)

NEW PRODUCTS IN OLD CEYLON DISTRICTS:

Cacao—Coffee—Croton-Oil—Tobacco.

"Better late than never," and now that the accumulation of arrears created by holiday-making in a busy office is in a fair way to be cleared off, we may give the continuation of our story of a very brief visit to some of the old Kandy districts and what we saw of new products. The Pangwella or Watagama district is a comparatively modern planting division, the nucleus of cultivation being in olden days part of the Hunasgiriya district. Mr. Holloway may fairly claim credit as the pioneer of a group of new plantations and of new products in this direction, and, though like all other experiments here and in other parts of the country, there have been ups and downs, still enough remains with a substantial show of prosperity, to warrant a good degree of pioneering pride. We have but a look at some of the plantations in passing, seeing a little more however of "Maria," and there the appearance and the crop on the cacao fields amply justify congratulations to Mr. Rowland Boustead. Cacao everywhere in the district is doing well this season, and we are sanguine that proprietors of "cacao walks" or gardens in sheltered situations and on good average soil, and where the trees are from seven years old and upwards, have now got over their difficulties and may henceforth feel that they have plantation property as free from risk almost as coconuts. In Dutch Guiana an old cacao planter has written that no cultivation has been more troublesome, variable or uncertain than cacao up to the tenth year; but, after that, there need be nothing to do but to gather the crops, and provide such cultivation as can be afforded, for a hundred years! Lucky proprietors of cacao walks in Guiana, and, we believe we may add, in "Ceylon."

But before leaving Pangwella district, we may refer to one or two other articles of experimental cultivation, such as rubber, with which much has not yet been done; and the croton-oil seed plant regarding which there was the extraordinary development of caterpillars by millions some months ago—these leaving every tree leafless. This enemy has now again completely disappeared and the trees are green and flourishing as ever; but in answer to our enquiry as to information respecting the cultivation of the shrub, a Haputale planter who, we imagine, was the first to give this "new product" a start, writes discouragingly as follows:—

In reply to yours *re* croton-oil-seed, what good can it possibly do my trying to give instructions in the cultivation of a product already almost overdone? The market is already showing signs of being overstocked and unless other uses are found for the oil, the sooner we begin to root out our croton trees the better. What do you think of this for a fall in price of the product? In October 1884 9 cwt. sold for 82s per cwt. in London. In October last 21 cwt. 2 lb. sold at 33s per cwt., and if you deduct say 23 per cent for discount and charges Colombo to London, say 25s 2d per cwt. nett. Ceylon has evidently quite enough acreage under crotons. In September 1883 my first despatch was:—

	lb.		cwt.	qr.	lb.
	601	equal to	5	1	13
During 1884 despatched	1,971	,,	17	2	11
,, 1885 ,,	10,616	,,	94	3	4
,, 1886 to date	15,630	,,	139	2	6

Pangwella planters will not, therefore, make their fortunes from croton-oil seed trees; but with limited cultivation there may be times still when a crop of seed will find a very remunerative market.

But this is a small matter by the way, compared with the Cacao industry. It was in the Dumbara Valley and on the farfamed, extensive Pallekelle plantation that we had the opportunity of leisurely inspecting a large area under cacao. The Dumbara Valley with its rich soil and easy lay of land was naturally one of the first scenes of European planting in Ceylon. Indeed, long before the British annexed Kandyan territory, Dumbara was celebrated for its royal domains and gardens surrounding royal palaces. The lowest point of the Valley is 1,200 feet above sea-level, and cultivation runs up to 2,000 feet. The soil, alluvial mould largely impregnated with lime has always been regarded as amongst the richest in Ceylon and but for prolonged droughts would be among the most productive. This was, and is, true of coffee cultivation; but fortunately cacao, with its deep feeding roots and more robust habits (at least after attaining full growth) is much better fitted to stand drought than coffee; and there can be little doubt that Dumbara has now found the plantation product best suited to its climate, soil, lay of land and general conditions. Very curious have been the different experiences of shade and no-shade cultivation in Dumbara. At first all the coffee was planted under shade, or rather large trees such as "kekuna" and "jak" were cultivated to afford shade; but at the instance of the then youthful Mr. R. B. Tytler, fresh from the West Indies, at the beginning of the "Forties" all the big trees were rung and taken down and the west Indian system of open clearings was universally adopted. In the case of Cacao, the West Indian system is that of shade, not so much for protection from the sun as from wind and Mr. Tytler rightly began after the example he had seen in Trinidad; but after a time several Dumbara and other planters thought they would do better without shade in the case of cacao as in that of coffee. They very soon found their mistake, not only through the effects of exposure to wind, but through continuous attacks of *Helopeltis*. Very marked has been the change since the renewal and growth of shade trees in removing the bad effects of such enemies; and now Dumbara presents a scene of thoroughly healthy vigorous cultivation. Mr. Vollar has a good deal of coffee still intermixed with his cacao on Pallakelly, and it is found that in such fields the cacao prospers more than under the shade of large trees. But there are all varieties of cultivation, as well as many experiments in preparation, still being tried in Dumbara, where barbacue and store room are not only in full request for large crops of the dark red or brown pods, but also for thousands of bushels of our old staple coffee. For, Mr. Vollar has extensive clearings of young coffee (and cacao) of the most refreshingly vigorous appearance. Planted from Nakanaad (Mysore) seed—said to be fungus proof, although that was not the experience in some others of our districts—in Dumbara so far, there has been no trouble with enemies whether fungus or bug-insect, and the season having been an exceptionally favourable one for blossoms and fruiting, a handsome coffee crop was expected to be gathered—the fields in blossom being "a cure for sore eyes." Of cacao too the gathering was expected to equal 6 cwt. per acre over a large area. Cultivation is still kept up on a handsome scale on Pallekelly and well it may in view of the crops now being harvested. Stall-fed cattle for manure are kept in large numbers, and what with the work of providing a supply of water from a large artificial tank and a host of minor aqueducts, of supplying fuel in

another direction for a steam engine, of cultivation, crop gathering and preparing, this fine old Dumbara plantation we were glad to find, affords profitable employment to a far larger number of hands—both Tamils and Sinhalese—than we had at all anticipated. Blackman's Air Propeller—an American fruit evaporating machine—Mr. Vollar has found very useful in drying his cocoa. Squirrels at one time so damaging to cacao pods in Dumbara have now nearly disappeared. Rats do a little injury and wild pigs occasionally are troublesome; but on the whole with the absence of the dread *helopeltis*, the cacao planter has no enemy worth mentioning.

Nothing can be more pleasant and refreshing than an early morning walk, ride or drive on a Dumbara plantation. Pallakelly is so well roaded and has such variety of cultivation that a new and delightful sense of the reality of a good basis for planting prosperity in modern Ceylon, is speedily borne in upon the interested inspector. Pallekelly ought to be called the "Philadelphia" of Ceylon; for, the plan which William Penn adopted in laying out his Quaker City across the Atlantic of giving the names of trees to his streets—pine, maple, elm, spruce and so on—has been adopted with cheering effect on modern Pallekelly. In this way, we have the Satinwood avenue, this estate road being bordered with a row of flourishing satinwood trees; we have the Sapuwood tree avenue; and the Halmillille, Grevillea and Inga Saman avenues or roads, and no better distinguishing, interesting and let us trust profitable feature could be desired.

Of minor, but still very interesting cultivation, we have on Pallekelly, the most careful piece of Vanilla training we have yet seen in Ceylon and the crops of pods averaging £100 a year in value ought to be remunerative for what is really a bit of Garden culture. With Rubber not much has yet been done, but the wonderful growth of the Ceara trees (apart from their usefulness for shade)—some of them a few years old being 30 feet high, 4½ in circumference—with ready gatherings of more than ½ lb. of rubber per tree experimented on, afford encouragement to look for profit when systematic tapping can be effected. In a slack year with cocoa and coffee crops, attention could well be given to tapping the rubber with surplus labour. Again, 50 acres of comparatively waste ground put under Sapan ought, some years hence, in their supply of dyewood, to go far to make up for short crops when such may be experienced.

More interesting was it to learn of a systematic experiment in the culture of tobacco in the neighbourhood of Pallekelle. Dumbara has long been famous for its tobacco; but hitherto the culture of the plant has, we believe, been confined to natives. In this case, a piece of virgin forest land, 50 acres in extent, was cleared, prepared and planted with the greatest care, and the result in a crop of 20 tons of very fine silky leaf, valued at 2s 3d per lb. is regarded as very satisfactory—the more so as it is felt that the proper time to plant was not chosen. But tobacco is too exhausting a crop to be profitably cultivated continuously, even in Dumbara.

In conclusion we can only mention in one word the charming and almost unequalled mountain, woodland and river scenery enjoyed by the visitor to Dumbara. From an elevation of 1,600 feet (about the level of Kandy) at the Pallekelly bungalow—the same but much improved on good old "R. B. T.'s" almost historical residence—one of the finest panoramic views in Ceylon is obtainable, extending from Yakdessagala above Kurunegala, past the bold Ettapolla and Asgeriya summits, with Hunasgiriyakande and the Knuckles round by Rangalla and the Medamahanuwara Gap to the far south-east of Madulsima, if not of Badulla's Namunukulakanda itself. How the panorama is filled in with hill, dale, river, glistening paddy-field and wide-extending jungle, or shade-covered plantations, with all the wonderful effects of light and shade visible in an upland tropical valley, no words of ours could do justice in describing; and our object in this imperfect notice of a brief visit has not been to write about the scenery, but rather to show how New Products in Old Districts are laying a new and substantial foundation for an approaching and, let us trust, comparatively permanent era of Planting Prosperity in Ceylon.

NOTES FROM UVA:—COFFEE PLANTING.

Haputale, 5th January 1887.—After wishing yourselves and the "Old Rag" long life and prosperity, with the New Year and many happy returns of the season, I must apologise for my long silence and explain that I was engaged on a small job of planting a clearing *with coffee* near a village in the centre of the plains of Uva midway between this and Wilson's Bungalow, and not as from my having lost the nib of my pen, as a friend surmised, or because you sat upon me for my report of the Gamarala's murdering his wife in June last, which case I shall allude to further on under the head of crime in Uva and British justice as administered in our petty Courts by sucking Magistrates. You will see by the above that there are still believers in the old product "King coffee," and while some are planting tea and cinchona, as well as coffee, there are not a few of us who believe in the revival of the coffee enterprise in Uva, and some are turning their attention to a better system of cultivation, of doing more justice to the coffee shrub by pruning, handling and manuring, which necessary works for some years back have been much neglected, owing to the sad visitation of leaf-disease, financial difficulties, grub, bug and other pests, such as Medical Inspector's Registers, &c., but now with better prices for the fragrant bean ruling in the markets of the world, suddenly, believers in the permanence and paying returns of coffee cultivation, especially in Uva, are turning up, while others are deploring that they dug up and destroyed good young coffee fields to make room for tea, cinchona, &c. Others are actually opening their eyes to see that leaf-disease is not nearly so bad as it used to be, and that it does less harm to coffee in Uva year by year; in fact that leaf-disease is wearing itself out, and "a consummation devoutly to be wished;" it will soon be a thing of the past, and perhaps leave us for ever; or like the potato-disease and phyloxera on vines, rust on wheat, we will get so accustomed to it, and as "familiarity breeds contempt" we will take little or no notice of leaf-disease in the future and go on cultivating coffee "with a heart for any fate still achieving, still pursuing, learn to labour and to wait," not at the same time putting all our trust in the one product or like eggs in a basket making a head-long rush at T or D—T as some wag wrote that some planters were afflicted with. Green bug is another thing some young men of my acquaintance have got on the brain, and fancy it flying about with wings all over the estate up their nostrils in their hair and in their boots! I pity these young men, but they will get cured of this mania when they get older and are as familiar as I am with bugs of all kinds, village bugs, black bug, white bug, green bug, feted bug and jiggers of every variety. Green bug is the new mania and "cholera morbus;" that is to snuff out all the remaining coffee bushes in the Island according to some wiseacres, while few persons take any measures to rid the coffee of this pest: they simply close their eyes and wait for the inevitable death and extinction of the coffee tree; these gents however don't sell an old stager like

myself so familiar with black bug in the "Forties and Fifties," for like Paddy I meet them with the query, "Do you see any green in my eye?"

INDIAN TEA COMPANIES AND THEIR DIVIDENDS.

It is seldom that the financial papers have anything to say about tea and tea companies, we, therefore, quote the following from the *Financial News* on the subject:—"This has been an eventful year in the Indian tea trade: it has witnessed the lowest prices ever recorded in Mincing Lane, and has also known some of the very highest. While some favoured companies may retain and even improve on their average returns, the generality will fall behind. These different results are due to the extremely variable qualities of the teas offered. Specimens have been shown which were rarely equalled, but the bulk of the lots were thin and poor. The coming dividends of the Indian Tea Company will reflect the fluctuations which have taken place in Mincing Lane. Some of them will be unexpectedly good, while others are bound to be disappointing. Shareholders will await with anxiety the announcements which now begin to fall due and which will go on for five or six months to come. Several interim declarations have already been made. The Assam Company, which is understood to have been very fortunate with its sales, announced the other day a dividend of £1 per share, or at the rate of ten per cent for the half-year. Interim reports have also been issued to the shareholders of the Jokai, the Panitola and the Jhanzie companies, conveying the pleasant news that their usual ten per cent is to be maintained.

"These reports, in explaining the results of the year so far as known, show that the loss in price has been largely compensated by advantages in other directions. The Jokai crop has turned out 696,000 lb., an excess of 16,000 lb. over the manager's estimate. About one-half has already been sold at an average price of rather more than 12½d per lb. The gain from the increase of quantity is consequently over £800, and through the fall in exchange, a considerable saving will have been made in cost of production. It is a question if the whole of the loss in price will not be recouped from this source. In the Jokai and other well-managed gardens tea has been grown this season at a very much lower cost than would have been thought possible a few years ago. Not long since a shilling per lb. was considered the standard cost of tea delivered on board steamer at Calcutta. The pioneer planters would have been horrified at the thought of having to pay their way no less, but this year a good many of them will have run their gardens on not much over sixpence per lb. Well for them that they have been able to do so, for great quantities of Indian tea have been literally given away in Mincing Lane at 7d or 8d per lb.

"It is to be hoped that such another season will not be seen again for a long while. In fact, it would be difficult to conceive of such a convergence of adverse circumstances happening again. The teas came in very early, and in great quantities. They were thrown precipitately on a dull and weak market. In the first part of the season sales followed each other so rapidly that brokers had hardly time to taste half of the samples submitted to them. Many lots went through a merely nominal show of bidding, and the price received for them was no criterion whatever of their value. Within the past week or two the situation has in these respects greatly improved. The supply of tea has been more moderate, and the sales better regulated. At the same time low prices have had their natural effect on consumption. Last month the deliveries of Indian tea for the first time in the history of the trade exceeded those of China, and they are still going on in greatly increased volume.

"China tea, which has always been inferior to Indian in quality, had up to this year a great advantage over it in its lower price. It was always taken for granted in Mincing Lane, that China tea could be sold at 2d or 3d per lb. under Indian. Hence it was the standard article for the cheap grocers, who were able to put enormous quantities of it into consumption. But this season the relation of the two teas has been entirely reversed, India having been actually sold below China prices. Two very important effects may be expected from such a change. The importation of China tea will probably suffer a check, while the use of Indian tea in this country and in Europe generally will be extended. Low prices are therefore not without a redeeming feature; they have done, and are still doing, much to expand the market for Indian teas; they have reduced competition with China to a level where even Chinese cuteness cannot go much lower. Altogether 1886 will be a memorable year in the history of the tea trade. It ought to make a turning point in a long downhill course, and the next year should see the tea market tending in a different direction."

JOKAI (ASSAM) TEA COMPANY, LIMITED.

The following interim report of the directors, for season, 1886, has been issued:—Telegraphic advices received, report that the season had closed with a total crop of 696,000 lb. of tea, against the manager's estimate of 680,000 lb. costing within the estimated Indian expenditure of R244,000, as given in detail in the last annual report. The above information is subject to adjustment, eleven months being actuals and one month, December, being estimated. Of the season's crop, just over 300,000 lb. have been sold in Mincing Lane, averaging 1s 0·60d per lb. gross. The market for Indian teas has, during the greater portion of the year, been depressed for all except the finest grades, and the medium and common sorts are now selling at much lower rates than have ever before been known. These very low prices will, beyond doubt, lead to far greater consumption, and it is hoped consequent recovery of values within a reasonable time. The ascertained results of the season being so far satisfactory, the Board has resolved to pay the usual interim dividend of 5 per cent on the paid up capital of the Company, payable on the 20th inst.—*Home and Colonial Mail.*

THE PRODUCTION OF THE "SENEGAL" GUM ARABIC.—The "Senegal" gum of commerce is found in the territory of the tribes inhabiting several cases between the Senegal and the Atlantic Ocean; the largest forest gum trees are those of Sabel-el-Tatack and El-Hiebar; the former produce the white gum, which is most valued; the other the grey and red varieties. The acacia trees which grow in the desert are inferior to and have a more crooked appearance than those growing near the river, where the soil is more favourable for vegetation. The acacia of the desert rarely attains a height of more than 30 feet, and it has the shrivelled appearance which is peculiar to vegetation in these regions, which are exposed to strong winds. In Western Africa there are only two seasons, the rainy and the dry one. The nearer to the equator, the longer the duration of the rainy season. In Senegambia it lasts two months and is preceded and followed by a month of tempest. In November the bark of the gum trees cracks in numerous places and the gum exudes. About this time the hot winds begin to blow and the burnt trees lose their leaves, assuming the appearance they have with us during the winter. The gum dries quickly, outwardly it looks dull, but on breaking it is brilliant and shiny; it becomes very transparent if put into the mouth for an instant. About a month is required to make the tree produce its full crop. The natives then prepare for the gathering in, and the whole tribe, men, women, and children, some on foot, others on horseback, proceed to the forests. A camp is established for the duration of the crop, and all set to work. The gum collected is placed in sacks of tanned bullock hide, which are fastened by twos to the backs of camels and bullocks. The work is done slowly, there being no fear of rain; when finished, the whole tribe return, and proceed towards the banks of the Senegal, which are at a great distance from Fort Louis. The merchants come to Golam, a small

station situate about 1,000 kilometres from St. Louis on the Senegal, and there wait for the tribes and their crop of gum, which is generally paid for in printed calico, which the collectors resell in the interior.—*Chemist and Druggist.*

Mariawatte Tea Garden gave over the 1000 acres, 1,059 lb per acre from Jan. to Dec. 1886, we learn from Mr. Rutherford. This ought to re-assure sceptics in India about Ceylon tea continuing to yield heavy returns.

"An Inexhaustible Mine of Wealth."—Such is the term which has oftentimes been applied to the Pitch Lake of Trinidad; and although in the past the Government have made very little out of this natural product, it may be hoped in the future, now that the "ring" has been broken, that a very considerable revenue will be derived by the issue of licences "to dig." We learn from Trinidad that the royalty has been fixed at 2s 6d per ton, which is the sum named all through the legal proceedings. This figure ought to prove remunerative to all concerned. For the last four years the crude asphalte has been valued at 1*l* per ton, and the boiled (*epuree*) at exactly double, and it is curious to note that while the exports of the latter during the last three years have slightly increased, the figures being 4,863½, 6,562, and 6,371 tons respectively for the years 1883-84-85, the exports of the former have slightly decreased, being 34,277 tons for 1883, 33,383 tons for 1884, and 28,505 tons for 1885. Under the new regulations, however, there is every reason to anticipate that a very much larger trade will be done both in raw asphalte, *epuree*. West Indian Colonists have cause to be grateful for small mercies nowadays, and the opening up of the Trinidad Pitch Lake, which has hitherto only been looked upon simply as the island's chief natural curiosity is certainly a matter for general congratulation.—*Colonies and India.*

Coconuts.—Maha Oya Valley.—After seven months visited I this district and could see signs of improvement in almost every estate that I have known and visited for the last twenty years. I found the principal road from Negombo to Giriulla bridge at the latter end almost choked up with lantana growing on both sides, covering up the side drains and actually overtopping the fences of the estates bordering the road. I was surprized to learn that for the first time this year a gang of coolies have been busy clearing this road in this district; they are now busy about the 20th mile-post. Robbery and pillage seem to be making rapid advancement, a large brass bell and other valuables belonging to a Roman Catholic church having all been removed. Cattle stealing not so rife, but illicit sale of arrack and coconut stealing steadily progressing. What has astonished me most is to have witnessed the manner in which estates belonging to native proprietors are now kept, as compared with what was the practice say five years back. Without exception the estates are all in splendid order and the valley is well worth a visit from those who care to see coconut planting well done. I send you herewith the rainfall registered in one of the "crack" Maha Oya Valley coconut estates, belonging to a wealthy native gentleman. You can make any use of same. If necessary, I could most likely procure the registered quantity for last year as well. [Would certainly be interesting.—Ed.]

Registered rainfall in Mahaoya Valley for 1886 ending 10th December:—

January	...	3·41
February	...	2·53
March	...	1·26
April	...	8·95
May	...	10·78
June	...	15·15
July	...	4·54
August	...	2·86
September	...	3 55
October	...	12·53
November	...	10·90
December (1—10)	...	·71
Total	...	77·17

Andrew's Patent Metal Tea Chests.—The first break packed in these chests is now being despatched from Mariawatte estate. Tea planters will watch with interest the report from London brokers on these packages. We understand there are two kinds being sent: the full sized chests, of steel sheets lined with paper inside to prevent rust coming in contact with the tea; the half-chests are lead-coated steel sheets and require no inner lining. Taking into consideration that wooden boxes require lead linings, hoop iron, solder, and nails, and that there is a saving in freight of 15 per cent in favor of the steel boxes, we are not surprized to learn that the total cost of the steel sheet is slightly under the wooden package. Should they be approved by the trade and be preferred to the wooden leaden package, the patentee will have a "good thing" on his hands. He had the pleasure of seeing the packages being put together at Mariawatte, and although the men were quite new to the work, they were already fixing them up in an expert manner under contract at 12 cents per chest. The packages all tare exactly alike, and if they had no other advantage but this, it would alone make them more suitable than the present package.—Local "Times."

Cutting Rose Flowers.—Exhibitors of roses who cut daily are said to have the most continuous display of blooms on their plants. This should be good news for the inexperienced grower; there are many who are afraid of weakening their plants by cutting the flowers, but in practice this does not happen if the blooms are taken singly. If with the first flower that is cut several buds are also removed, the flowering season will be short. My own experience is that the more roses are cut, the better for those are left, and this applies to all classes of roses, whether grown under glass or in the open. I think cut roses for room decoration never look better than when displayed in the Munsted glasses, or glasses of a similar pattern. I like to have the glasses half filled with water, and then a layer of green moss as a bed for the flowers which, with sufficient leaves, is capable of making a very tasteful arrangement; but in whatever way the flowers are arranged, there should be a plentiful supply of their own foliage. Roses without leaves never look well, however much taste may be displayed in arranging them. Cheshunt Hybrid is deficient in richness of colour, but its delightful fragrance more than makes up for its lack of brightness. Under glass, we have it here every year in the middle of April very beautiful.—Taunton.—*Field.*

Testing Seeds.—When you want new seed Peas put one from the stock into your mouth and bite it. If it is very hard it is more than one year old. If the teeth enter it with moderate ease it is new seed. New Carrot seed always has a green shade on it. Old seed loses this, and is of a dead pale brown, and less fragrant. New Parsnip seed has a shade of green, which it loses if more than one year old. Onion seed is more difficult to prove than most other seeds, but if you take a single seed at a time and carefully bite it you will find that old seed has a tough dry skin, with a very white and harsh kernel, while new seed has a more tender, moist skin, and the kernel possesses a greater degree of moisture, and is somewhat oily. The seed may be cut with a penknife instead of bitten. Onion seed that has no vitality at all has no kernel, or one perfectly dry. Test this by pressing the seed on a piece of white writing-paper. If it leaves no moisture on the paper it is of no use, and has been tampered with, or has lost its vitality by age. New cabbage and Broccoli seed possesses a pale green shade in the kernel when pressed out or cut, and a tinge of green in the brown skin also. But old seed loses this in proportion to its age, becoming of a dull, dark brown. Cabbage, Broccoli, Kales, &c., will retain their vitality longer than any other seeds, and will grow well when three years old, or even six years, if well kept. Beet seed has a faint tinge of pale green if new, but is a dull brown if old, and its vitality is very doubtful if old. New Celery seed has a faint tinge of green, and is very aromatic, but it loses the green and becomes less fragrant if more than a year old, and is doubtful.—*American Horticulturist.*

SOME OF THE DRUG EXHIBITS AT THE COLONIAL AND INDIAN EXHIBITION.*

BY E. M. HOLMES, F. L. S.,

Curator of the Museum of the Pharmaceutical Society.

In the first place the quality of the products exhibited indicated that the requirements of the London drug market are not well understood in the colonies. I say advisedly the London drug market, because it is generally acknowledged that London is the principal market for drugs in the world. In the majority of cases drugs had been evidently collected with the least possible trouble and apparently in ignorance of the fact that the price realised will depend in great measure on the care bestowed in preparation for the market. Thus the bitter orange peel exhibited in the West Indian Court possessed neither the form nor colour required in the drug trade. Cinnamon was also shown from several colonies, which would not compare in flavour or appearance with that from Ceylon, with which it must compete if it is grown for the drug or spice market. Beeswax affords another instance in point. Although it is easily clarified there was hardly a clean specimen of good colour to be seen in the Exhibition.

In the second place, it was noticeable that the best and most important of the drugs exhibited were those prepared either by colonists who combined pharmaceutical and chemical knowledge with operative skill, or by analytical chemists in the employ of the Colonial Governments. I may instance the excellent samples of essential oils and various pharmaceutical products manufactured by Mr. Bosisto, of Victoria, and Mr. Sharp, of the Seychelles, both of whom are members of this Society; the very interesting preparations sent by Dr. Bancroft, of Queensland; and the fine series of pharmaceutical products of essential oils from Mr. Staiger, of the same colony, from Mr. McCarthy, of Trinidad, Mr. J. J. Bowrey, of Jamaica, and Mr. F. Bert, of Barbadoes, all of whom are analytical chemists.

In the third place, an ignorance of the physical appearance by which drugs are distinguished was evident from the fact that several drugs were exhibited under erroneous names. Thus the ipecacuanha shown in the West Indian Court was not the true drug, but that of *Asclepias curassavica*, which is locally used under that name. The sarsaparilla exhibited in several of the West Indian Courts was the root of *Bromelia Karatas*, although the true drug was shown in the Honduras and Barbadoes Court. This want of accurate knowledge in the colonists has probably often to be deplored by the drug merchants and brokers in this country, to whom such drugs are consigned for sale.

In the fourth place it seems remarkable that a large number of colonial products which could be obtained in almost unlimited quantity, are practically unknown in commerce in this country. Thus the oil of the purging nut, and even the seed itself, does not appear to be known here, although about 300,000 bushels of the seed are annually sent from the Cape de Verde Islands to Portugal for the expression of the oil. Crab-nut oil, which thirty-five years ago was awarded a prize medal at the International Exhibition, and which could be procured in almost unlimited quantity from both British Guiana and West Africa, is not yet an imported article of trade in this country, and many other instances could be adduced. These facts suggest the importance to the colonies of employing thoroughly competent chemists, possessing not merely a knowledge of applied chemistry, but a familiarity with the appearance and character of ordinary commercial products, whose business it should be to investigate and report on the native productions in such papers or publications as come under the cognizance of commercial men.

The lack of knowledge in the colonies of the requirements of the home markets and the absence of information in this country concerning valuable colonial products indicate the necessity for a central building in London and other large commercial towns where samples of colonial products sufficiently large for examination and experiment could be obtained, together with all published information concerning them. Such an institution, containing series of samples from different colonies, would prove doubly instructive: in the first place by showing whence the finest qualities of any product could be most easily and cheaply obtained; and, secondly, as an educational department in commercial knowledge for intending emigrants to the colonies.

I will now pass on to notice some of the drugs exhibited at the Colonial and Indian Exhibition. For our present purpose these may be grouped under the following heads:—Medicinial drugs, medicinal species, essential oils and camphor, fixed oils and fats, gums, resins, and saccharine substances.

Of the official medicinal drugs, *i.e.*, those recognized in the British Pharmacopœia, the following possessed of tonic or febrifuge properties were shown, viz, cinchona, nux vomica, quassia, hops, bitter orange peel, chirata, cascarilla, and bebeeru.

The most important exhibits of cinchona bark occurred in the India, Ceylon, and Jamica Courts; the principal barks shown being those of *C. Ledgeriana*, *C. robusta*, *C. officinalis*, *C. Calisaya*, and *C. succirubra*. The last-named was also exhibited from the Mauritus, Perak and Fiji.

By far the larger proportion of cinchona bark is purchased for the manufacture of quinine, and as each bale is usually analysed before being sold the appearance of the bark is to the quinine manufacturer but of little consequence. To the pharamacist, however, it is of importance to be able to distinguish between the different varieties by their physical appearance, since one variety of bark is sometimes prescribed in preference to another. Lately a great quantity of cinchona bark in the form of shavings has been sent to this country, which it would be almost impossible to refer to any particular species. Fine bold quills for druggists' purposes often fetch a higher price in the market than they are intrinsically worth, *i. e.*, judged by the percentage of crystalline sulphate of quinine they afford. In view of this fact, and of the low price at present paid for cinchona bark, a careful selection of well-marked varieties might prove as advantageous to the planter as it would be welcome to the pharmacist. The barks most suitable for this purpose are the Calisaya bark from Madras, which presents the same characteristic appearance as the cultivated Bolivian bark, viz, a predominance of longitudinal fissures, with comparatively few nearly circular transverse cracks; the variety of *C. officinalis*, known as *C. crispa*, which yields a peculiarly corky bark of good quality, and which is thus easily recognized from other varieties; and the red bark of India and Ceylon, having a peculiar warty appearance. But on the other hand the hybrids between *C. officinalis* and *C. succirubra* cultivated in Ceylon and elsewhere, and the variety of red bark chiefly grown in Jamaica, are by no means easily recognized. Renewed bark and shavings are still more difficult to assign to their respective species. These are therefore less suitable for the use of the pharmacist.

Nux vomica seeds were shown from Trinidad and Ceylon. It may be interesting to exporters of these seeds to direct attention to the fact lately demonstrated by Messrs. Dunstan and Short (*Pharm. Journ.*, [3], xv., p. 6), that the seeds grown in Ceylon are much richer in strychnine than those either of Bombay, Madras or Cochin China, and that as the principal use of these seeds is for the preparation of strychnine the Ceylon variety would best repay cultivation.

The specimens of quassia exhibited in the Tobago and British Guiana Courts were derived from *Quassia amara*, and not from the official tree, *Picræna excelsa*.

The hops exhibited in the Canadian Court were of very good colour and aroma, and the specimen in the New Zealand Court was of fairly good quality. Bitter orange peel, which was exhibited by several colonies, was badly dried, and consisted of quarter sections, instead of carefully dried strips of good

* Read at an Evening Meeting of the Pharmaceutical Society, Wednesday, November, 17th, 1886.

colour as sold in this country. Chirata, bebeeru and cascarilla did not present any feature worthy of special notice, except that the latter was shown in very slender quills, as if derived from the twigs or small branches only.

Of sedative or anodyne medicinal drugs the following were exhibited:—Opium and poppyheads, coca leaves, Indian hemp and aconite. With these Calabar beans may be classed for the sake of convenience. Opium was, of course, well represented in the Indian Court, but elsewhere was observed only in the Victoria Court, where excellent specimens were exhibited by Mr. Bosisto. These have been shown by analysis to yield 10 per cent of morphine in the crude state, and 11½ per cent when dried. The Victorian-grown opium is protected by a duty of 20s. per pound on imported opium, but the quantity produced in the colony is not at present sufficient to meet the local demand for it. Indeed it appears doubtful, owing to the high price of labour in the colony, whether it could be produced at a sufficiently low price to compete with Turkish opium. It is a suggestive fact that the great bulk of the official or medicinal opium used in the world is supplied by Turkey, although there can be little doubt that opium of quite as good quality could be prepared in India. As at present made in the latter country opium usually contains more narcotine and morphine than Turkish opium. This may be due to the tedious process of preparation of the drug for the Chinese market, or to the particular variety of poppy employed (var. γ *album*) which differs from that used in Turkey (β *glabrum*). In view of the immense increase of opium production in China during the last few years, and the probable growth of a taste for the home-made article in that country, the suggestion naturally occurs, whether the preparation of medicinal opium in India might not yield an important addition to the revenue of that country, and at the same time, render this country independent of the Turkish product.

The poppy heads exhibited in the Victoria Court were born on stems more than six feet in height, which shows the luxuriance with which the plant grows in that colony.

Coca leaves were exhibited from Jamaica and Dominica, but as yet are probably grown there only as an experiment. The alkaloid contained in the leaves so readily undergoes decomposition that the greatest care will be necessary in drying and preserving the leaves, if they are intended to compete with the South American drug as recently imported.

Aconite root and *Cannabis indica* were exhibited only from India. Concerning the latter it is important to note that the strength of the drug appears to vary greatly, according to the district in which it grows. According to Dr. Watt, the flowering tops which are more or less cylindrical are possessed of much greater medicinal activity, and fetch a considerably higher price in India, than those which are simply compressed. The tincture made from the former is likely to produce alarming symptoms if given in the same dose as that prepared from the latter. This difference does not appear to be recognized in the British Pharmacopœia.

The aconite root did not appear to be sufficiently uniform in character for use in medicine in this country, although some good specimens from Nepal, collected by Dr. Grimblett, were exhibited.

Fine specimens of Calabar bean were shown in the Ceylon Court and also from Lagos and Gambia. It may be here pointed out that a variety of this bean which contained more alkaloid than the ordinary kind was imported into England a few years ago. It was more oblong in shape and had a longer hilum or scar. In the case of many drugs, and especially poisonous drugs of which a limited quantity is used, the market is often spoiled, so far as the interests of the colonies are concerned, by an over supply being sent at one time, so that the prices realized hardly pay for collection, or may even entail a loss.

Of purgative drugs, aloes, jalap, *Cassia Fistula* and senna were exhibited. Aloes was very poorly represented, a solitary gourd of Barbadoes aloes, apparently of inferior quality, being shown in that Court, while in those of Natal and the Cape of Good Hope no specimens were noticeable. It may be here mentioned that the botanical source of the opaque aloes known in commerce as "Natal" or "Hepatic Cape" has not been accurately determined and that the cause of its opacity is also unknown. Barbadoes or Curaçoa aloes is sometimes translucent at first and becomes opaque on keeping, but there is no evidence that this is the case with Natal aloes. Fine pods of the *Cassia Fistula* were shown in the St. Lucia Court. Senna leaves were shown in the India Court and in that of the Cape of Good Hope. That from the Cape had been collected in the Hopetown district, where the plant is exceedingly abundant. The leaves appeared to be those of *Cassia obovata*, a species the leaves of which were formerly mixed with those of *C. acutifolia* in Alexandrian senna, but are now rarely found in it. This kind of senna is stated to be less active than the leaflets of *C. acutifolia* and *C. angustifolia*. Some very large leaflets from plants cultivated at Barcelona were offered in the London market a year or two since and some has this year been sent from Tinnevelly, but neither, I believe, were purchased; nevertheless, comparative experiments concerning the relative strength of these species might be useful to confirm or otherwise previous statements; in any case it might serve as a substitute for senna at the Cape. Indian bael is intermediate in character between the purgatives and astringents and may be mentioned here as occurring in the Indian Court. The fresh fruit has so delicate and pleasant a flavour that a conserve or syrup of the fruit might possibly meet with acceptance as a laxative in this country.

Of astringent official drugs there were exhibited catechu, kino, logwood, galls, and arecanuts.

Pale catechu was shown in the Straits Settlements Court in two or three forms, viz., in large and small cubical pieces and in the form of flattened discs; the latter were of a pale colour and intended for chewing with betel nut. In this connection it may be useful to recall the fact noticed by Dr. Haygarth Addison that pale catechu produces a tonic effect on the nervous system entirely apart from its astringent action (*Pharm. Journ.*, [3,] xvi., p. 720.) It has not yet been determined whether this action is due to quercetin or to catechin, or to some other constituent of the drug. Kino was represented by several different preparations. The official drug was exhibited only in the Indian Court. From the Seychelles an elegant product obtained from *Pterocarpus indicus* was shown by Dr. Brooks, and in the Victoria Court Mr. Bosisto exhibited an Australian kino, entirely and readily soluble in cold water, side by side with the crude insoluble product obtained from the red gum tree, *E. rostrata*. In the Queensland Court several products of the kino class obtained from various species of eucalyptus were shown by Dr. Bancroft; of these I have been unable to obtain specimens from the Executive Commissioner.

It is remarkable that the original kino, which is a product of gambier and which affords a satisfactory tincture, is not represented in the West African Court, although the tree that yields it (*Pterocarpus erinaceus*, Poir.) is a native of West Africa, from Senegambia to Angola. A product intermediate in character between kino and catechu was shown by Mr. Bosisto in the Victoria Court. It resembled kino in appearance, but was styled Australian catechu. It was an extract made from the waste chips of wattle bark, and could doubtless be made on a scale sufficiently large for tanning purposes if required.

Logwood may be noticed under the head of astringents, being used in medicine for that purpose. It is of interest also on account of its use for staining microscopical preparations. It does not appear to be generally known that microscopists distinguish different varieties of logwood, one of which gives a bluish and another a purplish-red stain; whether thisdue is

to inherent differences in the wood or to more or less exposure to light and air is not clear. It appears, however, from the Official Catalogue of British Honduras that there are two varieties of the tree, of which the broad-leaved one is considered the most valuable, on account of the solidity of the timber and of its yielding a larger quantity of the dye, whilst the smaller-leaved tree is said to yield the better quality. Specimens from Jamaica, British Honduras, Dominica and Tobago are shown in the Exhibition. The varieties recognized in the London market are, I believe, the following, which are here placed according to their relative values:—Campeachy, Honduras, St. Domingo and Jamaica.

Galls and arecanuts were shown in variety in the Indian Court. Of the former I may observe in passing, that the galls of the *Tamarix articulata* and of *Terminalia Chebula* appear likely to prove of considerable value for tanning purposes, on account of the richness in tannic acid and the pale colour of their extract. Pomegranate bark was shown in the Jamaica Court, of a quality much superior to that ordinarily met with in commerce.

Of demulcent medicinal drugs, linseed is the most important, and was shown in great variety in the Indian Court. It is worthy of note that the cultivation has commenced in Canada, and that samples were exhibited in the Court of that colony. Hitherto nearly the whole, if not all the linseed used for flax growing has been derived from Russian-ports, the product of a cold climate being apparently more suitable for growing purposes. It may be hoped that Canadian linseed, or that from the northern parts of India, will in future years replace that of Russia for this purpose. Indian linseed frequently contains numerous seeds of cruciferous weeds, particulary of species of *Brassica*, which by reason of their containing a sweet or non-drying oil render the linseed oil obtained by pressure of a less drying character, and therefore of less value commercially. The only other official drug conveniently referable to this class, worthy of notice, is buchu, concerning which it may be observed that certain varieties of these leaves, which are more highly esteemed to the Cape of Good Hope than those official in the British Pharmacopœia are frequently sent to this country to the loss both of the shipper and of the consignee. Such varieties are always rejected by English druggists.

Of alternative drugs sarsaparilla was exhibited from British Honduras and Jamaica. The latter, however, was not the article known in commerce as Jamaica sarsaparilla (which really comes from Panama,) but resembled the Honduras sort in having a thick and mealy bark, while it differed from it in the orange-red colour of the bark. The Panama drug, which fetches the highest price in the market, and is the most esteemed, has a thin wrinkled brownish bark.

The sarsaparilla exhibited by the other West Indian colonies was the root of *Bromelia Karatas*, and would not be recognized in this country as sarsaparilla.

Several colonial remedies that have recently been introduced into Europe and America were shown in various Courts. The pretty scarlet and black seeds of *Abrus precatorius* formed a conspicuous object in several of the West Indian Courts and also in that of British Guiana. *Alstonia constricta* bark, *Duboisia* and *Euphorbia pilulifera* were shown in the Queensland Court, *Piscidia erythrina* in the Jamaica, and papaine in the Seychelles and Dominica exhibits.

With respect to the non-official medicinal products of the Exhibition it is possible to regard them from two points of view: the one being that of Colonial Governments, which are naturally anxious to obtain indigenous substitutes of equal value for expensive drugs imported from the mother country; the other is that of the pharmacists of Europe and America who may be desirous of ascertaining if any of the colonial drugs possess medicinal properties which are worthy of careful investigation or are superior in quality or value to others at present in use. The latter point of view is the only one which falls within my province to-night, the former may safely be left to the medical profession in the colonies.

The following list includes the colonial drugs which were accompanied by statements indicating that they possess medicinal properties worthy of closer investigation both by the chemist and the medical profession.

As an alterative *Siegesbeckia orientalis* is highly recommended by Dr. Daruty, of Mauritius, in infantile cachexia and as an application to gangrenous wounds. The active principle, darutyne, was shown in the Mauritius Court. The root of *Arctopus echinatus* has long been used at the Cape of Good Hope for cutaneous eruptions; *Rourea fulgens* is used for leprosy in the Straits Settlements, and lukrubau seeds at Hong Kong. For skin diseases, henna leaves are employed in the Straits Settlements and henna seeds in Gambia, and the bark of *Acacia falcata* in New South Wales, and *Melianthus major* at the Cape. For ringworm the yellow juice of *Haronga madagascariensis* is employed in the Mauritius, and that of *Bocconia frutescens* in Jamaica, and the sap of *Laplacea Hæmatoxylon* in St. Vincent; also the leaves of *Cassia alata* in India, and the seeds of *Vatairea guianensis* in British Guiana.

For asthma *Gymphocarpus fruticosus* and *Gleichenia dichotoma* are used in the Mauritius, and *Euphorbia maculata* in St. Vincent. *Atherosperma moschatum* is highly spoken of by Mr. Bosisto as giving relief in asthma and bronchitis and *Phytolacca stricta* is used at the Cape for pulmonary diseases.

As antiperiodics the bark of *Michelia Champaca* is used in Mauritius, *Thevetia Neriifolia* in the Straits Settlements, and proteacin, prepared from a species of *Leucadendron*, at the Cape, the latter drug being recommended by Dr. J. H. Meiring Beck. As a tonic in flatulent indigestion boiari root seems to find general acceptance in British Guiana.

As anthelmintics, *Quisqualis indica* is used in Mauritius, and *Leucas linifolia*, in the Straits Settlements.

As resolvents, *Coleus atropurpureus* and *Plumbago rosea* are employed in the Straits Settlements.

As nervine tonics, *Eryngium fœtidum* is considered useful in Jamaica, and keng root in Gambia.

Emmenagogue properties are attributed to *Poinciana pulcherrima* in Mauritius. *Cissus capensis* and *Sansoviera thyrsiflora* are stated in the Cape of Good Hope Catalogue to give relief in hæmorrhoidal complaints.

Antiseptic properties appear to be present in *Cyperus articulatus*, used in Jamaica to stop vomiting: in *Lichtensteinia interrupta*, *Teucrium africanum* and *Cluytia hirsuta*, used at the Cape of Good Hope, the two former being employed in splenic fever. The following, from their poisonous properties, also seem worthy of chemical investigation: aromata, coroo-coroo and moraballi bark, dividora root, haiari root (*Lonchocarpus densiflorus*) and the seeds of *Cacoucia coccinea*, from British Guiana: tuba root (*Derris elliptica*) from the Straits Settlements; *Toxicophlœa Phunbergii* and *Hyœnanche globosa* from the Cape of Good Hope; poison-wood from British Honduras, and *Elœodendron orientale* from the Mauritius.

Medicinal Spices.

The best exhibit of cinnamon was that of Ceylon, the specimens from Jamaica, Barbadoes, Fiji and Sierra Leone being all inferior in aroma as well as in appearance; that from St. Lucia was by no means deficient in aroma, but consisted of thick bark, and would only be marketable for making the powdered drug or for distillation of the essential oil.

The cardamoms from Ceylon were the finest in the Exhibition, but official cardamoms were also shown from Jamaica and Grenada, and round cardamoms from the Straits Settlements. The seeds of the latter are hardly distinguishable by taste from the official kind. The long grey cardamoms, known in commerce as Ceylon cardamoms, were also shown. These are said to be obtained always from wild plants by the natives. The seeds possess less aroma than the official kind and are of a slightly different character,

nevertheless they appear frequently in the London drug market.

Nutmegs were shown in the Ceylon Court and also in those of Jamaica, Grenada, St. Vincent, St. Lucia and Dominica, the Grenada specimens preserved in brine being particularly fine. The nutmegs and mace in the Fiji Court were valueless as spice, being entirely deficient in aroma,

Cloves were exhibited from the Seychelles, Ceylon, St. Lucia and Dominica, the two first-named being the finest.

Ginger was shown by Jamaica, Barbadoes, St. Lucia Dominica, Montserrat, British Honduras, the Gold Coast, and Sierra Leone. None of the exhibits presented a very good appearance, and some being in the growing state it was difficult to pronounce any opinion upon them.

Pepper was shown by Ceylon, North Borneo, and the Straits Settlements, but none of the specimens appeared to be particularly fine.

Allspice was shown by Jamaica and Ceylon, and the berries of the nearly-allied *Pimenta acris* in the St. Lucia Court.

Dill and fennel fruits were observed in the West Indian Court, and coriander fruit in that of Natal.

Mustard was exhibited in variety from India and sparingly from Natal and the West Indies.

Excellent specimens of chillies were exhibited from Natal, and both chillies and capsicum in great variety in nearly all the West Indian Courts and in British Guiana.

Canella bark was shown from Jamaica, Trinidad and the Bahamas, but none of the specimens were equal to those frequently obtainable in the London market.

Of non-official spices, vanilla was well represented in the Exhibition; the finest specimens were those from the Seychelles and Mauritius. Tonka beans, as fine as those of Para, were shown in the British Guiana Court.

Essential Oils.

Comparatively few of the essential oils used in medicine were shown, but there were many others that should possess considerable value in perfumery.

Oil of cloves was represented by some excellent specimens in the Seychelles Court. These had been prepared respectively from green cloves, dried cloves and clove stalks.

The oils of cinnamon bark and leaf were shown both from Ceylon and from Seychelles. The oil from the leaf possesses an odour different from that of the bark, resembling a mixture of cloves and cinnamon, and is, I believe, chiefly used for scenting soaps. Oil of cassia distilled from the leaves and twigs was shown in the Hong Kong Court, and oil of cajuput only from the Straits Settlements. An oil prepared from the fresh leaves of *Melaleuca Leucadendron*, var. *Lancifolia*, Bail., exhibited in the Queensland Court, and supposed to be "similar, if not identical with cajuput," differs in having a much more disagreeable odour; that of *Eucalyptus populifolia* does, however, closely resemble cajuput in odour.

Oil of lavender was shown only by Mr. Bosisto, as a product of Victoria. Although not equal to Mitcham oil, there is little doubt that this able and energetic pharmacist will succeed ultimately in having an excellent article prepared from Victorian flowers.

Oil of peppermint of excellent quality, prepared from plants grown in Victoria, was also exhibited by Mr. Boisto. Some years ago it was offered in this country, but the price obtained (25*s.* per lb.) was not sufficiently remunerative to lead to a repetition of the experiment. Peppermint oil and menthol were also exhibited in the Hong Kong Court by Messrs. A. S. Watson and Co. According to information furnished by these gentlemen the oil is distilled from several kinds of mint, and is used in neuralgia and indigestion.

Oil of sandal-wood was exhibited in the India Court and also in that of Victoria (*see Pharm. Journ.*, [3], xvi., p. 820). The oil imported from India is generally so adulterated with fixed oil, and is so opaque, that English dealers prefer to distil the oil from the imported wood. There can be no reason, however, why the pure oil should not be imported direct for medicinal use, if carefully prepared in Mysore under the superintendence of a qualified chemist. Some fine logs of sandal-wood (*Santalum Yasi*) were shown in the Fiji Court, but no sample of the oil. A specimen prepared from Australian sandal-wood was shown by Mr. Bosisto. Besides the above official oils there were a large number of others deserving of notice, as capable of being used as flavoring agents, or in perfumery. Oils prepared from the rind of the lemon, lime, orange, shaddock and citron formed prominent features in several of the West India Courts. A sample of oil of limes in the Trinidad Court, prepared from what seems to be a hybrid between a lemon and a lime, was shown, together with the fruit from which it was obtained; it resembles a very fine specimen of essence of lemon in flavour and odour, but gives chemical reactions like oil of limes. The ecuelled oils both of limes and lemons were far superior in point of odour to those prepared by distillation. The ecuelled oil of lemons from the West Indies might well compete in the European market with much that is now derived from Sicily. Other essential oils that might be employed as flavouring agents are the oil of sweet basil, exhibited by the Montserrat Company and by Dr. Hollings in the Montserrat Court, the oils of pepper and mace from the Straits Settlements, and the oil of pimento from Jamaica and St. Lucia.

Some of the oils which might be made available in perfumery are the following. In the Indian Court, oil of *Pandanus odoratissimus*, having an ordour like honey; oil of henna flowers, resembling in odour a tea rose; and the aromatic oil of champaca flowers. In the Straits Settlements Court, oil of balsam of Peru pods, resembling the perfume of bean flowers in odour; and the oils of *Canella alba* and cascarilla. In the Montserrat Court the Montserrat Company exhibited a specimen of oil of lime leaves, which had a peculiar fragrance of its own, quite distinct from that of neroli. Apparently the only specimen of oil of bergamot in the Exhibition was shown by the same firm. An oil of wild ginger (*Renealmia sp.?*) was shown in the Dominica Court that possessed a peculiar fragrance of its own. In the Jamaica Court several novelties in essential oils were exhibited, including those of *Critonea Dalea*, which has an odour of new-mown hay; *Hedyosmum nutans* and *Micromeria obovata*, which are not especially attractive in odour, and the oil of *Juniperus Bermudiana* which has a perfume resembling that of oil of cedar. The oil of bay leaves (*Pimenta acris*), used in making bay rum, was exhibited in several of the West Indian courts; it appears to be chiefly sent to the United States.

In the Queensland Court several oils derived from different species of ecualyptus were shown. Of these the oils of *E. Planchoniana* and *E. dealbata* resemble citronelle, and these of *E. Staigeriana*, *E. citriodora* and of *Backhousia citriodora* resemble the oil of lemon grass.

It is remarkable that there appears to be a much larger demand for oil of citronelle than for that of lemon grass, or verbena as it is commonly called, the former being probably more largely used for perfuming soaps. The oil of *Atherosperma moschatum*, exhibited in the Victoria Court, and that of *Nesodaphne obtusifolia* in the Queensland Court, both resembles sassafras in odour; the former, however, in a dose of a very few drops, is, according to Mr. Bosisto, quite poisonous, producing stoppage of the heart's action. Other essential oils worthy of notice are the fine specimens exhibited in the Victoria Court of the oils, of *Eucalyptus amygdalina*, *E. dumosa*, *E. oleosa*, and *E. globulus*. These oils, particularly *E. oleosa*, possess a remarkably solvent action on many resins that are not soluble or only partially so in alcohol, but on account of their high price could only be used for varnishes employed by artists, for which purpose they are said to have the advantage of rendering the colours brighter. According to Mr. Bosisto the oil of *Eucalyptus globulus* soon darkens in colour and becomes oxidized and resinified when exposed to light. A very fragrant essence of the flowers of *Acacia pycnantha*, prepared by enfleurage, was shown in the Victoria Court. It

seemed quite equal in fragrance to the *pommade de cassie* prepared in the South of France. In the North Borneo Court the oil derived from the Borneo camphor tree was exhibited. This also might possibly be useful in dissolving some resins or in rendering them soluble in alcohol.

This oil does not appear to be so well known as the Chinese camphor oil, of which as much as 94,500 lb. is said to have been imported into the United States during the past sixteen months. Chinese camphor was shown only in the India and Hong Kong Courts, and specimens of Borneo camphor in that of North Borneo. Under the supposition that Borneo camphor is probably not preferred by the Chinese without reason, I forwarded some specimens kindly supplied by the Acting Commissioner at the North Borneo Court to Mr. R. Stockman of Edinburgh University. The taste is not so unpleasant as that of Chinese camphor.

Before leaving the subject of essential oils it may be pointed out that nearly all the essential oils obtained from flowers in India are spoiled by mixing them with sandal-wood oil and after with fixed oils. Until prepared in a state of purity they are not likely to come into the demand that might otherwise arise on account of the exquisite fragrance of many of them.

Fixed Oils and Fats.

The principal official oils exhibited were castor oil and olive oil. The former was shown from nearly all the West Indian Courts, British Guiana, South Australia, Ceylon, Fiji, and the Seychelles, but only that from the last-named colony possessed the clearness and brilliancy to which we are accustomed in this country. Olive oil was shewn from South Australia and New South Wales, but as yet it is only prepared in South Australia in commercial quantities. There appears to be no reason why this colony, as well as the Cape and Natal, should not in future years supply a better and purer oil than the too often adulterated product now obtained from the shores of the Mediterranean, especially if the best varieties of the olive be cultivated for the purpose.

Croton oil was shown in the Hong Kong Court, and some very fine specimens of the seeds were noticeable in that of Ceylon. Of the official fats cacao butter occured in the Trinidad Court, but was not of superior quality. Beeswax, obtained either from domesticated or wild bees, was exhibited in nearly every Court, but for the most part the specimens exhibited were very dirty and inferior, some flat circular cakes exhibited by Mr. Fabien in the Trinidad Court being the only presentable specimens that were noticed. A large number of non-official oils were exhibited in the different Courts, some of them being obtainable in large quantities from more than one colony. This was the case with carapa or crab oil, which was shown in the British Guiana and Trinidad Courts, and is a product also of Western Africa. It has a bitter taste, and is used by the natives as an insecticide, a property which, if retained when the oil is saponified, might be turned to useful account.

The oil of *Jatropha Curcas* appears to be largely used in some parts of the Continent. It yields a purgative sweet oil of pale colour, and of a consistence much thinner than castor oil. Probably it might prove valuable as a stimulant hair oil, possessing the advantage over castor oil of being free from any disagreeable odour. It could be obtained in sufficient quantity for soap making and illuminating purposes, the plant being common in all semi-tropical countries.

The oil of various species of *Aleurites* was shown in several Courts, that from Queensland and the Seychelles being almost colourless and quite clear. This oil could be obtained in unlimited quantity, and might also be useful as an illuminating oil or in soap making, being comparatively inexpensive. The oil of *Aleurites cordata*, exhibited by Messrs. A. S. Watson and Co. in the Hong Kong Court under the name of wood oil, is remarkable for its drying properties, which have already been described in the *Pharmaceutical Journal* ([3], xv., p. 636, 637). Other Chinese oils exhibited by the same firm were those of tea seed (*Camellia oleifera*), which is used by the Chinese as a substitute for olive oil, and also as a lamp oil, oil of cabbage seed, oil of peach and apricot kernels, and oil of soy beans, used both for cooking and illuminating purposes, all of the above being obtainable in large quantities. A very pale, sweet and bland oil is obtained both in China and West Africa from the seeds of several varieties of a melon, which yield on an average about 30 per cent of oil. Under the name of "egusi" these seeds are exhibited in the West African Court.

Numerous specimens of coconut oil were shown in several Courts, that from Seychelles being very white, and a specimen in the British Guiana Court was not only very white but unusally solid, and was pronounced by experts to be the best in the exhibition. The yellowish oil of the king coconut was shown in the Ceylon Court. This is remarkable for being free from the odour of the coconut, and is therefore more suitable for use in perfumery.

In the Tobago Court the oils derived from the seeds of the grugru (*Acrocomia sclerocarpa*) and cokerite (*Maximiliana insignis*) palms; in the British Guiana Court, that of the acuyuru palm (*Astrocaryum Tucuma*); and in the British Honduras Court a white semi-solid fat from the seeds of *Attalea Cahune*, known as Cahoon oil, were shown.

In the India Court a large number of oils were exhibited, but many of these from exposure to light had become rancid. The white semi-solid oil derived from the kernels of *Anacardium occidentale* was, however, noticed to be still sweet.

The oil of *Bassia longifolia*, exhibited in the Mauritius Court, is a sweet oil having the colour and consistence of butter, but has a peculiar flavour, although almost free from odour. Another solid oil in the India Court, obtained from the seeds of *Garcinia indica*, is used in India as a substitute for spermaceti ointment, and having hardly any odour and a pleasant bland taste deserves more attention than it has hitherto received.

Myrtle wax, obtained from the berries of *Myrica cordifolia* and other species, was shown in the Cape of Good Hope Court. It is hard but brittle wax.

Oleoresins and Resins.

Of those official in the British Pharmacopœia copaiba was exhibited in the British Guiana Court. The specimens were of a pale colour and good consistence, but it is remarkable that it does not appear to be recognized as a commercial variety in this country. Gamboge was exhibited in the Ceylon Court; guaiacum in that of the West Indies; benzion, of very inferior quality, was but poorly represented in the Straits Settlements Court; and Chian turpentine in the Cyprus Court. The Ceylon gamboge is not as yet well known in this country; a consignment sent to England three years ago fetched £14 5s. per cwt.

A kind of elemi was shown in the British Guiana and West African Courts, but in both cases of too hard a consistence to replace the Manila drug. There was also in several of the West Indian Courts a product resembling elemi in appearance and consistence, but having a more terebinthinate odour that in the St. Lucia Court having a pleasant odour more resembling olibanum. These products are used as incense, the dirty and inferior pieces being made into torches.

Resins suitable for making varnishes were shown by several colonies. Fine specimens of Kauri resin were observed in the New Zealand Court. In the British Guiana Court there was a very hard resin, known as Demerara or Brazilian copal; of this there were two varieties, one pale in colour and evidently of more recent production than the other, which was more yellow and harder. This resin appears to be but little known in English commerce as yet, but I am informed that those who know how to dissolve it find that it makes an excellent copal varnish. I may remark in passing that the oil of *Eucalyptus oleosa* dissolves it perfectly and in considerable quantity. A very white and tolerably hard resin, which said to form an excellent picture varnish, was shown by Dr,

Ondaatje in the Ceylon Court. It is the product of *Doona zeylanica*. A very white specimen of copal resin was shown in the West African Court. But there were many other resins in the Straits Settlements, India, and other Courts that may be worthy of attention, a particularly fine specimen being shown in the North Borneo Court of a yellowish hard copal, soluble in eucalyptus oil.

A remarkable substance shown in the British Guiana Court, called karamanni is deserving of notice on account of its low melting point and its great tenacity. It appears to be a mixture of the yellowish resin known as hog gum, the product of *Moronobea coccinea* and beeswax, and may be compared to marine glue for its usefulness.

Gums.

The India Court was undoubtedly the richest in gums, but many of these are collected so carelessly that their commercial value is much reduced thereby. Only one of them, that of *Anogeissus latifolia*, at all approaches gum arabic in character, but none of those as yet examined appear to be capable of entirely replacing the Soudan gum. For this purpose the gum should be easily soluble in cold water, give a clear mucilage of an adhesive character, should not be darkened by iron salts, and the froth formed in dissolving it should quickly disappear.

A very good sample of gum was shown from Gambia, which bore a strong resemblance to the Soudan gum. From the Cape of Good Hope the gum of *Acacia horrida* was shown. This resembles gum arabic in appearance, but is somewhat yellower and gives a weaker mucilage. A much better gum has, however, recently been sent from the Cape than the sort generally received from that colony.

The Gums shown in the Australian Courts were of the usual dark-coloured characteristic appearance. In the West Indian Court were two gums worthy of notice. One of these, the gum of *Anacardium occidentale*, dissolves but slowly, but makes an adhesive mucilage which is used in Jamaica as a substitute for gum arabic. It is obtainable in large quantities. The other was that described under the name of white cedar gum. It does not possess adhesiveness, but a small piece gives a thick mucilage with a large quantity of water, a quality which if the gum proves to be harmless in character might prove very useful for suspending powders in mixtures, or for sizing purposes.

Saccharine and Dietetic Substances.

Of the official substances of the character, honey was exhibited by the majority of the colonies, but the finest display was that made by Canada, which exhibited two varieties, called clover and linden honey, which in point of colour and flavour left nothing to be desired.

Tamarinds were exhibited in several Courts, those from the West Indian Court being particularly fine.

Lime juice was largely represented by the exhibits of the Montserrat Company, and good specimens were also observed in the Dominica and Trinidad Courts.

In connection with lime juice, a specimen of citrate of calcium shown in the Trinidad Court may be mentioned. It is well known that both lime juice and citrate of calcium gradually lose citric acid, probably through decomposition caused by fungoid growths. Mr. McCarthy claims to have succeeded in preparing the citrate so that it will keep, if not exposed to air and moisture, without loss of the acid.

There were doubtless many food products in the Exhibition, that might be employed either as diets for invalids or in the manufacture of palatable laxatives. I will only mention a few of them. Cassava root, dried and used like arrowroot, has already been experimented with in the National Training School for Cookery at the request of Mr. G. H. Hawtayne, and the Lady Superintendent has reported very highly of its value as a variety for invalid or infant diet. Certain it is that the natives who feed on cassava rapidly put on fat. The curious preparation known as cassareep in British Guiana and the West Indian Islands also deserves notice as a harmless addition to food, possessing at the same time valuable antiseptic properties. Cassareep is prepared by evaporating the poisonous juice of the bitter cassava, which loses during evaporation the prussic acid it contains as well as a volatile poison described by Dr. Peckolt (*Pharm. Journ.*, [3], xvii., p. 267) under the name of manihotoxin; but the antiseptic properties, due to a substance with Dr. Peckolt has named sepsicolytin, or fermentation hinderer, is retained in the cassareep. Albumen to which a small quantity of sepsicolytin had been added is stated to have been kept without deterioration for six months. The value of a harmless antiseptic for preserving food can hardly be overestimated. The advantages of cassareep as an adjuvant to diet is also worthy of investigation.

In conclusion it only remains for me to express my regret that it has been possible to allude to so few of the many very interesting exhibits related directly or indirectly to pharmacy.

I gladly take this opportunity also to thank the several Commissioners for the Colonies, who have so kindly lent a number of valuable specimens for this occasion, without which the remarks that I have made would have been almost valueless.

I desire also to record my most cordial thanks for the courtesy that I have received at the hands of these gentlemen during frequent visits to the Exhibition, in allowing me to examine specimens, and in affording all the information in their power concerning them.

DISCUSSION.

His Excellency C. A. MOLONEY, C. M. G., Governor of Lagos and President of the Gambia Commission, said his only knowledge of pharmacy was that derived from taking cinchona, which, or the quinine derived from it, was a necessity of life in West Africa.

The economic botany of West Africa was comparatively unknown, and its agricultural development was in its infancy; its growth would be mainly dependent on the establishment of either agricultural branches of the Government nursery gardens or some allied institutions in Government hands. Private enterprise had been tried, but it had, it was to be much regretted, signally failed, and the results were comparatively nil. In reference to allusions in the lecture, he would say that Calabar beans could be supplied in any quantity if required. With regard to kino, he himself sent to the Forestry Exhibition in Scotland two years ago a very fair specimen of the extract, but he heard nothing further of it, and therefore presumed it was not wanted. The *Jatropha Curcas*, was grown largely in the Cape Verde Islands, and it grew wild in West Africa, but no particular attention was paid to it, although in the Cape Verde Islands the export of its seed was about 300,000 bushels a year. The melon seeds were used not only for extracting oil from, but also largely as food: he presumed the lecturer referred to egusi seed. The trade in gum was quite in its infancy. For some years there had been a considerable export of it from Sierra Leone, and to a small extent from the Gold Coast, and he was rather surprised, when he was Governor of the Gambia, to find to the right and left of that enormous river the export of gum from Senegal represented by millions of money annually, and that a little further south, at Sierra Leone, there was also a large export; but none from that particular district. From the Gold Coast, further south, the export had been very limited, but the field was very extensive and deserved every encouragement. Now, South of Lagos, his present Government, there was an immense field for the export of a fossil gum, known as Ogea. He had directed attention to this for some time past, but it had had no commercial result as yet. About two-and-a-half years ago he had a few hundredweights sent to England, which was passed through a prominent manufactory, and when he inquired the result, he was told that it was very difficult to introduce a new article, but after some questions he found that it might prove worth from £80 to £120 a ton, and that large quantities could be readily taken.

The two previous speakers had referred to the advisability of investigating the native practice of medicine; as a medical man he had given some attention to that subject, and he found that in India there was very little to learn. A great many of

the preparations used were very much of the type of mummia, and were in fact the most loathsome things that could be imagined. There were in India some two thousand plants of a medicinal nature more or less used by the people, but not more than forty or fifty were worth the least attention. It had been said that many of the specimens in the India Court were very imperfect, and no doubt they were; many were of no interest to anyone but the native doctors who never by any chance used drugs until they were eaten through and through with insects. They stored them until they were perfectly rotten, and in many cases it was impossible to get drugs in any other way than by going to these people. He had forgotten to mention one or two facts with regard to ganja. It was made from the female flower-heads of the plant, and it was a most remarkable thing that if you left one single male flower in a whole field cultivated for ganja not a single particle would be produced. The bhang was obtained entirely from the wild plant, but ganja could not be made from it because in that state the male plants grew with the female; of course by male and female he meant plants with pistillate and staminate flowers. Long before the flowers were produced the native ganja doctor came round to the cultivator, and having agreed on his fee, crawled away underneath the tiny little plants, and with a knife slipped every male plant out of the field. He had often followed the ganja doctor, though without being able to discover, even with a microscope, how he distinguished the plants, but it was marvellous how successful he was, and it was rarely necessary to go after him to remove a male plant. The female plants were allowed to reach maturity, when they were cut down and taken to the manufactory, where they were trodden under foot to produce the flat and round forms. The earth was hollowed out and the plants were all laid with their heads in the hollow and rolled with the feet; he believed that in some way the rolling shook out something in the round form which made it much stronger than the flat; it was more condensed, and a given weight contained more of the extract. Mr. Holmes had referred to pale catechu, meaning he supposed, gambier, which was eaten all over India; but there was another substance which was also used, real pale catechu, or acacia catechu. They had also a form of cutch which was quite as pale as that shown obtained from the acacia catechu, and that also was more extensively eaten than that exhibited. The red cutch was never eaten at all. He did not know exactly the chemical difference, not having examined them with sufficient accuracy to determine, but there was a difference, and the process of preparing the two kinds was quite different. In Pegu the tree was cut down, the bark removed and the hard wood split up into little fragments; these were put into large iron caldrons and boiled down until a thick decoction was obtained; this was then thrown into moulds made of the teak wood leaf and allowed to harden. A layer of leaves was put over the top and another coating thrown on, and thus the ordinary red cutch was obtained. In Northern India, another preparation was made. The plant was treated in the same way, but it was boiled in earthen caldrons and to about one half the extent; the pots were then taken off the fire and a number of twigs put into each, on which the substance crystallized much in the same way as sugar candy on a thread. The twigs were then removed, the crystals shaken off, again put into hot water and made into a sort of mucilage; it was then thrown into moulds and made into cakes like gambier, only larger. This was a more carefully prepared article. The pale cutch of Northern India was in fact very much like gambier and took the same place in pharmacy and as an article of food. Cardamoms were also largely grown in India. The seeds of melons were also used for making oils to a large extent, and so were tea seeds. With reference to the gums, he might say there was a resin in India which was used for a curious purpose. It was from the *Shorea robusta*, known as the saal tree, and was extensively used for soldering broken pots. Any metal pot that got cracked was joined together again with saal resin, and he had seen such vessels in use on a roaring fire years after they had been mended in this way. He should think this resin was worthy of attention.

Mr. BOSISTO, President of the Victorian Commission, said:—It would take too much time to mention all the medicinal plants of Australia, but it had not such a grand field of medical products as India and some other countries. There were the eucalypti, a number of acacias, and some melaleucas, particularly the *M. Leucadendron*, which gave an oil resembling cajuput oil. There were also a great many which yielded aromatizing oils, but he did not think they were of any great value in commerce. Then there was the *Atherosperma moschatum* bark, in common language called the native sassafras bark, but it was not a sassafras. It contained a very fine bitter, and also a volatile oil of high specific gravity, two drops of which would almost stay the action of the heart, and this was well worth attention, and should be brought before the medical men of Great Britain. Many years ago he brought it under the notice of some of the leading medical men in this country, who reported well of its action on diseases of the heart, but it seemed to have been lost sight of again. There were 150 species of *Eucalyptus*, which yielded a vast variety of essential oils that contained many aromas, more particularly one, a native of Queensland, and which was also grown in Victoria, *E. citriodora*. He thought if the colonists would pay more attention to it, it would yield a good profit. There were many other aromas, but they were too far away from population to be brought into commerce. People in England would always speak principally of the *E. globulus*, but the fact was that was considered in Australia to be the worst of the whole lot. *E. dumosa* and *E. amygdalina* were the chief species of value for medicinal purposes. He had had the pleasure of presenting to the Society some essential oils of the ordour, *Myrtaeeæ* which he guaranteed were true to species, and therefore when any of the young men present examined them he hoped they would pay attention to the labels, and not look upon them all as *E. globulus*.

Mr. SHAND, Official Representative of the Ceylon Planters' Association, said he was not a scientific man, but a practical agriculturist, and the drug in which he was principally interested as a producer was cinchona bark. He wished the honorable representatives from West Africa and British Guiana, who laid stress on the utility of this bark, could, without any prejudice to themselves, consume a great deal more of it, because so much was now produced in Ceylon that the markets of the world were completely glutted. Cinchona seed was first brought into Ceylon in 1861 as an experiment, and fortunately it fell into the hands of an excellent scientific man, the late Dr. Thwaites, head of the Royal Botanic Gardens, who from the first recognized the adaptation of the plant to Ceylon, and urged on the planters the desirability of cultivating it. They were all so wedded to coffee at that time that to a great extent they neglected this matter, and for several years the cinchona cultivation was only carried on experimentally. In the years 1874 and 1875 they exported 4,000 lb. of bark, and in the two following years only 15,000 or 16,000 lb.; what led to the great rush of cinchona cultivation was a little enterprise with which he himself was connected. In 1874 he was manager of a group of estates, a small portion of which had been accidentally, devoted to cinchona for the following reason. In Ceylon they suffered periodically from the ravages of rats. There was a jungle tree, the nelu, which periodically died down, and when it did so the rats which had been in the habit of feeding on the pith came into the clearings and attacked the coffee. Almost the first cultivation of cinchona in Ceylon was on a small plot of about two and a half acres where the coffee had been completely spoilt by the ravages of rats. In 1874 the cinchona trees were eight years old, and it fell to his lot to harvest it. The result was most wonderful; from that two and a half acres he reaped 15,000 lb. of good cinchona bark. Not much was known then about the preparation of it, and the only process they knew that was likely to render it marketable was the quilling process, which had now to a great extent been superseded. He took great pains in that matter, getting cinnamon peelers, who formed a special caste in Ceylon, and

the result was a fact almost unprecedented in any agricultural enterprise, for that one harvest resulted in a yield of £600 sterling per acre. That naturally led to what was commonly called a "boom" in cinchona agriculture. He himself came home the following year and telegraphed out at once to his brother to purchase 1,000 acres suitable for cinchona. The history of the cultivation was like that of many others, accompained by disappointments, for although Ceylon planters had flooded the markets of the world, they had not all been successful. If all the cinchonas planted in Ceylon had reached maturity there would be ten times the quantity in the market, and all present would allow there was quite enough, because the unit of cinchona for which when he began he used to get 2*s*. had now fallen to 2½*d*., and did not show much prospect of rising. What he complained of was that though he had to suffer very severely in the prices realized for the bark, when he went into a chemist's shop in London to buy a quarter of an ounce of quinine he had to pay an enormous price for it. He did not know if anything so commercial were within the range of the Society, but if it were he wished they would pay a little attention to it, because it was held out as a great inducement in the beginning.—Never mind how much you send, there will be the grand result of conferring an inestimable boon on humanity, because you will place cheap quinine within the reach of the very poorest people. He hoped for the sake, at any rate, of the cinchona growers in the East, that every effort would be made to disseminate the use of it throughout Great Britain. Cardamoms had been mentioned, and he was sorry to say that they also in Ceylon had been so completely successful that their success led to failure, the price having come down to one-third of what it was two years ago. This would show that they were a go-ahead people in Ceylon, and what he wanted to know was what other drugs they could supply the English markets with. They had suffered very much in the cultivation of coffee from having all their eggs in one basket, and he was very much afraid they were inclined to go to the same extent in tea. He was quite sure that there were many drugs which could be profitably carried out as adjuncts to other enterprises. On one point he was a little in opposition to Dr. Watt, for he must say he attached great value to the native remedies which were in the hands of native doctors. He had derived benefit from them himself, and had thought that the scientific gentlemen who came out from medical colleges to the East made a great mistake in not exchanging ideas with their native brethren, and in looking down upon them too much. In the use of vegetable oils, especially in rheumatic affections, he had derived great benefit. Very often natives possessed remedies and secrets which were still unknown to the Pharmacopœia. Mr. Holmes had been described by Mr. McCarthy as a persistent beggar, but he must say that if so he had deceived him because he came to him a day or two ago in the guise of a borrower. Still he must say, after the privilege he had had of being there that evening, he should be most happy to present to the Museum the samples which were to have returned, and as long as his connection with the Ceylon Court lasted, if there were anything else Mr. Holmes would like to beg or borrow he should be most happy to present it to the Museum.

Mr. Umney drew attention to the very fine samples on the table of vanilla which came from the Seychelles, and it might be interesting to inform the meeting that Dr. Brook, whose name had been so favourably referred to in the paper, had much benefited in the harvesting and curing of his vanillas by a report which appeared in the *Pharmaceutical Journal* some years ago. It would seem, therefore, that even on this side they could be of great service to gentlemen in the colonies. What made the Seychelles exhibit of more interest, also was, that some two or three years since he sent out a pharmaceutical chemist, who for many years was with the old firm of Jacob Bell, and it was through him, under Dr. Brook's direction, that these essential oils had been placed on the table, and when in the Museum he felt sure they would be well worthy of examination. There were essential oils of geen cloves, dried cloves, green stems and dried stems, and chemically there was very little difference between them. He was sorry to say that in the drug market they did not always appreciate these goods when they came in, for only last week a large parcel of essential oil of cloves was offered at the drug auction in Mincing Lane, and with very great difficulty a purchaser was found, because it was thought to be adulterated, coming from abroad. Another exhibit was that of turtle oil, which he looked upon as one of the most nauseating things which could be taken. Dr. Brook assured him that the natives took it in the place of cod liver oil, but its power of repeating probably could not be equalled. He had tried to introduce it, but no one would take it up.

Mr. David Howard said, there were on the table some of the most beautiful specimens of cinchona barks he had ever seen, and they were interesting in two opposite ways. One was about the most typical specimen of what was the very finest calisaya quill bark of his younger days; another was calisaya bark, no doubt of a similar strain, from Perak; but you could hardly have two things less resembling one another, and after a great many years' experience he should have called it a very inferior sample of red bark. Yet he had very little doubt that the analysis would be very satisfactory. One could by no means judge entirely by the eye. Again, there were two samples from Jamaica; they were very familiar to him, one of the very finest strains of succirubra bark he had ever met with, and a very fine specimen of calisaya bark. But in appearance the calisaya bark looked like a very nice sample of red bark, and the succirubra looked like a very fair sample of calisaya. Yet botanically, and as far as tests went, there was no doubt they were each a most excellent strain of its own kind. Mr. Holmes had mentioned the very high prices given for fine quill barks for pharmaceutical purposes, and it was not entirely a mistake to do so. Of course to the manufacturer anything which would give quinine was valuable. He did not much mind how much cinchotannic acid or resin he had to deal with if he could get rid of it; but on the other hand for galenical preparations there was no doubt that fine quills were infinitely better than barks that might be much richer in alkaloid. He did not see any specimens of succirubra, which was now the official bark, but there was the renewed bark, a most interesting and valuable specimen. With regard to the crispa he might say that the knotty appearance was not essential to the true crispa. In some varieties it grew with an exceedingly thin epidermis. This knotty tendency was noticed by Jussieu a good many years ago, but so far as it went it was a disadvantage. The cork did not contain any quinine, as far as could be discovered; only mere traces were found, and he believed they were derived from small portions of the real bark, which it was difficult to remove. The crispa with a fine thin epidermis was really the best. Having forsaken his hereditary pharmacy for chemistry he might put in a word in favour of applying chemistry to some of these new drugs. There was a beautiful sample of coca leaves, and there could not be a better example of how chemistry and pharmacy should work together than the history of cocoa and cocaine. When it was first brought over it was on account of the great value the natives attached to it, and the great benefits they found to arise from it; but curiously enough its first introduction into English therapeutics was comparatively a failure, and it did not appear to have the merits ascribed to it. He believed it was simply because they had hardly discovered what its merits were. It was assumed it was simply a beneficial drug to stay hunger, without having any idea how it was. Then chemistry came in and cocaine was extracted. It was at first a curiosity, but then its anæsthetic property was noticed. He would point out, therefore, that it was entirely owing to chemistry that it had become possible to utilize this property, since a heavy dose of cocoa leaves in the eye would not be wholly desirable before an operatation. It appeared to him that many of these comparatively unknown drugs should not be merely dealt with galenically, but chemically also. If you could get a definite principle from them to operate with you might, as in the case of coca leaves, trace the actual cause of the value which had been discovered by the natives by long practice, and having got the real cause of the value it might be applied far better to pharmacy under altered circumstances than

by merely trusting to the information of native doctors. They were no fools, and had found out by long experience and wonderful skill a great deal more than we gave them credit for, but by taking their experience, and bringing modern science to bear upon it, the best results would be obtained, and it would thus become possible to dispense with some of the elegant forms of pharmacy of which they had heard. The question of new drugs wanted a great deal of study, and a great deal of hard work, but like all other things you never got any good results without hard work, and you never did hard work without some results.

Mr. CHARLES CHRISTY said, that recently some remarkable specimens of gums had been received from India, but up to the present time there was no gum which had come under his notice which would supersede that from the Soudan, known in Commerce under the name of "Turkey sorts." This sold, before the breaking out of the Soudan war, with difficulty at 35*s.* to 40*s.* a hundredweight, but at the present moment it was worth £10 to £11. What was wanted was some gum to replace it, and it seemed a very strange thing that they had not yet been able to find one. What was wanted was a sweet gum, which could be used medicinally as a mucilage. The gums hitherto brought forward were more or less of a bitter nature, containing a large amount of tannin, and the consequence was when used for dyeing purposes, if the dye contained any mixture of iron it turned black. He hoped the gentlemen from the different colonies would bear this in mind. They were getting gums from Australia, but none of them that he knew of were of the sweet character which could be used in pharmacy. The nearest thing to it was the produce of Senegal. The vanillas from Seychelles were much finer than were generally seen in commerce.

Mr. STOCKMAN said he had been carrying on some investigation on the Borneo camphor which Mr. Holmes kindly sent him two or three months ago, but he could only speak at present in a very general way of its action, chiefly in comparing it with ordinary laurel camphor. There was no doubt that the earliest camphor brought to this country was Borneo camphor, and the earliest experiments about one hundred and fifty years ago were probably carried out with this substance, but they had got so mixed up that at the present time it was quite impossible to say which kind was used. Lately, owing to the difficulty of getting Borneo camphor, some experiments which were made in Germany were made with an artificially prepared substance, as it only required two atoms of hydrogen to be added to ordinary camphor to make Borneo camphor. But these experiments were few in number and incomplete, and he believed the investigation he was now carrying on was the first which had been made with Borneo camphor. Physiologists usually began with frogs, and with them the action was very much the same as that of common camphor.

Mr. KEMP (Bombay) said he had been much interested by the remarks on Indian drugs, but the science of modern therapeutics he really believed was in a very early stage, although the materia medica of India was very ancient; many articles had dropped out of use, and might be taken up with great profit for modern investigation. It was said that sandal-wood oil as imported from India was much adulterated. He was not aware that sandal-wood oil was exported from India in any quantity, but it was certainly produced in considerable purity, the only adulterant being moisture. It could be obtained in considerable quantities and good quality, if care were taken in selecting specimens. It was principally distilled in the Mysore territory. In Australia it was preferred in many cases, whether from its superior cheapness or from its quality he could not say. It was not exported in the crude state in which it came into the market, but was either re-distilled or carefully filtered. With regard to the *Cannabis indica* he had no knowledge, but when in India he had had repeated applications from persons in this country for it, as he understood to apply the Cooly markets of the West Indies, and other colonies where it was used in large quantities, and he understood that was its destination. The kind in demand was the round top, generally imported in bundles of 1 lb. each, which was exported from Calcutta and possibly through Bombay from Bengal. The Bombay cannabis, Dr. Watt has said, was of the flat kind, which abounded in stalks and probably that was one reason for its inferiority. Mr. Holmes had also mentioned oil from melon seeds, and he might remark that although melon seeds were obtainable only in small quantities in India, they yielded about 25 per cent of oil and were very good for feeding purposes. The *Jatropha Curcas* was used to a considerable extent in India, and he should like to see it come more into the market. Another drug not mentioned was the *Ipomea cærulea*, one of the convolvulus family, the seeds produced a resin resembling that of the jalap, if not identical with it, and it yielded about four or five per cent. He imagined it would be a profitable source of jalapin. He hoped the scheme of the Institute would be taken up and thoroughly carried out, for really, London being the central market of the world for drugs, there was a better opportunity for studying the Indian materia medica here, both in a theoretical and practical form than there was to any ordinary person in India, and this would be still more the case if the Institute were established. The difficulty in India was to communicate with the depositaries of the native medicines owing to the multifarious languages they spoke, and the different accounts they gave of the different drugs, and the way in which they locked up their medical knowledge in their own breasts. Dr. Dymock, in his recent work, had done a great deal to overcome these difficulties, and his was one of the most accurate and interesting books published on the subject. He had often heard him refer to the great assistance he had derived at various times from Mr. Holmes.

Mr. THOMAS CHRISTY said it was very interesting to see these valuable exhibits, but after all Mr. Howard had really touched the vital point:—How were they to be turned to account? On an occasion like the present he might be allowed to say that although the young men coming on might be able to work at these things, the next thing was to get them used.

Mr. LEOPOLD FIELD said there was only one point which came within his ken as a practical soap and candle maker, and that was the remark made by Mr. Bosisto with regard to the eucalyptus. For the last two years his firm had been trying to get hold of something besides the globulus, but found the Australians unwilling to let them have any, and he did not believe there was one gallon of the dumosa oil to be obtained in the market.

Mr. BOSISTO said they never sent a pound weight of *E. globulus* oil into the market.

Mr. FIELD said it was labelled so at any rate.

Mr. BOSISTO said he must emphatically contradict that. He had only one label, and that label, was rigistered.

Mr. FIELD said he did not allude to Mr. Bosisto personally at all. The oil they obtained always came to them in iron tins holding about fifty-six pounds, and it was labelled *E. globulus*, and sometimes by way of change *E. amygdalina*, for the two things seemed exactly the same. They had had one sample of *E. dumosa*, which was vastly superior, and they had tried to get it again and again, but they had never been able to obtain a similar oil. They had now sent out an extensive order hoping it would induce the distillation of this oil. Naturally their only knowledge was derived from those standards which came under their notice, and if they were supplied with the wrong article, how could their knowledge be correct? With regard to the various scents which the eucalyptus and its isomers were capable of assuming, they were of the greatest value and interest to the soap maker. The lemon-scented iron bark, which he believed was the citriodora, was to him a most interesting substance, and no doubt might if worked into soap give the public very great satisfaction, inasmuch as the odour appeared to be pleasanter than lemon grass, and not so sickly as that of citronelle. All the odours the various eucalypti

were capable of assuming had the peculiar property common to camphoraceous odours, and no doubt the soap maker would be able to utilize them largely. But it all pointed to the necessity there was for some competent authority in these subjects, and especially of having a Museum where these things should be distinctly and correctly labelled. He was not aware that they derived their samples from Mr. Bosisto's firm; they had got them through the London brokers, and did not know where they came from. He knew they had got very different things under the same name, and that what they really wanted they could not obtain at all.

Mr. Hall (of Messrs. Edward Cook and Son) remark that essential oils were of great interest to soap makers. He was also interested in the beautiful specimens of white coconut oil from Trinidad. It would be very desirable to have a coconut oil without any scent, but at the same time it should be of a white colour. Most of those oils could be used by soap makers, but they only came into their hands when produced in such large quantities as to be cheap.

Mr. Holmes, in reply, said he thought the gums referred to by Captain Molony were resins, though they were called gum in commerce. The gum Mr. Christy alluded to was a gum soluble in water, and that was much wanted at present—one which possessed adhesive properties and which would not darken when a little iron of salt was added to it. There was no question that the resins or gums to which Captain Molony alluded were much more largely used than adhesive gums, and were very important articles. Mr. Shand had greatly excited his curiosity with regard to the oils that cured him of rheumatism, and he should be very glad to know what they were. With reference to the cinchona crispa, there was a specimen in the Museum, sent from Madras and analysed by Dr. Paul, which gave very good results, quite within the requirements of Pharmacopœia. He merely alluded to that variety as exhibited to pharmacists because no one could make any mistake about it. Mr. Howard's remark that sometimes specimens came over without that peculiar corkiness interested him very much from a botanical point of view; because anyone who had observed the common birch tree would know that when young it had one of the smoothest barks, though later on it developed cork abundantly. The same might be the case with the cinchona crispa. At all events the corky form was easily recognized, and there could be no mistake about it, because no other cinchona was at all like it. With regard to the coca leaves not being valued when they first came over, he thought it arose in a great degree from the fact that the leaves were of a very bad quality. When the price went up very much better leaves came over. He would direct Mr. Charles Christy's attention to the gums from West Africa in the Gambia Court, which had very much the appearance of gum arabic, and also to some of those from Mexico. With respect to the *E. globulus* he should be glad to show Mr. Field at any time the specimens named true to species which Mr. Bosisto had kindly presented to the Museum, and he would be then able to judge of the kind required. He believed that the *E. globulus* in the English market had come to a certain extent from Nice, and also from San Francisco, but where else he did not know.—*Pharmaceutical Journal.*

WHAT THEY SAY IN "THE LANE."

That they don't want such heavy sales of Indian tea three days before Christmas.

That since the 1st of June there have been about 100,000 packages more Indian and Ceylon tea printed for public sale than in 1885.

That according to reliable estimates this extra quantity sold to date represents nearly the whole increase in the crop over last season.

That the necessary tasting and valuing of such a largely increased quantity has been extremely trying and laborious to both brokers and dealers.

That two weeks cessation of business in the markets whilst travellers were off work, and grocers too busy to look at tea, would have afforded the overworked tea tasters of Mincing Lane a chance of recruiting their energies for the heavy trade of January and February.

That the importers and the selling brokers in forcing on such heavy sales, and thereby curtailing the holidays, have raised up a very unfriendly feeling which far more than counterbalances any supposed gains.

That in consequence of such heavy sales having taken place just on the eve of the holidays, all the buying brokers and dealers are full of stock; and as they have no chance of selling it till the second or third week in January, the new year bids fair to open flatly.

That unless Ceylon planters pack their tea in larger breaks there will soon come a deadlock in Mincing Lane, and a considerable decline in value of Ceylon tea by reason of buyers being unable to see all the little lots.

That those who divide up fairly large-seized breaks in Calcutta into three or four divisions, thereby necessitating fourfold labour on the London tasters when the separate divisions have to be valued in Mincing Lane, deserve condign punishment.

That if the practice be not discontinued, a committee of buyers will be formed to trace all such divided lots and refuse to bid for them.

That the old motto of "Live and let live" has been changed to "Every man for himself and devil take the hindmost."—*H. & C. Mail*, Dec. 31st.

Tea in the Andamans.—Ten years ago the Government tea garden in the Andaman Islands started with an area of 3½ acres, which last year had extended to 288¾ acres. The out-turn of tea during the year amounted to 26,600 lb. and of this quantity 23,273 lb. were sold.—*Madras Mail.*

Granadilla and Tree Tomato.—In Covent Garden Market may now be seen fruits of the tree Tomato, Cyphomandra betacea, labelled as Granadilla, which is an error, as that name applies to the fruit of the Passion-flower. The fruit of the tree Tomato is cooked and made into a kind of jelly. It was highly recommended by Mr. Morris when in the West Indies but it does not find so much favour in India. We believe the market is supplied from the Azores.—*Gardeners' Chronicle.*

Pearl Fishing by Electric Light.—The steam yacht "Chic," belonging to Messrs. Alley and McLellan, engineers, Glasgow, which has been berthed in the Greenock harbour for the past few weeks, has been fitted up with a Brush dynamo for the purpose of suiting her for the pearl fishing in South Australian waters. The "Chic" left on Saturday for the Gareloch, where she will remain until the arrangements are complete for fitting up the electric lamp.—*Electrical Review.*

Another Ceylon Tea Company.—Companies interested directly or indirectly in Ceylon tea are becoming numerous. The Ceylon Tea Growers Limited, is the name of a new undertaking registered a few days since, with a capital of £6,000, divided into 600 shares of £10 each. It is formed to carry on as principals, consignees, agents, or otherwise, the business of importing and dealing in tea, coffee, cocoa, cinchona, and spice, and other produce grown in the island of Ceylon, and other places, and to acquire the business of Messrs. Delmege, Collinson and Whitham, of No. 1, St. Michael's House, Church Alley, E. C., and to acquire certain trade marks. The first subscribers are:—H. Whitham, planter, Ceylon, 1 share; A. Delmege 17, St. Helens-place, E C., 1; J. R. Collinson, planter, Ceylon, 1; R. Godfrey, planter, Ceylon, 1; A. H. Reid, clerk, 17, St. Helens Place, E. C., 1; W. Hollick, 28, Barnsbury Park, N., 1; A. Hutchinson, merchant, Chingford, 1.—*Home and Colonial Mail.*

HOW TO USE GAS-LIME.

This substance should be freely exposed to the air for two or three months before applying to any soil on which is a growing crop, because, besides many sulphides, it contains a compound of sulphur and cyanogen, that is very deadly to plants. In anticipation of a Turnip crop, it may be applied to the fallow up till, say, February, which would allow sufficient time for oxidation to alter the poisonous qualities of the cyanogen. It is, perhaps, best to slightly harrow it into the stubbles after they have been ploughed because in this case the ammonia—or a portion of it—resulting on the conversion of the cyanogen will be retained in the soil if there is in it lime, salt, kainit, or substances containing bases on which the ammonia can form as nitrates. This simple view of it may be borne in mind in making it into composts, for unless there are substances on which the ammonia can form, it will combine with carbonic acid and escape into the air. The compost should therefore contain a little superphosphate, salt, or kainit, or even a small portion of old lime. But in making a compost heap it must be kept well away from a growing fence or the roots of valuable trees, or it will kill them.

I may add that in my experience it is the most effective substance that is to be had for the destruction of fungoid and insect pests in the soils, and applied to the fallow as above, at the rate of about 5 tons per acre, there need be little fear of finger-and-toe.—"FARMER," *in the "North British Agriculturist."*

COCONUT OIL.

Referring to the recent discussion on this subject in our columns, a Merchant who has had longer experience perhaps, than any one in the Island in the Oil trade, informs us that Cochin Oil has always been considered richer in stearine than Ceylon Oil. The fact must, therefore, have been ascertained by analysis in England, where Cochin, we are told, has been mainly used in the manufacture of candles. Ceylon being chiefly used for soaps. Even for the latter purpose, Cochin beats Ceylon owing to its whiteness, which we are now emulating and which, we fancy, can easily be attained by the rejection of smoke-dried and blackened Copperah. Wether this is worth striving for is another matter, the decision on which must depend on results. If it pays the manufacturer better to purchase black and inferior stuff, which generally goes by the name of cart Copperah, at R4 or 5 a candy less than clean white boat Copperah fetches, he will continue to use it in his Mills. The question is whether the difference in price between white Oil and ordinary Oil is sufficient to compensate for the higher rate demanded for clean sun-dried Copperah, for which there is a good inquiry both in continental Europe and in India. The distinction of being first in the list of Oil-producing countries will hardly be sought for by mill-owners at the expense of their pocket.

The question of stearine is different from that of the whiteness of Oil, and it is in respect of the former that the Agricultural Association should institute inquiries. Is the poverty of stearine due to deficiencies in the soil, or to the mode of preparation? If to the former, how can the soil best be enriched in the constituents it needs; if to the latter, what changes in the mode of drying the kernel and extracting the Oil are called for? The services of an Agricultural Chemist are in any case needed, and should be put into requisition, so that by analyses of soils, Oil and Copperah, a solution of the difficulty may be suggested. Even to the unprofessional mind it must seem reasonable that ripe nuts should be richer in stearine than immature ones; but does the mode of drying them also affect the fatty substance in Oil which gives it its special value? If the temperature at which Oil congeals is a test of its richness in stearine, it is worthy of note that cold drawn Oil, or Oil extracted from the kernel slightly dried congeals sooner than ordinary chekkoo or Mill Oil. This would seem to suggest that too much heat, whether in drying the kernel or extracting the Oil reduces the stearine. The inquiry is an interesting one, and may beneficially affect our trade in Oil, and as such deserves the attention of the Association. The normal difference in price between Cochin Oil and Ceylon is, we are assured, only from £3 to £4—the difference of £11 per ton recently reported being confined to London, and due to some jugglery among speculators. Still, a difference of £3 to £4 is not immaterial, and is worth striving for.—Local "Examiner."

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, Nov. 27th.

The Marquis de St. Aigan finds fattening calves remunerative. He depends for his success on a special part—substitute for milk, composed of 132 lb. white maize flour, 22 lb. linced meal, 64 lb. cooked pea meal, 2¼ lb. beetroot sugar, 2¼ lb. phosphate of lime,—at a cost of 44 frs. The flour is blended in cold water, then cooked in a *bain marie*, and given to his calves daily during their first month at the rate of six ounces in two-thirds of a gallon of water, mixed with the same quantity of milk. From the thirtieth to the forty-fifth day the milk is diminished and discontinued at the latter date, when the meal-mixture is doubled, and given in 1½ gallon of water. The following twenty days the mixture is raised to 18 ounces and the water to two gallons. Following the season, the calves have always within their reach tender herbage, or cut mangolds dusted with barley meal. After the 75th day, the calves receive no more of the compound; they are given ¾ lb. of maize flour, and the feed of grass or roots is increased. If the season permits they are turned into a meadow. When aged six months the calves are treated as ordinary stock. The Marquis buys the calves in his neighbourhood and they are always the progeny of good Normandy cattle. With four milch cows and the substitute milk diet, he rears 80 calves yearly. He attributes much of his success to his good pasture land. Phosphate of lime is gradually creeping into use as an aliment, the average dose being quarter of an ounce daily. It is best given when mixed with some wetted meal or cooked roots; for poultry, the grain is first moistened and then dusted with the phosphate. The same process for horses.

Some persons maintain that the exuded sap from vines when pruned is not a loss of strength and so not debilitating for the plant. Others view the exudation as a sign of health and strength. Hales proved that the sap which overflows can ascend in a glass tube as high as 21 feet, and could raise a column of mercury to the height of 32 inches. Now when the leaves unfold this sap, ascension diminishes. In pruning the vines the large wounds are often covered with putty, the smaller cicatrise themselves. The development of the roots can diminish the flow of the sap and the Southern exposure of the stems can augment it; but temperature, humidity and rain, exercise an important influence. Sachs laid down that the development of the roots, the capillary force of the cavities of the wood and the changes of temperature act, and differently on the ascent of the sap. However when the leaves commence to function, the roots cease to develop while serving to maintain as well as capillary action, the ascending column of sap. The liquids imbibed flow out at the cut sections when the heat dilates the fluids and gases in the plant.

It is not then a matter of indifference in Spring to judge beforehand when the sap will flow most abundantly. One day nine times more sap will exude than on another. Hence, if the soil permit, prune vines early; if it be necessary to perform the operation later, select a cool day, commencing with those varieties which develop leaves and roots most rapidly. Late cutting tends to produce irregular development, late flowering and hence late ripening.

Plants have two marked and different functions: the leaf-organs by their green matter when acted

upon by the sun decompose carbonic acid and give off oxygen. This is a process of nutrition since by that decomposition the plant assimilates the carbon for its tissue. On the other hand the branches, flowers, fruits and seeds absorb oxygen and emit carbonic acid. Respecting the roots de Saussure has laid down in a general manner that oxygen is indispensable to them. Messrs. Vesgue and Deherain have concluded their experiments showing that the roots must find in the atmosphere of the soil, oxygen, just as the leaves obtain it in the air. The root however disengages but little carbonic acid; thus little, is not due to any decomposition of the plant's organs, but to the regular circulation of the gas in the plant.

How to obtain heavy crops from the soil and at the same time secure for them a good market price, are the problems engrossing all attention. French farmers have been leaning to the raising of cereals, as the road to remunerative culture, but were all to do likewise, France would be a granary of abundance, and excess would reduce profits below zero, then it is never prudent to put one's eggs in a single basket. These considerations lead to the new departure of keeping cattle simultaneously with grain raising, falling back, where required on the market for a supplement of fertilizers.

The question of the exciting property of oats as a measure of their feeding value, is again being discussed. It is admitted that this stimulating or exciting virtue resides in the pericarp of the grain and is highly nitrogenous. It acts powerfully on the motor-nerves. It exists in oats in a different degree varying with the soil on which it grown. Black possess a greater percentage of this stimulating substance than white oats; crushing the grain lessens its stimulating action. The duration of the influence of this exciting influence is estimated to be one-half hour per each pound of whole grain.

Dr. L. Hecht, has tried to produce a cereal by crossing wheat with rye, and thus obtain a grain with a tendency to ripen earlier and perhaps in suiting poor soils might thereby enhance their value. The flower of wheat is hermaphrodite, that is capable of impregnating itself like an oyster. The male and female organs are so enclosed in a capsule that it is extremely difficult for the pollen of any neighbouring ear to penetrate, and still less that of any different plant. Hence it was necessary to artificially impregnate, by opening carefully the flower capsule and remove the stamina when green. When the pistels—left alone—were deemed fit for fecundation the pollen of an ear of rye was shaken on them, the capsule carefully closed, and protected by a papering. The experiment upon ear yielded ten grains of wheat. These were sown in autumn, nine germinated. The sowings were continued. Results: some of the years naked; others bearded—the original wheat was the bearded Armstrong variety—but all resembled more the wheat than the rye. The seed stooled well. The expeiment never can rank higher than a curiosity.

Gum Arabic.—The Soudan rebellion, threatening as far as Wady-Halfa, and thus preventing communication on all the caravan routes, has put a complete stop to exports of gum arabic. The stocks at Cairo, Trieste, Marseilles, and England being nearly exhausted, there is no doubt that the real article will eventually disappear from the general market. From the annual report for 1885 of the Breslau Chamber of Commerce it seems that even if order were re-established (an event which is not likely to happen for a long time) they could not yet rely upon arrivals of any importance, since the small accumulations of gum in the Soudan have partly been used as food and partly destroyed.—*Das Handels-Museum.* [This ought to encourage the collectors of gum from our cadjunut trees in the Cinnamon Gardens and lowcountry generally.—Ed.]

Cactus Spirit.—In Spain Don Fernando de la Camara recommends the employment of the fruit of the Prickly Pear—Opuntia vulgaris—for the manufacture of alcohol. As this plant is very common in many of our tropical and subtropical dependencies it may be worth the consideration of some of our Colonial friends.—*Gardeners' Chronicle.*

Nova-Scotian Apples.—Some idea of the immense consumption of Apples from across the Atlantic may be gathered from the fact that frequently in a single day one auctioneer in Covent Garden Market sells under the hammer 10,000 or more barrels of fruits from Nova Scotia. And the same may be said of other salesmen.—*Gardeners' Chronicle.*

Fruit Development.—The cause of the fertility produced in fruit trees by bending the twigs at an acute angle has been investigated by Professor Sorauer. He finds that the bark on the lower surface of the twig below the bend is thrown into transverse folds, here and there detached from the wood. In these cavities new woody tissue is formed, filled with starch grains and afterwards new woody tissue of a normal character, but always thicker there than elsewhere, and especially on the convex upper surface. The mass of woody tissue checks the flow of water towards the tip of the branch to the great advantage of the bud immediately beneath, which is thus more likely to develop as a fruit bud. Pressor Sorauer does not appear (*Gard. Chron.*, Dec. 18, p. 785) to have taken into cosideration the obstruction to circulation of the sap caused by the partially broken or compressed wood cells at the bent portion. In bending poppy head stems to ripen the heads, this is probably the chief factor in the case, by arresting more or less the upward flow of the sap.—*Pharmaceutical Journal.*
